The unlimited potential of virtual worlds in creating digital space leads to the situation when the customers-avatars can be 'immersed' in an environment which is far different from traditional distribution channels. The digital world allows entrepreneurs to create the venue for meeting with their customers which is the most preferable for selling a particular brand and does not reflect a traditional office. The employees can meet customers in a space craft or old castle – depending which architectural surroundings better express the nature of the company. The company can enhance the level of interaction using music, videos, podcasts, interactive presentation and voice communication. There is also no technological barrier in teleportation - avatars can easily move in a particular place. The creation into virtual worlds seems to be limited only by imagination of the entrepreneurs. But the aim of this marketing is to put customer into the space which strongly enhances consumer's involvement in purchasing and their engagement into brand.

Consumption inside SL can be perceived as a substitute to consumption in the real world without causing an environmental effect. Because customers do not travel in order to receive services, companies do not build expensive headquar-

Table II.
Key features of analyzed virtual communities in distribution services

| Feature | Second Life | Facebook.com | Fotka.pl | Moja Generacja.pl | Nasza klasa.pl |
|---|---|---|---|---|---|
| Tools of communication | Chat, voice communication, messages send to avatar's e-mail, notes | E-mails and instant messaging, forums | Chat, e-mails, forums | Forums, instant messaging (Gadu-Gadu), recording audio information, Internet phone (Gadu-Gadu – is not fee of charge) | Forums, e-mail |
| Time of communication | Mostly real-time | Mostly asynchronous, real-time possible | Mostly asynchronous, real-time possible | Mostly asynchronous, real-time possible | Asynchronous |
| Currency | Not real currency, Linden Dollars | Dollar | Polish zloty | Polish zloty | Polish zloty |
| Customers appearance | Avatars 3D | Name/nick – image 2D | Name/nick – image 2D | Name/nick – image 2D | Name/nick – image 2D |

ters, the ecological footprint of providing services in the virtual world is significantly lower than in the traditional market [14] and for some customers there could be an important reason for purchase.

Also the environment created in virtual worlds is much more friendly for visually impaired people than traditional web sites, including social networks web sites.

## V. Limitation of virtual worlds

### A. Moving avatars

There is difficulty in 'moving' avatars between different virtual words – the market is limited to the members of users of a particular virtual world. In other Internet services such as instant messaging, Internet phone and social networks the process of integration has just started – allows the customers to integrate their content from different site e.g. Facebook allows to implement user's content from del.icio.us. Naszaklasa integrates contact from Gadu-Gadu etc.

### B. Currency

Using internal currency, e.g. Linden Dollars, can be perceived as a limitation of virtual worlds compare to social networks. Facebook sells its virtual gifts for American dollar (even at Polish language site), although there is a plan for introducing on-line currency at Facebook [16].

### C. Profile of users

Many social networks attract users from a particular regional market and the potential customers are people with the same cultural and sociological background. On the contrary Second Life has users from all nations, although some markets such as US, Western Europe and the Far East have major representation. Second Life is mostly suitable for companies which selling services at global scale.

## VI. Conclusion

Service companies which resort to virtual worlds receive an immersive environment, which allows using real-time, three dimensional audio and video and software to enable companies to communicate and interact with individuals or groups of customers. Due to the potential of creation in virtual worlds companies can build the selling environment which strongly enhances consumer's involvement, their perception of brand and influences the satisfaction from products. Nowadays the main limitation of using virtual worlds is the lack of connection between different platforms. Moreover in virtual worlds many business aspects still become unclear e.g. law regulation (taxes) or the consumers' rights. Social networks compare to virtual worlds are more useful as a promotion board and the selling environment is limited to digital gadgets or a few items connected with web site. Although there are a few examples of companies which resort to social networks as a distribution channel [6] the 2D Internet web-site has many disadvantages compared with 3D virtual worlds.

***Abstract*—Currently, the issue of information search is based on processing a large number of documents, indexing their contents, and then evaluating the level of their adaptation to the question asked by the user. The development of the web allows to offer certain on-line services which make it possible to shop, book tickets or deal with public-administration issues. The objective of the WKUP system (Virtual Consultant of Public Services) is to assist the user in the process of searching and selecting services. The system gives a possibility of natural language communication in the first stage of interaction. This functionality has been achieved by means of the SKOS ontology. The article presents a general outline of the WKUP system architecture and the functioning of the search engine which interprets the user's natural-language questions semantically. The article describes the use of the SKOS ontology in the applied answers searching algorithm.**

## I. Introduction

The objective of the WKUP project is to develop a personalized information system which will carry out public administration services with the use of the Virtual Consultant of Public Services (WKUP) based on semantic techniques.

Administration services which can be offered via the Internet are introduced into the public administration step by step, making the citizens' lives easier. These services usually reflect certain procedures and regulations which govern the work of public institutions. On the other hand, the citizen usually uses these services with respect to a larger scale issue he/she wants to settle. In this situation it is necessary to develop a tool which would enable to identify the user's need—the life case, and then guide the user through invoked web services provided by the public administration so that the situation could be dealt with in a complex manner.

The role of WKUP will be to identify the user's issue—life case, give him/her necessary information about that issue, find a relevant public service (or several services), and then to guide the user through the process of complementing the information indispensable to execute the service.

Searching out an adequate process will be done through a preliminary analysis of the user's question and then specifying the issue during the dialogue with the user carried out (to as much extend as possible) in a natural language. At a certain stage of the dialogue, the interaction can be based on selecting the options proposed to the user by the system. During the dialogue the system will collect information about the user (the user's profile will be one of the information sources when user will use system again) and the data necessary to execute the selected process. The user's profile is to facilitate the solution of his/her successive life cases. Both the dialogue and the process of complementing information and the user's profile will be carried out with the use of semantic techniques. The selected service, along with the complemented parameters (those that can be complemented at a preliminary stage of service execution and on the basis of legal and administration terms of the service) will be invoked in a government electronic system.

The architecture will consist of four functional layers (Fig. 1). Two layers, i.e.: the natural language processing layer and knowledge layer, will refer to the WKUP user interface functionality, while the processes layer and web services layer are related to the functional range of the Semantic Broker.

The natural language processing layer will consist of two modules—chatterbot and semantic search engine based on the SKOS ontology. The role of the chatterbot will be to make conversation with the user about casual issues (weather etc.) The role of the semantic search engine will be to find out what the users' need is.

The following chapters describe a part of the system related to the semantic search engine.

## II. General outline of search issues

There are many solutions in the realm of information search which allow to index the information contents and search for documents based on the contents. The full-text search solutions are mostly based on statistics and there have been many algorithms developed in order to standardize the search results [1]. A relatively new solution are algorithms which allow to cluster the search results [2]. Clusterization introduces the documents selection with respect to areas of interest (a sort of categorization) based on words used in a given text. A category is, to certain extent, a representation of the document contents determined on the basis of the statistics of words used in the document. Examples of such solutions are Vivismo [3] and Carrot2 [4].

One of the full-text search products is the Lucene search software [5]. The software enables to create a properly compressed index and to efficiently search for documents (even concrete places in documents) which are the answer to the question asked by the user. Additonally, Lucene makes it possible to create adapters which allow to browse different types of documents (Microsoft Office documents, XML documents, PDF documents, etc.)

The accuracy of the information search is achieved due to the use of semantic webs solutions [6]. Semantic webs allow to describe information in a formal way and to introduce interdependencies between particular pieces of information. This way the information search is broader. The use of semantic webs will allow the search tools developers to design new–quality products. The search tools, equipped with the knowledge about the concepts hierarchy and their interdependencies, will make an impression of intelligent software. Such knowledge allows to search not only for the key words given by the user but also for the related concepts, and shows how this relation is made. The example are synonims of terms given by the user, semantic relations whole-part or other relations between words.

Irrespective of the development of information technologies there are works caried out in the realm of text corpuses[1], which enable to determine, among others, dependencies between words and the frequency of their occurrence in texts [7]. Such works allow to create word nets (WordNet [8]). The works on the word net for the English language have been carried out since 1985. The works on other European languages (Czech, Danish, German, Spanish, Italian, French, Estonian) were carried out between 1996-1999 within the EuroWordNet project [9]. In Poland the works have been conducted within the plWordNet project [10]. Constructing a word net is done automatically, to a certain extent, thanks to the use of the Polish text corpus. The data from word nets, actually—relations between words, can be used to associate the words which appear in the indexed texts. This way it is possible for the user to find documents on the basis of the question in which the key words included in the document have not been used directly. Thus this solution is similar to proposals derived from the semantic webs concept.

In the realm of information search it is possible to determine the qualities of systems whose objective is to answer the questions. An example is the AnswerBus system [11] based on the knowledge indexed by Internet search tools. The search results are interpreted in an adequate way so that the information looked for by the user could be extracted from the document found by the search tool.

Another interesting solution is the PowerSet search tool [12]. The objective of the tool is to answer the user's questions on the basis of resources in the Wikipedia service. The tool operates on the basis of structures which enable to determine the question context, to select answers into certain thematic categories, and to find related concepts.

## III. Motivation of the execution

Full-text search is based on the statistical analysis of words included in the processed documents. The works ”An Introduction to Information Retrieval” [2] and “Term weighting approaches in automatic text retrieval” [1] present different issues related to full-text search tools operations (indexing, compressing the index, analysis of the user's question and the answer to this question). It is worth mentioning that this approach to searching is based on statistical methods and requires plenty of data in order to achieve accurate and appropriate results. A large number of words in a document, as well as a large number of documents, allow to better select the words which are characteristic of the given document—key words. The solutions based on full-text search tools achieve better results in the case of a large number of long-text documents.

[1] A large and structured set of texts (now usually electronically stored and processed). They are used to do statistical analysis, checking occurrences or validating linguistic rules on a specific universe. They are the main knowledge base in corpus linguistics. The analysis and processing of various types of corpuses are also the subject of much work in computational linguistics, speech recognition and machine translation. (*source: Wikipedia*)

Within the WKUP project a different solution was applied.

As it was mentioned before, the objective of the information system which is currently being developed is, among others, to give the user advice on the life case described by the user. Thus the user will ask a question and the system will propose one or a few possible pieces of advice (previously defined in the system). The advice will have a form of short descriptions explaining the operations the user will have to do in order to solve his/her issue (the descriptions have to be readably short and understandable to the user). For example, if the user asks for help because he/she has a stomachache, the advice given should be a message advising the user to see a GP and proposing an appointment via the WKUP system.

The solution can be briefly described as a set of a large number of answers to potential questions of the users - similarly to FAQ lists (Frequently Asked Questions). A potentially large number of the pieces of advice is the encouragement to develop a search tool which proposes a piece of advice (answer) best related to the real-life situation (question).

A small number of words in the text (short contents of the advice) has a negative impact on the efficiency of the document indexing process. The algorithm calculating potential key words for a given document may take into account wrong words due to limited size of the text.

It is also possible to assume that the potential questions range is, to a certain extent, determined. For example, if the system provides information from the field of medicine, the questions asked to the system will be related to illnesses, symptoms or advice connected with the organization of the national health system.

Additionally, it is important to notice that the users who ask questions will not necessarily use the words and terms included in the advice. Associations between the terms used in the question and in the advice may be even more distant than previously described terms associations in semantic webs. The application of semantic techniques will allow the user to use casual words to form the questions which are asked to the domain system comprising specialized vocabulary. The semantic technique allows an average skilled user to make use of the domain system.

Two presented reasons: small size of questions and answers, as well as different ranges of vocabulary used by the user and the information system, are the basis for the solution which allows to interpret the users' questions and to control the results displayed by the search tool.

## IV. Ontologies and SKOS

In order to present the solution we will focus on issues related to technologies applied in the solution development.

Ontology is a branch of philosophy which tries to describe the structure of reality. As understood by philosophy, ontology allows to explain relations between entities, qualities of these entities, etc., so that the reality could be described. In order to "understand" a section of reality, a computer needs the data that describe this reality, i.e. ontologies. The ontologies (as understood by the information technology) and their application are within the interests of the World Wide Web Consortium (W3C). In 1997 a standard was proposed, and as early as in 1999 W3C published the Resource Description Framework (RDF) standard [13]. The standard was complemented in 2004 with the RDF Schema (RDF-S) specification [14].

RDF allows to record triples of concepts. Each triple is a subject-predicate-object expression. Such a way of concepts recording forms a network of definitions (each object can be a subject in a different triple). Fig. 2 features a sample ontology diagram on which the concepts (circles and squares) are depicted along with their relations (arrows with names).

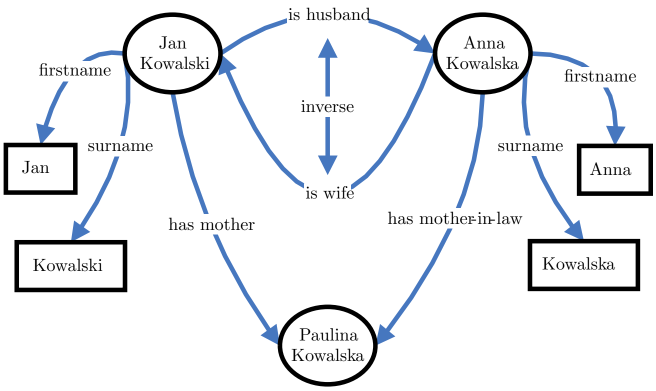

Fig. 2. Sample ontology

RDF-S introduced the possibility to build meta-concepts: classes, sub-classes, features. It also launches a non-standard way of defining the name of the notion (*label*) and its description (*comment*).

The next stage to extend the semantic web standards was to increase the expressiveness of languages intended for ontology recording. W3C published the OWL (Web Ontology Language) standard [15]. The language allows, among others, to express the number of concept sets, to show how one concept belongs to or differs from the other, to identify necessary and sufficient conditions for a given concept. Greater expressiveness of the language allows to verify concepts added to the ontology and to search out certain facts and features indirectly. Additionally, OWL makes it possible to integrate two ontologies by means of associating their identical concepts.

Therefore, ontology description standards allow to describe concepts and the network of links between concepts.

The SKOS specification (Simple Knowledge Organization System) [16], developed and extended under the auspices of W3C, defines an ontology which allows to express the basic structure and contents of concept diagrams, including thesauruses, thematic lists, heading lists, taxonomies, terminologies, glossaries, and other kinds of controlled dictionaries. The specification is divided into three parts: SKOS-Core [17] [18], SKOS-Mapping [19] and SKOS-Extensions [20].

SKOS-Core defines basic concepts and relations which enable to develop concepts and relations between them. SKOS-Mapping introduces relations which allow to describe similaries between concepts created in different ontologies. SKOS-Extensions introduces extentions of the intensity of hierarchical relations from SKOS-Core.

The SKOS ontology assumes that concepts are described by elements linked by means of the *subClassOf* relation with the *Concept* element.

Each concept can be labelled. The SKOS ontology extends the labels that can be used:

- *prefLabel* (chief label of a given concept)
- *altLabel* (auxiliary label, alternative for a given concept)
- *hiddenLabel* (hidden label, e.g. for casual words or other words treated as "hidden" due to other reasons).

The concepts can be linked into hierarchies by means of *broader* and *narrower* relations. The SKOS-Extensions specification introduces extra semantics of hierarchy relations, among others by the following relations:

- *broaderInstantive*/*narrowerInstantive* (express context hierarchies—instances, e.g. Dog and Azorek[2]).
- *relatedPartOf*/*relatedHasPart* (express the whole-part semantics, e.g. Car and Wheel).

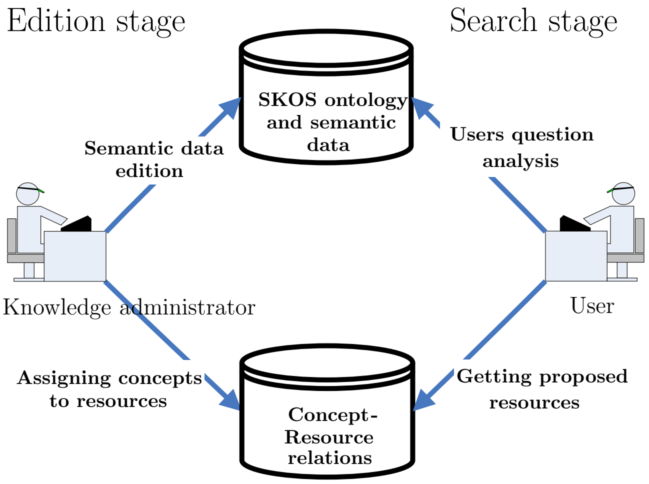
The SKOS ontology also provides the class definition which describes a set of concepts—*Collection*. Such a set can help to manage the ontology and facilitate its edition by grouping concepts of similar meanings. Possible ways to use the structures of concepts built on the basis of the SKOS ontology were described in use cases [21]. What is derived from these use cases is, among others, the application of SKOS to the following:

- to order and formalize the concepts used in a given domain, to search—on the basis on the concepts and a part of relations between them—for resources assigned to the concepts,
- to search for information in different languages (thanks to an easy method of translating labels in the ontology with an unchanged relation structure),
- to label press articles, TV programmes, etc. with key words from a thesaurus recorded in accordance with the SKOS ontology.

The above objectives of the SKOS ontology satisfy, to a high degree, the requirements of the search tool in the WKUP system. Therefore a decision was made to apply this ontology. The application was justified by the possibility to provide the tool with a wide and, at the same time, precise "understanding" of concepts. Thanks to semantics it is possible to record the relations between concepts which, in turn, allows to better interpret the questions.

## V. Performance method

The use of the SKOS ontology in the WKUP system consists of two stages: edition and production (search tool operations). Fig. 3 presents the way of using the concepts, defined in accordance with the SKOS ontology, with a view to search for certain resourses—data—related to these concepts.



Edition stage
Search stage
SKOS ontology and semantic data
Semantic data edition
Users question analysis
Knowledge administrator
User
Assigning concepts to resources
Getting proposed resources
Concept-Resource relations

Fig. 3. The use of concepts defined in accordance with the SKOS ontology in the search process

At the edition state (before the system starts) the administrator defines concepts and their mutual relations. Then he/she creates relations of the defined concepts with the data which are to be searched for. The ontologies defined in this manner are used at the search stage (production operations of the system). The user's question is analyzed based on the used concepts. The identified concepts are processed. On the basis of mutual relations between concepts, the best fitting answers of the system are found—the resources the user is looking for.

The analysis algorithm of the user's question was divided into successive stages. The first stage is "cleaning" the user's question from redundant non-alphanumeric signs as well as lemmatization of particular words in the sentence. For the statement prepared in such a way, at the next stage the best-fit concepts are searched for based on their labels (relations *prefLabel*, *altLabel* and *hiddenLabel*). In the case when the found concepts are not related to the resources, the relations *broaderInstantive*, *broader* and *relatedPartOf* are used in order to search the web for the concepts which have certain resources assigned. This allows to find the concepts whose meaning is broader than the meaning of the concepts used in the sentence.

The *related* relation is treated in a special way. Thanks to the *related* relation, several concepts which lead to the same resource make the resource "stronger" by assigning a higher searching priority to it. This way it is possible to model the relations between concepts derived from the knowledge about the specifics of the given domain for which the concepts are modelled. The last stage of the sentence analysis is the use of information about the words location with respect to one another in the user's sentence. The words which are closer to one another and point at the same resource simultaneously raise the priority of the found resource. This results from the prerequisite that, usually, the words which determine the same object are located close to one another in the sentence.

Such analysis allows to present the found resources to the user according to the assigned search ranking.

[2] Popular dog name in Poland.

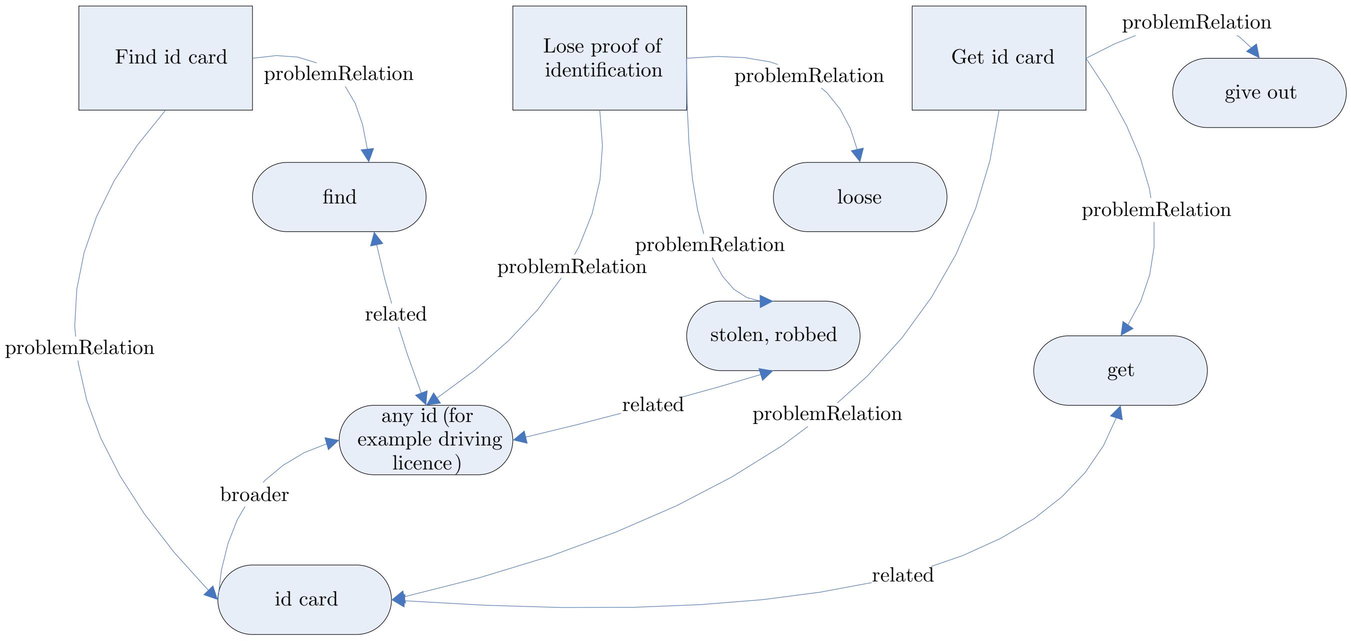


Fig. 4. Sample SKOS structure and its relation to the resources to be searched for

Fig. 4 features a sample SKOS concepts structure and its relation to resources that are to be searched for. Three issues (real life situations) have been defined: finding an ID, losing an ID and getting a new ID. Additionally, the following concepts have been defined: finding, loss, theft, getting and issuing. The *related* relations allow to "strengthen" certain relations other than *broader* and *relatedPartOf*.

Building a net of concepts and assigning resources to the concepts allow to model the system answers to the user's questions. This way the data administrator, who defines the system answer by himself/herself, has a clear picture of the system behaviour with respect to a given class of questions. Such a solution is more deterministic than full-text search tools which operate on the basis of statistical methods only. Additionally, to improve the data administratord's operations in the system, the mechanisms were introduced which function in traditional search tools solutions, but at the edition stage of the ontology. Thus the possibility of automatic collection of concepts from the indexed elements (descriptions of life cases) was applied, and.the process of assigning the concepts to life cases was automatized. In order to perform this task, the algorithm was used to calculate normalized words priorities for documents (*dt* indicator) [2]. The algorithm allows to calculate the adequacy ranking of a given word for the indicated life case. Therefore the work with the tool can start from automatic indexing of life cases and then proceed to successive introduction of revisions by means of successive introduction of relations between concepts, changing labels and their classification (pref, alt, hidden), etc.

## VI. Conclusions

The presented solution is a proposal to solve a certain issue related to information search. It seems that the solution can improve the search in resources which are limited in terms of the number of indexed documents, and in the situation in which it is assumed that the users will ask "questions" to the search tool. The solution appears especially adequate in the case of the so called FAQ lists. They define ready answers to certain questions and, more importantly, the questions are usually relatively short. In such cases full-text search tools can have problems to properly index the contents.

The solution is at the prototype stage now and its operations have not been checked in practice yet. On the basis of the conducted tests it seems, however, that the efficiency of the search tool operations depends mainly on a well constructed ontology. Therefore the ontology is the key element which affects the functioning of the system.

Practical results of the search tool operations and the drawn conclusions will be the topic of the next publication.

# Security Perception in E-commerce: Conflict between Customer and Organizational Perspectives

Mohanad Halaweh, Christine Fidler
School of Computing
De Montfort University
Leicester, UK
Email: {Mohanad, cf} @dmu.ac.uk

***Abstract*—Security is one of the principal and continuing concerns that restrict customers and organizations engaging with e-commerce. The aim of this paper is to explore the perception of security in e-commerce B2C and C2C websites from both customer and organisational perspectives. It explores factors that influence customers' perceptions of security. It also highlights conflicts between customer concerns with respect to security and those of an organization; existing research has not highlighted this issue greatly. This research provides a better understanding of customer needs and priorities on the subject of security, and enriches the currently available security perception literature, by providing new insights from empirical research conducted in Jordan. A qualitative research approach was adopted, since the research seeks an understanding of human (i.e., customer and organisational employee) perceptions.**

## I. Introduction

SECURITY is the challenge and the main problem for successful e-commerce implementation, as stated by many researchers [1]-[6]. However, there is wide agreement between academic researchers that security is not only a technical challenge; rather it involves managerial, organizational and human dimensions to be more effective [7]-[12]. Therefore, understanding (and acting upon) the customer's perception of security is vital to successful e-commerce interactions, because even when a company uses the best technical solutions that provide full security, without the underlying perception and awareness from customers that their particular website is secure, then these technical solutions may mean nothing. Salisbury [13, p.2] defined security perception as "…the extent to which one believes that the Web is secure for transmitting sensitive information…" (e.g. credit card details), where the meaning of security is subjective and which can therefore vary from one person to the next. The target sample of this research, which seeks to understand security perception from both customer and organisational perspectives, is taken from selected Jordanian organizations and Internet users. The reason for choosing the Jordanian context is justifiable, as most existing research conducted in Jordan confirms the security concern in e-commerce and Internet banking, without exploring the issue in depth [14]-[18]. This barrier (i.e. security) makes both Jordanian organizations and individual customers hesitant to participate in e-commerce transactions, and thus reducing the growth of e-commerce. Therefore, security in e-commerce is a vital area of research, both in general and for Jordan in particular. This research will be the first of its nature in Jordan, focusing on security in these applications from both customer and organizational perspectives. It specifically addresses Business-to-Customer (B2C) and Customer-to-Customer (C2C) e-commerce websites.

## II. Literature Review

In the literature, most security research that is relevant to e-commerce within the IS domain, focuses either on the organization (including technical implementations), or on the customer. In particular, these studies identify systematic processes and factors that need to be considered when implementing a secure e-commerce application from the organizational perspective [19]-[24]. Other research have investigated customers' perceptions and beliefs about security controls and features in e-commerce [25]-[29]. Little research has been conducted which investigates the customer and the organization jointly as a single phenomenon with respect to e-commerce security. This "holistic" view leads to research insight that enables organizations to use certain security solutions that are wholly aligned with customer's objectives and perceptions, thereby reducing the gap between the technology utilized and solutions implemented by organizations, on the one hand, and that being perceived by customers, on the other.

With the existing literature, several factors have been identified as having influence on the customer's perception of security, such as attitude toward security, user's knowledge and experience of security features, ease of use of the interface and presentation of the website, presence of third party security seals such as Verisign and of third party privacy seals like TRUSTe, presence of SSL encryption as indicated by a small padlock, presence of https in the address bar, presence of a security and privacy policy, and the electronic receipt and acknowledgement of the process [25]-[30].

## III. Research Method

A qualitative approach which is suggested by [31] is adopted. Qualitative research is subjective in nature, and involves examining and reflecting on meanings and perceptions of individuals in order to gain an understanding of so-

978-83-60810-14-9/08/$25.00 © 2008 IEEE

cial and organizational phenomenon. It assists the researcher in understanding the target phenomenon in depth and in its natural setting. A total of 27 interviews were carried out; 15 with customers, and 12 with organizations' business managers and IT staff. The questions that were used for asking customers were open, and focused on exploring their perception of security and how they would check to see if a certain website was secure or not. On the other hand, the questions posed of organizational staff focused on identifying their perception of, and viewpoint on, customers' concerns of security and what issues customers needed to know for distinguishing between a secure website from a non-secure one. During the presentation of the results that emerged from the fieldwork, the researchers provide several quotations from the interview transcripts (presented in italics during the results narrative), in order to show how the "story" derived from this research is relevant and grounded on the meanings that were assigned by the participants themselves (as understood by the researchers).

## IV. Research Findings

This section presents the findings regarding Jordanian customer e-commerce security perceptions, from both customer and organizational (through the eyes of selected technical and managerial employees) perspectives.

### A. The Customer perspective

Customer answers with regard to how to check security of a website and what criteria to consider when doing so can be categorized into those referring to tangible features and those referring to intangible features. Tangible features are technological security features on the website that can be checked by users visiting the website, such as https, padlocks, security certificates and security symbols, while intangible ones are not seen on a website yet the user needs to understood or have knowledge of them. They are affected by society in terms of communication and the environment where the customer lives and what they hear from others, as well as their past experience, such as whether the website is well-known and reputable. The perception of the intangible features is constructed by informal word-of-mouth communication between people.

Tangible features need to be understood and checked by the customer on a website, rather than captured through social discourse between people; understanding is gained by having knowledge and experience of these features: for example, in the case of security certificates, a customer needs to know what it means to have one, and how s/he can check to see if it has expired or not.

Some customers indicated that tangible indicators meant very little to them, and much less that the intangible indicators. When considering Website security, the intangible issues surrounding that website were given priority, and only after these had been considered might the tangible ones be checked. For example, the following participant indicated that the presence of a padlock on a website provides him with an indicator of security, but that he does not rely solely on that indicator; rather, he relies more heavily on other people's experience and commendation of the website (an intangible factor).

> *In fact this depends on what people say, for example, I heard that the padlock in the bottom of the page means this website is secure… but the main thing for me is what other people say because they have had experimentations with these websites before me.*

Some respondents indicated that the presence of details about security features on the website and information about website policies, besides the interface design, would make them feel that it is more secure. Examples from the participants' responses are:

> *I mean sometimes the website provides you information that makes you feel a sense that this website is secure and also through transferring between Internet pages, step by step, until arriving at the confirmation page. This gives me feeling that they are serious and secure.*

> *If the website shows the customer a brief description of what security issues they should be aware of and an understanding, then this makes the customer more trusting of the website.*

*In fact this depends on what people say, for example, I heard that the padlock in the bottom of the page means this website is secure… but the main thing for me is what other people say because they have had experimentations with these websites before me.*

Some respondents indicated that the presence of details about security features on the website and information about website policies, besides the interface design, would make them feel that it is more secure. Examples from the participants' responses are:

*I mean sometimes the website provides you information that makes you feel a sense that this website is secure and also through transferring between Internet pages, step by step, until arriving at the confirmation page. This gives me feeling that they are serious and secure.*

*If the website shows the customer a brief description of what security issues they should be aware of and an understanding, then this makes the customer more trusting of the website.*

> *I read their policy and all information that was relevant to the website if I have doubts about this website…*

Participants reported that the availability of a third party, who is neutral and international, can act as an intermediary and be accepted by all parties, thereby guaranteeing that security is provided, making them perceive that a website is secure and consequently enabling their engagement in e-commerce. For example, one participant suggested:

> *I think if there is a security company that is recognized internationally, then this shows that they have a list of websites they registered, as well as mentioning they give these websites a reference number, then the customer once entering a certain website can check this reference number or the brand name of this company in the security company's list…not merely a stamp, rather a reference number… this method makes buying over the internet secure.*

> *Well, some websites mention that they have secure payment but this does not mean indeed it is secure unless it is provided by a third party.*

Several participants perceived that if a site is well known then it must be secure, when they were asked how they would check that a certain website was secure or not. Some participants referred to websites that were trusted by others, and relied on the rating scheme that was provided via that website. For example:

> *As I told you the famous company provides security …. I suppose they do that because they respect their customer. Besides, it shows the security policy on the website and details regarding freight and delivery.*

> *I think the issue here depends on the website, I mean if the website is well known and rated by users, then that is secure and includes an actual address and telephone number then this site is secure.....*

> *If I find the payment via PayPal, then I complete the transaction without any reluctance because it is a well known worldwide company. The reputation of feedback on a website and the rating by customers, and their experience with a website gives proof that the website is secure and credible.*

In this last quotation, the participant highlighted the familiarity of an electronic payment service provider such as PayPal, and the influence on security perception that the presence of such a familiar service has. This was also asserted by another participant when he said:

> *I didn't hear any one censure Amazon… you know why - because this website deals with the largest company in the world; like PayPal, it undertakes the security on the website, these websites pay millions for that.*

The reputation of a website was also reported by other participants, and that it is the base upon which customers relied when considering to buy online:

> *I think there is no way to say this website is secure or not, the only thing is the reputation of the company's website.*

> *If I do... I do just from a company I have already dealt with or a company that has a good reputation in Jordan.*

A few participants highlighted the significance of the website's existing known (and typically physical) identity, such as that of the banks and telecommunications companies in Jordan; participants appear not to use websites which are anonymous and have no real physical location:

> *I trust only the bank …. Suppose if anything happens then I can go to them and refer to them since they have a physical place.*

> *In fact, I was a customer of this bank for long time so I discarded the fact that the bank would steal or trick me. But there are some instructions, I should know them as a customer to protect myself from any person. For example, the first time when I logged onto the system (website page) it forced me to change the password after six months, I did that but later on I tried to enter it... I forgot the new password I tried many times and then the system asked me to contact my branch to activate my password, because I entered the incorrect password more than three times…… all of these processes are in order to protect me so they are very concerned on security*

The last quotation also showed that, from this participant's perspective, the security of his online account is addressed by providing a strong password procedure. This reinforced his perception that the bank is working to provide on-line security for its customers.

Some participants reported that the characteristics of the company (e.g. respected and large size) would lead them to feel that it supports and provides secure website access.

> *The company that respects its customers, is well known and especially larger ones, implicitly provides the required conditions in order to complete the transaction in secure way.*

One of the participants has not yet bought online but in his opinion there are definitely secure websites. He stated:

> *I hear that there are many people purchasing over the internet and some people buy and sell shares as well, so certainly it is secure as there are people doing it, otherwise why do they buy and sell if it is not secure.*

Table I. summarizes all the tangible and intangible indicators of security from a customer's viewpoint that were derived from the fieldwork, many of which have been touched upon within the preceding discussion (others were not discussed due to paper length limitations, and those that were provide more sufficient evidence of the process of research narrative development). On close inspection, it may appear that several of the intangible indicators appear to be identical: for example, famous, well-known and recognized could be considered to be synonyms. However, the researcher has kept to the customer's exact phrases rather than presenting (and thereby enforcing) his own interpretation of the words used.

Table II.
Tangible and intangible security features on e-commerce websites from customers' perspectives

| Security features in e-commerce website | Categorizing of security features |
|---|---|
| Padlock | Tangible |
| Security certificate | Tangible |
| Transferring between interfaces of the website<br>Website presentation | Tangible |
| Security policy | Tangible |
| Acknowledgment via email | Tangible |
| Third party symbols | Tangible |
| Physical address , telephone # and email | Tangible |
| Brief description of the security issues that the customer should be aware of on the website | Tangible |
| Known identity (company has physical building, i.e. Bank) | Intangible |
| Support password system | Tangible |
| Well-known electronic payment gateway such as PayPal | Tangible-Intangible |
| Famous brand/company | Intangible |
| International | Intangible |
| Recognized | Intangible |
| Trusted | Intangible |
| Well-known | Intangible |
| Formal website | Intangible |
| Respected company, large size | Intangible |
| Reputable | Intangible |
| Well-rated | Intangible |

### *B. The organizational perspective*

Some respondents indicted their impression in general about a customer's acceptance and engagement in e-commerce. For example, one participant believed that customers have a generally negative attitude towards online shopping, and that there is no trust and transparency between the customer and merchant:

> *In fact, and by my experience with an e-commerce website for several months, I arrived at an unbelievable fact that Jordanian citizens and Arabic customers in general don't believe or trust shopping online, they think no transparency is provided by the websites. For example traditionally, when the customer buys a computer from a store, he faces a problem if he wants to fix his computer, he is countered with violation of the deal by the merchant, and he is always the weakest party and will ultimately carry the cost of fixing the produce. So, how do we persuade the customer buying online that whilst he does not see anything tangible in front of him, and is not able to touch it with his hands, where he already had faced problems with a physical store ... he needs guarantees.... really, where the detailed information that is provided by the first page on the website is not sufficient to convince him… briefly, the trust between the customer and merchant is nonexistent as it is not between the customer and Arabic governments.*

In contrast, however, another participant was optimistic by showing the achievement of her company, and the degree of online acceptance from customers. She commented that customers nowadays are more aware and have greater propensity to accept online trading given their experiences of using ATMs and the generally wider availability of credit cards.

> *We applied an electronic ticketing system on our website which was an important factor in enabling our business, as a result it has become easy for customers to book a ticket and pay online from anywhere… people are accepting that they are ready more than you think, there was minor rejection but in general it was accepted smoothly by our customers…really, we are surprised how people are ready to accept it…… Customers nowadays become used to an ATM and it is not big deal, most of people have a credit card… people are more developed than in previous years.*

She asserted that her company focuses on strong customer support to allay and respond to customer concerns, by saying:

> *The customer viewpoint is considered and we have a customer service centre that is responsible for customer's enquires, claims and problems, and we take on their feedback which is important for us.*

Another participant pointed out how his company's concern was about the customer in respect of the website design. Here, the respondent correlated ease of use in the website with a feeling of security, but immediately went on to say that this, in itself, is not really security.

> *The user's viewpoint is necessary for us, providing a website that is easy to deal with, friendly, motivates the customer to use it, which makes him feel it is secure to some extent...but not exactly secure.*

The next participant showed how his company considers the customer viewpoint, and what it does to provide secure online transactions. In his viewpoint, a simple and true (i.e., product exactly matches what the customer expects) transaction with the customer makes him/her feel that the website is secure, and this makes the customer experiment and eventually become a repeat user of the website.

> *In fact, the facilities and services that we provide and our security is not just talk, but the fact that when a customer enters our website and obtains the product that he wants with the same specifications, this happens without any complexity and is easy. This makes them come again because they found our sincerity of treatment. Now we have more than 10,000 active users who buy and sell over our website. Those, once they have tried and succeeded, and have found it is secure, they will then become one of our customers and users of our website….it is just the first experimentation.*

He continued by pointing out that the company website also has a forum where sellers and buyers can chat, get to know each other, share opinions, provide suggestions, report transaction problems, recommend certain sellers and certain products, provide feedback, and request support from the website. In addition, the website provides a rating system which makes customers feel that the website has greater credibility.

> *One of the important things that makes customers feel that our website is secure and credible is the rating system which indicates positive and negative ranking for buyers and seller, and the best buyers and sellers……We have a forum on our website and we have seen for example one customer ask a question and another customer tell him to refer to our policy, the clause number#. If the customer faces any problem, we resolve it within 24 hours, the nature of our website is that easy to deal with. It is so that it makes customers feel happy and confident and in control over the work on our website, it is not complicated.*

He added that their website is 100% secure and they guide their customers on the first page to check the padlock.

> *We put on our website 'secure 100%', we carry the responsibility for that, there are websites that say that they are secure 100 % but they are not secure and just talk rubbish. On our website, we also provide customers with an explanation regarding the security privacy policy*

And on that the website, the following instructions are found :

> *Look for the item with this icon* 🔒
>
> *This means that the auctions displaying on it are more secure.*

In contrast, another participant stated that customer concerns are addressed solely by the services provided on the website:

> *The customer viewpoint is considered at service level what he would like to see and what he wouldn't like.*

Some of the technical staff involved in the development and maintenance of organizational websites did not consider the checking of tangible indicators as a sufficient mechanism for determining the security, or otherwise, of a website. This is firstly because technical staff appeared to be unconvinced that tangible indicators provide real security; websites are hacked despite the presence of these indicators, so customers could be led into a false sense of security by relying solely on them. Secondly, these indicators assure customers of the organization's honesty, for example, by using security certificates as an indicator that the website is guaranteed by a third party, and thus that the website is secure, but this is no assurance that it cannot be breached by hackers.

> *It is difficult to consider that a website is secure or not even if you are professional, no way to say 100 % secure, and using security certificates just means that you are not lying to your customers by doing your responsibility and this is not a guarantee that you are not hacked by hackers.*

These indicators (e.g. security certificate) are thus not sufficient to assure that the website is completely secure. Here, the risk does not come from the website itself but might be from outside parties (e.g. hackers). One participant maintains that there is no way to confirm that their websites are secure or not, even when such websites are very well-known.

> *Frankly, there is no way to judge that a certain website is secure, even though it is Amazon and eBay…. it is reputation and ease of use, the guarantee is the experiment and reputation.*

From the interviews with organizational members, it was also found that naïve customers are sometimes not aware of technological details, such as the meaning of terms like https. Examples from participants reported that security understanding is not an important thing for the customer and that the only concern is others people's experiences or reputation of the website.

> *Some people don't care about security, they don't think is it secure or not, they are just concerned about what other people say if it is well know-company and credible by others, then they use it and trust it.*
>
> *To say this website is secure 100 % means noting for the customer, I think the reputation of the website makes the customer feel it is secure.*
>
> *The main concern for users is the reputation of the company, they are looking for a well-known company, and people here in Jordan deal with national companies like telecommunications because they know them well.*

Thus, from an organizational perspective, customers look for intangible indicators such as reputation, a well known company, and the system of rating by previous customers of the website, in order to assess whether or not a website is sufficiently trustworthy to engage with, regarding online purchases.

## V. Discussion

Based on the findings in the previous section, conflict between the some of the views of organizations (in the eyes of management and technical personnel) as to what customers consider important, and those views of the customers themselves, can be clearly seen. The research findings showed that some of the participating organizations indicated their acknowledgement of customer security concerns by stating them on the first page of the website that it was 100% secure. One participant stated that their website then guides customers to check whether a padlock symbol appears when a transaction is performed, advising them that if it does then the website is secure. This raises the question of whether such advice is sufficient to convince a customer purchasing online or performing online transactions. In essence, while it is important, it may indeed not be sufficient; a responsible company should explain website security to its customers, not merely present a logo or use a short sentence to state that it is secure. Rather, they need to make clear what the padlock means, what technology is used to encrypt the data and what protocols are applied. One participant from an organization pointed out that customers' concerns are considered at the service level, and this should be accepted as a premise and therefore it should be considered that customers are only concerned with the quality of the service provided on the website and whether it is easy to operate. In essence, this can be refuted by the argument that some users know the meaning of security indicators on websites, so that in this context, new thoughts are required; a change of attitude is needed among technical staff, because they tend to underestimate customers' perceptions and their ability to understand what is involved. Thus, organizations exempt themselves from fulfilling their responsibility to educate their customers in issues related to security.

On the other hand, customers' responses have revealed that they do not intensively check tangible security features, being more interested in knowing the identity of the other party; they want to know whether they are dealing with a national company which is well-known, famous and reputable, which are intangible features. If these questions are answered affirmatively, then the customer feels secure. For such customers, security is guaranteed on the basis of the abovementioned features. Consequently, more effort is required by the organizations in this field, namely, to seek strategies to make their websites better known and to boost their reputation. For example, if a customer wants to buy something from Amazon, then does he check whether the site is secure or not? This example would suggest that tangible security features on the website are not essential, but that the customer will decide to buy from the website without checking, simply because he depends on the reputation of this website – and in this case the reputation of the company implies by default that the website provides the required security. This raises another question: does every company which has a good reputation actually guarantee the security of its website? In essence, it can do so only if the company is responsible for the protection of the customer's data from its actions. For example, if a company's website applies the best technology for encryption of customer's data, but then their private data is transferred by the website to another party without the customer's consent, then the violation of security (i.e. confidentiality/privacy requirement) has come from the website itself, despite its supposed reputability; so, the responsibility of the company for security should have two dimensions: protection of data from hackers, and from misuse by the parent organization of the website itself.

Organisational staff indicated that tangible features do not totally guarantee security. The consideration addressed by organisational staff, that there is no way to judge whether a website is secure or not, leads to a reasonable enquiry: if there are no dependable criteria for distinguishing a secure site from an insecure one, what should the customer depend on when purchasing online securely? The justification for this doubt is that while security features (e.g. using SSL, security certificates) of the website may mean that its operator has an honest stance towards its customers, that while their data is encrypted for transmission, that the website's identity is authenticated by a third party and that this, as reported by one participant, means that they do not deceive their customers, and that while the website undertakes to provide secure transactions, none of this means that the company is able to totally guarantee that their site will not be hacked or its security breached. In other words, as another participant stated, it is difficult for even well-known websites to guarantee total security. In essence, this shows how such a significant role is played here by the intangible indictors of security, such as the fame or reputation of the website, which represents the first priority for a customer in deciding whether to buy online. Fame or reputation of the website assures him that the website's operators undertake the responsibility to protect his data. This concurs with the organisation's view that customer concerns are about the reputation of the website, how well known it is, and how it scores on rating schemes, for example. It may be concluded that tangible and intangible security features are both important and need to be checked by customers, who should not depend entirely on one or the other.

Although the core idea of this paper is to investigate security perceptions from the customers' and organizations' perspectives, the researcher has found it is difficult to put some of the participants' responses with respect to trust away, where this terminology was mentioned in their answers. The literature review provides, theoretically and empirically, a set of antecedent factors for trusting e-commerce websites. These factors include the characteristics of the online vendor, third-party certification, the individual's propensity to trust, the influence of perceived risk, perceived security control (i.e. authentication, no-repudiation, confidentiality, privacy concern and data integrity), perceived competence, legal framework, previous experience, perceived credibility, perceived ease of use, perceived privacy, perceived company reputation and willingness to customize products and services, perceived website usefulness, third party recognition, perceived investment, perceived similarity, perceived control, perceived familiarity, and perceived size [32]-[37]. Based on the above, it can be said that perception of security from the customer perspective is determinant on trusting the website, where perceived security is one amongst many other factors that can increase or decrease this trust. Intangible features of security were revealed by the customers, mentioned in Table I., such as reputation, well-known or perceived familiarity of the website, also increase or decrease in belief that whatever certain website is secure or not, even though these features are similar to some of antecedent factors for trust, such as reputation. As a result, this paper extends current literature to show that these factors also influence customer perception of security which is similar to the influence on customers trusting a website.

## VI. Conclusion

This paper has provided a valuable contribution, by providing insight into the customer's perception of e-commerce security. It has clearly identified that both tangible and intangible features play a major role in the customer perception and judgement of the security of a website. It has highlighted and discussed differences between customer and organizational viewpoints of customer e-commerce security perception, and has delivered guidelines for organizations such as the taking on of the responsibility to educate customers towards security features (e.g. security certificate), what these mean and how to check that the website has these. By taking and achieving this responsibility in protecting customer's data in line with making promotional strategies to make their website more well-known and used, its reputation will increase.

In addition, the paper extends the existing body of knowledge by providing evidence that some factors that influence customer's perception of security are similar to that which makes them trust the website as reported in reviewed literature. Therefore, and to provide sound evidence, this stimulates future research which can address the relation between security and trust, and which can identify, by empirical research, whether the factors that influence customers' security perceptions are the same as those that influence trust (or indeed where they differ). This could be achieved by investigating the perceptions on the two issues together based on the same respondent set.

# 4th Workshop on Large Scale Computations on Grids

LARGE Scale Computations on Grids (LaSCoG) Workshop will be organized within the framework of the International Multiconference on Computer Science and Information Technology and co-located with the XXIV Autumn Meeting of the Polish Information Processing Society.

The emerging paradigm for execution of large-scale computations, whether they originate as scientific or engineering applications, or for supporting large data-intensive calculations, is to utilize multiple computers at sites distributed across the Internet. In particular, computational grids are collections of distributed, possibly heterogeneous resources which can be used as ensembles to execute large-scale applications. While the vision of the global computational Grid is extremely appealing, there remains a lot of work on all levels to achieve it. In this context the LaSCoG workshop is envisioned as a forum to promote exchange of ideas and results aimed at addressing complex issues that arise in developing large-scale computations on Grids and running applications on them.

Covered topics include (but are not limited to) Grid-focused aspects of:

- Large-scale algorithms
- Symbolic and numeric computations
- High performance computations for large scale simulations
- Large-scale distributed computations
- Agent-based computing
- Data models for large-scale applications
- Cloud computing
- Security issues for large-scale computations
- Science portals
- Data visualization
- Performance analysis, evaluation and prediction
- Programming models
- Peer-to-peer models and services for scalable grids
- Collaborative science applications
- Business applications
- Data-intensive applications

***Abstract*—The paper shows a possibility of arranging a desktop grid based on the UNICORE 6 which is a well established grid middleware. The grid consists of a number of PC computers which can communicate with the server in a secure way and perform scheduled computational tasks. The main advantage of this system is ease of deployment, flexibility and ease of integration with the large scale grid. We present here results of a simple performance test as well.**

## I. Introduction

Nowadays the community grid computing becomes more and more popular with a number of architectures available. Boinc [2] package, Condor [3] are good examples here. At the same time we observe rapid development of full featured grid middlewares such as Unicore and Globus Toolkit. Intense works are carried out which aim at connecting desktop grids and full size grid infrastructures. One of the simplest propositions is to create an interface that would allow to run Globus or Unicore jobs on the desktop grid. Condor/G is a good example here. Currently, interfaces that would allow using full size grid nodes for desktop grid are available. Both solutions have one great disadvantage—they make a connection between two different systems and middlewares which causes technical problems. Of course there are some current works which uses this solutions, however they usually mean creating some kind of bridge between middlewares[4][5][6].

In our work we present a new solution: Unicore 6 middleware is used to create a desktop grid. This solution makes the connection of systems really easy, simplifies all problems related with authorisation and authentication and minimises cost of middleware. This, only a very beginning stage of creating a desktop grid middleware proves that Unicore suits well as a middleware for creation of a desktop grid.

## II. Unicore

Unicore is a Java based grid middleware. Early versions of the system (up to Unicore 5) had communication based on the exchange of serialised Java objects. This solution was very fast and easy to implement, but it worked only if both sides of a given communication used the same version of Java. Unicore 5 has been still in use, and one of its main advantages is good separation of the user from the computing system executing his job. This allows connecting computing nodes with completely different architectures. For a certain time now a completely new version of Unicore has been available with the communication based on web-services. It combines simplicity of previous version with portability and independence of Java version from web services. In this paper we refer to Unicore 6 [1].

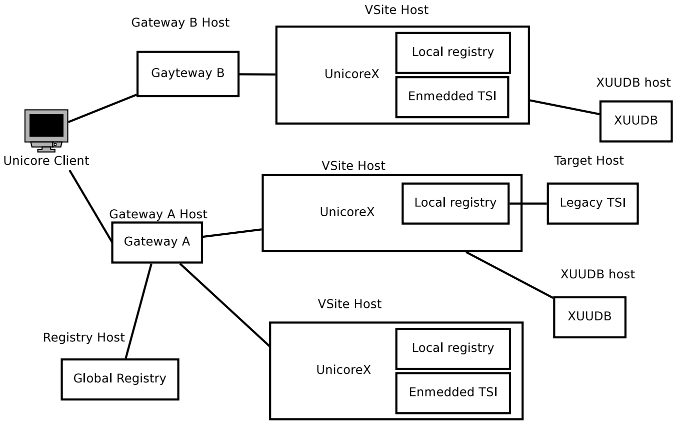

Fig. 1. Example Unicore installation

The Unicore system consists of the following parts:

- Gateway - a module that allows other modules to connect to the grid. It ensures that no unauthenticated user has any access to the protected part of a grid.
- Virtual site (VSite) and a target system (i.e. UnicoreX) - the part of Unicore that is responsible for execution of applications.
- Registry - a holder of information on services used by clients.
- Storage - used for data storage on the grid.
- XUUDB - user database for authentication of users.
- Client - part of Unicore which runs on client's side.

An example Unicore 6 installation is presented on Fig. 1.

A virtual site splits into UnicoreX and Legacy TSI which provides for connecting to target systems built using Unicore 5.

Additionally Unicore has been extended by UVOS system for Virtual Organisations [7]. This extension will allow integrating created desktop grid with the computational grid, as one of possible sites.

978-83-60810-14-9/08/$25.00 © 2008 IEEE

*1) Why Unicore?:* Unicore and Globus Toolkit are two most popular grid middlewares. They both, in their new versions are based on web services. Unicore has two great advantages—it is easy to be configured and run, and it has a simple but very extensible and powerful authentication and authorisation infrastructure which have been based on industry standards such as the X.509 PKI.

## III. Desktop Grid Architecture

The goal of this work is to build, using Unicore modules, an architecture model consisting of:

- computing element (desktop node, potentially unreliable)
- manager node

Current architecture of desktop grid is presented in the Fig. 2.

### A. Computing Element—Node

Computing element which does the most of computations has been built based on gateway and target system—UnicoreX. It uses XUUDB that works as manager for authorisation.

The problem was to minimise the application so that to make it running on the computing element under the target system. An ideal application consists of code that could be downloaded with a job to be executed. Unfortunately, this leads to serious security problems. It is possible only if the application run inside the target system, has the same security as unsecured java applet. This means that the application can not:

- run or read from disk,
- connect to host other then a Desktop Grid Manager,
- use only a secure classloader.

At the early stage of project we still use a disk for keeping logs and keystores, but in the future, after all optimisations we plan to totally disallow the application to use disk for execution. Data for computation is kept on the manager computer and downloaded straight to the memory space of application.

*1) Application Runner:* All jobs submitted to computing element could be divided into three parts:

1) obtaining data from grid storage using the key provided in the job description,
2) doing actual computations using a module described in the job description (Application),
3) sending back the data to the grid storage.

All data is kept in the memory, thus involving no need to use a disk. The private key used for data transferring is encoded into the ASCII string and it could be given to the application as a normal run time argument.

### B. Manager Node

Desktop Grid Manager node software consists of the following elements:

- gateway—which allows accessing to the registry and storage,
- registry,
- grid storage accessible via RBYTEIO,
- XUUDB which is accessible on its own port,
- Desktop Grid Manager.

Additionally, on the manager node we separate the storage space for finished tasks results. It would increase the security, because Desktop Grid Manager is responsible for moving the results there and, after such moving, is the only one who has access to the data. More detailed description of Desktop Grid Manager is presented in III-C.

It is also possible to split Desktop Grid Manager among registry, storage, XUUDB and computations manager. This would allow running jobs from a computer that has no external IP address and/or open ports. Of course, another solution is to create Desktop Grid Manager that works as a service under Unicore.

The architecture we have chosen is very good at this stage of development of desktop grid. It allows us to easily experiment and change parameters of tested architecture.

### C. Desktop Grid Manager

Desktop Grid Manager is a multithreaded application. It uses threads for controlling different aspects of desktop grid work. It allows running a job on a desktop grid and getting results, and is responsible for:

1) checking available nodes in registry,
2) dividing job into sub-tasks and merging results,
3) submitting tasks to a computing element,
4) fetching sub-tasks results,
5) monitoring state of nodes.

Desktop Manager uses separate threads for:

- checking registry—this thread is used for checking if any new computing element has registered, and if there is a new node, thread tries to do the rescheduling.
- checking node—checks if node is still alive, and what is state of computations. If node is down, or if it has finished computations, the thread tries to do rescheduling.
- running manager tasks—some tasks have to be done on the manager server, i.e. dividing job into sub-tasks and merging the results. There is a specially designated thread with its own queue for doing such job. When it finishes a task it tries to do the rescheduling.

*1) Checking Available Nodes in the Registry:* When the owner of a private computer turns on desktop grid infrastructure on his computer, the UnicoreX registers in the Registry located at the Desktop Grid Manager. A thread that checks the registry finds out whenever a new node becomes available and, if so it runs a new thread for checking the node.

*2) Dividing Job Into Subtask and Merging the Results:* When the desktop grid receives a job to do, it divides it into sub-tasks. It is performed by a thread used for running manager tasks. This thread also runs a part that merges results after they are fetched.

*3) Submission of Task to a Computing Element:* If any of the following events happen in the system, such as:

- node is up or node is down,
- new job has been submitted,

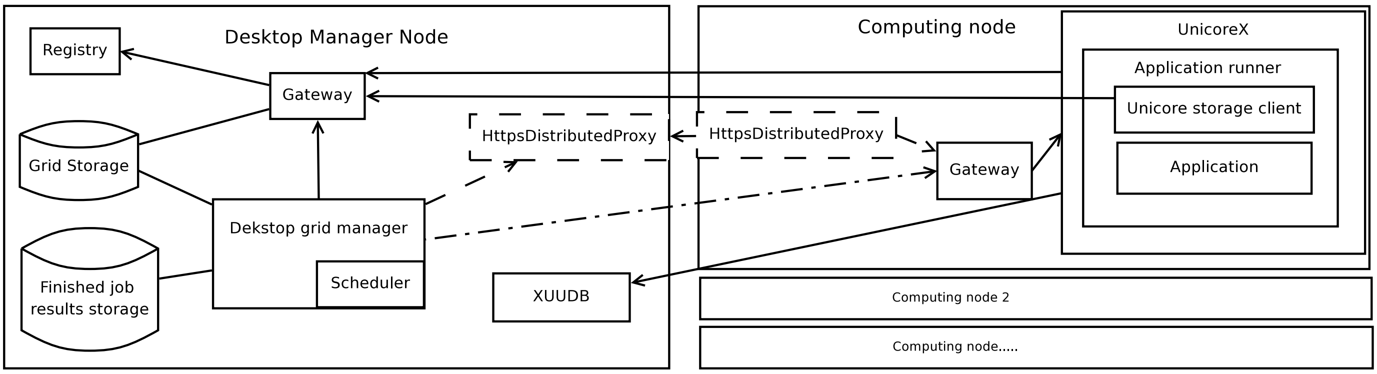

Fig. 2. Architecture of desktop grid

- node has finished computations,
- manager task has finished,

the Desktop Manager tries to run a new task on free computing elements. It runs a scheduler module which is responsible for matching tasks with the computing elements. The actual running and fetching of a task to a private computer is done by Node Manager which is part of Desktop Manager.

*4) Fetching Sub-Tasks Results:* When a job finishes computations, which means that all data is sent to a grid storage (see III-A1),the node monitoring thread receives information that the job has finished (by executing Unicore check job state call). Then, it copies all data from desktop grid storage to the finished job storage, and tries to perform the rescheduling. Or, possibly, if all tasks for the job have finished, it tries to queue a new manager thread for merging the results.

*5) Monitoring State of Nodes:* The system monitors two indicators for node activity:

- node down or up,
- state of job on the node

Because the registry can have out-of-date information about nodes, we have to monitor its status by our own. For this purpose, we call the Unicore check node time call, which is a common method of testing if the whole node Unicore infrastructure is running.

*6) Use of Desktop Grid Manager:* Desktop Grid Manager is built of two parts—core manger described above and the User interface which can be easily modified and adopted to the user's needs. Different possible settings of usage of the desktop grid are presented in Fig. 3, Fig. 4, Fig. 5 and Fig. 6.

In Fig. 3 Desktop Grid Manager plays a role of target system. Additionally, because the desktop grid uses the same middleware as Unicore grid, we can utilise free time of Unicore grid computing nodes.

In Fig. 4 there is presented a desktop grid as a standalone system. This would be achieved by changing authorisation database for Desktop Grid Manager from Unicore grid authorisation database to local one.

Standalone settings could be slightly modified by allowing clients to be computing units at the same time. Such settings are presented in Fig. 5.

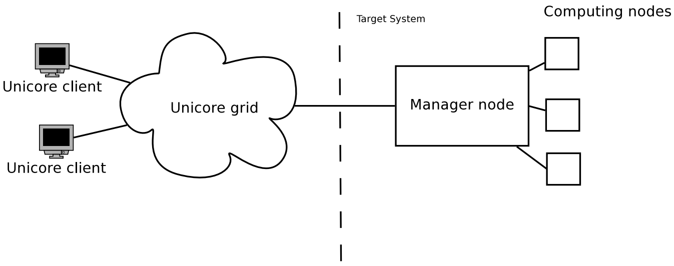

Fig. 3. Desktop grid manager server as target system for Unicore

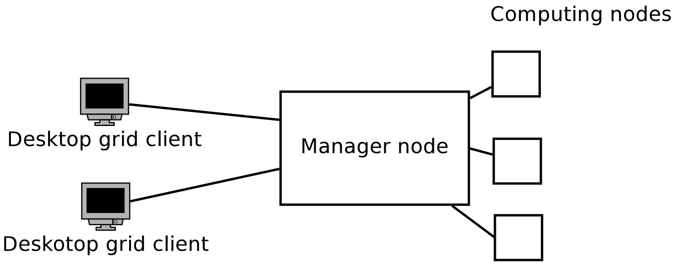

Fig. 4. Desktop grid manager as standalone server

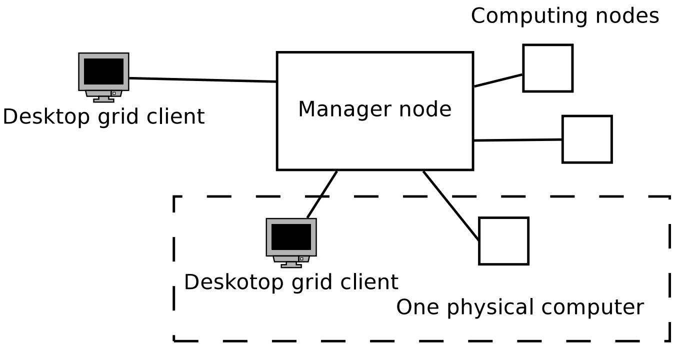

Fig. 5. Desktop grid manager as standalone cooperative system

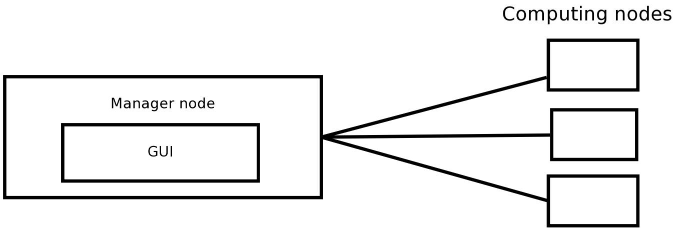

Fig. 6. Desktop grid system—development setting

Finally, Fig. 6 presents a currently implemented development setting.

With respect to this setting we created a simple GUI for Desktop Grid Manager. This solution makes monitoring of jobs execution really easy and, moreover, it simplifies debugging.

*7) Scheduler:* Scheduler used in our Desktop Manager is a random scheduler with added backup policy. It tries to assign tasks with lower number of running instances first. If tasks have the same number of running instances, then the one belonging to job that was assigned first is run.

### *D. HttpsDistributedProxy*

As it is presented in Fig. 2, the system could contain distributed https proxy. This part has already been implemented but it hasn't been incorporated into the desktop grid yet. Because the computing elements could be put behind firewall or NAT, we introduce https distributed proxy. This proxy is built of two parts:

- server part—where https client connects and asks for page
- computing node part—the part that opens a connection to a server part and waits for data coming from server, that should be tunnelled to a site.

Because https protocol does not allow looking into packets by the proxy, the tunnelling is the only available option. Because the whole communication is started by a computing node part, the computing node may be located behind NAT gateway and be not visible from Internet.

### *E. Security*

The security in the Desktop Grid is based on X.509 certificates. Desktop Server has one certificate, and every computing elements group should have their own one, too. Because certificates should be generated when the owner of computers gets a software package, and we cannot guarantee that few instances of one package will not work at the same time, we introduce a computing elements group—i.e. different computers working with the same certificate set.

Additionally, every sub-task is given its own certificate that will allow getting and putting on the desktop grid storage only such files which belong to it.

Currently, our desktop grid works with one set of certificates—all parts use the same certificate.

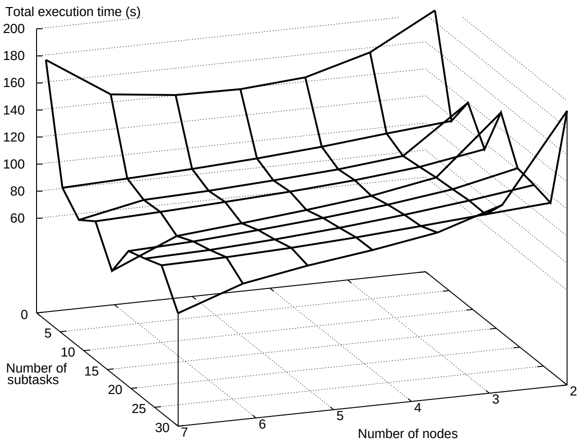

Fig. 7. Efficiency of presented system

## IV. Efficiency Tests

Desktop grid was tested on naive implementation of concurrent Mandelbrot set computing algorithm. For purposes of tests we used jobs that took 236 seconds on a single computer (run locally).

In Fig. 7 there are presented results of efficiency tests for the created system. On one axis there is presented the number of working nodes (manager node is not counted), on another one the number of sub-tasks which the job was divided to. What seems unclear here is a fact that the minimum time of execution has been achieved for a number of tasks larger than the number of nodes(not slightly larger but double or triple). This is caused by pure balancing of tasks in naive concurrent version of algorithm.

In Fig. 8 there is presented the speedup of computations as a function of number of nodes. Speedup is a time taken by computations on one machine, divided by minimum total execution time for specified number of nodes. Below 5 nodes this function is of linear nature, however worse than optimum line $y = x$. Above 5 nodes, the constant cost gains in importance, thus making the difference in speedup between 6 and 7 nodes much smaller than that between 3 and 4 nodes. These results show that our system is quite effective, although it should be optimised.

## V. Conclusions

Our work shows that Unicore 6 could be used as a basic middleware for desktop grid. It is easy to be configured and it needs only small efforts to develop Desktop Grid Manager.

## VI. Future Work

In the future we plan to:

- incorporate https distributed proxy to desktop grid,
- incorporate architecture for managing certificates from project Chemomentum [8], and add Uvos in a further step,
- complete detaching the application run by nodes from disks—by using Java policy,

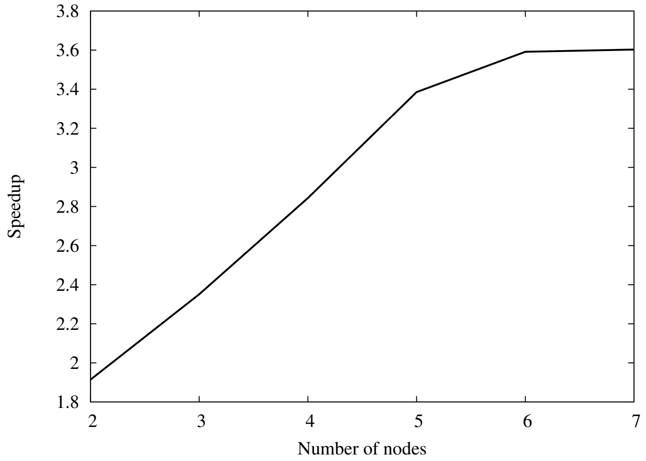

Fig. 8. Scalability of system—speed up

- attaching Java code to be executed, as an part of a task, to the task submission.

## Acknowledgment

***Abstract*—The aim of the Service Oriented Adaptative Java Applications (SOAJA) project is to develop a service-oriented infrastructure, which enables efficient running of Java applications in complex, networked computing Grid environments. The SOAJA environment provides components and services for static and dynamic load balancing based on Java object observation. SOAJA can be used to design large scale computing tasks to be executed based on idle time of processor nodes. Java distributed applications consist of parallel objects which SOAJA allocates to Grid nodes at runtime. In this paper, we present mechanisms and algorithms for automatic placement and adaptation of application objects, in response to evolution of resource availability. These mechanisms enable to control the granularity data processing and distribution of the application on the Grid platform.**

***Index Terms*—Service Oriented Applications, Adaptative Applications, Load balancing, Grid Computing Distributed Computing**

## I. Introduction

LOAD balancing is one of important procedures applied to heuristically optimize execution time of parallel programs. A general classification and an overview of load balancing methods are presented in [3], [4]. The paper deals with an asynchronous approach to load balancing, in which the load balancing activities are performed in parallel with computations. Load balancing can be further divided into static load balancing where an computational load is partitioned among executive units by an algorithm executed before program execution and dynamic load balancing, where the load decomposition is adaptively changed during computations, following the system resources availability. This paper is concerned equally with static and dynamic load balancing. In Java-based computing on Grid static load balancing has received relatively small attention. In this paper we present a two phase approach to load balancing of Java programs execution in Grid. The first phase consists of a static load balancing, which determines an initial deployment of application Java objects over the network of Java Virtual Machines. This static load balancing algorithm scenario includes execution of the application for a representative set of data to be able to detect some static properties concerning computational and communication aspects and to be able to use this properties for an initial deployment of program elements before execution. This phase of load balancing is based on tracing of the load of virtual machines and method invocations. The second phase of the load balancing process is dynamically organized during program execution. It is based on three basic operations: JVM load observation, detection of the load imbalance and load migration if the imbalance exists. A dynamic agent approach is used to implement these operations. Some metrics to detect and measure the load imbalance of processors have been proposed in the paper. They differ from standard measures known in the literature [2].

This paper describes SOAJA overall architecture and then deals with its internal concepts. The rest of the paper is composed of 5 parts. In the first part the general assumptions for the SOAJA framework are presented. Part 2 explains the use of web services in SOAJA. Part 3 discusses the relations between web services and functions of DG-ADAJ. Part 4 describes the load imbalance detection mechanisms in SOAJA. Part 5 describes the load imbalance correction mechanisms.

## II. SOAJA and Grid

The SOAJA (Service Oriented Adaptative Java Applications) infrastructure provides components and services enabling a platform-independent access, sharing and application of potentially distributed complex data mining workflows [7] and resources, including database and information systems and hardware resources. It supports resource discovery and will supply context-aware recommendations for the dynamic composition of data mining operations and workflows. The underlying agent-based layer of the SOAJA infrastructure will provide means to orchestrate very large, heterogeneous and dynamic hardware and software resources across multiple platforms. The SOAJA is deployed in a grid infrastructure with a JVM on each processor node. The main services of this framework are observation, measuring of the JVM load, measuring of the physical processor load, load balancing service, and data parallel services. The SOAJA environment is the extension of the ADAJ environment to make it scalable on the Grid and to support service oriented architecture [5].

ADAJ is a programming and execution environment for parallel and distributed applications, which facilitates the design and optimizes performance. ADAJ is a Java environment based on JavaParty [14], which optimizes the RMI protocol. The JavaParty allows execution of distributed Java applications on workstations connected via a network. JavaParty has introduced the concept of remote objects that can be distributed in a transparent manner. It compensates for the drawbacks of the RMI protocol because it conceals the addressing and

978-83-60810-14-9/08/$25.00 © 2008 IEEE

communication mechanisms. Indeed, it is sufficient to annotate Java classes with the word “remote” that will give access to remote objects from any JavaParty environment without publishing them explicitly in service names space as RMI.

Unfortunately, designing distributed programs and optimizing their performance does not remain as simple. Indeed, a programmer must consider construction of its application in the most effective way, while taking account of heterogeneity of the executive environment. This is what the role of ADAJ is. Principles of ADAJ:

- Simplifying the programmer’s work by hiding problems related to the management of parallelism,
- Facilitating the development of applications and allowing their automatic or quasi-automatic deployment in heterogeneous environments,
- Ensuring effective implementation of parallelism, by mechanisms of inter- and intra-applications load balancing.

ADAJ includes four major features:

- A library containing the necessary tools to facilitate parallel programming,
- An observation system which scans the environment during its execution and retrieves the information necessary to optimize the program,
- A system that calculates the load of JVM and physical processors using the information gathered by the observation system,
- A system that allows correcting load imbalance by objects migration based on information from the the observation and the calculation of loads.

DG-ADAJ is the ADAJ environment implemented for Desktop-Grid. Initially, DG-ADAJ was conceived as an extension of the ADAJ system (see [10]), built for cluster computing. It has been re-engineered to extend its for larger scale distributed computing and to introduce some special security mechanisms, which provide reliable application execution [12].

The Figure 1 illustrates the main web services that belong to SOAJA environment.

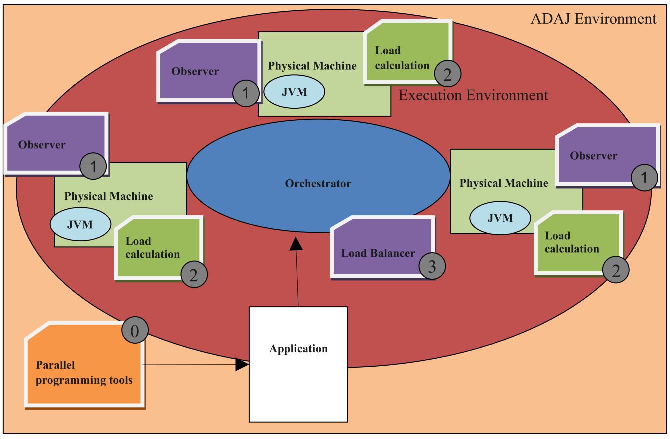

Fig. 1. SOAJA Environment

SOAJA is based on WSRF [9] and allows instantiation of statefull services for applications. The statefullness of the services is exploited in relation with application clients that will allow asynchronous communication with software components instantiated for the client on different platforms.

Various middleware components were considered to enable SOA services. In close relation with these components, specific technologies were defined and implemented in order to achieve interoperability. The Enterprise Service Bus (ESB) is a middleware technology providing the necessary characteristics in order to support SOA. In a typical ESB architecture, the ESB layer itself is deployed over the existing infrastructure. Based on this infrastructure, the ESB layer offers the necessary support for transport interconnections while it exposes the existing subsystems through a specific set of adapters.

With the help of the ESB, services are exposed in a uniform manner, based on open standards, so that any client, who is able to consume web services over a generic or specific transport, is able to access them. For example, the SOAJA has been used to implement data mining application in the WODKA project [11].

## III. ADAJ Web Services

SOAJA is a platform developed on top of DG-ADAJ, by adding the web services layer and gaining SOA-specific properties. With computing grid as a central target, the SOAJA platform provides a uniform and transparent interface to the infrastructure of the DG-ADAJ platform. The SOAJA platform, through its orchestration layer, implements an alternative to facilitate execution in the DG-ADAJ environment [1], [13]. With DG-ADAJ executions controlled via an ESB, the orchestration layer is able to offer both the support for execution of complex compositions, as well as elementary execution of the underlying DG-ADAJ environment.

The solution is hiding implementation details of different Grid environments behind various web service standards and technologies, offering the necessary support for integration, interoperability, and reliable messaging. As a side effect, by employing the orchestration layer, we enable a programming-in-the-large paradigm necessary to assure the development and support of long living, asynchronous processes.

The SOAJA platform is going to help efficient execution of heterogeneous applications enabled by DG-ADAJ by offering basic support for workflow deployment and enactment. The DG-ADAJ environment could thus be freed from some of the placement, distribution and execution tasks, by moving significant parts of these to the higher layer of the ESB and the enactment environment. With SOAJA, the ability to design component-based and service oriented applications, developed over the DG-ADAJ platform is extended with the help of web services open standards, by offering the possibility to access both local and remote components, eventually deployed on different DG-ADAJ environments.

We have found no tool to transform packages containing many classes, directly into a web service package. We had to go through the implementation of interfaces to identify methods that might be invoked by other web services.

Let us now describe the internal mechanism of DG-ADAJ.

## IV. Execution optimization in SOAJA

Distribution of the application components (objects) among active Grid nodes should guarantee a possibly high efficiency of the overall application execution. Thus, the following two aspects of execution optimization have been taken into account in the SOAJA environment:

- initial objects deployment,
- dynamic load balancing.

### *A. Initial object deployment optimization*

An optimization feature of SOAJA is an initial application objects deployment on JVMs, which results in a shorter execution time. The initial placement of application objects to JVMs is the service of the orchestrator shown in Fig. 1. The initial object deployment optimization algorithm follows the pattern of static parallelization method in multithreaded Java program. It defines decomposition of Java code into parallel threads distributed on a set of JVMs, so as to reduce program execution time [13]. The control decisions are taken to determine which of the classes should be distributed and what the mapping of objects and data components (fragments) should be to JVM nodes, to reduce direct inter-object communication and to balance loads of the JVMs. When applied to an application run under DG-ADAJ control, it will determine an initial distribution of its objects among Java Virtual Machines (JVMs) assigned to Grid active nodes, thus leading to a reduction of the total execution time.

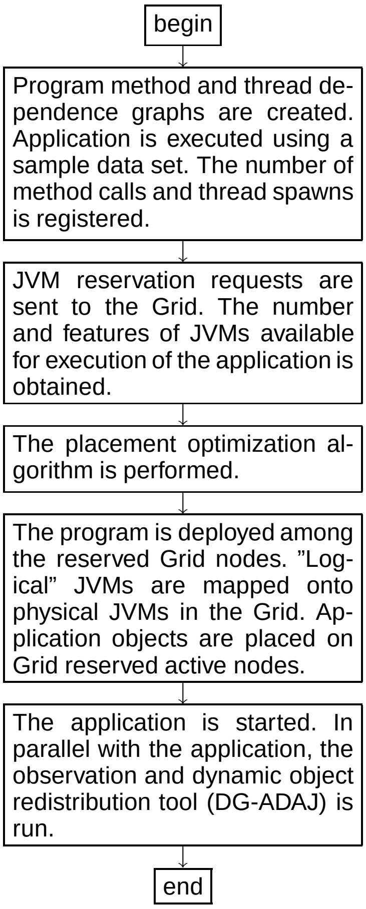
The proposed optimization algorithm employs an image of application program, based on an analysis of the byte code generated by Java compiler. This analysis identifies control dependencies between byte code instructions. They are represented in adequate MDG (Method Dependence Graph) and MCG (Method Call Graph) graphs of the program [6], [13]. The number of mutual method calls and the number of thread spawns during program execution for representative input data are measured using observation mechanisms described later in the paper. Program behavior, including all created objects in each class, all called methods, as well as all spawned threads, are registered in trace files.

The flow of actions during application execution is shown in the diagram in Fig. 2. The first three blocks in the diagram determine an initial optimized placement of application objects and perform the respective objects distribution over Grid on JVMs nodes. This part of the algorithm starts with execution of the application using some representative sample data. For that, the number of available JVMs nodes on the Grid must be known. The number of method calls and spawned threads that have appeared during execution is recorded. Next, the program method and thread dependence graphs are annotated with the recorded data.

At the beginning of the object deployment optimization algorithm we treat all objects as remote objects (respectively all classes are distributed classes). Based on the recorded control data, the algorithm decides which classes should remain distributed and how the involved objects should be placed on a set of JVMs assigned to active nodes on the Grid. We use the heuristics based on the following principles: the strong locality of method calls has to be preserved inside each parallel thread and the number of inter-thread calls, which cross the boundaries of JVMs has to be reduced. To fulfill such object requirements we designate all calls inside a single thread to the same JVM and optimize distribution of threads across available sets of JVMs by applying load balancing methods.

The algorithm consists of two phases (see [6] for details). In the first phase the MCG graph is traversed in the DFS (Deep-First-Search) manner to agglomerate method calls executed in single thread. In this step, the algorithm finds the MCG subgraphs, which are constructed of vertices connected by edges connecting calls inside threads. We assume that each subgraph is executed on a dedicated JVM. Subgraphs are built at the level of single objects. In case when an object belongs to different subgraphs, the new subgraph is constructed and a unique JVM number is assigned to it. We expect that, in most cases, at the end of this phase, the number of found subgraphs is far bigger than the number of available JVMs in the system.

In the second phase of the algorithm, we clusterize the



Program method and thread dependence graphs are created. Application is executed using a sample data set. The number of method calls and thread spawns is registered.

JVM reservation requests are sent to the Grid. The number and features of JVMs available for execution of the application is obtained.

The placement optimization algorithm is performed.

The program is deployed among the reserved Grid nodes. ”Logical” JVMs are mapped onto physical JVMs in the Grid. Application objects are placed on Grid reserved active nodes.

The application is started. In parallel with the application, the observation and dynamic object redistribution tool (DG-ADAJ) is run.

Fig. 2. The control flow of an application execution.

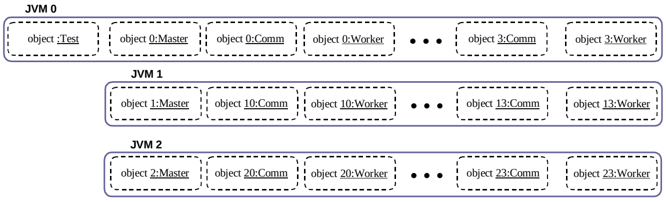

Fig. 4. Final distribution of application objects across JVMs.

subgraphs obtained in the previous phase until the number of clusters is equal to the number of JVMs. The general outline of this phase is similar to Sarkar's [15] edge-zeroing clustering heuristics. At each clustering step, the algorithm finds the subgraphs, which are connected by edges with the biggest weight value and which connect nodes placed on different JVMs. All nodes of those subgraphs are assigned to the same JVM while the total number of remote calls decreases. The algorithm stops when the number of clusters is equal to the assumed number of JVMs.

An exemplary result of the first phase of the algorithm is shown in Fig. 3. A MCG has been partitioned into sub-graphs and objects, which belong to more than one sub-graph, are assigned to unique JVM. During clustering phase, objects that frequently invoke methods in different objects are moved to the called object's JVM. Final distribution of program objects across JVMs is shown in Fig. 4.

The first phase of the algorithm makes that method calls inside programmer-declared threads are local to the JVM. This allows exploiting thread level parallelism without introducing large inter-JVM communication overheads. The gain of the second step of the heuristics comes from reduction of RMI calls to remote objects.

## *B. Load balancing*

The workstations used in the network are heterogeneous, but they have different and variable computing capabilities over time. The load imbalance occurs when the differences in workload between the workstations become too big. An application execution may not be optimal because some workstations have too much work and the others have not enough. Let's consider that the network works correctly and that the DG-ADAJ environment is running. We distinguish two main steps in load balancing: detection of imbalance and its correction, if necessary. The first step uses measurement tools to know the functional state of workstations. The second consists in migrating of the load from overloaded workstations to underloaded workstations in order to balance the workload.

The observation mechanism of applications in the DG-ADAJ environment aims at providing knowledge of the applications behavior during their execution. This knowledge is gathered by observing activity of constituent objects.

There are two types of objects in DG-ADAJ (Fig. 5):

- **global objects:** These are global objects that can be created remotely in any JVM. They are remote accessible. There is only one copy of a global object in all environment. The global objects are also migratable, i.e. they can be moved from one JVM to another.
- **local objects:** These objects are traditional Java objects. They can be used in only one JVM at the place where they reside. If another JVM needs such object, it will create of a new copy of the object concerned. Obviously, local objects cannot be migrated.

We decide to observe only global objects as the observation and migration of all objects would generate a considerable work overhead compared to the profit brought by load balancing.

## V. Detection of load imbalance

In this first phase, the purpose is to obtain knowledge about of the functional state of workstations composing the cluster. As the environment is heterogeneous, it is necessary to know not only the load of workstations but also their working capabilities. Such capability is directly related to the workstation computing power, so we have to estimate it. This measurement needs to be made only once when the workstation joins the system. We call it *the calibration* in this paper.

We then need the workstations workload measurement at a given time. For this purpose, we observe this part of the CPU time that is used by DG-ADAJ applications. However, such measurement is not normalized and cannot serve for comparisons between different workstations. It is thus necessary to balance it against different computing power of the workstations. After a series of measures, we compare the values found on different machines and we determine if there is a load imbalance.

The heterogeneity disallows us to compare measurements taken on workstations whose computing powers are different. Before we are able to compare the workstations load, we have to normalize the measurements. The normalization of the workloads is made by means of the power indications. After experiments to determine the workstation power, we found that the formula, which allows us to compare the workstations load is the product of the power index and the CPU time use rate by a thread, which gives the availability index of a CPU:

$$Ind_{availability} = Ind_{power} * \%Time_{CPU}$$

At this point, we have availability indices of all workstations. By comparing these indices, we will be able to detect the load imbalance. An imbalance is characterized by too big dispersion of the availability indices of workstations composing the network. It is difficult to fix a threshold not to be overpassed to characterize a load imbalance. But we can define an interval in which the dispersion of the availability indices remains acceptable at a given moment. We are going to be interested in the gap between the minimal and maximal availability indices found during a series of measures. If the distance between these values is too big, we conclude that there is a load imbalance, which can to be considered using the following condition:

$$Stability = (max(Ind_{availability}) \leq \alpha * min(Ind_{availability}))$$

If this inequality is verified, the availability indices are close enough not to present a too big imbalance. Otherwise, the range of the values is too big and an imbalance of workload between workstations is detected. The central point of this inequality is the value taken by the coefficient $\alpha$. We tried to clarify it first by using statistical tools then by using an experimental way. We cannot finally give a unique value for this coefficient. Nevertheless, we can restrict its value to the interval $[1.5 \ldots 2.5]$. These experimental values give good results because they are neither too restrictive nor too tolerant for the load imbalance.

The tolerance for the load imbalance among all workstations depends directly on the value of the coefficient $\alpha$. The smaller this coefficient is, the more we are demanding as to the load balance between workstations. Indeed, a low coefficient allows only a small difference between loads of workstations. This can be seen as a guarantee of the quality of the balancing results. However, a low tolerance of the imbalance leads to much more frequent detection of the imbalance. The consequence is to activate the mechanism of load balancing more frequently and therefore make it more expensive in time. Not only the migrated objects can not do their computing, but they can also block the execution of others objects, which are awaiting results. In addition, the coefficient $\alpha$ is to be chosen according to the number of machines in the network. When this number is big, the coefficient must be increased and vise versa.

## VI. Correction of load imbalance

### A. Classification of workstations

In this phase, we are in the state in which a load imbalance has been detected. To correct this imbalance, we have to classify the workstations into three categories according to their availability index:

- Overloaded workstations: availability indices are low,
- Normally loaded workstations: availability indices are medium,
- Underloaded workstations: availability indices are high.

The purpose of the load balancing is to transform the workstations categories: overloaded and underloaded into the category normally loaded. To do it, we need to migrate the workstations load from the first category to the third one.

We use the K-Means algorithm [8] to build the categories of workstations based on the computed availability indices. The K-Means algorithm allows to classify a distribution of $n$ values into $k$ categories by choosing $k$ centers for categories. We want to classify workstations into the categories: overloaded, normally loaded and underloaded. For this, we use this algorithm by taking the computed availability indices and $k = 3$, to obtain 3 categories finally.

The three centers that we choose are the minimum, average and maximum availability indices. The average index is simply the average of indices measured during the last series of measures over the whole network. By comparing the distances of workstations availability indices from the three centers, the three categories of workstations will be identified. The center represented by the minimum index builds the category of overloaded workstations, the center using the average one builds the category of normally loaded workstations and finally the center based on the maximum index is used to build the category of underloaded workstations. The important thing is therefore to have the overloaded and underloaded categories in order to be able to move the load from the overloaded workstations to the underloaded workstations.

### B. Choice of candidates for migration

To correct load imbalance, we have to migrate the load from overloaded workstations to underloaded workstations. Firstly, we must identify the load that we want to migrate. The loads are represented by the activities of the objects which are running on the JVMs. We need to select an object on each JVM in the overloaded nodes. Let's see how to choose such an object, so that its migration changes the load balance in the network.

The migrated entity is necessarily a global object because it is not intrinsically linked to the JVM on which it currently runs. Among the global objects in a JVM, some of them have more suitable characteristics to be migrated. These characteristics are related with the other computer objects and the load quantity carried out. Two relations are involved:

- the attraction of a global object to the JVM,
- the weight of the global object.

The attraction of a global object to a JVM is expressed in terms of communication links, which it shares with other global objects inside the same JVM on the computing node. A strong attraction involves frequent communication, which will be realized as remote communication after object migration. This communication will then have a higher cost than the current cost. A small attraction will permit to leave a global object the current computing node and to run it on another one, without introducing significant amount of additional remote communication. So, the less the object is attracted by the current JVM, the more interesting it is to be selected as a migration candidate.

The computational weight of migrated global object gives the quantity of load to be removed from the current machine. An object, whose quantity of work is big i.e. shows a continuous activity, should not be migrated. In addition, by migrating a too big quantity of work (load), we could reverse the role of the involved machines (the source will become target and vice-versa). In contrast, the migration of an object with small quantity of a work does not bring significant load variation improvements. Furthermore, the migration cost will not be compensated with the new generated load distribution. In conclusion, the decision should be to move an object whose quantity of work is neither too big, nor too small. Thus, the smaller the distance is to the average object loads, the more the object is interesting for migration.

The observation of the objects activity is done by counting the activation methods. These activations can be done by global or local objects. The observation of a global object (only these objects are observable), includes:

- observation of object invocations to each global object, including him: OGI (OutputGlobalInvocation),
- the observation of object invocations to all local objects: OLI (OutputLocalInvocation),
- the observation of others objects invocations to the considered object: II (InputInvocation).

The attraction of the global object $obj$ to the actual JVM:

$$attr(obj) = \sum_{o \in JVM} (OGI(obj, o) + OGI(o, obj))$$

Distance compared to the average quantity of work of the $obj$:

$$dist_{m_{WP}}(obj) = |WP_{obj} - m_{WP}|$$

where $m_{WP} = \frac{\sum_{o \in JVM} WP_{obj}}{n}$ ($n$ is the number of global objects on the JVM) and
$WP_{obj} = OGI(obj, obj) + II(obj) + OLI(obj)$.

These formulas allow to compute the attraction of an object to the local JVM in order to compare it with the attractions of other objects of this JVM. The comparison formulas are:

- The percentage of the global attraction:

$$\%attr(obj) = \frac{attr(obj)}{\sum_{o \in JVM} attr(o)}$$

- The percentage of distance, compared to the average quantity of work of the object:

$$\%dist_{m_{WP}}(obj) = \frac{dist_{m_{WP}}(obj)}{\sum_{o \in JVM} dist_{m_{WP}}(o)}$$

Finally, we compute the weighted sum of these relations in order to determine the most interesting object to migrate:

$$Classification(obj) = \alpha_{attr} * \%attr(obj) + (1 - \alpha_{attr}) * \%dist_{m_{WP}}(obj)$$

$\alpha_{attr}$ is a real between 0 and 1. Its choice remains experimental. Let us notice however that the bigger $\alpha_{attr}$ is, the bigger is the added weight to the object attraction.

### C. Selection of the target for migration

The migration of global objects reduces the load of a JVM running on an overloaded workstation and therefore the global load cost of this workstation. The question now is: where migrate these objects? Naturally, the potential destinations are one or more underloaded workstations. However, the choice of one of these computing nodes can be more or less convenient from the point of view of work and communication quantity of the object to migrate. For an object selected for migration, we must find the best target according to these criteria.

The first criterion to quality as a target is the attraction of the selected object to this workstation. We say that the attraction of an object – candidate for migration, is big when it communicates a lot with the global objects in the target JVM. A relationship of attraction of the global object $obj$ to $JVM_i$ is defined as follows:

$$attrext_i = \sum_{objext \in JVM_i} (OGI(objext, obj) + OGI(obj, objext))$$

The more the object is externally attracted by an underloaded machine, the more it is interesting that this machine is chosen as a migration destination for it. This criterion should not be the only one during selection of target for migration. In fact, it is possible that two underloaded workstations have the same amount of communication with the candidate for migration. In this case, the second criterion will be the workstations' availability indices. We naturally prefer the one whose availability index is the highest, because it is actually the least loaded.

To complete discussion of the criteria for choosing a target for migration, we should take into account the number of *(waiting)* threads in the JVM of the potential targets. We consider them, however, as potential load, which must be taken under consideration with the related load currently done on the machine.

These three points are obvious constraints to be met by the target machine:

- the external attraction of the object is maximal to the target machine,
- the quantity of work on the target machine is minimal,
- the number of waiting Java threads is minimal.

These three conditions are gathered in a formula in order to designate the underloaded workstation, which is the most favorable for the selected object migration. Firstly, we have to normalize all the values related in the interval $[0\ldots1]$. We then obtain:

$$\%attrext_i = \frac{attrext_i}{\sum_j attrext_j}$$

$$\%Ind^*_{availability_i} = \frac{Ind^*_{availability_i}}{\sum_j Ind^*_{availability_j}}$$

where

$$Ind^*_{availability} = Ind_{availability} - Ind_{availability} * \frac{NbThread_{wait}}{NbThread_{total}}$$

The availability index was corrected by the potential work of the workstation, represented by the waiting threads. We have not considered this index during the classification of workstations into three categories, because we want to classify workstations according to their measured quantity of work and not a potential one. Indeed, threads waiting must be seen as supplementary work about which we know nothing. They may start executing in one second quite well as in one hour. Their consideration is thus justified only when we want to examine our measurements in perspective as it is the case here. We thus chose to decrease the raw indication of availability by means of the relationship between the number of waiting threads and the total number of threads staying in the machine.

The aggregation function should account for the two described components by giving them different weights. The balanced sum of them is:

$$Quality_i = \alpha_q * \%attrext_i + \beta_q * \%Ind^*_{availability_i}$$

with $\alpha_q$ and $\beta_q \in [0\ldots1]$

For an object which is a candidate for migration, this formula is applied to all JVM potential node targets. The workstation which maximizes this sum will be chosen as new location for the object. The choice of coefficients $\alpha_q$ and $\beta_q$ is experimental but the sum of the two must be equal to 1 (it was therefore $\alpha_q = 1 - \beta_q$). The weight of one or the other value can be increased by changing these coefficients. The migration of the object allows to eliminate communication on the network and to reduce considerably the waiting time for replies. For that purpose, the coefficient $\alpha_q$ must be the most important to promote the machines for which the attraction of the object is maximal. For example, we can use the coefficients $\alpha_q = 0.6$ and $\beta_q = 0.4$.

## VII. Conclusions

This paper has presented the mechanisms and algorithms, which ensure automatic support for Java distributed programs execution on Grids. It includes initial placement of the application objects to the current used host system configuration and further dynamic program execution adaptation in response to the computing system evolution and to modifications of the resource availability. The proposed program execution optimization mechanisms provide control to adjust the initial granularity of the application program parallelization and the dynamic re-distribution of the application on the Grid platform. The SOAJA infrastructure with its observation mechanisms provides components and services enabling static and dynamic load balancing using idle CPU time of the nodes of a Grid. The system is currently under implementation based inside the GRID 5000 project.

# Parallel Performance Prediction for Numerical Codes in a Multi-Cluster Environment

Giuseppe Romanazzi, Peter K. Jimack
School of Computing
University of Leeds
LS2 9JT Leeds, United Kingdom
Email: {roman,pkj}@comp.leeds.ac.uk

***Abstract*—We propose a model for describing and predicting the performance of parallel numerical software on distributed memory architectures within a multi-cluster environment. The goal of the model is to allow reliable predictions to be made as to the execution time of a given code on a large number of processors of a given parallel system, and on a combination of systems, by only benchmarking the code on small numbers of processors. This has potential applications for the scheduling of jobs in a Grid computing environment where informed decisions about which resources to use in order to maximize the performance and/or minimize the cost of a job will be valuable. The methodology is built and tested for a particular class of numerical code, based upon the multilevel solution of discretized partial differential equations, and despite its simplicity it is demonstrated to be extremely accurate and robust with respect to both the processor and communications architectures considered. Furthermore, results are also presented which demonstrate that excellent predictions may also be obtained for numerical algorithms that are more general than the pure multigrid solver used to motivate the methodology. These are based upon the use of a practical parallel engineering code that is briefly described. The potential significance of this work is illustrated via two scenarios which consider a Grid user who wishes to use the available resources either (i) to obtain a particular result as quickly as possible, or (ii) to obtain results to different levels of accuracy.**

***Index Terms*—Parallel Distributed Algorithms; Grid Computing; Cluster Computing; Performance Evaluation and Prediction; Meta-Scheduling.**

## I. Introduction

As GRID computing becomes available as a practical commodity for computational science practitioners the need for reliable performance prediction becomes essential. In particular, when a variety of computational resources are available to a scientific research team they need to be able to make informed decisions about which resources to use, based upon issues such as the size of the problem they wish to solve, the turn-around time for obtaining their solution and the financial charge that this will incur. In order to make such decisions in a reliable way, it is necessary that they are able to predict the performance of their software across different combinations of these resources.

In this work we present a robust methodology for predicting the performance of parallel numerical multilevel software across different clusters (in terms of both processor and communications architectures) and across combinations of these clusters. The long term goal of this research is to model numerical software that requires a large computational cost, in a simple and cheap way using only few parallel runs across few processors.

Multilevel software (such as multigrid) has been selected for this work due to its growing importance in practical high performance computing software: as the maturity of multilevel algorithms continues to develop, it is able to provide excellent efficiency for very wide classes of problem [1], [2], [3], [4].

The methodology is first described and its predictive capability is then assessed for five different cluster configurations, using a typical parallel multigrid code. It is of course desirable that the predictive methodology proposed should be appropriate to the widest possible classes of numerical algorithms and the paper concludes with a discussion of these issues along with an illustrative example.

## II. Related Work

In previous work [5] we have begun to consider the use of simple (and cheap to implement) predictive models for the solution of certain classes of parallel multigrid codes when executed on distributed memory hardware. Whilst the results obtained in [5] are very encouraging, in this work we develop the ideas further in a number of significant ways.

1) A more general model for inter-processor communication is used which enables less-scalable communications patterns to be captured than previously. This is important when there are all-to-all communications at any point in the code and/or when the hardware does not scale well (e.g. Ethernet switching). The additional generality of this work also ensures that both blocking and non-blocking communication patterns can be reliably captured and modelled.
2) We extend our previous work to consider inter-, as well as intra-, cluster communications. Specifically, we now permit a single parallel job to be split across two entirely different clusters and the performance to be reliably predicted in advance.
3) In addition to reporting on the performance of our model as applied to benchmark multigrid codes, we also provide preliminary results which demonstrate that this performance is also achieved when applied to a practical multilevel engineering code [2].

978-83-60810-14-9/08/$25.00 © 2008 IEEE

There is a very substantial body of research into performance modelling [6] that varies from analytical models designed for a single application through to general frameworks that can be applied to many applications on a large range of high performance computing (HPC) systems. For example, in [7] detailed models of a particular application are built for a range of target HPC systems, whereas in [8] or [9] an application trace is combined with some benchmarks of the HPC system that is being used in order to produce performance predictions.

Both approaches have been demonstrated to be able to provide accurate and robust predictions, although each has its potential drawbacks: significant code specific knowledge being required for deriving the analytic models, whereas the trace approach may require significant computational effort. Moreover, in the former approach, when a different HPC system is used it would generally be necessary to change the model, adding new parameters for example. Instead, in the latter, we need to add or to find new benchmarks when a new code is used. Considering these limits, the choice between the two approaches can depend also on other factors. For example, when it is more important to predict the run-time of a large-scale application on a given set of systems, as opposed to comparing the performance of the systems in general, researchers (like those in the LANL group [7]) prefer to study deeply their application in order to obtain its own analytic model for the available set of HPC systems. On the other hand, when it is more interesting to compare performances of different machines on some real-applications, the latter approach is preferable; in that case different benchmark metrics can be used and convoluted with the application trace file.

Our approach lies between these two extremes. We use relatively simple analytic models (compared to the LogP model [10] for example), that are applicable to a general class of multigrid algorithms and then make use of a small number of simulations of the application on a limited number of CPUs of the target architecture in order to obtain values for the parameters of these models. Predictions as to performance of the application on larger numbers of processors may then be made.

As already indicated, our emphasis in this paper is to provide computational science practitioners with the tools to be able to make informed decisions concerning the Grid resources that they request. Indeed, the scenarios that we consider specifically relate to situations in which the Grid users are aware of which resources are immediately available (and can be reserved) or they are able to reserve resources at some future point in time. More generally however exactly the same information regarding the predicted execution time of a code on different resources, and different combinations of resources, is required by a Grid meta-scheduler for it to be able to work effectively. The job of such a scheduler is to evaluate different candidate resource sets and to select the “most suitable” resources for the execution of the application, e.g. [11]. It is with this in mind that our relatively light-weight approach to performance prediction becomes particularly attractive, since it is both simple and cheap to execute automatically.

There is of course a significant body of literature relating to performance models for large Grid environments. An excellent recent example is the research described in [12] which breaks the execution time of a parallel application into two parts, representing computation and communication costs, that are subsequently estimated for the target platform. Unlike our approach [12] is restricted to tasks that run on a single Grid resource, however the situation in which the load on the resource varies dynamically is included. Other researchers have also considered this situation, including the possible use of stochastic information to predict an application’s behaviour when there is contention for resources [13], [14]. In our work we assume that once a set of resources have been allocated they will be held exclusively by the application for the duration of the run or the reserved time slot, whichever is the shorter. Hence we do not consider this issue of contention here.

A variety of other papers on the subject of performance modelling in both dedicated and non-dedicated environments are described in [6] or [12], for example, so we do not repeat such reviews here. However, we finish this introduction by noting that the precise scheduling mechanism that is used for executing jobs on a Grid may have a significant influence on the performance of the prediction models themselves. Throughout this work we are focused on the situation where we are interested solely in the computational resources that are either available and ready to be used immediately, or the resources that may be reserved for use at some specified time in the future. All of the tests that were undertaken for this work were executed without the intervention of a scheduler. Instead, available resources were reserved and then the required jobs were launched.

## III. Parallel Numerical Software

Most numerical methods for the solution of partial differential equations (PDEs) are based upon the use of a spatial mesh for performing the discretization (as in finite difference, element, etc.), see for reference [15], [16].

Using parallel resources we are able to solve problems on finer grids than would be otherwise possible, so as to achieve greater accuracy. When the work per processor is kept constant, a parallel numerical software is considered efficient if there is only a slow increase in the execution time as the number of processors used grows. With multigrid algorithms, when the problem size is increased by a factor of $np$ then the solution time also grows by this factor, and so when solving on $np$ processors (instead of a single processor), the solution time should be unchanged. This would represent a perfect efficiency but is rarely achieved due to parallel overheads such as inter-processor communications and computations that are repeated on more than one processor.

In this research our aim is to be able to predict the execution time, including these overheads, of parallel numerical software running on $np$ processors. In some of the runs that follow we use more than one core per physical processor and for other runs we use a parallel architecture with a single core per physical processor. In each case we use the generic term processor to refer to each core or processor respectively. As suggested above, we restrict our attention to mesh-based PDE solvers, in this case considering a finite difference code with a series of non-blocking sends and receives in MPI, that solves a model PDE problem over a square two-dimensional domain (of size $N \times N$, say), see the multigrid code $m1$ in [5]. This domain is uniformly partitioned across the processors by assigning contiguous rows of the mesh to each processor in turn. In the case of a multigrid solver, the partitioning of the coarsest mesh ensures that all finer meshes are uniformly partitioned too (see [3], [17] for further details).

The top diagram in Fig. 1 illustrates a typical partition when $np = 4$. Each stage of the parallel numerical solver requires communications between neighbouring processors in order to update their neighbouring rows. This is typical in parallel numerical software of this type, e.g. [2], [3], [17].

## IV. The Predictive Model

The underlying observation upon which our model is based is that when we scale the size of our computational problem with respect to the number of processors used, the parallel overheads observed using just a small number of processors can describe the communication pattern for runs using a much larger number of processors. This occurs when the problem size per processor is kept fixed. In our methodology we therefore use parallel runs across few processors for predicting the performance of the parallel run across a large number of processors ($np$), with the same work assigned to each processor across all these runs. For convenience, here we define as “work per processor” the memory required by each processor: this is because the work load per processor in a multigrid code is proportional to the problem size assigned and therefore to the associated memory required by each processor.

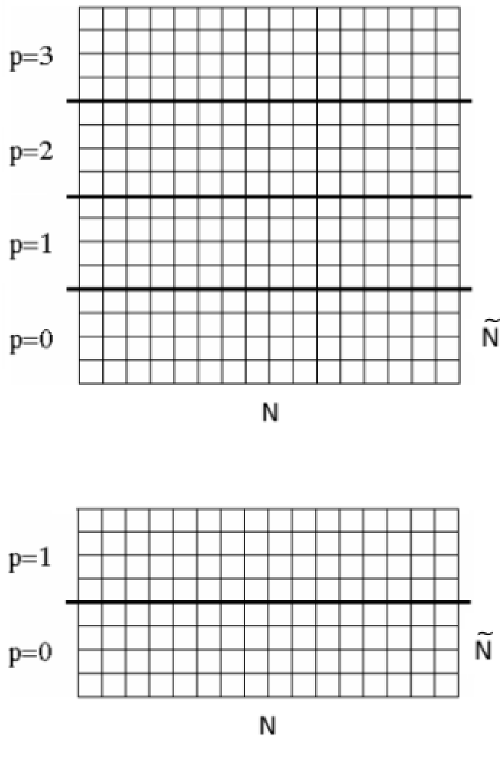

Fig. 1. Partitioning of a square mesh across four processors (top) and the equivalent problem considered on two processors (bottom).

The next basic assumption that we make is that the parallel solution time (on $np$ processors) may be represented as

$$T = T_{comp} + T_{comm}. \quad (1)$$

In (1), $T_{comp}$ represents the computational time for a problem of size $N \times \widetilde{N}$ on a single processor (where $\widetilde{N} = N/np$), and $T_{comm}$ represents all of the parallel overheads (primarily due to inter-processor communications).

The calculation of $T_{comp}$ is straightforward since this simply requires the execution of a problem of size $N \times \widetilde{N}$ on a single processor. Note that it is important that the precise dimensions of the problem solved on each processor in the parallel implementation are maintained for the sequential solve in order to obtain an accurate value for $T_{comp}$. This is because the memory access and contention patterns observed in the parallel runs (such as cache and multicore effects at the node-level) vary with respect to the geometrical dimensions of the memory allocated to each processor, and they can consequently influence the computational time measured.

The more challenging task is to model $T_{comm}$ in a manner that will allow predictions to be made for large values of $np$. Recall that our goal is to develop a *simple* model that will capture the main features of this class of numerical algorithm with just a small number of parameters that may be computed based upon runs using only a few processors. We present this model in (2) and then justify its simplicity in the remainder of the section.

$$T_{comm} = \alpha(np) + \gamma(np) \cdot work. \quad (2)$$

In (2) the term $work$ is used to represent the work on each processor, and is expressed in MBytes of the memory required, which is proportional to the computational cost. Also note that the length of the messages ($N$) does not appear in this formula since it is assumed that for a given size of target problem (e.g. a mesh of dimension $65536 \times 65536$) the size of the messages is known *a priori* (in this case, since the partition is by rows, the largest messages will be of length $65536$). Hence there is no need to include $N$ in the model as it is fixed in advance. This is the primary reason that the expression (2) can be so simple.

Furthermore, we will assume that the following relations also hold:

$$\begin{aligned} \alpha(np) &\approx c + d\log_2(np) \quad (3) \\ \gamma(np) &\approx \text{constant.} \quad (4) \end{aligned}$$

The justification for this model and the above assumptions are based upon our own empirical evidence gained using different parallel architectures. Two such illustrations are provided in Fig. 2 and Fig. 3. These show plots of overhead against work

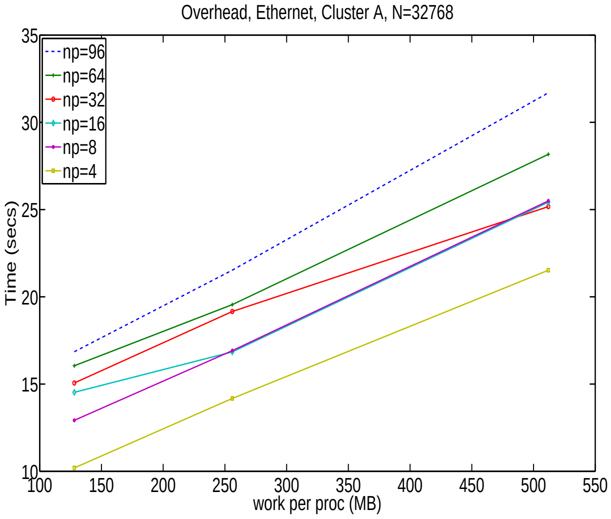

Fig. 2. Overhead ($T_{comm}$) associated to a fixed size of messages ($N$) using Fast Ethernet switching

for two different systems: one based upon a Fast Ethernet switching and the other based upon Myrinet. In each case we observe an almost linear growth in overhead with work, where the slope is approximately constant and there is an almost constant difference between graphs as $np$ is doubled. Note that the length of the messages is the same in all of these runs (see Fig. 1 for constant work with two different choices of $np$ and Fig. 4 for the same $np$ but half the work per processor).

In order to be able to use the model (2) it is necessary to evaluate the parameters $c$, $d$ and $\gamma$. These are determined using measurements taken for $np = 4$ and $np = 8$: $\gamma = \gamma(8)$ whilst $c$ and $d$ are obtained using a simple linear fit through the two data points.

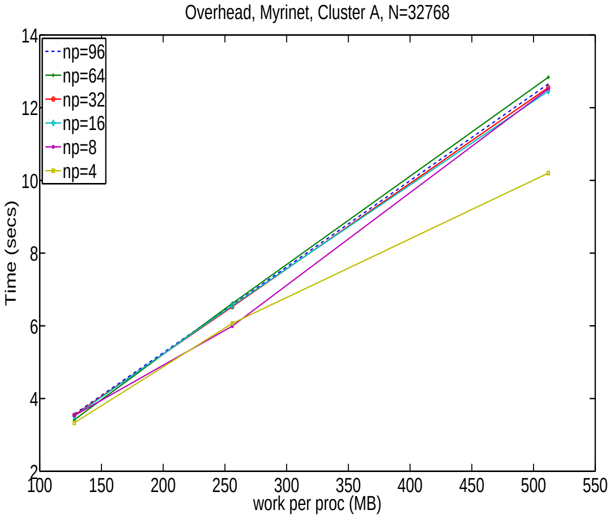

Fig. 3. Overhead ($T_{comm}$) associated to a fixed size of messages ($N$) using Myrinet switching.

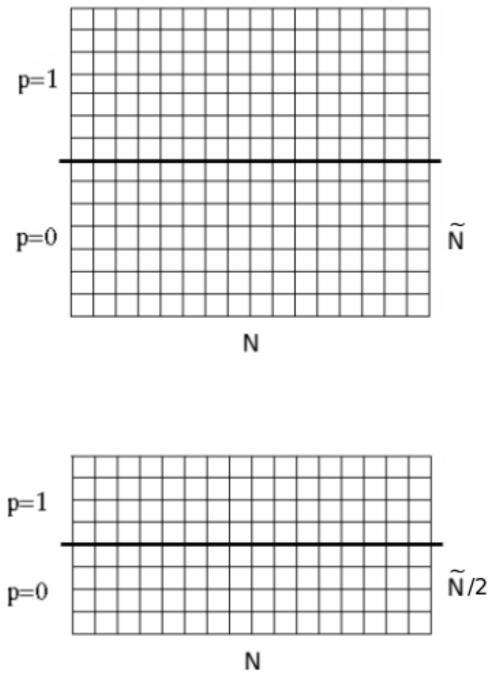

Fig. 4. Scaling the work per processor whilst maintaining the communication volume.

A summary of the overall predictive methodology is provided by the following steps. We define as $N \times N$ and $np$ the target problem size and number of processors respectively (i.e. we wish to predict a code's performance for these values). Also, let $\widetilde{N} = N/np$ and define $N \times \widetilde{N}$ to be the size of problem on each processor in the target configuration.

1) Run the code on a single processor with a fine grid of dimension $N \times \widetilde{N}$ and then with dimension $N \times \frac{\widetilde{N}}{4}$. In each case collect the computational time $T_{comp}$ and define as $work$ the memory allocated in the processor.
2) Run the code on $np0 = 4, 8$ processors, with a fine grid of dimension $N \times (np0 * \widetilde{N})$ and $N \times \left(np0 * \frac{\widetilde{N}}{4}\right)$. In each case collect the parallel time $T$ and then compute $T_{comm} = T - T_{comp}$.
3) Fit a straight line as in Eq. (2) (for both choices of $np = np0$) through the data collected in steps 1 and 2 to estimate $\alpha(np0)$ and $\gamma(np0)$.
4) Fit a straight line as in Eq. (3) through the points $(2, \alpha(4))$ and $(3, \alpha(8))$ to estimate $c$ and $d$: based upon Eq. (3) now compute $\alpha(np)$ for the required choice of $np$.
5) Use the model in Eq. (2) to estimate the value of $T_{comm}$ for the required choice of $np$ (using the values $\gamma(np) = \gamma(8)$ and $\alpha(np)$ determined in steps 3 and 4 respectively).
6) Combine $T_{comm}$ from step 5 with $T_{comp}$ (determined in step 1, with finest size $N \times \widetilde{N}$) to estimate $T$ as in Eq. (1).

In the parallel runs described in step 2, we use messages at all levels with lengths equal to those used in the parallel run that we are interested to predict. As we show in the next section, this permits us to describe accurately the communication patterns at all mesh levels of the multigrid code.

## V. Numerical Results

The approach described in the previous section is now used to predict the performance of a typical numerical code running on two different clusters, either individually or together.

### A. The White Rose Grid

The White Rose Grid is a collaborative project involving the Universities of Leeds, Sheffield and York [18]. In these tests we make use of two clusters on this Grid.

- Cluster A (White Rose Grid Node 2) is a cluster of 128 dual processor nodes, each based around 2.2 or 2.4GHz Intel Xeon processors with 2GBytes of memory and 512 KB of L2 cache. Either Myrinet or Fast Ethernet switching may be used to connect the nodes.
- Cluster B (White Rose Grid Node 3) is a cluster of 87 Sun microsystem dual processor AMD nodes, each formed by two dual core 2.0GHz processors. Each of the $87 \times 4 = 348$ batched processors has L2 cache memory of size 512KB and access to 8GBytes of physical memory. Again, both Myrinet and Fast Ethernet switching are available.

In addition to running jobs on either cluster, using either switching technology, it is also possible to run a single parallel application across both clusters together (using Fast Ethernet only).

Because users of clusters A and B do not get exclusive access to their resources some variations in the execution time of the same parallel job can be observed across different runs. A simple way to reduce such effects in the predictive methodology is to take average timings on a limited number of runs. However, this approach alone is not sufficient since specific hardware features must also be accounted for.

For cluster A, for example, there are 75 2.4GHz and 53 2.2GHz dual processors, hence it is necessary to ensure that all runs used in the parameter estimation phase make use of at least one slower processor. This is because if only the faster processors are used to estimate $T_{comm}$ and $T_{comp}$, then the resulting model will under-predict solution times on large numbers of processors (where some of the processors will be 2.2GHz rather than 2.4GHz). Similarly, on the multicore cluster B, care needs to be taken to account for this architectural feature. For example, all of the sequential runs are undertaken using four copies of the same code: each running on the same (four-core) node. Again, this decision is made bearing in mind the situation that will exist for a large parallel run in which all the available cores in a node are likely to be used. Moreover on this cluster the $8$ core runs, distributed as two full nodes, are able to catch both intra- and inter-node communications, see [5] for further details. This strategy permits to reproduce the effects [19] of the memory contention at the node-level in a multi-core architecture.

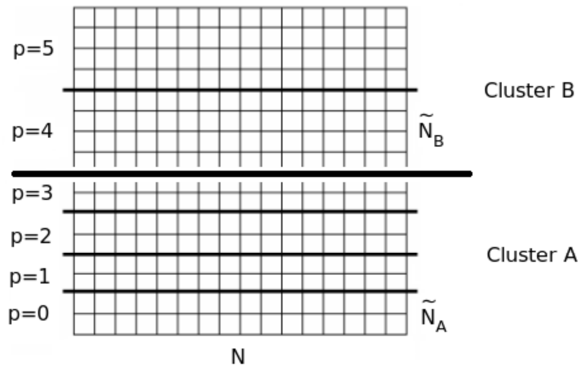

Fig. 5. Example partitions by rows of a fine square mesh across two clusters: A and B.

### B. Methodology for Inter-Cluster applications

As mentioned above, it is also possible to run a single job across both clusters using Fast Ethernet switching. Fig. 5 illustrates a typical partition, for which the work per processor may be different on each cluster. In this example a target configuration with $np_A$ processors on cluster A (each working with a sub-mesh of size $N \times \widetilde{N}_A$) and $np_B$ processors on cluster B (each working with a sub-mesh of size $N \times \widetilde{N}_B$) is assumed. In order to predict the overall solution time for such a multi-cluster run we make the assumption that the inter-cluster communication costs, whilst greater than those within each cluster, will generally be negligible compared to the inevitable imbalance of execution times between the clusters. Hence our methodology is to use the approach of the previous section to predict $T_A$ for the problem of size $N \times (np_A * \widetilde{N}_A)$ assigned to the $np_A$ processors of cluster A and $T_B$ for the problem of size $N \times (np_B * \widetilde{N}_B)$ on the $np_B$ processors of cluster B. We then take the simple estimate

$$T = \max (T_A, T_B). \tag{5}$$

### C. Results

We have tested our models for a range of problems with five different cluster architectures and present a selection of typical results in Tables I and II below. These tables are focused around two potential applications of the predictions within a Grid environment, which we refer to here as scenarios. However the key observation that wish to we make here is the consistent accuracy of the predictions when compared to the actual run times that have subsequently been computed.

### Scenario 1

In this scenario, it is assumed that a problem of a particular size must be solved and that two clusters are scheduled to be partially available, with $np_A$ and $np_B$ processors free on clusters A and B, respectively. Specifically, we consider the

TABLE I
MEASUREMENTS AND PREDICTIONS (BOTH QUOTED IN SECONDS) FOR SCENARIO 1.

| procs | $np_A = 64$ | $np_A = 64$ | $np_B = 32$ | $np_B = 32$ | $(np_A, np_B) = (64, 32)$ |
|---|---|---|---|---|---|
| switching | Ethernet | Myrinet | Ethernet | Myrinet | Ethernet |
| size | $65536^2$ | $65536^2$ | $65536^2$ | $65536^2$ | $65536^2$ |
| mem. per core/proc | 2GB | 2GB | 4GB | 4GB | ( 1GB, 2GB ) |
| measurement | 1703.9 | 1014.9 | - | - | 1104.6 |
| prediction | 1715.7 | 983.9 | - | - | 1044.4 |
| $\lvert$error$\rvert$ | 0.69% | 3.05% | - | - | 5.45% |

case $np_A = 64$, $np_B = 32$ for a target problem size of $N \times N$ with $N = 65536$, see Table I. The memory requirement across some different combinations of processors is shown in the fourth row. The columns entitled "$np_A = 64$" show two sets of predicted and actual results using 64 processors on cluster A: based upon Ethernet and Myrinet switching respectively. The columns entitled "$np_B = 32$" are empty, reflecting the fact that insufficient memory is available to execute a job of this size on 32 cores of cluster B alone. The final column shows predicted and actual results when the job is split equally between the two clusters (using 64 and 32 cores on clusters A and B respectively). In all cases, the model is demonstrated to provide excellent predictions to the actual measured run times.

The purpose of this scenario is to illustrate a situation in which the user wishes to decide which of a number of combinations of available resources will deliver the required answer in the shortest time. Here the user is able to determine whether it will be better to use 64 processors of cluster A alone or a combination of these processors along with the 32 available cores of cluster B. In this particular case, if only Ethernet is available then the latter approach is faster whereas the former would be better if Myrinet is available on cluster A. Assuming that pricing information is available to the user (based upon a different rate per cpu hour on each cluster) it is also possible to predict the financial cost of each option in advance.

Other combinations of processors and job partition may be assessed in the same manner according to what resources are scheduled to be available at any given time. For example if there are an equal number of processors available on cluster A and B then it is likely to be desirable to give the faster cluster more than half of the computational domain to work with.

### *Scenario 2*

In the second scenario that we present, a user wishes to consider solving a problem with different levels of mesh resolution. That is, given two Grid resources that are simultaneously available, they can either choose to solve on the larger of these two resources or else they can make use of both resources together in order to solve a problem with even more unknowns (using the memory of both resources together). In the latter case it will clearly be possible to get more resolution but the user may wish to know how much extra this will cost, and will therefore need a reliable estimate of the solution time for each alternative.

Table II shows five different predictions, along with the corresponding measured runs times, for different cluster configurations. It is assumed that up to 32 processes are available on either of cluster A or B, or on each of them together. In the single-cluster cases the largest problem that may be solved for which $N$ is a power of 2 is $32768 \times 32768$, which corresponds to approximately 1GByte of memory per processor. By combining the two clusters however it is possible to obtain a solution with $N = 65536$. As for the previous table of results, it is again clear that the predictions obtained using the methodology described in this paper prove to be remarkably robust given their simplicity.

The significance of this scenario is that, in a Grid computing environment, our predictions provide users with the tools required to make an informed decision as to what resources they wish to request. By combining resources from two different clusters it is possible to solve a problem with greater mesh resolution however the cost of doing so may be substantial. In this specific case if, for example, cluster A is charged at 1 unit per cpu hour and cluster B is charged at 2 units per cpu hour, then the financial cost (both predicted and actual) of obtaining the greater resolution by using both clusters would be approximately 10 times the cost of the $32768 \times 32768$ resolution run using cluster B with Myrinet.

Note that, as with scenario 1, it is possible to consider other combinations of available processors using this same approach. Unlike scenario 1 however, in this case our focus is on maximizing the amount of memory available rather than minimizing the run time required.

## VI. DISCUSSION

In this paper we have proposed a simple methodology for predicting the performance of parallel numerical codes within a multi-cluster environment. The philosophy upon which this methodology is based is to produce a general empirical model that involves a minimum number of parameters, and then to determine appropriate values for these parameters for any given combination of code and hardware resources. These parameter values are determined based upon the characteristics of the code when it is executed on much smaller numbers of processors than are ultimately required. This allows resources that are not currently available to be reserved for future execution based upon the predicted need. Results presented in the previous section demonstrate that the methodology is both robust and accurate across five different combinations of parallel architecture for a given multigrid code. Furthermore,

TABLE II
MEASUREMENTS AND PREDICTIONS (BOTH QUOTED IN SECONDS) FOR SCENARIO 2.

| procs | $np_A = 32$ | $np_A = 32$ | $np_B = 32$ | $np_B = 32$ | $(np_A, np_B) = (32, 32)$ |
|---|---|---|---|---|---|
| switching | Ethernet | Myrinet | Ethernet | Myrinet | Ethernet |
| size | $32768^2$ | $32768^2$ | $32768^2$ | $32768^2$ | $65536^2$ |
| mem per core/proc | 1GB | 1GB | 1GB | 1GB | ( 2GB, 2GB ) |
| measurement | 776.7 | 628.3 | 444.4 | 281.0 | 1645.5 |
| prediction | 739.2 | 628.6 | 451.9 | 259.5 | 1686.0 |
| $\|\text{error}\|$ | 4.83% | 0.05% | 1.69% | 7.65% | 2.46% |

two different Grid scenarios have been considered, for which the performance prediction is of clear practical value.

Although the results presented in this work have been computed without the aid of any automatic scheduling software, it is clear that the performance prediction capability that has been demonstrated is of great potential value to Grid middleware and meta-schedule developers. When applications are submitted to a Grid, the scheduler needs accurate information regarding the potential performance of those applications on different resource combinations in order to be able to make optimal choices regarding the allocation of jobs to resources. We hope to explore this feature of our work further in future research. In order to be of maximum value however it will be necessary to demonstrate the generality of our approach to other numerical software.

In addition to the standard linear multigrid code that has been used for testing here, the methodology can be shown to extend to other parallel multilevel software too. Examples from our current work include the simulation of the spreading of fluid droplets [3] and the simulation of nonlinear lubrication problems involving fluid-structure interaction [2]. Details of the practical application to these engineering problems on a single cluster form the subject of another publication [20], however sample results are included here as evidence of the generality of our approach. Table III illustrates timings and predictions for the code described in [2], where we use the same methodology as described in this paper, based upon the separate prediction of $T_{comp}$ and $T$. In this case the code has additional components to the pure multigrid codes used for the rest of this paper and the work no longer scales linearly with memory. Nevertheless, as Table III clearly shows, provided this is taken into account the basic methodology that we propose again provides excellent predictions.

In addition to applying and testing our methodology to practical scientific codes in 2-d, one of the next steps that we wish to undertake is the application in 3-d. When the same linear partition of the problem is used then it is expected that the approach will be equally successful however further developments are required in order to deal with more general partitioning strategies. It is also our intention to assess the quality of the methodology when applied to other numerical schemes than the multilevel finite difference and finite element codes so far investigated. Candidates for a successful application includes other structured approaches such as Lattice-Boltzmann simulations [21].

## ACKNOWLEDGEMENTS

We are very grateful to Drs. Chris Goodyer and Jason Wood for their valuable input to this research which is supported by EPSRC grant EP/C010027/1. We also thank anonymous referee for their comments concerning Grid meta-scheduling.

***Abstract*—In this paper, we consider task scheduling in distributed computing. In distributed computing, it is possible that tasks fail, and it is difficult to get accurate information about hosts and tasks. WQR (workqueue with replication), which was proposed by Cirne et al., is a good algorithm because it achieves a short job-completion time without requiring any information about hosts and tasks. However, in order to use WQR for distributed computing, we need to resolve some issues on task failure detection and task cancellation. For this purpose, we examine two approaches—the conventional task timeout method and the soft state method. Simulation results showed that the soft state method is more robust than the task timeout method.**

## I. Introduction

DISTRIBUTED computing, in which large-scale computing is performed using the idle CPU times of many PCs, has attracted considerable attention recently. The jobs executed in distributed computing comprise many tasks. These tasks are allocated to PCs and are processed in parallel. Some well-known active distributed computing projects are SETI@home[1] and distributed.net[2].

So far, distributed computing has been mainly used in the limited area of scientific computing for analysis of protein folding, climate simulations, nuclear physics, etc. In these type of applications, the jobs are usually so large that they often take several months to be completed. For such large jobs, the effect of task scheduling on the job completion time is relatively small. Therefore, an efficient task scheduling algorithm is not that important in traditional distributed computing projects.

In the future, it is expected that distributed computing will be applied to various types of large-scale computing applications such as analysis of DNA, data mining, simulations of atmospheric circulation or ocean circulation, structural and stress analysis and fluid analysis of the air resistance of cars or planes and the water resistance of ships. These type of applications require many medium-sized jobs that take several hours or days to complete. The job completion time of such medium-sized jobs are affected by task scheduling.

In this paper, we discuss task scheduling in distributed computing.

Task scheduling in distributed computing has two main goals. The first goal is to minimize the job completion time. In order to complete a job, all tasks that are executed on various hosts should be completed. The delay in a single task can affect the completion time of the whole job. Therefore, the scheduler has to monitor the task execution at each host and perform appropriate actions in response to the change in a situation. The second goal is to minimize the wastage of CPU cycles. In distributed computing, it is common to replicate tasks to achieve good performance. However, using task replicas results in a wastage of CPU cycles. In traditional distributed computing projects, this wastage of CPU cycles has been tolerated because such CPU cycles otherwise go into idle cycles. However, the wastage of CPU cycles implies the wastage of electric power if PCs have power-saving function. Considering recent trend of energy saving, the importance of the reduction in wastage of CPU cycles in distributed computing is increasing.

Task scheduling is not a new problem. It has been studied in the area of parallel computers or clusters. However, the distributed computing systems targeted in this paper are different from parallel computers or clusters. The characteristics of distributed computing are listed as follows:

- Hosts are heterogeneous and autonomous[3].
- It is difficult to obtain good information about the hosts[4].
- Hosts are often behind NATs (network-address translations) or firewalls[5].
- Hosts are frequently turned off by users[5].

In BOINC[5], the well-known distributed computing platform, task scheduling is performed on the basis of the information regarding the processing power of each host and the estimation of the processing time of each task. When this information does not reflect the actual performance, the job completion time deteriorates.

In this paper, we investigate a task scheduling method known as WQR (workqueue with replication)[6], which was

978-83-60810-14-9/08/$25.00 © 2008 IEEE

originally proposed for heterogeneous Grid environments. The main feature of WQR is that it does not require any kind of information about the hosts or tasks. WQR has the same performance as the existing scheduling method used, which requires informations on the hosts and tasks. For this reason, the use of the WQR method in distributed computing appears promising. The drawback of WQR is the wastage of CPU cycles. In WQR, some CPU cycles are wasted because tasks are replicated and processed by multiple hosts.

There are some issues to consider when WQR is applied to distributed computing. First, the original WQR method does not take into account task failures and therefore it is possible that the job will not be completed if task failures occur frequently. In distributed computing, however, task failures are not exceptional because the hosts are frequently turned off by users. Second, the original WQR method assumes that the scheduler is able to cancel executing tasks by sending messages to the hosts. However, in distributed computing, it is difficult for the scheduler to send messages to the hosts because of NATs or firewalls. Therefore, in order to use the WQR method in distributed computing, it is necessary to add additional mechanisms to enable task failure detection and task cancellation.

A common approach to solve these issues is to set a timeout for task execution. Most existing distributed computing platforms use this approach[7]. If a scheduler does not receive the result of an allocated task before the timeout, the scheduler creates another replica of the task and allocates it to another host. We call this method as the task timeout method. The task timeout method ensures the completion of all tasks of the job. The problem in this approach is the determination of the appropriate timeout value. The appropriate timeout value depends on the average task execution time and therefore cannot be determined uniquely. The wrong timeout value may cause a delay in job completion and wastage of CPU cycles.

Another approach involves the use of the soft state protocol, which improves the robustness of distributed systems[8]. In this approach, hosts and schedulers exchange messages periodically in order to monitor each other's states. Messages are sent in a best-effort (unreliable) manner[9], that is, they are not retransmitted if they are lost.

In this study, we used the task timeout method and the soft state method with WQR and compared their performances through simulations. The simulation results showed that the soft state method had a better performance than the task timeout method.

The rest of this paper is organized as follows. In section II, we define the distributed computing model and the terms used in this study. In section III, we provide an overview of WQR. In section IV, we explain the issues in applying WQR to distributed computing. In section V, we describe two approaches to deal with these issues. In section VI, we evaluate the performance of these approaches through simulations. Finally, in section VII, we conclude the paper.

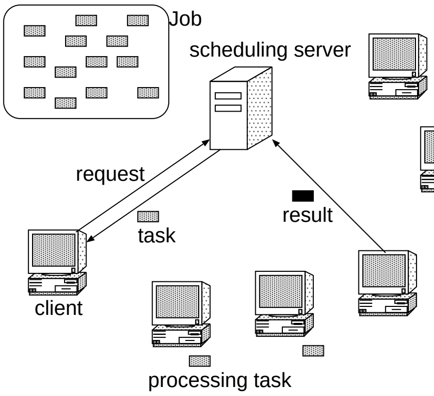

Fig. 1. Model of the distributed computing environment

## II. The distributed computing environment model

Distributed computing involves performing large-scale computations using the idle CPU cycles of many PCs in a network. The participating PCs are known as *hosts*. We use the term *users* to refer to the people using the hosts. A *task* is a unit of scheduling that consists of a program and input data. A *job* is defined as a set of tasks.

Task scheduling involves the allocation of tasks to hosts along with the allocation of the order of execution. Like most distributed computing projects, we consider Bag-of-Tasks applications in which tasks are completely independent[4].

Fig. 1 shows the model of the distributed computing environment considered in this paper. It consists of one scheduler and many hosts.

When the scheduler receives a job, it allocates the tasks in the job to hosts. The hosts receive the tasks from the scheduler and send back the results after task completion. We assume that the transfer of tasks and results are performed in a reliable manner using retransmissions.

However, hosts sometimes crash because of hardware failures or shutdowns by users. When hosts crash, their tasks also fail. Task failures are not notified explicitly to the scheduler.

In this paper, we distinguish between task failure and task cancellation. The former implies that task execution is stopped unexpectedly due to crashing of the host. The latter implies that the task execution is stopped as the task is considered unnecessary by the scheduler.

## III. Workqueue with Replication

Workqueue with replication (WQR)[6] is a task scheduling algorithm originally proposed for large-scale distributed systems such as Grids. The main feature of WQR is that it does not require any kind of information about the hosts or tasks. The performance of WQR is equivalent to that of FPLTF[10] or Sufferage[11], which require information about the hosts and tasks[6].

The WQR algorithm uses task replication to achieve a good performance. The scheduler chooses tasks in an arbitrary order and sends them to the hosts. When a host completes its task, it sends the result back to the scheduler and receives a new task from the scheduler. This scheme continues until all the tasks in the job are allocated. In the simple Workqueue algorithm, hosts that complete their tasks become idle. In WQR, however, these hosts are allocated replicas of tasks that are still running. When a task replica finishes at any host, its other replicas are cancelled.

Using task replication, WQR can improve the performance of a distributed computing by reducing the delay in completion of tasks allocated to slow/busy hosts. Task replication increases the possibility that at least one replica is allocated to a fast/idle host.

However, to avoid wastage of CPU cycles, there is a predefined limit on the number of task replicas. Tasks are replicated until the number of replicas reaches this predefined limit.

## IV. Issues in application of WQR to distributed computing

The concept of WQR is very desirable in a distributed computing environment in which it is difficult to obtain accurate information about the performance of hosts. However, the original WQR algorithm is not recommended for use in a distributed computing environment. When the WQR method is applied to distributed computing, there are some issues to consider.

### A. Detection of task failure

When a task fails, the scheduler should detect the failure and reschedule the failed task to a different host. However, it is very difficult for the scheduler to detect task failures without any notification.

In the original WQR method, the number of task replicas that can be created is limited. If all the replicas of a task fail and these failures are not detected by the scheduler, the task can never get completed. Such a situation can be avoided if the number of task replicas is unlimited. However, this increases the wastage of CPU cycles[6].

### B. Explicit task cancellation

In the original WQR method, when a task replica is completed by any host, the executions of its other replicas are cancelled in order to reduce the wastage of CPU cycles.

However, in distributed computing, it is difficult for the scheduler to cancel the tasks executing on hosts. This is because in a distributed computing environment, the hosts are generally behind NATs or firewalls. In this situation, communications are always initiated by the hosts and not by the scheduler. The scheduler cannot send any messages unless the hosts open a connection to the scheduler. Therefore, even though the scheduler receives the results of the completed task, it cannot send messages to the other hosts to cancel the replicas.

## V. Extensions of WQR

We consider two approaches to improve the WQR method, i.e., the task timeout method and the soft state method, in order to deal with the issues discussed in section IV.

### A. Task timeout method

In BOINC, the task timeout method, which has an upper limit for task execution time, is used.

The scheduler allocates a task to a host and sets the timeout value on the timer. If the scheduler does not receive the result of the task from the host before the timeout period elapses, it reschedules the task to another host. This method ensures the completion of all tasks of the job.

A problem with the timeout method is the determination of an appropriate timeout value. The appropriate timeout value depends on the average task execution time. An inappropriate timeout value delays job completion and wastes many CPU cycles. For example, if the timeout value is too small, the scheduler creates redundant replicas of tasks that are still running, while if the timeout value is too large, there is a delay in the detection of failed tasks by the scheduler.

The explicit task cancellation mentioned in section IV-B is impossible in the task timeout method. All task replicas are executed until they have completed or failed.

### B. Soft state method

The soft state method was originally proposed for state management of communication protocols[12]. It is characterized by periodic refreshing of information and the initialization of information by timeout. Lui et al. showed that the use of the soft state method makes communication protocols highly robust[8].

In the soft state method, the scheduler and hosts exchange information with each other. Hosts that are executing tasks send refresh messages to the scheduler periodically. On receiving the refresh message, the scheduler sends a reply message to the host. Messages are sent in a best-effort (unreliable) manner, that is, they are not retransmitted if they are lost. If the scheduler does not receive a refresh message before the message timeout, it reschedules the corresponding task to another host. On the other hand, if the host does not receive a reply message before the message timeout, it aborts its task and sends a request for a new task to the scheduler.

The main feature of this method is that the scheduler and the hosts are aware of each other's states due to the periodic exchange of messages. On receiving refresh messages from the hosts, the scheduler confirms that the allocated tasks are running normally. The reply messages from the scheduler to the hosts confirm that the scheduler is still waiting for the results of the tasks, that is, the tasks are not cancelled. Thus, the soft state method can perform explicit task cancellation, which cannot be achieved with the task timeout method. By stopping the flow of refresh messages, the scheduler can inform the host that the task is no longer necessary.

However, problems can arise if message losses occur frequently. If refresh messages are lost consecutively, the scheduler regards the corresponding task as failed and creates redundant replicas of the task. If reply messages are lost consecutively, the host regards its task replica as cancelled and aborts the necessary task replica. This false task abortion is another cause of task failure.

In order to exchange messages with the scheduler, hosts should always be connected to the network. However, since the sizes of refresh and reply messages are very small, the network load added by these messages is negligible compared to the tasks and their results.

## VI. Performance Evaluation

We evaluated the performance of the two methods mentioned in section V through simulations.

We assumed that the network transfer times were negligible because our target applications were CPU bound. As the performance criteria, we considered the job completion time and the number of wasted CPU cycles The job completion time is the time between the start of the first task and the completion of the last task. The wasted CPU cycles are the sum of all the CPU cycles that are used for executing task replicas that did not contribute to the final result. Such task replicas include cancelled replicas, failed ones, and redundantly completed ones.

In the rest of this section, we will refer to the task timeout method and the soft state method as the TT and SS methods, respectively.

### A. Simulation settings

In our simulations, the scheduler runs a single job. Therefore, all hosts execute tasks of the same job. Further, each host executes only one task at a time.

The processing power of each host is taken from a uniform distribution $U(1, 7)$ and therefore the average processing power of the hosts is 4. The total processing power of all the hosts in the system is fixed to 1000.

The size of a task is defined as the processing power required to process the task. For example, a task with a size of 10 is processed in 5 s by a host with a processing power of 2. The average task size (denoted as $\mu$) is 10000 (large tasks) or 100 (small tasks). The size of each task is an integer taken from a normal distribution with a standard deviation of $0.4\mu$. In both cases, the total size of all tasks included in a job is fixed as 1000000.

The number of task replicas is limited to 4 on the basis of the results of the study by Cirne et al.[6], which states that the performance of WQR with a limit of 4 is close to that when the number of task replicas is unlimited.

The task failure rate is defined as the inverse of the MTBF (mean time between failures) of tasks. All tasks have the same failure rate regardless of their size. This reflects the fact that large tasks stay in the hosts for a long time and therefore they are more likely to be involved in host crashes.

The message loss rate is defined as the ratio of lost messages to total messages sent. If the message loss rate is 0.1, it implies that 10% of the messages are lost.

For the TT method, the simulations were performed by changing the task timeout value. We used three timeout values $e_s$, $2e_s$, and $4e_s$. $e_s$ is the estimated average task execution time given by $e_s = \mu/p$, while $p$ is the average processing power ($p = 4$, as mentioned in section VI-A). For example, if the average task size is 10000, then the task timeout values are 2500, 5000, and 10000. In the following graphs, “TT-$X$” indicates a task timeout method with timeout value $X$.

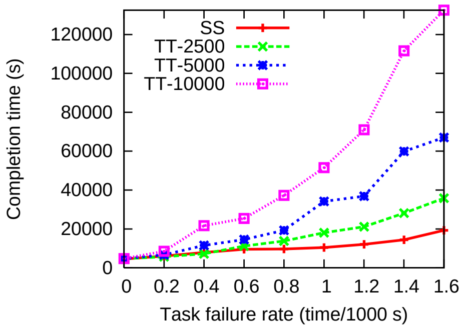

Fig. 2. Plot of the job completion time ($\mu = 10000$)

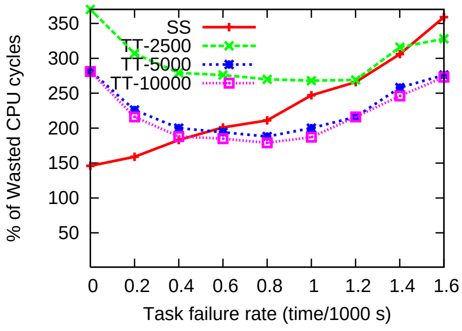

Fig. 3. Plot of the wasted CPU cycles ($\mu = 10000$)

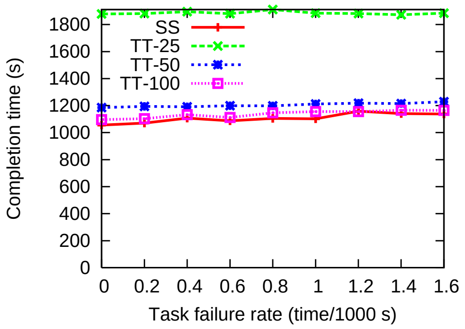

Fig. 4. Plot of the job completion time ($\mu = 100$)

In the simulations of the SS method, refresh messages were sent every 10 s and the message timeout value was set to 100(s). This implies that 10 or more consecutive message losses resulted in rescheduling or abortion of tasks, as mentioned in section V-B.

### B. Simulation results

For each parameter setting, we performed 10 simulations using different jobs. The presented results are the average of the results of the 10 simulations.

*1) Effect of task failures:* The task failure rate was changed for all simulations. The message loss rate was fixed at 0.

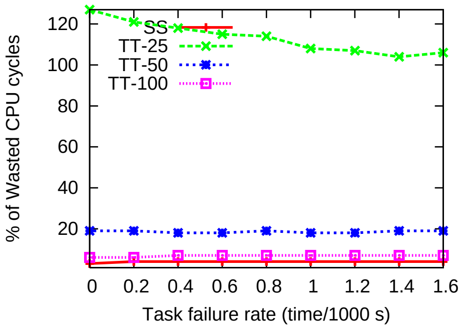

Fig. 5. Plot of the wasted CPU cycles ($\mu = 100$)

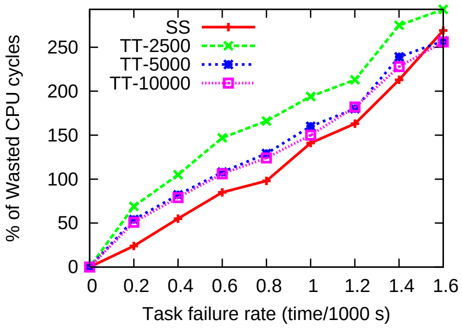

Fig. 6. Plot of the CPU cycles wasted by failed tasks ($\mu = 10000$)

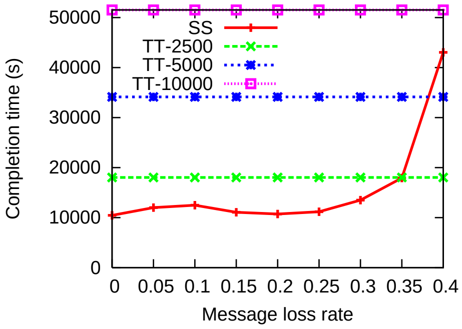

Fig. 7. Plot of the job completion time ($\mu = 10000$)

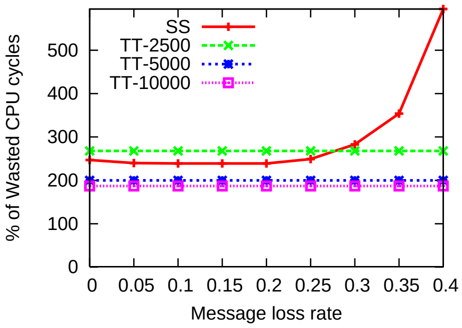

Fig. 8. Plot of the wasted CPU cycles ($\mu = 10000$)

Fig. 2 shows the job completion time when the average task size $\mu$ is large. It can be observed that the job completion time of the SS method is short and the impact of the task failure rate is relatively small. In the case of the TT method, the larger the timeout value, the larger the impact of the task failure rate. The reason for this is the difference in the task failure detections in the TT and SS methods. When a task fails, the TT method has to wait for the timeout in order to allocate a new replica to another host. Therefore, the large timeout value delays the start of the replica and also delays the task completion. On the other hand, a scheduler using the SS method can detect task failures immediately because the refresh messages stop when a task fails.

Fig. 3 shows the number of wasted CPU cycles. The impact of task failures in the TT method is almost the same regardless of the timeout value. This is because the replica creation in the TT method is triggered by a timeout and therefore is independent of task failures. On the other hand, the number of wasted CPU cycles in the SS method is almost proportional to the task failure rate. This implies that the number of replicas in the SS method increases with the number of task failures. However, these replicas reduce the job completion time of the SS method and therefore they are accepted as a necessary cost.

Fig. 4 and Fig. 5 show the performances of the two methods when $\mu$ is small. The impact of task failures is very small in both the TT and SS methods. The reason for this is that small tasks are not likely to be involved in host crashes because of their short stay in the hosts and they do not waste many CPU cycles even if they fail.

*2) Effect of the task timeout value:* It should be noted that the performance of the TT method is significantly affected by the task timeout value. Since the timeout value defines the maximum task execution time, the appropriate timeout value depends on the average task execution time. Calculation of the average task execution time requires information such as the average task size and the processing power of hosts. The fact that the performance of the TT method depends on this information contradicts the advantage of WQR, which does not require any information about tasks and hosts.

Moreover, even if we can calculate the average task execution time (denoted as $e$), the appropriate timeout value for the TT method cannot be determined by a simple calculation such as $e \cdot F$, where $F$ is some fixed value. There are two ways in which the task timeout value affects task execution.

1) If the timeout value is extremely large, the creation of a new replica of a failed task is delayed, and as a result, the completion of the task is also delayed.
2) If the timeout value is very small, many redundant replicas are created and they consume computing resources.

Fig. 2 (when $e$ is large) shows that a timeout value smaller than $e$ is desirable. However, Fig. 4 (when $e$ is small) shows the opposite behavior. These results indicate that effect (1) is dominant for large $e$ and effect (2) is dominant for small $e$. It is very difficult to estimate the effect of the timeout value on task execution for a given value of $e$.

*3) Effect of task cancellation:* It should be noted that in Fig. 3, the number of wasted CPU cycles in TT increases as the task failure rate decreases. The scheduler using TT is not able to cancel the execution of task replicas even if they are unnecessary. Therefore, even for a low task failure rate, many redundant replicas are executed to the end, and they waste many CPU cycles. On the other hand, the number of wasted CPU cycles in the SS method decreases as the task failure rate decreases. The scheduler using the SS method cancels task replicas as soon as they became unnecessary. Therefore, redundant replicas are cancelled before they waste CPU cycles. This result shows that SS's explicit cancellation of redundant replicas is effective in reducing the wastage of CPU cycles.

When the task failure rate is high, however, the difference between SS and TT is small. This is because a high task failure rate implies that many replicas including redundant ones fail frequently. Fig. 6 shows the wasted CPU cycles of failed tasks. From the graph, it can be observed that most of the wasted CPU cycles are those of failed tasks. In this case, most redundant replicas in SS failed before they were cancelled explicitly.

*4) Effect of message losses:* We also investigated the effect of changing the message loss rate of the simulations. The average task size is 10000 and the task failure rate is fixed to 1 (time/1000 s).

Fig. 7 and Fig. 8 show the job completion time and the number of wasted CPU cycles, respectively. It is obvious that the performance of the TT method is not affected by the message loss rate because the TT method does not exchange any messages during task execution. The performance of SS is also not affected as long as the message loss rate is lower than a threshold value (approximately 0.3 in the graph). However, as the message loss rate increases above the threshold, the performance of the SS method degrades significantly.

In the SS method, consecutive message losses cause false task abortion (as mentioned in section V-B). If the host aborts its task replica, the scheduler regards the task as failed and allocates a new task replica. However, when the message loss rate is very high, this new task replica may be aborted again. If the message loss rate is higher than the threshold, such abortions occur repeatedly, and the task completion is significantly delayed. The threshold is determined by the refresh interval and the timeout value of the SS method.

It should be noted that this result does not necessarily mean that the SS method is not robust against message losses. A significant degradation in performance occurs only when the high message loss rate continues permanently, which is impractical in real networks. A temporary increase in message losses does not affect the performance of SS.

## VII. Conclusions

In this paper, we investigated task scheduling in distributed computing. We selected WQR as the scheduling method because it does not require any kind of information about the hosts or tasks. We used the conventional task timeout method and the soft state method with WQR and compared their performances through simulations. The simulation results are summarized as follows.

- The soft state method is more robust than the task timeout method against task failures.
- The performance of the task timeout method depends on the timeout value, and it is difficult to calculate the appropriate timeout value.
- The soft state method wastes less CPU cycles than the task timeout method when the task failure rate is low.
- There is a threshold for the message loss rate, over which the performance of the soft state method degrades significantly.

From these results, we can conclude that the soft state method is preferable to the task timeout method for task scheduling in distributed computing.

# First International Symposium on Multimedia—Applications and Processing

RECENT advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices —such as laptops, iPods, personal digital assistants (PDA), and cellular telephones—have stimulated the development of intelligent pervasive multimedia applications. These key technologies are creating a multimedia revolution that will have significant impact across a wide spectrum of consumer, business, healthcare, and governmental domains. Yet many challenges remain, especially when it comes to efficiently indexing, mining, querying, searching, and retrieving multimedia data.

The Multimedia—Processing and Applications 2008 (MMAP'08) Symposium addresses several themes related to theory and practice within multimedia domain. The enormous interest in multimedia from many activity areas (medicine, entertainment, education) led researchers and industry to make a continuous effort to create new, innovative multimedia algorithms and application.

As a result the conference goal is to bring together researchers, engineers and practitioners in order to communicate their newest and original contributions on topics that have been identified (see below). We are also interested in looking at service architectures, protocols, and standards for multimedia communications—including middleware—along with the related security issues, such as secure multimedia information sharing. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages offered by multimedia computing techniques, including home-networked entertainment and games. However, innovative contributions that don't fit into these areas will also be considered because they might be of benefit to conference attendees.

Topics of interest are related to Multimedia Processing and Applications including, but are not limited to the following areas:

- Image and Video Processing
- Speech, Audio and Music Processing
- 3D and Stereo Imaging
- Distributed Multimedia Systems
- Multimedia Databases, Indexing, Recognition and Retrieval
- Data Mining
- E-Learning, E-Commerce and E-Society Applications
- Multimedia in Medical Applications
- Authentication and Watermarking
- Entertainment and Games
- Multimedia Interfaces

# Similar Neighborhood Criterion for Edge Detection in Noisy and Noise-Free Images

Ali Awad and Hong Man
Stevens Institute of Technology Hoboken, NJ 07033 USA
Email: {aawad, hman}@stevens.edu}

***Abstract* — A novel approach for edge detection in noise-free and noisy images is presented in this paper. The proposed method is based on the number of similar pixels that each pixel in the image may have amongst its neighboring in the filtering window and within a pre-defined intensity range. Simulation results show that the new detector performs well in noise-free images but superior in corrupted images by salt and pepper impulse noise. Moreover, it is time efficient .**

## I. Introduction

THERE are many techniques in the literature used for edge detection some of them are based on error minimization [1], maximizing an object function [2], fuzzy logic [3], genetic algorithms [4], neural network[5], and Bayesian approach[6]. But the most popular approaches are the gradient- based filters such as Sobel filter [7], and Canny method [8]. However, they show unsatisfactory performance in noisy images. In this paper, we present a new method based on the similarity criteria by which any pixel in the image has a specific number of similar pixels in the filtering window and within a predefined intensity range is labeled as an edge point. In this approach, we say that pixel $y$ is similar to pixel $x$ if the absolute intensity difference between $x$ and y is ≤ $D$. Where $D$ is a pre-defined intensity value represents the maximum intensity difference between any two similar pixels. It is clear that, the edge pixel has a large intensity differences with its neighboring pixels [9]. Therefore, for a pre-defined value of $D$ we find that the similar pixels number of an edge pixel is small compared to that of a pixel located in a smoothing area. Thus, we can say that the location of each pixel in the image is specified by two factors. 1- The intensity difference of the pixel with its neighbors. 2- The number $N$ of similar pixel that any pixel in the image may have within the intensity range of [0, $D$]. As a result, we divide the pixel location into two sectors the first one includes the edge pixels and the second one contains the smoothing areas pixels. The general characteristics of the pixels in the first division are 1- They are very small number compared to the total number of the pixels in the image. 2- The intensity difference between the edge pixel and its surrounding ones is high 3-The similar number of the edge pixel is small. The pixels in the second division have the following features 1-They are majority, since they represent most of the image pixels. 2-The intensity differences between them are very small due to the homogeneity among them. 3-The numbers of their similar pixels are high. Let us look at the following example for pixels in 7x7 window from Lena image in Fig.1-a, we find that there are $N$=14 similar pixels make with the middle edge pixel $x$=218 intensity differences ≤ 20. $N$ is a small number because $x$ is located between two regions of high intensity variations, but in fig.1-(b), there are $N$=48 similar pixels make with $x$=194 intensity differences ≤ 20. $N$ in this case is a large number because $x$ is located among smoothing area pixels. That also is very obvious in Fig.2. It shows that 67.3% of all the Lena image pixels have similar pixels number between (45-48] and the other 32.7% remaining pixels have similar pixels number less than or equal to 45 pixels in a 7x7 window.

Fig 1. 7x7 windows in different regions in Lena image.(a) shows pixels in abrupt areas (b) pixels in smoothing areas.

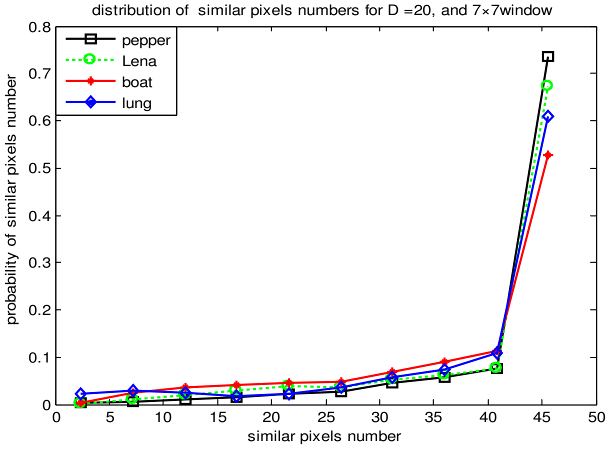

Fig.2 The distribution of similar pixels numbers within a 7×7 window size and within an intensity difference ≤ 20 for different images.

Fig.3- *a, b, c,* and *d* show the locations of the pixels that have similar pixels number $N$ ≤ 40 within $D$=20, $N$ ≤ 25 within $D$=20, $N$ ≤ 10 within $D$=10 and $N$ ≤ 5 within $D$=5, respectively for Lena image. It is obvious that all of those pixels are minority pixels and located on the edges of the image. Therefore, we can define a new parameter called similarity parameter $S = \dfrac{D}{N}$ to measure the similarity of a

978-83-60810-14-9/08/$25.00 © 2008 IEEE

pixel with its surrounding ones in the filtering window within an intensity range [0, *D*] and would give an acceptable edge detection results. It is clear from the last example that at $S \approx 1$ satisfactory performance is obtained. This value can be used as a threshold.

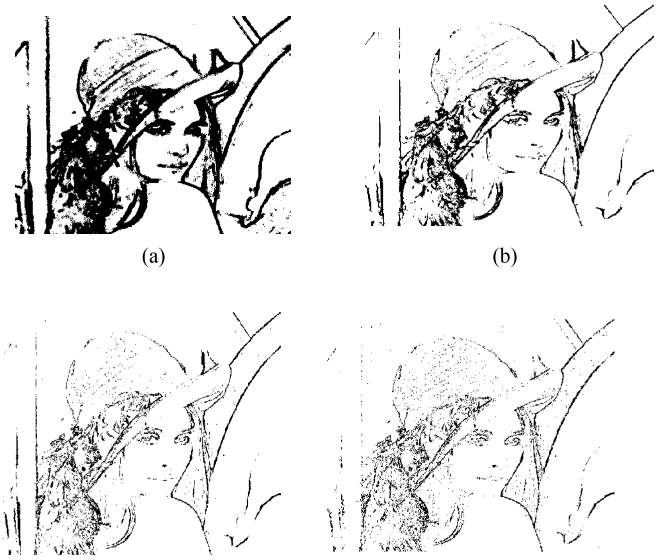

Fig.3 The locations of the minority pixels in Lena image based on their similar pixels number *N within* an intensity range [0, *D* ] (a) $N \leq 40$, $D$ =20 (b) $N \leq 25$, $D$ =20, (c) $N \leq 10$, $D$ =10, (d) $N \leq 5$, $D$ =5.

## II. Algorithm Description

Define the filtering window $W(p_{ij})$ of $k \times k$ size centered at the pixel $p_{i,j}$ and the location $(i, j)$ in the image *P*. In this algorithm each pixel $p_{ij}$ is transformed to a binary value $L_{ij}$ based on a pre-defined value of $S^{th}$ in each phase *r* as :

$$T(p_{ij,r}) = L^r{}_{ij} \quad \forall p_{ij,r} \in P_r \tag{1}$$

$$L^r_{ij} = \begin{cases} 255 & if \;\; S_r \, {}^{\geq}\!/\!_{\leq} \, S_r{}^{th} \\ 0 & else \end{cases} \tag{2}$$

$$S_r = \frac{D_r}{N_r} \leq \frac{D_r}{k^2 - 1} \qquad r = [1,2] \tag{3}$$

${}^{\geq}\!/\!_{\leq}$ means one of the two signs $\{\geq \; or \leq\}$ . As *S* decreases the similarity level increases and hence more edge pixels detected. $S^{th}$ is the threshold of the similarity level that helps judging if the current pixel *x* is an edge pixel or not. The proposed approach consists of two phases as illustrated below:

### *A. Edge Identification Phase*

In this phase we try to differentiate between the edge pixels and the other pixels in the image as the following. Take the absolute intensity difference between the current central pixel $p_{i,j}$ and each of its surrounding pixels in the window as:

$$d(p_{i-s,j-t}, p_{i,j}) = |p_{i-s,j-t} - p_{i,j}| \tag{4}$$

where $\{s, t = 0 \pm 1, \ldots, \pm \frac{k-1}{2}, (s,t) \neq (0,0)\}$

Then, count the number $C(p_{ij})$ of the pixels in the filtering window that make intensity differences $\leq D$ with $p_{i,j}$

$$C(p_{\,ij}) = \; number \; \left\{ d(p_{i-s,j-t}, p_{i,j}) \leq D \right\} \tag{5}$$

any pixel $p_{i\text{-}s,j\text{-}t}$ satisfies (5) is called a similar pixel to $p_{ij}$. The pixel $p_{ij}$ is considered as an edge point and replaced by a zero in the corresponding location in another binary image *U* if $C(p_{ij}) \leq S_1^{th}$ , otherwise it is replaced by 255 as:

$$U(u_{i,j}) = \begin{cases} 0, & C(p_{i,j}) \leq S_1^{th} \\ 255 & else \end{cases} \tag{6}$$

Note that, the threshold $S_1^{th} \cong 1$ delivers satisfactory results for many images.

### *B. Complementary phase:*

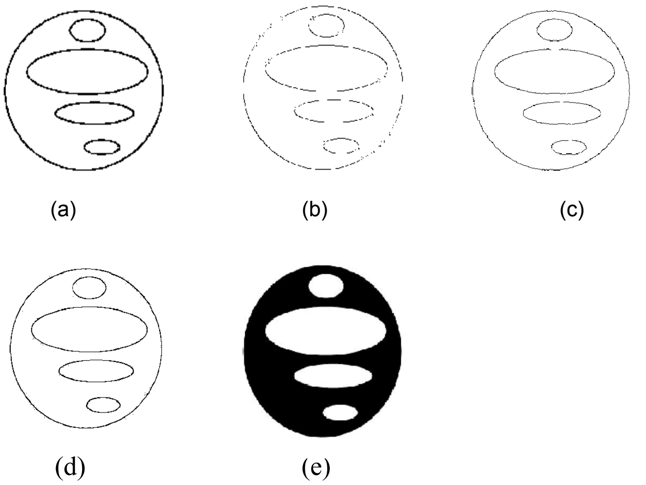
If the detected image is noise –free image, then we have to stop by phase 1. But if the detected image is a noisy image then image *U* will contain all the detected edge pixels, the noisy pixels that satisfy the first threshold, and the background white pixels. Note that the noisy pixels in image *U* have a small number of similar pixels compared to that of the edge pixels, because the edge pixels are condensed along the edge lines; however the line shape, but the noisy pixels are scattered through the background pixels (white pixels) which make a large intensity differences with the noisy pixels. Also, we can increase the similar pixels number for the edge pixels by increasing the first threshold. Therefore, for extracting the edge points we need to repeat step 1 and 2 on the image *U.* Any pixel $u_{ij} = 0$ in *U* is considered as an edge point in a binary image *V* if $C(u_{ij}) \geq$ the second similarity parameter $S_2^{th}$ , otherwise it is replaced by 255 in *V a*s the following:

$$V(v_{i,j}) = \begin{cases} 0, & C(u_{ij}) \geq S_2^{th} \\ 255 & else \end{cases} \tag{7}$$

$S_2^{th}$ should be decreased as the noise rate increases and vice versa. In all the simulation experiments we maintain the value of *D* constant and change only the value of *N* .

## III. Simulation Results

To show the performance of the proposed approach we apply it on different 8-bit grey-level images and compare the results with other well known methods in the literature as Sobel and Canny detectors. The results are compared subjectively in terms of the edge quality, and computationally in terms of the relative processing time in seconds for the different methods (measured by MATLAB COMAND “etime”). CPU of 1.73GHZ and RAM of 1MB are used in all the simulation experiments.7×7 window size is used with the proposed detector. Similarity parameter $S_1^{th} \cong 0.8$ is used with the noise-free image and in the 1st phase of the noisy images. The threshold *Th*=120 is used with Sobel method and the ones that are used with Canny approach are $Th_{max}$=120, $Th_{min}$=70.



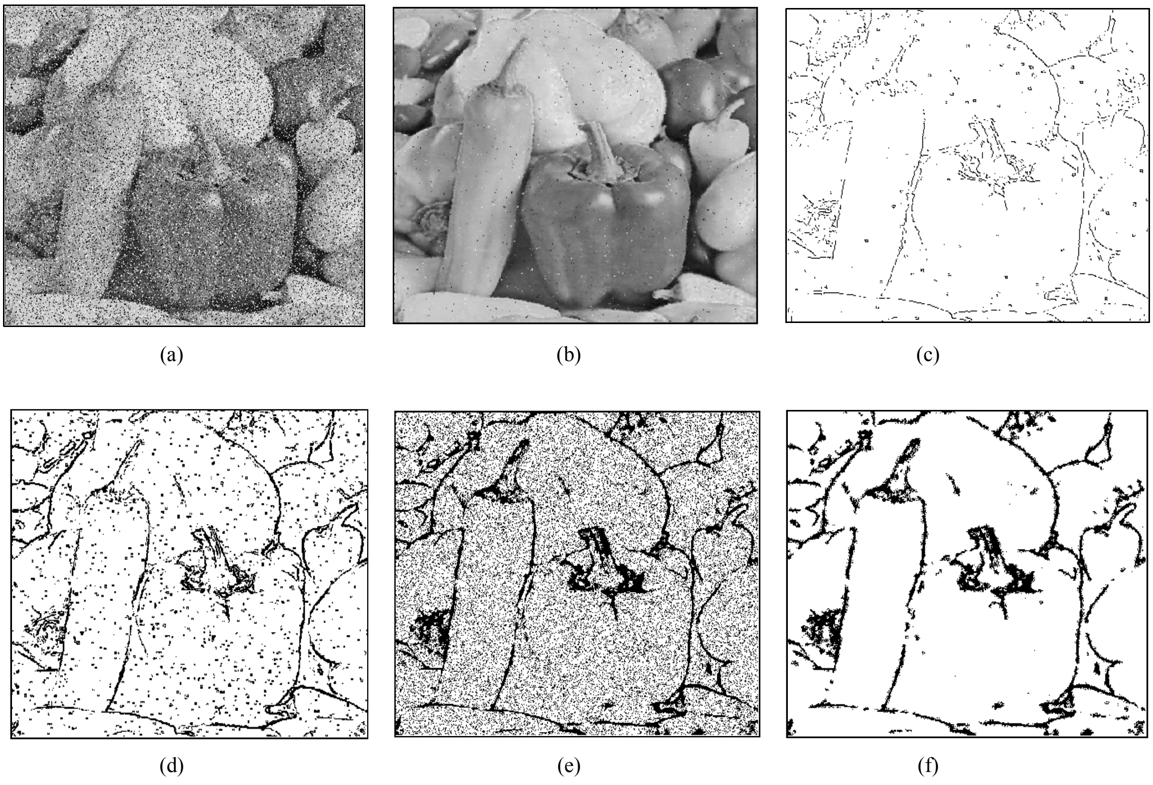
(a) (b) (c)

(d) (e)

Fig.4 Edge detection results for different filters on a synthetic image: (a) Sobel (t= **2.5 sec** ), *Th* =120 (b) Canny (t= **5.1 sec** ), $Th_{max}$=120, $Th_{min}$=70(c) EMO (t= **25.1 sec**), (d) New (t= **3.9** sec), ($D_l$=20, $N_l$=25), (e) original image.

Fig. 4 is applied on a noise-free synthetic image of 323×393 size. In this experiment we compare our method with EMO approach [2] that is proposed for uncorrupted images, besides Sobel and Canny methods. It is clear that the proposed method shows a continuous thin edge line while the other methods suffer either from discontinuity in the edge line or show a thicker edge. Besides, the processing time of the proposed detector is comparable to Canny and Sobel filters while it is faster 6.4 times than the EMO filter, see the caption of fig. 4. The slow convergence that shown by the EMO method is due to the enormous using of the subtraction operations, i.e., it needs 4x18 subtraction operations in each window in the four directions.

Fig. 5 and Fig. 6 show the results of different methods for edge detection in corrupted pepper and Lena images with 20% and 25% salt and pepper impulse noise rates, respectively. Pepper and Lena images are both of 512× 512 sizes. For appropriate comparison the corrupted images are firstly restored by using 3 ×3 median filter since it high efficiency in impulse noise removal, and then we apply the Sobel and Canny approaches on the restored images. It is noticeable that the proposed method delivers better performance than Canny, and Sobel methods since it effectively removes the impulse noise and maintains the main image features, while the other methods are still contain residual noise and miss some of the image details. The edge lines that are obtained by the new method look somewhat thick; the reason is that some of the neighboring noisy pixels are able to satisfy the threshold criterion. However, they illustrate the main feature of the image to be used for any higher level image processing task. Moreover, the proposed detector is faster than the Sobel and Canny approaches, respectively. Note that the computational times



(a) (b) (c)

(d) (e) (f)

Fig. 5 Edge detection for 20% impulse noise corrupted pepper image: (a) corrupted image, (b) restored version by median filter,(c) Canny after restored image, time= **21.3** sec, $Th_{max}$ =120, $Th_{min}$ =70 (d) Sobel after restored image, time= **15.1** sec , *Th=120* (e) proposed filter after corrupted image -1 st phase ( $N_1^{th}$ =25, $D_1$ =20) time=7 sec (f) proposed filter-2 nd phase ( $N_2^{th}$ = 20, $D_2$ =20,), time= **12.3** sec

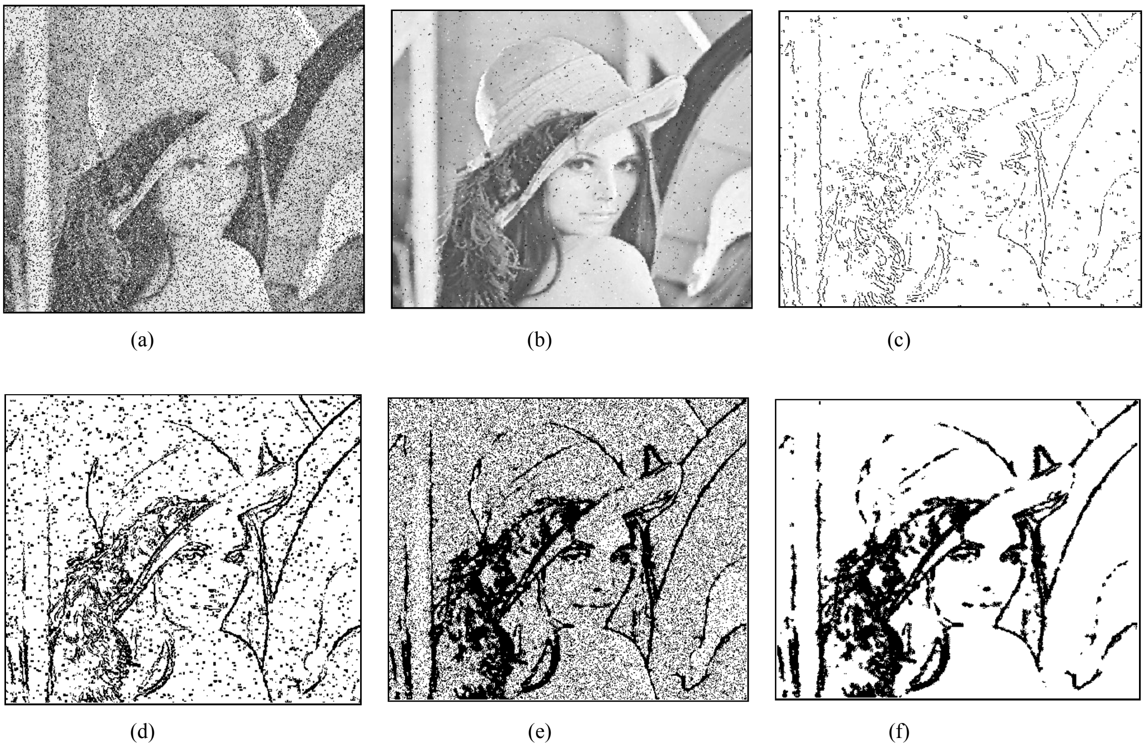


Fig.6 Edge detection for 25% impulse noise corrupted Lena image: (a) corrupted image, (b) restored version by median filter,(c) Canny after restored image, time= **21.3** sec, $Th_{max}$ =120, $Th_{min}$ =70 (d) Sobel after restored image , time= **15.1** sec, $Th$= 120 (e) proposed filter -1 st phase after corrupted image( $N_1^{th}$ =25, $D_1$ =20) time=7 sec (f) proposed filter-2 nd phase ( $N_2^{th}$ = 25, $D_2$ =20,), time= **12.3** sec,

that are obtained after one or more iterations are the same for all the methods. In the 2nd phase the edge quality increases as the similarity parameter decreases and vice versa. The reason is that, as the noise rate increases the number of similar pixels for the residual noise in the 1st phase images increases. Therefore, we have to decreases $S_2^{th}$ by increasing $N_2$ as shown in fig. 5 and 6. Since the edge pixels have larger number of similar pixels than any other noisy pixels, we expect that most of the original edge pixels will satisfy the second similarity parameter threshold.

## IV. Conclusion

A high performance edge detection approach based on the similarity criteria is proposed in this paper. In which, the pixels that have minimum numbers of similar pixels is consider as edge pixels in free-noise images, and the pixels that have maximum numbers of similar pixels are considered as edge pixels in the noisy images. Simulations results indicate that the proposed approach achieves superior performance than other well known methods, particularly in images corrupted by impulse noise. Moreover, it is time efficient method and has a low computational complexity.

***Abstract*—In order to maximize the utilization of mobile sensor network, formation of sensor set and localization of each sensor node must be implemented. It is required that localization is one of the most important functionality of mobile sensor nodes. In this paper, we present a technique which improves the relative location of the MSN with a computer vision technology.**

**This technique effects only in short distance but only with low price sensors, we achieved precise localization in the resolution of 10 centimeters. The well known perspective-3-point problem have been exploited for the precise short distance localization. By experiment we present an interrelation between angle of camera view and a LED pattern interval. We measures the distance of the counterpart vehicle and vehicles shares distance information of obstacle and the relative vehicles with possible cooperation of vehicles. The angle of a vehicle can be identified by digital compass. Finally, with a share of location information we can achieve localization of mobile sensor nodes with high accuracy.**

## I. Introduction

THIS research is regarding short distance localization with use of computer vision technology under Mobile Sensor Network (MSN) environment. In order to maximize the utilization of mobile sensor network, formation of sensor set and localization of each sensor node must be implemented.

We built several Mobile Sensor Vehicles (MSVs) as mobile sensor nodes for a mobile sensor network. Each MSV can identify locations of companion MSV and can share such information in order to achieve accurate localization of whole MSVs. We used a micro camera as a visual sensor of MSV. The result of localization can be presented on maps based on grid or topology. We believe this research can be applied formation of UAV (Unmanned aerial vehicle), a formation for a deep-sea fishing vessel and other related area.

This paper is structured as follows. In section II we will show related problems and possible solutions of localization. Section III discusses retailed experiment procedure for localization and section IV will show the result of localization. The final section V will conclude this paper with discussions of possible future research.

## II. Research Background

There have been variety forms of Mobile Sensor Nodes (MSN) which utilizes various techniques of localizations such as RSSI, GPS, Raider, Laser, Camera, and so on [1] [2]. One of the most prominent one, an RSSI based localization, usually measures radio signal strength and it works well with popular network devices. Moreover, an 802.11 device based software approach can be realize easily. However, RSSI method is prone to be fragile with a presence of obstacles or so which will diminish or attenuate radio signal strength. In a short distance, RSSI signals usually is too high that nullify accurate localization thus it is good for long distance, low accurate localization.

For medium distance, a trajectory based approach is a useful one. Usually mobility is recorded and the accumulated records are used to calculate current location of mobile sensor nodes. However, also traveling errors are accumulated as traveling distance increased.

In this paper we will discuss about short distance, high accurate localization. It is based on computer vision and of course it has limitations of distance with visibility.

We combined these three levels of localization technique and will focus on computer vision based one. For the purpose of experiments, we designed and implemented Mobile Sensor Vehicle (MSV) which has all three levels of localization features aforementioned as shown in [3].

In this section, we will discuss about related problem.

### A. Identification of Colleague MSVs as a base for localization

Localization is required for MSN in order to maximize its usefulness. However, a single MSV cannot locate its location precisely. The ultimate localization can only be done with the cooperation of nodes in MSN.

The first requirement for localization is to identify the location of colleague MSV as a base point. For this purpose, we prepared three facilities for each MSV. Each MSV can estimate its location by trajectory trail. Moreover, each MSV can identify other colleague MSV with their infrared LED signal. In addition, this location information can be communicated by wireless network device equipped with each MSV.

Of course, a camera or a set of cameras are installed on an MSV in order to identify colleague MSVs. This set of cameras have infrared filters in order to diminish the effect of extra light noise in operating environment.

### B. Location Determination Problem

With a set of camera, the required information for localization is collected from the view of cameras. For example, an infrared LED light can be a parameter to calculate the colleague's location. In this research, we applied two previous results. The first one is Sample Consensus(RANSAC) Method [4] and the second one is PnP Method [5] [6].

This work was supported by 2007 Hongik University Research Fund.

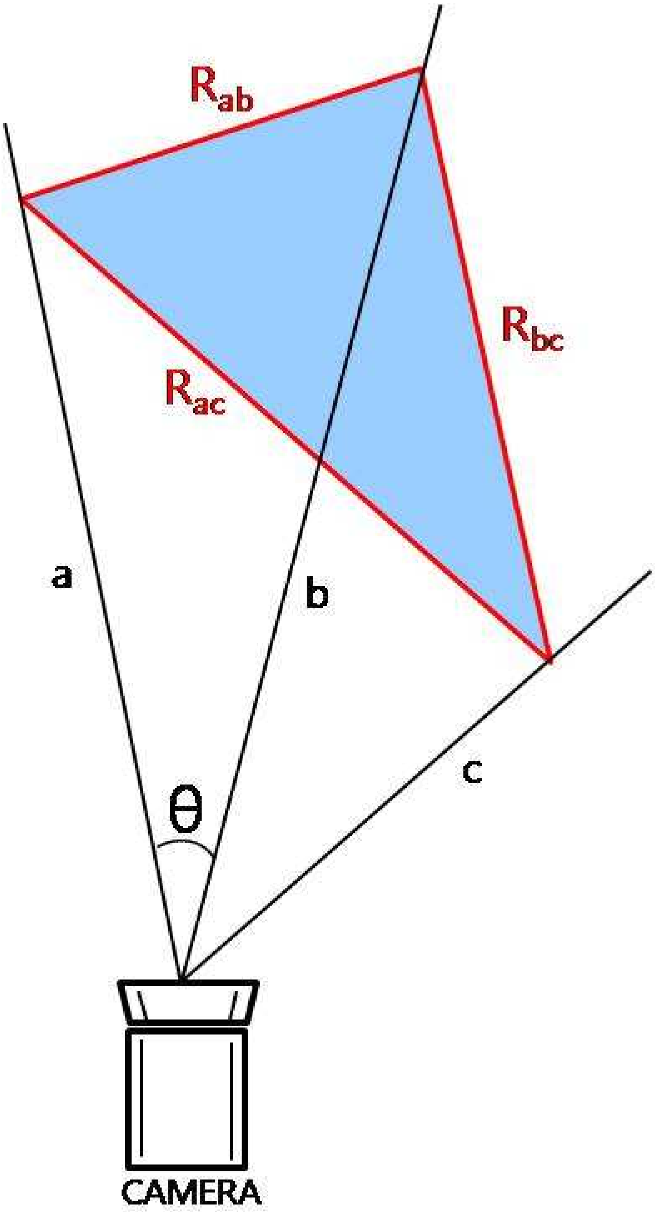

Fig. 1. Calculation of distance from Camera Lens to Vertex of triangle ABC

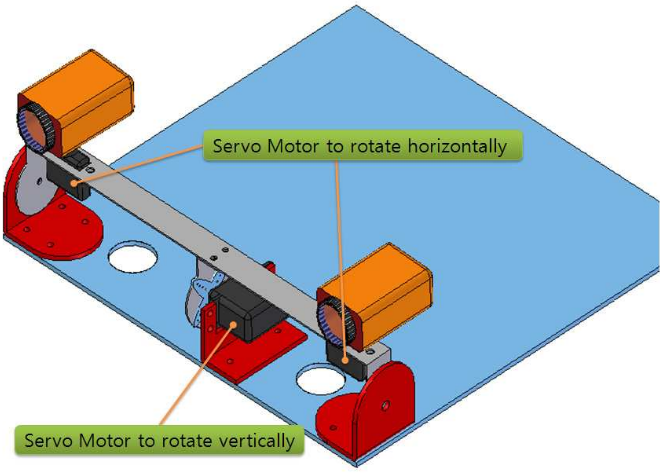
For RANSAC method, because of least square method, there is no possibility of wrong computation with gross error value. This is the major reason why we applied RANSAC method. In order to solve the problem of converting 3-dimensional view to 2-dimensional camera image, which has lost distance problem, we applied perspective-3-point (P3P) problem.

Figure 1 shows the basic principle of P3P problem. The gray triangle is composed by infrared LED installed on each MSV. Points $A, B, C$ stand for each infrared LEDs and these vertices compose a triangle. The distance $R_{ab}, R_{bc}, R_{ac}$ is known constants.

From figure 1 we can drive the following, very well-known, mathematical equation as shown in equation 1.



Servo Motor to rotate horizontally
Servo Motor to rotate vertically

Fig. 2. Stereo Eye System

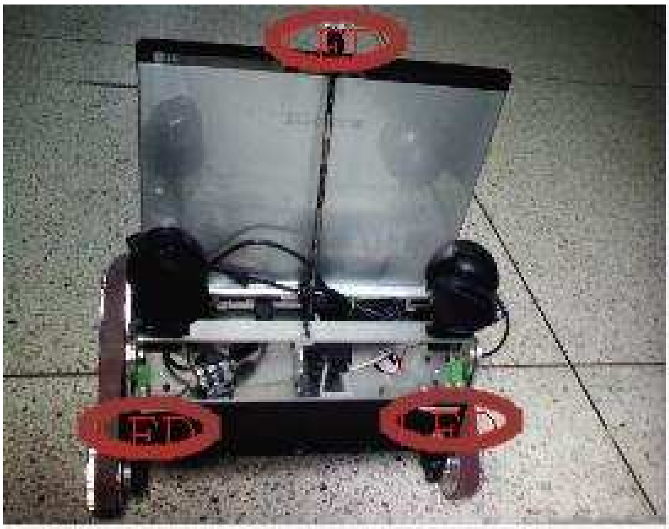


Fig. 3. Mobile Sensor Vehicle for Experiment

$$\begin{aligned} {R_{ab}}^2 &= a^2 + b^2 - 2ab \cdot cos\theta_{ab} \\ {R_{ac}}^2 &= a^2 + c^2 - 2ac \cdot cos\theta_{ac} \\ {R_{bc}}^2 &= b^2 + c^2 - 2bc \cdot cos\theta_{bc} \end{aligned} \tag{1}$$

The equation 1 is in closed form. The number of solutions from these equations will be up to eight. However, there are up to four positive roots.

With this P3P based method, we can only measure distances between observer and observed. For precise localization, we must identify angle of MSVs as well. Our MSV is equipped with digital compass in order to identify the angle of MSV based on magnetic poles. As predicted, digital compass also has its own error in angle measurement but is tolerable.

| SI5315-H | ±30° | 950nm |
| OPE5685 | ±22° | 850nm |
| OPE5194WK | ±10° | 940nm |
| TLN201 | ±7° | 880nm |
| EL-1KL5 | ±5° | 940nm |

## III. Implementation and Experiments

### A. Experimental Environment

Each MSV has a set of Infrared LED (IR-LED) in a form of triangle and the length of edges are all 30 centimeters. The IR lights from these LEDs can be viewed by stereo camera system from other colleague MSV. The stereo eye system as shown in figure 2 has two cameras. Three servo motors controls two stereo eyes vertically and horizontally.

The stereo cameras are equipped with IR filters. The front view of MSV for these equipments are as shown in figure 3. Three IR-LEDs forms a triangle and a stereo camera system are also presented.

With fixed length of triangle edges, i.e. interval between IR-LED, is fixed by 30 centimeters. Therefore by using P3P method, the distance between camera and MSVs with IR-LED triangle can be calculated. Embedded software for each MSV has a realtime part for P3P solution. The software also shows the image from stereo camera as a part of P3P solution as shown in figure 4.

The ideal situation starts by estimating the angle between two cameras. Once camera direction is fixed, we can estimate angles between tracked object and cameras, however, MSV can move every direction which causes difficulties to measure that angle. Moreover, if these cameras have pan-tilt functionalities, it is impossible to measure such an angle in real time.

Another method with P3P technique is to assume the distance to the object. The distance to object and the scale of triangle in camera view is proportional inversely thus the size of LED triangle can be a starting point to estimate the distance to obstacles. We decided to standardize the reduced scale of LED triangle in order to estimate distance to objects. The basic concept of this method is depicted in figure 5. We will discuss this figure in the subsection III-C in detail.

This approach has limits of camera visibility, i.e. objects beyond visibility cannot be identified. However, two other localization methods are already prepared for beyond sight localization as described in II. In addition with the help of digital compass, we can measure the direction of each MSV. The combination of this information can achieve short distance accuracy for localization.

### B. Preliminary Experiment

We conduct preliminary experiment in order to choose optimal device for computer vision based localization. The first purpose of this experiment is to select the best LED in order to increase the range of localization. Our past result showed 250 centimeter of localization range however our aim is to enlarge the range to 400 centimeters or farther.

We choose five infrared light emitting diodes with typical characteristics. We first concentrated on the visible angle of LED lights since we assumed wider visible angle guarantees the clearer identification of LED light and more precise localization.

Table I shows the specifications of various IR-LEDs with visible angle and peak wavelength. The major reason why we choose those IR-LEDs are as follows:

- Smaller half angle of LED enables long distance tracking however increase invisibility from the side.
- Larger half angle of LED enables tracking from the side however decrease tracking distance.

With infrared filter equipped cameras we planned experiments to evaluate the LEDs for vision based localization. Table II show the result of visible distance and visibility of IR-LEDs. Twelve experiments have been made and average

TABLE II
IR-LED VISIBILITY EXPERIMENTS

| MODEL NO. | Max Length | Visible Angle | Visibility |
|---|---|---|---|
| SI5315-H | 500cm | ±60° | Stable |
| OPE5685 | 490cm | ±45° | Somewhat Unstable |
| OPE5194WK | 520cm | ±35° | Most Stable |
| TLN201 | 510cm | ±20° | Unstable |
| EL-1KL5 | 450cm | ±10° | Indiscriminable |

values are shown. From the specifications of IR-LEDs, 5 volts DC voltage is supplied for the experiment.

Among five IR-LEDs, two showed stable visibility and acceptable visibility distance. Between these two candidates, we finally choose the best LED of MODEL NO.SI5313-H since it has the widest half angle as well with reasonable visibility distance.

### C. Main Experiments

Figure 5 shows the relationship between LED triangle size ($d$) and distance from camera to LED triangle ($h$). The relation between $d$ and $h$ can be directly drawn from the following equation 2

$$\begin{aligned} \tan\theta &= \frac{d}{2h} \\ \theta &= \arctan\frac{d}{2h} \end{aligned} \tag{2}$$

Most of cameras has angle of view in $54^\circ \sim 60^\circ$. Since we used camera with angle of view in $60^\circ$, from the equation 2 we can solve ratio about $h : d = 1 : 1.08$. The actual value of $d$ is 30 centimeter for our experiment.

Thus we can summarize the following:

- High angle of view camera can increase minimum measure distance.
- With narrow LED pattern interval, we can decrease actual distance $h$ but practically meaningless.
- With wider LED pattern interval, we can increase actual distance but dependent on MSV size.

From the experiments, we can identify the vision based localization is effective within the range from 30 centimeters to 520 centimeters with our LogiTech CAM camera. The 30 centimeter lower bound is due to the 30 centimeter interval of LED triangle edges. The 520 centimeter upper bound is due to the visible sight capability of LogiTech CAM camera. Thus 520 centimeter would be a maximum distance of computer vision based localization. However it is still meaningful since we can achieve very high accuracy in localization with these cheap, low grade cameras. The other idea for more localization distance is to use cameras with higher resolution.

From our experiments, we identified the correlation between actual distance from camera to colleague MSV and size of

LED triangles in camera view. Table III shows correlations between actual distance and triangle size in camera view. The results in table III can be translated into graphical form as shown in figure 6.

From figure 6 the result shows the fluctuation of results with more than 430 centimeters which makes localization unstable. For applications which require the error range of 20 centimeters, we can use the results to 520 centimeters. Since our aim is to keep localization errors within the range of 10 centimeters, we decided to discard results more than 430 centimeters.

## IV. Experimental Result

From our experiment in the previous subsections we will provide the final result of computer vision based localization in this subsection.

Table IV shows the final result. Figure 7 shows graphical version of table IV.

Apart from the results in previous section, these table and figure shows actual distance up to 420 centimeters. From figure 6 we can observe errors in calculated values of P3P for more than 420 centimeter distance. These errors is due to the resolution limit of CAM camera which is $640 \times 480$. Even a small noise can vary actual distance of ten centimeters in the distance more than 420 centimeters.

Thus we conclude the accurate localization by computer vision can be done in the range of 70 centimeters to 420 centimeters with our camera equipments.

For the localization in more than 420 centimeters, localization based on MSV trajectory tracking will be effective. In addition, for the localization in more than 30 meters, localization based on RSSI will be effective [3].

## V. Conclusion and Future Research

We built mobile sensor vehicle as nodes for mobile sensor network. Our mobile sensor nodes has capabilities in multilevel localization. In this paper we discussed regarding computer vision based localization.

We can achieve very precise and short distance localization with the help of computer vision technology.

Within the distance of 420 centimeters, we can identify the location of each mobile sensor nodes in a resolution of 10 centimeters. And within the distance of 520 centimeters, we still have the possibility of localization in a resolution of 20 centimeters.

However our experiment has several limitations due to the resolution of cameras and the vertices distance of LED triangle. Since the vertices distance of LED triangle is limited by the chassis size of MSV, we cannot extend the distance more than current configuration.

Therefore for future researches, we plan to upgrade cameras and the angle of view for cameras as well for longer localization distance. With this better sensors and calibration of sensors we expect that we can extend the localization distance up to 1,000 centimeters.

TABLE IV
Calculated distance from measured relative distance

| Relative Distance Measured | Actual Distance Assumed (Cm) |
|---|---|
| 99.99999 ∼ 95.20465 | 70 |
| 95.20464 ∼ 84.94255 | 80 |

| 22.54654 ∼ 21.78945 | 420 |

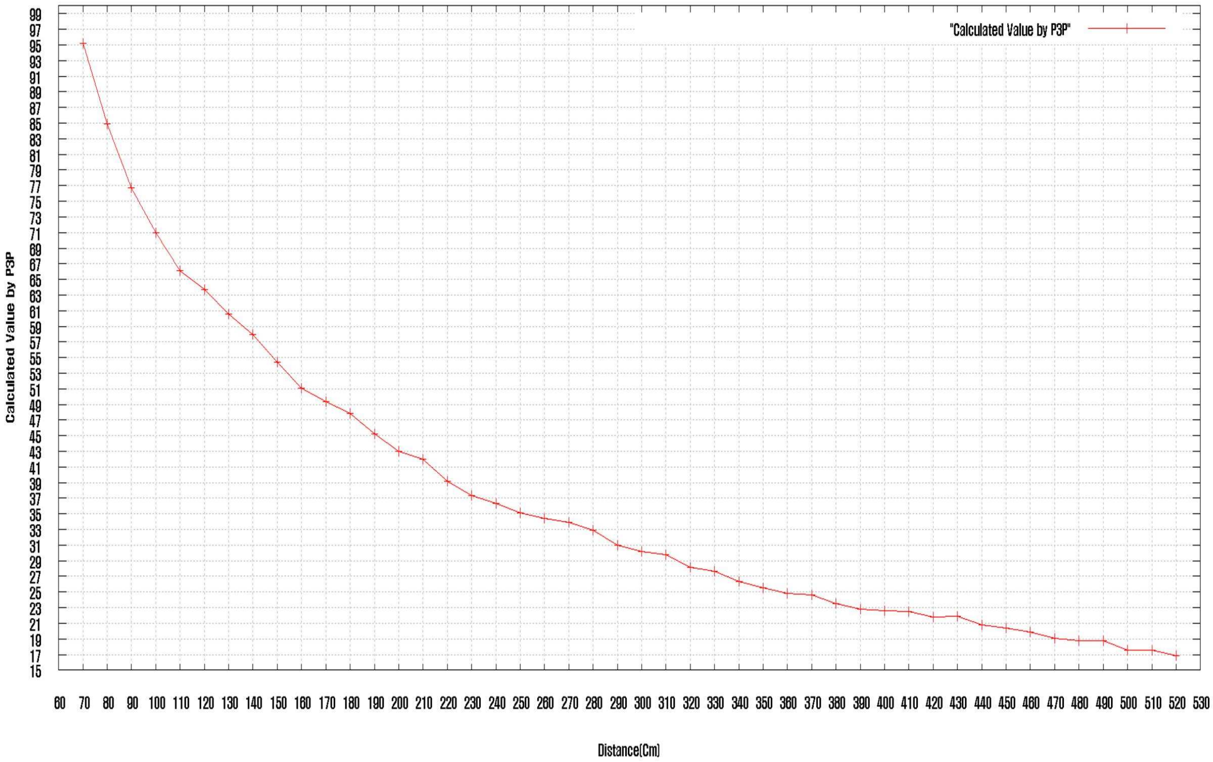

Fig. 6. Relative size of triangle calculated by P3P on actual distance

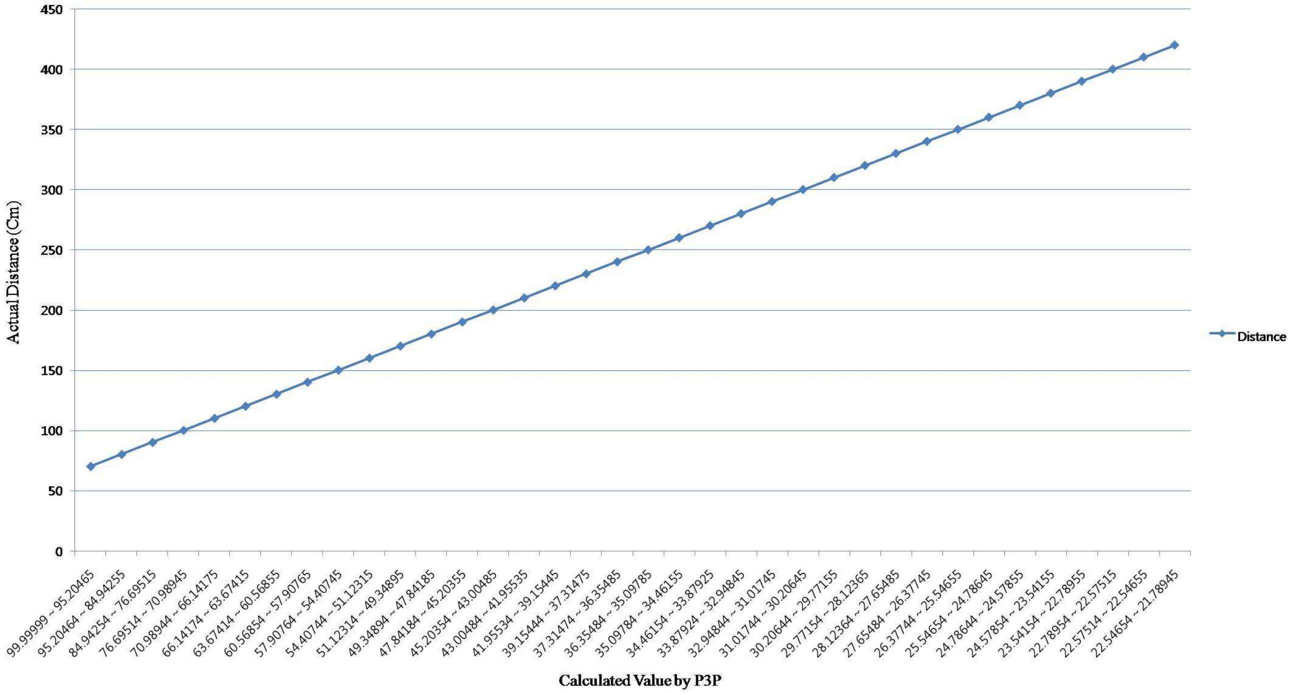

Fig. 7. Actual distance calculated from measured relative distance

We believe we showed an example of high accuracy localization and this research will help researchers for such applications in a field of mobile sensor network as well as robotics.

With these precise localization methods, a sensor formation technique will be a feasible one.

***Abstract*—This paper describes the method of handwritten characters recognition and the experiments carried out with it. The characters used in our experiments are numeric characters used in post code of mail pieces. The article contains basic image processing of the character and calculation of characteristic features, on basis of which it will be recognized. The main objective of this article is to use Radon Transform and Principal Component Analysis methods to obtain a set of features which are invariant under translation, rotation, and scaling. Sources of errors as well as possible improvement of classification results will be discussed.**

## I. Introduction

THE today's systems of automatic sorting of the post mails use the OCR (Optical Character Recognition) mechanisms. In the present recognizing of addresses (particularly written by hand) the OCR is insufficient.

The typical system of sorting consists of the image acquisition unit, video coding unit and OCR unit. The image acquisition unit sends the mail piece image to the OCR for interpretation. If the OCR unit is able to provide the sort of information required (this technology has 50 percent effectiveness for all mails), it sends this data to the sorting system, otherwise the image of the mail pieces is sent to the video coding unit, where the operator writes down the information about mail pieces.

The main problem is that operators of the video coding unit have lower throughput than an OCR and induce higher costs [1]. Therefore the OCR module is improving, particularly in the field of recognition of the characters. Although, these satisfactory results were received for printed writing, the handwriting is still difficult to recognize. Taking into consideration the fact, that manually described mail pieces make 30 percent of the whole mainstream, it is important to improve the possibility of segment recognizing the hand writing. This paper presents the proposal of a system for recognition of handwritten characters, for reading post code from mail pieces.

The process of character recognition process can be divided into stages: filtration and binaryzation, normalization, Radon transform calculating, accumulator analysis, Principal Component Analysis, feature vector building, and character recognition stage.

The first step of the image processing is binarization. The colourful image represented by 3 coefficients Red, Green and Blue from the acquisition unit must be converted to the image with 256 levels of grey scale. The next step of processing of the image of mail piece is digital filtration. The filtration is used for improving the quality of the image, emphasizing details and making processing of the image easier. The filtration of digital images is obtained by

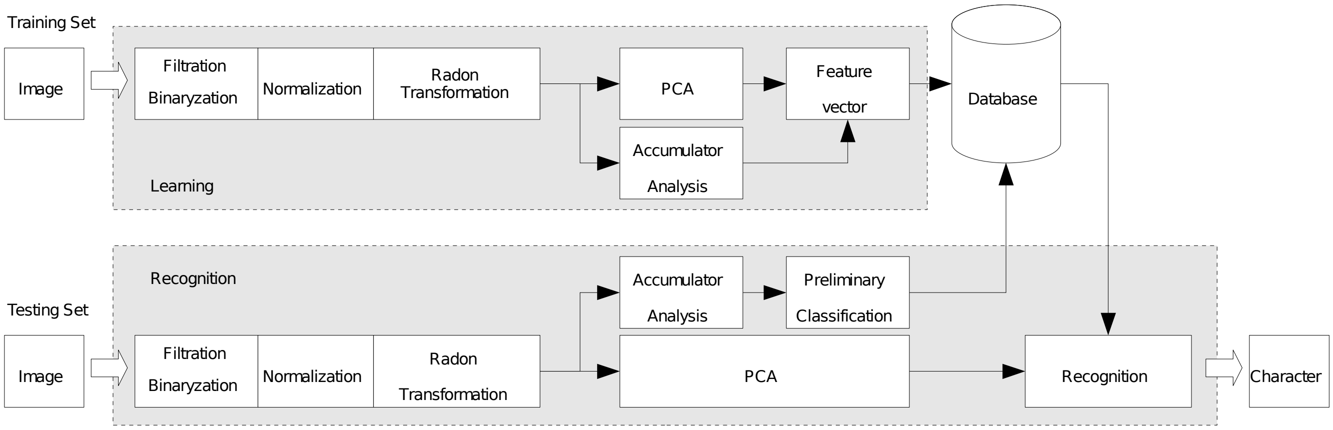

Fig 1. Character recognition system

convolution operation. The new value of point of image is counted on the basis of neighbouring points value. Every value is classified and it has influence on new value of point of the image after filtration [2].

Fig 2. Median filtering

In the pre-processing part non-linear filtration was applied. The statistical filter separates the signal from the noise, but it does not destroy useful information. The applied filter is median filter, with mask *3*x*3*.

The image of character received from the acquisition stage have different distortion such as: translation, rotation and scaling. The character normalization is applied for standardization size of the character. Images there are translated, rotated and expanded or decreased. The typical solutions takes into consideration the normalization coefficients and calculate the new coordinates given by:

$$[x,y,1]=[i,j,1]\begin{bmatrix}1&0&0\\0&1&0\\-I&-J&1\end{bmatrix}\times \begin{bmatrix}m_i&0&0\\0&m_j&0\\0&0&1\end{bmatrix}\times\begin{bmatrix}\cos\beta&\sin\beta&0\\-\sin\beta&\cos\beta&0\\0&0&1\end{bmatrix} \qquad (1)$$

where: *I,J* is a center of gravity given by :

$$I=\frac{\sum_i\sum_j if(i,j)}{\sum_i\sum_j f(i,j)} \qquad J=\frac{\sum_i\sum_j jf(i,j)}{\sum_i\sum_j f(i,j)} \qquad (2)$$

In the reality we haven't got this parameters starting right now, so we use new coordinate system where center is equals to center of gravity of the character. The value of angle rotation is according to main axes of the image. The value of scale coefficient is calculated by mean value of variation of the character. So the center of gravity of the character is good candidate point of the center of image as a product of normalization stage.

## II. Radon Transformation

In recent years the Radon transform have received much attention. This transform is able to transform two dimensional images with lines into a domain of possible line parameters, where each line in the image will give a peak positioned at the corresponding line parameters. This have lead to many line detection applications within image processing, computer vision, and seismic [3][18]. The Radon Transformation is a fundamental tool which is used in various applications such as radar imaging, geophysical imaging, nondestructive testing and medical imaging [20].

The Radon transform computes projections of an image matrix along specified directions. A projection of a two-dimensional function *f(x,y)* is a set of line integrals. The Radon function computes the line integrals from multiple sources along parallel paths, or beams, in a certain direction. The beams are spaced 1 pixel unit apart. To represent an image, the radon function takes multiple, parallel-beam projections of the image from different angles by rotating the source around the centre of the image. The "Fig.3" shows a single projection at a specified rotation angle.

The Radon transform is the projection of the image intensity along a radial line oriented at a specific angle. The radial coordinates are the values along the $x'$ -axis, which is oriented at $\theta$ degrees counter clockwise from the $x$ -axis. The origin of both axes is the center pixel of the image .

For example, the line integral of *f(x,y)* in the vertical direction is the projection of *f(x,y)* onto the $x$ -axis; the line integral in the horizontal direction is the projection of *f(x,y)* onto the $y$ -axis. The "Fig.4" shows horizontal and vertical projections for a simple two-dimensional function.

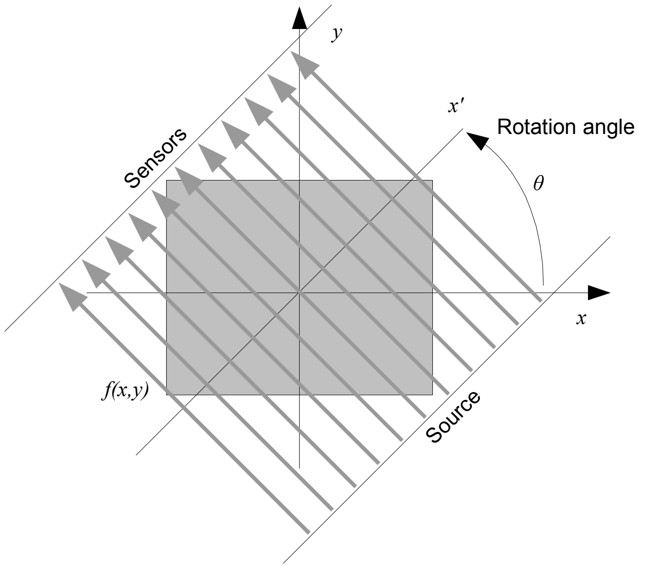

Fig 3. Single projection at a specified rotation angle

Projections can be computed along any angle $\theta$, by use general equation of the Radon transformation [23][24][25] :

$$R_{\Theta}(x')=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y)\,\delta(xcos\Theta+ysin\Theta-x')\,dydy \qquad (3)$$

where $\delta\ (\cdot)$ is the *delta* function with value not equal zero only for argument equal 0, and:

$$x'=xcos\Theta+ysin\Theta \qquad (4)$$

$x'$ is the perpendicular distance of the beam from the origin and $\theta$ is the angle of incidence of the beams. The "Fig. 5" illustrates the geometry of the Radon Transformation. The

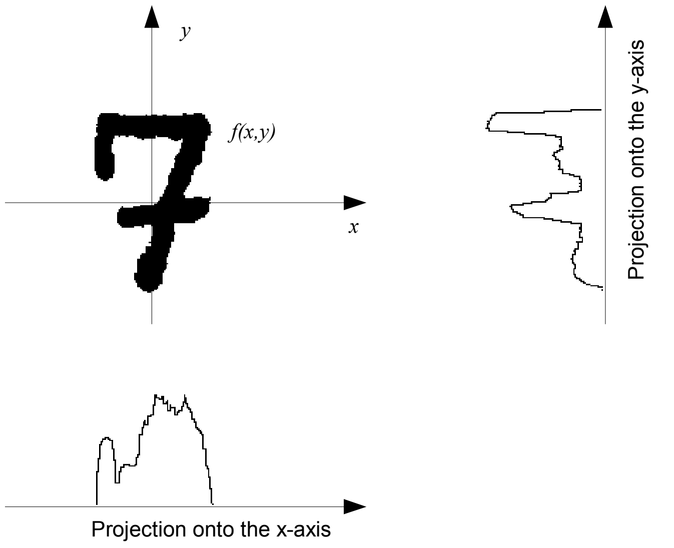

Fig 4. Horizontal and Vertical Projections of a Simple Function

very strong property of the Radon transform is the ability to extract lines (curves in general) from very noise images. Radon transform has some interesting properties relating to the application of affine transformations. We can compute the Radon transform of any translated, rotated or scaled image, knowing the Radon transform of the original image and the parameters of the affine transformation applied to it.

This is a very interesting property for symbol representation because it permits to distinguish between transformed objects, but we can also know if two objects are related by an affine transformation by analyzing their Radon transforms [19]. It is also possible to generalize the Radon transform in order to detect parametrized curves with non-linear behavior [3][4][5].

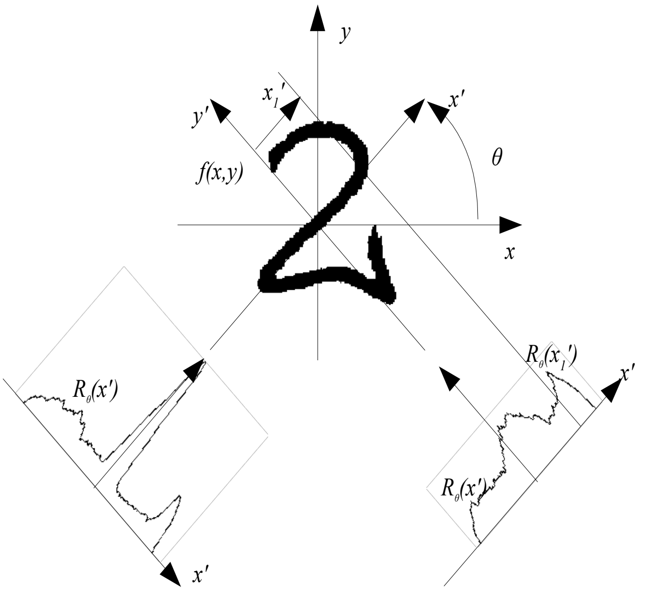

Fig 5. Geometry of the Radon Transform

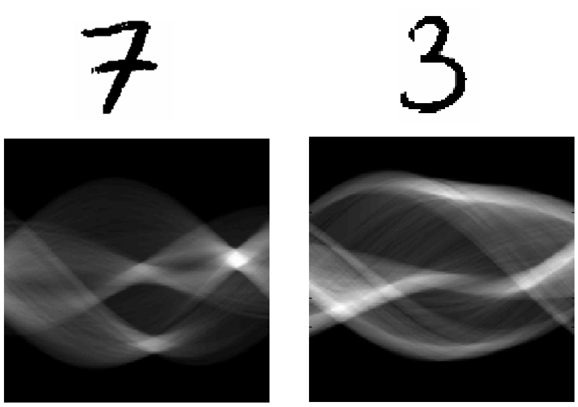

Fig 6 Sample of accumulator data of Radon Transformation

## III. Principal Components Analysis

PCA is mathematically defined [6][7][8] as an orthogonal linear transformation that transforms the data to a new coordinate system such that the greatest variance by any projection of the data comes to lie on the first coordinate (called the first principal component), the second greatest variance on the second coordinate, and so on. PCA is theoretically the optimum transform for a given data in least square terms. The main idea of using PCA for character recognition is to express the large 1-D vector of pixels constructed from 2-D character image into the compact principal components of the feature space [21].

PCA can be used for dimensionality reduction in a data set by retaining those characteristics of the data set that contribute most to its variance, by keeping lower-order principal components and ignoring higher-order ones. Such low-order components often contain the "most important" aspects of the data.

For all $r$ digital images *f(x,y)* from the normalization stage is creating column vector $X_k$ by the concatenate operation, where $k=(1,...,r)$ . For that prepared images we can calculate mean of brightness intensity $M$, difference vector $R$ and covariance matrix $\Sigma$ .

$$M_k = \frac{1}{r} \sum_{k=1}^{r} X_k \qquad (5)$$

$$R_k = X_k - M_k \qquad (6)$$

$$\sum = \frac{1}{r} \sum_{k=1}^{r} R_k R_k^t \qquad (7)$$

where:

$$X = \begin{bmatrix} X_1 \\ X_2 \\ . \\ X_r \end{bmatrix} \qquad (8)$$

$$M = \begin{bmatrix} M_1 \\ M_2 \\ . \\ M_r \end{bmatrix} \qquad (9)$$

$$R=\begin{bmatrix} R_1 \\ R_2 \\ . \\ R_r \end{bmatrix} \qquad (10)$$

Principal components are calculating from the eigenvectors $\Phi_l$ and eigenvalues $\lambda_l$ of the covariance matrix $\Sigma$. The eigenvectors $\Phi_l$ are normalized, sorted in order eigenvalue, highest to lowest and transponed, to obtain transformation matrix $W$, where $K$ is the number of dimensions in the dimensionally reduced subspace calculated by:

$$\frac{\sum_{i=1}^{K} \lambda_i}{\sum_{i=1}^{l} \lambda_i} \geq p \qquad (11)$$

where: $p$ is assumed as threshold [21]. The matrix $W$ is given by:

$$W=\begin{bmatrix} \Phi_1^1 & \dots & \Phi_1^K \\ . & \dots & . \\ \Phi_l^1 & \dots & \Phi_l^K \end{bmatrix} \qquad (12)$$

After image projection into eigenvectors space we do not use all eigenvectors, but these with maximum eigenvalues, this gives the components in order of significance. The eigenvector associated with the largest eigenvalue is one that reflects the greatest variance in the input data. That is, the smallest eigenvalue is associated with the eigenvector that finds the least variance. They decrease in exponential fashion, meaning that the roughly 90% of the total variance is contained in the first 5% to 10% of the dimensions [21].

The projection of $X$ into eigenvectors space is given by:

$$Y=W(X-M) \qquad (13)$$

where:

$$Y=\begin{bmatrix} Y_1 \\ Y_2 \\ . \\ Y_r \end{bmatrix} \qquad (14)$$

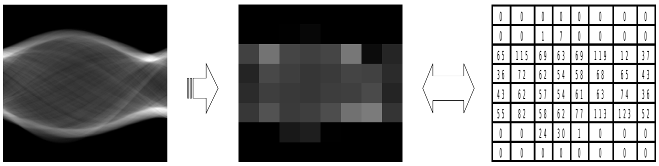
The final data set will have less dimensions than the original [8], after all we have $r$ column-vector for each input image with $K$ values *:*

$$Y_k=(y_{1,} y_2, \dots, y_K)^t \qquad (15)$$

The PCA module in proposal system generate a set of data, which can be used as a features in building feature vector section. For instance when we use input matrix 8x8 from Radon transformation stage, as a result we obtained $K$=8 values vector, using Cattell's criterion [9].

## IV. Feature Vector

Two sets of data received from the PCA module and accumulator analysis stage are used to create vector of features of character. The amount of data from Radon transformation depends from the image of character size and numbers of projections. For example, we use image with size 128x128 pixels and step $\theta$ equals one degree. With those parameters we can retrieve accumulator matrix with 180 width and 185 height cells. To produce feature vector we don't use all values from the accumulator. The reduction the accumulator data is possible by the resizing operation - when generally size of matrix is most commonly decreased. The most known scaling techniques are: method used with Pixel art scaling algorithms, Bicubic interpolation, Bilinear interpolation, Lanczos resampling, Spline interpolation, Seam carving [10][11][12]. In our research we make tests with Linear, Bicubic and Bilinear methods. The results with other methods was very similar and do not have influence on the recognition rate of proposed system. As a result of resize operation in our system is a matrix 8x8 elements as in "Fig.7".



| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 7 | 0 | 0 | 0 | 0 |

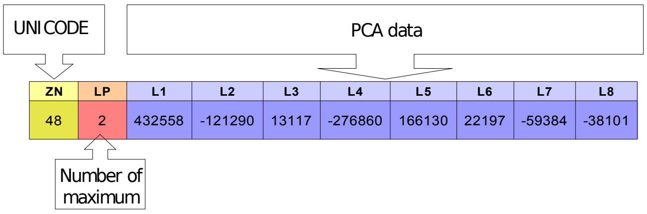
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Fig 7. Scaling operation

The next step of vector features preparing is concatenate operation and Principal Component Analysis of resized matrix from Radon Transformation, see on "Fig.8".

Fig 8. Creating vector $X$ by concatenate operation.

As a result of PCA is 8 element vector *L1-L8* of main values from input data, which will be used to feature vector. The second set of data are: code of known character *ZN* as a Unicode [13] and number of local maximum *LP* from the Accumulator Analysis stage. The feature vector consists a 10 values "Fig.9".



| ZN | LP | L1 | L2 | L3 | L4 | L5 | L6 | L7 | L8 |
|---|---|---|---|---|---|---|---|---|---|
| 48 | 2 | 432558 | -121290 | 13117 | -276860 | 166130 | 22197 | -59384 | -38101 |

Fig 9. Creating feature vector in proposed system

## V. Preliminary Classification

The aim of the preliminary classification is to reduce the number of possible candidates for an unknown character, to a subset of the total character set. For this purpose, the selected domain is categorized into six groups with number of local maximum as in "Fig.10".

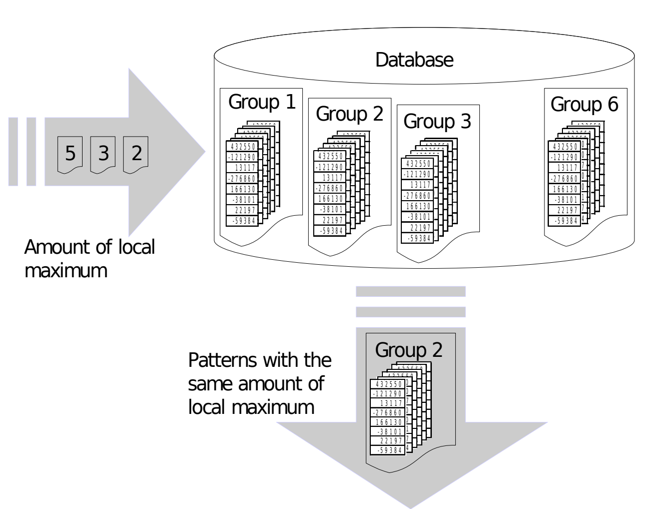


Fig 10. The organizations of feature vectors in database

The preliminary classification is based on the amount of local maximum calculating in the Accumulator Analysis stage "Fig.11".

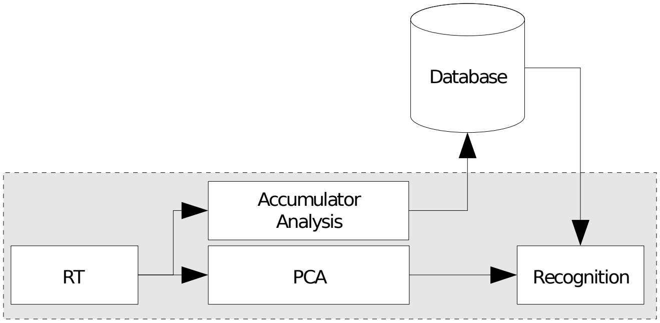

Fig 11. The Preliminary classification scheme

## VI. Recognition and Classification

The classification in the recognition module compared features from the pattern to model features sets obtained during the learning process. Based on the feature vector *Z* recognition, the classification attempts to identify the character based on the calculation of Euclidean distance [22] between the features of the character and of the character models [14].

The distance function is given by:

$$D(C_i, C_r)=\sum_{j=1}^{N}[R(j)-A(j)]^2 \qquad (16)$$

where:
*Ci* - is the predefined character,
*Cr* - is the character to be recognized,
*R* - is the feature vector of the character to be recognized,
*A* - is the feature vector of the predefined character,
*N* - is the number of features.

The minimum distance *D* between unknown character feature and predefined class of the characters is the criterion choice of the character [14].

## VII. The Experiment

For evaluation experiments, we extracted some digit data from various paper documents from different sources eg. mail pieces post code, bank cheque etc. In total, the training datasets contain the digit patterns of above 130 writers. Collected 920 different digits patterns for training set and 300 digits for test set. Each pattern is represented as a feature vector of 10 elements.

Comparing results for handwritten character with other researches is a difficult task because are differences in experimental methodology, experimental settings and handwriting database. Liu and Sako [15] presented a handwritten character recognition system with modified quadratic discriminant function, they recorded recognition rate of above 98 %. Kaufman and Bunke [16] employed Hidden Markov Models for digits recognition. They obtained a recognition rate of 87 %. Aissaoui and Haouari [14] using Normalized Fourier Descriptors for character recognition, obtained a recognition rate above 96 %. Bellili using the MLP-SVM recognize achieves a recognition rate 98 % for real mail zip code digits recognition task [17]. In this experiment recognition rate 94 % was obtained. The detailed results for individual testing sets was presented in Table I.

Table I.
Recognition rate for testing sets

| Testing Set | Recognition rate |
|---|---|
| Set 1 | 94.7 % |
| Set 2 | 94.2 % |
| Set 3 | 93.3 % |

## VIII. Conclusions

The selecting of the features for character recognition can be problematic. Moreover fact that the mail pieces have different sizes, shapes, layouts etc. this process is more complicated. The paper describes often used the character image processing such as image filtration, binaryzation, normalization and the Radon Transformation calculating.

The character recognition algorithms were proposed. In connection with this work the application included the algorithms is in progress. So far the application reached recognition speed 30 characters/sec without any optimization.

In the future work is planning to use another statistical methodology such as JDA/LDA. Moreover the will be upgraded to remaining all alphanumerical signs and special signs often placed on regular post mails.

***Abstract*—This paper describes a one-way function for use in an image watermark to improve authentication ability. The one-way function is popular in cryptography and can prove encryption security. The existence of the one-way function has not been proved yet, while the public key encryption procedure is widely used in practical commerce. The authors proposed a quasi-one-way function, which is weakly defined for practical use. The differences between the strict one-way-function and the proposed quasi-one-way function are discussed. Applications of the quasi-one-way function to image watermarking are shown. Two watermarking systems with SVD method and Jordan canonical form are tried. The robustness of the proposed watermarking method is high.**

## I. Introduction

Watermarking is a prospective method to enable forensic tracking of content distribution [1]. A robust one-way operation is expected to be an important component of any system to improve security for authentication of watermarking. The so-called "inversion attack" on watermarked data is based on the addition property of embedding. For an image, embedding is usually done by add operation to cover data. If that addition can be subtracted inversely by an inverse element in that algebraic domain, the inversion attack can be committed easily on any newly determined watermark [2]. The problem originates from this algebraic system's inclusion of an inverse element. A one-way function is a breakwater to prevent inversion attacks and improve system security. Several one-way function candidates have been discussed in the encryption world. Though procedures based on the one-way function are widely used in practical commerce and authentication, the existence of the one-way function has not been proved by a mathematical method.

In this paper, we re consider such a quasi-one-way function and also compare it with the strict one-way function. Watermark embedding is an addition to a cover image. Transforming the cover image into some specific constrained region, the addition is restricted by the region rule. The restriction induces prohibition of subtraction of the data. In such an arrangement, a directional function with addition, whose subtraction can be difficult, is expected to be developed.

A survey paper pointed out the gap between theoretical and practical security. Information-theoretic models for security represent the worst-case, while practical applications exist for optimistic security [3]. Two major security methods are shown; spread-spectrum and asymmetric. This paper takes on a kind of asymmetric method. Four methods were pointed out for security establishment [4]. They are the use of a Trusted Third Party, the asymmetric watermarking scheme, watermark detection using a group of proxies and the Zero-knowledge watermarking detection protocol.

This paper presents a description of a new one-way property for image watermarking. The framework of the algebraic domain is an integer set of image data.

Singular Value Decomposition (SVD) diagonalizes matrix elements by multiplying orthogonal matrices to obtain zero values for off-diagonal elements. The addition of watermarking elements to off-diagonal positions is a quasi-one-way functional operation. The quasi-one-way operation means, in this discussion, that a forward operation result is easily obtained, but it is more difficult to find an inverse value from the result than a forward value. A strict one-way function is not known in mathematical formulation [5]. A quasi-one way operation is one method of realizing a very effective countermeasure against the so-called inversion attack. Many research papers have described inversion attacks, but the best method of dealing with them remains an open problem. Some methods embed a watermark into a random sequence instead of into normal images. One method theoretically embeds a watermark cryptographically. Then it uses a Zero-Knowledge detection method, which differs from an image watermark and is too vulnerable to small attacks.

Gorodetski et al. [5] introduced a watermarking method using SVD in 2001. Ganic [6] surveyed SVD-based watermarking methods in 2003. Many other papers have presented the use of SVD, but the problems of embedding methods remain. Features of SVD that have been discussed include robustness, combination with DCT, and wavelet transformation. A countermeasure to inversion attacks remains elusive. At present, we can not find an SVD watermarking method that features a quasi-one-way function to protect against inversion attacks.

In the study described in this paper, SVD is renovated from a mathematical perspective. Discussions of this matter are revised, and an improved SVD-based watermarking method is developed with a quasi-one-way function to cope

978-83-60810-14-9/08/$25.00 © 2008 IEEE

with inversion attacks. An outline of the SVD watermarking and the quasi-one-way function is proposed in [7]. In this paper, the difference between the strict one-way function and the proposed quasi-one-way function is discussed. Applications of the SVD to image watermarking with one-way directional property are also described. Improved results for a larger size of images compared to the previous experiments [7] are shown, together with experiments using the Jordan canonical form.

## II. Image Watermarking

### A. Inversion Attack

Embedding a watermark into a cover image usually involves an addition of the image and the watermark. As shown in Fig. 1, for an input image G and a watermark W, we obtain $G_w\ w=G+W$ . For this result, an attacker first makes a new his own new watermark W", which he derives by embedding a watermark information $W''$ into an image $G'$ to get $G_w\ '=G'+W''$ and subtracting image $G'$ to get $W''=G'w-G'$ . Using this watermark $W''$ , he declares that he had possessed another image $G_w -W''$ and then embedded watermark W" to get $(G_w -W'')+W''$ , which is the same data as $G_w$ . $G_w$ can have the watermark of $W''$ . Viewing this process, for an arbitrary watermarked image, another person can claim that he had embedded another watermark. This is an inversion attack. The inversion attack always works on the images embedded using a simple addition.

To prevent such inversion attacks it is necessary to introduce a new kind of one-way addition or to transform the embedding procedure into a region with a one-way operation.

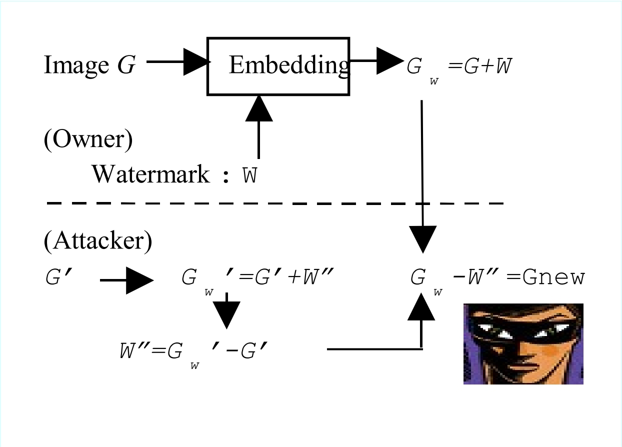

Fig 1. Inversion Attack.

### B. Authentication

For authentication of an image watermark, it is necessary to prove that a detected watermark is definitely the embedder's mark and that the procedure for detecting the watermark from the image is true. If we disclose the procedure to the public, it would mean that everyone knows the detection method and the embedding method and would be able to remove the watermark from that procedure. It is necessary to prove an ownership without disclosing the knowledge of how the watermark truly corresponds to the ownership, because it is also possible to remove the watermark from the image using such knowledge. A zero-knowledge watermark system was presented [5], however, the image is a random number.

A watermark suffers a high error rate as a transmission media, only a restricted number of bits are available for watermarking [8]. At present, it is difficult and impractical for the moment, to construct a watermarking authentication system with public key encryption and zero-knowledge proof. Hence, it would be practical to develop a watermarking system for an application so that watermarks can be embedded into images for web publication. The application would still require authentication at some prescribed level, and to attack such a system would entail certain costs, though it is not perfect to protect the ownership. Examples of authentication methods are to show matrices U and V of singular value decomposition, and to disclose the watermark to someone who can play a role of witness.

## III. One-Way Function For Watermarking

### A. Necessity For One-Way Function

Let us consider a one-way operation and the inversion attack in regard to the embedding process of a watermark. Given a watermark W and an embedded image $G_w$ $(G_w =G+W)$ , whose embedding function is $f$ , the inverse function of the embedding function $f$ is easily obtained as the inverse of the addition. In the case of embedding a watermark in a frequency domain, it is also easy to find the inverse function if the embedding method uses the standard Fourier transform. As long as the embedding process uses an addition for embedding, the inverse function can be easily found using a subtraction. Usually, image data are integer values between [0,255], and all watermarks are represented as additions. It is expected that a one-way operation for the embedding process will be introduced. A one-way function or determining a new algebraic field are candidates for this.

An example of realizing a kind of one-way function is presented [2]. An SVD watermarking system is shown in Fig. 2. An input Image $G$ is decomposed into a diagonal matrix $S$ by the singular value decomposition method using orthogonal matrices $U$ and $V$ . The matrix $S$ is diagonal, and its diagonal elements are singular values while the off-diagonal elements are zeroes. Then, let us consider a procedure in which adding a watermark $Ws$ , which has non-zero elements on off-diagonal positions, recovers image data from $S+Ws$ by multiplying $U$ and $V$ to get $G_w$ . If we re-decompose this embedded image $G_w$ again, we will obtain another set of $U'$ and $V'$ SVD matrices that are different from $U$ and $V$ . So, if we try to subtract $W_s$ from $G_w$ , we cannot get the original image $G$ . Furthermore, elements of the embedded image $G_w$ are usually truncated to integer values, which brings about a non-linear relationship to the watermark embedding system.

### B. Quasi-One-Way Function

The o ne-way function is formalized mathematically

A function $f:\{0,1\}^* \rightarrow \{0,1\}^*$ is called one-way if the following two conditions hold [9]:

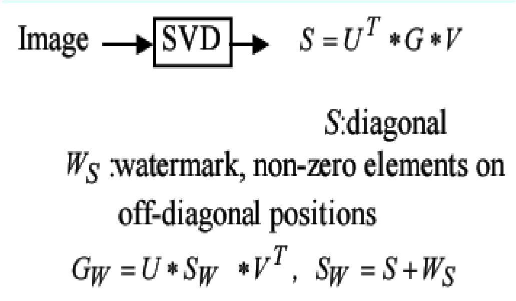

Image
SVD
$S = U^T * G * V$
S:diagonal
$W_S$ :watermark, non-zero elements on off-diagonal positions
$G_W = U * S_W * V^T$, $S_W = S + W_S$

Fig. 2 SVD Watermarking

1. Easy to Evaluate: There exists a probabilistic polynomial-time algorithm *A L* such that *A L* ( *x* ) = *f* ( *x* ) for every *x*.
2. Hard to Invert: For every probabilistic polynomial-time Turing machine *M* and for any polynomial *p(n)* , for all *n>N*,

$$\Pr\left(M\left[f\left(U_n\right),1^n\right]\in f^{-1}f\left(U_n\right)\cap\sum{}^n\right)<\frac{1}{p(n)} \qquad (1)$$

where, $U_n$ is a uniform probability distribution and the probability is taken over in {0,1}* and the coin tosses in *M* .

Several one-way function candidates have been discussed. It is computationally difficult to obtain an original number from a squared number or from a multiple of two prime numbers under a modulo rule, as indicated by the Robin function. Given a number, there is no fast algorithm of factorization of the number into prime factors. P ro ving the existence of a one-way function is still an open problem. However, difficulty in find ing prime factors is common in practical applications without mathematical verification. This indicates that there should be more sub-classes for practical applications below the polynomial time *(P)* . The term "quasi-one-way function" was mentioned by Whitfield Diffie in a paper [7] which said that "a quasi one-way function is not one-way in that an easily computed inverse exists. However, it is computationally infeasible , even for the designer, to find the easily computed inverse. Therefore a quasi one-way function can be used in place of a one-way function with essentially no loss in security ". Based on this concept, it is useful to newly create practical computational classes below polynomial. Here, we will extend the statement from computationally infeasible to having more complex mandatory operations than that for forward operation as an inverse function. It is a more realistic and constructive approach to weaken the definition and utilize the number of times of a finite computation.

Definition of a quasi-one-way function:

For a function *y=f(x)* , evaluating the minimum number of times of the forward operation *y=f(x)* and the inverse operation $x=f^{-1}(y)$ , a quasi-one-way function should have a larger number of inverse operations than forward operations, as shown by formula (2).

$$\min\left(Num\left(y=f\left(x\right)\right)\right)<\mathrm{Min}\left(Num\left(x=f^{-1}\left(y\right)\right)\right) \qquad (2)$$

It is recommended that the number of operations of the inverse function is noted.

### 1. C. SVD and Quasi-ONE-WAY FUNCTION

We will consider the relation between the SVD watermark embedding in Fig. 2 and the quasi-one-way function. If we are given a SVD watermark embedded image $G_w$ and its watermark $W_s$ , then to derive SVD decomposing matrices *U* and *V* may be possible by correcting SVD of $G_w$ using $W_s$ if we neglect the quanti z ing error of $G_w$ . However, the watermark embedded image $G_w$ is truncated to an integer value, which means $G_w$ loses some of the information required to recover the correct SVD decomposing matrices *U* and *V* . It is anticipated that the inverse function will require several times as many operations as the forward function. Concerning the image size of *nXn* , the number of forward operations is order $O(n^3)$ for a non-sparse matrix. The uniqueness of the SVD, which was already proved, governs the inverse operation to be difficult.

## IV. Singular Value Decomposition

### A. Method 1

In consideration of the preceding section, after embedding a watermark into the singular value matrix *S* , it is not necessary to re- apply SVD. Moreover , a quasi-one - way characteristic of SVD lies in the fact that the off-diagonal position values are zeros. N o positive or negative values exist in the off-diagonal positions . Therefore, to put a value on an off-diagonal position is a quasi-one-way operation. For that reason, adding watermark values at off-diagonal positions is an important quasi-one-way operation. As long as the quasi-one-way operation is effective, it is difficult to find another watermark with an appropriate pair of *U* and *V* of SVD for the embedded image, $G_W$ .

To improve the SVD-based watermarking method, it is merely necessary to remove the operation of the second SVD. The embedded watermark is *SS=S+aW* . Then, the inverse SVD is performed to obtain an embedded image,

$$G_W = U * SS * V^T$$

If another SVD is applied to this $G_W$ , then

$$G_W = U_W * S_W * V_W^T .$$

In general, $SS \neq S_W$ , $U \neq U_W$ , and $V \neq V_W$ .

It is noteworthy that *SS* has off-diagonal elements other than zero, although $S_W$ has only diago nal elements; from $S_W$, an embedded watermark cannot be detected.

On the other hand, the first and real owner who embedded the watermark can detect *SS* and *W* using *U, V* and *S* . This is "Method 1" of improved SVD-based watermarking with a quasi-one-way function.

However, this Method 1 present s a problem. Alt hough neither *SS* n or *W* can be derived directly from $G_W$ , another effective *U', V'* and *W* ', which m ight differ from the correc t *U, V* and *W* , can be computed using basic linear algebra. Consequently, an inversion attack can be made on this Method 1. Fo r example, after another SVD,

$$G_W = U_W * S_W * V_W^T .$$

Using a proper regular matrix *T*, $S_W = U_W^T * G_W * V_W$ can be modified, by multiplying *T* from the left and $T^{-1}$ from the right, to

$$T * U_W^T * G_W * V_W * T^{-1}$$

Putting $T_U = T, T_V = T^{-1}$, we obtain

$$T_U * S_W * T_V = T_U * U_W^T * G_W * V_W * T_V \quad , (3)$$

using a pair of example matrices for $T$, as

$$T_U = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \varepsilon & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

$$T_U^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -\varepsilon & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = T_V \quad .$$

Then, (3) is modified to yield the following [10].

$$T_U * S_W * T_V = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \varepsilon & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} * \begin{bmatrix} s_1 & 0 & 0 & 0 \\ 0 & s_2 & 0 & 0 \\ 0 & 0 & s_3 & 0 \\ 0 & 0 & 0 & s_4 \end{bmatrix} * T_V$$

$$= \begin{bmatrix} s_1 & 0 & 0 & 0 \\ 0 & s_2 & 0 & 0 \\ 0 & 0 & s_3 & 0 \\ 0 & 0 & 0 & s_4 \end{bmatrix} + \begin{bmatrix} 0 & 0 & 0 & 0 \\ \varepsilon s_1 - \varepsilon s_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$= S_W^* \quad (4)$$

Subsequently, (4) is decomposed into a sum of two matrices as,

$$S_W^* = S_W^D + W' \quad ,$$

where $S_W^D$ is a diagonal component and $W'$ is an off-diagonal component.

On the other hand, (3) can be decomposed into a product of two matrices as follows:

Using $T_U * S_W * T_V = T_U * U_W^T * G_W * V_W * T_V$ , we obtain

$$(T_U * U_W^T)^{-1} * T_U * S_W * T_V * (V_W * T_V)^{-1} = I_W \quad .$$

Now we can find another SVD for the embedded image $G_W$ with re-defined decomposition matrices as

$$U^* = (T_U * U_W)^{-1} * T_U \quad , \quad V^{*T} = T_V * (V_W * T_V)^{-1} \quad .$$

The following (5) can be inferred from the above [10]. In fact, $T_U$ is a versatile matrix for any watermarked image embedded using Method 1.

$$U^* V^{*T} = (T_U * U_{W^T})^{-1} * T_U * T_V (V_W * T_V)^{-1} \quad (5)$$
$$= I.$$

### B. Method 2

An improved method was proposed to overcome the problem presented in the preceding section [10] . This Method 2 was devised because Method 1 includes the defect that using an appropriate orthogonal matrix $T$ , the diagonal matrix *S* can be transformed easily into another matrix with off-diagonal components , which breaks the quasi-one-way function. The diagonal matrix *S* and watermark matrix *W* are first reviewed to formulate Method 2.

For image matrix $G$ , SVD produces a pair of orthogonal matrices, $U$ and $V$ , where $U$ stands for column transformation and *V* is the row transformation. Multiplying an orthogonal matrix *"T"* to the diagonal singular matrix S can generate the watermark matrix *W*, which contains non-zero off-diagonal components. In fact, *SS* has two expressions,

$$SS = S + W$$

and

$$SS = T_U * S \quad .$$

Then, from $S+W= T_U * S$ ,

$W = (T_U - I) * S$ or $T_U = (S + W) * S^{-1}$

are obtained. Observing the latter formula, in the case of matrices S and $T_U$ in Method 1, *W* is not regular, and its diagonal components diminish. The rank of the watermark matrix *W* increased if the number of embedded watermarks increased . Increasing the rank of *W* tends to decrease the rank of $T_U$ .

Based on these considerations , Method 2 proposes a non-regular matrix $T_U$ . To reduce the rank of $T_U$ , a partial copy of S into *W* generates the linearly dependent matrix SS and consequently , $T_U = (S + W) * S^{-1}$ is also non-regular. In SVD, the rank of $U^* = T_U * U_W$ decreases and is not regular. By this operation, the embedded image $G_W$ is decomposed as,

$$G_W = U_W^{**} * S_W^{**} * V_W^{**} \quad .$$

The rank of $S_W^{**}$ , $U_W^{**}$ and $V_W^{**}$ decreases. Thereby it is computationally difficult to obtain regular matrices which match the original $G_W$ from these reduced rank matrices . The simplest example of *W* is,

$$W(i,i+1)=S(i,i) \ , \ W(i+1,i)=S(i+1,i+1).$$

A flowchart of Method 2 is shown in Fig. 3.

## V. Experimental Results

In this section, the proposed SVD-based watermarking algorithm is described using numerical data to confirm the operational methods in detail.

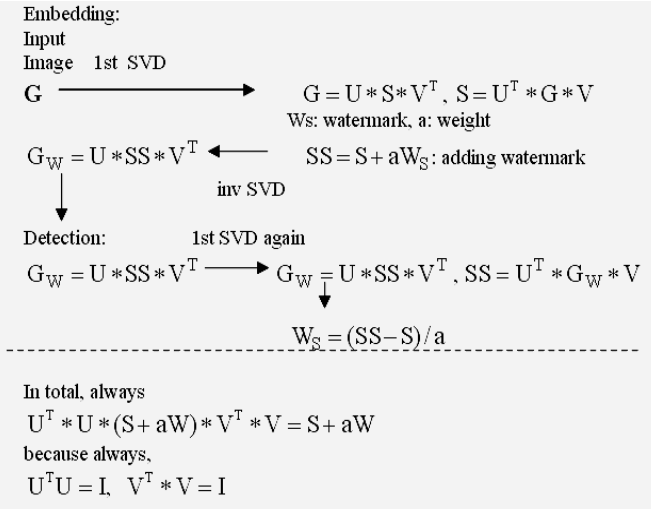

Fig 3.: Proposed SVD-Based watermarking embedding and detection.

### A. Basic Analysis

For a 4 × 4 image **G**, SVD is shown as the following.

$$\mathbf{G} = \begin{pmatrix} 132 & 122 & 114 & 108 \\ 122 & 116 & 110 & 106 \\ 110 & 116 & 106 & 107 \\ 104 & 107 & 109 & 99 \end{pmatrix}$$

$$\mathbf{S} = \begin{pmatrix} 447.9 & 0 & 0 & 0 \\ 0 & 13.0 & 0 & 0 \\ 0 & 0 & 6.5 & 0 \\ 0 & 0 & 0 & 1.1\ 5 \end{pmatrix}$$

$$\mathbf{U} = \begin{pmatrix} -0.533 & -0.652 & 0.108 & -0.528 \\ -0.507 & -0.252 & 0.003 & 0.824 \\ -0.490 & 0.415 & -0.747 & -0.172 \\ -0.468 & 0.582 & 0.656 & -0.112 \end{pmatrix}$$

$$\mathbf{V} = \begin{pmatrix} -0.524 & -0.827 & 0.114 & 0.168 \\ -0.515 & 0.118 & -0.439 & -0.727 \\ -0.490 & 0.407 & 0.769 & -0.051 \\ -0.469 & 0.370 & -0.450 & 0.664 \end{pmatrix}$$

Next, as a watermark matrix **W**, to make the second column of the singular value matrix conform to the third column,

$$\mathbf{W}(2,3)=\mathbf{S}(2,2),\ \mathbf{W}(3,2)=\mathbf{S}(3,3).$$

are processed. Then **SS**=**S**+**W** is obtainable.

$$\mathbf{W}= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 6.5 & 0 \\ 0 & 13.0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$\mathbf{SS} = \begin{pmatrix} 447.9 & 0 & 0 & 0 \\ 0 & 13.0 & 6.5 & 0 \\ 0 & 13.0 & 6.5 & 0 \\ 0 & 0 & 0 & 1.15 \end{pmatrix}$$

Next, the embedded image $\mathbf{G}_w = \mathbf{U} * \mathbf{SS} * \mathbf{V}^{\mathrm{T}}$ is obtained by inverse SVD using **SS**, **U**, **V**.

$$\mathbf{G}_w= \begin{pmatrix} 130.3 & 124.0 & 111.3 & 110.4 \\ 121.8 & 116.7 & 108.7 & 106.8 \\ 118.3 & 113.7 & 104.1 & 102.2 \\ 97.4 & 106.3 & 115.4 & 100.4 \end{pmatrix}$$

An attacker will attempt to find the singular value matrix **SS** to obtain the embedded watermark matrix **W**. To do so, $\mathbf{G}_w$ is decomposed as,

$$\mathbf{G}_w = \mathbf{Uw}^{**} * \mathbf{Sw}^{**} * \mathbf{Vw}^{**\,\mathrm{T}},$$

$$\mathbf{Uw}^{**} = \begin{pmatrix} -0.532 & -0.387 & -0.454 & -0.601 \\ -0.509 & -0.175 & 0.840 & -0.071 \\ -0.490 & -0.232 & -0.278 & 0.793 \\ -0.466 & 0.875 & -0.107 & -0.070 \end{pmatrix}$$

$$\mathbf{Vw}^{**}= \begin{pmatrix} -0.524 & -0.684 & 0.197 & -0.468 \\ -0.516 & -0.099 & -0.747 & 0.407 \\ -0.490 & 0.711 & -0.030 & -0.503 \\ -0.469 & 0.130 & 0.634 & 0.601 \end{pmatrix}$$

$$\mathbf{Sw}^{**}= \begin{pmatrix} 447.4 & 0 & 0 & 0 \\ 0 & 20.5 & 0 & 0 \\ 0 & 0 & 1.40 & 0 \\ 0 & 0 & 0 & 0.19 \end{pmatrix}$$

The rank of $\mathbf{Sw}^{**}$ is theoretically 3, although it seems to be 4, the fourth value is extremely small, almost zero. Most parts of singular values are sufficiently large, indicating that Method 2 is valid for use in pictures of a general nature.

Many other images were tested with application of SVD. Table 1 shows the maximum and minimum of the singular values of matrix **S**. The maximum values are from **S**(1,1) and the minimum values are from the last non-zero diagonal component. The images in Table 1 are all natural ones; the rank of **S** is the same value as the image size, except for the circles image. It is an artificial image, not a natural one. Such images usually contain the same value in lines as background parts, and the rank might decrease. For all other images shown in Table 1, SVD operations were all well performed: the ranks of the singular matrix *S* are all the same value as the image size, implying that the proposed method is stable in decomposition for many natural scene images.

### B. Jordan Canonical Form

Another basic analysis with the Jordan canonical form was carried out. For an image matrix *G* as,

$$G= \begin{bmatrix} 236 & 10 & 11 & 12 \\ 10 & 177 & 12 & 10 \\ 10 & 12 & 174 & 12 \\ 10 & 12 & 14 & 222 \end{bmatrix}$$

Eigenvalues are well obtained because this matrix is regular

$$\Lambda = P^{-1} * G * P = \begin{bmatrix} 249.3 & 0 & 0 & 0 \\ 0 & 217.3 & 0 & 0 \\ 0 & 0 & 179.2 & 0 \\ 0 & 0 & 0 & 163.3 \end{bmatrix}$$

Table 1
Ranks of Images and the Maximum and Minimum Values of Singular Values . (girl * is a partial image from the center of an image girl from (126,126) to (129,129). Circles** is an artificial computer graphic image.)

| image name | size | rank of S | singular value | |
|---|---|---|---|---|
| | | | maximum | minimum |
| girl_* | 4×4 | 4 | 447 | 0.2 |
| car | 240×240 | 240 | 29761 | 0.4 |
| girl | 256 × 256 | 256 | 16511 | 0.3 |
| couple | | 256 | 10003 | 0.1 |
| lena | | 256 | 31956 | 0.0 1 |
| peppers | | 256 | 27203 | 0.1 |
| circles ** | | 125 | 28509 | 40 |
| lena | | 512 | 38638 | 0.0 03 |

where $P=\begin{bmatrix} 0.805 & 0.603 & 0.163 & -0.023 \\ 0.218 & -0.076 & -0.731 & -0.624 \\ 0.222 & -0.100 & -0.562 & 0.779 \\ 0.505 & -0.788 & 0.351 & -0.054 \end{bmatrix}$

To modify the matrix to have the Jordan canonical form, let the third and fourth components of eigenvalues be the same for having double root and putting a value “1” on the off-diagonal right-hand position of the third eigenvalue. This operation forces the matrix to have the Jordan canonical form that contains a watermark. Let the Jordan’s mark $W$ be

$$W=\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

then, the embedded matrix is,

$$\Lambda_m w=\begin{bmatrix} 249.3 & 0 & 0 & 0 \\ 0 & 217.3 & 0 & 0 \\ 0 & 0 & 179.2 & 1 \\ 0 & 0 & 0 & 179.2 \end{bmatrix}=\Lambda_m+W \quad .$$

Inverse transformation derives the embedded image matrix as,

$$GwI=R(P*\Lambda_m w*P^{-1})=\begin{bmatrix} 236 & 10 & 11 & 12 \\ 10 & 184 & 4 & 11 \\ 10 & 5 & 183 & 11 \\ 10 & 12 & 14 & 222 \end{bmatrix}$$

where $R$ (*) represents rounding.

Because the uniqueness of the Jordan canonical form is guaranteed by mathematical theory, the obtained image data matrix is the Jordan matrix.

Multiplying a pair of matrices $P$ and $P^{-1}$ can detect the Jordan’s mark.

$$P^{-1}*G_{w^I}*P=\begin{bmatrix} 249.3 & 0 & -0.1 & 0.3 \\ 0 & 217.3 & 0 & -0.2 \\ -0.2 & 0.1 & 179.6 & 1.41 \\ -0.2 & 0.6 & 0 & 178.8 \end{bmatrix} \quad .$$

To get the Jordan canonical form from the truncated matrix, $G_w{}^I$ could not be done by the change of rounding of integer data. Actually, the result of getting the Jordan canonical form from $G_w{}^I$ is,

$$\Lambda_m wI=\begin{bmatrix} 249.3 & 0 & 0 & 0 \\ 0 & 217.3 & 0 & 0 \\ 0 & 0 & 179.4 & 1 \\ 0 & 0 & 0 & 179.0 \end{bmatrix}$$

which has no double root any more and is not a Jordan matrix, but rather a normal regular matrix .

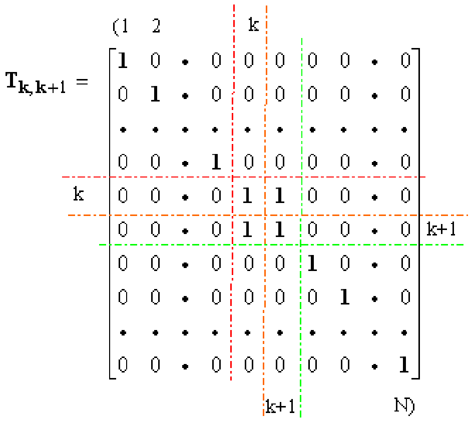
This Jordan canonical form method is theoretically interesting. However, error sensitivity is large. Therefore, it might not be robust. The example above shows a difference of the embedded mark from 1.00 to 1.41. Embedding trials were done for several image datasets, but the example’s performance and robustness remained unsatisfactory. Eigenvalues can be complex even for real integer data.

### C. Embedding Watermarks

Based on the above considerations, watermark-embedding experiments were carried out using Method 2. Fig. 4 shows that the embedding was realized by multiplying a matrix $T_{k,k+1}$ . The embedded images were modified using JPEG compression. Detection ratios are shown in Fig. 5 . Table 2 shows their embedded position and singular values. The actual added data are,

*SS(k,k+1)=S(k;1,k+1)* and *SS(k+1,k)=S(k,k)*.

The detection rule for these experiments is that all singular values are maintained at specified levels. The specified levels are half of the original values. The detection ratios shown in Fig. 5 are normalized by the original values. The dotted line at 50% represents the borderline between detectable and non-detectable. Without JPEG compression, 100% detection is achieved because only a small fractional error exists. Compression ratios of 11-13 are the maximum for detection. In the figure, *SVD_min* means the minimum value of two modified SVD values by JPEG at $S$ ( $k,k$ ) and $S$ ( $k+1,k+1$ ). These values are maintained as larger than the borderline for JPEG compression ratio of 30. In addition, *WM_min* means the minimum value of the embedded two watermarks modified by JPEG at $S$ ( $k,k+1$ ) and $S(k+1,k$ ). These values are kept larger than the borderline for JPEG compression ra-



$$\mathbf{T_{k,k+1}} = \begin{array}{c|cccccccccc|c} & (1 & 2 & & & k & & & & & & \\ \hline & 1 & 0 & \cdot & 0 & 0 & 0 & 0 & 0 & \cdot & 0 & \\ & 0 & 1 & \cdot & 0 & 0 & 0 & 0 & 0 & \cdot & 0 & \\ & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ & 0 & 0 & \cdot & 1 & 0 & 0 & 0 & 0 & \cdot & 0 & \\ k & 0 & 0 & \cdot & 0 & 1 & 1 & 0 & 0 & \cdot & 0 & \\ & 0 & 0 & \cdot & 0 & 1 & 1 & 0 & 0 & \cdot & 0 & k+1 \\ & 0 & 0 & \cdot & 0 & 0 & 0 & 1 & 0 & \cdot & 0 & \\ & 0 & 0 & \cdot & 0 & 0 & 0 & 0 & 1 & \cdot & 0 & \\ & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ & 0 & 0 & \cdot & 0 & 0 & 0 & 0 & 0 & \cdot & 1 & \\ \hline & & & & & & k+1 & & & & N) & \end{array}$$

Fig 4. Embedding Matrix $T_{k,k+1}$ .

tio 11 or 13. *Ripple _ Max* means the maximum value among all other elements in the neighbouring area except the four elements; *S(k,k)* , *S(k,k+1)* , *S(k+1,k)* and *S(k+1,k+1)* . The *Ripple_Max* area values are originally zeroes and are modified by JPEG compression. The *Ripple_Max* is generally small. For JPEG compression ratio 30, the *Ripple_Max* is less than 15%.

Table:2
Embedded positions and Singular Values.

| Image | Embedded Position(1) k | SVD Value | Embedded Position(2) k+1 | SVD Value |
|---|---|---|---|---|
| girl | 50 | 205.06 | 5 1 | 195.68 |
| couple | 5 0 | 197.62 | 51 | 189.70 |
| lena | 85 | 202.40 | 86 | 201.46 |
| peppers | 74 | 204.88 | 75 | 199.37 |
| lena2 | 80 | 406.16 | 81 | 395.78 |

### *D. Detection M ethod 2*

The detection method above is an elementary version. An improved detection method (DM 2) can be devised from Fig. 5. Room exists between ripples and the 50% detection boundary line. Ripples around diagonal positions with SVD values on them are generally small. Therefore, the detection threshold level *Lw* of embedded watermarks is expected to be smaller than that of a logical value. Furthermore, the SVD value threshold level *Ls* ha s been adjusted. Fig. 6 depicts the results for other images. Detection r atios are improved by this change of threshold. The image quality of JPEG-coded images can be recognized easily for compression ratio s higher than 15 for these experiments. Some degradation is apparent for the compression ratio of 10. The coded images will be shown at oral presentation. Fig. 7 shows a comparison of robustness related to the image size. Images of 256 × 256 were used for the first experiment. An image that wa s twice as large as that used in the previous experiment ha d larger singular values and show ed higher robustness for embedding. Detection ratios of lena_506 we re much higher than the images of 256. For a JPEG compression ratio of 30, the detection wa s well carried out: the larger the image, the higher the obtained robustness.

## VI. Conclusions

Quasi-one-way functions are proposed for watermarking applications. Singular Value Decomposition and Jordan canonical form are introduced for obtaining computationally asymmetrical structures. Jordan canonical form is said to be difficult to calculate precisely for a large matrix. Error sensitivity is large. For real values image data eigenvalues can be complex numbers. Imaginary parts of a pair of conjugate complex eigenvalues resulting from double rooting processing in making Jordan canonical form are likely to be large. Reorganizing the SVD-based watermarking system, an improved SVD-based watermarking method was developed with a quasi-one-way function by reduced rank matrix. The developed matrix with reduced-rank for watermark embedding in singular value decomposition cannot be restored using simple methods, such as simply multiplying a matrix. So-called inversion attacks cannot be activated as long as the proposed quasi-one-way operation framework holds. They would require computationally complex procedures to derive the exact set of singular value decomposition matrices. Results of experiments underscore the effectiveness of the proposed system for smaller sizes of image data. For larger sizes of image data, the detection ratio increases under JPEG compression attacks. In the future, an iterative operation for increasing computational complexity must be investigated. In addition, detection performance can be improved using a smart er and more complicated algorithm

***Abstract*—In the last decade the electronic learning became a very useful tool in the students' education from different activity domains. The accomplished studies indicated that the students substantially appreciate the e-learning method, due to the facilities: the facile information access, a better storage of the didactic material, the curricula harmonization between universities, personalized instruction. The paper presents a software tool that can be used in the e-learning process in order to automatically generate questions from course materials, based on a series of tags defined by the professor. The Test Creator tool permits generation of questions based on electronic materials that students have. The solution implies teachers to have a series of tags and templates that they manage. These tags are used to generate questions automatically.**

## I. Introduction

IN THE last decade, the electronic learning became a very useful tool in the students' education from different activity domains. The accomplished studies indicate that the students substantially appreciate the e-learning method, due to the facilities offered [1], [2], [3], [6], [7]: the facile information access, a better storage of the didactic material, the curricula harmonization between universities, personalized instruction, informational content standardization, real time access to qualitative information resources and friendly interfaces. They don't consider it as a replacement of the traditional learning that has other advantages [8].

As it is known, an essential aspect in the learning process (either electronic or traditional) is the possibilities to evaluate the students. It is very important both for professor and student to test the understanding degree of the course. One of the best possibilities is to ask questions from the studied course. It is tested this way the degree of understanding of each studied material and the integration of new knowledge with the previous ones (that should already be known). These facts will have as a result an in-depth understanding of the learning materials. The studies showed that a high number of questions from the same subject in-depth understanding. That is why a series of questions can be found as exercises at the end of many high rated courses.

The paper presents the implementation of a tool that can generate questions automatically based on the tags defined by the professor. He can add new tags, delete the existing ones and generate questions specifying the part of the course that should be used for questions.

The structure of the paper is: in the second part it is presented the related work. In the third part it is presented the application, the architecture of the application, and in the last part, the conclusions.

## II. Related Work

Taking into consideration the high number of learning material existing in electronic format, the importance of the testing and evaluation systems has increased. Most of these systems use tests that were generated by teachers that permit a good evaluation and pursuance of the student evolution.

In the last years, new preoccupations appear for automatic question generation. It's a subclass of Natural Language Generation (NLG) that is very important in a series of areas as: learning environment, data mining or information extraction. For example in [1] it is introduced a template-based approach to generate questions on four types of entities. It is considered that his approach failed in producing questions that can enhance the students' knowledge level. The authors present in [2] an interesting solution to the problem of presenting students with dynamically generated browser-based exams with significant engineering mathematics content. They introduce WTML (Web Testing Markup Language), which is an extension of HTML. A very interesting approach is found in [3]. Here, the main idea is to generate the questions automatically based on question templates which are created by training on many medical articles. This idea has advantages (easiness in building medical learning system, no additional work to build the question database or grading), but also disadvantages: the generated questions are factual and maybe less meaningful than the manual questions, time consuming to parse the articles and obtain the semantic interpretation, missing some important information.

Taking into account the advantages and disadvantages of the presented solutions, we tried to design and implement a software instrument (Test Creator) that permits generation of questions based on electronic materials that students have. The solution implies teachers to have a series of tags and templates that they have to manage. These tags can be used to generate questions automatically.

## III. Question Generation

### A. General Description

In this paragraph there are presented concepts and the working style for the Test Creator software tool. The main window is organized in several sub-windows, each of them permitting some operations in a very simple manner. It is easily compatible with any learning domain: engineering, medical, or economical. In order to generate questions, based on a specific course material, there should be followed 3 steps:

1. Defining tags or questions categories
2. Defining templates for a specific tag
3. Parsing the text in order to generate the templates.

The basic idea for generating questions based on the course material is to define a list of tags, chosen by the teacher. Each tag represents a class of questions with similar formatting that are applicable for certain theoretical notions from the course.

For example, the <DEFINE> tag will be used to formulate some questions where the student has to define some concepts. The <EXAMPLE> tag will be used for questions where it should be presented an example for a specific concept.

In the TestCreator software tool there is a sub-window where there are presented the tags that already exists in the database. They can be updated using insert/delete operations. The most important thing is that the teacher has total freedom in choosing these tags, as he considers being most suitable for his course domain.

For each tag, the teacher defines one or several forms of a question, suitable for a specific category. These forms of the questions were called templates (figure 1).

For example, for the <DEFINE> tag it can be defined the following template: "DEFINE #". For the tag <WHAT IS>, the template can be "What is a/an #". The use of "#" sign represents for this application the reserved word or phrase to which it is applied the tag.

One of the problems was to have several forms for the same tag in order to give the possibility to the teacher to create questions that are correct from the syntactic and semantic point of view. Another situation that appears frequently refers to the possibility to formulate the same questions both in the native language and in an international language.

The final step is represented by the questions generation. The professor has to load first the course material in the main window. Then, in order to generate questions, he has to select the keyword or key-phrase from the text and then to select the tag and template. The "#" sign will be replaced with the chosen word/phrase from the course.

For example, for the DEFINE # template, and the keywords "Boyce-Codd normal form" there will be generated the question: DEFINE Boyce-Codd normal form.

As soon as it was generated, the question is displayed in another window of the software tool. The teacher has to decide if it is correct and if it should be kept and stored in the database (figure 2).

14.1 Informal Design Guidelines for Relation Schemas

14.1.1 Semantics of the Relation Attributes
14.1.2 Redundant Information in Tuples and Update Anomalies
14.1.3 Null Values in Tuples
14.1.4 Generation of Spurious Tuples
14.1.5 Summary and Discussion of Design Guidelines

We discuss four informal measures of quality for relation schema design in this
section:
Semantics of the attributes.
Reducing the redundant values in tuples.
Reducing the null values in tuples.
Disallowing the possibility of generating spurious tuples.
These measures are not always independent of one another, as we shall see.

14.1.1 Semantics of the Relation Attributes
Whenever we group attributes to form a relation schema, we assume that a certain
meaning is associated with the attributes. In Chapter 7 we discussed how each
relation can be interpreted as a set of facts or statements. This meaning, or
semantics, specifies how to interpret the attribute values stored in a tuple of the
relation—in other words, how the attribute values in a tuple relate to one
another. If the conceptual design is done carefully, followed by a mapping into
relations, most of the semantics would have been accounted for and the resulting
design should have a clear meaning.
In general, the easier it is to explain the semantics of the relation, the better
the relation schema design will be. To illustrate this, consider Figure 14.01, a

```

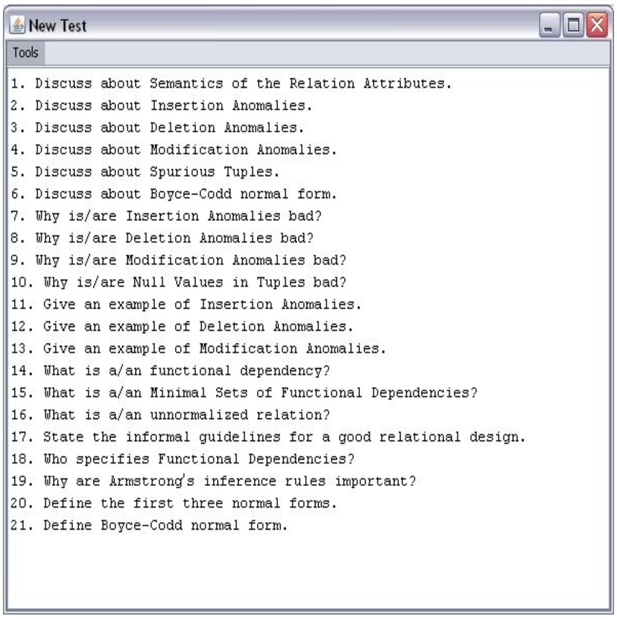
Fig. 2 The main window of the software tool

Another window of the application is the one in figure 3, where can be displayed all the questions generated by the teacher for the course material currently loaded in the system. These questions are managed by the teacher giving him the possibility to delete, update and store them in the database. He will also have the possibility to reload a course material and see the questions generated for it.

### B. The Structure of the Database

The entity-relation model of the database used by the software tool is presented in the figure 4. The Tags table is the one that stores information about existing query categories. The Templates table has a connection of 1:m with the table Tags.



1. Discuss about Semantics of the Relation Attributes.
2. Discuss about Insertion Anomalies.
3. Discuss about Deletion Anomalies.
4. Discuss about Modification Anomalies.
5. Discuss about Spurious Tuples.
6. Discuss about Boyce-Codd normal form.
7. Why is/are Insertion Anomalies bad?
8. Why is/are Deletion Anomalies bad?
9. Why is/are Modification Anomalies bad?
10. Why is/are Null Values in Tuples bad?
11. Give an example of Insertion Anomalies.
12. Give an example of Deletion Anomalies.
13. Give an example of Modification Anomalies.
14. What is a/an functional dependency?
15. What is a/an Minimal Sets of Functional Dependencies?
16. What is a/an unnormalized relation?
17. State the informal guidelines for a good relational design.
18. Who specifies Functional Dependencies?
19. Why are Armstrong's inference rules important?
20. Define the first three normal forms.
21. Define Boyce-Codd normal form.

Fig. 3 The questions generated by the system

It is used to store for each query category, different forms of the queries. The tables Course and Chapters stores information about electronic courses and their chapters. Actually these chapters will be loaded into the application in order to generate questions from them. Between tables Chapters and templates there is a m:m connection. In the relational model this will lead to a new relation, called Questions where it is stored the effective content of the generated query

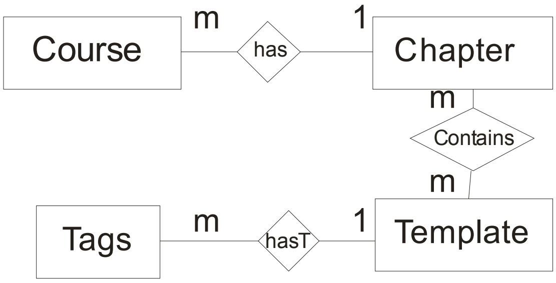


Fig. 4 The Entity-Relationship model for database structure

## IV. Software Architecture

The document type that is the most used is the MS Word .doc type. For this we have implemented a class (POIDoc) that opens and returns the content of a MS Word document. This class uses Apache POI libraries: poi-3.0.1.jar, poi-contrib-3.0.1.jar, poi-scratchpad-3.0.1.jar.

The POI project consists of APIs for manipulating various file formats based upon Microsoft's OLE 2 Compound Document format using pure Java. We can read and write MS Word, Excel files using Java. POI is your Java Word solution as well as your Java Excel solution. HWPF is the name of our port of the Microsoft Word 97 file format to pure Java. It does not support the new Word 2007, .docx file format, which is not OLE2 based.

For basic text extraction, we make use of org.apache. poi.hwpf.extractor.WordExtractor. It accepts an input stream or a HWPFDocument. The getText() method can be used to get the text from all the paragraphs, or getParagraphText() can be used to fetch the text from each paragraph in turn. The other option is getTextFromPieces(), which is very fast, but tends to return things that aren't text from the page.

## V. Concept Maps Applied for Questions Generation

### A. General Description

Concept maps are a result of Novak and Gowin's (1984) research into human learning and knowledge construction. Novak (1977) proposed that the primary elements of knowledge are concepts and relationships between concepts are propositions. Novak (1998) defined concepts as "perceived regularities in events or objects, or records of events or objects, designated by a label." Propositions consist of two or more concept labels connected by a linking relationship that forms a semantic unit.

Concept maps are a graphical two-dimensional display of concepts (usually represented within boxes or circles), connected by directed arcs encoding brief relationships (linking phrases) between pairs of concepts forming propositions. The simplest concept map consists of two nodes connected by an arc representing a simple sentence such as 'flower is red,' but they can also become quite intricate.

One of the powerful uses of concept maps is not only as a learning tool but also as an evaluation tool, thus encouraging students to use meaningful-mode learning patterns.

Concept mapping may be used as a tool for understanding, collaborating, validating, and integrating curriculum content that is designed to develop specific competencies. Concept mapping, a tool originally developed to facilitate student learning by organizing key and supporting concepts into visual frameworks, can also facilitate communication among faculty and administrators about curricular structures, complex cognitive frameworks, and competency-based learning outcomes. To validate the relationships among the competencies articulated by specialized accrediting agencies, certification boards, and professional associations, faculty may find the concept mapping tool beneficial in illustratingrelationships among, approaches to, and compliance with competencies [9].

According to this approach, the responsibility for failure at school was to be attributed exclusively to the innate (and, therefore, unalterable) intellectual capacities of the pupil. The learning/ teaching process was, then, looked upon in a simplistic, linear way: the teacher transmits (and is the repository of) knowledge, while the learner is required to comply with the teacher and store the ideas being imparted [10].

It should be made a very important distinction between rote learning and meaningful learning.

Meaningful learning requires three conditions:

1. The material to be learned must be conceptually clear and presented with language and examples relatable to the learner's prior knowledge. Concept maps can be helpful to meet this condition, both by

identifying large general concepts held by the leaner prior to instruction of more specific concepts, and by assisting in the sequencing of learning tasks though progressively more explicit knowledge that can be anchored into developing conceptual frameworks;

2. The learner must possess relevant prior knowledge. This condition can be met after age 3 for virtually any domain of subject matter, but it is necessary to be careful and explicit in building concept frameworks if one hopes to present detailed specific knowledge in any field in subsequent lessons. We see, therefore, that conditions (1) and (2) are interrelated and both are important;
3. The learner must choose to learn meaningfully. The one condition over which the teacher or mentor has only indirect control is the motivation of students to choose to learn by attempting to incorporate new meanings into their prior knowledge, rather than simply memorizing concept definitions or propositional statements or computational procedures. The indirect control over this choice is primarily in instructional strategies used and the evaluation strategies used. Instructional strategies that emphasize relating new knowledge to the learner's existing knowledge foster meaningful learning. Evaluation strategies that encourage learners to relate ideas they possess with new ideas also encourage meaningful learning. Typical objective tests seldom require more than rote learning [7].

### *B. Concept maps for queries generation*

The concept map helps the professor to have a better overview of the course and what aspect he should pay attentions. If he generate first a concepts map he will be able to define tags for every concept and implicit to have questions for each concept.

Before defining the tags position in the text the professor has to specify a list of concepts and the connections between them. The list of concepts that will be included is chosen by the professor. He will decide what the most important concepts in the course are and which are not.

There are many tools that generate concept maps. The most used are:

- C-TOOLS – Luckie (PI), Implemented to the University of Michigan NSF grant. It is available for download to the address:

http://ctools.msu.edu/ctools/index.html

- TPL-KATS – Implemented to the University of Central Florida (e.g., Hoeft, Jentsch, Harper, Evans, Bowers, & Salas, 1990). TPL-KATS: concept map, a computerized knowledge assessment tool. Computers in Human Behavior, 19 (6), 653-657.
- SEMNET – Downloadable from: http://www.semanticresearch.com/about/

The steps that should be followed are:

1. The specialist will use one of these specialized tools to generate a concept map for the course material, similar to the one presented in figure 5.
2. Load the course in the system
3. Add/Delete existing tags templates to be according to his needs.
4. For each concept in the map define one or several templates that will be applied.
5. Generate questions. For each edge in the graph it will correspond a certain number of quiz questions.

The algorithm transforming the Concept Map into General Graph is strait forward. Each proposition becomes an edge with a weight assigned by domain knowledge expert. In this way it was obtained the Binary Search Tree General Graph. Once the General Graph has been set, up the professor has to set up the quiz questions for the chapter. For each edge in the graph it will correspond a certain number of quiz questions.

Once the quiz questions have been set up, for each student there may be constructed the learner's associated graph.

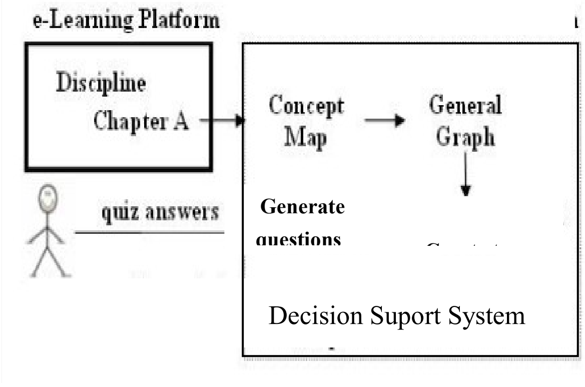

Fig. 6 Functionality of Test Creator tool using on Concept Maps.

This graph will have associated with the edges the history of correct and wrong answered questions. The Calculus engine will reconstruct an Annotated Concept Map which will present to the learner the current status of his knowledge level at Concept level. In this way, the learner will have an exact overview of his knowledge level regarding that chapter. The Annotated Concept Map may represent the important information for learner in having a decision regarding which part of the chapter needs more study.

## VI.Conclusions and Future Work

The paper presented a software tool that can be used in the e-learning process in order to generate automatically questions from course materials. The professor can define tags and templates that will be used in query generation.

The Test Creator tool permits generation of questions based on electronic materials that students have. The solution implies teachers to have a series of tags and templates that they have to manage. These tags can be used to generate questions automatically.

In order to find the most important part in a course material and it will be created a list of concepts and a Concept map. For these steps of the process it should be used a third party software tool specialized in concept maps aspects.

It is preferable to include concept maps concepts in the learning process for two reasons:

- you can be sure that you will have questions about all important concepts existing in the course
- you can monitor learning activity to be sure that students learn meaningful and not only several separate aspects, with no connection between.

# International Conference on Principles of Information Technology and Applications

INTERNATIONAL Conference on Principles of Information Technology and Applications (PITA '08) is the most general Event of the IMCSIT. PITA invites contributions presenting research results in any area of computer science or information technology, which are not covered by other Events of the IMCSIT.

Topics include but are not limited to:

- Computer systems development and maintenance
- Foundations of computer science
- System dependability
- Modeling and simulation
- Formal methods
- Software engineering
- Parallel and distributed processing
- IT applications
- E-country, E-learning
- IT Management

We are especially interested in any novel, may be controversial solutions. The interdisciplinary contributions and papers that hardly classify to typical topics of conferences are invited as well.

We would like to extend a particularly warm welcome to young researchers whose research is supported by EU, national and local grants. We are interested in papers concerning theory and applications as well as case studies of successful transfer of technology from academia to industry.

***Abstract*** **— Model driven approach for program development can assist in quick generation of complex and highly reliable applications. Framework for eXecutable UML (FXU) transforms UML models into C# source code and supports execution of the application reflecting the behavioral model. The framework consists of two parts code generator and run time library. The generated and executed code corresponds to structural model specified in class diagrams and behavioral model described by state machines of these classes. All single concepts of state machines included in the UML 2.0 specification (and further) are taken into account, including all kinds of events, states, pseudostates, submachines etc. The paper discusses the correctness issues of classes and state machine models that have to be decided in the framework in order to run a model-related and high quality C# application. The solution was tested on set of UML models.**

## I. Introduction

MODEL Driven Engineering (MDE) represents software development approaches in which creation and manipulation of models should result in building of an executable system [1].

Industrial product development puts a lot of attention on fast implementation of the needed functionalities. Model-driven approach to program development offers a promising solution to these problems. The complex behavioral models can be designed and verified at the early stages of the whole product creation cycle and automatically transformed into the code preserving the desired behavior.

State machines, also in the form of statecharts incorporated in the UML notation [2], are a widely used concept for specification of concurrent reactive systems. Proposal for execution of behavioral UML models suffers from the problem that no generally accepted formal semantics of UML models is available. Therefore, validation of UML transformation and model behavior depicted in the resulting code is difficult. Rather than completely formalizing UML models, we try to deal with selected aspects of the models.

Checking of models is important in Model Driven Architecture (MDA) approaches [3], [4] where new diagrams and code are automatically synthesized from the initial UML model: all the constructed artifacts would inherit the initial inconsistency [5].

Inconsistency and incompleteness allowed by UML can be a source of problems in software development. A basic type of design faults is concerned with the well-formedness of diagrams [2]. Typically, completeness of a design requires that introduced model elements are specified with their features and usage of one element can imply a usage of another, directly related model element. In the current modeling CASE tools some completeness conditions can be assured automatically (e.g., default names of roles in associations, attributes, operations etc.). Incompleteness of models can be to be strongly related to their inconsistency, because it is often impossible to conclude whether diagrams are inconsistent or incomplete [6]. Therefore, within this paper we will refer to model defects as to correctness issues.

The Framework for eXecutable UML (FXU) offers a foundation for applying MDA ideas in automation of software design and verification. The FXU framework was the first solution that supported generation and execution of all elements of state machine UML 2.0 using C# language [7]. In order to build an application reflecting the modeled classes and their behaviors specified by state machines, we resolved necessary semantic variation points [8]. Semantic variation points are aspects that were intentionally not determined in the specification [2] and its interpretation is left for a user.

It was also necessary to provide some correctness checking of a model. This paper is devoted to these issues. To present potential problems we selected one target application environment, i.e., creation of application in C# language. The verification of an input UML model is based on a set of hard coded rules. Some of the rules are general and can be applied for any object-oriented language, as they originate directly from the UML specification [2]. Other rules are more environmental specific because they take also into account the features of the target language - C#. The verification is performed during transformation of class and state machine models into the corresponding code; it is so-called static verification. Other set of rules is used during execution of the code corresponding to given state machines; so-called dynamic verification. For all correctness rules the appropriate reaction on the detected flaws were specified.

This work was supported by the Dean of the Department of Electronics and Information Technology, Warsaw University of Technology under grant no 503/G/1032/4300/008

In the next section we discuss the related works. Next, the FXU framework, especially solutions used for state machines realization, will be presented. In Sec. IV we introduce correctness issues identified in the transformation process and during execution of state machines. Remarks about experiments performed and the conclusions finish the paper.

## II. Related Work

A huge amount of research efforts is devoted to formalization of UML models, specification of their semantics and verification methods [9]-[13]. However they are usually not resolving the practical problems which are faced while building an executable code, because of many variation semantic points of the UML specification.

An attempt for incorporation of different variation points into one solution is presented in [14]. The authors intend to build models that specify different variants and combine them with the statechart metamodel. Different policies should be implemented for these variants.

Our work relates also to the field of consistency of UML models. The consistency problems in UML designs were extensively studied in many papers. It could be mentioned workshops co-located to the Models (former UML) series of conferences, and other works [5], [6], [15]-[17].

An interesting investigation about defects in industrial projects can be found in [18]. However the study takes into account only class diagrams, sequence diagrams and use case diagrams, mostly the relations among elements from different diagram types. The state machines were not considered.

Solutions to consistency problems in class diagrams were presented in [19]. The problem refers to constrains specifying generalization sets in class diagram, which is still not commonly used in most of UML designs.

Current UML case tools allow constructing incorrect models. They provide partial checking of selected model features, but it is not sufficient if we would like to create automatically a reliable application. More comprehensive checking can be found in the tools aimed at model analysis. For example, the OO design measurement tool SDMetrics [20] gives the rules according to which the models are checked. We used the experiences of the tool (Sec. IV), but it does not deal with state machine execution nor with C# language.

Many modeling tools have a facility of transforming the models into code in different programming languages. However, the most of them consider only class models. We compared functionality of twelve tools that could also generate code from state machines. Only few of them took into account more complex features of state machines, like choice pseudostates, deep and shallow history pseudostates, deferred events or internal transitions. The most complete support for state machines UML 2.0 is implemented in the Rhapsody tool [21] of IBM Telelogic (formerly I-Logix). However it does not consider C# language.

Different approaches to generation of the code from behavioral UML models can be used. The semantics of a state machine can be directly implemented in the generated code [22]. Another solution is usage of a kind of a run-time environment, for example a run-time library as applied in the FXU framework.

The consistency problems remain also using tools for building executable UML models [23], [24]. Different subsets of UML being used and we cannot assure that two interchanged models will behave in the same way. Specification of a common subset of UML specialized for execution is still an open idea.

## III. Code Generation and execution in FXU

Transformation of UML models into executable application can be realized in the following steps.

1. A model, created using a CASE modeling tool, is exported and saved as an XML Metadata Interchange (XMI) file.
2. The model (or its parts) is transformed by a generator that creates a corresponding code in the target programming language.
3. The generated code is modified (if necessary), compiled and linked against a Runtime Library. The Runtime Library contains realization of different UML meta-model elements, especially referring to behavioral UML models.
4. The final application, reflecting the model behavior, can be executed.

It should be noted, that steps 1) and 2) can be merged, if the considered code generator is associated with the modelling tool.

The process presented above is realized in the FXU framework [7]. The target implementation language is C#. The part of UML model taken into account comprises classes and state machines. The input models are accepted in UML2 format, an XMI variant supported by Eclipse. Therefore it is not directly associated with any modelling tool. However, all experiments mentioned in Sec. V were performed with UML models created using IBM Rational Software Architect [25].

The FXU framework consists of two components - FXU Generator and FXU Runtime Library. The Generator is responsible for realization of step 2. The FXU Runtime Library includes over forty classes that correspond to different elements of UML state machines. It implements the general rules of state machine behavior, independent of a considered model, e.g., processing of events, execution of transitions, entering and exiting states, realization of different pseudostates. It is also responsible for the runtime verification of certain features of an executed model.

Transforming class models into C# code, all model elements are implemented by appropriate C# elements. The template of a resulting programming class can be found in [7]. Principles of code generation from the class models are similar to other object-oriented languages and analogues to solutions used in other tools.

A distinctive feature of FXU is dealing with all UML state machine elements and their realization in C# application. Therefore we present selected concepts of state machines with their implementation in C#. We point out different C# specific mechanisms used in the generated application. Using selected solutions we would like to obtain an efficient and reliable application.

State machines can be used at different levels of abstraction. They can model behavior of an interface, a component, an operation. Protocol state machines are intended to model protocols. The primary application of behavioral state machine in an object-oriented model is description of a class. A class can have attributes keeping information about a current state of an object. Classes have operations that can trigger transitions, send and receive events. Therefore, we assumed that the code will be generated and further executed only for behavioral state machines that are defined for certain classes that are present in the structural model.

An exemplary UML model is shown in Fig. 1. A given class has an attribute, four operations and its behavior specified by a state machine. The state machine consists of simple state S1 and complex state S2 including two orthogonal regions. In guard conditions and triggers the operations and attribute of the class are used. Extracts of the C# code corresponding to the example and created by the FXU generator are given in the Appendix.

For any state machine of a class, a new attribute of *StateMachine* type is created. Each class having a state machine has also two additional methods *InitFXU* and *StartFXU*. Method *InitFXU* is responsible for creation and initialization of all objects corresponding to all elements of state machine(s) associated with the class, such as regions, states, pseudostates, transitions, activities, events, triggers, guards, actions, etc. Method *StartFXU* is used for launching a behavior of state machine(s).

Any state can have up to three types of internal activities *do, entry, exit.* The activities of a state are realized using a delegate mechanism of C#. Three methods *DoBody, EntryBody* and *ExitBody* with empty bodies are created for any state by default. If an activity exists a corresponding method with its body is created, using information taken from the model. Applying delegate mechanism allows defining the methods for states without using of inheritance or overloaded methods. Therefore the generated code can be simple, and generation of a class for any single state can be avoided. A state machine is not generated as a state design pattern [26], because we would like to prevent an explosion of number of classes.

Three transition kinds can be specified for a transition, *external, internal* and *local* transitions. Triggering an internal transition implies no change of a state, exit and entry activities are not invoked. If an external transition is triggered it will exit its source state (a composite one), i.e. its exit activity will be executed. A local transition is a transition within a composite state. No exit for the composite (source) state will be invoked, but the appropriate exits and entries of the substates included in the state will be executed.

A kind of a transition can be specified in a model, but in praxis this information is rarely updated and often inaccurate. Therefore we assumed that in case of composite states a kind of generated transition is determined using a following heuristics:

- If the target state is different than the source state of a transition and the source state is a composite state, the transition is external.
- Else, the transition is defined in a model as internal it is treated as an internal transition.
- Otherwise, the transition is local.

A transition can have its guard condition and actions. They are created similarly to activities in states, using delegate mechanism of C#. If a body of an appropriate guard condition or action is nonempty in a model, it is put in the generated code. It should be noted that verification of logical conditions written in C# is postponed to the compilation time.

States, pseudostates, transitions and events are created as local variables. Signals are treated in different way. They are created as classes, because they can be generalized and specialized building a signals hierarchy. If a certain signal can trigger an event also all signals that are its descendants in the signal hierarchy can trigger the same event. This feature of signals was implemented using the reflection mechanism of C# [27].

Events should have some identifiers in order to be managed. Change events and call events are identified by unique natural numbers assigned to the events. A time event is identified by a transition which can be triggered by this event. A completion event is identified by a state in which the event was generated. Finally, for a signal event the class of the signal, i.e., its type, is used as its identifier.

There are some elements of a UML model that include a description in a form not precisely specified in the standard, but dependent on a selected notation, usually a programming

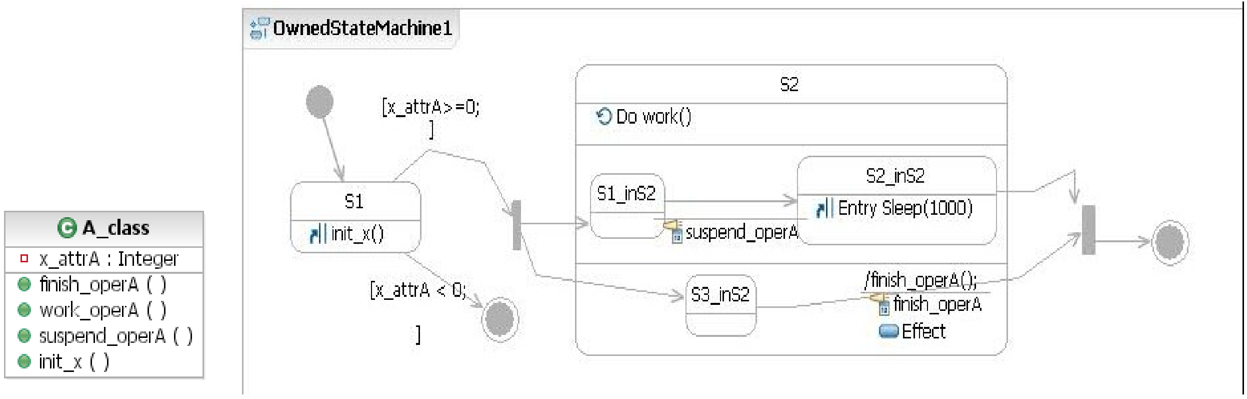

Fig. 1 Example - a class and its state machine

language. There are, for example, guard conditions, implementation of actions in transitions or in states, body of operations in classes. They can be written directly in a target implementation language (e.g., C#). During code generation these fragments are inserted into the final code. Verification of the syntax and semantics of such code extracts is performed during the code compilation and execution according to a selected programming language.

Interpreting different concepts of state machines we can use parallel execution. In the FXU RunTime Library it is implemented by multithreading. Multithreading is used for processing of many state machines which are active in the same time, e.g., state machines of different classes. It is used also for handling submachine states and orthogonal regions working within states, and for other processing of events. In the Appendix, parts of an output trace generated during execution of the exemplary state machine (Fig. 1) are shown. We can observe different threads, identified by number in brackets, that were created to deal with encountering events. For example, realization of transition from the pseudostate fork to substate S3_in S2 launched thread "[11]". Thread "[12]" was created to implement transition from the fork pseudostate to substate S1_inS2. In other execution run of the application the numbers and ordering of threads can be different.

Event processing during state machine execution is performed according to the rules given in UML specification [2]. Basic algorithms of FXU realization, like execution of a state machine, entry to a state, exit from a state, were presented in [7]. For every state a queue was implemented that pools incoming events. Events can be broadcasted or sent directly to the selected state machines. Events trigger transitions that have an active source state and their guard conditions evaluate to true. If many transitions can be fired, transition priorities are used for their selection. We had proposed and implemented an extended definition of transitions priority, in order to resolve all conflicts in case many transitions can be fired. This could not be achieved based only on the priority definition given in [2]. The detailed algorithm of selecting non-conflicting transitions can be found in [8]. Also resolving of other variation points, especially dealing with entering and exiting orthogonal states, is shown in [8].

## IV. Verification of model correctness

While generating valid C# code from UML class and state machine diagrams the certain conditions should be satisfied. There are many possible shortcomings present in the models that are not excluded by the modeling tools, or should be not prohibited due to possible model incompleteness at different evolution stages. They were analyzed taking into account the practical weaknesses of model developers.

The prepared correctness rules were based on three main sources: the specification of UML [2], the rules discussed in related works and other comparable tools, in particular in [20], and finally the own study, especially taking into account the features of C# language - the target of the model transformation [27].

Various shortcomings can be detected during different steps of application realization (Sec. 3). Many of them can be identified directly in the model, and therefore detected during model to code transformation step (step 2). Verification of such problems will be called static, as it corresponds to an automated inspection of a model. Other flaws are detected only during execution of the resulting application (step 4). Such dynamic verification will be completed by the appropriate classes of the FXU Runtime Library.

In tables I-III defects identified in classes and state machines are presented. The last column shows severity associated to the shortcomings. Three classes of severity are distinguished. If a defect detected in a model is called as *critical* the model is treated as invalid and the code generation is interrupted without producing the output. Later cases are clas-

Table I.
Defects detected in Uml class diagrams (static)

| No | Detected defects | Reaction | Severity |
|---|---|---|---|
| 1 | A generalization of an interface from a class was detected | Stop code generation | critical |
| 2 | A name of an element to be generated (e.g. a class, an interface, an operation, an attribute) is a keyword of C# language | Stop code generation | critical |
| 3 | A class relates via generalization to more than one general class | Stop code generation | critical |
| 4 | A cycle in class generalization was detected | Stop code generation | critical |
| 5 | A name of an element to be generated is missing | Generate the element pattern without its name. The element name has to be supplemented in the generated code. | medium |
| 6 | A name of an element to be generated is not a valid C# name. It is assumed that white characters are so common shortcoming that they should be automatically substituted by an underline character. | As above | medium |
| 7 | An interface visibility is *private* or *protected* . | Use *package* visibility . | low |
| 8 | A class visibility is *private* or *protected* . | Use *package* visibility . | low |
| 9 | An interface is *abstract.* | Treat the interface as no abstract. | low |
| 10 | An interface has some attributes. | Ignore attributes of the interface. | low |
| 11 | An interface has nested classes | Ignore classes nested in the interface. | low |
| 12 | A class that is no *abstract* has abstract operations. | Treat the class as *abstract*. | low |

TABLE II.
DEFECTS DETECTED IN UML STATE MACHINES (STATIC)

| No | Detected defects | Reaction | Severity |
|---|---|---|---|
| 1 | A cycle in signal generalization was detected | Stop code generation | critical |
| 2 | A signal inherits after an element that is not another signal | Stop code generation | critical |
| 3 | A signal relates via generalization to more than one general signal | Stop code generation | critical |
| 4 | A region has more than one initial pseudostate | Stop code generation | critical |
| 5 | A state has more than one deep history pseudostate or shallow history pseudostate | Stop code generation | critical |
| 6 | There are transitions from pseudostates to the same pseudostates (different than a choice pseudostate) | Stop code generation | critical |
| 7 | There are improper transitions between orthogonal regions | Stop code generation | critical |
| 8 | A transition trigger refers to an nonexistent signal | Stop code generation | critical |
| 9 | An entry point, join or initial pseudostate has no incoming transition or more than one incoming transition | Stop code generation | critical |
| 10 | A deep or shallow history pseudostate has more than one outgoing transition | Stop code generation | critical |
| 11 | A transition from an entry/exit point to an entry/exit point | Stop code generation | critical |
| 12 | An exit point has no any incoming transition | Stop code generation | critical |
| 13 | Transitions outgoing a fork pseudostate do not target states in different regions of an orthogonal states | Stop code generation | critical |
| 14 | Transitions incoming to a join pseudostate do not originate in different regions of an orthogonal state | Stop code generation | critical |
| 15 | There is a transition originating in an initial pseudostate or a deep/shallow history pseudostate and outgoing a nested orthogonal state | Stop code generation | critical |
| 16 | The region at the topmost level (region of a state machine) has no initial pseudostate | Warn a user | medium |
| 17 | A transition outgoing a pseudostate has a trigger | Ignore the trigger | medium |
| 18 | A tgransition outgoing a pseudostate (different from a choice or junction vertex) has a nonempty guard condition | Ignore the guard condition | medium |
| 19 | A transition targeting a join pseudostate has a trigger or nonempty guard condition | Ignore the trigger and/or condition | medium |
| 20 | A trigger refers to a non-existing operation | The transition will be generated but it cannot be triggered by this event | medium |
| 21 | A trigger refer to an abstract operation or to an operation of an interface | as above | medium |
| 22 | A time event is deferred | Treat the event as not being deferred | medium |
| 23 | A final state has an outgoing transition | Warn a user | medium |
| 24 | A terminate pseudostate has an outgoing transition | Warn a user | low |

sified as *medium* and *low*. In both cases the code generation is proceeded, although for *medium* severity it can require corrections before compilation. In all cases information about all detected shortcomings is delivered to a user. A detailed reaction to the found defect is described in the third column. While assigning severity levels and reactions to given defects we took into account general model correctness features but also requirements specific for C# applications.

### *A. Verification of Class Models*

Class diagrams describe a static structure of a system, therefore many their features can be verified statically before code generation. Table I summaries defects that are checked during static analysis of UML class models. It was assumed that some improvements can be added more conveniently in the generated code than in a model. The class models can be incomplete to some extend and we can still generate the code. Admission of certain model incompleteness can be practically justifiable because of model evolution.

It should be noted that not all requirements of generated code are checked by the generator. Some elements are verified later by the compiler. It concerns especially elements that are not directly defined by the UML specification, like the bodies of operations.

### *B. Verification of State Machines*

Similarly to class diagrams, different defects of state machines can be detected statically in the models. They are listed in Tab. II. Static detection of shortcomings in state machines is realized twice. First, it is made before model to source transformation (step 2). Second correctness checking is fulfilled before state machine execution. It is a part of step 4, during the initialization of the structure of a state machine.

For example, a static verification can be illustrated using a state machine from Fig. 1. Transition outgoing state *S3_inS2* has an event trigger - calling of an operation *finish_operA()*. However, this transition targets the join pseudostate. Therefore neither a trigger nor a guard condition can be associated with the transition. It violates the correctness rule 18 (Tab. II). This model flaw is quite often and is not critical. The

TABLE III.
DEFECTS DETECTED IN UML STATE MACHINES (DYNAMIC)

| No | Detected defects | Reaction | Severity |
|---|---|---|---|
| 1 | There is no enabled and no "else" transition outgoing a choice or junction pseudostate | Suspend execution - terminate | critical |
| 2 | A deep or shallow history pseudostate was entered that has no outgoing transitions and is "empty", i.e. either a final state was a last active substate or the state was not visited before | Suspend execution - terminate | critical |
| 3 | More than one transition outgoing a choice or junction pseudostate is enabled | Select one enabled transition and ignore the others | medium |
| 4 | There is no enabled transition outgoing a choice or junction pseudostate and there is one or more "else" transition outgoing this pseudostate | Select onr "else" transition and ignore other transitions | medium |
| 5 | More than one transition outgoing the same state is enabled | Select one transition and ignore the others | medium |

trigger will be omitted in the generated code and the designer will be warned about this exclusion.

State machines model system behavior; therefore not all their elements can be statically verified. A part of defects is detected dynamically, i.e., during execution of state machines. For example, a situation that two enabled transitions are outgoing the same choice pseudostate can be detected after evaluation of appropriate guard conditions, namely during program execution. Defects detected dynamically in state machines are presented in Tab. III.

## V. EXPERIMENTS

The presented approach for building the C# code and executing the automatically created applications was tested on over fifty models. The first group of ten models was aimed at classes. In experiments the correct and incorrect constructions encountering in class diagrams were checked, concerning especially association and generalization. Moreover, two bigger projects were tested. The first one was a part of MDA project called Acceleo [28]. The model described a design of a web page. The second one presented a metamodel of an object-oriented modeling language [29].

Models from the next group (above forty models) comprised different diagrams, including both classes and state machines. All possible constructs of UML 2.x state machines were used in different situations in the models. The biggest design included five state machines with about 80 states and 110 transitions, using complex and orthogonal states, different kinds of pseudostates and submachine states.

The programs realizing state machines were run taking into account different sequences of triggering events. The behavior modeled by state machines was observed and verified using detailed traces generated during program runs. They helped to test whether the obtained program behavior conforms to desired state machine semantics. For complex models, filtered traces that included selected information were also used.

The performed experiments have showed that an application realizing a behavior specified in state machine models can be developed in an effective and reliable way.

## CONCLUSION

In this paper we discussed the problems of creation of valid C# applications realizing ideas modeled by classes and their state machines. Different C# mechanisms were effectively used for implementation of the full state machine model defined in the UML 2.x specification. We showed which correctness issues of models have to be checked during model transformation (static verification) and during application execution (dynamic verification). The detailed correctness rules help a developer to cope with possible flaws present in UML models. In the difference to other tools, using FXU the state machines including any complex features can be effectively transformed into corresponding C# application. The tool support speeds up building of reliable applications including complex behavioral specifications. It can be especially useful for developing programs in which nontrivial state machines are intensely used, e.g., dependable systems, embedded reactive systems.

## APPENDIX

The appendix includes extracts of C# code generated for an exemplary class and its state machine shown in Fig. 1. Code of class operations are omitted (line 3). Method *InitFxu()* creates appropriate structure of the state machine. Method *StartFxu()* initializes behavior of the state machine.

```
1 public class A_class   {
2   private int x_attrA;
3   // operations of A_class (omitted)
4   StateMachine sm1 = new
     StateMachine("OwnedStateMachine1");
5 public void InitFxu(){
6   Region r1 = new Region("Region1");
7   sm1.AddRegion(r1);
8   InitialPseudostate v2 = new
              InitialPseudostate("");
9   r1.AddVertex(v2);
10  FinalState v3 = new FinalState("");
11  r1.AddVertex(v3);
12  State v4 = new State("S1");
13  v4.EntryBody = delegate(){ init_x();  };
14  r1.AddVertex(v4);
15  State v5 = new State("S2");
16  v5.DoBody = delegate(){ work_operA(); };
17  r1.AddVertex(v5);
18  Region r2 = new Region("Region1");
19  v5.AddRegion(r2);
20  Region r3 = new Region("Region2");
21  v5.AddRegion(r3);
22  State v6 = new State("S2_inS2");
23  v6.EntryBody = delegate()
    {System.Threading.Thread.Sleep(10000); };
24  r2.AddVertex(v6);
```

```
  State v7 = new State("S1_inS2");
  r2.AddVertex(v7);
  State v8 = new State("S3_inS2");
  r3.AddVertex(v8);
  Fork v9 = new Fork("");
  r1.AddVertex(v9);
  FinalState v10 = new FinalState("");
  r1.AddVertex(v10);
  Join v11 = new Join("");
  r1.AddVertex(v11);
  Transition t1 = new Transition(v2, v4);
  Transition t2 = new Transition(v4, v9);
  t2.GuardBody = delegate(){return x_attrA>=0;};
  Transition t3 = new Transition(v4, v10);
  t3.GuardBody = delegate(){return x_attrA<0;};
  Transition t4 = new Transition(v6, v11);
  Transition t5 = new Transition(v7, v6);
  t5.AddTrigger(new CallEvent("suspend_operA",
                                         1));
  Transition t6 = new Transition(v8, v11);
t6.AddTrigger(new CallEvent("finish_operA",
                                           2));
  t6.ActionBody = delegate(){finish_operA(); };
  Transition t7 = new Transition(v9, v8);
  Transition t8 = new Transition(v9, v7);
  Transition t9 = new Transition(v11,v3);
} //End of InitFXU
public void StartFxu()
  {   sm1.Enter(); }
}
```

Fragments of a detailed execution trace of the exemplary state machine (Fig. 1) are shown below. Time stamps of all log items are omitted for the brevity reasons. The trace was created under condition of two call events occurrences, suspend_operA() and finish_operA(). A number in brackets denotes a number of a thread that realizes a considered part of machine execution.

*Abstract*— **OLAP (Online Analysis Processing) applications have very special requirements to the underlying multidimensional data that differs significantly from other areas of application (e.g. the existence of highly structured dimensions). In addition, providing access and search among multiple, heterogeneous, distributed and autonomous data warehouses, especially web warehouses, has become one of the leading issues in data warehouse research and industry. This paper proposes a new message interface for a new platform independent data warehouse architecture that can deliver location, platform, and schema transparency for clients that access autonomous data warehouses. The new message interface uses XML in order to provide interoperable way to query and administrate federated data warehouses in addition to compose the multidimensional query result sets.**

## I. Introduction

### A. Background

SINCE its evolution XML, accompanied with its related technologies (XQuery, XPath, XSL,…etc), has been considered the main standardized technology for the data exchange over information networks [1], [2]. By the time, the XML usage has increased with many applications. Recently, XML has significantly influenced building databases [2]. XML data is generated by applications and it can be consumed by applications. It is not too hard to imagine that some data sources in the enterprise are repositories of XML data or that they are viewed as XML data independently on their inner implementation.

In this case we could try to build a new data warehouse (DW) architecture that uses XML as its base for designing the messaging interface for that new architecture. In [3] a new data warehouse architecture (that is called XWarehouse) has been introduced. This architecture proposes the idea of utilizing XML as well as other design ideas in order to be able to build a platform independent multi- federated DW. In [3] the need for XML based messaging interface that has been called `eXtensible multiDimensional XML XDXML` has been introduced. As being part of the XWarehouse architecture, XDXML purpose is to compose all request, and response messages between the XWarehouse clients and orchestration. This will gives the opportunity to establish a communication between DW clients and a DW server with no regard to the platform compatibility issues. Moreover, XDXML provides the multidimensional format needed for caching the Multi-federated DW data as well as the DW Metadata on the Warehouse orchestration server that is responsible of orchestrating the multiple federated incompatible data warehouse at the backend with the DW query requests by the XWarehouse clients. In consequence, a need for dimensional modeling of XML data is appearing through the introduction of the XDXML. This paper proposes the XML based multidimensional messaging interface (XDXML) that the proposed XWarehouse uses. The paper depicts XDXML design goals, its basic structure, its embedded support for multi dimensions, its new operators, and the active capabilities into it. This XML based interface has been implemented into a real world case study that has been already presented previously [3].

### B. Contribution

The contribution of this paper aims to propose a new Multidimensional messaging interface in order to interchange multidimensional data, schemas, queries, and other administrative commands over XWarehouse data warehouse architecture [3]. This interface will be called `eXtensible Multidimensional XML (XDXML)`. The remainder of this study is organized. Specifically; to describes the architecture by means of:

- Overview of the related research work
- The XDXML design objectives.
- The XDXML schema description.
- The XDXML active commands as well as predicates

### C. Outline

This paper is organized as follows. At the beginning this paper presents a literature review that has conducted a survey about the previous efforts that tried to tackle using XML in dimensional modeling [4], [5]. The section analyzes each of those efforts and tells what is/are the negative point(s) into each proposed effort. Afterwards, the paper presents the

This work was supported into its practical side with Johnson & Johnson – Medical Egypt

main design objectives that the XDXML tries to fulfill. Prior to that, the paper delves into the XDXML basic multidimensional schema. In order present more details about the XDXML; the paper presents part of a real life implementation that has been used in order to validate the XDXML applicability. This helps in depicting the last part of the paper that depicts the XDXML ability to not only to compose multidimensional data as well as queries but also to send some administrative commands too.

### *D.Literature Review*

The study has made a reviews for finding out the research efforts that has tackled the same problem domain, or part of it. For the time being, and as to the researcher knowledge, only few research efforts have been done regarding utilizing the XML [6], [7] in creating an architectural foundation for storing, administrating, and integrating data warehouse data (i.e. multidimensional data).

#### *1)The Common Warehouse Metamodel (CWM)*

The CWM is an Object Management Group (OMG) initiative. Its version 1.0 has been released in Feb. 2001. Through the CWM specifications[7], [8], OMG is targeting the creation of standard format for data warehouse Metadata based on a foundation Metamodel [4]. Based on the UML, CWM builds a complex model for describing data warehouse Metadata. The main goal of its specification is to create a standard interface to data warehouses that every vendor tool can access, e.g. OLAP tools [5], ETL tools etc. [8], [9], The specification concentrate on building a standard between vendor tools for data warehouse interchange based on certain XML format [9]. The data warehouse multidimensional data interchange is out of scope of this specification. The CWM XML package only contains XML based definitions for classes and associations that represent common data warehouse Metadata. Based on this, the CWM just targets to bridge the gaps between data warehouse tools in order to be able to work together but, it doesn't provide message interface for exchanging and querying data in an open environment [8] ,[10],[11], [12]. By other words, CWM is a data interchange format more than being a multidimensional message interface that includes action commands to take remote actions. This is left for the application level not the CWM itself.

#### *2) MetaCube-X XML Metadata Foundation*

The MetaCube-X is an XML instance of the Metacube concept, [11], [12]. While MetaCube is a conceptual multidimensional data model that some vendors are currently using (e.g. Informix, and Microstrategy), MetaCube-X seeks providing the user with a query mechanism for accessing information on the different web warehouses. This concept of MetaCube-X concentrate on defining an XML based schema for querying multidimensional data from different web warehouses [11]. Based on this MetaCube-X only concentrates on Metadata and doesn't take care of the data itself (the fact data as well as the dimensions)[6]. Moreover, when proposing the data MetaCube-X proposes it tightly coupled with its Metadata. By other words, it doesn't make separation between schema and the multi-dimensional data. The MetaCube-X whole contribution is only targeting querying activities. Similarly to CWM it doesn't utilize the web services technology to provide access to remote web warehouse, and OLAP systems. Finally it doesn't support a specific architecture to implement its model as a complete solution.

#### *3) XML for Analysis (XMLA)*

XMLA is an initiative that has been co-sponsored by Microsoft and Hyperion (SAS has joint them in April 2002). Its version 1.0 specification has been released in April 2001 [13], [14], [15]. This specification utilizes the popularity of web services in providing data warehouse users with SOAP and XML based access to remote OLAP systems. While proposing an appropriate architecture, XMLA is concerned with how to query multidimensional data as well as Metadata through the use of the md/XML interface [13]. By other words, XMLA along with md/XML is designed to retrieving data not for manipulating and recapitulating cubes [13][14],. Moreover, XMLA doesn't support querying the galaxy schema for data retrieval

#### *4) XCube*

XCube is a family of XML based document templates that aim to exchange data warehouse data (i.e. data cubes) over any kind of networks [17]. In spite of releasing a way to exchange data as well as format, XCube schema is dedicated for the purpose of querying the web warehouse data , not any other purpose (i.e. exploring cube facts and dimensions, and managing a web warehouse) [18]. Not only that but also, the XCube schema is complicated to the extent that it is hard to be processed. This means that it doesn't support multiple Hierarchies dimensions. Within the schema description there is no distinction between the dimension itself and its dimensional hierarchies. XCube main target is to supply a standard format for exchanging data warehouse data, not a complete architectural solution for managing, querying, and exchanging data. There is no support for utilizing XSD for Schema validation or XSLT for presentation layer flexibility. There is no concrete definition for an architecture that defines how to deploy this format, or where its parsers will be deployed. Subsequently, XCube doesn't discuss how could be a level of integration between federated data warehouses, or web warehouses. Finally, it is not concerned with granting a high level of access to the data warehouses through something like Thin OLAP (ThOLAP) that X-Warehouse.

#### *5) INRIA's GEMO Project*

GEMO is a three-years project that has been born from the merging of INRIA (Institut National De Rechercha En Informatique Et En Automatique). With Members of another multinational research group. This project depends heavily on the usage of XML related technologies in order to insure data exchange as well as management. One of the main application domains for this project is the data for data warehouses. The Gemo 2006 activity report that has been published by INRIA doesn't talk about tackling the idea of the integration between federated data warehouses [19]. In order to promote their project foundation, the members of INRIA has contributed in releasing many publications regarding there diversified research points.

#### *6) Concluding Remarks*

These are all the known scientific contributions regarding the study research point. As has been clarified each one of the five contributions has some weak points that is fulfilled in this paper's contribution. Based on the above review it could be seen that none of the depicted efforts has proposed a complete architecture that enables platform independent data warehouse architecture that can enable integrating multi-federated data warehouses together which could be accessed transparently. While not supported by some of the efforts depicted above, XDXML proposes this through its architecture (XWarehouse). In addition to that, XDXML supports querying Galaxy schema. Moreover, XDXML supports making remote actions over the remote cubes.

## II. XDXML Design Goals

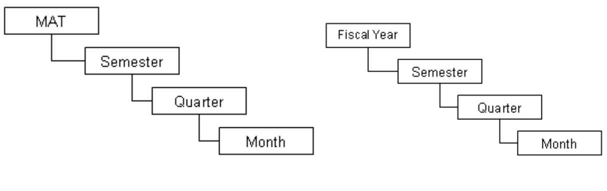
The XDXML format has been designed according to certain objectives. These objectives target functional as well as nonfunctional requirements. At the following are the main five design objectives that based on them the XDXML XML based Multidimensional Message Interface has been designed.

### *A. Minimizing Size*

At the core of the XDXML, the well formed XML resides. The main nature of any well formed XML document is that it is being constructed hierarchal. The hierarchal structure in turn imposes a larger size than other ways of composing documents (e.g. relational). According to that the XDXML should try to minimize the redundancies that may appear into the single document without scarifying any required functional requirement. Minimizing the size of the XDXML data and commands can enhance the performance of sending requests and receiving responses to and from the X-Warehouse server. In addition to that it can minimize the time needed to parse

### *B. Supporting Multiple Hierarchies*

In multidimensional design any cube can support multiple hierarchies [20], [21], [22]. This helps when same fact data is needed to get navigated with specific dimension according to multiple hierarchal points of view. As an example for that, for a pharmaceutical company they need to track the net sold amounts (after calculating all type of discounts) according to the time dimension. They have multiple time hierarchies Fig. 1 a, and b.



(a) Time Hierarchy 1 (b) Time Hierarchy 2

Fig. 1a: Time Dimension Hierarchy 1

The first hierarchy is concerned with dynamic periods. People at the pharmaceutical company have the need to track the sales values over the last 12 months (Moving Annual Time- MAT). This period is divided into two semesters (6 months). Each semester in turn is divided into 2 quarters (3 months) for each (see Fig. 1a). At the same time, people need to navigate the data for the current fiscal year, semester, and quarters. This brings up the second hierarchy (see Figure 1b). Incentives at the pharmaceutical companies are calculated based on each quarter sales and performance. Most of the work that has been proposed previously in this research field neglects delivering a schema that supports multiple hierarchies for the same dimension. This put them in a bad corner when it comes to the real implementation practices [18], [11].XDXML should deliver a multi-hierarchal dimension support.

### *C. Supporting Actions Declaration*

The XDXML doesn't target only the regular decision makers. By other words it doesn't only provide DW reports and queries requests and responses but, it targets supporting DW administrators too. That is why the Proposed X-Warehouse XDXML format supports two action commands that could be sent by administrators and other querying users to perform certain actions on the server. These commands are *Act* and *Get*

### *D. Supporting New Dimensional Operators*

XDXML should propose new dimensional operators. The new operators should deliver better querying capabilities. The new operators should help to get only data that is really needed.

### *E. Supporting Galaxy Schema*

The multi-fact cubes are not regular cubes but, sometimes the business needs impose having it. This may happen when extending the data warehouse schema with new measures that changes the core approach that the business work on. At this time, it is highly recommended to overcome the problems that may arise at this time. Moreover, the multi fact cube could be beneficial when targeting to build the data warehouse according to the Ralph Kimball's Bus architecture [21], [22]. Multi-Fact cube creates a multi-star schema that is called Galaxy Schema, or Fact Constellation schema [23]. In Galaxy Schema same dimensions are utilized by more than one fact table. XDXML X-Warehouse messaging interface should support the Galaxy Schema that is not supported into any of the previous work [24].

## III. The XDXML Schema

In order to fulfill the previous design objectives XDXML differentiates between the schema and the data itself. The schema could be explained separately through an XSD based file then the XDXML data comes accompanied with. At the following is an explanation of the XDXML schema, and how the data will get composed to.

### *A. The XDXML Cube*

The XDXML Cube is the key component of the XDXML schema. The cube is the container of the rest of the multidimensional data that will be gotten from the server. For better network performance, the XWarehouse architecture implements the idea of Cubes Client-Side Cashing

`(3Cs)` [3]. The 3Cs feature imposes transferring data into cube format not a report format. This can minimize the size of data transferred which fulfils the first design objective for the XDXML protocol which is Minimizing. Moreover, transferring the requested data as facts and dimensions can give the user more flexibility to make some slicing and dicing operations while not being connected to the server. According to that the *XDXML Cube* consists of *XDXML Facts,* and one or more *XDXML Dimensions.* Fig. 2 shows the main structure of the XDXML Cube.

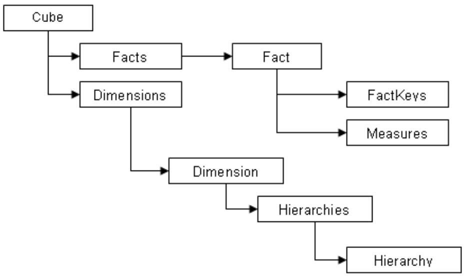


Fig. 2 The XDXML Cube main structural schema

As it is depicted each cube consists of one or many fact as well as one or many dimensions. As has been stated above the first design objective for the XDXML which is Minimizing Size has been fulfilled by transferring the multidimensional data not as cells but as facts and dimensions. This doesn't not only minimize the size of data received from the server but also, gives the flexibility to process the data on the client while being disconnect off the server. It is important to note here that each XDXML Cube node has an attribute called name for the cube name.

Fig. 3 Depicts the XDXML schema elements as classes using the UML based Class diagram.

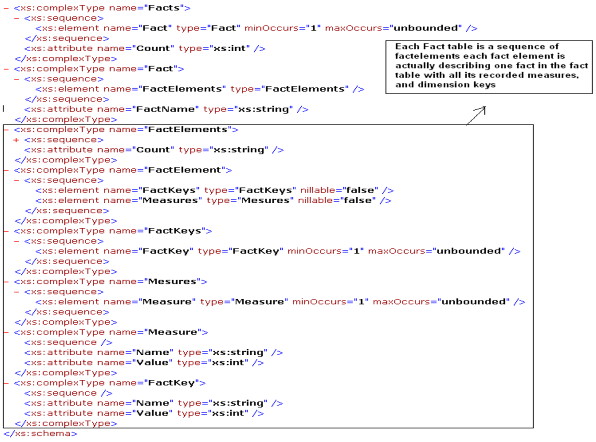
Fig. 4 the XDXML Cube Schema

### *B. The XDXML Fact*

`XDXML Fact` is the heart of the cube. At most cases, cubes have just one fact table but, at some case their maybe more than one fact table. This happens in what is called galaxy schema. XDXML format supports both cases. Based on that XDXML schema may contain one or many cubes within the `XDXML Facts`. The `Facts` contains the sequence of `XDXML Fact`. Each Fact represents a fact table. Actually, this fulfils the fifth design objective for the XDXML protocol which is; Supporting Galaxy Schema. Each Fact consists of an attribute `FactName` and a Collection of `FactElements`. This is a of sequence of `FactElement` that represent one fact along with its measures and keys. That is why, each `FactElement` consists of two children elements; `Measures` element, and `Factkeys` element. The `Factkeys` element contains inside it all XDXML `FactKey` nodes. Each FactKey element node describes one of the FactKeys that connect the facts to their related dimensions. Each `FactKey` has two describing attributes. The `Measures` element contains a sequence of `Measure` nodes. Each Measure element has two attributes. Fig. 5 shows a fragment of the XDXML Cube schema that describes the XDXML Fact.



```
- <xs:complexType name="Facts">
  - <xs:sequence>
      <xs:element name="Fact" type="Fact" minOccurs="1" maxOccurs="unbounded" />
    </xs:sequence>
    <xs:attribute name="Count" type="xs:int" />
  </xs:complexType>
- <xs:complexType name="Fact">
  - <xs:sequence>
      <xs:element name="FactElements" type="FactElements" />
    </xs:sequence>
    <xs:attribute name="FactName" type="xs:string" />
  </xs:complexType>
- <xs:complexType name="FactElements">
  + <xs:sequence>
    <xs:attribute name="Count" type="xs:string" />
  </xs:complexType>
- <xs:complexType name="FactElement">
  - <xs:sequence>
      <xs:element name="FactKeys" type="FactKeys" nillable="false" />
      <xs:element name="Measures" type="Mesures" nillable="false" />
    </xs:sequence>
  </xs:complexType>
- <xs:complexType name="FactKeys">
  - <xs:sequence>
      <xs:element name="FactKey" type="FactKey" minOccurs="1" maxOccurs="unbounded" />
    </xs:sequence>
  </xs:complexType>
- <xs:complexType name="Mesures">
  - <xs:sequence>
      <xs:element name="Measure" type="Measure" minOccurs="1" maxOccurs="unbounded" />
    </xs:sequence>
  </xs:complexType>
- <xs:complexType name="Measure">
    <xs:sequence />
    <xs:attribute name="Name" type="xs:string" />
    <xs:attribute name="Value" type="xs:int" />
  </xs:complexType>
- <xs:complexType name="FactKey">
    <xs:sequence />
    <xs:attribute name="Name" type="xs:string" />
    <xs:attribute name="Value" type="xs:int" />
  </xs:complexType>
</xs:schema>
```

Each Fact table is a sequence of factelements each fact element is actually describing one fact in the fact table with all its recorded measures, and dimension keys

Figure 5: The XDXML Fact Schema

### *C. The XDXML Dimension*

The Dimension element has a count attribute. This helps in defining explicitly how many dimensions is contained into any XDXML document that can enhance the parsing algorithm performance. Each XDXML Dimension element describes one dimension table. The Dimension element has two children, and three attributes. The first Attributes is the Name attribute (This attributes is not presented into figure 6 because of the space limitation), the second, and third attributes are attributes for declaring the Dimension Key, and the Application Key. These are DimensionKeyAttributeID, and ApplicationKeyAttributeID attributes respectively.

The first child is the `Attributes` element of `Attributes` type. The Attributes type is a sequence of XDXML Attribute element that compose up the dimension table. Each `Attribute` element usage purpose is depicted into a XML attribute called Description describing what this is used for. In addition to that each attributes has four describing nodes. The `Name` node element states the attribute name. The `Value` node contains the attribute value. The `AttributeID` node grants each attribute an integer id. This ID helps in referring to each attribute for many purposes that will appear later. Using integer ID instead of the string attribute id (attribute name) to refer for the XDXML attribute can enhance the parsing performance as well as minimizing the XDXML size. It is important here to state that the Dimension Key as well as the Dimension Application Key [21], [22] are included as two XML attribute elements. The values of these two attributes refer to the values of the AttributeID element node value within the two XDXML Attributes that act as Dimension ID and Application ID. The fourth attribute is The `Default Parent` node element is the AttributeID of the upper level for each attribute in the default hierarchy. Fig. 6 shows the XDXML Dimension Schema. The second child for *the XDXML Dimension* element node is the Hierarchies of a Hierarchies type. The Hierarchies Type contains a sequence of *XDXML Hierarchy* element nodes.

### *D. The XDXML Hierarchy*

The `XDXML Hierarchy` is no more than a definition for how data will get organized. It has no more user data than that already exists into the dimension attributes. Instead, it organizes the existing attributes by specific organization only into certain granularity levels. According to that, the `XDXML Hierarchy` is a part of the `XDXML Dimension` (see Fig. 6). As it is apparent at the figure, the XDXML Hierarchy schema contains one direct child node; the `Levels` element node of Levels type. In turn, the Levels element is a sequence of Level element nodes type. Each Level element node has one attribute that describe the Level number of each level in the hierarchy. The description of the attribute that resides at each level comes for two element nodes; the AttributeID and the ParentAttributeID that contains the AttributeID value for the attribute above it in the Hierarchy. This approach of describing the multi-hierarchal schema in the XDXML schema makes it distinctive of the other related work that talked about the multi-hierarchal schema because; it makes the Multi-hierarchal description on the schema itself not on the data, as others do [7],[9], [11], [18],. Again, this can minimize the size aggressively. The XDXML Hierarchy Schema fulfills the second design objective for that XDXML that has been stated above which is: *Supporting Multiple Hierarchies.*

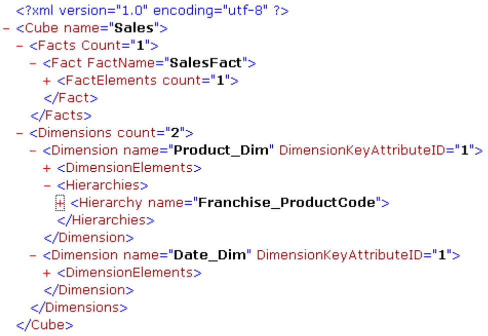
## IV. Applying the XDXML Schema on a Real Multidimensional Data

In order to validate this architecture, a case study has been conducted in one of the Medical equipment multinational companies in Egypt (Johnson & Johnson-J&J- medical Egypt), the architectural components have been belt using .NET C# code and then got deployed. The company hosts two data marts. The first one is the In Market Sales data marts (this includes facts about selling the devices and items from the distributor to the end-user) that keep the sales team distribution, Sales budgets and sales actual achievements. This data mart is about 2.54 GB in size. The Financial data mart is a 3.2 GB data mart that is hosted on an AS/400 server that is located on Europe (this includes the financial facts as well as the facts of sales between the company and distributors). This data mart is related to the internal sales between the Egyptian subsidiary and the EMEA headquarter. Previously all strategic planning used to be done on the numbers of the To Market sales. According to some deficiencies that has been discovered during the last two years, the corporate has changed its global strategy to make both the To-market Sales, and the In-Market Sales equally important. Based on this, new measures have been emerged based on the new interest of having the ability to process the internal To-Market sales(J&J/ Distributor) along with the In-Market Sales(distributor/end customer) . That is why a new need has been emerged to navigate to both of measurements together. All used examples below are extracted out of this case study as a try to highlight practical examples for using the

XDXML in exchanging a subset of a multidimensional data of a multinational medical company. This multinational medical company is specialized in producing and selling the medical materials (bondage, medical threads, plasters…). Fig. 7 depicts an overview of the multidimensional data that is retrieved from the orchestration server of this company. As it is clear from the figure, the cube is composed of one Fact called *SalesFact* and two dimension elements. The first one is the *Product_Dim* dimension while the second is the *Date_Dim*.

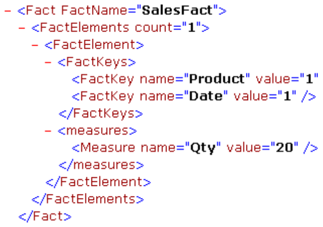


```
  <?xml version="1.0" encoding="utf-8" ?>
- <Cube name="Sales">
  - <Facts Count="1">
    - <Fact FactName="SalesFact">
      + <FactElements count="1">
      </Fact>
    </Facts>
  - <Dimensions count="2">
    - <Dimension name="Product_Dim" DimensionKeyAttributeID="1">
      + <DimensionElements>
      - <Hierarchies>
        + <Hierarchy name="Franchise_ProductCode">
        </Hierarchies>
      </Dimension>
    - <Dimension name="Date_Dim" DimensionKeyAttributeID="1">
      + <DimensionElements>
      </Dimension>
    </Dimensions>
  </Cube>
```

Fig. 7 Practical Example for a XDXML Cube

### *A. The SalesFact XDXML Fact*

For the sake of simplicity this fact has only one measure which is the *Qty*. Actually this depicts the quantity sold from the referred product at the referred time. These three pieces of data compose all together one fact that is recorded as one `FactElement`. Fig. 8 depicts the `SalesFact` XDXML fact. As it is opposed, This XDXML fact has just one fact element (this done to simplify the example) The fact element shows up that this XDXML has two keys that refer to two dimensions (remember that the cube has two dimensions that are referred to by these two keys). The first `FactKey` is the *Product* key that refers to the dimension key number 1 in the `Product_Dim` dimension. The second key is the Date key that refers to the dimension key number 1 in the *Date* dimension.

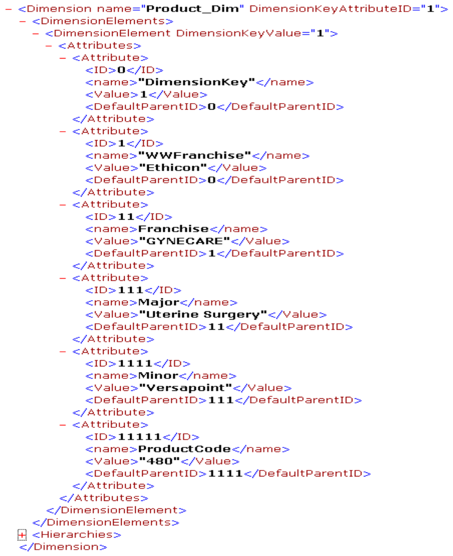


```
- <Fact FactName="SalesFact">
  - <FactElements count="1">
    - <FactElement>
      - <FactKeys>
          <FactKey name="Product" value="1" />
          <FactKey name="Date" value="1" />
        </FactKeys>
      - <measures>
          <Measure name="Qty" value="20" />
        </measures>
      </FactElement>
    </FactElements>
  </Fact>
```

Figure 8 The *SalesFact* XDXML Fact

### *B. Product_Dim XDXML Dimension*

Fig. 9 depicts the Product_Dim XDXML dimension. As it is apparent from the figure, this dimension has one default hierarchy and another defined hierarchy. For the sake of simplicity just one dimension element has been defined here. As it is clear from the figure the only dimension element available has a dimension key with value 1. This is the same value for the fact key at the SalesFact XDXML fact. It is important here to highlight that the DefaultParentID element is used to represent the default hierarchy.



```
- <Dimension name="Product_Dim" DimensionKeyAttributeID="1">
  - <DimensionElements>
    - <DimensionElement DimensionKeyValue="1">
      - <Attributes>
        - <Attribute>
            <ID>0</ID>
            <name>"DimensionKey"</name>
            <Value>1</Value>
            <DefaultParentID>0</DefaultParentID>
          </Attribute>
        - <Attribute>
            <ID>1</ID>
            <name>"WWFranchise"</name>
            <Value>"Ethicon"</Value>
            <DefaultParentID>0</DefaultParentID>
          </Attribute>
        - <Attribute>
            <ID>11</ID>
            <name>Franchise</name>
            <Value>"GYNECARE"</Value>
            <DefaultParentID>1</DefaultParentID>
          </Attribute>
        - <Attribute>
            <ID>111</ID>
            <name>Major</name>
            <Value>"Uterine Surgery"</Value>
            <DefaultParentID>11</DefaultParentID>
          </Attribute>
        - <Attribute>
            <ID>1111</ID>
            <name>Minor</name>
            <Value>"Versapoint"</Value>
            <DefaultParentID>111</DefaultParentID>
          </Attribute>
        - <Attribute>
            <ID>11111</ID>
            <name>ProductCode</name>
            <Value>"480"</Value>
            <DefaultParentID>1111</DefaultParentID>
          </Attribute>
        </Attributes>
      </DimensionElement>
    </DimensionElements>
  + <Hierarchies>
  </Dimension>
```

Fig. 9 The Product_Dim XDXML Dimension

## V. Establishing Actions Using XDMQueries

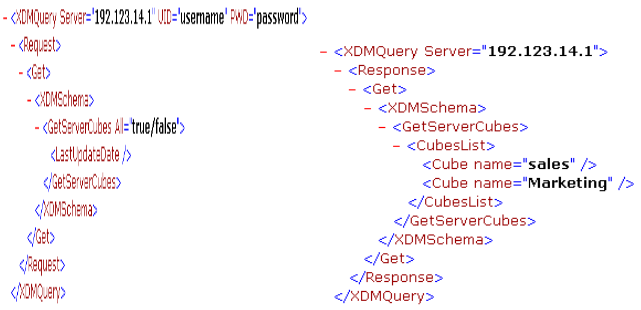
The third XDXML design objective imposes Supporting Actions Declaration. In order to fulfill this objective XDXML has introduced a way to query and administer the XWarehouse. This is done through `XDMQueries`**.** Actually, XDMQuery is part of the XDXML. This type of queries is sent within a XDMQuery XDXML node that can include *Get* and/or *Act* statements. The Get statement is primarily concerned with querying data and schemas, while the Act statement is concerned with performing some administrative actions on the remote cubes. Each query is sent within a request. The request may contain *Get* or *Act* statements. The answer is received within a XDMQuery Response tag.

### *A. The XDMQuery Get Statement*

Using the `XDMQuery` Get command it is possible to explore data as well as schema. This is done through sending an XDMQuery Request and receiving the response using the XDXML protocol for the schema or/and the data. Get statement works by using some XDMQuery predicates. The first predicate is <GetServerCubes>. If the request is containing a query with a response containing a schema(Metadata) then the statement should contain the predicates inside a `XDMSchema` tag. If the query needs to respond by data, not a schema then, the query predicates should be contained inside a `XDMData` tag. As depicted as Fig.10 the `XDMSchema` and `XDMData` tags are containing the predicates. This helps in containing multiple predicates at the same request some to receive data and others to receive Metadata.

#### *1) GetServerCubes Predicate(Schema only)*

Fig.10 depicts the first XDMQuery Get statement predicate; the `GetServerCubes` predicate. This predicate is responsible of acquiring the server cubes available at specific server. This could be unlimited to all available cubes on the server or limited to the cubes last updated at specific time.



```
- <XDMQuery Server="192.123.14.1" UID="username" PWD="password">
  - <Request>
    - <Get>
      - <XDMSchema>
        - <GetServerCubes All="true/false">
            <LastUpdateDate />
          </GetServerCubes>
        </XDMSchema>
      </Get>
    </Request>
  </XDMQuery>
```

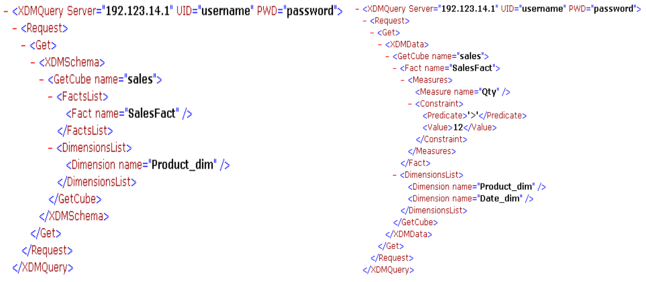
```
- <XDMQuery Server="192.123.14.1">
  - <Response>
    - <Get>
      - <XDMSchema>
        - <GetServerCubes>
          - <CubesList>
              <Cube name="sales" />
              <Cube name="Marketing" />
            </CubesList>
          </GetServerCubes>
        </XDMSchema>
      </Get>
    </Response>
  </XDMQuery>
```

(a) GetServerCubes Predicate Query (b) Query Response

Fig. 10 The GetServerCubes Request and Response in Get Statement

### 2) GetCube Predicate(Schema and data)

This predicate targets querying both; part of the specific cube data and/or its Metadata. As explained before, in order to define whether you need the schema for the required query or the Metadata you Should use either the XDMSchema or the XDMData tags. Fig. 11(a) shows how to use the GetCube predicate within the Get Statement in order to query the Cube Metadata. Fig. 11(b) shows an Example for the GetCube predicate when is used to retrieve data. If nothing else has been specified, the default is to return the data with the most granular dimensional level. The example that is depicted below doesn't mention any granularity levels for the Product_Dim dimension. If nothing else has been mentioned, the default hierarchy is retrieved, and the most granular level is used. If nothing else has been specified, the default is to return the data with the most granular dimensional level. The example that is depicted above doesn't mention any granularity levels for the Product_Dim dimension. If nothing else has been mentioned, the default hierarchy is retrieved, and the most granular level is used.



```
- <XDMQuery Server="192.123.14.1" UID="username" PWD="password">
  - <Request>
    - <Get>
      - <XDMSchema>
        - <GetCube name="sales">
          - <FactsList>
              <Fact name="SalesFact" />
            </FactsList>
          - <DimensionsList>
              <Dimension name="Product_dim" />
            </DimensionsList>
          </GetCube>
        </XDMSchema>
      </Get>
    </Request>
  </XDMQuery>
```

```
- <XDMQuery Server="192.123.14.1" UID="username" PWD="password">
  - <Request>
    - <Get>
      - <XDMData>
        - <GetCube name="sales">
          - <Fact name="SalesFact">
            - <Measures>
                <Measure name="Qty" />
              - <Constraint>
                  <Predicate>'>'</Predicate>
                  <Value>12</Value>
                </Constraint>
              </Measures>
            </Fact>
          - <DimensionsList>
              <Dimension name="Product_dim" />
              <Dimension name="Date_dim" />
            </DimensionsList>
          </GetCube>
        </XDMData>
      </Get>
    </Request>
  </XDMQuery>
```

(a)Retrieving Schema (b) Retrieving Data

Figure 11 GetCube Predicate Request

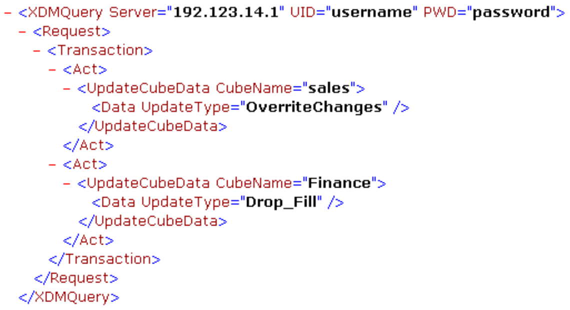
### B. The XDMQuery Act Statement

The *Act* is primarily directed to the administrators. By using the `Act` statement, it is possible to take action over existing cubes. One of the most important activities that the administrator may need to accomplish is to update his cubes. The `UpdateCubeData` is a predicate that could be used in order to initiate this task by the administrator remotely. For the time and resources limitation, this study presents only this predicate with the `Act` statement. More predicates could be provided for both the `Get` and the `Act` statements during future work.

Fig.12 depicts an example for the Act statement with the UpdateCubeData operator. As it is clear from the figure, the Act statement is enclosed inside a transaction. This to tell that all the statements contained inside the transaction elements are in just one transaction. The XDMQuery transaction can contain Act as well as Get statements. Enclosing Get statement inside a Transaction maybe helpful because that the XDMQuery may work in asynchronous mode. Based on this enclosing the Get statement inside a transaction will be a declaration that all enclosed statements will work as one batch. If one fails all will fail too. The Transaction purpose is clearer in Act statement. If one fails all actions taken on the cubes will rollback.

The *UpdateCubeData* predicate has one attribute to define the cube name. In addition to that it has one child element to define how data will be updated inside the cube. Whether data will be completely deleted and added again, or just the modified data will be overwritten. The former could be used if the cube data has changed massively at the base data warehouse since last update while, the later could be useful if there is no massive change in the data warehouse data.

Separating the update of each cube in separate Act statement rather than having Cubes child element will give the opportunity to make one cube got updated when others fail to perform their updates. If *All or Nothing* is needed it is possible to use the *XDMQuery Transaction* processing is needed. It is important the mention here that the cube updating alternative is supported if on ly the server side cubes management system supports this feature otherwise; the default cube updating method will take place.



```
- <XDMQuery Server="192.123.14.1" UID="username" PWD="password">
  - <Request>
    - <Transaction>
      - <Act>
        - <UpdateCubeData CubeName="sales">
            <Data UpdateType="OverriteChanges" />
          </UpdateCubeData>
        </Act>
      - <Act>
        - <UpdateCubeData CubeName="Finance">
            <Data UpdateType="Drop_Fill" />
          </UpdateCubeData>
        </Act>
      </Transaction>
    </Request>
  </XDMQuery>
```

Fig. 12 a Sample for the XDMQuery Act Statement

### C. Presenting the Pump-Up and Dump-down new Multidimensional Operators for Get command

The *XDQuery* supports two new operators for better multidimensional querying. These operators are directed to minimize the hierarchy declarations. Using these operators, the user can ask for a retrieving the data based on certain schema but without having all its intermediate levels. As an example for this, the hierarchy shown in figure 10(a) is depicting the default dimension hierarchy which is; WWFranchise/Franchise/Major/Minor/ProductCode. The question her is, what if the decision maker needs to retrieve the data according to the following Hierarchy; WWFranchise/Franchise/ProductCode? In order to fulfill this requirement, it is needed to define a new hierarchy with this structure. The new XDQuery operators help at this case. The `DumpDown` operator is responsible of aggregating data to one of the indirect parent of specific level. This means that when using the `PumpUp` operator, the query should define the most granular level and which parent level is direct aggregating the data. By other words using the DumpDown and PumpUp operators, the same required results could be gotten but DumpDown will retrieve some extra data that are not retrieved by PumpUp operator. This is means that using the same facts/dimensions/ level names Dump-Down data set is s upper se t of the PumpUp data set. The other difference is the hierarchy level that is used to refer to the data; whether it is an upper level or lower one. Figure 13 shows a sample hierarchy of the case study in subject of this study. This hierarchy is based on the same data of the previous figures.

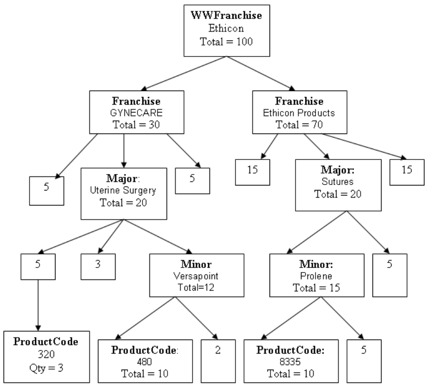


Fig. 13 Sample Data Hierarchy for the XDXML Cube Presented in figure 7 and all its subsequent figures

### *1) The Pump-Up XDMQuery Operator*

Fig.14 depicts syntax for using the PumpUp operator. The *Get* is the *XDMQuery's Get statement*. *With* is a reserved word for defining specific dimensions. *For* is another reserved word for defining specific value for the required hierarchy level.

***Get*** Sales**:** SalesFact(Qty)
***With** Product-Dim*
**On** ProductCode ***PumpUp*** Franchise
***For*** ProductCode = 8335

Fig 14 an example for Using PumpUp XDQuery Operator

According to figure 15, the result for this query will be as depicted in figure 16 but using XDXML. Figure 17 shows the same result but in XDXML The importance of using DumpDown and DumpUp operators comes from the fact that they minimize the amount of data that could be retrieved because it gives the ability to omit the unwanted intermediate levels of dimensional levels

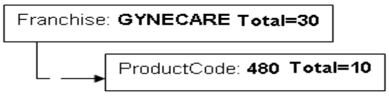

Fig. 15 Block Diagram for the Result of Query Shown in Fig.14

      - <FactElements count="1">
        - <FactElement>
          - <FactKeys>
              <FactKey name="Product" value="1" />
            </FactKeys>
          - <measures>
              <Measure name="Qty" value="10" />
            </measures>
          </FactElement>
        </FactElements>
      </Fact>
    </Facts>
  - <Dimensions count="1">
    - <Dimension name="Product_Dim" DimensionKeyAttributeID="1">
      - <DimensionElements>
        - <DimensionElement DimensionKeyValue="1">
          - <Attributes>
            - <Attribute>
                <ID>11</ID>
                <name>Franchise</name>
                <Value>"GYNECARE"</Value>
                <AggregateValue>30</AggregateValue>
                <DefaultParentID>-1</DefaultParentID>
              </Attribute>
            - <Attribute>
                <ID>11111</ID>
                <name>ProductCode</name>
                <Value>"480"</Value>
                <DefaultParentID>11</DefaultParentID>
              </Attribute>
            </Attributes>
          </DimensionElement>
        </DimensionElements>
      </Dimension>
    </Dimensions>
  </Cube>
```

Fig 16 The XDXML Cube of the Get Statement at Fig 15

### *2) Dump-Down XDMQuery Format*

Fig. 17 shows the *DumpDown* operator. As presented, the *DumpDown* operator is a way that can be used to omit a lot of unneeded data. Fig.17 expresses that the user needs only to get the Qty Measure that is inside the SalesFact using the Franchise Level and its children up to the Product Code directly at the Product_Dim dimension. The result for this query is depicted in Fig. 18. As it is clear the main difference between *DumpDown* and *PumpUp* operators is that, *PumpUp* operator is used to get certain upper level data along with its all children at the dimensional hierarchy, while the *PumpUp* operator retrieves certain measurement value according to its value for certain leaf node value at specific hierarchy along with its defined parent at certain level. According to that, *DumpDown* will most probably returns amount of data that is larger in size of that returned by the PumpUp if same level names have been used at both statements.

***Get*** Sales: SalesFact(Qty)
***With Product-Dim***
***On*** Franchise ***DumpDown*** ProductCode
***For*** Franchise = GYNECARE

## VI. Future Work and Conclusion

### A. Future Work

This scientific work could be extended at the future by many ways. The following are just some examples of the potential future work:

-Designing more predicates for the existing Get and Act commands. These predicates could be related to more administrative tasks (e.g. building and dropping cubes)

-Taking in considerations the security aspect of XDXML as this paper doesn't discuss that aspect.

-Implementing optimized parsing algorithm for parsing XDXML at the XWarehouse client-side as well as service-side.

-Extending XDMQuery in order to be able to query available mining models.

-Extending XDXML to include querying data mining models [23].

### B. Conclusion

This work presented a message Interface for exchanging data as well as commands over the XWarehouse Architecture [19] using XML as well as its related technologies (e.g. XSD, XSLT,…). The XWarehouse architecture is a newly proposed data warehousing architecture that uses Web Warehousing infrastructure for building better platform independent and more integrated and accessible data warehouses. Web warehousing refers to whether the use of the power of web infrastructure in architecting data warehouses, or the use of data warehouse techniques into keeping historical data about the click stream backlog [22]. In the case of XWarehouse first meaning is the intended and meant.

The paper used the XML technology as the base for building up the XDXML. XDXML used inside XWarehouse to get used by clients and servers for exchanging their data, schemas, and query as well as administrative commands. This paper is not concerned with the security details of the XDXML. XWarehouse uses http and SOA (Service Oriented Architecture) in order to build interoperable, vendor neutral data warehouse architecture that can enable clients as well as servers that depends on different platforms, DWMS (Data Warehouse Management Systems), and Operating systems to interoperate together transparently from the client. Moreover X-Warehouse architecture provides a way in order to integrate multi-federated data warehouse to act transparently as one logical data warehouse in front of the X-Warehouse clients.

This research has introduced the XDXML by providing a review for the related work that used XML for encapsulating data warehouse data and queries. Moreover, this paper tried to unveil the weak points for each effort that XDXML tries to overcome [23]. Moreover, the paper clarified what is the major design objectives that has been build based on. Presenting the design objectives has illustrated how does XDXML overcomes all the depicted weak points at the related research efforts surveyed. Prior to that, the paper began to delve into the detailed design of the XDXML by explain the key constructing components of the XDXML data schema. This paper has used the same case study at which the XWarehouse has been implemented in order to apply the XDXML. Part of the sample data of this case study has been used as an example for depicting examples of the XDXML Cube, XDXML Fact, and XDXML dimension schemas. All these schemas are mainly based on the XSD (XML Schema Definition). In addition to that the paper showed how XDXML can express action either for querying multidimensional data or to do some administrative actions at the server side through what has been called XDMQuery. XDMQuery is a dual-verb XML based language that is considered part of the XDXML. The two verbs are *Get* for querying data, and *Act* for sending action requests including administration actions. Get verb can use to newly proposed operators at this paper in order better retrieve what is needed accurately without any extra dimensional data member levels. Thus, reducing the retrieved the size of the XDXML which is one of its design goals.

It is important to mention here that the case study has been conducted to apply the X-Warehouse along with its XDXML messaging interface using a real life environment that is brought from the medical industry of one of the multinationals in Egypt In order to verify the applicability of the architecture [3]. The result showed that:

-The X-Warehouse Architecture is possible to get implemented and fulfilling its design goals.

Figure 19 depicts the deployed X-Warehouse architecture. As it is apparent, in addition to the regular desktop as well as web based access, this architecture permits mobile devices from accessing web warehouses data.

XDXML
Desktop
XDXML
Mobile Device

Fig 19 The X-Warehouse Architecture

-Using Caching in both server side as well as client side of the X-Warehouse architecture enhance the performance in average by 313%

-The performance overhead of using the X-Warehouse is in average just 5.11% which could be worthy to be incurred in order to solve the compelling problems that X-Warehouse tackles.

- The ThOLAP could be implemented based on the same architecture using the XDXML application protocol.

To conclude this work has successfully implemented the XDXML XML based XWarehouse Messaging Interface. A future studies will be made in order to more predicates to the Get and Act verbs for performing other administrative tasks. The XDXML at it is current state doesn't tackle how to query the data mining structures out from the server side.

This is expected to be the subject of one of the future research efforts.

# PAFSV: A Process Algebraic Framework for SystemVerilog

K. L. Man
Centre for Efficiency-Oriented Languages (CEOL)
Department of Computer Science
University College Cork (UCC), Ireland
Email: pafsv.team@gmail.com

***Abstract*—We develop a process algebraic framework, called process algebraic framework for IEEE 1800$^{\text{TM}}$ SystemVerilog (PAFSV), for formal specification and analysis of IEEE 1800$^{\text{TM}}$ SystemVerilog designs. The formal semantics of PAFSV is defined by means of deduction rules that associate a time transition system with a PAFSV process. A set of properties of PAFSV is presented for a notion of bisimilarity. PAFSV may be regarded as the formal language of a significant subset of IEEE 1800$^{\text{TM}}$ SystemVerilog. To show that PAFSV is useful for the formal specification and analysis of IEEE 1800$^{\text{TM}}$ SystemVerilog designs, we illustrate the use of PAFSV with some examples: a MUX, a synchronous reset D flip-flop and an arbiter.**

## I. Introduction

THE goal of developing a formal semantics is to provide a complete and unambiguous specification of the language. It also contributes significantly to the sharing, portability and integration of various applications in simulation, synthesis and formal verification. *Formal languages* with a semantics formally defined in *Computer Science* increase understanding of systems and clarity of specifications; and help solving problems and remove errors. Over the years, several flavours of formal languages have been gaining industrial acceptance. *Process algebras* [1] are formal languages that have formal syntax and semantics for specifying and reasoning about different systems. They are also useful tools for verification of various systems. Generally speaking, process algebras describe the behaviour of processes and provide operations that allow to compose systems to obtain more complex systems. Moreover, the analysis and verification of systems described using process algebras can be partially or completely carried out by mathematical proofs using equational theory.

In addition, the strength of the field of process algebras lies in the ability to use *algebraic reasoning* [1] (also known as equational reasoning) that allows rewriting processes using axioms (e.g. for commutativity and associativity) to a simpler form. By using axioms, we can also perform calculations with processes. These can be advantageous for many forms of analysis. Process algebras have also helped to achieve a deeper understanding of the nature of concepts like observable behaviour in the presence of non-determinism, system composition by interconnection of system components modelled as processes in a parallel context and notions of behavioural equivalence (e.g. bisimulation [1]) of such systems.

Serious efforts have been made in the past to deal with systems (e.g. real-time systems [2] and hybrid systems [3], [4]) in a process algebraic way. Over the years, process algebras have been successfully used in a wide range of problems and in practical applications in both academia and industry for analysis of many different systems.

On the other hand, the need for a formal and well-defined semantics of a *Hardware Description Languages* (HDL) is widely accepted and desirable for architects, engineers and researchers in the electronic design community. IEEE 1800$^{\text{TM}}$ *SystemVerilog* [5] (in what follows, we abbreviate the IEEE 1800$^{\text{TM}}$ SystemVerilog as SystemVerilog) is the industry's first unified hardware description and verification language (HDVL) standard; and SystemVerilog is a major extension of the established IEEE 1364$^{\text{TM}}$ *Verilog* language [6] (see also [7]).

However, the standard semantics of SystemVerilog is informal. We believe that the fundamental tenets of process algebras are highly compatible with the behavioural approach of systems described in SystemVerilog. Hence, in this paper, we present a process algebraic framework called **PAFSV** that is suitable for modelling and analysis of systems described in SystemVerilog (in a formal way). **PAFSV** covers the main features of SystemVerilog (i.e. a significant subset of SystemVerilog) including decision statements and immediate assertions; and also aims to achieve a satisfactory level of abstraction and a more faithful modelling of concurrency. Although it is desirable and very important to have pure parallelism for hardware simulation, the SystemVerilog simulators "*in-use*" at this moment still implement parallelism via non-determinism.

Therefore, we realise that it is more fruitful to develop our process algebraic framework for SystemVerilog such that the execution of a system described in such a framework (**PAFSV**) consists of interleaving transitions from concurrent processes. Moreover, we adopt the view that a system described in **PAFSV** is a system in which an instantaneous state transition occurs on the system performing an action and a delay takes place on the system idling between performing successive actions. A technical advantage of our work is that, in contrast to other attempts to formalise semantics of SystemVerilog and HDLs, specifications described in **PAFSV** can be directly executable.

978-83-60810-14-9/08/$25.00 © 2008 IEEE

The formal semantics of $\mathbf{PAFSV}$ is defined by means of deduction rules in a standard structured operational semantics (SOS) [9] style that associate a *Time Transition System* (TTS) with a $\mathbf{PAFSV}$ process. A set of properties of $\mathbf{PAFSV}$ is presented for a notion of bisimilarity. Overview of process algebras, Verilog and SystemVerilog is not given in this paper. Some familiarity with them is required. The desirable background can, for example, be found in [1], [5], [6].

Over the years, different formal approaches have been studied and investigated for VHDL [10], Verilog [11], [12] and SystemC [14], [15]. Most of these works could only be considered as theoretical frameworks, except a few trails ([13], [17]), because they are not executable. Research work in the formal semantics of SystemVerilog based on *Abstract State Machines* (ASMs) [16] and rewrite rules already exist [5]. Also, ASM specifications and rewrite rules are not directly executable. It is also generally believed that a structured operational semantics (SOS) provides more clear intuitions; and ASM specifications and rewrite rules appear to be less suited to describe the dynamic behaviour of processes.

Since processes are the basic units of execution within SystemVerilog that are used to simulate the behaviour of a system, a process algebraic framework in a SOS style is a more immediate choice to give the formal semantics of SystemVerilog (these motivated us to develop $\mathbf{PAFSV}$ in a process algebraic way with SOS deduction rules). Based on the similar motivations and needs, three years ago, $SystemC^{\mathbb{FL}}$ [17], [18], [19] (a timed process algebra) was introduced for formal specification and analysis of SystemC designs. $SystemC^{\mathbb{FL}}$ initiated an attempt to extend the knowledge and experience of the field of process algebras to SystemC designs. Clearly, SystemVerilog and SystemC are similar and our research work in this direction was highly inspired by the theoretical aspects of $SystemC^{\mathbb{FL}}$. Hence, a formal comparison between them is indispensable (as future work). Furthermore, an introduction (paper) of $\mathbf{PAFSV}$ can be found in [20]. Such a paper only informally presented the syntax and semantics of $\mathbf{PAFSV}$. Also, no deduction rules were given, validation of the semantics was not discussed and no analysis example of $\mathbf{PAFSV}$ specifications was provided.

This paper is organised as follows. Section II shows the goals, the data types, formal syntax and formal semantics of our process algebraic framework $\mathbf{PAFSV}$. To illustrate the use, effectiveness and applicability of the deduction rules, in Section III, some simple specifications of $\mathbf{PAFSV}$ are provided. In Section IV, the correctness of the formal semantics of $\mathbf{PAFSV}$ defined in Subsection II-E is discussed; and a notion of equivalence is defined, which is shown to be a congruence for all $\mathbf{PAFSV}$ operators. Also, a set of useful properties of closed $\mathbf{PAFSV}$ process terms is given in the same section. Samples (modelling some SystemVerilog designs) of the application of $\mathbf{PAFSV}$ are shown in Section V. A formal analysis (by means of a complete mathematical proof) of a SystemVerilog design via $\mathbf{PAFSV}$ is presented in Section VI. Finally, concluding remarks are made in Section VII and the direction of future work is pointed out in the same section.

## II. $\mathbf{PAFSV}$

Obviously, it is not possible to cover all the aspects of SystemVerilog and define a process algebraic framework for it in one paper. Hence, in this section, we outline the goals to achieve in this paper.

We propose a process algebraic framework namely $\mathbf{PAFSV}$ that has a formal and compositional semantics based on a time transition system for formal specification and analysis of SystemVerilog designs. The intention of our process algebraic framework $\mathbf{PAFSV}$ is as follows:

- to give a formal semantics to a significant subset of SystemVerilog using the operational approach of [9];
- to serve as a mathematical basis for improvement of design strategies of SystemVerilog and possibilities to analyse SystemVerilog designs;
- to serve as a coherent first step for a semantics interoperability analysis on semantics domain such as SystemC and $SystemC^{\mathbb{FL}}$;
- to initiate an attempt to extend the knowledge and experience of the field of process algebras to SystemVerilog designs;
- to be used as the formal language for a significant subset of SystemVerilog.

### A. Data types

In order to define the semantics of processes, we need to make some assumptions about the data types:

1) Let $\mathrm{Var}$ denote the set of all variables $(x_0, \ldots, x_n, \mathtt{time})$. Besides the variables $x_0, \ldots, x_n$, the existence of the predefined reserved global variable `time` which denotes the current time, the value of which is initially zero, is assumed. This variable cannot be declared.
2) Let $\mathrm{Value}$ denote the set of all possible values $(v_0, \ldots, v_m, \perp)$ that contains at least all $\mathrm{Integers}$, all $\mathrm{Reals}$, all $\mathrm{Shortreals}$, all $2-\mathrm{statevalues}$ and all $4-\mathrm{statevalues}$ as defined in SystemVerilog (see [5] for details); all $\mathrm{Booleans}$ and $\perp$, where $\perp$ denotes the "*undefinedness*".
3) We then define a *valuation* as a partial function from variables to values. Syntactically, a valuation is denoted by a set of pairs $\{x_0 \mapsto v_0, \ldots, x_n, \mapsto v_n, \mathtt{time} \mapsto t\}$, where $x_i$ represents a variable and $v_i$ its associating value; and $t \in \mathbb{R}_{\geq 0}$.
4) Further to this, the set of all valuations is denoted by $\Sigma$.

Note that the type "$\mathrm{array}$" in SystemVerilog is not formalised yet in $\mathbf{PAFSV}$. However, the behaviour of elements in an array in SystemVerilog can be modelled in $\mathbf{PAFSV}$ by introducing fresh variables. As an example, for an array A[0:10] in SystemVerilog, we can introduce fresh variables $A_0, \ldots, A_{10}$ in $\mathbf{PAFSV}$ to associate correspondingly A[0] with $A_0$, A[1] with $A_1$ and so on.

### B. Formal syntax

To avoid confusion with the definition of a process in SystemVerilog, it is important to clearly state that, in our process algebraic framework **PAFSV**, we choose the terminology "***a process term***" as a formal term (generated restrictively through the formal syntax of **PAFSV**) to describe the possible behaviour of a **PAFSV** process (see Subsection II-E) and not a process as defined in SystemVerilog.

Furthermore, process terms $p \in P$ are the core elements of the **PAFSV**. The semantics of those process terms is defined in terms of the core process terms given in this subsection. The set of process terms $P$ is defined according to the following grammar for the process terms $p \in P$:

$$\begin{array}{rll} p \ ::= & \textbf{deadlock} \ \mid \ \textbf{skip} \ \mid \ x := e \\ \mid & \textbf{delay}(n) \ \mid \ \textbf{any}\ p \ \mid \ \textbf{if}(b)\ p\ \textbf{else}\ p \\ \mid & p;\ p \ \mid \ \textbf{wait}(b)\ p \ \mid \ \textbf{while}(b)\ p \\ \mid & \textbf{assign}\ w := e \ \mid \ @_{(\eta_1(l_1),\ldots,\eta_n(l_n))}\ p \\ \mid & p \circledast p \ \mid \ p \parallel p \ \mid \ \textbf{repeat}\ p \\ \mid & \textbf{assert}(b)\ p \ \mid \ p\ \textbf{disrupt}\ p \end{array}$$

Here, $x$ and $w$ are variables taken from $\mathrm{Var}$ and $n \in \mathbb{R}_{\geq 0}$. $b$ and $e$ denote a boolean expression and an expression over variables from $\mathrm{Var}$, respectively. Moreover, $\eta_1, \ldots, \eta_n$ represent boolean functions with corresponding parameters $l_1, \ldots, l_n \in \mathrm{Var}$.

In **PAFSV**, we allow the use of common arithmetic operators (e.g. $+, -$), relational operators (e.g. $=, \geq$) and logical operators (e.g. $\wedge, \vee$) as in mathematics to construct expressions over variables from $\mathrm{Var}$. The operators are listed in descending order of their binding strength as follows: $\{$**if**(_)**_else_**, **wait**(_)_, **while**(_)_, **assert**(_)_$\}$, _; _, **_disrupt_**, $\{\_ \circledast \_, \_ \parallel \_\}$. The operators inside the braces have equal binding strength. In addition, operators of equal binding strength associate to the right, and parentheses may be used to group expressions. For example, $p;\ q;\ r$ means $p;\ (q;\ r)$, where $p, q, r \in P$. Apart from process terms: **deadlock**, **skip**, **any_**, **_disrupt_**, and $\_ \circledast \_$, all other syntax elements in **PAFSV** are the formalisation of the corresponding language elements (based on classical process algebra tenets) in SystemVerilog.

Process terms **deadlock** and **skip**; and operator $\_ \circledast \_$ are mainly introduced for calculation and axiomatisation purposes. The **any_** operator was originally introduced in Hybrid Chi [3] (to be precise, in Hybrid Chi, such an operator is called "*the any delay operator*" and denoted by "[ ]"). It is used to give an arbitrary delay behaviour to a process term. We can make use of this operator to simplify our deduction rules in a remarkable way. The **_disrupt_** is inspired by the analogy of the disrupt operator in HyPA [4]. This can be used to model event controls in **PAFSV** in a very efficient way. A concise explanation of the formal syntax of **PAFSV** is given below. Subsection II-E gives a more detailed account of its meaning.

### C. Atomic process terms

The atomic process terms of **PAFSV** are process term constructors that cannot be split into smaller process terms. They are:

1) The *deadlock* process term **deadlock** is introduced as a constant, which represents no behaviour. This means that it cannot perform any actions or delays.
2) The *skip* process term **skip** can only perform the internal action $\tau$ to termination, which is not externally visible.
3) The *procedural assignment* process term $x := e$ assigns the value of expression $e$ to variable $x$ (in an atomic way).
4) The *continuous assignment* process term **assign** $w := e$ continuously watches for changes of the variables that occur on the expression $e$. Whenever there is a change, the value of $e$ is re-evaluated and then propagated it immediately to $w$.
5) The *delay* process term **delay**$(n)$ denotes a process term that first delays for $n$ time units, and then terminates by means of the internal action $\tau$.

### D. Operators

Atomic process terms can be combined using the following operators. The operators are:

1) By means of the application of the *any* operator to process term $p \in P$ (i.e. **any** $p$), delay behaviour of arbitrary duration can be specified. The resulting behaviour is such that arbitrary delays are allowed. As a consequence, any delay behaviour of $p$ is neglected. The action behaviour of $p$ remains unchanged. This operator can even be used to add arbitrary behaviour to an undelayable process term.
2) The *if_else* process term **if**$(b)$ $p$ **else** $q$ first evaluates the boolean expression $b$. If $b$ evaluates to *true*, then $p$ is executed, otherwise $q \in P$ is executed.
3) The *sequential composition* of process terms $p$ and $q$ (i.e. $p;\ q$) behaves as process term $p$ until $p$ terminates, and then continues to behave as process term $q$.
4) The *wait* process term **wait**$(b)$ $p$ can perform whatever $p$ can perform under the condition that the boolean expression $b$ evaluates to $true$. Otherwise, it is blocked until $b$ becomes $true$.
5) Similarly, the *while* process term **while**$(b)$ $p$ can perform whatever $p$ can do under the condition that the boolean expression $b$ evaluates to $true$ and then followed by the original iteration process term (i.e. **while**$(b)$ $p$). In case $b$ evaluates to $false$, the while process term **while**$(b)$ $p$ terminates by means of the internal action $\tau$.
6) The *event* process term $@_{(\eta_1(l_1),\ldots,\eta_n(l_n))}\ p$ can perform whatever $p$ can do under the condition that any of the boolean functions $\eta_1(l_1), \ldots, \eta_n(l_n)$ returns to $true$. If there is no such a function, $p$ will be triggered by $\eta_1(l_1), \ldots, \eta_n(l_n)$. Intuitively, functions $\eta_1, \ldots, \eta_n$ are used to model event changes as event controls $levelchange$, $posedge$ and $negedge$ in SystemVerilog.
7) The *alternative composition* of process terms $p$ and $q$ (i.e. $p \circledast q$) allows a non-deterministic choice between different actions of the process term either $p$ or $q$.
8) The *parallel composition* of process terms $p$ and $q$ (i.e. $p \parallel q$) executes $p$ and $q$ concurrently in an interleaved fashion. For the time behaviour, the participants in the parallel composition have to synchronise.

9) The *repeat* process term **repeat** $p$ represents the infinite repetition of process term $p$. Note that the idea behind the *repeat* statement in SystemVerilog is slightly different from **repeat** $p$ in $\mathbf{PAFSV}$. The repeat statement specifies the number of times of a loop to be repeated. The same goal can be achieved by using the repeat process term in combination with the if_else process term in $\mathbf{PAFSV}$.
10) The *assert* process term **assert**$(b)$ $p$ checks immediately the property $b$ (expressed as a boolean expression). If $b$ holds, $p$ is executed.
11) The *disrupt* process term $p$ **disrupt** $q$ intends to give priority of the execution of process term $p$ over process term $q$. The need and use of this operator will be illustrated in Section VI.

### E. Formal semantics

In this subsection, we give a formal semantics to the syntax defined for $\mathbf{PAFSV}$ in the previous subsection, by constructing a kind of time transition system (TTS), for each process term and each possible valuation of variables.

**Definition 1** *We use the convention $\langle p, \sigma\rangle$ to write a $\mathbf{PAFSV}$ process, where $p \in P$ and $\sigma \in \Sigma$.*

**Definition 2** *The set of actions $A_\tau$ contains at least $aa(x, v)$ and $\tau$, where $aa(x, v)$ is the assignment action (i.e. the value of $v$ is assigned to $x$) and $\tau$ is the internal action. The set $A_\tau$ is considered as a parameter of $\mathbf{PAFSV}$ that can be freely instantiated.*

**Definition 3** *We give a formal semantics for $\mathbf{PAFSV}$ processes in terms of a time transition system (TTS), and define the following transition relations on processes of $\mathbf{PAFSV}$:*

- $\_ \xrightarrow{\_} \langle \checkmark, \_\rangle \subseteq (P \times \Sigma) \times A_\tau \times \Sigma$, *denotes termination, where $\checkmark$ is used to indicate a successful termination, and $\checkmark$ is not a process term;*
- $\_ \xrightarrow{\_} \_ \subseteq (P \times \Sigma) \times A_\tau \times (P \times \Sigma)$, *denotes action transition;*
- $\_ \overset{\_}{\longmapsto} \_ \subseteq (P \times \Sigma) \times \mathbb{R}_{>0} \times (P \times \Sigma)$, *denotes time transition (so-called delay).*

For $p, p' \in P$; $\sigma, \sigma' \in \Sigma$, $a \in A_\tau$ and $d \in \mathbb{R}_{>0}$, the three kinds of transition relations can be explained as follows:

1) Firstly, a termination $\langle p, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle$ is that the process executes the action $a$ followed by termination.
2) Secondly, an action transition $\langle p, \sigma\rangle \xrightarrow{a} \langle p', \sigma'\rangle$ is that the process $\langle p, \sigma\rangle$ executes the action $a$ starting with the current valuation $\sigma$ and by this execution $p$ evolves into $p'$, where $\sigma'$ represents the accompanying valuation of the process after the action $a$ is executed.
3) Thirdly, a time transition $\langle p, \sigma\rangle \overset{d}{\longmapsto} \langle p', \sigma'\rangle$ is that the process $\langle p, \sigma\rangle$ may idle during a $d$ time units and then behaves like $\langle p', \sigma'\rangle$.

### F. Deduction rules

The above transition relations are defined through deduction rules (SOS style). These rules (of the form $\frac{\textit{permises}}{\textit{conclusions}}$) have two parts: on the top of the bar we put *premises* of the rule, and below it the *conclusions*. If the premise(s) hold(s), then we infer that the conclusion(s) hold(s) as well. In case there is no premise, the deduction rule becomes an axiom.

Apart from the syntax restriction as already shown in Subsection II-B (e.g. $x, w \in \mathrm{Var}$), for all deduction rules, we further require that $p, q, p', q' \in P$; $\sigma, \sigma', \sigma'' \in \Sigma$; $a, b \in A_\tau$, $d \in \mathbb{R}_{>0}$, $\mathrm{dom}(\sigma) = \mathrm{dom}(\sigma') = \mathrm{dom}(\sigma'')$; $\sigma$, $\sigma'$, $\sigma''$ and $\bar{\sigma}(e)$ are defined, where the notation $\bar{\sigma}(e)$ is used to represent the value of expression $e$ in $\sigma$.

Also, we make use of the sets of variables $\mathrm{Var}^- = \{x^- \mid x \in \mathrm{Var}\}$ and $\mathrm{Var}^+ = \{x^+ \mid x \in \mathrm{Var}\}$, modelling the current and future value of a variable, respectively. Similarly, $e^-$ and $e^+$ are used to represent the current and future value of $e$ respectively.

In order to increase the readability of the $\mathbf{PAFSV}$ deduction rules, the notation $\overset{z}{\twoheadrightarrow}$ is used as a short-hand for $\xrightarrow{a}$ and $\overset{d}{\longmapsto}$.

***Deduction rules:*** It is not our intention to define deduction rules for all inductive cases for all operators in this paper. For simplicity, only relevant deduction rules for the use of this paper are shown in this subsection.

*1) Procedural assignment:*

$$\frac{}{\langle x := e, \sigma\rangle \xrightarrow{aa(x, \bar{\sigma}(e))} \langle \checkmark, \sigma[\bar{\sigma}(e)/x]\rangle}\ 1$$

By means of a procedural assignment (see Rule 1), the value of $e$ is assigned to $x$. Notice that $\sigma[\bar{\sigma}(e)/x]$ denotes the update of valuation $\sigma$ such that the new value of variable $x$ is $\bar{\sigma}(e)$.

*2) Sequential composition:*

$$\frac{\langle p, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle}{\langle p;\ q, \sigma\rangle \xrightarrow{a} \langle q, \sigma'\rangle}\ 2 \qquad \frac{\langle p, \sigma\rangle \overset{z}{\twoheadrightarrow} \langle p', \sigma'\rangle}{\langle p;\ q, \sigma\rangle \overset{z}{\twoheadrightarrow} \langle p';\ q, \sigma'\rangle}\ 3$$

The process term $q$ is executed after (successful) termination of the process term $p$ as defined by Rules 2 and 3.

*3) Parallel composition:*

$$\frac{\langle p, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle}{\langle p \parallel q, \sigma\rangle \xrightarrow{a} \langle q, \sigma'\rangle}\ 4 \qquad \frac{\langle q, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle}{\langle p \parallel q, \sigma\rangle \xrightarrow{a} \langle p, \sigma'\rangle}\ 5$$

$$\frac{\langle p, \sigma\rangle \xrightarrow{a} \langle p', \sigma'\rangle}{\langle p \parallel q, \sigma\rangle \xrightarrow{a} \langle p' \parallel q, \sigma'\rangle}\ 6 \qquad \frac{\langle q, \sigma\rangle \xrightarrow{a} \langle q', \sigma'\rangle}{\langle p \parallel q, \sigma\rangle \xrightarrow{a} \langle p \parallel q', \sigma'\rangle}\ 7$$

$$\frac{\langle p, \sigma\rangle \overset{d}{\longmapsto} \langle p', \sigma'\rangle,\ \langle q, \sigma\rangle \overset{d}{\longmapsto} \langle q', \sigma'\rangle}{\langle p \parallel q, \sigma\rangle \overset{d}{\longmapsto} \langle p' \parallel q', \sigma'\rangle}\ 8$$

The parallel composition of the process terms $p$ and $q$ (i.e. $p \parallel q$) has as its behaviour with respect to action transitions the interleaving of the behaviours of process terms $p$ and $q$ (see from Rule 4 to Rule 7). If both process terms $p$ and $q$ can perform the same delay, then the parallel composition of process terms $p$ and $q$ (i.e. $p \parallel q$) can also perform that delay, as defined by Rule 8.

## III. Examples

Deduction rules offer preciseness, because they come with a mathematically defined semantics. Formal specifications can be analysed using deduction rules providing an absolute notion of correctness.

Also, these deduction rules can ensure the correctness of **PAFSV** specifications and can help modellers to make correct specifications.

In order to demonstrate the effectiveness and applicability of the deduction rules, two toy specifications in **PAFSV** are given in this section. These specifications also show how (illustrated by means of transition traces) process evolves during transitions.

Using the deduction rules, for instance, we can show that:

1) the process $\langle x := 5;\ y := 7, \{x \mapsto 0, y \mapsto 1\}\rangle$ can terminate successfully after a finite number of transitions.
   - ***Transition traces:*** According to Rule 1, the process $\langle x := 5, \{x \mapsto 0, y \mapsto 1\}\rangle$ can always perform an assignment action to a terminated process as follows: $\langle x := 5, \{x \mapsto 0, y \mapsto 1\}\rangle \xrightarrow{aa(x,5)} \langle \checkmark, \{x \mapsto 5, y \mapsto 1\}\rangle$. Due to this, we can apply Rule 3 to obtain $\langle x := 5;\ y := 7, \{x \mapsto 0, y \mapsto 1\}\rangle \xrightarrow{aa(x,5)} \langle y := 7, \{x \mapsto 5, y \mapsto 1\}\rangle$. Applying Rule 1 again, we have $\langle y := 7, \{x \mapsto 5, y \mapsto 1\}\rangle \xrightarrow{aa(y,7)} \langle \checkmark, \{x \mapsto 5, y \mapsto 7\}\rangle$.
2) the process $\langle (x := 1 \parallel y := 2);\ z := 3, \sigma\rangle$ cannot terminate successfully in two transitions.
   - ***Semantical proof:*** We assume to have $\langle (x := 1 \parallel y := 2);\ z := 3, \sigma\rangle \xrightarrow{a} \langle z := 3, \sigma'\rangle$ for some $a$ and $\sigma'$ in such a way that the process can terminate successfully in two transitions. This means that we must have the action transition $\langle x := 1 \parallel y := 2, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle$ as a premise necessarily for Rule 2. However, this is not possible due to Rules 4 and 5.

## IV. Validation of the Semantics

This section first shows that the term deduction system of **PAFSV** is well-defined. Then a notion of equivalence called *Stateless Bisimilarity* is defined (see also [3], [21]).

It is also shown that this relation is an equivalence and a *Congruence* [1] (which also means that compositionality preserved operationally in **PAFSV**) for all **PAFSV** operators.

A set of useful properties of **PAFSV** is sound with respect to the stateless bisimilarity that is also introduced.

### A. Well-definedness of the semantics

The deduction rules defined for **PAFSV** constitute a *Transition System Specification* (TSS) as described in [22]. The transitions that can be proven from a TSS define a time transition system (TTS).

The TTS of **PAFSV** contains terminations, action transitions and time transitions that can be proven from the deduction rules. In general, TSSs with negative premises[1] might not be *meaningful* (see [22] for details).

As we know that no negative premise is used in our deduction rules for **PAFSV**. So, it is not hard to see that the term deduction system of **PAFSV** is well-defined. This means that the system defines a unique transition system for each closed process term of **PAFSV**.

### B. Bisimilarity

Two closed **PAFSV** process terms are considered equivalent if they have the same behaviour (in the bisimulation sense) from the current state.

We also assume that the valuation (of the current state) contains at least the free occurrences of variables in the two closed **PAFSV** process terms being equivalent.

**Definition 4 (Stateless bisimilarity)** *A stateless bisimilarity on closed process terms is a relation $R \subseteq P \times P$ such that $\forall (p,q) \in R$, the following holds:*

1) $\forall \sigma, a, \sigma' : \langle p, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle \Leftrightarrow \langle q, \sigma\rangle \xrightarrow{a} \langle \checkmark, \sigma'\rangle$,
2) $\forall \sigma, a, p', \sigma' : \langle p, \sigma\rangle \xrightarrow{a} \langle p', \sigma'\rangle \Rightarrow \exists q' : \langle q, \sigma\rangle \xrightarrow{a} \langle q', \sigma'\rangle \wedge (p', q') \in R$,
3) $\forall \sigma, a, q', \sigma' : \langle q, \sigma\rangle \xrightarrow{a} \langle q', \sigma'\rangle \Rightarrow \exists p' : \langle p, \sigma\rangle \xrightarrow{a} \langle p', \sigma'\rangle \wedge (p', q') \in R$,
4) $\forall \sigma, d, p', \sigma' : \langle p, \sigma\rangle \overset{d}{\longmapsto} \langle p', \sigma'\rangle \Rightarrow \exists q' : \langle q, \sigma\rangle \overset{d}{\longmapsto} \langle q', \sigma'\rangle \wedge (p', q') \in R$,
5) $\forall \sigma, d, q', \sigma' : \langle q, \sigma\rangle \overset{d}{\longmapsto} \langle q', \sigma'\rangle \Rightarrow \exists p' : \langle p, \sigma\rangle \overset{d}{\longmapsto} \langle p', \sigma'\rangle \wedge (p', q') \in R$.

*Two closed process terms $p$ and $q$ are stateless bisimilar, denoted by $p \underline{\leftrightarrow} q$, if there exists a stateless bisimilarity relation $R$ such that $(p,q) \in R$.*

Stateless bisimilarity is proved to be a congruence with respect to all **PAFSV** operators. As a consequence, algebraic reasoning is facilitated, since it is allowed to replace equals by equals in any context.

**Theorem 1 (Congruence)** *Stateless bisimilarity is a congruence with respect to all* **PAFSV** *operators.*

***Proof:*** *All deduction rules of* **PAFSV** *are in the process-tyft format of [21]. It follows from [21] that stateless bisimilarity is a congruence.*

### C. Properties

In this subsection, some properties of the operators of **PAFSV** that hold with respect to stateless bisimilarity are discussed. Most of these correspond well with our intuitions, and hence this can be considered as an additional validation of the semantics.

It is not our intention to provide a complete list of such properties (complete in the sense that every equivalence between closed process terms is derivable from those properties).

[1] We write a negative premise for action transition as $\langle p, \sigma\rangle \overset{a}{\nrightarrow}$ for the set of all transitions formulas $\neg(\langle p, \sigma\rangle \xrightarrow{a} \langle p', \sigma'\rangle)$, where $p, p' \in P$, $a \in A_\tau$ and $\sigma, \sigma' \in \Sigma$. In a similar way, we can define negative premises for termination and time transition.

**Proposition 1 (Properties)** *A set of properties is introduced for **PAFSV** described in this paper for $p, q, r \in P$. These properties are sound with respect to the stateless bisimilarity.*

1) ***skip*** $\underline{\leftrightarrow}$ ***delay***$(0)$,
2) ***deadlock***$;\ p \ \underline{\leftrightarrow}$ ***deadlock****,*
3) $(p;\ q);\ r \ \underline{\leftrightarrow}\ p;\ (q;\ r)$,
4) ***any*** $p;\ q \ \underline{\leftrightarrow}$ ***any*** $(p;\ q)$,
5) $p \circledast q \ \underline{\leftrightarrow}\ q \circledast p$,
6) $(p \circledast q);\ r \ \underline{\leftrightarrow}\ p;\ r \circledast q;\ r$,
7) $(p \circledast q) \circledast r \ \underline{\leftrightarrow}\ p \circledast (q \circledast r)$,
8) $p \parallel q \ \underline{\leftrightarrow}\ q \parallel p$,
9) $(p \parallel q) \parallel r \ \underline{\leftrightarrow}\ p \parallel (q \parallel r)$,
10) ***any*** $p \circledast$ ***any*** $q \ \underline{\leftrightarrow}$ ***any*** $(p \circledast q)$,

***Proof:*** *We leave out the proofs, because most of the proofs are proofs for distributivity, commutativity and associativity as in classical process algebras. Similar proofs can also be found in [3].*

### Intuition behind the properties

The intuition of the above properties is as follows:

- Since **skip** and **delay**$(0)$ can only perform the internal action $\tau$ to termination, both process terms are equivalent.
- A deadlock process term followed by some other process terms is equivalent to the **deadlock** itself because the deadlock process term does not terminate successfully, i.e. **deadlock** is a left-zero element for sequential composition.
- Sequential composition is associative.
- The any operator distributes to the right argument of a sequential composition.
- Alternative composition and parallel composition are commutative and associative.
- Alternative composition distributes over sequential composition from the left, but not from the right.
- The any operator distributes over the alternative composition.

## V. Examples of **PAFSV** Specifications

This section is a sample of the application of **PAFSV**. It is meant to give a first impression of how one can describe the behaviour of some SystemVerilog designs in **PAFSV** (in a complete mathematical sense). We describe the behaviour of a simple MUX and a simple synchronous reset D flip-flop.

### *A. MUX*

In electronic designs, a multiplexer (MUX) is a device that encodes information from two or more data inputs into a single output (i.e. multiplexers function as multiple-inputs and single-output switches). A multiplexer described below (in SystemVerilog) has two inputs and a selector that connects a specific input to the single output. Figure 2 depicts such a MUX.

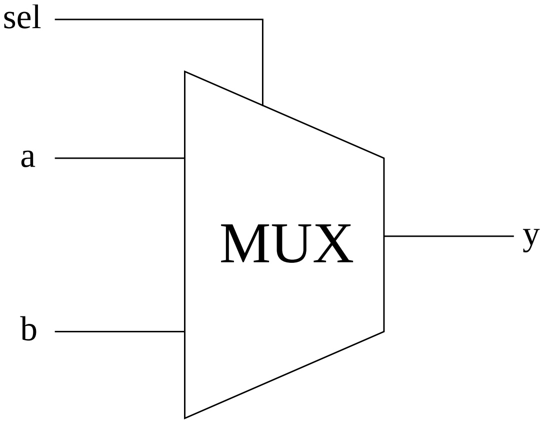

Fig. 1. A MUX.

```
module  simple_mux (
input  wire  a,
input  wire  b,
input  wire  sel,
output wire  y
);
assign y = (sel) ? a : b;
endmodule
```

The formal **PAFSV** specification (as a process term) below can be regarded as the (formal) mathematical expression of the above multiplexer (described as a SystemVerilog module):

$$\textbf{if}(sel)\ y := a\ \textbf{else}\ y := b$$

Needless to mention that, in SystemVerilog, the conditional operator “(condition) ? (result if true):(result if false)” can be considered as an **if(_)_else_** statement. In the **PAFSV** specification, an if_else process term is used to model the behaviour of such a MUX.

### *B. Synchronous reset D flip-flop*

Synchronous reset D flip-flops are among the basic building blocks of RTL designs. A synchronous reset D flip-flop has a clock input ($clk$) in the event list, a data input ($d$), a reset ($rst$) and a data output ($Q$). Figure 2 depicts such a synchronous reset D flip-flop.

A synchronous reset D flip-flop described below (as a module in SystemVerilog) is inferred by using posedge clause for the clock $clk$ in the event list.

```
module dff_sync_reset (
input  wire d,
input  wire clk,
input  wire rst,
output reg  Q
);
always_ff @ (posedge clk)
if (~reset) begin
  Q = 1’b0;
end  else begin
  Q = d;
end
endmodule
```

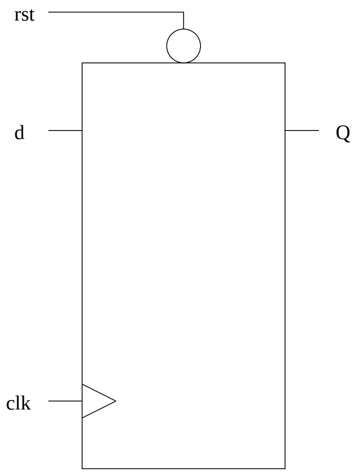

Fig. 2. A synchronous reset D flip-flop.

The formal **PAFSV** specification (as a process term) of the above synchronous reset D flip-flop (described as a module in SystemVerilog) is given as follows:

$$\begin{array}{rl} \mathrm{DFF} & \approx \textbf{repeat}(@_{(\eta_{negedge}(clk))}\mathrm{OUT}) \\ \mathrm{OUT} & \approx \textbf{if}(\neg rst)\ Q := 1'b0\ \textbf{else}\ Q := d \end{array}$$

In the **PAFSV** specification (i.e. process term DFF), the behaviour of the synchronous reset D flip-flop is modelled by means of the if_else process term using “$\neg rst$ (active low reset)” as the condition of such a process term.

This if_else process term is further triggered repeatedly by the event process term, which is positively sensitive to the clock (i.e. $clk$).

## VI. Analysis of an PAFSV Specification

We have already shown in Section V that **PAFSV** specifications can be used to formally represent SystemVerilog designs. Therefore, in this section, we formally analyse a simple arbiter described in SystemVerilog via **PAFSV**.

### A. An arbiter

Arbiter circuits are standard digital hardware verification benchmark circuits. In general, the role of an arbiter is to grant access to the shared resource by raising the corresponding $grant$ signal and keeping it that way until the $request$ signal is removed.

A test for the arbiter can be generated by an immediate assertion as follows:

$$\text{“}assertion : grant \wedge request\text{”}.$$

This immediate assertion can be considered as a *liveness property* of the arbiter. If the assertion holds, this means that the arbiter works as expected. Below is a SystemVerilog design of the simple arbiter as described above:

```
module assert_immediate();
reg clk, grant, request;
time current_time;
initial begin
   clk = 0;
   grant = 0;
   request = 0;
   #4 request = 1;
   #4 grant = 1;
   #4 request = 0;
   #4 $finish;
end
always #5 clk = ~ clk;
always @ (negedge clk)
begin
if (grant == 1) begin
 CHECK_REQ_WHEN_GNT:
   assert(grant && request) begin
   current_time = $time;
    $display {‘‘Works as expected’’);
    end
 end
endmodule
```

A formal **PAFSV** specification of the above SystemVerilog arbiter is given as follows:

$$\langle\ \mathrm{INIT} \parallel \mathrm{ARB} \parallel \mathrm{CLK}\ \textbf{disrupt}\ \mathrm{ASSER}, \sigma\ \rangle, \text{ where}$$

$$\begin{array}{cl} \mathrm{INIT} & \approx clk := 0;\ grant := 0;\ request := 0 \\ \mathrm{ARB} & \approx \mathrm{R}_1;\ \mathrm{G};\ \mathrm{R}_0;\ \mathrm{S} \\ \mathrm{R}_1 & \approx \textbf{delay}(4);\ request := 1 \\ \mathrm{G} & \approx \textbf{delay}(4);\ grant := 1 \\ \mathrm{R}_0 & \approx \textbf{delay}(4);\ request := 0 \\ \mathrm{S} & \approx \textbf{delay}(4);\ \textbf{skip} \\ \mathrm{CLK} & \approx \textbf{repeat}(\textbf{delay}(5);\ clk := \neg clk) \\ \mathrm{ASSER} & \approx \textbf{repeat}(@_{(\eta_{negedge}(clk))}\mathrm{PROP};\ \textbf{skip}) \\ \mathrm{PROP} & \approx \textbf{assert}(grant \wedge request)\ t := \mathtt{time} \end{array}$$

$$\sigma = \{clk \mapsto \bot, grant \mapsto \bot, request \mapsto \bot, t \mapsto \bot, \mathtt{time} \mapsto 0\}.$$

The formal specification of the arbiter is a parallel composition of process terms INIT, ARB and CLK **disrupt** ASSER:

- INIT - It assigns the initial values to variables $clk$, $grant$ and $request$ (i.e. the initialisation).
- ARB - It models the change of behaviour of variables $clk$, $grant$ and $request$ according to time.
- CLK - It models the behaviour of a clock (i.e. $clk$) which swaps the values between “0” and “1” every 5 time units.
- ASSER - It expresses the immediate assertion for the arbiter (as indicated above).
- CLK **disrupt** ASSER - It models the fact that the test of the immediate assertion is executed whenever there is a negative change in $clk$. When this happens, the current time is assigned to the variable $t$. ***Remark:*** This also explains the need and the use of the “**disrupt** process term”, because the execution of process term CLK must have a higher priority than the execution of process term ASSER (since the change of the clock causes the test to be run).

### B. Formal analysis of the arbiter

The arbiter described in **PAFSV** was analysed by means of a complete mathematical proof via transition traces according to deduction rules of **PAFSV**. The liveness property (i.e. the immediate assertion holds at least for some times) of the arbiter was proved to hold. In this paper, due to the reason of spaces, the above-mentioned proof is omitted.

## VII. Conclusions and Future Work

In order to illustrate our work clearly, only simple examples were given in this paper. Nevertheless, the use of **PAFSV** is generally applicable to all sizes and levels of SystemVerilog designs. Nevertheless, we reached our goals (as indicated in Section II). We also believe that our process algebraic framework **PAFSV** can serve as a mathematical basis for improvement of the design strategies of SystemVerilog, and possibilities to analyse SystemVerilog designs, because **PAFSV**

1) comprises mathematical expressions for SystemVerilog;
2) allows for analysis of specifications in a compositional way;
3) allows for equational reasoning on specifications;
4) contributes significantly to the investigation of interoperabilites of SystemVerilog with SystemC and $SystemC^{\mathbb{FL}}$.

We have the idea that, like $SystemC^{\mathbb{FL}}$, **PAFSV** can serve as a *single-formalism-multi-solution*. This means that we can formally translate a **PAFSV** specification to the input languages (e.g. SMV [23], Promela [24] and timed automata [25]) of several verification tools (e.g. SMV [23], SPIN [24] and Uppaal [26]) and it can be verified in those verification tool environments.

Our future work will develop/investigate such translations. For practical applications, we will apply **PAFSV** to formally represent SystemVerilog designs (for formal analysis purposes) in the design flow of the project: "$\mathcal{MOQA}$ Processor: An Entirely New Type of Processor for Modular Quantitative Analysis" as reported in [27].

## VIII. Availability

The full set of **PAFSV** deduction rules and the complete mathematical proof of the correctness of the arbiter (see VI-B for details) are available by email at pafsv.team@gmail.com.

## IX. Acknowledgement

The author wishes to thank Jos Baeten, Bert van Beek, Mohammad Mousavi, Koos Rooda, Ramon Schiffelers, Pieter Cuijpers, Michel Reniers, Kees Middelburg, Uzma Khadim and Muck van Weerdenburg for many stimulating and helpful discussions focusing on process algebras for distinct systems in the past few years.

Many thanks go to Michel Schellekens and Menouer Boubekeur for their contributions to the introduction paper of **PAFSV** (see [20]) and the industrial collaborators Solari—Hong Kong (http://www.solari-hk.com/), International Software and Productivity Engineering Institute—USA (http://www.intspei.com), Intelligent Support Ltd.—United Kingdom (http://www.isupport-ltd.co.uk) and Minteos—Italy (http://www.minteos.com) of the research work presented in this paper.

***Abstract*—In this paper we discuss the problem of redundancies and data dependencies in XML data while an XML schema is to be normalized. Normalization is one of the main tasks in relational database design, where 3NF or BCNF, is to be reached. However, neither of them is ideal: 3NF preserves dependencies but may not always eliminate redundancies, BCNF on the contrary—always eliminates redundancies but may not preserve constraints. We discuss the possibility of achieving both redundancy-free and dependency preserving form of XML schema. We show how the XML normal form can be obtained for a class of XML schemas and a class of XML functional dependencies.**

## I. Introduction

As XML becomes popular as the standard data model for storing and interchanging data on the Web and more companies adopt XML as the primary data model for storing information, XML schema design has become an increasingly important issue. Central objectives of good schema design is to avoid data redundancies and to preserve dependencies enforced by the application domain. Existence of redundancy can lead not only to a higher data storage cost but also to increased costs for data transfer and data manipulation. It can also lead to update anomalies.

One strategy to avoid data redundancies is to design redundancy-free schema. One can start from an intuitively correct XML schema and a given set of functional dependencies reflecting some rules existing in application domain. Then the schema is normalized, i.e. restructured, in such a way that the newly obtained schema has no redundancy, preserves all data (is a lossless decomposition) and preserves all dependencies. In general, obtaining all of these three objectives is not always possible, as was shown for relational schemas [1]. However, in the case of XML schema, especially thanks to its hierarchical structure, this goal can be more often achieved [2].

The normalization process for relational schemas was proposed in the early 70s by Codd [3], [4]. Then a number of different normal forms was proposed, where the most important of them such as 2NF, 3NF [3], BCNF [4], and 4NF [5] are discussed today in every database textbook [1], [6], [7]. These normal forms together with normalization algorithms, aim to deal with the design of relational database taking into account different types of data dependencies [8], [7]. The result of the normalization should be a well-designed database [9]. The process of normalization of an XML schema is similar: we have to choose an appropriate XML schema for a given DTD and a set of data dependencies.

Recently, research on normalization of XML data was reported in papers by Arenas and Libkin [10], [11], Kolahi and Libkin [2], [12], [13], Yu and Jagadish [14].

In this paper we discuss a method for normalizing a class of XML schemas into an XML normal form that is redundancy-free and preserves all XML functional dependencies. To this order we apply the theory proposed in [12] and [11]. The novelty of the paper is the following:

- We use a new language (preliminarily proposed in [15]) for expressing schemas in a form of tree-pattern formulas, and for specifying XML functional dependencies.
- We show how the proposed formalism can be used for normalizing XML schemas into normal form similar to that of BCNF with eliminating redundancies but preserving all functional dependencies.

The structure of the paper is the following. In Section 2 we introduce an running example and motivate the research. In Section 3 a relational form of the running example is considered and some problems with its normalization are discussed. Basic notations relevant to the discussed issue from the XML perspective, are introduced in Section 4. We define a notation for defining tree-pattern formulas and for specifying data dependencies: XML functional dependencies and keys. Next, in Section 5, we discussed different normalization alternatives—we show advantages and drawbacks of some schema choices. Finally, in Section 6, an XML normal form (XNF) is defined (according to [11]) and we show how this form can be reached for our running example. We discuss the problem from theoretical and practical points of view. Section 7 concludes the paper.

## II. Motivation—Redundancies in XML Data

In XML data, like in relational ones, redundancies are caused by bad design of schemas. There are two kinds of design problems [11]: first of them is caused by non-key functional dependencies and is typical for relational schema design, while the other is more closely related to the hierarchical structure of XML documents.

As we mentioned above, in the case of XML schemas some redundancy problems may also occur because of bad design of hierarchical structure of XML document.

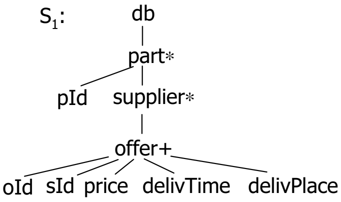

Fig. 1. Sample XML schema tree

```
db          →  part∗
part        →  pId supplier∗
pId         →  ϵ
supplier    →  offer+
offer       →  oId sId price delivTime delivPlace
oId         →  ϵ
sId         →  ϵ
price       →  ϵ
delivTime   →  ϵ
delivPlace  →  ϵ
```

Fig. 2. A DTD describing the XML schema in Fig. 1. The symbol $\epsilon$ denotes the empty string.

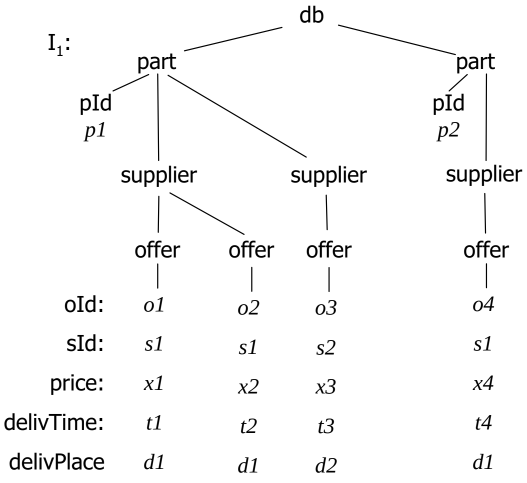

Fig. 3. Sample instance of schema $S_1$

*Example 2.1:* Let us consider the XML schema tree in Fig. 1 that describes a fragment of a database for storing data about parts and suppliers offering these parts. Its DTD specification is given in Fig. 2, and an instance of this schema is depicted in Fig. 3.

Each $part$ element has identifier $pId$. For each part may be zero or more suppliers offering this part. Offers are stored in $offer$ elements. Each offer has: offer identifier $oId$, supplier identifier $sId$, price $price$, delivery time $delivTime$, and delivery place $delivPlace$.

We assume that the following constraints must be satisfied by any instance of this schema:

- all $offer$ children of the same $supplier$ must have the same values of $sId$; this is similar to relational functional dependencies, but now we refer to both the values (text value of $sId$), and to structure (children of the same $supplier$).
- $delivPlace$ functionally depends on part ($pId$) and supplier ($sId$), i.e. when a supplier has two different offers for the same part (possibly with different $delivTime$ and/or $price$) the $delivPlace$ is the same - see offers $o1$ and $o2$ in Fig. 3.
- $delivPlace$ functionally determines supplier ($sId$). It means that having a delivery place ($delivPlace$) we know exactly which supplier is associated to this place; although one supplier can own many delivery places. For example, in Fig. 3 $d1$ is delivery place uniquely associated to the supplier $s1$.

It is easy to show that schema in Fig. 1 leads to redundancy: $sid$ (an also all other data describing suppliers such as e.g.: name and address) and $delivPlace$ are stored multiple times for a supplier.

Further on we will show that a special caution should be paid to such kind of dependencies as these in which participates $delivPlace$. In this case we have to do with "cyclic" dependencies, i.e. $delivPlace$ depends on $pId$ and $sId$ ($pId, sId \rightarrow delivPlace$) and $sId$ depends on $delivPlace$ ($delivPlace \rightarrow sId$).

First, we will discuss difficulties caused by such "cyclic" dependencies in relational databases, and next, we will show how this problem can be solved in the case of XML data.

## III. Dealing With Redundancies and Dependencies in Relational Databases

### A. Relational schemas and functional dependencies

In relational data model, a relational schema is understood as a pair

$$\mathcal{R} = (U, F),$$

where $U$ is a finite set of *attributes*, and $F$ is a set of *functional dependencies* over $F$. A functional dependence (FD) as an expression of the form

$$X \rightarrow Y,$$

where $X, Y \subseteq U$ are subsets of $U$. If $Y \subseteq X$, then $X \rightarrow Y$ is a *trivial* FD. By $F^+$ we denote all dependencies which can be inferred from $F$ by means of Armstrong's axioms [16], [7].

A *relation* of type $U$ is a finite set of tuples of type $U$. Let $U = \{A_1, ..., A_n\}$ and $dom(A)$ be the *domain* of attribute $A \in U$. Then a tuple $[A_1 : a_1, ..., A_n : a_n]$, where $a_i \in dom(A_i)$, is a tuple of type $U$.

A relation $R$ conforms to schema $\mathcal{R} = (U, F)$ (is an instance of this schema) if $R$ is of type $U$, and all dependencies from $F^+$ are satisfied by $R$. An FD $X \to Y$ is satisfied by $R$, denoted $R \models X \to Y$, if for all tuples $r_1, r_2 \in R$ holds

$$\pi_X(r_1) = \pi_X(r_2) \Rightarrow \pi_Y(r_1) = \pi_Y(r_2),$$

where $\pi_X(r)$ is the *restriction* (*projection*) of tuple $r$ on the set $X$ of attributes.

A *key* in $\mathcal{R} = (U, F)$ is such a minimal set $K$ of attributes that $K \to U$ is in $F^+$. Then each $A \in K$ is a *prime* attribute.

### B. Normalization of relational schemas

The main task in relational schema normalization is producing such a set of schemas that posses the required form, usually 3NF or BCNF. The normalization process consists in decomposition of a given input schema. The other approach consists in synthesizing 3NF from functional dependencies [8].

Ideally, a decomposition of a schema should be lossless, i.e. should preserve data and dependencies. Let $\mathcal{R} = (U, F)$, $U_1, U_2 \subseteq U$, and $U_1 \cup U_2 = U$, then schemas $\mathcal{R}_1 = (U_1, F_1)$ and $\mathcal{R}_2 = (U_2, F_2)$ are a lossless decomposition of $\mathcal{R} = (U, F)$, iff:

- The decomposition preserves data, i.e. for each instance $R$ of $\mathcal{R}$ the natural join of projections of $R$ on $U_1$ and $U_2$ produces the relation equal to $R$, i.e.
$$R = \pi_{U_1}(R) \bowtie \pi_{U_2}(R).$$
- The decomposition preserves dependencies, i.e.
$$F^+ = (F_1 \cup F_2)^+,$$
where $F_1 = \{X \to Y \mid X \to Y \in F \wedge X \cup Y \subseteq U_1\}$, and similarly for $F_2$.

The decomposition $((U_1, F_1), (U_2, F_2))$ of $(U, F)$ preserves data, if $U_1 \cap U_2 \to U_1 \in F^+$ (or, symmetrically, $U_1 \cap U_2 \to U_2 \in F^+$) [9], [7]. Then we say that the *decomposition is determined* by the functional dependence $U_1 \cap U_2 \to U_1 \in F^+$.

A schema $\mathcal{R} = (U, F)$ is in 3NF if for every FD $X \to A \in F^+$ holds:

- $X$ is a superkey, i.e. a key is a part of $X$, or
- $A$ is prime.

The second condition says that only prime attributes may be functionally dependent on a set of attributes which is not a key. A schema is in BCNF if only the first condition of the two above is allowed. It means, that if whenever a set $X$ determines functionally an attribute $A$, then $X$ is a superkey, i.e. determines the whole set $U$.

The aim of a normalization process is to develop normal forms by analyzing functional dependencies and successive decomposition of the input relational schema into its projections. This way a well-designed schema can be obtained, where unnecessary redundancies and update anomalies had been eliminated. In practice, 3NF is accepted as the most desirable form of relational schemas It does not eliminate all redundancies but guaranties dependency preservation. On contrast, BCNF eliminates all redundancies but does not preserve all dependencies. In [13] it was shown that 3NF has the least amount of redundancy among all dependency preserving normal forms. The research adopts a recently proposed information-theoretic framework for reasoning about database designs [10].

### C. Relational analysis of XML schema

Let us consider the relational representation of data structure presented in Fig. 1. Then we have the following relational schema:

$$\begin{aligned}
\mathcal{R} = \;& (U, F),\ \text{where} \\
U = \;& \{oId, sId, pId, price, delivTime, delivPlace\}, \\
F = \;& \{oId \to sId, pId, price, delivTime, delivPlace, \\
& \; sId, pId \to delivPlace, \\
& \; delivPlace \to sId\}.
\end{aligned}$$

In $\mathcal{R}$ there is only one *key*. The key consists of one attribute $oId$ since all attributes in $U$ functionally depends on $oId$. Thus, $R$ is in 2NF and $oId$ is the only prime (key) attribute in $\mathcal{R}$. Additionally, we assume that a given supplier delivers a given part exactly to one place ($pId, sId \to delivPlace$). Moreover, delivery place $delivPlace$ is connected with only one supplier ($delivPlace \to sId$).

$R$ is not in 3NF because for the functional dependency $sId, pId \to delivPlace$:

- $sId, pId$ is not a superkey, and
- $delivPlace$ is not a prime attribute in $U$.

Similarly for $delivPlace \to sId$.

The lack of 3NF is the source of redundancies and update anomalies. Indeed, for example, the value of $delivPlace$ will be repeated as many times as many different tuples with the same value of the pair $(sId, pId)$ exist in the instance of $\mathcal{R}$. To eliminate this drawback, we can decompose $\mathcal{R}$ into two relational schemas, $\mathcal{R}_1$ and $\mathcal{R}_2$, which are in 3NF. The decomposition must be based on the dependency $sId, pId \to delivPlace$ which guarantees that the decomposition preserves data. As a result, we obtain:

$$\begin{aligned}
\mathcal{R}_1 = \;& (U_1, F_1),\ \text{where} \\
U_1 = \;& \{oId, sId, pId, price, delivTime\}, \\
F_1 = \;& \{oId \to sId, pId, price, delivTime\}.
\end{aligned}$$

$$\begin{aligned}
\mathcal{R}_2 = \;& (U_2, F_2),\ \text{where} \\
U_2 = \;& \{sId, pId, delivPlace\}, \\
F_2 = \;& \{sId, pId \to delivPlace, \\
& \; delivPlace \to sId\}.
\end{aligned}$$

The discussed decomposition is both data and dependencies preserving, since:

$$R(U) = \pi_{U_1}(R) \bowtie \pi_{U_2}(R),$$

for every instance $R$ of schema $\mathcal{R}$, and

$$F = (F_1 \cup F_2)^+.$$

However, we see that $\mathcal{R}_2$ is not in BCNF, since $delivPlace$ is not a superkey in $\mathcal{R}_2$.

The lack of BCNF in $\mathcal{R}_2$ is the reason of redundancies. For example, in table $R_2$ we have as many duplicates of $sId$ as

$R_2$

| $sId$ | $pId$ | $delivPlace$ |
|---|---|---|
| s1 | p1 | d1 |
| s1 | p2 | d1 |
| s1 | p3 | d2 |
| s2 | p1 | d3 |

many tuples with the same value of $delivPlace$ exist in this table.

We can further decompose $\mathcal{R}_2$ into BCNF schemas $\mathcal{R}_{21}$ and $\mathcal{R}_{22}$, taking $delivPlace \rightarrow sId$ as the base for the decomposition. Then we obtain:

$$\begin{aligned}\mathcal{R}_{21} = &\ (U_{21}, F_{21}),\ \text{where}\\ U_{21} = &\ \{delivPlace, sid\},\\ F_{21} = &\ \{delivPlace \rightarrow sId\}.\end{aligned}$$

$$\begin{aligned}\mathcal{R}_{22} = &\ (U_{22}, F_{22}),\ \text{where}\\ U_{22} = &\ \{pId, delivPlace\},\\ F_{22} = &\ \emptyset.\end{aligned}$$

After applying this decomposition to $R_2$ we obtain tables $R_{21}$ and $R_{22}$:

$R_{21}$

| $sId$ | $delivPlace$ |
|---|---|
| s1 | d1 |
| s1 | d2 |
| s2 | d3 |

$R_{22}$

| $pId$ | $delivPlace$ |
|---|---|
| p1 | d1 |
| p2 | d1 |
| p3 | d2 |
| p1 | d3 |

This decomposition is information preserving, i.e.

$$R_2 = R_{21} \bowtie R_{22},$$

but does not preserve functional dependencies, i.e.

$$F_2 \neq (F_{21} \cup F_{22})^+ = F_{21}.$$

We can observe some negative consequences of the loss of functional dependencies in the result decomposition.

Assume that we insert the tuple $(p1, d2)$ into $R_{22}$. The tuple will be inserted because it does not violate any constrain imposed on $\mathcal{R}_{22}$. However, taking into account table $R_{21}$ we see that supplier $s1$ (determined by $d2$ in force of $delivPlace \rightarrow sId$) offers part $p1$ in the place $d1$. Thus, the considered insertion violates functional dependency $sId, pId \rightarrow delivPlace$ defined in $\mathcal{R}_2$.

The considered example shows that in the case of relational databases we are not able to completely eliminate redundancies and also preserve all functional dependencies. It turns out ([13]) that the best form for relation schema is 3NF, although some redundancies in tables having this form can still remain.

In next section we will show that the hierarchical structure of XML documents can be used to overcome some of the limitations of relational normal forms [11]. As it was shown in [12], there are decompositions of XML schemas that are both information and dependency preserving. In particular, we can obtain a form of XML schema that is equivalent to BCNF, i.e. eliminates all redundancies, and additionally preserves all XML functional dependencies.

## IV. XML SCHEMAS AND INSTANCES

Schemas for XML data are usually specified by DTD or XSD [17]. In this section we will define XML schema by means of *tree-pattern formulas* (TPF) [18], [15]. Furthermore, we do not consider attributes in XML trees since they can always be represented by elements. Schemas will be used to specify structures of *XML trees*. Some other properties of XML trees are defined as *schema constraints*.

*Definition 4.1:* Let $L$ be a set of *labels*, and $\mathbf{x}$ be a vector of variables. A schema TPF over $L$ and $\mathbf{x}$ is an expression conforming to the syntax:

$$\begin{aligned} S\ &::=\ /l[E]\\ E\ &::=\ l = x \mid l[E] \mid E \wedge ... \wedge E,\end{aligned}$$

where $l \in L$, and $x \in \mathbf{x}$. In order to indicate the set and ordering of variables in $S$ we will write $S(\mathbf{x})$.

□

*Example 4.1:* For the schema tree from Fig. 1, the schema TPF has the following form:

$$\begin{aligned} S_1 = \ &/db[part[pId = x_1 \wedge supplier[offer[\\ &oid = x_2 \wedge sid = x_3 \wedge price = x_4 \wedge\\ &delivTime = x_5 \wedge delivTime = x_6]]]].\end{aligned}$$

□

We see that a schema TPF has the following properties:

- reflects the tree structure of XML data,
- binds variables to paths in the schema tree,
- is a well-formed XPath predicate according to [19].

*Definition 4.2:* Let $S$ be a schema TPF over $\mathbf{x}$ and let an atom $l = x$ occur in $S$. Then the path $p$ starting in the root and ending in $l$ is called the type of the variable $x$, denoted $type_S(x) = p$.

□

The type of $x_1$ in $S_1$ is: $type_{S_1}(x_1) = /db/part/pId$.

An XML database consists of a set of XML data. We define XML data as an unordered rooted node-labeled tree (XML tree) over a set $L$ of labels, and a set $Str \cup \{\perp\}$ of strings and the distinguished null value $\perp$ (both strings and the null value, $\perp$, are used as values of text nodes).

*Definition 4.3:* An *XML tree* $I$ is a tuple $(r, N^e, N^t, child, \lambda, \nu)$, where:

- $r$ is a distinguished *root node*, $N^e$ is a finite set of *element nodes*, and $N^t$ is a finite set of *text nodes*;
- $child \subseteq (\{r\} \cup N^e) \times (N^e \cup N^t)$ – a relation introducing tree structure into the set $\{r\} \cup N^e \cup N^t$, where $r$ is the root, each element node has at least one child (which is an element or text node), text nodes are leaves;
- $\lambda : N^e \rightarrow L$ – a function labeling element nodes with names (labels);
- $\nu : N^t \rightarrow Str \cup \{\perp\}$ – a function labeling text nodes with *text values* from $Str$ or with the null value $\perp$.

□

It will be useful to perceive an XML tree $I$ with schema $S$ over tuple of variables $\mathbf{x}$, as a pair $(S, \Omega)$ (called a $description$), where $S$ is the schema TPF, and $\Omega$ is a set of valuations of variables in $\mathbf{x}$. A valuation $\omega \in \Omega$ is a function assigning values from $Str \cup \{\perp\}$ to variables in $\mathbf{x}$, i.e. $\omega \ : \ \mathbf{x} \rightarrow Str \cup \{\perp\}$.

*Example 4.2:* The instance $I_1$ in Figure 3 can be represented by the following description:

$I_1 := (S_1(x_1, x_2, x_3, x_4, x_5, x_6), \{(p1, o1, s1, x1, t1, d1),$
$(p1, o2, s1, x2, t2, d1), (p1, o3, s2, x3, t3, d2),$
$(p2, o4, s1, x4, t4, d1)\})$.

□

An XML tree $I$ satisfies a description $(S, \Omega)$, denoted $I \models (S, \Omega)$, if $I$ satisfies $(S, \omega)$ for every $\omega \in \Omega$, where this satisfaction is defined as follows:

*Definition 4.4:* Let $S$ be a schema TPF over $\mathbf{x}$, and $\omega$ be a valuation for variables in $\mathbf{x}$. An XML tree $I$ satisfies $S$ by valuation $\omega$, denoted $I \models (S, \omega)$, if the root $r$ of $I$ satisfies $S$ by valuation $\omega$, denoted $(I, r) \models (S, \omega)$, where:

1) $(I, r) \models (/l[E], \omega)$, iff $\exists n \in N^e \ child(r, n) \wedge (I, n) \models (l[E], \omega)$;
2) $(I, n) \models (l[E_1 \wedge ... \wedge E_k], \omega)$, iff $\lambda(n) = l$ and $\exists n_1, ..., n_k \in N^e(child(n, n_i) \wedge (I, n_i) \models (E_i, \omega))$ for $1 \leq i \leq k$;
3) $(I, n) \models (l = x, \omega)$, iff $\lambda(n) = l$ and $\exists n' \in N^t(child(n, n') \wedge \nu(n') = \omega(x))$.

□

A description $(S, \Omega)$ represents a class of $S$ instances with the same set of values (the same $\Omega$), since elements in instance trees can be grouped and nested in different ways.

For example, the XML tree in Fig. 4 satisfies two descriptions $(S_1, \Omega_1)$, and $(S_2, \Omega_2)$ where:

$$\begin{aligned} S_1 = \ & /A[B = x_1 \wedge C = x_2], \\ \Omega_1 = \ & \{(b, c1), (b, c2)\}; \\ \\ S_2 = \ & /A[B = x_1 \wedge C = x_2 \wedge D = x_3], \\ \Omega_2 = \ & \{(b, c1, d1), (b, c2, d1)\}. \end{aligned}$$

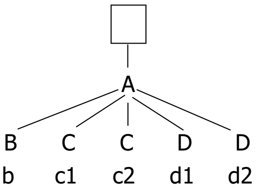

Fig. 4. A simple XML tree

## V. XML FUNCTIONAL DEPENDENCIES AND KEYS

Over a schema TPF we can define some constraints, which specify functional dependencies between values and/or nodes in instances of the schema. These constraints are called XML functional dependencies (XFD).

*Definition 5.1:* An XML functional dependency (XFD) over a set $L$ of *labels* and a set $\mathbf{x}$ of variables is an expression with the syntax:

$$\begin{aligned} fd \ & ::= \ /P[C]/.../P[C], \\ P \ & ::= \ l \mid P/l, \\ C \ & ::= \ TRUE \mid P = x \mid C \wedge ... \wedge C, \end{aligned} \tag{1}$$

where $l \in L$, and $x$ is a variable in $\mathbf{x}$. If variable names are significant, we will write $fd(\mathbf{x})$.

□

An XFD is an XPath expression that for a given valuation $\omega$ of its variables returns a sequence of objects (nodes or text values). An XML tree $I = (S, \Omega)$ satisfies an XFD $f(x_1, ..., x_k)$ if for each valuation $\omega \in \Omega$ of its variables, $f(x_1, ..., x_k)$ returns a singleton.

*Definition 5.2:* Let $I$ be an instance of schema TPF $S(\mathbf{x})$ and $f$ be an XFD defined over $S$. The instance $I$ satisfies $f$, denoted $I \models f$, if for every valuation $\omega$ of variables in $\mathbf{x}$, the implication holds

$$I \models (S, \omega) \Rightarrow count([\![f(\omega)]\!]) \leq 1,$$

where $[\![f(\omega)]\!]$ is the result of $f$ computed by the valuation $\omega$.

□

In the following example we discuss some XFDs over $S_1$.

*Example 5.1:* Over $S_1$ the following XFDs can be defined:

$$\begin{aligned} f_1(x) \ & = \ /db/part[supplier/offer/oId = x], \\ f_2(x) \ & = \ /db/part[supplier/offer/oId = x]/pId, \\ f_3(x_1, x_2) \ & = \ /db/part[pId = x_1]/supplier/offer[ \\ & \quad\ sId = x_2]/delivPlace, \\ f_4(x) \ & = \ /db/part/supplier/offer[ \\ & \quad\ delivPlace = x]/sId, \\ f_5(x_1, x_2) \ & = \ /db/part[pId = x_1]/supplier[ \\ & \quad\ offer/sId = x_2]. \end{aligned}$$

According to XPath semantics [19] the expression $f_1(x)(\omega)$ is evaluated against the instance $I_1$ as follows: (1) first, a set of nodes of type $/db/part$ is chosen; (2) next, for each chosen node the predicate $[supplier/offer/oId = x]$ is tested, this predicate is true in a node $n$, if there exists a path of type $supplier/offer/oId$ in $I_1$ leading from $n$ to a text node with the value $\omega(x)$. We see that $count([\![f_1(x)(\omega)]\!])$ equals 1 for all four valuations satisfied by $I_1$, i.e. for $\omega_i = [x \mapsto o_i]$, $1 \leq i \leq 4$.

Similarly, execution of $f_2(x)(\omega)$ returns a text value of the path $/db/part/pId$, where from the set of nodes determined by $/db/part$ are taken only nodes satisfying the predicate $[supplier/offer/oId = \omega(x)]$. We see that also this XFD is satisfied by $I_1$.

However, none of the following XFDs is satisfied in $I_1$:

$$\begin{aligned} g_1(x) \ & = \ /db/part[supplier/offer/sId = x], \\ g_2(x) \ & = \ /db/part[pId = x]/supplier/offer/sId \\ g_3(x) \ & = \ /db/part[pId = x]/supplier/offer \\ g_4(x_1, x_2) \ & = \ /db/part[pId = x_1]/supplier/offer[ \\ & \quad\ sId = x_2], \\ g_5(x) \ & = \ /db/part/pId/supplier/offer[ \\ & \quad\ delivPlace = x]. \end{aligned}$$

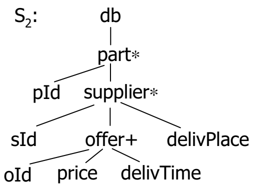

Fig. 5. Restructured form of schema in Fig. 1

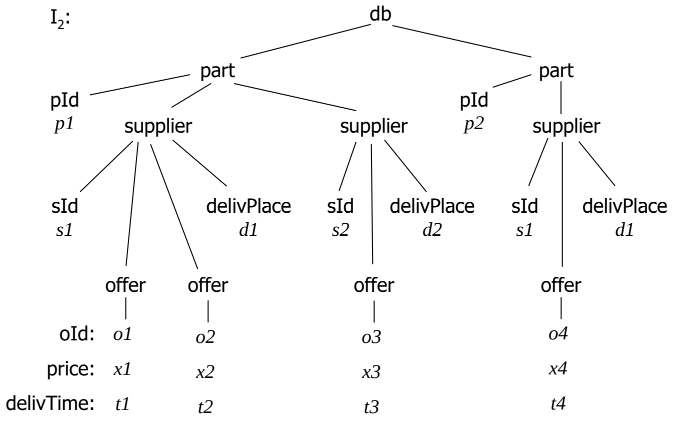

Fig. 6. Instance of schema in Fig. 5

Evaluating the above XFDs against $I_1$, we obtain:

$$\begin{array}{lcl} count([\![g_1(x)([x \mapsto s1])]\!]) & = & 2, \\ count([\![g_2(x)([x \mapsto p1])]\!]) & = & 2, \\ count([\![g_3(x)([x \mapsto p1])]\!]) & = & 3, \\ count([\![g_4(x_1,x_2)([x_1 \mapsto p1, x_2 \mapsto s1])]\!]) & = & 2, \\ count([\![g_5(x)([x \mapsto d1])]\!]) & = & 3. \end{array}$$

An XFD can determine functional relationship between a tuple of text values of a given tuple of paths and a path denoting either a text value (e.g. $f_2(x)$) or a subtree (a node being the root of the subtree) (e.g. $f_1(x)$).

There are also different notations to express functional notations. For example, according to the notation used in [11], the XFD $f_5(x_1, x_2)$ can be expressed as:

$$\begin{array}{l} db.part.@pId, db.part.supplier.offer.@sId \rightarrow \\ db.part.supplier, \end{array}$$

and using the language proposed in [20], as

$$\begin{array}{l} (db.part, \{pId\}), \\ (db.part, (supplier, \{offer/sId\})), \end{array}$$

where the first expression is an *absolute key* saying that $db.part$ is absolutely determined by $pId$, and the second expression is a *relative key* saying that in the context of $db.part$ a tree $supplier$ is determined by the path $offer.sId$.

Further on, by $(S, F)$ we will denote a schema TPF $S$ together with a set of XFDs defined over $S$. The closure of $(S, F)$, denoted by $(S, F)^+$, is the schema TPF $S$ and the set of all XFDs which can be derived from $(S, F)$.

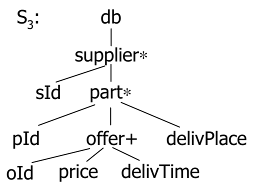

Fig. 7. Restructured form of schema in Fig. 1

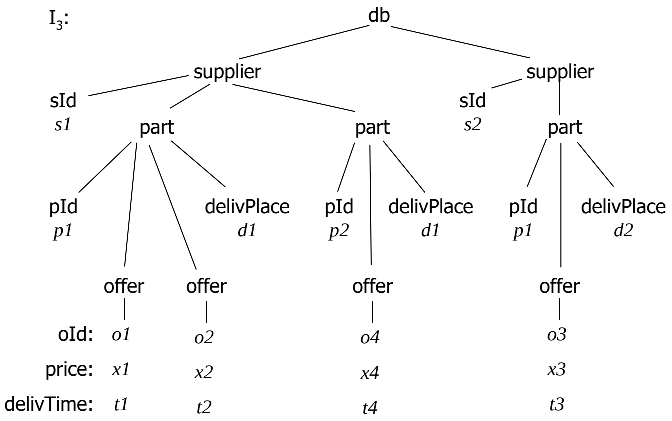

Fig. 8. Instance of schema in Fig. 7

## VI. Normal form for XML

To eliminate redundancies in XML documents, some normal forms for XML schemas have been proposed [21], [11], [2], [12]. We will define XNF (XML Normal Form) using tree-pattern formulas and functional dependencies defined in the previous section and adapting the approach proposed in [21].

*Definition 6.1:* Let $S$ be a schema TPF and $F$ be a set of functional dependencies over $S$. $(S, F)$ is in XML normal form (XNF) iff for every XFD $f/l \in (S, F)^+$, also $f \in (S, F)^+$, i.e.

$$(S, F) \text{ is in } XNF \text{ iff } f/l \in (S, F)^+ \Rightarrow f \in (S, F)^+.$$

□

Intuitively, let $f(x_1, ..., x_k)/l$ be XFD and $I$ be an instance of $S$. $I$ satisfies $f(x_1, ..., x_k)/l$, if for any valuation $\omega$ of the tuple of variables $(x_1, ..., x_k)$, there is at most one text value of the type $type(f/l)$. Thus, to avoid redundancies, for every valuation of $(x_1, ..., x_k)$ we should store the value of $f/l$ only once, i.e. there must be only one subtree of type $type(f)$ denoted by the expression $f(x_1, ..., x_k)$. In other words, XFD $f$ must be implied by $(S, F)$ [11].

Let us consider schema $S_2$ in Fig. 5 and its instance $I_2$ in Fig. 6. Then

$$f(x_1)/sId = /db/part/supplier[delivPlace = x_1]/sId$$

is XFD over $S_2$. This dependency corresponds to relational functional dependency $delivPlace \rightarrow sId$ and says that delivery place determines the supplier ($sId$).

However, $S_2$ is not in XNF, since its instance $I_2$ does not satisfy

$$f(x_1) = /db/part/supplier[delivPlace = x_1],$$

because for the valuation $\omega = [x_1 \mapsto "d1"]$ there are two different element nodes $supplier$ with value $d1$ of $delivPlace$. It means that $I_2$ is not free of redundancy.

In the case of schema $S_3$ (Fig. 7) the corresponding XFD has the form:

$$f(x_1)/sId = /db/supplier[part/delivPlace = x_1]/sId.$$

This dependency and also the XFD

$$f(x_1) = /db/supplier[part/delivPlace = x_1]$$

are satisfied by $I_3$ in Fig. 8. We see that this time for the valuation $\omega = [x_1 \mapsto "d1"]$, there is only one element node of type $supplier$ from which we can reach $delivPlace$ with value $d1$. This means that schema $S_3$ not only captures the XML functional dependency under consideration, but also is free of redundancies which may be caused by capturing this dependencies that happens in the case of schema $S_2$.

The other dependency of interest is $sId, pId \to delivPlace$. Its specification with respect to $S_2$ and $S_3$ is as follows:

$$/db/part[pId = x_1]/supplier[sId = x_2]/delivPlace,$$

and

$$/db/supplier[sId = x_1]/part[pId = x_2]/delivPlace.$$

It is easy to show that if these XFDs are satisfied by valuations, respectively, $\omega$ and $\omega'$ in instances of $S_2$ and $S_3$, then also

$$/db/part[pId = x_1]/supplier[sId = x_2],$$

and

$$/db/supplier[sId = x_1]/part[pId = x_2]$$

are satisfied by these valuations and these instances.

However, neither $S_2$ nor $S_3$ is in XNF. We have already shown that there is redundancy in instances of $S_2$. Similarly, we see that also in instances of $S_3$ redundancies may occur. Indeed, since one part may be delivered by many suppliers then the description of one part may be multiplied under each supplier delivering this part, so such data as *part name*, *type*, *manufacturer* etc. will be stored many times.

In Fig. 9 there is the final schema, $S_4$, for schemas under considerations: $S_1$, $S_2$, and $S_3$; $S_4$ is in XNF. To make the example more illustrative, we added node $name$ to $part$ data. Also the instance in Fig. 10 was slightly extended as compared with instances $I_2$ and $I_3$.

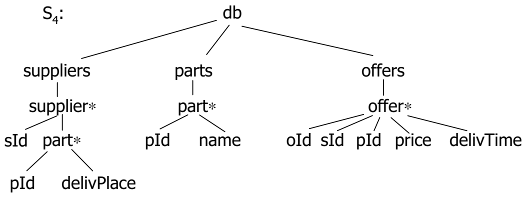

Fig. 9. XNF schema of schemas $S_1$, $S_2$, and $S_3$

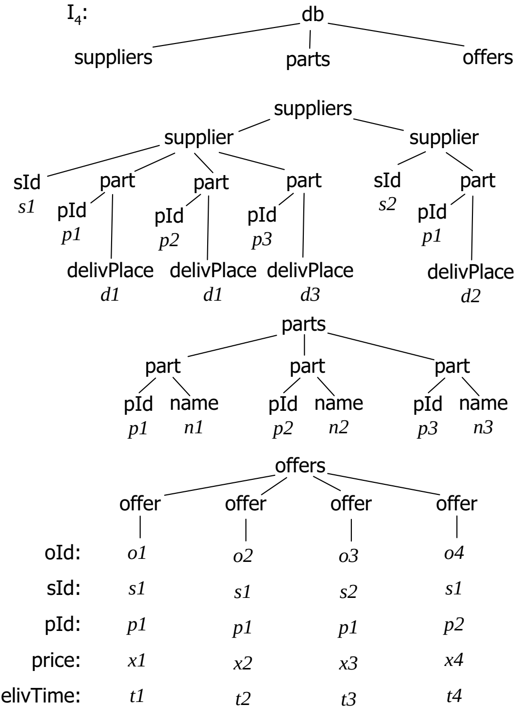

Fig. 10. Instance of schema in Fig. 9

XSD (XML Schema Definition) for $S_4$ in notation proposed in [17] is shown in Fig. 11.

$$\begin{array}{lll}
db & \to & \mathrm{db}[content] \\
content & \to & \mathrm{suppliers}[suppliers], \mathrm{parts}[parts], \\
 & & \quad \mathrm{offers}[offers] \\
suppliers & \to & \mathrm{supplier}[supplier]* \\
parts & \to & \mathrm{parts}[part_1]* \\
offers & \to & \mathrm{offers}[offer]* \\
supplier & \to & \mathrm{sId}[\epsilon], \mathrm{part}[part_2] \\
part_2 & \to & \mathrm{pId}[\epsilon], \mathrm{delivPlace}[\epsilon] \\
part_1 & \to & \mathrm{pId}[\epsilon], \mathrm{name}[\epsilon] \\
offer & \to & \mathrm{oId}[\epsilon], \mathrm{sId}[\epsilon], \\
 & & \quad \mathrm{pId}[\epsilon], \mathrm{price}[\epsilon], \mathrm{delivTime}[\epsilon]
\end{array}$$

Fig. 11. An XSD describing the XML schema in Fig. 9. The symbol $\epsilon$ denotes the empty string.

Note that we cannot use DTD since there are two subtrees labeled $part$, where each of them has different type: the $part$ subtree under $supplier$ consists of $pId$ and $delivPlace$, whereas the $part$ subtree under $parts$ consists of $pId$ and $name$. Recall that in the case of DTD each nonterminal symbol (label) can have only one type (definition), i.e. can appear on the left-hand side of exactly one production rule [17].

A set of XFDs for $S_4$ is defined in Fig. 12. XFDs derived from them are listed in Fig. 13.

$$\begin{array}{lcl}
f_1(x) & = & /db/suppliers/supplier[sId = x] \\
f_2(x_1, x_2) & = & /db/suppliers/supplier[sId = x]/ \\
 & & \quad part[pId = x_2]/delivPlace \\
f_3(x) & = & /db/suppliers/supplier[ \\
 & & \quad part/delivPlace = x]/sId \\
f_4(x) & = & /db/parts/part[pId = x]/name \\
f_5(x_1, x_2) & = & /db/offers/offer[sId = x_1 \wedge \\
 & & \quad pId = x_2]/oId \\
f_6(x) & = & /db/offers/offer[oId = x]/price \\
f_7(x) & = & /db/offers/offer[oId = x]/delivTime
\end{array}$$

Fig. 12. A set of XFD for the schema $S_4$

$$\begin{array}{lcl}
f'_2(x_1, x_2) & = & /db/suppliers/supplier[sId = x]/ \\
 & & \quad part[pId = x_2] \\
f'_3(x) & = & /db/suppliers/supplier[ \\
 & & \quad part/delivPlace = x] \\
f'_4(x) & = & /db/parts/part[pId = x] \\
f'_5(x_1, x_2) & = & /db/offers/offer[sId = x_1 \wedge pId = x_2] \\
f'_6(x) & = & /db/offers/offer[oId = x]
\end{array}$$

Fig. 13. A set of XFD derived from those in Fig. 12

We see that the schema $S_4$ satisfies the condition of XNF. Thus, this schema is both redundant-free and dependency preserving.

## VII. Conclusion

In this paper, we discussed how the concept of database normalization can be used in the case of XML data. Normalization is commonly used to develop a relational schema free of unnecessary redundancies and preserving all data dependencies existing in application domain. In order to apply this approach to design XML schemas, we introduced a language for expressing XML functional dependencies. In fact, this language is a class of XPath expressions, so its syntax and semantics are defined precisely. We define the notion of satisfaction of XML functional dependence by an XML tree. To define XNF we use the approach proposed in [11].

All considerations are illustrated by the running example. We discuss various issues connected with normalization and compare them with issues faced in the case of relational databases. We show how to develop redundancy-free and dependency preserving XML schema. It is worth mentioning that the relational version of the schema cannot be structured in redundancy-free and dependency preserving form. In this case, preservation of all dependencies requires 3NF but then some redundancy is present. Further normalization to BCNF eliminates redundancies but does not preserve dependencies. In the case of XML, thanks to its hierarchical nature, we can achieve both properties. However, it is not clear if this is true in all cases (see e.g. [12]).

In [15], [22], [23], XML functional dependencies (XFD) have been used in XML data integration settings, in particular for controlling query propagation in P2P environment and for reconciliation of inconsistent data.

# Separation of Crosscutting Concerns at the Design Level: an Extension to the UML Metamodel.

Adam Przybyłek
Gdańsk University, Department of Business Informatics,
Piaskowa 9, 81-824 Sopot, Poland
Email: adam@univ.gda.pl

***Abstract*—Aspect-oriented programming (AOP) was proposed as a way of improving the separation of concerns at the implementation level by introducing a new kind of modularization unit - an aspect. Aspects allow programmers to implement crosscutting concerns in a modular and well-localized way. As a result, the well-known phenomena of code tangling and scattering are avoided. After a decade of research, AOP has gained acceptance within both academia and industry. The current challenge is to incorporate aspect-oriented (AO) concepts into the software design phase. Since AOP is built on top of OOP, it seems natural to adapt UML to AO design. In this context the author introduces an extension to the UML metamodel to support aspect-oriented modelling.**

## I. Introduction

### *A. The evolution of the aspect-oriented paradigm*

THE TERM "crosscutting concern" describes part of a software system that should belong to a single module, but cannot be modularized because of the limited abstractions of the underlying programming language [20], [27], [33]. When crosscutting concerns are implemented using an object-oriented (OO) language, their code usually spreads over several core concerns [20], [26], [27]. Aspect-oriented programming (AOP) overcomes this problem by introducing a new unit of modularity—an aspect. Aspects allow programmers to avoid the well-known phenomena of code tangling and scattering, which adversely affect the readability, understandability, maintainability and reusability of the software [6], [20], [27], [30].

Programming and modelling languages exist in a relationship of mutual support. A software design co-ordinates well with a programming language when the abstraction mechanisms provided at both levels correspond to each other [26]. Successful adoption of AOP in both academia and industry has led to growing interest in aspect-oriented (AO) techniques for the whole software development lifecycle. Currently, one of the most active topics of research is modelling languages in support of aspect-orientation. Taking into account that (1) UML is considered to be the industry standard for OO system development and that (2) the AO paradigm complements the OO paradigm, it is quite natural to investigate UML as a possibility for the notation for aspect-oriented modelling (AOM) [2]–[4], [7], [18], [25], [28], [32], [34], [37]. Although UML was not designed to provide constructs to describe aspects, its flexible and extensible metamodel enables it to be adapted for domain-specific modelling [4], [23]. Thus in recent years a large number of proposals have been put forward in this area, but none of them has gained common acceptance. This paper is one more step towards closing the gap between AO concepts and UML.

### *B. The UML extensibility mechanisms*

There are two alternative methods of extending UML to incorporate aspects: by elaborating a Meta Object Facility [1] (MOF) metamodel or by constructing a UML profile. A UML profile is a predefined set of stereotypes, tagged values, constraints, and graphical icons which enable a specific domain to be modelled [1], [7], [9], [23], [30], [35]. It was defined to provide a light-weight extension mechanism [23], termed light-weight because it does not define new elements in the metamodel of UML. The intention of profiles is to give a straightforward mechanism for adapting the standard UML metamodel with constructs that are specific to a particular domain [23]. The advantages of choosing the light-weight extension mechanism are that models can be defined by applying a well-known notation and that generic UML tools can be used. On the other hand, the drawbacks are that, since stereotypes are extensions to the existing elements, certain principles of the original elements must be observed, and consequently expressiveness is constrained.

Elaborating an MOF metamodel is referred to as heavy-weight extension and is harder than constructing a profile. It also has far less tool support. However, the metamodel constructed can be as expressive as required. Another drawback of the heavy-weight mechanism is the introduction of interdependency between specific versions of UML and its extensions. If UML changes in any way, its extensions may also have to change.

### *C. Motivation and goals*

In the last few years, research in to AOM has concentrated on providing UML profiles, while less attention has been given to constructing heavy-weight extensions. The common

[1] Meta Object Facility (MOF) is the Object Management Group (OMG) standard, specifying how to define, interchange and extend metamodels.

978-83-60810-14-9/08/$25.00 © 2008 IEEE

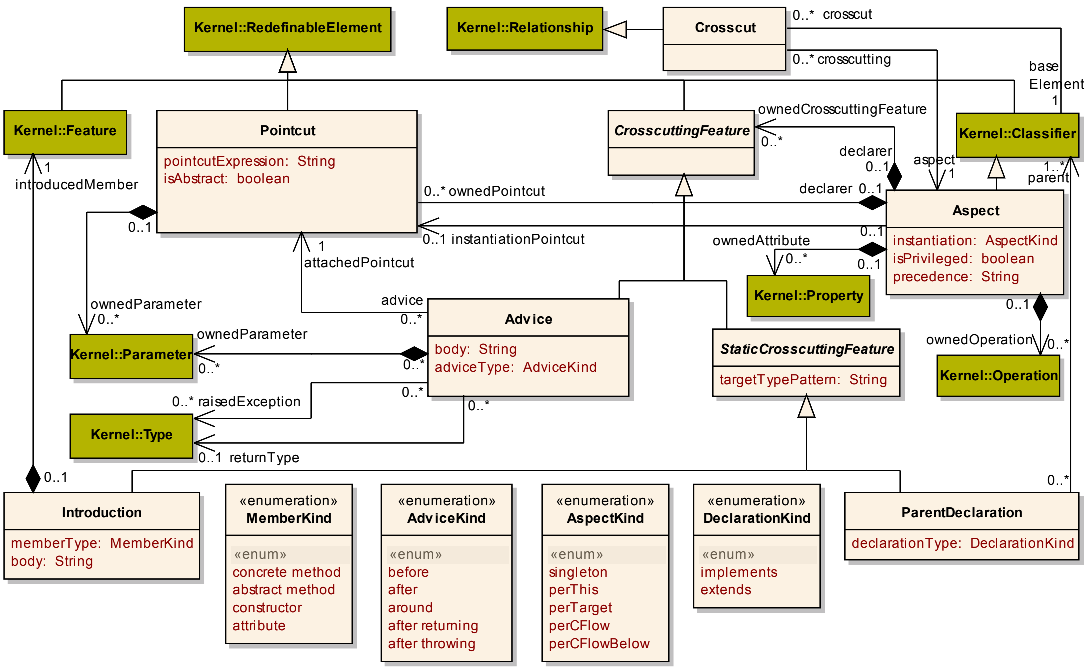

Fig. 1 . The AoUML package

practice [7], [9], [10] – [12], [22], [31], [32], [37] used to be to stereotype the class element as <<aspect>> and the method element as <<advice>>, although an aspect is not a class, nor is an advice a method. While such stereotyping was acceptable until UML 1.5, it can no longer be used; the 2.0 release requires semantic compatibility between a stereotyped element and the corresponding base element. In this context, using light-weight extensions is more an intermediate step in supporting the transition from OO modelling to AOM than a final solution.

The most valuable contributions to AOM have been made by Hachani [13], [14] and Yan [36], who proposed elaborately created and carefully specified metamodels for AspectJ. The main drawback of these extensions is the lack of graphical representation for new modelling elements. Moreover, they contain too much implementation detail and so seem to overwhelm the designer. Hachani's proposal is specified more strictly and in a more formal fashion but now needs updating, because it extends UML 1.4.

The motivation behind this research is to integrate the best practices of the existing AO extensions (particularly [5], [7], [13], [14], [16], [17], [19], [21], [29], [31], [32]) and to define a MOF metamodel that supplements the UML with means to AOM. The metamodel, which is presented in the next section, is based on the AspectJ approach to the AO paradigm. AspectJ has been chosen as the most representative AO programming language because of its mature implementation, industrial-strength tool support and wide popularity. Efforts [1], [8], [13], [28] to create a generic metamodel which could be fitted to each AO implementation have been unsuccessful, because a metamodel of this kind introduces an impedance mismatch between the design constructs and the language constructs. The conceptual differences between aspect implementations such as AspectJ, JAsCo, Spring, AspectWerkz are significant and cannot be captured effectively in a single metamodel. Moreover, generalizing aspects at the design level would be counter-productive at a time when AspectJ is squeezing out other technology at the implementation level.

## II. An extension to the UML metamodel

The elaborated extension is described by using a similar style to that of the UML metamodel. As such, the specification uses a combination of notations:

- UML class diagram – to show what constructs exist in the extension and how the constructs are built up in terms of the standard UML constructs;
- OCL – to establish well-formedness rules;
- natural language – to describe the semantic of the meta-classes introduced.

The proposed extension introduces a new package, named AoUML, which contains elements to represent the fundamental AO concepts of aspect, pointcut, advice, introduction, parent declaration and crosscutting dependency (Fig. 1).

The proposal reuses elements from the UML 2.1.2 infrastructure and superstructure specifications by importing the Kernel package. Fig. 2 shows the dependencies between the UML Infrastructure [23], the UML Superstructure [24] and the AoUML package.

### *A. Aspect meta-class*

#### *1) Semantic s*

An Aspect is a classifier that encapsulates the behaviour and structure of a crosscutting concern. It can, like a class, realize interfaces, extend classes and declare attributes and

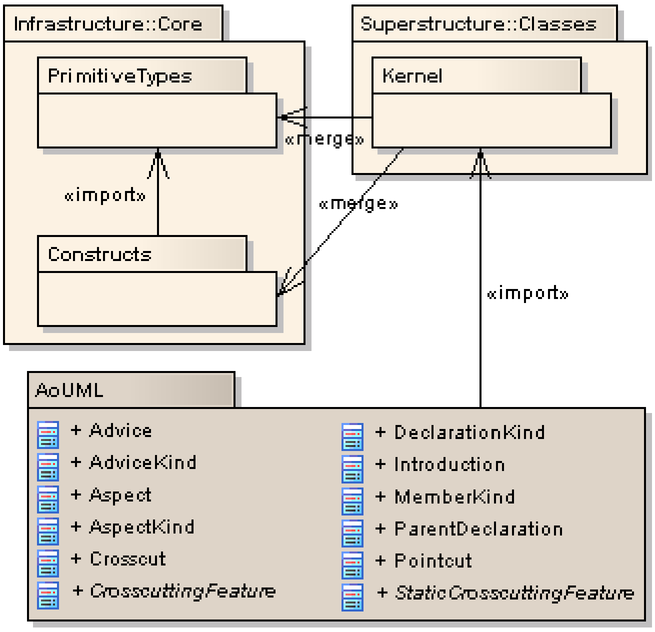

Fig. 2 . Dependencies between packages

operations. In addition, it can extend other aspects and declare advices, introductions and parent declarations.

*2) Attributes*

isPrivileged – if true, the aspect code is allowed to access private members of target elements as a "friend"; the default is false.

instantiation – specifies how the aspect is instantiated; the default is a singleton.

precedence – declares a precedence relationship between concrete aspects.

*3) Associations*

ownedPointcut – a set of pointcuts declared within the aspect.

instantiationPointcut – the pointcut which is associated with a per-clause instantiation model.

ownedCrosscuttingFeature – a set of crosscutting features owned by the aspect.

ownedAttribute – a set of attributes owned by the aspect.

ownedOperation – a set of operations owned by the aspect.

*4) Notation*

The aspect element looks similar to the class but has additional sections for pointcuts and crosscutting features declarations. Fig. 3 provides a graphical representation for an aspect.

### *B. CrosscuttingFeature meta-class*

*1) Semantic s*

A CrosscuttingFeature is an abstract meta-class, which declares a dynamic (an advice) or static feature to be combined to some target elements.

*2) Associations*

declarer – the aspect that owns this crosscutting feature.

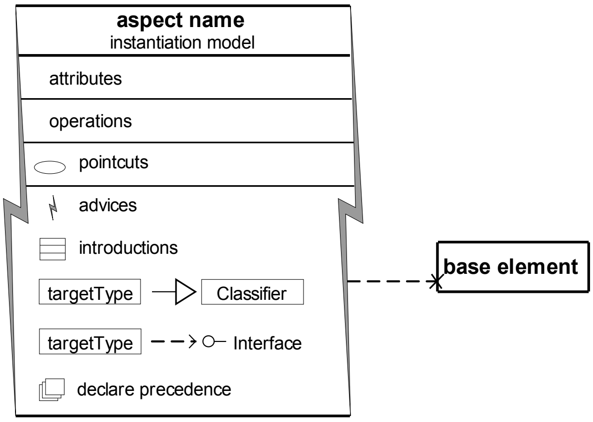

Fig. 3 . Aspect representation

### *C. StaticCrosscuttingFeature meta-class*

*1) Semantic s*

A StaticCrosscuttingFeature is a crosscutting feature that can be woven with core concerns on the basis of information available before runtime.

*2) Attributes*

targetTypePattern – a pattern that matches classes, interfaces or aspects which are affected by the crosscutting feature.

### *D. Introduction meta-class*

*1) Semantics*

An Introduction allows designers to add new attributes or methods to classes, interfaces or aspects.

*2) Attributes*

memberType – specifies the kind of the inter-type member declaration.

*3) Associations*

introducedMember – the new member which has to be added to the target type.

### *E. ParentDeclaration meta-class*

*1) Semantics*

A ParentDeclaration allows designers to add super-types to classes, interfaces or aspects.

*2) Attributes*

declarationType – specifies the kind of the declaration.

*3) Associations*

parent – the type implemented or extended by the target type.

### *F. Advice meta-class*

*1) Semantic s*

An Advice is a dynamic crosscutting feature that affects the behaviour of base classifiers. Each advice has exactly one associated pointcut and specifies the code that executes at each join-point picked out by the pointcut. The advice is able to access values in the execution context of the pointcut.

*2) Attributes*

adviceType – specifies when the advice code is executed relative to the join-points picked out.

body – the code of the advice.

*3) Associations*

ownedParameter – an ordered list of parameters to expose the execution context.

attachedPointcut – refers to the pointcut that defines a set of join-points at which the advice code is to be executed.

raisedException – a set of checked exceptions that may be raised during execution of the advice.

returnType – specifies the return result of the operation, if present (the "before" and "after" advice cannot return anything).

*4) Constraints* [2]

Advice parameters should have a unique name:

self.ownedParameter->forAll (p1, p2 | p1.name = p2.name implies p1=p2).

The before and after advice cannot return anything:

(self.adviceType = #before or self.adviceType = #after) implies (self.ownedParameter->forAll ( p | p.kind = #in)).

An advice can have at most one return parameter:

self.ownedParameter->
select (par | par.direction = #return)->size() <= 1.

### *G. Pointcut meta-class*

*1) Semantics*

A Pointcut is designed to specify a set of join-points and obtain the context surrounding the join-points as well. Join-points are well-defined places in the program flow where the associated advice must be executed. The purpose of declaring a pointcut is to share its pointcut expression in many advices or other pointcuts. A pointcut cannot be overloaded.

*2) Attributes*

isAbstract—if true, the Pointcut does not provide a complete declaration; the default value is false.

pointcutExpression—if a pointcut is not abstract, it specifies a set of join-points picked out by this pointcut; it has the same form as in AspectJ.

*3) Associations*

ownedParameter—an ordered list of parameters specifying what data is passed from runtime context to the associated advice.

advice—an advice that executes when the program reaches the join points.

*4) Notation*

The pointcut signature is as follows:

[visibility-modifier] pointcut name([parameters]): PointcutExpression

### *H. Crosscut meta-class*

*1) Semantics*

A Crosscut is a directed relationship, from an aspect to one or more base elements, where the additional structure and/or behaviour will be combined.

*2) Associations*

aspect – the aspect specifying the crosscutting concern affecting the base element.

baseElement – refers to the classifier that is crosscut .

## III. An Example

This section illustrates how the presented extension works in practice by modelling the Observer pattern adopted from Hannemann and Kiczales [15]. The participants in the Observer pattern are subjects and observers. The subject is a data structure which changes over time (such as a figure), and the observer (a screen) is an object whose own invariants depend on the state of the subject (Fig. 4).

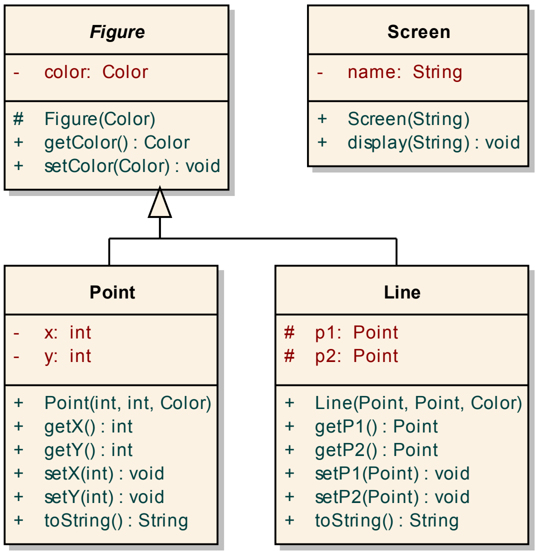

Fig. 4 . A typical scenario for the Observer pattern

The intent ion of the Observer pattern is to define a one-to-many dependency between a subject and multiple observers, so that when the subject changes state, all its observers are notified and updated automatically [15], [26]. The main problem with the OO implementation of this pattern is that it requires modification either to the structure of the classes that play the roles of Subjects and Observers or to the structure of the class hierarchy. It is therefore hard to apply the pattern to an existing design. Hanneman and Kiczales showed how the Observer pattern could effectively be implemented using AOP (Listing 1) [15].

To keep a figure display updated, the ColorObserver and PositionObserver aspects are introduced (Listing 2). Their after advices are triggered whenever a figure should be updated (the subjectChange pointcut is reached).

This paper shows how the Observer pattern could be specified using the AoUML extension. Fig. 5 gives a visual representation of Listing 1 and Listing 2.

## IV. Conclusion

The evolution of the AO paradigm is progressing from programming towards the design stage. Modularization of crosscutting concerns at the design phase should provide benefits in two areas: (1) the system model will be consistent with system implementation; (2) the artefacts developed will be more reusable and maintainable.

The contribution of this research is a MOF metamodel that enriches UML with constructs for modelling crosscutting

[2] Due to limitations on space, OCL constraints are not included for other elements.

```
public abstract aspect ObserverProtocol {
  protected interface Subject {};
  protected interface Observer {};
  private WeakHashMap perSubjectObservers;
  protected List getObservers(Subject s) {
    if (perSubjectObservers == null) perSubjectObservers = new WeakHashMap();
    List observers = (List)perSubjectObservers.get(s);
    if ( observers == null ) {
      observers = new LinkedList();
      perSubjectObservers.put(s, observers);
    }
    return observers;
  }
  public void addObserver(Subject s, Observer o) {
    getObservers(s).add(o);
  }
  public void removeObserver(Subject s, Observer o) {
    getObservers(s).remove(o);
  }
  protected abstract void updateObserver(Subject s, Observer o);

  protected abstract pointcut subjectChange(Subject s);
  after(Subject s): subjectChange(s) {
    Iterator iter = getObservers(s).iterator();
    while ( iter.hasNext() ) updateObserver(s, ((Observer)iter.next()));
  }
}
```

Listing 1. The AO implementation of the Observer pattern

concerns. Although many existing works on AOM either do not fit the UML standard or are not complete, there is some valuable research [7], [13], [14], [21], [36] which has inspired this work. Nevertheless, the presented research offers some advantages over these previous proposals. Firstly, the extension put forward is easier to comprehend for UML users than [14] and [21], while at the same time being powerful enough to express crosscutting concerns precisely.

```
public aspect ColorObserver extends ObserverProtocol {
  protected void updateObserver(Subject s, Observer o) {
    ((Screen)o).display(s + " has changed the color");
  }

  protected pointcut subjectChange(Subject s):
    call(void Figure.setColor(Color)) && target(s);
  declare parents: Point implements Subject;
  declare parents: Line implements Subject;
  declare parents: Screen implements Observer;
}

public aspect PositionObserver extends ObserverProtocol {
  protected void updateObserver(Subject s, Observer o) {
    ((Screen)o).display(s + " has changed the position");
  }

  protected pointcut subjectChange(Subject s): target(s) &&
    !call(void Figure.setColor(Color)) && call(void Figure+.set*(..));
  declare parents: Point implements Subject;
  declare parents: Line implements Subject;
  declare parents: Screen implements Observer;
}
```

  while ( iter.hasNext() ) updateObserver(s, ((Observer)iter.next()));
}
```

Fig. 5 . The class diagram using the AoUML extension

Moreover, in contrast to [7], [13], [14], [36] the presented metamodel provides dedicated icons for the aspect concepts. Graphical representation improves the understanding of models. Secondly, the proposal allows all aspect-related concepts to be specified in metamodel terms, so that no textual specification or notes are necessary. This means that automatic verification of the created models are simplified. Furthermore, the proposed metamodel does not modify the UML metamodel in any way; it merely adds some metaclasses. This contrasts with proposals that either are based on light-weight extensions [7] or modify the UML metamodel [13]. Thirdly, the extension put forward is adjusted to the newest UML specification (version 2.1.2). The main drawback of the proposal is that it has no support from the available modelling tools.

***Abstract*—This paper presents a Timed Coloured Petri Nets based programming tool that supports modeling and performance analysis of distributed World Wide Web environments. A distributed Internet system model, initially described in compliance with Queueing Theory (QT) rules, is mapped onto the Timed Coloured Petri Net (TCPN) structure by means of queueing system templates. Then, it is executed and analyzed using Design/CPN toolset. The proposed distributed Internet systems modeling and design methodology has been applied for evaluation of several system architectures under different external loads.**

## I. Introduction

ONE OF modern Internet (or Web) systems development approaches assumes that the systems consist of a set of distributed nodes. Dedicated groups of nodes are organized in layers (clusters) conducting predefined services (e.g. WWW service or data base service). Simultaneously, for a significant number of Internet applications some kind of soft real-time constraints are formulated. The applications should provide up-to-date data in set time frames [13]. The appearing of new abovementioned development paradigms cause that searching for a new method of modeling and timing performance evaluation of distributed Internet systems seems to be an up-to-date research path.

One of intensively investigated branch of Internet systems software engineering is formal languages application for modeling and performance analysis. Amid suggested solutions there are: algebraic description [7], mapping through Queueing Nets (QN) [4], [12], modeling using both Coloured Petri Nets (CPN) [8] and Queueing Petri Nets (QPN) [5].

Our approach proposed in this paper may be treated as extension of solutions introduced in [5]. Queueing Petri Nets (QPN) idea has been transferred onto formalism of Timed Coloured Petri Nets (TCPNs) [3]. To create classic queueing system models defined as in [2] we used Design/CPN tool package [1]. As a result we developed a programming tool which is able to map timed behavior of queueing nets by means of simulation. The Design/CPN performance tool [6] has been used to effectively capture and analyze data for created models. The main features of the preliminary version of our software tool were announced in [10].

The remaining work is organized as follows. In section 2, we introduce rules of mapping queueing systems into TCPNs. In the next section, we present a method of applying the TCPNs based queueing systems models (TCPNs templates) to distributed Internet system modeling. Section 4 focuses on results of simulation some detailed Internet system models while section 5 sums up the paper and includes our future research plans.

We assumed that the reader is familiar with TCPN formalism [3], [9] and with main features of Design/CPN tool [1], [6].

## II. Queueing System Implementation

*Queueing Net* usually consists of a set of connected *queueing systems*. Each *queueing system* is described by an arrival process, a waiting room and a service process. In the proposed programming tool, we worked out several TCPNs based *queueing system templates* (Processor Sharing (PS) and First In First Out (FIFO)) most frequently used to represent properties of distributed Internet system components. Each template represents a separate TCPN net (subpage) which may be included in the model of the system as a substitution transition (using hierarchical CP nets mechanisms [3]).

Queueing system properties are mapped to the TCPNs net as follows. At a certain level of system description, a part of hardware/software is modeled as a TCPN, where some dedicated *substitution transitions* are understand as queueing systems. To have the queueing functionality running ”under” selected transitions the mapping to adequate TCPNs subpages must be done. The corresponding subpages include the implementation of the adequate queueing system.

In fig. 1a a simple TCPN is presented where PS substitution transition is interpreted as a certain queueing system. The PS transition acquires the queueing system functionality when the subnet as in fig. 1b is substituted for it. Figure 1b illustrates an example queueing system -/M/1/PS/$\infty$ (exponential service times, single server, Processor Sharing service discipline and unlimited number of arrivals in the system; the queue’s arrival process in our modeling approach is defined outside of queueing system model). Packets to be served by given queueing system are delivered by port place `INPUT_PACKS`. Then, they are scheduled in a queue in `PACK_QUEUE` place. Every given time quantum (regulated by time multiset included in `TIMERS` place) the first element in the queue is selected to be served

978-83-60810-14-9/08/$25.00 © 2008 IEEE

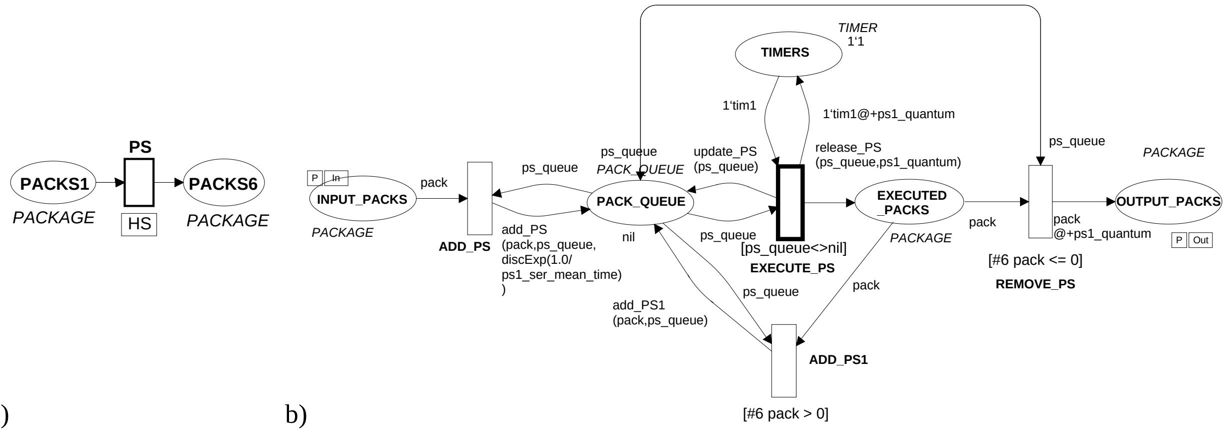

Fig. 1. TCPNs model of -/M/1/PS/∞ queuing system: a) primary model page b) detailed model page

(execution of transition EXECUTE_PS). Then, it is placed at the end of the queue or directed to leave the system (execution of transition ADD_PS1 or REMOVE_PS respectively). Number of tokens in TIMERS place represents number of servers for queueing system.

Full description of the model requires colors and functions definition in CPN ML language connected to the net elements:

```
val ps_ser_mean_time=1.0;
val pack_gen_mean_time=1.0;
color ID=int;    color PRT=int;
color START_TIME=int; color PROB=int;
color AUTIL=int; color RUTIL=int;
color INT=int; color TIMER=int timed;
color random_val=int with 1..100;
var tim_val:INT; var n:INT;
var tim1:TIMER; color PACKAGE=
   product ID*PRT*START_TIME*PROB*AUTIL*RUTIL timed;
var pack:PACKAGE; color PACK_QUEUE=list PACKAGE;
var ps_queue:PACK_QUEUE;
```

Corresponding arc functions (add_PS(), add_PS1(), update_PS(), release_PS()) release or insert tokens within the queue:

```
fun add_PS(pack:PACKAGE, queue:PACK_QUEUE,
ser_time:int)=if queue = nil
then [(#1 pack,#2 pack,#3 pack,#4 pack,
ser_time,ser_time)]
else (#1 pack,#2 pack,#3 pack,#4
pack,ser_time,ser_time)::queue;
fun add_PS1(pack:PACKAGE, queue:PACK_QUEUE)=
if queue=nil
then [pack] else pack::queue;
fun update_PS(queue:PACK_QUEUE)=rev(tl(rev queue));
fun release_PS(queue:PACK_QUEUE, ps_quantum:INT)=let
val r_pack=hd (rev queue) In
(#1 r_pack,#2 r_pack,#3 r_pack,ran'random_val(),
#5 r_pack, #6 r_pack-ps_quantum) end;
```

The state of the system is determined by the number and distribution of the tokens representing data packet flow. Each of the tokens representing a packet is a tuple PACKAGE = (ID, PRT, START_TIME, PROB, AUTIL, RUTIL) (compare source code including color's definitions), where: ID - token identification (allowing token class definition etc.), PRT - priority, START TIME - time of a token occurrence in the system, PROB - probability value (used in token movement distribution in the net), AUTIL - absolute value of token utilization factor (for PS queue) and RUTIL - relative value of token utilization factor. Tokens have *timed* attribute scheduling them within places which are not queues.

While packets are being served, the components of a tuple are being modified. At the moment the given packet leaves the queueing system, a new PROB field value of PACKAGE tuple is being generated randomly (release_PS function). The value may be used to modify the load of individual branches in the queueing system model. Generally, the queueing system template is characterized by the following parameters: average tokens service time (ps_ser_mean_time), number of servers (number of tokens in TIMERS place) and service discipline (the TCPN's structure).

In the software tool developed, it is possible to construct queueing nets with queueing systems having PS and FIFO disciplines. These disciplines are the most commonly used for modeling Internet systems. Some our previous works include the rules of mapping TCPNs into queues of tokens scheduled according priorities [9], [8]. The presented templates have been tested on their compatibility with mathematical formulas determining the average queue length and service time as in [2].

## III. Internet System Modeling and Analysis Approach

Having a set TCPN based queueing systems models a systematic methodology of Internet system modeling and analysis may be proposed. Typically, modern Internet systems are composed of layers where each layer consist of a set of servers—a server cluster. The layers are dedicated for proper tasks and exchange requests between each other.

To efficiently model typical Internet systems structures we proposed 3 modeling levels:

- superior—modeling of input process, transactions between layers and requests removal,
- layer—modeling of cluster structure,

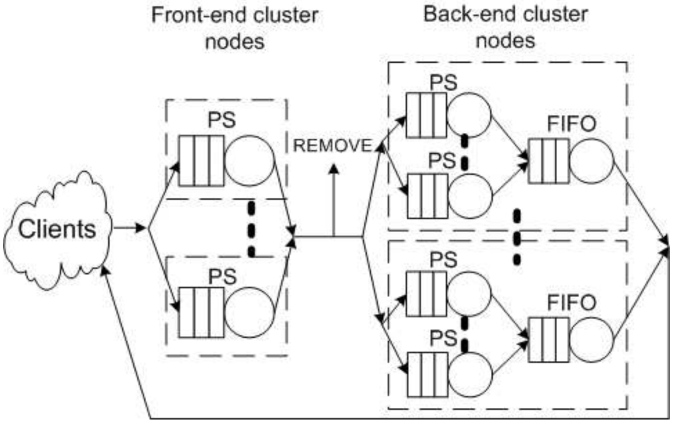

Fig. 2. Example distributed Internet system environment

- queue—modeling of queueing system.

To explain our approach to Internet system modeling a typical structure of distributed Internet system structure will be modeled and simulated. The example queueing model of the system consists of two layers of server clusters (fig. 2) and is constructed following the rules introduced in [4] and [5].

The front-end layer is responsible for presentation and processing of client requests. Nodes of this layer are modeled by PS queues. The next layer (back-end) implements system data handling. Nodes of this layer are modeled by using the serially connected PS and FIFO queues. The PS queue models the server processor and FIFO models the hard disc drive of server. Requests are sent to the system can be processed in both layers or removed after processing in front-end layer. The successfully processed requests are turned to the customer.

Figure 3 shows the TCPN based model of abovementioned queueing network. The superior level of system description is presented in fig. 3a, whereas in fig. 3b and 3c detailed queueing systems topologies at each layer of the system are shown (compare fig. 2). Server cluster of the first layer (e.g. WWW servers; fig. 3b) as well as the second layer cluster (e.g. database; fig. 3c) have been demonstrated on the main page of TCPN net as substituted transitions: `front-end_cluster` and `back-end_cluster`.

`T2` and `T3` transitions (compare fig. 3a) are in conflict. Execution of transition `T2` removes a token from the net (modeling the possible loss of data packet). However, if `T3` fires, the data packet is transferred for processing in the second layer of the system. Guard functions connected to the mentioned transitions determine proportions between the tokens (packets) rejected and the ones remaining in the queueing net (in the example model approximately `30%` of the tokens is rejected).

On the superior level of system description (fig. 3a) we have also defined arrival process of the queueing network (`T0` transition with `TIMER0` and `COUNTER` places). `TIMER0` place and `T0` transition constitute a clock-like structure that produces tokens (requests) according to random, exponentially distributed frequency. These tokens are accumulated in a form of timed multiset in `PACKS1` place and then forwarded into the queueing-based model of the Internet system. When each token is being generated its creation time is memorized in the `PACKAGE` tuple. This makes it possible to conduct an off-line analysis of the model.

Consequently, an executable (in a simulation sense) queueing network model is obtained. Tokens generated by arrival process are transferred in sequence by models of WWW server layer, by the part of the net that models loss (expiration) of some packets and by database layer. Provided that the system is balanced and has constant average arrival process, after some working time, the average values of the average queue length and response time are constant. Otherwise, their increase may occur.

The main parameters of the system modeled are the queue mean service time, the service time probability distribution function and the number of servicing units defined for each queueing system in the model. In the demonstrated model it has been assumed that queues belonging to a given layer have identical parameters.

At this stage of our research it has been decided that simulation will be the main mechanism used to do analysis of the constructed model. In our simulations we applied the performance analysis subsystem built in Design/CPN toolkit [6], [8]. It allows collecting selected elements of the net state at the moment of an occurrence certain events during simulation. It has been assumed that in each of the model layers, queue lengths and response time will be monitored. Monitoring of the abovementioned parameters helps to determine whether the model of the system is balanced. Fig. 4 shows example plots obtained in the simulation of the discussed model.

The example experiment covered model time range from `0` to `100 000` time units. Fig. 4a shows the state of selected queue when the modeled system was balanced. Response time does not increase and remains around average value. System is regarded as balanced if the average queue lengths in all layers do not increase. In fig. 4b response time for unbalanced system was shown. The results concern the same layer as previously and identical time range for the simulation. It is clear that response time (fig. 4b) increase during the experiment. On the basis of the plot in fig. 4b, it can be concluded that the modeled system under the assumed external load would be overload and probably appropriate modifications in the structure of the system would be necessary. The software tool introduced in our paper makes it possible to estimate the performance of developing Internet system, to test and finally to help adjust preliminary design assumptions.

Having the possibility to capture the net's state during the simulation within a certain time interval, it can be possible to select model parameters in such a manner that they meet assumed time restrictions. Additionally, the parameters of real Internet system can be used to fit parameters of the constructed model.

## IV. Example System Model with Front-end Cluster and Back-end Replication

The worked out modeling and analysis methodology was used for construction and evaluation of several detailed models of architectures of distributed Internet systems. The analysis of the models were executed with use of performance analysis tools for TCPN nets [13]. CSIM [11] simulating environment and experiments on real Internet system were used for TCPNs simulations evaluation. The overview of typical TCPNs based Internet system models analyzed so far can be found in [8]. In the remaining part of the paper one example detailed model will be discussed: ”front-end cluster and back-end cluster with replication”.

### *A. Model description*

The queueing model of the example system is introduced in fig. 5. It consists of two cluster layers of servers. Let `A` be the number of homogeneous servers in the first and `B` in the second cluster layer respectively. Customer requests are sent to the chosen node of front-end cluster with `1/A` probability. Then they are placed in the queue to get service. The service in the service unit (processor) can be suspend many times, if for example the requests need the database access. When the database access occures, requests are sent to back-end layer. Any request can also be removed following `pREMOVE` path. In case of sending to the database, a requests steers itself to service in one of back-end nodes with `1/B` probability. The service in the database service unit may be suspend if access

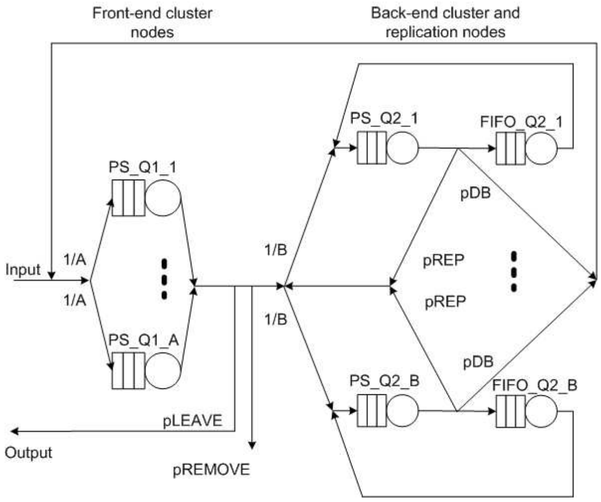

Fig. 5. Queueing model with cluster in front-end layer and replication in back-end layer

to the input/output subsystem of the database storage device is necessary. Requests are returned to the database service unit after the storage device is served. This operation can be repeated many times. After finishing servicing in the back-end layer, requests are returned to front-end servers (pDB). Requests can visit back-end layer during processing many times. After finish servicing in front-end server requests are sent to the customer (pLEAVE).

If the necessity of the database replication appears the requests are sent to next database node (pREP). Unless none of these two situations appear the requests are send to front-end layer (pDB). Replication can also cause resignation from transaction. Both the replication and the rejection of realizing transaction are modeled in simplistic way as delivery of task to the next location of replication.

In this model:

- PS_Q1_A is A queue PS modeling element that processes in front-end layer,
- PS_Q2_B is B queue PS modeling element that processes in back-end layer,
- FIFO_Q2_B is B queue FIFO modeling device that stores data in back-end layer.

Tab. I includes the probabilities values for Internet requests distribution for considered model. The parameters assumed for discussed model are as follows:

- external load,
- the identical parameters of queues,
- request distribution probabilities,
- the number of nodes in experimental environment.

In fig. 6a the main page (superior model level) of TCPN model that corresponds to the queueing model discussed above was presented. It makes it possible to transfer tokens from back-end layer back to front-end layer. It models the possibility of multiple tokens transfer to the server disk queue and replication. A subpage, which models back-end layer for database replication, is described on fig. 6b. The example shown contains two nodes of database (B=2) and its most essential properties are as following:

TABLE I
THE VALUE OF PROBABILITIES FOR MODEL

| Probability | Probability values for model [%] |
|---|---|
| pREMOVE | 30 |
| pLEAVE | 30 |
| pDB | 55 |
| pREP | 10 |

- the possibility of directing tokens to any node (the location of replication),
- the return of tokens at the beginning of the layer,
- the realization of data synchronisation in individual locations.

### B. Experimental and simulating model verification

Three example cases (configurations) of considered model were used to derive the architecture features. Individual cases mean as follows:

- case 1—A=2, B=2,
- case 2—A=4, B=2,
- case 3—A=4, B=4.

Experimental environment and the CSIM packet were used to verify proposed TCPN models. The experimental system consisted of a net segment (100Mb/s), set of computers (Pentium 4, 2.8 GHz, 256 MB RAM) with Linux operating system (kernel 2.4.22) and Apache2 software (for WWW servers) as well as MySQL, version 4.0.15 (for database servers) [8].

The verification model was written by using CSIM simulator. This is a process oriented discreet event simulation package used with C or C++ compilers [11]. It provides libraries that a program written can be used in order to model a system and to simulate it. The models created by using CSIM [8] were based on presented queue models (fig. 5) (similarly as TCPN models).

As a result we obtained the evaluated TCPNs based model of the Internet system discussed. The model made it possible to predict response time of the system developed. Average error between TCPN and CSIM models amounts to (tab. II) 9,5 % for response time. The comparison of results for TCPN models and experiments gave the following errors for individual model cases (tab. III) 14,9 %. In compare with experimental environment the average error of simulation for response time amounted to 15,1 % for TCPN and 14,1 % for CSIM respectively. In case of experiments (tab. III) there is the lack of compare for case 3 because of number of nodes in laboratory environment.

### C. Performance analysis

In fig. 7 the queue lengths for the model (cases 2 and 3) were shown. These cases differ from each other by a number of nodes in corresponding layers. Values of queue lengths

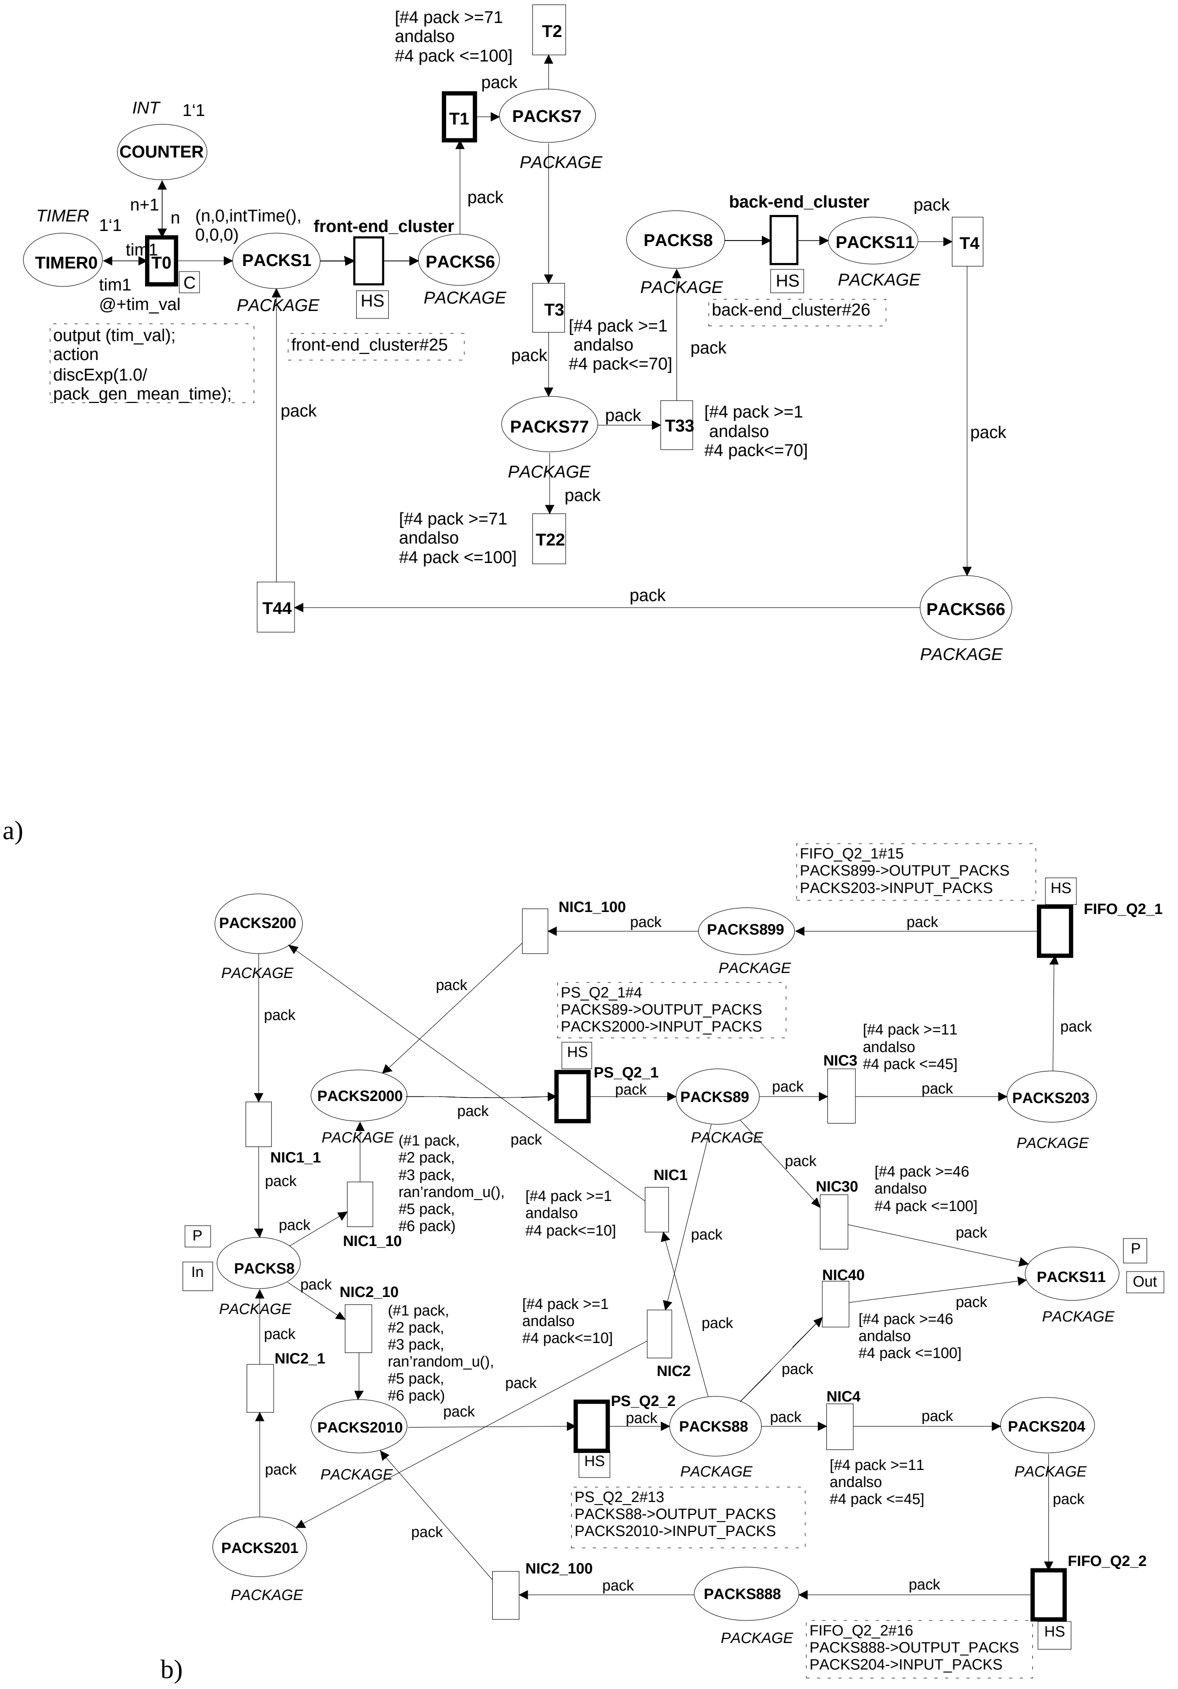

Fig. 6. TCPNs based queueing system model with cluster in front-end layer and replication in back-end layer: a) main page and b) back-end_cluster subpage

TABLE II
LAYERS RESPONSE TIME FOR TCPN MODEL AND CSIM MODEL

| Load [req./s] | Layer | TCPN Model [ms] | CSIM Model [ms] | Error [%] |
|---|---|---|---|---|
| Case 1 | | | | |
| 100 | front-end | 49 | 50 | -2.0 |
| 100 | back-end | 567 | 598 | -5.5 |
| 300 | front-end | 701 | 743 | -5.9 |
| 300 | back-end | 813 | 798 | 1.8 |
| 500 | front-end | 1001 | 1109 | -1.8 |
| 500 | back-end | 1050 | 1083 | -3.1 |
| Case 2 | | | | |
| 100 | front-end | 75 | 73 | 2.7 |
| 100 | back-end | 1083 | 867 | 19.9 |
| 300 | front-end | 79 | 85 | -7.6 |
| 300 | back-end | 1144 | 989 | 13.5 |
| 500 | front-end | 1042 | 1191 | -14.3 |
| 500 | back-end | 965 | 950 | -9.8 |
| Case 3 | | | | |
| 100 | front-end | 210 | 282 | -34.2 |

| 500 | front-end | 512 | 595 | -16.2 |
| 500 | back-end | 520 | 384 | 5.2 |

TABLE III
LAYERS RESPONSE TIME FOR TCPNS MODEL AND FOR EXPERIMENTAL REFERENCE SYSTEM

| Load [req./s] | Layer | TCPN Model [ms] | Experiments [ms] | Error [%] |
|---|---|---|---|---|
| Case 1 | | | | |
| 100 | front-end | 49 | 36 | 26.5 |
| 100 | back-end | 567 | 409 | 27.5 |
| 300 | front-end | 701 | 579 | 17.4 |
| 300 | back-end | 813 | 648 | 20.3 |
| 500 | front-end | 1001 | 921 | 8.0 |
| 500 | back-end | 1050 | 973 | 7.3 |
| Case 2 | | | | |
| 100 | front-end | 75 | 65 | 13.3 |
| 100 | back-end | 1083 | 791 | 26.9 |
| 300 | front-end | 79 | 79 | 0.0 |
| 300 | back-end | 1144 | 910 | 20.4 |
| 500 | front-end | 1042 | 975 | 6.4 |
| 500 | back-end | 965 | 925 | -6.9 |

in second layer were presented in charts (case 2—model for A=4, B=2): PSQ2_1 (fig. 7a) and PSQ2_2 (fig. 7b). Values of corresponding queue lengths for second layer in case 3 (A=4, B=4) were presented in charts: PSQ2_1 (fig. 7c) and PSQ2_2 (fig. 7d). Charts of both cases follow assumptions presented above and the same load. Queue lengths in case 2 are significantly longer than in case 3. It is easy to see benefits of enlarging number of nodes in back-end layer.

The performance problems were noticed during the distributed Internet systems analysis. Results of response time individual layers analysis (tab. II) illustrates behaviour observed by system customer. The growth of workload generally increases response time of the system. It was noticed that the use of clustering and nodes replication reduce the response time.

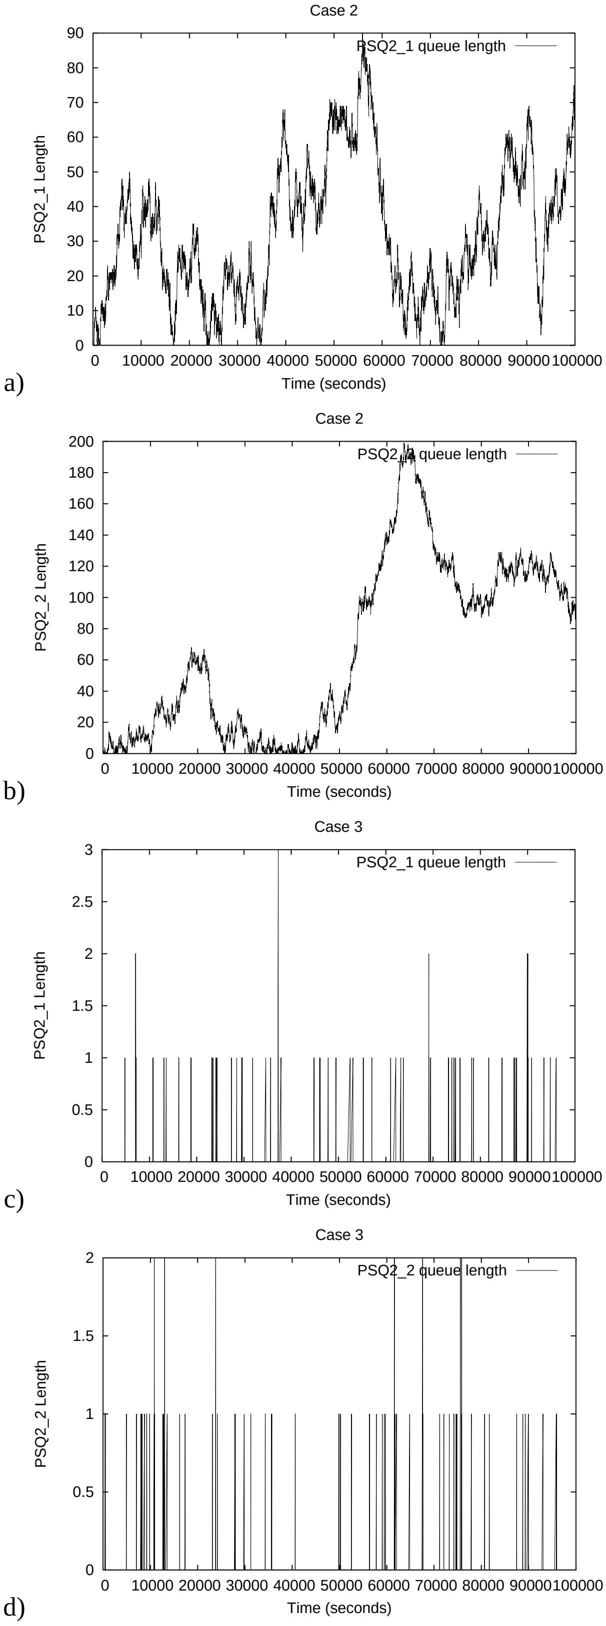

Fig. 7. PS queues lengths history in back-end layer: a), b) for case 2 and c), d) for case 3

In case of workload by more than 200 requests per second the system having the case 1 structure is overloaded. Backend layer becomes the system bottleneck. By the adequate modification of the number of computers in the second layer the overload condition under 200 request per second has been overcame. The presented performance analysis methodology makes it possible to detect early performance problems and to counteract them.

## V. Conclusion

It is still an open issue how to obtain an appropriate distributed Internet system. The demonstrated research results are an attempt to apply Queueing Theory (QT) and TCPNs formalism to the development of a software tool that can support distributed Internet system design. The idea of linking Queueing Nets Theory and Coloured Petri Nets was proposed previously by other authors in [5]. However, in the presented approach queueing systems have been implemented using TCPNs formalism exclusively. As a consequence, alternative implementation of Coloured Queueing Petri Nets has been proposed. What was more, the rules of modeling and analysis of distributed Internet systems applying described net structures was introduced.

This paper deals with the problem of calculating performance values like the response time in distributed Internet systems environment. The values are calculated by using the Design/CPN tool (TCPN). It is shown how the Coloured Petri net model of a distributed Internet system is created with some of its data structures and functions, and gives an examples of system analysis. A comparison of the results obtained by using the software tools (Design/CPN and CSIM) with the results acquired from the real system is presented.

The proposed approach is attempted to make a contribution to performance analysis of distributed Internet systems. This analysis is useful to determinate number and distribution of elements in the distributed Internet system architecture for specified requests load.

Our future research will focus on modeling and analyzing another structures of distributed Internet systems using the software tool developed. It will be also significant to demonstrate compatibility of the models with the real systems. TCPN features such as tokens distinction will be of more extensive use. We will also make an attempt to create queueing model systems with defined token classes and consider a possibility to use state space analysis of TCPN net to determine properties of the system.

# International Workshop on Real Time Software

INTERNATIONAL Workshop on Real Time Software will be held within the framework of the International Multiconference on Computer Science and Information Technology, and will be co-located with the XXIV Fall Meeting of Polish Information Processing Society.

Proliferation of computers interfacing with real world and controlling their environment requires careful investigation of approaches related to the specification, design, implementation, testing, and use of modern computer systems. Timing constraints, dependability, fault-tolerance, interfacing with the environment, reliability and safety constitute integral components of the software development process. Appropriate education of engineers developing such systems, working in interdisciplinary teams and in a global environment is of paramount importance.

In addition to traditional papers, we plan to organize a round table discussion forum on safety critical aspects of the education/training. We are soliciting brief one-page position papers on education and training of engineers developing dependable software intensive systems - presenting the views of academia and industry (in the submission clearly identity the "position paper" for the engineering education round table discussion). The accepted position papers will be a base for 10 minutes presentation followed by a discussion.

The workshop is planned around three main focus areas

- Real-Time Control
- Safety, Reliability, and Dependability
- Real-Time Education

Traditional Papers topics include but are not limited to:

- Real-time system development
- Scheduling
- Safety
- Reliability
- Dependability
- Fault-tolerance
- Feedback control real-time scheduling
- Hardware-software co-design
- Standards and certification
- Control software
- Robotics and UAV
- Software development tools
- Model-based development
- Automatic code generation
- Real-time systems education
- Related engineering curricula
- Laboratory infrastructure
- Internet-based support

***Abstract*—Nowadays, most embedded systems become distributed systems structured as a set of communicating components. Therefore, they display a less deterministic global behavior than centralized systems and their design and analysis must address both computation and communication scheduling in more complex configurations.**

**We propose a modeling framework centered on data. More precisely, the interactions between the data located in components are expressed in terms of a so-called observation relation. This abstraction is a relation between the values taken by two variables, the source and the image, where the image gets past values of the source. We extend this abstraction with time constraints in order to specify and analyze the availability of timely sound values.**

**The formal description of the observation-based computation model is stated using the formalisms of transition systems. Real time is introduced as a dedicated variable.**

**As a first result, this approach allows to focus on specifying time constraints attached to data and to postpone task and communication scheduling matters. At this level of abstraction, the designer has to specify time properties about the timeline of data such as their freshness, stability, latency…**

**As a second result, a verification of the global consistency of the specified system can be automatically performed. A forward or backward approach can be chosen. The verification process can start from either the timed properties (e.g. the period) of data inputs or the timed requirements of data outputs (e.g. the latency).**

**As a third result, communication protocols and task scheduling strategies can be derived as a refinement towards an actual implementation.**

## I. Introduction

DISTRIBUTED Real Time Embedded (DRE) systems become more and more widespread and complex. In this context, we propose a modeling framework centered on data to specify and analyze the real time behavior of these DRE systems. More precisely, such systems are structured as time-triggered communicating components. Instead of focusing on the specification and verification of time constraints upon computations structured as a set of tasks, we choose to consider data interactions between components. These interactions are expressed in terms of an abstraction called observation, which aims at expressing the impossibility for a site to maintain an instant knowledge of other sites. In this paper, we extend this observation with time constraints limiting the time shift induced by distribution. Starting from this modeling framework, the specification and verification of real time data behaviors can be carried out.

In a first step, we outline some related works which have adopted similar approaches but in different contexts and/or different formalisms.

Then, we describe the underlying formal system used to develop our distributed real time computation model, namely state transition systems. In this formal framework, we define a dedicated relation called observation to describe data interactions. An observation relation describes an invariant property between so-called “source” and “image” variables. Informally, at any execution point, the history of the image variable is a sub-history of the source variable. In other words, an observation abstracts the relation between arguments/results of a computation or between inputs/outputs of a communication protocol.

To express timed properties on the variables and their relation, we extend the framework so as to be able to describe the timeline of state variables. Therefore, for each state variable $x$, an abstraction of its timeline is introduced in terms of an auxiliary variable $\hat{x}$ which records its update instants. Then, real time constraints on data, for instance periodicity or steadiness, are expressed as differences between these dedicated variables and/or the current time. These auxiliary variables are also used to restrict the time shift between the source and the image of an observation. The semantics of the observation relation is extended to express different properties: for instance time lag or latency boundaries between the current value of the image and its corresponding source value.

The real time constraints about data behavior can be specified by means of these timed observations as illustrated in an automotive speed control example.

Lastly, we discuss the possibility to check the consistency of a specification. A specification is consistent if and only if the verification process can construct correct executions. However, the target systems are potentially infinite and an equivalent finite state transition system must be derived from the initial one before verification. The feasibility of this transformation is based upon assumptions about finite boundaries of the time constraints.

## II. State of the Art

We are interested in systems such as sensors networks. Our goal is to guarantee that the input data dispatched to processing units are timely sound despite the time shift introduced by distribution.

Most approaches taken to check timed properties of distributed systems are based on studying the timed behavior of tasks. For example, works like [1] propose to include the timed properties of communication in classical scheduling analysis.

Our approach is state-based and not event-based. We express the timed requirements as safety properties that must be satisfied in all states. The definition of these properties do not refer to the events of the system and is only based on the variable values. We depart from scheduling analysis by focusing on variable behavior and not considering the tasks and related system events.

Others approaches based on variables are mainly done in the field of databases. For example, the variables semantics and their timed validity domain are used in [2] to optimize transaction scheduling in databases. Our work is at a higher level as we propose to give an abstract description of the system in terms of a specification of data relations. Our framework can be used to check the correctness of an algorithm with regards to the freshness of the variables. It can also be used to specify a system without knowing its implementation.

Similar works are done using temporal logic to specify the system. For example, in [3], OCL constraints are used to define the validity domain of variables. A variation of TCTL is used to check the system synchronization and prevent a value from being used out of its validity domain. This work also defines timed constraints on the behavior and the relations between application variables, but these relations are defined using events such as message sending whereas our definitions are based on the variable values.

In [4], an Allen linear temporal logic is proposed to define constraints between intervals during which state variables remain stable. In other words, this approach also uses an abstraction of the data timelines in terms of stability intervals. However, the constraints remain logical and do not relate to real time. Nevertheless, this approach is intended to be applied in the context of autonomous embedded systems.

Using a semantics based on state transition system, we give a framework which aims at describing the relations between the data in a system, and specifying its timed properties and requirements.

## III. Theoretical Basis

### A. State Transition System

Models used in this paper are based on state transition systems. More precisely, this paper relies on the TLA+ formalism [5]. A *state* is an assignment of values to variables. A *transition relation* is a predicate on pair of states. A *transition system* is a couple (set of states, transition relation). A *step* is a pair of states which satisfies the transition relation. An *execution* $\sigma$ is any infinite sequence of states $\sigma_0\sigma_1\ldots\sigma_i\ldots$ such that two consecutive states form a step. We note $\sigma_i \rightarrow \sigma_{i+1}$ the step between the two consecutive states $\sigma_i$ and $\sigma_{i+1}$.

A *temporal predicate* is a predicate on executions; we note $\sigma \models P$ when an execution $\sigma$ satisfies the predicate $P$. Such a predicate is generally written in linear temporal logic. A *state expression* $e$ (in short, an expression) is a formula on variables; the value of $e$ in a state $\sigma_i$ is noted $e.\sigma_i$. The sequence of values taken by $e$ during an execution $\sigma$ is noted $e.\sigma$. A *state predicate* is a boolean-valued expression on states.

### B. Introducing Time

We consider real time properties of the system data. To distinguish them from (logical) temporal properties, such properties are called *timed* properties. Time is integrated in our transition system in a simple way, as described in [6]. Time is represented by a variable $T$ taking values in an infinite totally ordered set, such as $\mathbb{N}$ or $\mathbb{R}^+$. $T$ is an increasing and unbound variable. There is no condition on the density of time and moreover, it makes no difference whether time is continuous or discrete (see discussion in [7]). However, as an execution is a sequence of states, the actual sequence of values taken by $T$ during a given execution is necessarily discrete. This is the digital clock view of the real world. Note that we refer to the variable $T$ to study time and that we do not use the usual timed traces notation.

An execution can be seen as a sequence of snapshots of the system, each taken at some instant of time. We require that there are "enough" snapshots, that is that no variable can have different values at the same time and so in the same snapshot. Any change in the system implies time passing.

*Definition 1:* Separation. An execution $\sigma$ is separated if and only if for any variable $x$:

$$\forall i, j : T.\sigma_i = T.\sigma_j \Rightarrow x.\sigma_i = x.\sigma_j$$

In the following, we consider only separated executions. This allows to timestamp changes of variables and ensures a consistent computation model.

### C. Clocks

Let us consider a totally ordered set of values $\mathcal{D}$, such as $\mathbb{N}$ or $\mathbb{R}^+$. A clock is a (sub-)approximation of a sequence of $\mathcal{D}$ values. We note $[X \rightarrow Y]$ the set of functions with domain $X$ and range contained by $Y$.

*Definition 2:* A clock $c$ is a function in $[\mathcal{D} \rightarrow \mathcal{D}]$ such that:

- it never outgrows its argument value:
  $\forall t \in \mathcal{D} : c(t) \leq t$
- it is monotonously increasing:
  $\forall t, t' \in \mathcal{D} : t < t' \Rightarrow c(t) \leq c(t')$

In the following, clocks are used to characterize the timed behavior of variables. They are defined on the values taken by the time variable $T$, to express a time delayed behavior, as well as on the indices of the sequence of states, to express a logical precedence. A clock subset is used:

*Definition 3:* A clock $c$ from $[\mathcal{D} \rightarrow \mathcal{D}]$ is a *liveclock* if and only if:

$$\forall t \in \mathcal{D} : \exists t' \in \mathcal{D} : c(t') > c(t)$$

## IV. Specification of Data Timed Behavior

We introduce here the relation and properties used in our framework to describe the properties that must be satisfied by a system. Our approach is state-based and gives the relation that must be satisfied in all states. We define the observation relation to describe the relation between variables. A way to describe the timed behavior of the variables, that is properties of the history of data, is then introduced. We then extend the observation relation to take into account the timed constraints on the relation between variables. For that purpose we define predicates which bind relevant instants of the timeline of the source and the image of an observation. The predicates are expressed as bounds on the difference between two relevant instants.

### A. The Observation Relation

We define an observation relation on state transition systems as in [8]. The observation relation is used to abstract the value correlation between variables. The values taken by one variable are values previously taken by another variable.

Thus the observation relation binds two variables, the source $x$ and the image $`x$, and denotes that the history of the variable $`x$ is a sub-history of the variable $x$. The relation is defined by a couple $< \ source, image >$ and the existence of at least a clock that defines for each state which one of the previous values of the source is taken by the image. The formal definition is:

*Definition 4:* The variable $`x$ is an observation of the variable $x$ in execution $\sigma$: $\sigma \models `x \prec x$ iff:

$$\exists\ c \in [\mathbb{N} \to \mathbb{N}] : liveclock(c) \wedge\ \forall i : `x.\sigma_i = x.\sigma_{c(i)}$$

This relation states that any value of $`x$ is a previous value of $x$. Due to the properties of the observation clock $c$, $`x$ is assigned $x$ values respecting the chronological order. Moreover, $c$ always eventually increases, so $`x$ is always eventually updated with a new value of $x$. Figure 1 shows an example of an observation relation.

The observation can be used as an abstraction of communication in a distributed system, but it can as well be used as an abstraction of a computation:

- Communication consists in transferring the value of a local variable to a remote one. Communication time and lack of synchronization create a lag between the source and the image, which is modeled by $distant \prec local$.
- In state transition systems, a computation $f(x)$ is instantaneously computed. By writing $y \prec f(x)$, we model the fact that the computation takes time and the value of $y$ is based on the value of $x$ at the beginning of the computation.

In order to extend the observation relation with real time properties, we define instants that are used to characterize the timeline of variables.

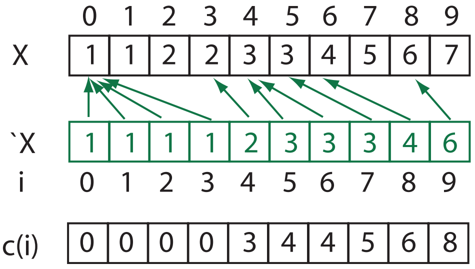

Fig. 1. The Observation Relation

### B. The Update Timeline of Variables

In order to state properties on the timed behavior of a variable $x$, we want to be able to refer to the last time this variable was updated. These are called the update instants $\hat{x}$. This referential can be either explicit or implicit. In the explicit case, the developer is responsible for giving its own variable $\hat{x}$. This can be the case if there is a periodic behavior of $x$ without having to describe actual values of $x$.

In the implicit case, a formal definition of $\hat{x}$ is given based on the history of the values taken by $x$. The goal is to capture the instant when the current value of $x$ appeared, e.g. the beginning of the current occurrence.

*Definition 5:* For a separated execution $\sigma$ and a variable $x$, the variable $\hat{x}$ is defined by:

$$\forall i : \hat{x}.\sigma_i = T.\sigma_{min\{j|\forall k\in[j..i]:\ x.\sigma_i = x.\sigma_k\}}$$

$\hat{x}$ is built from the history of $x$ values. For a variable $x$, the update instant of $x$ is defined as the value taken by the time $T$ at the earliest state when the current value appeared and continuously remained unchanged until the current state.

When $x$ is updated and its value changes then the value of $\hat{x}$ is also updated. Conversely if $\hat{x}$ changes then $x$ is updated. This property allows us to rely on the values of $\hat{x}$ to study the timed properties of $x$.

We also define the instant $Next(\hat{x})$ that returns the next value of $\hat{x}$ and thus the next instant when the value of $x$ is updated, i.e. the instant when the current value disappears. If $x$ is stable in a state $\sigma_i$ (no new update), then $Next(\hat{x}).\sigma_i = +\infty$.

### C. Variable Behavior

$\hat{x}$ is used to describe the timed behavior of a variable $x$. In this paper, we focus only on a certain type of variable. We expect each value of each variable to remain unchanged a bounded number of time units. We want to be able to give two characteristics for each variable: the minimum and the maximum duration between two updates. This basically describes two behaviors: a sporadic variable keeps each value for a minimum duration and, on the contrary, an alive variable has to be updated often, no value can be kept more than a given duration. These properties are expressed by a limit on the difference between $\hat{x}$ and $Next(\hat{x})$ using a characteristic called $Steadiness$. This bound denotes how long each value of $x$ can be kept.

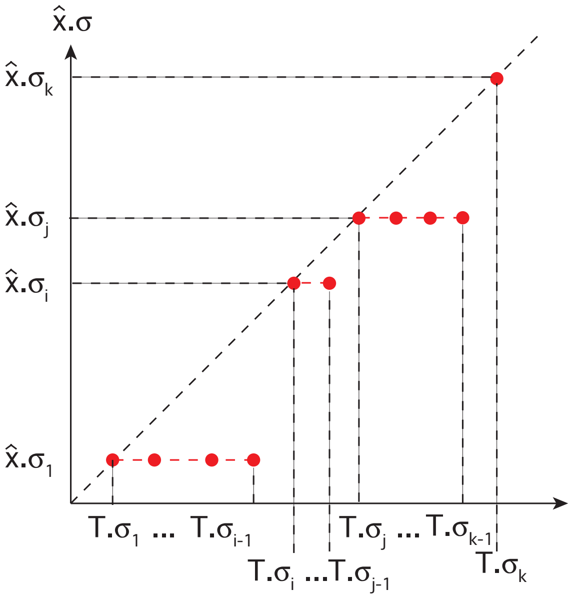

Fig. 2. Graph of $\hat{x}$

*Definition 6:* The steadiness of a variable $x$ is defined by:

$$\begin{array}{l}\sigma \models x\ \{Steadiness(\delta,\Delta)\} \triangleq\\ \qquad\qquad \forall i : \delta \leq Next(\hat{x}).\sigma_i - \hat{x}.\sigma_i < \Delta\end{array}$$

$\Delta - \delta$ is the jitter on $x$ updates. As long as there exists $\delta$ and $\Delta$ such that a variable timeline can be described using the $Steadiness$ feature then other properties can be given. For example, we introduce a stronger property, periodicity, where no time drift is allowed.

*Definition 7:* A variable $\hat{x}$ is periodic of period $P$ with jitter $J$ and phase $\phi$ iff:

$$\begin{array}{l}\sigma \models x\ \{Periodic(P,J,\Phi)\} \triangleq\\ \qquad\quad x\ \{Steadiness(P-2J,P+2J)\} \wedge\\ \forall i : \exists n \in \mathbb{N} : \hat{x}.\sigma_i \in [\phi + nP - J, \phi + nP + J]\end{array}$$

($J$ must verify $J < P/4$)
Such a variable is updated around all instants $\phi + nP$.

### D. Timed Observation

We use the update instants to extend the observation relation with timed characteristics. The timed constraints that extend the observation must capture the latency introduced by the observation and the modification of the timeline of the source to produce the timeline of the image. We define a set of predicates on the instants characterizing the source and the image timelines and the observation clock. Formally, a timed observation is defined as follows:

*Definition 8:* A timed observation is defined as an observation satisfying a set of predicates.

$$\begin{array}{l}\sigma \models {‘x} \prec x \left\{\begin{array}{l} Predicate_1(\delta_1,\Delta_1),\\ Predicate_2(\delta_2,\Delta_2),\\ \qquad\dots\end{array}\right\} \triangleq\\ \qquad\quad \exists c \in [\mathbb{N} \rightarrow \mathbb{N}] : liveclock(c) \wedge\\ \qquad\qquad\qquad \forall i : {‘x}.\sigma_i = x.\sigma_{c(i)} \wedge\\ \qquad\qquad\qquad Predicate_1(c,\delta_1,\Delta_1) \wedge\\ \qquad\qquad\qquad Predicate_2(c,\delta_2,\Delta_2)\dots\end{array}$$

The predicates that can be used to describe the timed properties of the relation between two variables are the following:

*Definition 9:* Given two variables ${‘x}$ and $x$ such that $\sigma \models {‘x} \prec x$ with a $liveclock$ $c \in [\mathbb{N} \rightarrow \mathbb{N}]$

$$\begin{array}{rcl} Lag(c,\delta,\Delta) & \triangleq & \delta \leq {‘\hat{x}}.\sigma_i - \hat{x}.\sigma_{c(i)} < \Delta\\ Stability(c,\delta,\Delta) & \triangleq & \delta \leq Next(\hat{x}).\sigma_{c(i)} - \hat{x}.\sigma_{c(i)} < \Delta\\ Latency(c,\delta,\Delta) & \triangleq & \delta \leq T.\sigma_i - \hat{x}.\sigma_{c(i)} < \Delta\\ Medium(c,\delta,\Delta) & \triangleq & \delta \leq T.\sigma_i - T.\sigma_{c(i)} < \Delta\\ Freshness(c,\delta,\Delta) & \triangleq & \delta \leq T.\sigma_{c(i)} - \hat{x}.\sigma_{c(i)} < \Delta\\ Fitness(c,\delta,\Delta) & \triangleq & \delta \leq Next(\hat{x}).\sigma_{c(i)} - T.\sigma_{c(i)} < \Delta\end{array}$$

When no lower (resp. upper bounds) is given, $0$ (resp. $+\infty$) is used.

These predicates have to be true at every state and every instant. The definition of an observation is done by giving which predicates must be satisfied. Other predicates can be proposed but we believe this set is sufficient to express the different behaviors that must be analyzed.

The first three predicates describe timed requirements on the system. $Lag$ is used to bound the lag introduced by the observation. The current value of the image was available on the source in one of the past instants. The bounds constrain how far in the past the image's current value is found on the source. They are the strongest needed to characterize all possible values of the image and so are defined using particular instants: the update instants of the image and the source. $Stability$ is used to get source values based on their duration. For example, we can eliminate transient values and keep sporadic ones, or the contrary. $Latency$ is a measure of the total duration between the current instant and the assignment of the image's current value on the source.

The last three predicates are used to define or restrict the behavior of the system due to its architecture. Predicate $Medium$ characterizes the medium implementing the observation, for example a communication bus or a processing unit. A lower bound is the shortest time needed to read the value of the source and assign it to the image. For example, it corresponds to the minimum communication time. An upper bound is the longest duration needed to create and send a message, for example, the maximum communication time plus the maximum time during which the source is unavailable.

When an observation denotes a computation, the bounds stand for the minimum execution time and the maximum execution time plus the blocking time (due to the scheduling policy for example). $Freshness$ and $Fitness$ are used to define intervals, relative to the update instants, where the value of the source is not available. The observation clock

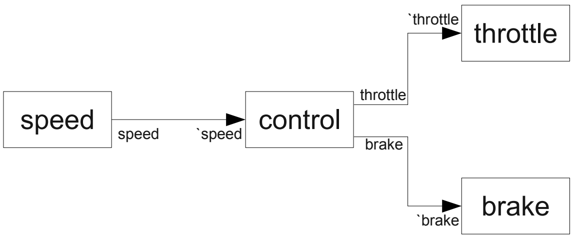

Fig. 3. Cruise Control System

is prevented from referring to one of these instants. An upper bound on $Freshness$ prevents values that are not fresh anymore to be read. On the contrary, a lower bound denotes an impossibility to access a value just after its assignment. $Fitness$ allows, or forbids, to read a value according to the time remaining until its removal; a lower bound prevents the value to be used just before a new update, for example when the computation of this new update has already started.

Note that, at the beginning of an execution, some predicates such as $Medium$ cannot be satisfied. In order to solve this problem, we define an observation where timed predicates do not have to be satisfied in initial states. The image values are replaced by a given default value. This extension is similar to the ”followed by” operator → in Lustre [9].

## V. A System Definition

### A. A Brief Description

We give here a system specification using previous properties. This system is a simplified car cruise control system used as an example.

The goal of such a system, when activated, is to control the throttle and the brakes in order to reach and keep a chosen speed. The system is based on different components (see Figure 3):

- a speed monitor which computes the current speed, based on a sensor counting wheel turns;
- the throttle actuator which controls the engine;
- the brakes which slow the car;
- the control system which handles the speed depending on the current and the chosen speed;
- a communication bus which links the devices and the control system.

The environment, the driver and the engine influence the speed of the car. Once the cruise control is activated and a speed is chosen, the control system chooses whether to accelerate by increasing the voltage of the throttle actuator or to decelerate by decreasing this voltage and by using brakes. The system has a maximum delay between each change to ensure a reactive behavior.

Each component uses and/or produces data. We use observations to specify the system and characterize correct executions. The notation is the one introduced when the timed observation and the variable behavior were defined.

### B. Relations Between Data

Firstly, we present some relations between the variables of the example. These relations, either computations or communications, are expressed as observations. The speed monitor computes the values of a variable $speed$ and these values are sent to the control system as a variable $`speed$. We express this as an observation $`speed \prec\!\!\cdot\; speed$.

The decisions of the control system are based on the current speed and more precisely on the value of $`speed$. Two functions are used to compute the values used as inputs by the brakes and the throttle actuator. Using the speed values, we compute the values of two variables: $throttle \prec\!\!\cdot\; control1(`speed)$ and $brake \prec\!\!\cdot\; control2(`speed)$.

Finally, the decisions $throttle$ and $brake$ are sent to dedicated devices into variables $`throttle$ and $`brake$, such that $`throttle \prec\!\!\cdot\; throttle$ and $`brake \prec\!\!\cdot\; brake$.

### C. Requirements and Properties

We state the requirements and known timed properties of the system and explain how to express them as characteristics of the system variables and observations. These characteristics are all given in Figure 4.

The speed is computed using the ratio between the number of wheel turns and the time. A minimum time is required to give a significant result. So the variable $speed$ must have a minimum time $\delta_1$ between each update. Due to scheduling constraints, computation of variables $throttle$ and $brake$ also have minimum times $\delta_2$ and $\delta_3$ between each update.

Each communication on the bus has a minimum communication time, regardless of the communicating protocol that is chosen. We introduce a lower bounded $Medium$ predicate on the observations denoting communication. Similarly there is also a lower bounded delay to represent the minimum computation time of the functions $control1$ and $control2$.

We expect each data to be used not too long after each update. More precisely we want each decision applied to the brake or to the throttle to be based on fresh values of the speed. Thus, we require the complete processing chain to be achieved in a short enough time.

A composition of observations is an observation, for example if $y \prec\!\!\cdot\; x$ and $z \prec\!\!\cdot\; f(y)$ then $z \prec\!\!\cdot\; f(x)$ [8]. We use this property to express the requirement on the complete processing chains between $`throttle$, $`brake$ and the variable $speed$. The definitions of these observations are compatible with the dependencies between the variables. The processing chains must satisfy upper bounded $Latency$ predicates on the observations. These are the only upper bounded characteristics given in the abstract system specification. Upper bounds on the $Medium$ and $Steadiness$ characteristics of the other observations and variables are implicitly imposed by the $Latency$ upper bound ($\Delta_7$).

### D. Case Study Analysis

The goal of the analysis is to prove that the specification is consistent and that there is at least one execution satisfying the requirements. In our example, the set of valid executions

`- variables behaviours:`

$$speed\ \{Steadiness(\delta_1, +\infty)\}$$
$$throttle\ \{Steadiness(\delta_2, +\infty)\}$$
$$brake\ \{Steadiness(\delta_3, +\infty)\}$$

`- communications:`

$$`speed \prec\!\cdot\ speed\ \{Medium(\delta_4, +\infty)\}$$
$$`throttle \prec\!\cdot\ throttle\ \{Medium(\delta_4, +\infty)\}$$
$$`brake \prec\!\cdot\ brake\ \{Medium(\delta_4, +\infty)\}$$

`- computations:`

$$throttle \prec\!\cdot\ control1(`speed)\ \{Medium(\delta_5, +\infty)\}$$
$$brake \prec\!\cdot\ control2(`speed)\ \{Medium(\delta_6, +\infty)\}$$

`- complete processing chains:`

$$`throttle \prec\!\cdot\ control1(speed)\ \{Latency(0, \Delta_7)\}$$
$$`brake \prec\!\cdot\ control2(speed)\ \{Latency(0, \Delta_7)\}$$

Fig. 4. System Specification

ensures the availability of timely sound values. From this set, we deduce the required update frequency of the *speed* variable. For example, we check the existence of a maximum time acceptable between each update. We analyze the admissible values of the $Medium$ to deduce the communication and computation times that are permitted. Finally, we determine the possible values of the observation clocks in the states corresponding to update instants of the image. These values give the instants at which the values of the source are caught and so, for example the instants when a message must be sent or a computation must start.

For all these properties, a choice must be done. For example, choosing a set of executions may alleviate the bounds on communication time but then reduce the instants where the message must be sent.

## VI. System Analysis

We give here properties of our framework based on observations in order to carry out an analysis. A system specified with observation relations must be analyzed to check the consistency of the specification, i.e. if there exists an execution satisfying the specification.

We discuss the analysis method in a discrete context. The semantics of the specification is restricted by discretizing time: i.e. the values taken by time $T$ are in $\mathbb{N}$. For discussion about the loss of information using discrete time instead of dense time and defending our choice, see [7] for example.

### A. Equivalence with a Finite System

Given a specification based on our framework, the value of $T$ is unbounded and we have no restriction on the values that can be taken by variables. Therefore the system defined by the specification is infinite. Nevertheless, we can build a finite system equivalent to the specification for the timed properties studied with this framework. This allows us to check the consistency of the specification in a finite time. Here are the main principles of this proof. The definition of a finite system bisimilar to the specified one is based on two equivalence relations.

Since the scope of this framework is to check the satisfaction of timed requirements, we focus on the auxiliary variables used to describe the timeline of each application variable. We define a system where only variables denoting instants are kept, i.e.. the variable describing the timelines and the observation clocks. The states and transitions of the system are defined by the values of these variables and the satisfaction of observations and variables properties. Allowed states and transitions do not depend on the values that can be taken by each variable but on the instants describing their timeline and on the observation clocks. Thus, when we build a system where only these instants are considered, we do not lose or add any characteristics about the timed behavior of the system. We define an equivalence where two states are equivalent if and only if the observation clocks and the variables denoting the update instants are equal. This equivalence is used to build a bisimilarity relation between the specified system and the one built upon only the instants.

The second reason preventing to consider a bounded number of states is the lack of bound on time. The values of the update instants and observation clocks are also unbounded. In order to reduce the possible values that can be taken by the system variables denoting instants, we define a system where all values of the instants are stored modulo the length of an analysis interval. We denote this number as $L$. $L$ must be carefully chosen, greater than the upper bounds on the variables $Steadiness$ and the observations $Latency$ characteristics and it has to be a multiple of the variable periods.

Such a number $L$ only exists if all variables and observations have upper bounded characteristics. When the source of an observation is bounded and so is the observation, such a bound is deduced for the image. Restricting the behavior by expecting variables to be frequently updated and the shift introduced by distribution to be bounded seems consistent for such real time systems.

In the system defined by the specification, transitions are based on differences between the instants characterizing the variable timelines. These differences cannot exceed the chosen length $L$. Thus, for each state, if the value of the time $T$ is known and if the values of the other variables are known modulo $L$, then for each variable there is only one possible real value that can be computed using the value of $T$. Consequently, considering the clock values modulo this length does not add or remove any behavior of the original system. We define an equivalence where two states are equivalent if the update instants and the observation clocks are equal modulo $L$. A system built by considering all values modulo $L$ is bisimilar with the original system using this equivalence.

Based on these two equivalences, we build a system by removing variables which do not denote update instants or observation clocks and by considering the values modulo $L$. This system is bisimilar to the specification and preserves the timed properties. Since all values are bounded by the length of the analysis interval and there is a bounded number of values, it defines a system with a bounded number of states. This result proves the decidability of the framework for the verification of safety properties that can be done using the finite system.

### B. Complexity

We have proved the existence of a finite system equivalent to our system. We give here the complexity of a process to effectively build this equivalent finite system. In order to build a transition from a state to a new state we build a set of inequalities deduced from the properties of the previous state and from the observation and variable properties. To solve this set of inequalities and so deduce the possible values of instant variables in the new state, we use difference bound matrices [10]. Considering a system where $n$ variables are studied, the size of each matrix is in $O(n^2)$ and thus the complexity for reducing it to its canonical form and so building the new state is in $O(n^3)$ [10]. The maximum number of states to build depends on all possible combinations of values taken by variables. Each timed variable can take values between $0$ and $L$ and the number of instant variables is a multiple of $n$ so we have $O(L^n)$ states. Lastly the complexity to build the system is in $O(n^3 * L^n)$ and considering the memory, we have to store $O(L^n)$ states and $O(L^{2n})$ transitions. Therefore this direct approach is technically feasible only with small enough systems.

### C. Other Approaches

Since our approach relies on the TLA+ formalism, we could have used the dedicated tool TLC, the TLA+ model checker. A logical definition of the observation requires the temporal existential quantifier $\boldsymbol{\exists}$, which is not implemented in TLC. Therefore a concrete definition of the observation based on an explicit observation clock has been used. It is only after we have reduced the system to a finite one that a model checker such as TLC could be used.

To be able to more precisely characterize executions satisfying the specification, we currently explore methods to build these executions more easily. A first proposal is to reduce the complexity of such a process by relying on proofs on system properties. The proof approach can easily be used only under certain conditions and in order to proceed to some system simplifications. For example, a periodic source induces properties for its image through an observation. Using these properties reduces the number of states we have to build by forecasting some impossible cases. Proving the full correctness of the system is possible but it is complex and it has not been automatized yet.

Another way is to use controller synthesis methods [11]. Properties of the observation can be expressed as safety properties using LTL and be derived as Bchi automata [12]. Two automata describe the behavior of the source and the image of an observation, exchanging values through a queue. Restrictions can be added to introduce the used implementation and its compatibility with executions defined by the specification. The complexity of controller synthesis methods has still to be explored.

## VII. Conclusion

We propose an approach focused on variables instead of tasks and processes, to model and analyze distributed real time systems. We specify an abstract model postponing task and communication scheduling. Based on the state transition system semantics extended by a timed referential, we express relations between variables and the timed properties of variables and communications. These properties are used to check the freshness of values, their stability, and the consistency of requirements. A possible analysis is to build a finite system bisimilar to the specified one. The results are used to help implementation choices.

Perspectives are to search other methods that decrease the complexity of the analysis of a specification and to use this approach with different examples to expand the number of available properties and increase expressivity. We also work on using analysis results to help generating an implementation satisfying the specification.

***Abstract*—Electrical measurement department of VSB-Technical University has been involved for more than 14 years in research and development of Power Quality Analyzer built on Virtual Instrumentation Technology. PC-based power quality analyzer with National Instruments data acquisition board was designed and developed in this time frame. National Instruments LabVIEW is used as the development environment for all parts of power quality analyzer software running under MS Windows OS. Proved PC-based firmware was ported to new hardware platform for virtual instrumentation – National Instruments CompactRIO at the end of 2007. Platform change from PC to CompactRIO is not just code recompilation, but it brings up many needs for specific software redesigns. Paper describes how the monolithic executable for PC-based instruments was divided into three software layers to be ported on CompactRIO platform. The code for different parts of CompactRIO instrument is developed in a unified development environment no matter if the code is intended for FPGA, real-time processor or PC running Windows OS.**

***Keywords*—CompactRIO, FPGA, VxWorks, LabVIEW, Power Quality**

## I. Introduction

THE MEMBERS of the Electrical Measurements Department have been involved into the research and development in the area of electrical power quality for more than fourteen years. During this period the PC-based power quality analyzer has been developed.

The basis of the solution is the software application designed and developed in the graphical development environment LabVIEW and running on a PC. The core of the application is the data acquisition process with adaptive sampling frequency. The sampling frequency and the length of the time window are chosen to follow the requirements of elemental standards for power quality area: IEC 61000-4-30 and IEC 61000-4-7. The software provides so called „gap free“ measurement by continuous data acquisition. The algorithm in conjunction with the 16-bit plug-in data acquisition board allows change of the sampling frequency on the fly. This eliminates measurement errors in frequency domain caused by the leakage that normally appears when the frequency of the measured signal is changing during the measurement period.

Under this data acquisition core the software modules provide particular instrument functionality from the user point of view, such as FFT analyzer, power and energy analyzer, voltage quality analyzer etc. The power quality analyzer allows analyzing up to 4 voltages and 4 currents.

The concept of PC-based instrumentation has been used by measurement instrument manufacturers for long time period; it has many advantages, but it is difficult to design such instruments with small size and low power consumption. A new possibility in this area is brought by the CompactRIO hardware platform described in this paper.

The goal of this paper is the description of software and instrument firmware developed by the authors for this particular problem.

## II. Virtual instrumentation

The instrumentation has often evolved into computer-based measurement systems. These systems are built with measurement hardware consisting of a digitizing element whose performance is characterized by its resolution and sample rate. The performance of this hardware, including bandwidth, accuracy and resolution, has increased dramatically in the past 10 years to the extent that the performance of the computer-based digitizers is comparable to traditional instruments. Virtual instruments are defined by the user while traditional instruments have fixed manufacturer-defined functionality, see Fig.1

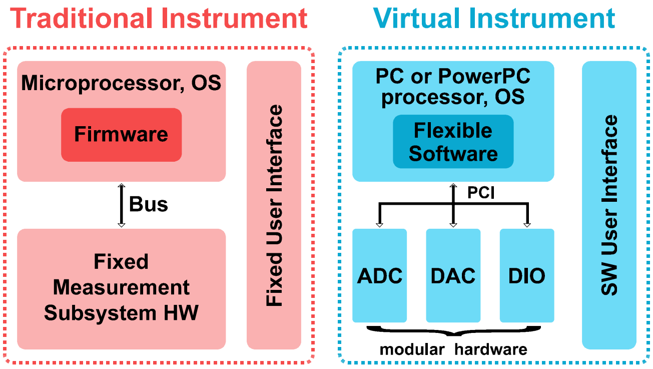

Fig. 1. Traditional instruments (left) and software based virtual instruments (right) share the same architectural components, but radically different philosophies

## III. PC based Power Quality Analyzer

The basic components of PC based power quality analyzer are common, no matter whether it is a desktop PC, stationary instrument or hand-held instrument.

The PC is equipped with the plug-in data acquisition board from National Instruments. Currently the M-series PCI and USB boards are supported. M-series boards provide 16 analogue inputs and the aggregated sampling rate is at least 250 kS/s. The data acquisition process of instrument SW uses sampling frequency 9.6 kS/s per channel.

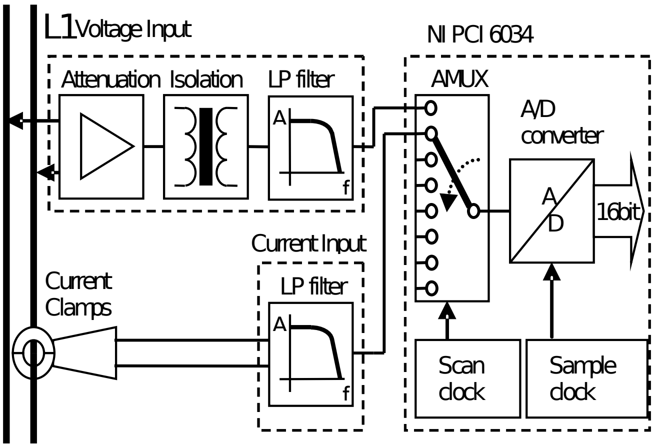

Fig. 2. Power Quality Analyzer input circuit diagram.

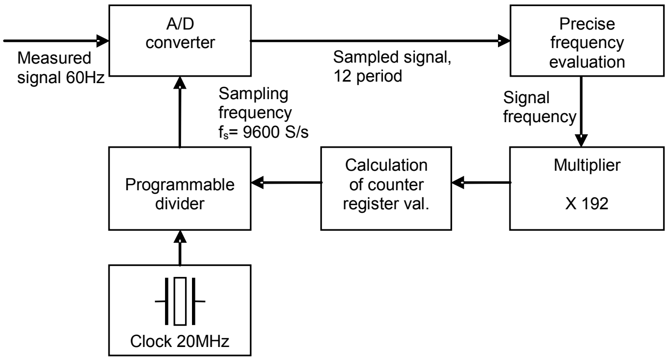
Modules for signal conditioning of voltage and current signals provide attenuation / amplification, isolation and anti-aliasing filtering. Modules for signal conditioning are programmable via digital lines or serial interface. This allows inputs range selection and anti-aliasing cut-off frequency set-up. The block diagram of signal conditioning modules connected to analog to digital converter is shown on Fig. 2.

The operating system used for the PC based instrument is Windows XP or Windows XP Embedded. Power quality analyzer firmware fully written in LabVIEW is running in the operating system as EXE application. In case if instrument is equipped with a touch-in display, the user can operate the instrument without keyboard or mouse, because complete firmware is ready to use soft-keyboards.

## IV. Signal Sampling According To IEC61000-4-30

According to IEC61000-4-30 the basic measurement time interval for voltage quality parameters (supply voltage, harmonics, interharmonics and unbalance) shall be a 10-cycle time interval for 50 Hz power system or 12-cycle time interval for 60 Hz power system. It is not a fixed interval in time, but measurement interval varies in time as the fundamental frequency of power network changes. The adaptive sampling frequency solves this requirement and avoids not wanted phenomena in frequency domain like leakage and scalloping loss.

The easiest way to achieve adaptive sampling frequency is PLL (Phase Lock Loop). Data acquisition boards are not equipped with PLL hardware and thus software version of PLL principle was developed, see Fig.3. The most important on the “software PLL” is a very precise frequency measurement algorithm from 12 periods of signal.



Measured signal 60Hz
A/D converter
Sampled signal, 12 period
Precise frequency evaluation
Sampling frequency $f_s$= 9600 S/s
Signal frequency
Programmable divider
Calculation of counter register val.
Multiplier
X 192
Clock 20MHz

Fig. 3. Software implementation of PLL

The method using envelope curve of the spectral lines in frequency domain was used. If rectangular window is used in time domain then the envelope curve in frequency domain is a function *sin(x)/x.* The precise frequency can be calculated from amplitudes of two nearest spectral line from signal frequency, even if the frequency is not integer multiply of the step in frequency domain.

## V. Analyzed quantities and Measurement uncertainty achievment

According to IEC61000-4-30 Power Quality Analyzer should analyze and evaluate these quantities: power frequency, magnitude of the supply voltage, flicker, harmonics and interharmonics, supply voltage unbalance, rapid voltage changes and voltage dips, swells and interruptions. It is suggested that currents will be also monitored and analyzed. For any mentioned quantity the measurement uncertainty is specified. The requested uncertainty on voltage and current magnitude should be better than 0.1% for the complete instrument including sensors (e.g. current clamps).

To understand the type and magnitude of errors, FLUKE 6100A Electrical Power Standard programmable calibrator has been used. Numerous errors were discovered: frequency amplitude errors, frequency phase errors, amplitude and phase error (depending on the magnitude of signal within the measurement range). After thorough analysis of the discovered errors a solution was designed to accomplish the error compensation. Some errors can be corrected in time domain; some errors must be corrected in frequency domain. An appropriate structure of calibration tables was designed and implemented as automated calibration software.

## VI. CompactRIO Hardware Description

CompactRIO does not replace PC-based instruments for virtual instrumentation, but it is collateral hardware platform with smart structure.

CompactRIO combines an embedded floating point processor (PowerPC) with real-time operating system VxWorks, a high-performance FPGA and hot-swappable I/O modules. Each I/O module is connected directly to the

FPGA, providing low-level customization of timing and I/O signal processing. The FPGA is connected to the embedded real-time processor via a high-speed PCI bus, see Fig.4. This represents architecture with open access to low-level hardware resources. Both PowerPC processor and FPGA are programmed in graphical programming language LabVIEW. LabVIEW contains built-in data transfer mechanisms to pass data from the I/O modules to the FPGA and also from the FPGA to the embedded processor for real-time analysis, postprocessing, data logging, or communication to a networked host computer.

CompactRIO in comparison with PC-based instruments brings compact solution, small size 88 x 180 x 90mm (HxWxD), wide operating temperature -40°C to +70°C and very low power consumption (approximately 8W).

## VII. CompactRIO Based Quality Analyzer

After long time development and improvements of PC-based Power Quality Analyzer it was decided to port the proved PC code to CompactRIO. The original code of PC-based instrument was divided into three layers:

- FPGA (data acquisition process, SW PLL)
- real-time processor, (data analysis functions)
- host PC (user interfaces)

All three described parts were implemented in the same development environment: National Instruments LabVIEW. Very powerful part of CompactRIO is FPGA. It can solve functionality between I/O modules without interaction with real-time processor. Fixed point arithmetic library and even FFT routines for FPGA are available in LabVIEW. The code on FPGA is extremely fast in comparison with embedded processor.

It was decided to move adaptive sampling frequency algorithm directly on FPGA. All blocks on Fig.3 are implemented on FPGA. FPGA ensures sampling of 3 voltage signals and 4 current signals. Other parallel task running on FPGA is mechanism of data transfer to real-time processor, digital input acquisition and transfer, GSM modem data transfer. LabVIEW code implementation for FPGA is not fast and easy, because compilation of this part of code takes several tens of minutes. As an optional way of software PLL was developed resampling algorithm. Resampling algorithm was implemented on FPGA and provides signal samples with different sampling frequency than AD converter. This algorithm is still under testing process.

PowerPC processor runs VxWorks operating system and LabVIEW application with several parallel tasks. Application receives data samples from FPGA and calculates from them many parameters including: RMS values, frequency, harmonic spectra, total harmonic distortion, flicker, three-phase system unbalance, active power, reactive power, energies and many other quantities. Calculated quantities are aggregated in time and some data are statistically evaluated before storing. Data are stored periodically with defined time interval and event-based data are stored just in time when event appears. Data are stored to local solid state disc. Real-time processor ensures also TCP communication with host PC. LabVIEW code implementation for PowerPC is fast because LabVIEW provide on the fly compilation of code fragments.

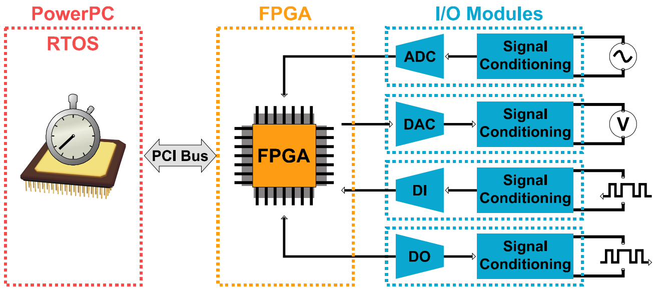


Fig. 4. Compact-RIO internal structure

Host PC applications, also developed in LabVIEW, serve as graphical user interface for CompactRIO instrument. CompactRIO and host PC are connected each other by Ethernet and they use TCP protocol to communicate.

## VIII. Power Quality Analyzer Software Suite

The project name of complete software suite for power quality analyzer is ENA. Directly on CompactRIO runs ENA-Node firmware. ENA-Node runs on FPGA and on PowerPC embedded in CompactRIO.

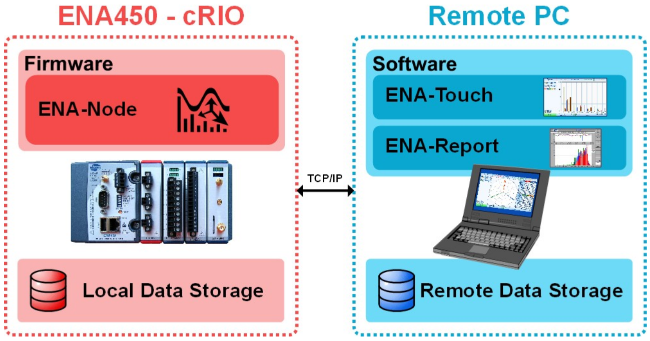

Fig. 5. ENA Power Quality Analyzer Software Suite

The user interface ENA-Touch runs on host PC connected to ENA450 and allows instrument set-up and on-line data visualization, see Fig.5.

The main concern of ENA-Touch development cycle was user friendliness, ease of operation and compliance with international standards. ENA-Touch can control ENA-Node remotely by using TCP protocol over Ethernet. New original approach to instrument set-up and to display measured quantities allows easy and well arranged configuration and measured data presentation. In ENA-Touch exist numerous ways how to present data: tables, time and frequency domain graphs, scope, vectorscope (see Fig.6) and statistical results for power quality.

## IX. Conclusion

CompactRIO is a combination of powerful hardware and software running on real-time processor and FPGA in parallel. CompactRIO brings even better flexibility for virtual instrumentation than PC platform. The same graphical development environment LabVIEW used for three levels of hardware FPGA, real-time processor and PC dramatically simplifies the SW maintenance and further

development. The development process for CompactRIO is not as fast as on PC platform, but there is no need to know VHDL language to program FPGA, no need to be deeply familiar with real-time operating system VxWorks. The main advantage of described CompactRIO-based solution is its flexibility and scalability. Big support of advanced math functions for FPGA becomes available; this will allow moving many calculation routines from real-time processor to FPGA.

Porting of PC-based instrument code to CompactRIO hardware platform was not a trivial task. There are many differences between PC and CompactRIO approaches to the same problem. Even an author with more than 12 years of experience and deep knowledge of LabVIEW needs several months to have fully functional and tested solution ready to be a product. There is a long way from simple CompactRIO demo showed on trade shows to functional and reliable complex instrument. The goal of the team was to test if CompactRIO hardware together with LabVIEW graphical development environment is a usable platform for future implementations of such complex measurement instruments like power quality analyzer is. The project confirms that a suite CompactRIO and LabVIEW is a reliable platform for virtual instrumentation of this sort.

*Abstract*—**Modern surveillance systems, such as those based on the use of Unmanned Aerial Vehicles, require powerful high-performance platforms to deal with many different algorithms that make use of massive calculations. At the same time, low-cost and high-performance specific hardware (e.g., GPU, PPU) are rising and the CPUs turned to multiple cores, characterizing together an interesting and powerful heterogeneous execution platform. Therefore, reconfigurable computing is a potential paradigm for those scenarios as it can provide flexibility to explore the computational resources on heterogeneous cluster attached to a high-performance computer system platform. As the first step towards a run-time reconfigurable workload balancing framework targeting that kind of platform, application time requirements and its crosscutting behavior play an important role for task allocation decisions. This paper presents a strategy to reallocate specific tasks in a surveillance system composed by a fleet of Unmanned Aerial Vehicles using aspect-oriented paradigms in order to address non-functional application timing constraints in the design phase. An aspect support from a framework called DERAF is used to support reconfiguration requirements and provide the resource information needed by the reconfigurable load-balancing strategy. Finally, for the case study, a special attention on Radar Image Processing will be given.**

## I. Introduction

In addition to timing constraints, several modern applications usually require high performance platforms to deal with different algorithms and massive calculations, varying from monitoring and processing of different data acquired by sensors to cryptography and large image data visualizations and processing. The development of low-cost powerful and application specific hardware (for example, the GPU —Graphics Processing Unit, the Cell processor, PPU—Physics Processing Unit, DSP—Digital Signal Processor, PCICC—PCI Cryptographic Co-processor, FPGA—Field Programmable Gate Array, among others) offer several execution alternatives aiming better performance, programmability and control. The resulting execution platform heterogeneity is intensified with multi-core CPUs, causing problems to achieve simple programming and efficient resource utilization.

Following that direction, low-cost inter-chip hybrid hardware architectures are becoming very attractive to compose adaptable execution platforms and, at the same time, software applications must benefit from that performance powerfulness. This leads to the creation of new methods and strategies to distribute the application's workload (tasks, algorithms, full applications) to execute in the specific processing units in order to better meet application requirements, such as performance and timeliness, without loosing flexibility. In this manner, reconfigurable load-balancing computing is a potential paradigm for those scenarios as it can provide flexibility, improve efficiency, and offer simplicity to high performance heterogeneous processor cluster and multi-core architectures. Figure 1 shows such a theoretical scenario.

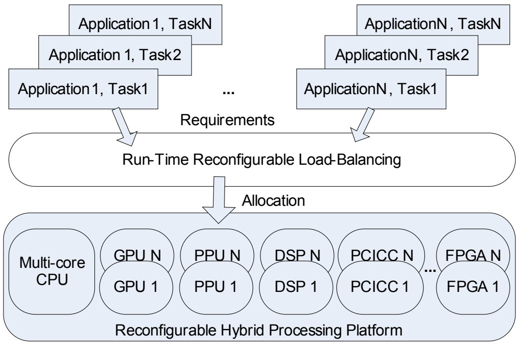

Fig. 1. System overview

The goal is to design proper methodologies, strategies, and support for management of a dynamic load-balancing by means of real-time reconfiguration of involved tasks. To reach this objective, thereby, the main step is to create a self reconfiguration framework that can be used by applications composed of different kinds of algorithms (graphics, massive mathematical calculations, sensor data processing, artificial intelligence, cryptography, etc) which runs on a single personal computer and needs to execute under time constraints and a minimal quality (performance). In addition, during execution time, the framework is intended to keep monitoring the tasks and provides online information in order to a possible new allocation balance, i.e., a reconfiguration of tasks is done if this procedure can promote a better performance for the overall current scenario.

978-83-60810-14-9/08/$25.00 © 2008 IEEE

In this paper, the focus is on the very first step in the design method framework: application requirements handling (reconfiguration) in a high-level design. The approach is to extract the requirements to find concurrency in order to base the load-balancing framework towards task parallelization and reallocation. For its accomplishment, the crosscutting concerns related to the real-time non-functional requirements are taken into account. The handling of these concerns by specific design elements called “aspects” (from aspect-oriented paradigm [1] plays an important role to improve understandability and maintainability during task (re)configuration. Based on the support offered by the aspects to monitor and control the above mentioned requirements, a strategy to assign tasks dynamically to units of execution is presented, being these tasks subject to an on-line reconfiguration.

The paper is organized as follows. We start in Section II with a previous work based on aspects and a description of the created ones for requirements identification, modeled using UML notation. Section III follows by a reconfigurable workload strategy implemented by the aspects. Composing these two concepts, Section IV outlines Unmanned Aerial Vehicle Surveillance system as application, focusing on radar image processing tasks. Finalizing, related works, conclusions and future works are presented.

## II. Aspect-oriented Handling of Real-time Concerns

In order to provide a reconfigurable solution in runtime with the goal to meet timing requirements, several mechanisms to control and monitor timing parameters must be inserted in the system. Moreover, the mechanisms related to the migration of tasks among processing units, which implements the system reconfiguration itself, also affect several elements in the system in a non-uniform way. Besides, all these mechanisms and controls are not the main goal or functionality of any system, but they must be present in order to achieve reconfiguration. These facts are clear characterized as non-functional crosscutting concerns, which can be successfully addressed by an aspect-orientation [1].

The non-functional requirements handling concerns hinder the system maintainability, reuse, and evolution in current approaches used in task reconfiguration such as those that use pure object-orientation. It occurs because the handling elements (such as timing requirements probes, serialization mechanisms, task migration mechanisms, among others) are not modularized in a single or few system elements, but spread over the system. Any change in one of these elements requires changes in different parts of the system, what besides to be a tedious and error-prone task, do not scale in the development of large and complex applications. The observation of these drawbacks motivates the use an aspect-oriented approach that makes possible to address such concerns in a modularized way. It separates the handling of the non-functional concerns in specific elements, increasing the system modularity, diminishing the coupling among elements, and though affecting positively the system maintainability, reuse and evolution. Moreover, the advantages of the aspect-oriented approach became clearer when applied to the aforementioned task allocation strategies using heterogeneous platforms due to the need of profiling each task in a different hardware, affecting several elements of the application. The use of aspects to address this concern represents an improvement as it helps to cope with the complexity in managing this handling that is spread allover the system.

In the next subsection, the aspects used to address timing related concerns will be presented, which come from the DERAF framework [2] that provides a high-level aspect library to handle Distributed Real-time Embedded (DRE) systems non-functional requirements.

### *A. Time-based Aspects*

In order to support Timing and Precision requirements, the proposal is to use some aspects from the DERAF framework. The packages designed to these types of requirements are presented in Figure 2 and a short description of each one is provided in the following paragraphs. Interested readers are referred to [2] and [3] for more details.

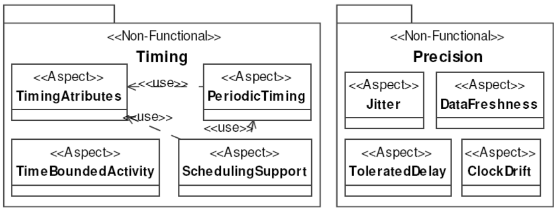

Fig. 2. Timing and Precision packages from DERAF

TimingAttributes: adds timing attributes to active objects (e.g., deadline, priority, start/end time, among others), and also the corresponding initialization of these attributes.

PeriodicTiming: adds a periodic activation mechanism to active objects. This improvement requires the addition of an attribute representing the activation period and a way to control the execution frequency according to this period.

SchedulingSupport: inserts a scheduling mechanism to control the execution of active objects. Additionally, this aspect handles the inclusion of active objects into the scheduling list, as well as the execution of the feasibility test to verify if the scheduling list is schedulable.

TimeBoundedActivity: temporally limits the execution of an activity by adding a mechanism or changing a parameter that can restrict the maximum execution time for an activity (e.g., limit the time which a shared resource can be locked).

Jitter: measures the start/end of an activity, calculates the variation of these metrics and whether the tolerated variance was overran.

ToleratedDelay: temporally limits the beginning of an activity execution (e.g., limits the time which an active task can wait to acquire a lock on a shared resource).

DataFreshness: associates timestamps to data, verifying their validity before using them [4].

ClockDrift: measure the time at which an activity starts and compares it with the expected beginning of this activity; it also checks if the accumulated difference exceeds the maximum tolerated clock drift.

Additional aspects were developed to compose the information provided by the DERAF aspects to inject the reconfiguration strategy. These aspects as described in the following.

### *B. Aspects for Supporting Reconfiguration*

As mentioned before, the task migration support characterizes a non-functional crosscutting concern that affects different parts of the system in different ways. On this way, we propose the use of aspects to address this concern. The new aspects proposed in this work are: **TimingVerifier**, **TaskAllocationSolver**.

Both use the time parameters inserted by the aspects of the Timing package, described previously, and the services provided by the aspects from the Precision package. An additional package from DERAF is also used in order to make the reconfiguration decisions take place; it is the TaskAllocation package, which is presented in more details latter on in this section. Figure 3 depicts the schema.

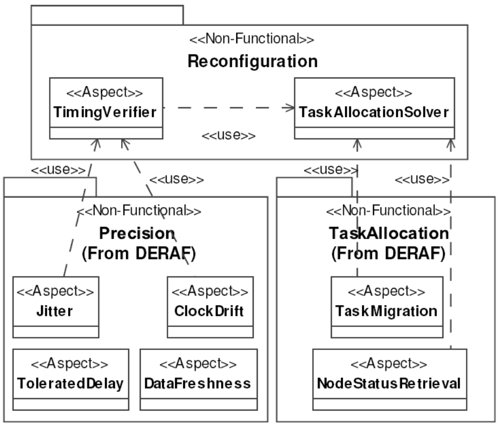

Fig. 3. Aspects for Reconfiguration

The **TimingVerifier** is responsible for checking if the processing units are being able to accomplish with the timing requirements specified by the TimingAttributes, PeriodicTiming, ToleratedDelay and TimeBoundedActivity aspects. In order to do this, it uses the services from the aspects Jitter and ClockDrift.

A mechanism to control the meeting of timing attributes is inserted in the beginning and end of each task. This mechanism consists of measuring these times, and comparing them with the requirement specified by the correspondent attribute. As an example, the accomplishment of a specified deadline can be checked by measuring the time in which the task actually ended its computation and comparing it with the time in which it was supposed to finish. It uses the service of the Jitter aspects to gather and analyze information about the jitter related to the corresponding requirement. Taking the deadline again as an example, it measures if a non-accomplishment of a deadline is constant or if the measure varies in different executions or in changing the platform scenario. It can be used, for instance, as base information to know if the interaction with other tasks is being responsible for the variance.

The ClockDrift aspect is used by the TimingVerifier to gather information about the synchronization among the different Processing Units (PUs). It is useful to calculate the cost, in terms of a task migration time. In order to illustrate the idea, consider a task that was migrated from a PU "A" to a PU "B". The difference in the clock drift between them can result in a waiting time for the result from the PU "B" that does not worth if compared with leaving the task running in the PU "A".

**TaskAllocationSolver** is the second key aspect. It is responsible for deciding whether a task will be migrated or not and to which of the available PUs. It also has to check possible overload of the PU candidate destinations in order to decide whether it is worthwhile to perform the migration. The TaskAllocationSolver uses the measurements available due to the work done by the TimingVerifier.

Based on these data, the reasoning about the feasibility or not of a task reconfiguration is done. The explanation of this reasoning is provided in the next section, where the reconfiguration strategy is presented.

The reconfiguration itself and the retrieval of PUs (nodes) status are done by two other aspects from DERAF, the NodeStatusRetrieval and the TaskMigration. This way, the reasoning and the performance of the reconfiguration are decoupled, allowing that changes performed in one aspect do not affect the other. A brief summary of the NodeStatusRetrieval and TaskMigration aspects is provided in the following.

TaskMigration: provides a mechanism to migrate active objects (tasks) from one PU node to another PU node. It is used by the aspects that control embedded concerns and, in the present work, by the allocation solver aspect TaskAllocationSolver.

NodeStatusRetrieval: inserts a mechanism to retrieve information about processing load, send/receive message rate, and/or the PU availability (i.e., the "I'm alive" message). Before/after every execution start/end of an active task, the processing load is calculated. Before/after every sent/received message, the message rate is computed. Additionally, the PU availability message is sent at every "n" message or periodically with an interval of "n" time units.

## III. Dynamic Reconfiguration Strategy

A task-based decomposition approach is used, in which each task is an independent algorithm. The tasks are grouped according derivation of the same high-level, simplifying the managing of possible dependencies. Besides, it is coherent to assume that a group of tasks will have the same characteristics or, in other words, the same designed features and hence would be desirable to execute in the same PU. However, this can lead to a non-optimal execution, as it will be discussed in the next sub-sections.

### *C. First Assignment of Tasks*

The strategy is to combine a costly method for assignment problems with a real-time measurement procedure based on the mentioned aspects. For the first assignment of tasks, we do not use the modeled aspects, since we do not have real time measurements of tasks. Therefore, we decided to offer two possibilities: assign all the tasks in the first time step to the CPU and then perform the dynamic reconfiguration; or model the first assignment as a common assignment problem using Integer Linear Programming (ILP), like the generic approach used by the authors of [5]. In this way, a set of tasks can be represented as $T = \{t_{i,j}\}$, where every task $i$ has an implementation based on the specific hardware API (considering each supported hardware) and an execution cost estimation on the PU $j$. The execution cost $c_{i,j}$ is simply estimated, in this paper, based on a correlation between the input data type used by the task (mapped within a weight scale) and the number of sub-cores presented in the corresponding processing unit. A flag is assigned for tasks that only execute in determined hardware. Note that these costs could not reproduce the reality with fidelity and are just a way to determine a "first guess" to the system.

The total execution time of the application is minimized by finding a schedule solution by means of its tasks execution times. The constraints for the presented model will be the maximum workload of each processing unit ($U_{max}$), which are represented by

$$U_j = \sum_{i=1}^{n} x_{i,j} c_{i,j} \leq U_{j_{\max}} \quad (1).$$

The objective function that minimizes the total application execution time is, then, defined as

$$\min \left\{ \sum_{j=1}^{m} \sum_{i=1}^{n} x_{i,j} c_{i,j} \right\} \quad (2),$$

being the variables $x_{i,j}$ the solution for the modeled ILP.

The ILP problem is considered of complexity NP-hard and it is costly to calculate every period of time to estimate the current optimal assignment. Due to that reason, some approaches concentrate on heuristic-based methods to estimate the best assignment, as the above mentioned work of [5]. Nevertheless, this direction neither considers real execution times nor could represent the best assignment.

In counter part, the approach presented in this paper allows taking into account real execution measurements extracted from the processing units (using aspects) and works with a dynamic reconfiguration module that deals with real execution variables and interferences, leading to a possible better task assignment.

### *D. Real-time Reconfiguration*

After the first tasks assignment, the dynamic reconfiguration strategy enters on scene in application run-time. At this point, we consider the information provided by the created aspects and the first assignment. The assumption is: based on involved migration costs and possible interferences of new loaded tasks, one task can be reconfigured to run in other PU just if the new PU already finished the processing of its tasks (is idle) and the estimated time to execute the task in the new PU will be less than the time to execute in the actual PU, i.e., just if there is a gain. In a simple equation, this relationship can be modeled in terms of the costs:

$$T_{reconfigPUnew} < T_{remainingPUold} - T_{estimatedPUnew} - T_{overhead} \quad (3),$$

where the remaining time ($T_{remainingPUold}$) and the estimated time ($T_{estimatedPUnew}$) are calculated, respectively, for the current PU and for the new candidate PU based on previous measurements or on the first assignment (in the case of first reconfiguration invocation); and an overhead ($T_{overhead}$) that explicit the execution time of the reconfiguration itself. The relationship between $T_{remainingPUold}$ and $T_{estimatedPUnew}$ is considered the partial gain.

The information needed to calculate the reconfiguration will be provided by the `TimingVerifier` aspect and can be modeled without such mathematical formality as:

$$T_{reconfigPUnew} = T_{setupReconfigPUnew} + T_{temporaryStorage} + T_{transferRate} + T_{executionPUnew} + L \quad (4),$$

where $T_{setupReconfigPUnew}$ represents the time for setting up a new configuration on the new PU; $T_{temporaryStorage}$ contributes with the time spent to save temporal data if needed (considering shared and global memory access parameters); $T_{transferRate}$ measures the cost for sending/receiving data from/to the CPU to/from the new PU, which can be a bottleneck on the whole calculation; $T_{executionPUnew}$ symbolizes the measured or estimated cost of the task processed in the new PU; and finally $L$ denotes a constant to represent possible system latency.

During the application execution, the load-balancing module will keep storing the execution times for each type of the tasks with the information gathered by the `TimingVerifier` aspect together with the data provided by the `NodeStatusRetrieval` aspect. These preliminary stored times will be useful as one of the basis to the reconfiguration decision done by the `TaskAllocationSolver`.

An overview about the created strategy is presented on Tables 1 and 2. The behaviors that compose this strategy are inserted in the core of the system by the above mentioned aspects and those used by them, as presented in section II.B.

## IV. UAV-based Area Surveillance System

The presented ideas are illustrated by a case study that consists of a fleet of Unmanned Aerial Vehicles (UAVs) used in area surveillance missions. Such UAVs can be equipped with different kinds of sensors that can be applied, depending on the weather conditions, time of the day and goals of the surveillance mission [6]. We consider a fleet of UAVs that might accomplish missions during all the day and under all weather conditions. The UAVs also must be able to provide different levels of information precision and detail, depending on the required data.

To start, the UAVs receive a mission to survey a certain area and provide required data according to the mission directives. Their movements are coordinated with the other UAVs in the fleet in order to avoid collisions and also provide optimum coverage of the target area. Details about the used coordination algorithm are out of the scope of this paper.

Each UAV is composed of six subsystems that make it able to accomplish its missions and coordinate with the other UAVs. These subsystems are: Collision Avoidance, Movement Control, Communication, Navigation, Image Processing, and Mission Management.

In order to run the tasks described above and meet the high-lighted requirements and constrains modeled on the previous sections, we consider UAVs equipped with the following sensors: Visible Light Camera (VLC); Synthetic Aperture Radar (SAR) and Infra-Red Camera (IRC). In order to support the movement control, communication devices and embedded sensors, each UAV will be equipped with a hybrid processing unit target platform which is used accordingly to the specific needs during the accomplishment of a certain mission, detailed in the following.

### *E. UAV Subsystems*

As mentioned above, each UAV has six subsystems. Each subsystem has a number of tasks that perform specialized activities related to a specific functionality. An UML Use Cases Diagram showing the UAV functionalities is presented in Figure 4.

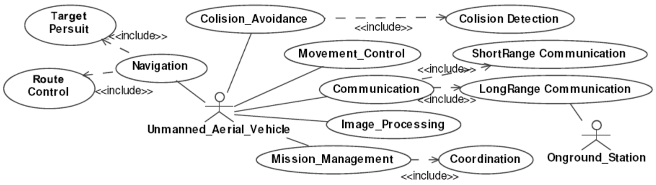

Fig. 4. UAV Use Cases Diagram

Based on the analyses of the UAV functionalities, a summary of the tasks that compose each subsystem is provided in the following paragraphs.

**Movement Control**: responsible to monitor and control the engines and direction mechanisms, such as flap actuators. It is composed by two tasks. The first is called `MovementController`, which performs the calculus that must be applied in the actuators and engines. The second task is called `MovementEncoder` and it is responsible for the sampling and encoding of the actual values in the engines and actuators, which will be used as feedback data for the `MovementController` task. These tasks are designed to have an implementation based on CPU, GPU, and PPU.

**Navigation**: control the directions of the UAV movements and sends control information to the Movement Control subsystem. It is composed by the `RouteControl` and `TargetPersuit` tasks. The first makes the calculation to guide the UAV through established waypoints, while the second performs the same, but for dynamic waypoints that varies accordingly to a moving object. These tasks have an implementation based on CPU, GPU, and PPU.

**Image Processing**: this subsystem gathers analog image information and performs its digitalization. It is composed of six tasks. The first is the `CameraController`, which is responsible by the movement of the camera, zoom and focus control of IRC and VLC, and antenna direction of the SAR. The second is the `Coder`, which codifies the analog input into digital data. The third is the `Compressor`, which compresses the digital images. The fourth is the `Reflectificator`, which is responsible for the reflection in the X and Y axis of radar image, as well as the rectification. These two processes are necessary to avoid distortions in the image. The fifth task is called `Filter`, which is responsible for filtering the radar images in order to eliminate the noise due to speckle effect [7]. The last task is called `PatternRecongnition` and is responsible to perform image segmentation and recognition of patterns from the previously processed data. These tasks are designed to have an implementation based on CPU, GPU, and PPU.

**Communication**: communication subsystem has two main tasks, the `LongRangeCom` and `ShortRangeCom`. The first provides connectivity with pair communication nodes in long distances, order of kilometers, while the second provides connectivity in short range, order of meters of distance. Both make use of a third, called `Codec`, which code and decode transmission data based on cryptographic techniques. These tasks have an implementation based on CPU, GPU, and PCICC.

**Mission Management**: this subsystem has two tasks, the `MissionManager` and the `Coordinator`. The first manages the information about the mission, like required data and mission policy, while the second drives the coordination with the other UAVs to avoid surveillance area overlap. Their implementation are based on CPU, and GPU.

**Collision Avoidance**: is composed by two tasks, `CollisionDetector` and `CollisionAvoider`. The first detects possible collisions with other UAVs of the fleet or non cooperative flying objects, and the second makes the calculus to avoid the collision and send them to the Movement Control subsystem. These tasks have an implementation based on CPU, GPU, and PPU.

### *F. Reconfiguration Approach*

In the presented experiment, the target architecture is composed of a four hybrid PUs platform: one CPU (Intel 2-core) and three types of co-processors, two GPUs (nVidia GeForce8800 GT – 512MB memory - using PCI Express x16 and CUDA-FFT/BLAS toolkit), a PPU (Ageia using PhysX SDK), and a PCICC (IBM using UDX toolkit). Figure 5 shows the desired execution platform, where the Profiling gathers information from the PUs and the Reconfiguration distributes the tasks along the PUs (intra allocation) and also consider sending data to be processed by other UAVs (inter allocation).

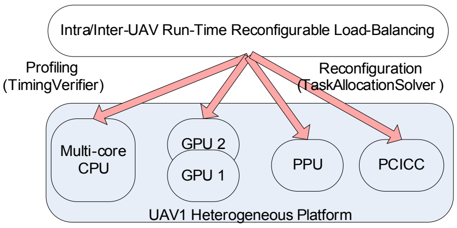

Fig. 5. UAVs Execution Platform with support for Load-balancing

Starting the mission, the UAVs have an initial task allocation throughout the CPU and co-processing units of the target platform according to one of the algorithms presented on sub-section III.A. In the current experiments, it was considered to use the ILP approach for the first distribution of the groups of tasks (and not the tasks individually). This simulation was done using the GLPK toolkit [8] and took in consideration the priorities of abstract tasks and its estimated execution costs in each PU, performing the following distribution: tasks from the Movement Control group (MovementController, MovementEncoder), and Navigation (RouteControl, TargetPersuit) are assigned to the PPU; the ones from Collision Avoidance (CollisionDetector, CollisionAvoider) are assigned to the GPU2; the Image Processing tasks (CameraController, Coder, Compressor, Reflectificator, PatternRecognition and Filter) are all assigned to the GPU1; and the sub-systems Communication (LongRangeCom, ShortRangeCom) and Mission Management (MissionManager, Coordinator) are firstly assigned to the CPU.

During execution, the mechanisms injected by the TimingVerifier and the aspects used by it - Jitter and ClockDrift - will start to generate values related to timing measurements. The Jitter and ClockDrift will take more time to generate more confident values, maybe after 100 executions in other to provide more meaningful measurements. But in an overall view, the TimingVerifier aspect will provide data to the TaskAllocationSolver, which will take data from the NodeStatusRetrieval and with the reasoning mechanisms that were inserted in the subsystems will analyze the data provided by these two aspects according to the algorithm introduced in III.B.

### *G. SAR Image Processing*

A special attention has to be given to the Image Processing sub-system. It is considered to be the group which requires more processing from the execution platform due to work with large data, being a key-factor to influence the dynamic reconfiguration of tasks. Figure 6 depicts the SAR Image Processing workflow. To summarize this figure, the captured data (brute scalar image) must be "adjusted" regarding the SAR position parameters (range and azimuth), followed by Fast Fourier Transforms (FFT) and image rotation and other corrections, to produce the final image. This process can be performed individually in the range and azimuth directions and it consists basically in a data compression on both directions using filters that maximize the relation between the signal and the noisy. Readers are addressed to [9] to get refined explanations about the workflow.

In terms of implementation, this sub-system can normally be developed based on CPU, but it fits better as a general processing on the GPU, since it involves mainly matrices multiplications applied to each scalar of the captured data. In addition, the data is represented using a complex number format (the real -32bits- and the imaginary -32bits- parts express the amplitude and phase of the scalar), generating large data ordering of gigabytes. Then, to optimize its execution time, a common approach is data partitioning. Individual regions can be processed in parallel by the available PUs (GPU, CPU, and PPU on this case) and, at the end, composed together to obtain the final SAR Image.

As a next step, the final image is submitted to a pos-processing phase, i.e., the PatternRecognition task aims to identify certain regions of interest that could contain objects specified in the mission directions as "pattern to be found". For that case, more resolution on those image parts will be needed and, consequently, new data will be generated, demanding more processing from the assigned PU(s) in order to produce the final images and extract new information (patterns). This scenario clearly influences the priority of tasks (old and new ones) since, at that moment, the new high-resolution images will have higher priorities comparing to others that became more "generic".

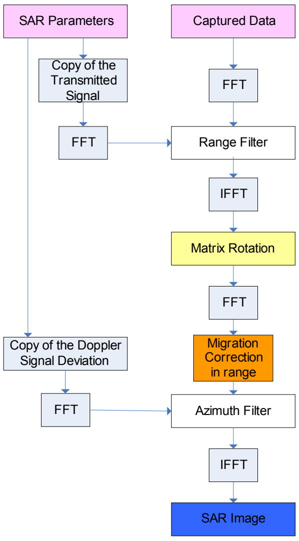

Fig. 6 – SAR Image Processing (based on the notes of [9] )

These events cannot be predicted a priory and the verification of such situation require, thus, a smart and dynamic reconfiguration support to reallocate the tasks, accomplishing the timing and requirements budget. On that case, the presented approach considers not just the balance of instructions inside an UAV execution platform, but also the data/image partitioning and interaction with other UAVs serving on the mission area. In this way, the reconfiguration support is applied to sending/receiving data to be processed by other idle UAVs and, at that point, encrypted communication must be applied in short and long range.

### *H. Previous results*

At this step of our research (reconfiguration and application architecture design), the UAV sub-systems algorithms, like Image Processing and Communication, were not implemented. The described scenario was simulated by means of creation of new tasks at run-time, where each task has an estimated cost to execute in each PU and a priority that change "on the fly". Table III exhibits the estimated costs and first priorities for the groups of tasks.

As the `TimingVerifier` aspect gathers online data about the execution of the tasks and the `NodeStatusRetrieval` gathers the PUs load parameters, the `TaskAllocationSolver` decides that the current allocation is possibly not the best configuration for the tasks that are waiting to be processed because it does not minimize the execution time. If confirmed, the reconfiguration takes place by using the `TaskMigration` aspect, which moves the tasks according to the decided new configuration presented by the `TaskAllocationSolver`. In the simplified simulation provided, evidences were gotten that when many new refined images are needed, the load-balancer tends to reallocate the Collision Avoidance tasks from the GPU2 to PPU (and then to CPU) and new instances of the Image Processing group (refined images) are assigned to be processed by GPU2 because of the Priority versus Estimated Cost compromise. In that situation, migration costs were estimated based on the throughput velocity of each PU bus (PCI, PCI-Express, etc.) and the other parameters considered on the equations (3) and (4).

Table III.
Estimation Costs for Tasks Groups

| Tasks Group | Estimated Costs (scale: 1 to 6) | | | | First Priority (scale: 1-6) |
|---|---|---|---|---|---|
| | GPU | PPU | CPU | PCICC | |
| **Image Processing** | 1 | 4 | 6 | - | 1 |
| **Collision Avoidance** | 3 | 2 | 5 | - | 2 |
| **Movement Control** | 2 | 2 | 3 | - | 1 |
| **Navigation** | 1 | 1 | 2 | - | 3 |
| **Communication Short/Long range** | 4/6 | - | 3/5 | 1/2 | 4 |
| **Mission Management** | 5 | - | 1 | - | 6 |

Moreover, as much as new refined images are required, it was verified assignment of tasks to other UAV that was idle, performing a drastic changing on the Communication task priority. The parameter ***L*** will, then, represent the communication latency between UAVs in short and long range. As it is reasonable to consider a grater ***L*** in long range than in short range, the simulation predicted that allocation in long range is not recommended and in most of the times the waiting time to access its PUs or other UAVs PUs in short range is worthwhile.

Based on that estimation and considering 2 UAVs, Table IV denotes the behavior of the dynamic reconfigurable load-balancer simulator.

The "first guess" represents one instantiation of each group of tasks that is assigned to a PU; and with the dynamic creation of new groups (4, 8, and 12 groups) of the Image Processing tasks, the assignment is changed and optimized, trying to minimize the total execution time. Note that these values cannot represent the best assignment since the simulator did not consider all parameters that influence the whole system. As it is an ongoing work, more accurate data about the reconfiguration will be provided along the refinement of the simulator in order to represent the scenario as reliable as possible.

Table IV.
Assignment of Tasks Groups for an UAV1

| Tasks Group | $1^{st}$ Guess | Dynamic Image Processing Created Tasks | | |
|---|---|---|---|---|
| | | 4 | 8 | 12 |
| **Image Processing** | GPU1 | GPU1<br>GPU2 | GPU1<br>GPU2<br>PPU | GPU1<br>GPU2<br>UVA2-<br>GPU1 |
| **Collision Avoidance** | GPU2 | PPU | CPU | CPU |
| **Movement Control** | PPU | PPU | CPU | CPU |
| **Navigation** | PPU | PPU | PPU | CPU |
| **Communication** | CPU | CPU | CPU | PCICC |
| **Mission Management** | CPU | CPU | CPU | CPU |

## V. Related Works

A set of tools named VEST (Virginia Embedded System Toolkit) [10] uses aspects to compose a distributed embedded system based on a component library. Those aspects check the possibility of composing components with the information taken from system models. This work also provides a library of aspects and has a type of model weaving, making different kinds of analysis to compose the system, such as schedule feasibility. However, it performs statically analysis at compiling time. In our presented proposal, aspects are used to change the system configuration at runtime, adapting its behavior to new conditions faced by the running applications.

Although there are some related works concerning dynamic reconfiguration in cluster computing, like [11] and [12], our approach concentrates on reconfiguration in off-the-shelf single PUs. This way, the work from [5] implements dynamic reconfiguration methods for Real-Time Operating System services running on a Reconfigurable System-on-Chip platform based on CPU and FPGA. The methods, based on heuristics and not on time measurements, take into account the idleness of the processing units and unused FPGA area to perform the load-balance.

In the field of programmability management, [13] gives an overview of the current programming models for multi-core processors, including the RapidMind API [14], which is a commercial tool that provides an interface to the programmer and abstracts specific co-processors development libraries, extracting parallelization automatically from its code. Besides, it supports load-balance in multi-core CPU, GPU, and the Cell, but, to our knowledge, not dynamically.

## VI. Conclusion and Future Works

Based on the need of non-functional parameters handling in modern applications and the advection of low-cost multi-core commodity hardware, this paper presents a new strategy of dynamic reconfiguration of tasks, involving aspect-oriented concepts to address the reconfiguration needs. It was presented real-time allocation and migration concepts applied to a modern heterogeneous execution platform.

An UAV surveillance system was used as case study and showed that modern application needs even more performance from "desktop" platforms, which are nowadays composed of several hybrid PUs. Real-time reconfiguration of groups of tasks was applied trough the UAV PUs and also considering the data sending to other UAVs.

Currently, we are defining even more suitable reconfiguration strategies and also working on finishing the implementation of the mentioned aspects that will effectively introduce the mechanisms to perform the reconfiguration in the real system. We plan to run and evaluate the tasks allocation in the platform of Figure 5 with algorithms that represents the real behavior of the tasks and according to the specific coprocessors. In the same way, we will work with the tasks individually and not just with its high-level groups and refine the strategy to allocate tasks among UAVs.

Finally, we intend to extract some knowledge about which task fits better on which platform according to different scenarios, i.e., distinct types of surveillance missions established to distinct UAVs platforms, improving the support on planning such missions.

***Abstract*—A recently announced university student's contest is based on a well-known entertainment – slot car racing. In contrary to the classical racing, here, the challenge is to build a car which can drive on an unknown track without any human interface and achieve the best possible time. This document describes the technical, algorithmic and educational aspects of a self-driven slot car development.**

## I. Introduction

THE proposal of the self-driven slot car contest was motivated by the idea to bring the university students into a development of a real-time software out of an isolated computer or laboratory environment. They would see the results of their work in real and could compare it with others on the contest. The contest subject is attractive. Probably every student knows and used to enjoy the slot car racing. Most of them think they know how to drive the car the best way.

It might look easy to drive a car which is guided and the only quantity to be controlled is the car speed. But it is not so. The development deals with a real-world compact standalone system, driven by a real-time software and using some kind of intelligence.

## II.Self-Driven Slot Car Principles

The development of the self-driven slot car requires a system engineering approach. The car mechanics, electrical hardware and the driving software need to fit together. The slot car mechanics is mostly fixed and done. For the electrical hardware a reference platform exists. The emphasis is taken to the software – the self-driving algorithms.

The key thing of a winning strategy is to learn the unknown track during the first lap and use the knowledge to achieve a maximum speed in the following laps. It might not be so easy to fully map the track during a single lap only. An adaptive process of getting better precision of the track parameters might be used during the whole run, enabling to get closer and closer to the optimum drive.

Before a self-driving algorithm can be implemented, the slot car electrical hardware needs to be built. The algorithm can run on an appropriate microcontroller, which has sensors connected to its inputs and a driver of the slot car DC motor connected to its outputs.

Regarding the sensors, the most suitable sensor for mapping the circuit is an accelerometer. There are easily accessible micro-electro-mechanical accelerometers in a small package, of a low weight and a low consumption. There is no rule which would restrict to mount for example a camera on the slot car, but one always needs to keep in mind its weight and processing demands. The slot car needs to race with all its equipment on.

Regarding the slot car DC motor drive, an integrated H-bridge or half-bridge power circuit is the easiest solution. These circuits usually have an integrated over-current protection and require just one pulse-width modulated signal to control the applied motor voltage.

In order to ease the student's development and let them focus on the slot car software, a reference hardware platform is available for reuse or as a starting point. This platform includes a choice of an 8-bit or a 32-bit microcontroller, a 3-axis accelerometer and a monolithic H-bridge.

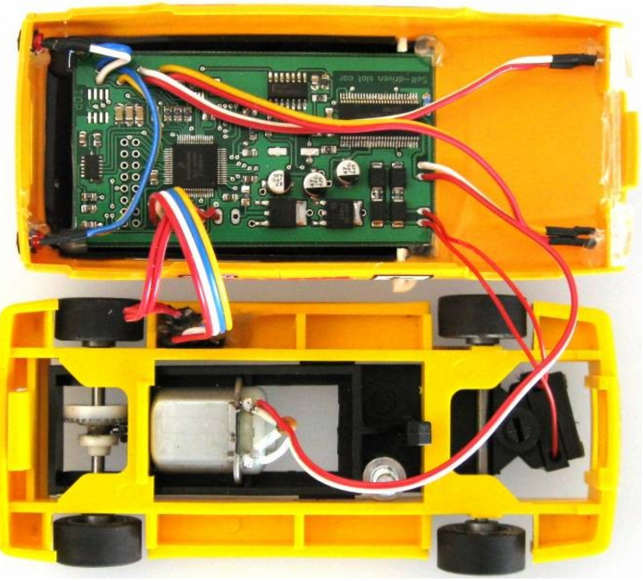

Fig. 1 The reference hardware platform built into a standard slot car

## III. Contest Rules

There are three sets of rules. Rules of racing make the race clear in terms of the number of laps, measurement of time, start procedure, etc. These rules are strictly defined, so that everybody knows how his product will be measured. On the other hand, the rules for the track properties and car properties are let as free as possible. There is a set of rules unifying the slot car and track mechanical aspects, but the student's have their hands free to invent and implement various slot car improvements.

### *A. Rules of Racing*

Each contestant races separately against time. The slot car is placed on the track about 30cm prior to the lap counter. Then, the track is powered on. On the first pass through the lap counter the time measurement is started. The race is for a specified number of laps (e.g. 10) and the total time is measured. There are two race rounds and the sum of both race times determines the final results. The slot cars are placed to the right line of the track for the first round and to the left line for the second round.

The starting order is random for the first round. For the second round, the start order is based on the first round results. The contestant with the best time in the first round starts as the last one in the second round.

### *B. Track Properties*

The principal rule is that the race track is unknown to the contestants until just before the race, so that they can't adjust their slot cars for specific track parameters. Only the following track properties are specified:

- Track pieces producer
- Track length range (e.g. min. 10m, max 16m)
- Set of pieces the track can consist of
- Allowance of barriers
- Allowance of grade-separated junctions and altitude differences

The track properties are planned to progress year by year. For example the set of track pieces is limited to straights and curves at the beginning. Later, the set will be expanded by lane changes and crossovers. These pieces, as well as the barriers and altitude differences, may require special algorithms or even hardware improvements to detect them correctly, but also brings benefits if correctly handled.

### *C. Slot Car Properties*

The slot cars are powered from the track. The track voltage is fixed to 12V DC. No communication between the slot car and a remote controller is allowed. The only exception is a one-way car monitoring. There might be up to one switch on the car, allowing choosing between two modes of operation. The car weight is not limited. The car size is limited such a way that the car must pass through a tunnel of defined inner height and width. The slot car chassis and guide blade must be standard. Traction magnets are not allowed.

## IV. Discussion About The Slot Car Intelligence

The following discussion concentrates on several important aspects which need to be very well examined during the intelligent slot car development. The goal is not to get to a conclusion or solution. That is the contestant's job. The object it to show what kind of doubts and real-world issues the developers need to go deeply into.

### *A. Track Mapping Algorithm*

The track mapping algorithm is mainly based on the accelerometer measurement results. Theoretically, the integration of an instantaneous acceleration determines the actual speed, and integration of a speed results in a position. This way the track shape could be mapped. Practically, the car vibrations, sensor output noise, or a small DC error on the accelerometer output overpowers the useful signal after some time of the double integration. Hence, a reasonable approach is to remember the track as a time sequence of centrifugal accelerations, which is measured at a slow speed of the first lap, and which can be converted to a high speed driving scheme for the additional laps.

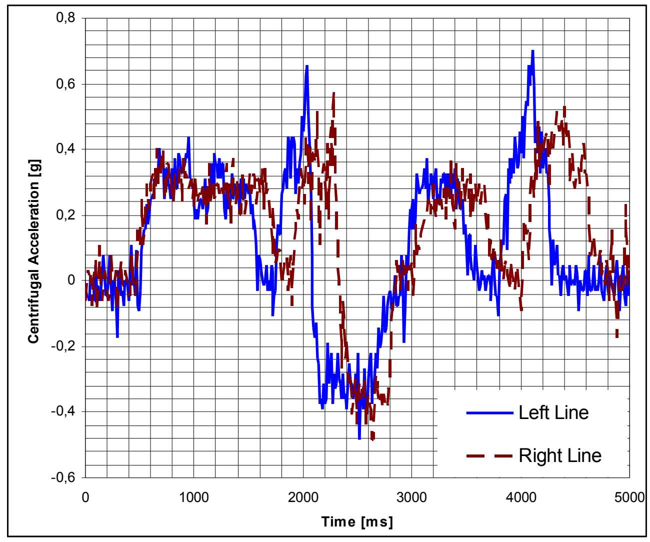

Fig. 2 A track and corresponding centrifugal accelerations measured by the slot car accelerometer

The most critical point is to recognize where the first lap ends and the second lap begins. After passing the minimal track length, the later measured part of the acceleration sequence can be compared (correlated) with the beginning part of the sequence. Once a match is found, the centrifugal acceleration sequence of the whole track is known, centrifugal forces can be predicted and the slot car can speed up.

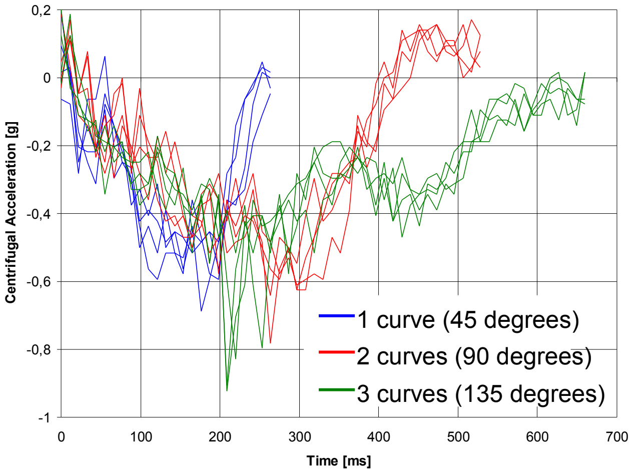

Fig. 3 Comparison of centrifugal acceleration courses measured in the smallest diameter curve of 3 different lengths (4 times each)

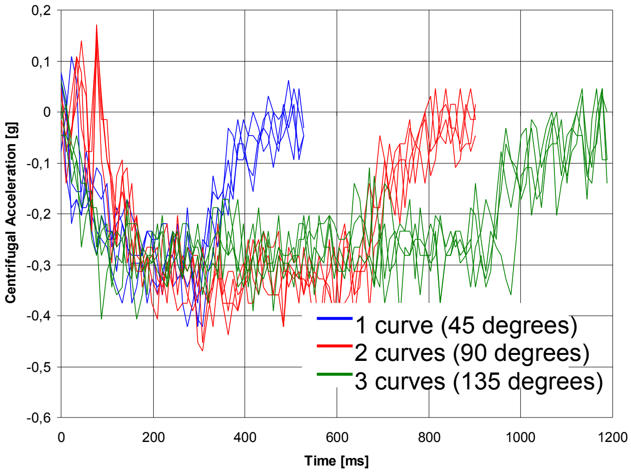

Fig. 4 Comparison of centrifugal acceleration courses measured in the biggest diameter curve of 3 different lengths (4 times each)

The described algorithm does not use any knowledgebase. With a knowledge base, the self-driving slot cars can work as a small expert system. The track property rules define a set of applicable track pieces. With the knowledge of each piece acceleration sequence, the measured sequence can be mapped to a sequence of the applicable pieces. This makes the measured acceleration sequence more reliable. Moreover, the track shape can be continuously compounded piece by piece into an XY plane. The point where the track closes corresponds to the moment when the car starts to drive the second lap. This way it can be found much sooner.

The knowledgebase may also include detailed drive schemes for various sequences of track pieces. For example, a left curve can be driven slightly faster if it is followed by a right curve, compared to if it is followed by a straight. Small differences like this one can make the big difference between the winner and the others.

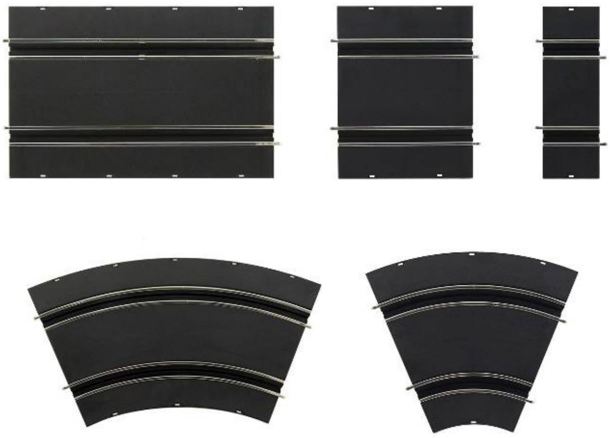

Fig. 5 Set of basic track pieces: straights and curves

An intelligent slot car might use track map information obtained during the first race round also for the second round, when the car goes in the other line. The lines are never similar, but a lot of important information of the right line can be transferred to the left line.

### B. Line Change and Crossover

The line change and crossover track pieces has interesting features. The most significant is the power supply gap. The slot car hardware needs to handle this in order to protect the microcontroller from a reset. On the other hand, the gap can be easily detected. It can serve as very reliable position information. There is always an even number of line changes within the track, usually two. It can be hardly confused with the crossover, because in case of the crossover there are two gaps shortly one after another. That is, again, a very reliable track mapping position feature.

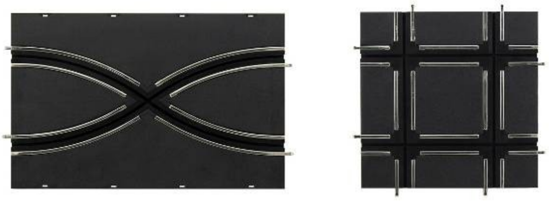

Fig. 6 Line change and crossover track pieces

### C. Barriers

The barriers might be not easy to detect with just the accelerometer. If reliably detected, the driving speed of the curve can be significantly faster.

### D. Altitude Differences and Grade-Separated Junctions

The track altitude differences, if allowed, bring the self-driving car several difficulties. The track mapping algorithm needs to be extended from mapping on an XY plane into mapping to an XYZ space. Also, on a flat track, the slot car speed is reasonably proportional to the applied motor voltage. This is not true on a track with altitude differences.

The car can map the altitude changes using the acceleration and tilt measurement using the Z-axis.

### *E. Slot Car Hardware Improvements*

The discussion above resulted into several hardware improvements required by some advanced algorithms.

The detector of a power supply gap can be a simple resistor divider and a low pass filter connected between the power input and a processor input pin. Note, that there are many short power supply losses and noise spikes caused by the movement of the power source braids and by their sparking, which should be filtered out preventing their detection.

A position sensor mounted on the DC motor shaft or an axle may bring significant advantages. The slot car speed can be measured and controller by a closed loop drive system. The information about the car position on the track, especially on a long straight track part, can be precisely calculated enabling to slow down as late as possible before the next curve. But even here are some limitations. Once the car goes into a skid, the tire speed is not equal to the car speed any more.

Many other hardware improvements could be identified. Addition of other sensors enables to process other quantities, but also requires handling the information fusion. The slot car weight and complexness might result in worse controllability and less robustness. It’s important to always question these aspects of hardware additions. On the other hand, the software changes are easily testable and there is a wide space open for the software improvements, for giving more and more intelligence to the self-driven slot car.

## V. Conclusion

The new contest should attract university student’s attention by the subject – slot car racing. This is a well-known and favorite entertainment all around the world. When the contestants start to work on the development of a self-driving slot car, with a motivation to win the contest, they discover wide possibilities how to improve the car intelligence and performance. On a deeper view, this brings them to handling real world issues in real-time software.

*Abstract* — **The use of sensor networks in different kinds of sophisticated applications is emerging due to several advances in sensor/embedded system technologies. However, the integration and coordination of heterogeneous sensors is still a challenge, especially when the target application environment is susceptible to changes. Such systems must adapt themselves in order to fulfil increasing requirements. Especially the handling of real-time requirements is a challenge in this context in which different technologies are applied to build the overall system. Moreover, these changing scenarios require services located at different places during the system runtime. Thus a support for adaptability is needed. Timing and precision requirements play an important role in such scenarios. Besides, QoS management must provide the necessary support to offer the flexibility demanded in such scenarios. In this paper we present the real-time perspective of a middleware that aims at providing the support required by sophisticated heterogeneous sensor network applications. We propose to address the real-time concerns by using the OMG Data Distribution Service for Real-time Systems approach, but with a more flexible approach that fits in the heterogeneous environment in which the proposed middleware is intended to be used. We also present a coordination protocol to support the proposed approach.**

## I. Introduction

SENSOR network applications are becoming more complex due to the use different kinds of mobile and sophisticated sensors, which provide more advanced functionalities [1] and are deployed in scenarios where context-awareness is needed [2]. To support those emerging applications, an underlying infrastructure is necessary. The current proposals suggest the use of a middleware, such as TinyDB [3] and COUGAR [4]. The main drawbacks of these state-of-the-art middleware are the following assumptions: (i) the network is composed only by a homogeneous set of basic or very constrained low-end sensors; (ii) the lack of intelligence of such network that compromises the adaptability required facing changing operation conditions, e.g. lack of QoS management and control. Adaptability is a major concern that must be addressed due to: (a) long deployment time of wireless sensor networks may require flexibility in order to accomplish changes in the requirements during usage life time of the network; (b) wireless sensor networks are deployed in highly dynamic environments, implying that applications have to be flexible enough in order to continue being used in these scenarios. In such environments, real-time requirements are especially hard to be met, because of variable operational conditions, and thus there is a need of adaptation of real-time parameters to operational conditions. QoS management must therefore be flexible, allowing renegotiation among nodes during the system runtime [5].

This paper reports a work in progress related to the development of an adaptive middleware to support sophisticated sensor network applications that must adapt its behavior according to changes in the environment and the application demands. We use the concept of multi-agents to provide the reasoning about the network and, besides other things, to decide about time-related requirements and QoS control. This paper focus in the real-time features itself without considering how the multi-agents perform the reasoning. Based on the main real-time concerns that affect heterogeneous sensor networks, we propose the use of mechanisms to address them supported by a coordination protocol. The main contributions provided by this paper are the description of the proposed handling of the outlined real-time concerns by means of the proposed mechanisms and coordination protocol. Besides, the overall middleware proposal consists in a contribution by providing a flexible variant of a middleware for heterogeneous sensor networks based on an OMG standard.

The remaining of the text is organized as follows: Section 2 presents an overview of the proposed middleware. Section 3 discusses some main related real-time issues in middleware for wireless sensor networks. Section 4 presents the proposed approach to support real-time requirements in the proposed middleware. Section 5 presents the coordination protocol that partially supports the proposed approach. In Section 6 some related works are outlined, while Section 7 gives some concluding remarks and directions of the future work.

## II. Overview of the Proposed Middleware

The general idea is to develop a flexible middleware that can be used to support applications in heterogeneous sensor networks. In the context of this paper, heterogeneity means that nodes in the network may have different sensing capabilities, computation power, and communication abili-

This work is partially supported by KK Foundation.

ties, running on different hardware and operating system platforms. The main goal is that the proposed middleware fits both low-end and rich sensors. In order to achieve this goal, aspect and component oriented techniques will be used in a way similar to the approach presented in [6][8] and the mobile multi-agents approach [9].

Low-end sensors are those with simple capabilities, such as piezoelectric resistive tilt sensors, needing limited processing support and communication resource capabilities. Rich sensors comprehend powerful devices like radar, visible light cameras or infrared sensors that are supported by moderate to high computing and communication resources. Thus, in order to deal with these very distinct capabilities, the proposed middleware must be lightweight, while being scalable and customizable. For instance, it might handle the node's resource usage in order to assist tasks distribution among different nodes that are capable to accomplish them. Another feature of the middleware is to help provide the quality of the data required by a certain user's demand, such as accuracy and precision. Better results can be achieved by choosing the correct set of sensors to perform measurements and data collection. The mobility characteristic is also related to the heterogeneity addressed by the middleware. Sensor nodes can be static on the ground or can move themselves on the ground or fly over the target area in which the observed phenomenon is occurring. The Fig. 1 graphically represents the idea of the heterogeneity dimensions considered in this work.

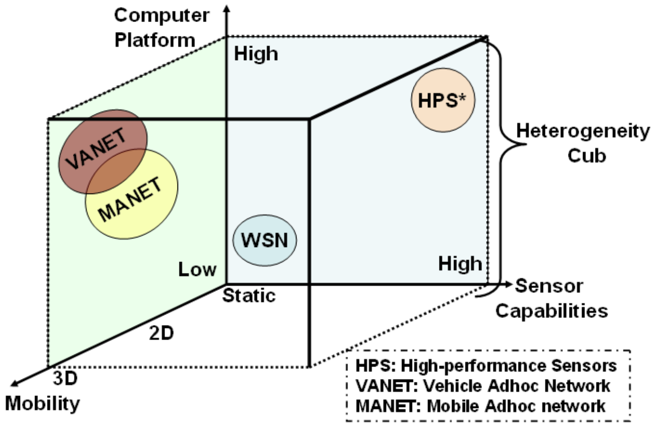

Fig. 1 Heterogeneity Dimensions

The input to the sensor network system, coordinated by the proposed middleware, is seen as a "mission" that the whole network has to accomplish. In order to allow that, a high-level Mission Description Language (MDL) is being formulated based on the C/ATLAS test language [10]. This language will allow the specification of data (at a high level of abstraction) in which the user is interested, including constraints regarding timing and location limits as well as the measurement rate or accuracy desired. This high-level user information will be translated to system parameters, such as QoS related parameters. The proposed language will also allow hierarchical description of the mission goals, with establishment of priorities and other details, for instance, the application of comparison metrics to evaluate how well the mission is being accomplished. The priorities given to missions will also affect QoS parameters. Consequently, the middleware must handle them in order to fit QoS parameters according the established priorities for each task. As an example of usage of the MDL, the user may want to gather data about a certain kind of vehicle that passes in a specific area during a given period, with a high accuracy level. In order to do this, it will specify the target area, a distinguish characteristic of the vehicle (e.g. over a certain weight or with a certain shape), provide the period during which the mission will be performed and how accurate results he or she desire from the system. This high-level information is though translated in internal parameters that will drive the network to perform the mission.

The middleware must perform its actions also in very dynamic and changing scenarios. Thus the set of sensors chosen in the beginning of a mission may not be the most adequate one during the whole mission. For example, an area surveillance system receives the mission to survey an area that may not allow traffic of certain kinds of vehicles. Ground sensors are set to alarm in the presence of unauthorized vehicles. Additionally, Unmanned Aerial Vehicles (UAV) equipped with visible-light cameras is set to fly to the area where a ground sensor has issued an alarm to verify the occurrence. However, a sudden change in the weather, e.g. the area becomes foggy or cloudy, turns the use of a visible-light camera useless. This type of change in the operational conditions must be supported by the middleware, which must be able to choose a better alternative, among the set of available options, for instance by choosing an UAV equipped with an infrared camera instead.

The dynamicity of the operation scenarios may force the adaptation of system's real-time parameters in order to accomplish a certain mission. As an example, certain data forwarding traffic may overload a node in the path from the data gathering points to the final user. Incoming data can experience problems like undesired delay or unpredictable jitter, so solutions as data flow priority assignment and/or use of another node as forwarder may take place. Priorities and choice of alternative paths may further not be static from the start of the system runtime, but can dynamically be changed according the user requirements and changes in the network such as node failures.

The middleware is divided in three parts or layers indicating that they are partly using each other in a specific order. Fig. 2 presents the overview of the layers of the proposed middleware, and a description of each layer is provided as follows.

The bottom layer is called *Infrastructure Layer*, which is responsible for the interaction with the underlying operating system and for the management of the sensor node resources, such as available communication capacities, remaining energy, and sensing capabilities. This layer also coordinates the resource sharing based on application needs passed through the upper layers. Services provided by upper layers may need some resource sharing support, which is encapsulated in the infrastructure layer. As an application uses such a service, the corresponding layer asks for the infrastructure layer to manage the access control to the required resources.

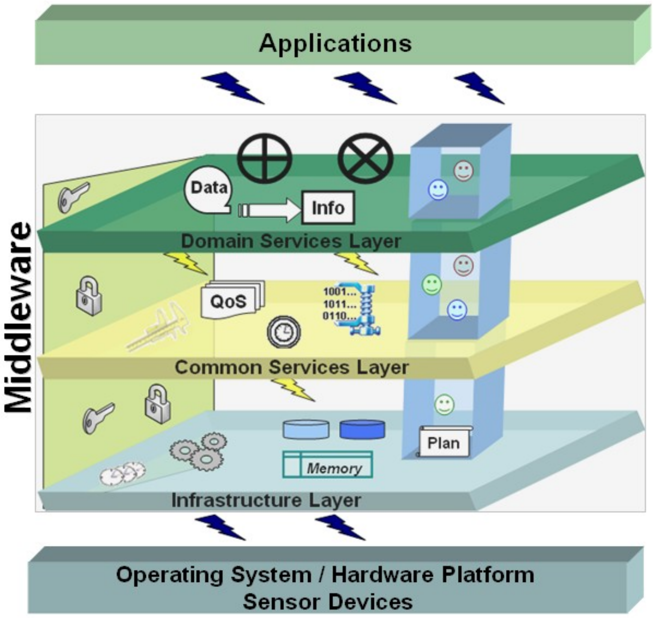

Fig. 2 Overview of the Middleware Layers

The intermediate layer is called *Common Services Layer*, which provides services that are common to different kinds of applications, such as QoS negotiation and control, quality of data assurance, data compression and the handling of real-time requirements, including storing of parameters. Other concerns such as deadline expiration alarms, timeouts for data transmissions, number of retries and delivery failure announcements, resource reservation negotiation among applications (based on priorities and operation conditions), dynamic bindings, synchronous and asynchronous concurrent requests are also handled by this layer.

The top layer is called *Domain-Services Layer* and has the goal to support domain specific needs, such as data fusion support and specific data semantic support to allow the production of application-related information from raw data processing. Fuzzy classifiers, special kinds of mathematical filters (e.g. like Kalman filter) and functions that can be reused by applications of the same domain will be found in this layer.

Multiple applications can run concurrently in the network. The middleware handles resource sharing and provides data sharing among applications that need the same type of data, allowing a better energy use in resource constrained nodes. In powerful nodes, with more energy available, the middleware can provide more complex services aiming at the handling of rich data, such as those related to image processing, and pattern matching. This also means that such nodes can take some of the burden from meager nodes.

"Smile faces" in the Fig. 2 represent agents that can provide specific services in a certain node at a certain moment of the system runtime. A special region (called *agents-space*) links them throughout the layers, allowing the exchange of information. The *Infrastructure Layer*, in the bottom, has just one agent, which is responsible for planning and reasoning activities. Interested readers can find more information about the use of agents in our middleware in [9].

Concerns that affect elements in more than one layer of the middleware, such as security, are represented as cross-layer features. In Fig. 2, the "locks" and "keys" in the left-side plan represent this idea for the security concern example. These crosscutting concerns will be addressed in our middleware with the aspect-oriented approach presented in [6] and [7]. Dark lightning bolts represent the communication activities between applications and the middleware in the upper part of the Fig. 2 and between the middleware and underlying operating system and hardware (including sensor devices) in the lower part of the Fig. 2. Light lightning bolts in the middle of Fig. 2 represent communication among internal elements of the middleware.

## III. Key Features for the Wireless Sensor Network Middleware

The proposed middleware is intended to be used in dynamic harsh environments. Changes in this kind of scenario occur frequently, requiring system adaptability. However, it is not useful to provide adaptability without guaranties that the desired data will be delivered in time. So, the timing related concerns about the network consist also in an adaptable dimension that the middleware must take into account in order to successfully provide the necessary support to applications running within those scenarios. With this thought in mind, some key features that the middleware for wireless sensor networks must take into account are presented [11] [12]:

- **Avoid Single Point of Failure:** no single node must centralize any type of registration or submission service for the entire network, as in broker-based architectures. This concern is related not only with the possible node fail, but also with node overload and incapacity to respond the demands of all clients;
- **Dynamicity in System Structure and Network Topology:** as operation conditions change, new nodes can come in and out. Moreover, different services can be required in different places at different times;
- **Reduce Data Communication:** As large amounts of data may need to be exchanged among nodes, the bandwidth must be carefully used to avoid congestions and flooding;
- **Meet Applications Requirements:** Applications must meet timing requirements, based on their users' needs for data, and on the conditions under which they want the data. These requirements may change during runtime, what requires a fine tuned QoS management and control;
- **Real-time Requirements:** The middleware must provide the specification of real-time requirements. At the same time, it must handle the translation of these requirements into specific QoS parameters, in order to accomplish the modification of this high-level requirements;

- **Fault-Tolerance:** Nodes may fail, links can go down and network errors occur, but the application that requests data cannot wait indefinitely. Mechanisms of errors reporting must be provided, as well as alternative resources may be offered. Activities such as time-bounded activities monitoring, delays and deadlines management must be handled in order to provide dependable support.

These above highlighted issues crosscut several concerns, i.e. they are intertwined with several characteristics. For example, QoS values, such as deadlines and bounded time actions/delays, impact in the management of communication and fault-tolerance. The resulting complexity indicates a need to use proper abstractions in order to deal successfully with these concerns.

## IV. Addressing Key Issues of Sensor Networks with the Proposed Middleware

The proposed middleware is inspired in the Data Distribution Service for Real-time Systems (DSS) specification, standardized by OMG [13]. The proposed approach is based on the publish-subscribe paradigm. Some nodes publish their capabilities and the offered data, while others subscribe to data, in which they are interested.

Although being inspired on the OMG DSS standard, the middleware does not follow the whole specification. As it is intended to fit both low-end nodes (based on simple and constrained platforms) and sophisticated ones, it must not only be lightweight but also provide capabilities for customizations in order to deal with the needs of the sophisticated sensors. Consequently, the middleware uses a minimalist approach, keeping it as simple as possible in each node. It may be considered as a "Lightweight Flexible DSS-based Middleware", in which the handling of some features will be presented in a soft version, such as the handling related to topics described in the ***Domain Module*** section of the DSS specification [13]. This soft version will simply data structure and check mechanisms that will be deployed middleware instance for low-end nodes, for instance.

Additionally, features can be included or modified in the middleware by using adaptation and extension mechanisms, such as the inclusion of additional components, as well as the weaving of specific behaviors by aspects. As an example of more explicitly of how the aspects will be used, the handling of QoS policies, which affect different elements in the system, can be concentrated in a aspect avoiding the spread of this concern over different classes, and like this, making it easier to promote maintainability and evolution of those policies. In the DSS specification, several classes (e.g. , `DomainParticipantFactory`, `Topic`, and `DomainParticipant`) have parameters and methods to handle the QoS policy concern. Using aspects, the behaviors encapsulated in those methods spread over several classes can be concentrated in one aspect that weaves classes in the system accordingly the policy needs. Other proposed adaptations in the DSS original specification are: (1) the simplification of the status model, which will consider a subset of the original proposed object inheritance tree presented in section dedicated to the details about communication status in [13]; (2) adaptation of the cache model in order to add the cache usage proposal that will presented further in this section.

The following subsections present how the proposed middleware will address the needs presented in Section 3.

### *A. Flexibility*

The middleware provide full control of the communication, it does not use underlying control mechanisms available in the nodes' network layer. Instead, it provides its own communication control. It means that all parameters related to communication are controlled by the middleware, using only basic connectionless communication services offered by the nodes' network layer. The middleware handles parameters like number of retries, message priority, memory usage for buffering and timing. This control over communication provides more flexibility to manage the messages exchanged by each node, with direct impact in the reduction of latency. Moreover, it gives a finer grained control if compared with the simple use of the communication primitives offered by the native nodes' operating system network services.

### *B. Dynamicity*

Using the publish-subscribe paradigm, when a node gets into the network, its services are announced and the interested nodes subscribe for them. This eliminates the need for a dedicated server node that centralizes the available services in the network. Additionally, it reduces latency in acquiring data because there is no intermediary node between the data producer and the consumer.

### *C. Minimum Message Exchange*

Using the publish-subscribe paradigm by itself already reduces the number of exchanged messages, due to the elimination of intermediate nodes, such as request-brokers. However, the use of bandwidth for control messages still exists. It can be reduced with the use of a smart protocol to avoid unnecessary messages exchange, as explained with details in the following section. The protocol is called CUME (Cut Unnecessary Messages Exchange).

### *D. Multicast Communication*

The middleware use a multicast communication to reach selected destination nodes. For instance, the publisher sends its data only to the nodes that subscribed to it. This type of communication affect positively the latency and throughput, as data is sent at the same time to several nodes without unnecessary broadcast and without delays that would occur if a unicast communication was used; since then the publisher node would have to resend the same data several times, one for each subscriber. A negative-acknowledgement (NACK) strategy is adopted in order to reduce acknowledgement messages in the network. However, very sensible data may require a positive acknowledgement in order to assure its delivery. To address this need, positive acknowledgement is also available and can be used when required. This acknowledgment strategy is also part of CUME.

### *E. Network Resources Usage Control*

The control of the use of the communication media and transmission buffers are crucial in order to improve the overall system performance. The middleware perform this task by taking into account two factors: (i) the priority associated to each application; and (ii) the resource sharing policy adopted in the system. There are three available resource sharing policies:

- **Fair Sharing:** the priorities are not considered and thus all applications have the same right to use the resources in a round-robin scheme, which is organized in a incoming FIFO queue;
- **Soft Priority Sorted** : the priorities are taken in account. However, if a higher priority application needs to use a resource already used by a lower priority one, it must wait until the later release the resource. Due to its higher priority, it will get access to the resource before other applications, which may be waiting for the resource;
- **Mandatory Priority** : higher priority applications can preempt lower priority applications in order to access the desired resources.

### *F. QoS Control*

The QoS control is done through a contract between the data provider and the data requester. When a node publishes a data service, it informs also the QoS level that it is capable to offer. Nodes interested in the published data service those accept the offered QoS level, subscribe to the service. However, if a node is interested in the data but does not agree with the offered QoS, it has two alternatives:

- If the application that is requiring the data has a priority lower than the others using the same service, it looks for another data provider;
- If its priority is higher than other applications, it negotiates with the data provider node, in order to obtain the desired QoS in spite of the bad consequences that it may imply to other lower priority applications.

As an example, a node may provide a certain type of data (D-1) at each 10 milliseconds and another type of data (D-2) at each 25 milliseconds. The first, D-1, has two subscribers and the second one, D-2, just one. A forth node wants to receive D-2, but at each 10 milliseconds. The data provider node does not have the available resources in terms of processing and communication power to deliver both data at each 10 milliseconds. It can deliver just one type at the desired rate. If the forth node has an application with a priority higher than the applications running in the other nodes, it will negotiate with the provider and, if it is feasible, the provider will change its behavior to accomplish the need of the requesting node with the highest priority. If it is not feasible, the requesting node will look for another provider.

### *G. Use of Cached Values*

Some measurements aim to gather information about changes in values of certain observed phenomena. The use of cache in both data providers and requesters may avoid unnecessary data communication. When the measurement device gathers a new value, the data provider updates its own cache and publishes the new value updating its subscribers. If the size of the data is large and requires several packets to be transmitted, a differential value can be send instead of the whole data value, for instance, using just one package. This differential value will be used to update the current value stored in cache. The use of this option is arranged in advance at the time when the nodes are negotiating the QoS contract.

### *H. Fault Tolerance*

In order to support the use of strategies like cached values and to detect node failures, fault tolerance mechanisms must be provided. A heartbeat mechanism is used when a node does not have any data to send. Thus it broadcasts a message in order to inform other nodes that it is still alive. It works well for nodes in the range, but for those not in the range and that are interested in the provider, directed heartbeats must be sent. The periodicity of the heartbeat sending is a configurable parameter. Another fault-tolerance support is a list of possible backup service providers. When a node that provides a certain kind of data service stops working, nodes interested in that data look for another node at the backup list that provides the missing data.

### *I. Network Partitioning*

Network partitioning can occur intentionally or by uncontrolled conditions. The first one occurs when groups of nodes have much communication among each other and little outside the group. Thus, they form a cluster in order to minimize the communication with outside nodes. A cluster-head, which is responsible for communications with clusters outside nodes, is elected. This election is based in the actual status of the involved nodes, concerning remaining resources and quality of the communication link. The use of a cluster-head does not characterize a single point of failure because any node in the cluster can be elected. If the current cluster-head fails, a new one is elected. The cluster-head formation is used only if the QoS requirements are met. For instance, if the presence of the intermediary communication with the cluster-head impact latency, a communicating node can leave the cluster. If it has a specific need for a data that is not interesting to the other nodes (or have different QoS requirements) it can make a contract directly with the provider of the required data, without passing the cluster-head. This way the cluster of nodes is not rigid, but flexible.

Uncontrolled conditions, such as node failures, communication obstacles and interference can also promote network partitioning. This kind of partitioning is not desirable and planned such as mission related clustering, and to handle this issue, isolated nodes store as much data as possible to send when the link be reestablished, what can be done by the deployment of new nodes, by the mobile nodes that come into the area or by the disappearance of the obstacles or interferences that caused the partitioning.

### *J. Data Segregation*

There are two kinds of data exchanged among nodes in the network: control data and application data. Control data is small and may not experience latency or unexpected delays to achieve its destination. So, control data is segregated from application data by receiving higher priority to be forwarded. On the other hand, there are several kinds of application data, e.g. simple values (integers and floats), video stream and character string. In spite of this sort of data have a priority lower than control data; they must fulfill the QoS requirements of the application. Moreover, jitter is also reduced by the segregation, because segregated data follows different buffers.

### *K. Synchronous and Asynchronous Calls*

The middleware is intended to support both synchronous and asynchronous calls. Synchronous calls are bounded in time in order to avoid unpredictable waiting periods by the caller applications. The waiting time and number of retries are configurable. In case of the expiration of the waiting time (timeout), or if the number of retries is reached, specific handling mechanisms can be triggered. Asynchronous calls are also provided and they are used, among for other proposals, to support the handling of asynchronous events.

## V. CUME Protocol

CUME (Cut Unnecessary Message Exchange) is a protocol that aims at minimizing the number of control messages exchanged among nodes, and additionally to optimize the use of data messages.

The publisher-subscriber approach proposed is slightly different from the state-of-the-art middleware available. Instead of announcing its service when coming into the network, a node does that in different manners depending on the situation, on the type of the node and data provided.

For instance, let's consider moving sensors embedded in UAVs, which fly in a cluster formation to accomplish a mission in a certain place (passing through several way-points). The group of UAVs can find another UAV flying in the same direction, which we call an alone-UAV. In this case, the protocol will perform the following: (i) exchange nodes' destination information; (ii) exchange capabilities and mission details information; and (iii) negotiate the use of the nodes' resources if it is the case. In the following each of these phases are explained with more details.

The alone-UAV just tells next way-point to the cluster-head of the UAV-cluster. Then the later sends a message with the next way-point destination to the cluster. If the destinations are the same, the alone-UAV joins the group without extra confirmation messages. There is no acknowledgement message, if one of these sent messages was lost, the other node that was expecting to receive the message send a NACK requiring retransmission. The waiting time for sending the NACK is estimated by the distance between the nodes, and then, a timeout is set in accordance.

Being in the cluster, the alone-UAV can use short range communication to announce its services and the mission that is supposed to accomplish. If there are common interests among the alone-UAV and the UAV-cluster, they cooperate. If there are not, they analyze the capabilities of each other and recognize if any of them is needed for its own mission and if it lacks this capability. Based on the established priorities and the mission conditions, they will decide which mission is more important and the resources will be allocated to that mission according to the priorities. This is an example in which unnecessary long-range communications were avoided.

In the case of different destinations, they will perform the exchange of the capabilities information anyway using long-range communication to make the same reasoning described above.

The CUME protocol in addition uses caches in the nodes to avoid unnecessary messages exchange. If a publisher has two subscribers of a certain data; one that requires the data at each 10 milliseconds (called node A) and another at each 20 milliseconds (called node B). After the data provider sends the first value for each, it stores the value in its local cache. Nodes A and B receive the data, giving it to the requesting applications and storing it in their caches. After 10 milliseconds, the provider compares the measured value with the one stored in its cache and, if it is different, sends it to node A, updating its cache. However, if the value is the same, it just sends a heartbeat to node A, which understands that the value is the same and gives the value in its cache to the requesting application. In the next 10 milliseconds, the same occurs, but the update or the heartbeat will be sent to both requesting nodes A and B. In this situation there is no acknowledgement for each message. If an expected message is lost, a NACK is sent from the consumer nodes to the data provider. In order to avoid a NACK storm in the case of several requesting nodes miss the sent data, a random timer is set in each node that loosed the message to send the NACK. The value that is set in the random timer is chosen in a range according to the established QoS requirements. When a value must be updated, it is possible that just the difference between the new and the old value is sent. This is also a parameter exchanged during the negotiation.

Caching negotiation is also part of the CUME protocol. It is done by an exchange of control information that will represent the agreement about the freshness time of the cached values, and the accepted delay to receive the refresh of the cached data or a new value. Besides, the cache space is not a fixed amount of memory but it is negotiated. These parameters can be renegotiated according to the needs and/or changes in the environment and operation conditions. Threshold values for renegotiations are established in the first negotiation round, in order to avoid unnecessary exchange of control messages due to small changes, which do not represent a real need for renegotiation. The parameters will depend on the application and the type of mission, thus a flexible set of parameters can be used according to the individual needs presented in different situations.

The CUME protocol is also responsible for monitoring the rate of messages forwarded by the nodes. If the node's throughput is arriving to its limit, the node informs the sending nodes to use different nodes to forward their messages, according to the priorities of the applications that require the communication. The limit of bandwidth usage is also a configurable parameter that can be adapted according to the operational conditions, such as interferences or amount of collisions.

## VI. Related Works

MiLAN [14] (Middleware Linking Applications and Network) is an adaptable middleware that explores the concept of proactively adaptation, in order to respond the needs in terms of QoS imposed by changes in the operational environment. The authors claim that a major drawback in the most of existing middleware for sensor networks is the fact that they just provide reactive adaptation. In dynamic environments as those in which wireless sensor networks are deployed, this behaviour does not cover the real needs for adaptation required by running applications. MiLAN allows the specification of the required QoS for data, adjusting the network to increase its lifetime, by efficiently using energy, in the same time that the quality needs are still meet. The major difference in relation to our approach is that MiLAN does not provide a customization mechanism to enrich the middleware features and support more sophisticated sensor nodes like those carried by UAVs. This difference points to a drawback indicating that MiLAN is not prepared to manage high intense data flow generated by traffic of images or video streams.

Atlas [15] is an architecture for sensor network based on intelligent environments. The main goal of this architecture is to provide services and support to applications like health care assistance in intelligent houses equipped for assist the elderly. The Atlas middleware is based on the OSGi Service Platform Specification [16], which is a framework that provides a runtime environment for dynamic and transient service modules called Bundles. This middleware offers some support to real-time, but as a secondary feature derived mainly from the adaptable service discovery feature and Bundles specification. However, this support is too simple and do not promote the desired control of real-time parameters as we proposed in our approach. Furthermore, the Atlas middleware does not fit into low-end nodes with constrained resources.

Real-time CORBA (RT-CORBA) [17] is a successful middleware that provides real-time support for distributed applications. It is based on the CORBA standard [18], which introduces a priority mechanism to map native operating system priorities into remote nodes priorities. It also provides predictability by managing resource allocations according to the established priorities. The use of thread pools prevent the unbounded blocking periods based on the resource usage by the lower priority applications, and priority inversion. RT-CORBA fits well in sophisticated sensors nodes with a rich computing platform, but it is too heavy to run in low-end nodes. In our approach instead, the proposal is to address the real-time needs in both low-end and rich sensor nodes with different computing platforms and available resources.

Quality Objects (QuO) [19] proposes the addition of a QoS adaptive layer on existing middleware, such as RT-CORBA. It provides means of specify QoS requirements, monitor and control the provided QoS, and also adapt the middleware behavior according to the QoS variations that may occur during runtime. This proposal presents an interesting approach to support those operations using: (i) *contracts*, which encloses the QoS requirements; (ii) *delegates*, which are proxies that can be inserted into the path of object interactions transparently to weave the QoS awareness and adaptive code; and (iii) *system condition objects*, which provide consistent interfaces to infrastructure mechanisms. However, as this framework relies on an existing middleware such as RT-CORBA, it has the same drawback indicated above, i.e. it cannot be used in low-end nodes.

## VII. Conclusion and Future Works

This paper presents the real-time support offered by an adaptable middleware for heterogeneous wireless sensor networks. Real-time concerns, which affect a network composed by heterogeneous sensor nodes and impose difficulties on the handling of them, are handle through the proposed middleware that fits both rich sophisticated nodes and low-end constrained nodes. Our proposal presents a protocol to cope with the unnecessary control message exchange, and use different mechanisms to address real-time issues. Besides bandwidth savings, it has the side effect to increase the security against eavesdroppers, by diminishing the number of exchanged messages. The use of mechanisms like caching and differential updating is also provided in order to diminish the bandwidth usage.

Related works in the area do not address both types of sensor nodes. The majority of middleware for sensor networks consider a homogeneous network composed by low-end nodes, producing very simple data, like the approach presented by MiLAN. In the other extreme there are middleware that consider a network composed by powerful sensor nodes that, in some cases, do not even have any concerns about energy consumption, as the assumption presented by Atlas. Conversely, the proposed middleware addresses both low-end and rich sensor nodes, using mechanisms that provide support to both simple and sophisticate data.

As future works we are refining the mechanisms of the CUME protocol in order to incorporate different strategies to provide a better response to problems like jitter. The coordination mechanisms are also under development. In this paper we gave an overview of the type of coordination that it will be provided, as presented in example of the UAV-cluster meeting the alone UAV. However, we are working to provide similar kinds of coordination in other situations and with different kinds of sensor nodes. Moreover, we still have to simulate a complete case study scenario and assess the measurements in order to validate our assumptions before the final implementation; and also concerning the implementation, proposals of use composed link metrics in the message forwarding decisions (routing) [20] and probabilistic tendencies for the cluster-head election [21] are being considered.

***Abstract*—This work is concerned with modelling, analysis and implementation of embedded control systems using RT-DEVS, i.e. a specialization of classic DEVS (Discrete Event System Specification) for real-time. RT-DEVS favours model continuity, i.e. the possibility of using the same model for property analysis (by simulation or model checking) and for real time execution. Special case tools are proposed in the literature for RT-DEVS model analysis and design. In this work, temporal analysis exploits an efficient translation in UPPAAL timed automata. The paper shows an embedded control system model and its exhaustive verification. For large models a simulator was realized in Java which directly stems from RT-DEVS operational semantics. The same concerns are at the basis of a real-time executive. The paper discusses the implementation status and, finally, indicates research directions which deserve further work.**

***Index Terms*—DEVS, real-time constraints, embedded control systems, model continuity, temporal analysis, timed automata, model checking, Java.**

## I. INTRODUCTION

THERE is a general agreement today about the importance of using formal tools for rigorous development of real-time systems which in general have safety and time critical requirements to fulfil. However, a known hard problem for the developer is how to ensure that a given formal model of a system, preliminarily analyzed from both functional and temporal viewpoints, is correctly reproduced in an implementation. This paper describes some work aimed to the realization of tools for modelling, analysis and implementation of embedded control systems, specifically for experimenting with model continuity [1], [2], i.e. seamless development where the same model is used both for property analysis (through simulation or model checking) and for real time execution. The modelling language is RT-DEVS [3], [4], i.e. is a specialization of classic DEVS (Discrete Event System Specification) [5] with a weak synchronous communication model and constructs for expressing timing constraints. RT-DEVS owes to DEVS for both atomic and coupled component formalization and model continuity. Special case tools are reported in the literature [4] to support a development methodology for RT-DEVS.

The original contribution of this work is twofold:

- proposing a mapping of the fundamental phases of modelling and safety/temporal analysis of RT-DEVS systems in terms of the popular and efficient UPPAAL toolbox with timed automata [6], [7], [8]
- building concrete tools in Java for RT-DEVS simulation and final system implementation. The Java-based approach aims to improve applicability and portability of RT-DEVS software.

This paper introduces RT-DEVS and its operational semantics, then a transformation process of RT-DEVS specifications into UPPAAL is suggested for exhaustive verification activities based on model checking. The approach is demonstrated through a realistic embedded control system. After that, current implementation status of Java-based development tools and programming style are clarified. Prototype tools were achieved by adapting existing tools for ActorDEVS [9], [10]. Finally, conclusions are presented with an indication of directions of further work.

## II. RT-DEVS DEFINITIONS

### A. DEVS Basics

DEVS [5] is a widespread modelling formalism for concurrent and timed systems, founded on systems theory concepts. A DEVS system consists of a collection of one or more components. Two types of components exist: *atomic* (or behavioural), and *coupled* (or structural) components. A DEVS atomic component is a tuple $AM$ defined as $AM =< X, S, Y, \delta_{int}, \delta_{ext}, \lambda, ta >$ where:

- $X$ is the set of input values
- $S$ is a set of states
- $Y$ is the set of output values
- $\delta_{int} : S \rightarrow S$ is the *internal transition* function
- $\delta_{ext} : Q \times X \rightarrow S$ is the *external transition* function, where $Q = \{(s, e) | s \in S, 0 \leq e \leq ta(s)\}$ is the set of *total states*, $e$ is the *elapsed time* since last transition
- $\lambda : S \rightarrow Y$ is the *output function*
- $ta : S \rightarrow \mathbb{R}^{+}_{[0,\infty]}$ is the time *advance function*.

The sets $X$, $S$ and $Y$ are typically products of other sets. $S$, in particular, is normally the product of a set of *control states* (also said *phases*) and other sets built over the values of a certain number of variables used to describe the component at hand. Informal semantics of above definitions are as follows. At any time the component is in some state $s \in S$. The component can remain in s for the time duration (*dwell-time*) $ta(s)$. $ta(s)$ can be 0, in which case $s$ is said a transitory state, or it can be $\infty$, in which case it is said a passive state because the component can remain forever in $s$ if no external event interrupts. Provided no external event arrives, at the end of (supposed finite) time value $ta(s)$, the component moves to its next state $s' = \delta_{int}(s)$ determined by the internal transition function $\delta_{int}$. In addition, just *before* making the internal transition, the component produces the output computed by the output function $\lambda(s)$. During its stay in $s$, the component can receive an external event $x$ which can cause $s$ to be exited earlier than $ta(s)$. Let $e \leq ta(s)$ be the elapsed time since the entering time in $s$. The component then exits state $s$ moving to next state $s' = \delta_{ext}(s, e, x)$ determined by the external transition function $\delta_{ext}$. As a particular case, the external event $x$ can arrive when $e = ta(s)$. In this (*collision*) case two events occur simultaneously: the internal transition event and the external transition event. A collision resolution rule is responsible for ranking the two events and determining the next state. After entering state $s'$, the new time advance value $ta(s')$ is computed and the same story continues. It should be noted that there is no way to directly generate an output from an external transition. To achieve this effect a transitory phase, used as destination of the external transition and whose lambda function generates the desired output, can be introduced (see Fig. 4).

In practice, an atomic component receives its inputs from typed *input ports* and similarly, generates outputs through typed *output ports*. Actually $X$ is a set of pairs $< inp, v >$ where $inp$ is an input port and $v$ the type of values which can flow through $inp$. $Y$ is a set of pairs $< outp, v >$ where $outp$ is an output port. Ports are architectural elements which enable modular system design. A component refers only to its interface ports. It has no knowledge about the identity of cooperating partners. A coupled component (subnet) is an interconnection of existing atomic or coupled (hierarchical) components. Formally, it is a structure $CM$ defined as $CM = (X, Y, D, \{M_d | d \in D\}, EIC, EOC, IC)$, where:

- $X$ and Y are input and output sets of the coupled component
- $D$ is a set of (sub) component identifiers (or names)
- $M$ is a set of (sub) DEVS components whose interconnection gives rise to the coupled model
- $EIC$ is the external to internal coupling function (for routing external events to internal components)
- $EOC$ is the internal to external coupling function (for routing internally generated events to the external environment of the coupled component)
- $IC$ is the internal to internal coupling function.

### B. RT-DEVS Concepts

RT-DEVS [4] refines basic DEVS with the following concepts.

1) The dwell-time $ta(s)$ in a state now mirrors the execution time of an *activity* associated with the state. In particular, the execution time is specified by a (dense and static) time interval $[lb, ub]$, where lower and upper bounds $lb, ub \in \mathbb{R}^+_{[0,\infty]}$, $0 \leq lb \leq ub$, express uncertainty in the activity duration. Default interval of passive states is $[\infty, \infty]$ and can be omitted. Transitory (or immediate) states have interval $[0, 0]$.
2) Non determinism is assumed as collision resolution rule.
3) The communication model is weak synchronous, i.e. non blocking with (possible) message loss. At any communication, an output event is always immediately consumed. If the receiver is not ready, the message is lost. If both sender and receiver are ready to communicate, the output event is converted into an input event which is instantly received.

A time interval $[lb, ub]$ is made absolute at the instant in time $\tau$ the corresponding state $s$ is entered. An internal transition outgoing $s$ can occur at any time greater than or equal $\tau + lb$ but, to avoid a timing violation, before or at $\tau + ub$. An external transition fires upon synchronization on an input event independently of the dwell-time of current phase. It is assumed that a self-loop external transition does not restart timing in current phase. Pre-emption and restarting of current timing, when desired, can be simulated with the help of an transitory phase. Graphically (see e.g. Fig. 2), an internal transition is depicted by a thin oriented edge terminating with a dashed arrow which specifies the execution of the lambda (output) function, which can be void. An external transition is instead drawn by a thick oriented edge. Sending event $ev$ through outport $OP$ is denoted by the syntax $OP!ev$. Similarly, readiness to accept event $ev$ through input port $IP$ is expressed by $IP?ev$. The abstract executor of RT-DEVS initializes current time to $0$ and iterates the following two basic steps.

1) The next minimal time at which new internal transitions can fire is determined and become the current time.
2) All candidate internal transitions which can occur at current time are determined. Let $C_i$ be an atomic component with one such a transition. Let the lambda function of current state of $C_i$ consist of $OP!ev$. Let $C_j$ be a component coupled with $C_i$ where input port $IP$ matches output port $OP$ of $C_i$. Provided $C_j$ has an outgoing transition from current state annotated with $IP?ev$, the two transitions (internal in $C_i$ and external in $C_j$) are immediately executed with the event sent by $C_i$ synchronously transmitted to $C_j$. In the case $C_j$ is not ready to receive $C_i$ event, the output transition in $C_i$ is still made but the event gets lost. The above activity is repeated for each candidate internal transition. When the candidate set empties, the executor goes back to step 1.

It is worthy of note that while weak synchronization is a useful feature in general real time systems (e.g., a message with a sensor reading can be lost for a missing synchronization, in which case a controller can use previous sensor data), it increases the burden of the RT-DEVS modeller when the system cannot tolerate synchronization losses. Model validation through simulation or verification can help in assessing correct system behaviour.

## III. A Traffic Light Controller

The following describes the modelling of a Traffic Light Control system (TLC) [11]. In the proposed scenario, the traffic flow at an intersection between an avenue and a street is regulated by two traffic lights. The lights are operated by a control device (controller) that, in normal conditions, alternates in a periodic way the traffic flow in the two directions. In addition, the controller is able to detect the arrival of an ambulance and to handle this exceptional situation by allowing the ambulance crossing as soon as possible and in a safe way. For the sake of simplicity, it is assumed that at most one ambulance can be in the closeness of the intersection at a given time. During normal operation conditions, the sequence green-yellow-red is alternated on the two directions with the light held green for $45$ time units (tu), yellow for $5$ tu and red on both directions for 1 tu. The intersection is equipped with sensors able to detect the presence of an ambulance at three different positions during its crossing. As soon as the ambulance arrival is detected, a signal named "approaching" is sent to the controller. When the ambulance reaches the nearness of the intersection the signal "before" is issued. After the ambulance completes the crossing the signal "after" is generated. The controller reacts to the "approaching" event by leading the intersection to a safe state, i.e. bringing both lights on red.

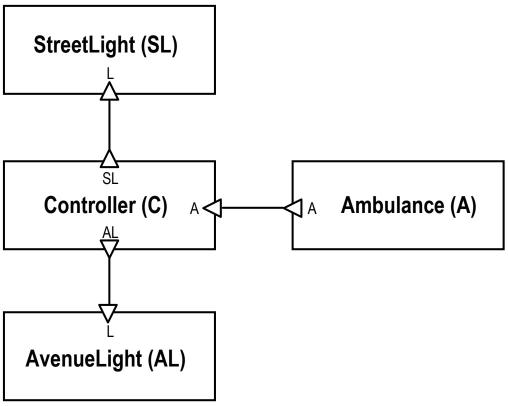

Fig. 1. Traffic light coupled model

When the signal "before" is received, the controller switches to green the light on the ambulance's arrival direction. After the ambulance leaves the intersection ("after" event) the controller turns the green light to red and resumes its normal sequence. Fig. 1 illustrates an RT-DEVS coupled model of the TLC system which is made of four connected components: there are two instances of the Light component, which respectively correspond to the light on the avenue and that on the street, one Ambulance component, which models the behaviour of the sensing equipments of the intersection, and one Controller component which implements the above described control logic. Couplings in Fig. 1 are realized between matching input/output ports. $X/Y$ sets for the Controller are as follows:

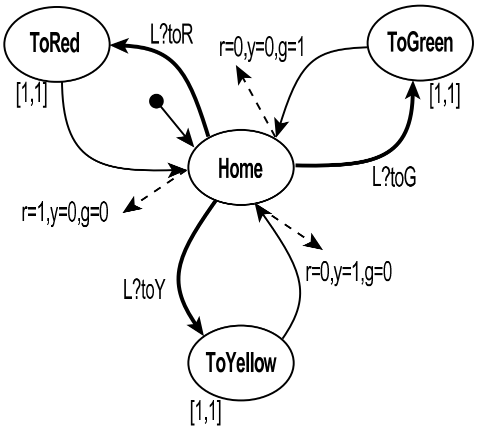

Fig. 2. Light behaviour

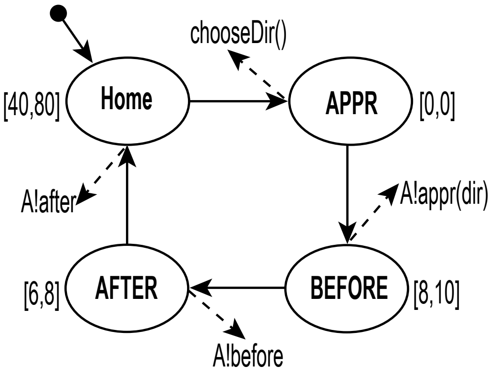

Fig. 3. Ambulance behaviour

```
X={<A,appr>,<A,before>,<A,after>}
Y={<SL,toR>,<SL,toY>,<SL,toG>,<AL,toR>,
    <AL,toY>,<AL,toG>}
```

Component behaviour is specified in Figg. from 2 to 4 where an oval box represents a phase of the component. The complete state set $S$ obviously depends also on the component local variables. For instance, the Controller has a dir variable whose value indicate the avenue or the street, and logical variable amb where information about an arriving ambulance is maintained when current phase of the controller cannot be pre-empted. Similarly, light components keep the light status in the three logical variables r,y, and g. A light component (Fig. 2) is normally in the Home phase with default interval $[\infty, \infty]$. The arrival of a toR, toY or toG event causes an external transition respectively to toRed, toYellow or toGreen phase which is then exited after 1 time unit by an internal transition reaching again Home. The lambda function associated with the internal transitions specifies the required state changes in the light.

Behaviour of the ambulance (Fig. 4) is cyclic. After a non deterministic time in $[40, 80]$, the ambulance announces itself by choosing an arriving direction and sending the appr event to the controller. From the BEFORE phase and after a time in $[8, 10]$ the ambulance sends a before event to the controller. Finally, form the AFTER phase the ambulance signals its passage through the intersection by sending an after event with an elapsed time in $[6, 8]$. In Fig. 4 the normal and exceptional

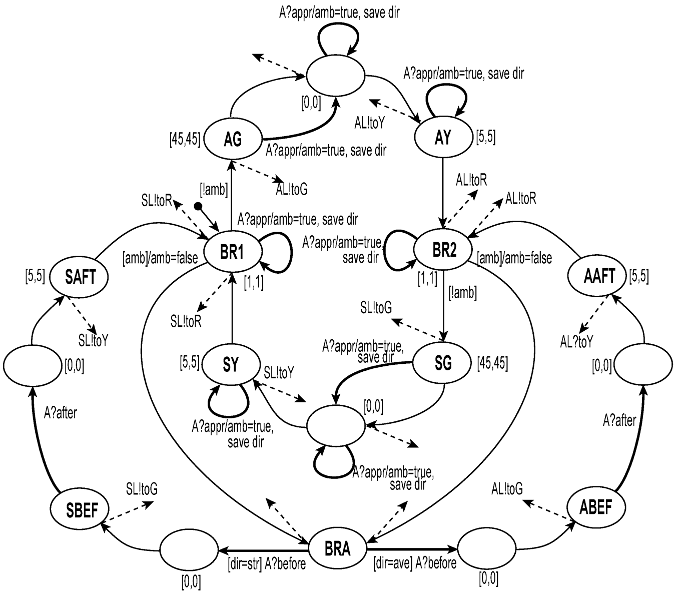

Fig. 4. Controller behaviour

behaviours of the controller can be distinguished. The initial phase is BR1 (both lights reds). Under normal behaviour, the controller steps through a light cycle (e.g. from BR1, to AV to AY to BR2 for the avenue, and from BR2 to SG, to SY to BR1 for the street). It should be noted that a "both reds" condition (BR1 or BR2) is always maintained for 1 time unit. Avenue and street cycles strictly alternate. A normal cycle is started provided no ambulance is sensed. During a light cycle the arrival of ambulance pre-empts normal behaviour. In particular, a green phase (AG or SG) is immediately abandoned by anticipating the next yellow phase and then finishing the cycle. However, current yellow phase is never pre-empted. All of this guarantees the duration of the yellow phase (in the example in [11] it was erroneously made possible, in worst case conditions, that a yellow phase doubles its duration). It should be noted the efforts taken in Fig. 4 for not losing the approaching signals. As soon as an ambulance is sensed, the logical variable amb is set to true. At cycle end, the presence of an ambulance requires an exceptional behaviour to be executed by first reaching the BRA (both reds with ambulance) phase. From BRA, and depending on the arriving direction of the ambulance, the controller senses events from the ambulance and commands accordingly the light by turning it first green, then yellow after ambulance passage and finally red. Ambulance events (e.g. before and after) are processed by external transitions. Light control is instead realized through internal transitions. Following an exceptional behaviour, the controller restarts the normal cycle by giving the turn to the other direction.

### *A. Property Requirements for the TLC*

The TLC has safety and (bounded) liveness (e.g. deadline) properties, besides absence of deadlock or livelock conditions.

1) *Traffic must never be allowed in both directions simultaneously*. For safety reasons it is required that the status of the traffic lights be consistent at all times. To avoid accidents among vehicles crossing the intersection, when on a direction the light is green or yellow, thus allowing traffic in the direction, the light on the opposite direction must be red.
2) *Lights should be both reds at a before event*. No vehicle should be allowed to cross the intersection at a before event.
3) *Deadline of* $3$ *tu for turning green the light after a before event*. Assuming that it takes at least $4$ tu for the ambulance to reach the intersection from the time instant of the before signal, it follows that there exists a deadline of 3 tu for the controller to turn green the light on the arriving direction, also considering that a light takes 1 tu for changing its status.
4) *Correct sequencing of the lights on each direction*. A correct behaviour requires that only transitions from red to green, from green to yellow and from yellow to red should be allowed. A transition out of this sequence denotes a wrong sequence.
5) *The ambulance must be live*. In particular, after signalling an approach, it must be guaranteed that the ambulance model comes back to its Home phase.

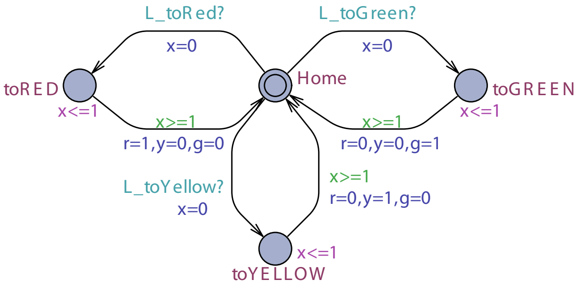

Fig. 5. Light template

## IV. Temporal Analysis using Uppaal

Weak synchronization and message losses increase the need for functional, safety and temporal analysis of an RT-DEVS model. In this work an RT-DEVS model is preliminary transformed into Uppaal [6] for model checking. Uppaal was chosen because it supports data variables and weak synchronization through broadcast channels [12]. The following summarizes the translation rules.

- An RT-DEVS component is mapped onto an Uppaal template, which has a local clock $x$.
- Phases of the source component correspond one-to-one to locations of the template.
- Each pair of matching ports (e.g. the output port A of Ambulance and the input port A of Controller) together with a data/control symbol, is mapped on to a broadcast channel. For instance, broadcast channels A_appr, A_before and A_after are shared between Ambulance and Controller etc.
- Templates receive as parameters the broadcast channels corresponding to used input/output ports.

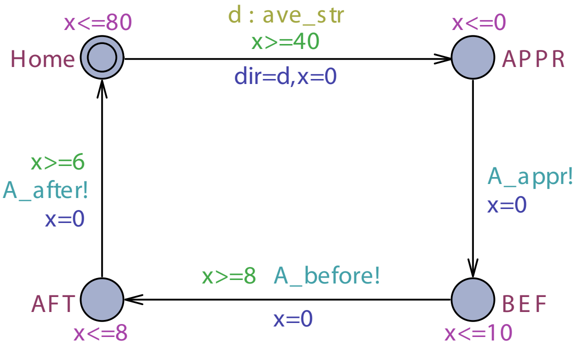

Fig. 6. Ambulance template

TABLE I
UPPAAL QUERIES FOR PROPERTY ANALISYS OF TLC

| Property | Query | Result |
|---|---|---|
| Absence of deadlocks | A[] !deadlock | satisfied |
| Lights consistency | A[] (AL.g==1\|\|AL.y==1) imply SL.r==1 | satisfied |
| Lights consistency | A[] (SL.g==1\|\|SL.y==1) imply AL.r==1 | satisfied |
| Lights must never be both green | E<> SL.g==1 && AL.g==1 | not satisfied |
| Ambulance is live | A.APPR --> A.Home | satisfied |
| Deadline checking | A[] flag imply z<=3 | satisfied |

- Shared communication data, e.g. the dir variable used by Ambulance and Controller, become global declarations.
- A strict time interval $[lb, ub]$ of a phase PH of an RT-DEVS component implies the invariant $x \leq ub$ is added to location PH. Default time interval $[\infty, \infty]$ is implicit. Time interval $[0, 0]$ of a transitory phase is mapped on the invariant $x \leq 0$. UPPAAL requires bounds of a time interval to be expressed by naturals.
- An internal transition of the RT-DEVS model is associated with a timed edge having the guard $x \geq lb$. The update portion of the command on the edge contains the effect of the output function. An external transition is associated with an untimed edge which in turn relates to an input synchronization with a broadcast channel.

The above rules were applied to obtain the models in Figg. from 5 to 7 which depict the UPPAAL version of RT-DEVS TLC components. In Fig. 6, random choice of the ambulance arriving direction is simply achieved by non-deterministic selection, on the edge between Home and APPR locations, of the value of the local variable d between ave and str values (type ave_str is an alias of int[ave,str]). As one can see, the UPPAAL templates correspond as close as possible to source RT-DEVS components. Therefore, the translation can be easily automated. The resultant UPPAAL system model is the parallel composition of one instance of the Controller template, two instances of the Light template and one instance of the Ambulance.

### A. Verification of the TLC

The timed automata model of the TLC was verified using the UPPAAL version 4.1.0. Table I illustrates some TCTL queries issued to the UPPAAL verifier used for property analysis.

Absence of deadlocks confirms the TLC model correctly behave despite weak synchronization and (possibly) message loss. That the unsafe state of both lights green is never reached is checked by asking the verifier if there exists a state in the state graph where the g data of both lights is 1. In addition, it was verified that whenever the traffic is allowed in one direction (the light is green or yellow), the light is red on the other direction.

Correct sequencing of lights was verified by introducing three additional variables in the Light template for storing the previous status of the light, by changing the Light behaviour so as to conserve previous status at any new assignment, and by checking that it is always true that a green status is preceded by the red status etc. These details and queries are omitted for simplicity.

A few additional words relate to deadline checking. The UPPAAL model was decorated by introducing the global logical variable flag and the extra clock $z$. Variable flag is set to true in the Ambulance template when the before event is sent to controller, and reset in the Light template (therefore in both instances of the template) when the green status is installed (on the exiting edge from the toGreen location in Fig. 5). It was found that not only the required deadline is fulfilled but that in reality 1 tu is always sufficient for the controller, following a before signal, to turn green the light in the arriving direction of the ambulance.

## V. IMPLEMENTATION STATUS

RT-DEVS was prototyped in Java using an adaptation of the ActorDEVS lean agent-based framework [9], [10]. The following provides some implementation hints and gives a flavour of the programming style. Both discrete and dense time models are supported, through the class hierarchy (interfaces are underlined): `Time`, `AbsoluteTime`, `RelativeTime`, `TimeInterval`, `AbsoluteDiscreteTime`, `AbsoluteDenseTime`, `RelativeDiscreteTime`, `RelativeDenseTime`, `DiscreteTimeInterval`, `DenseTimeInterval`. A concrete time object has a `value()` method which returns a `long` for discrete time, and a `double` for dense time. An RT-DEVS atomic component must be programmed as a class which derives directly or indirectly from the `RTDEVS` abstract base class, which provides the contract of operations (see the extract in Fig. 8) and basic behaviour.

A specific component must implement the abstract methods of `RTDEVS` in order to specify its specific behaviour. For simulation purposes the `activity()` method can be left to its default (no-operation) body. Phases are coded as integers. Internal and external transitions return the int of the next phase. It should be noted that component methods have direct access to the whole state by accessing the component local data variables. The `ti()` method returns the (dense or discrete) time interval associated with the given state. Method `now()` returns the `AbsoluteTime` value of current time.

Typed input/output ports are supported respectively by parametric classes `Input<V>` and `Output<V>`. Typically, `V` is a

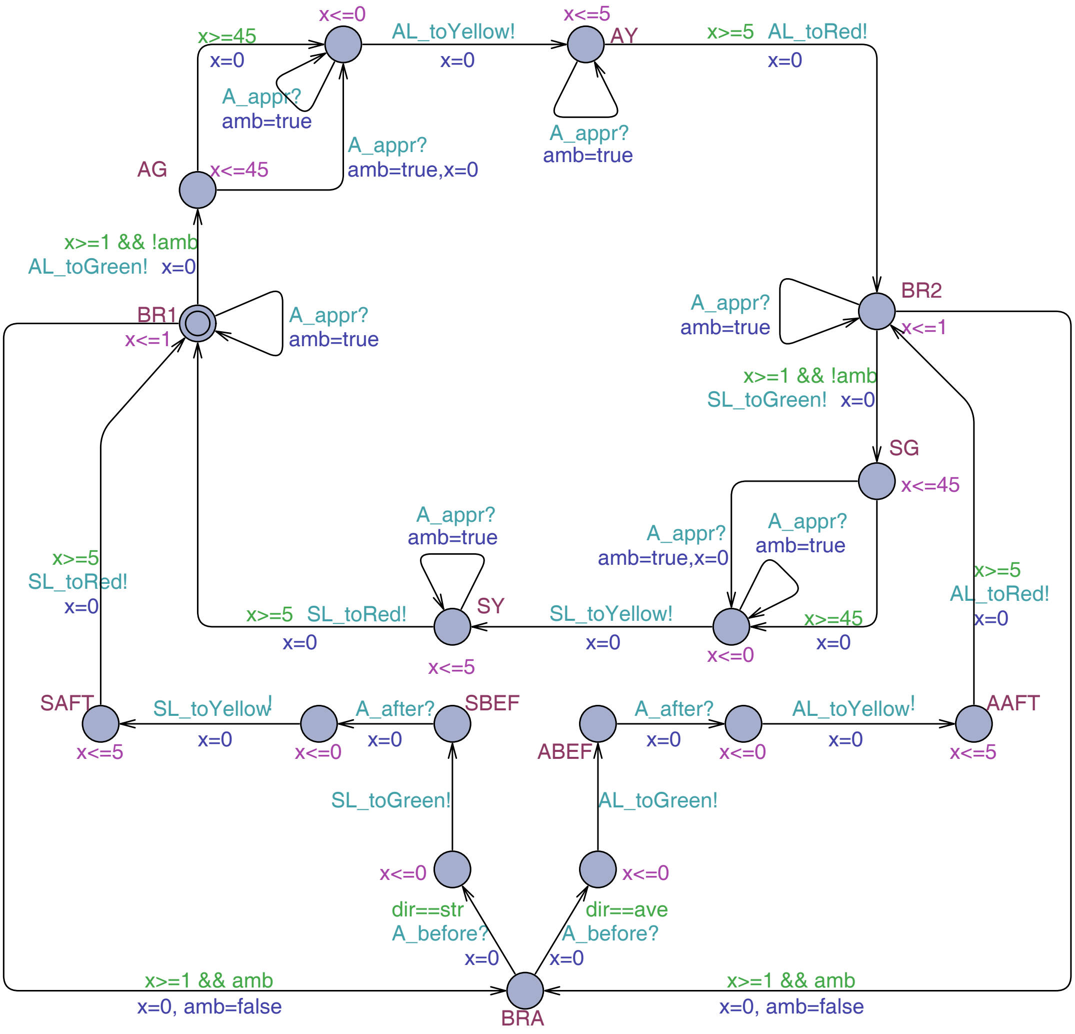

Fig. 7. Controller template

```
public abstract int delta_int( int phase );
public abstract int delta_ext( int phase, RelativeTime e, Message x );
public abstract void lambda( int phase );
public abstract RelativeTime ta( int phase );
public abstract TimeInterval ti( int phase );
public void activity( int phase ){}
public AbsoluteTime now();
```

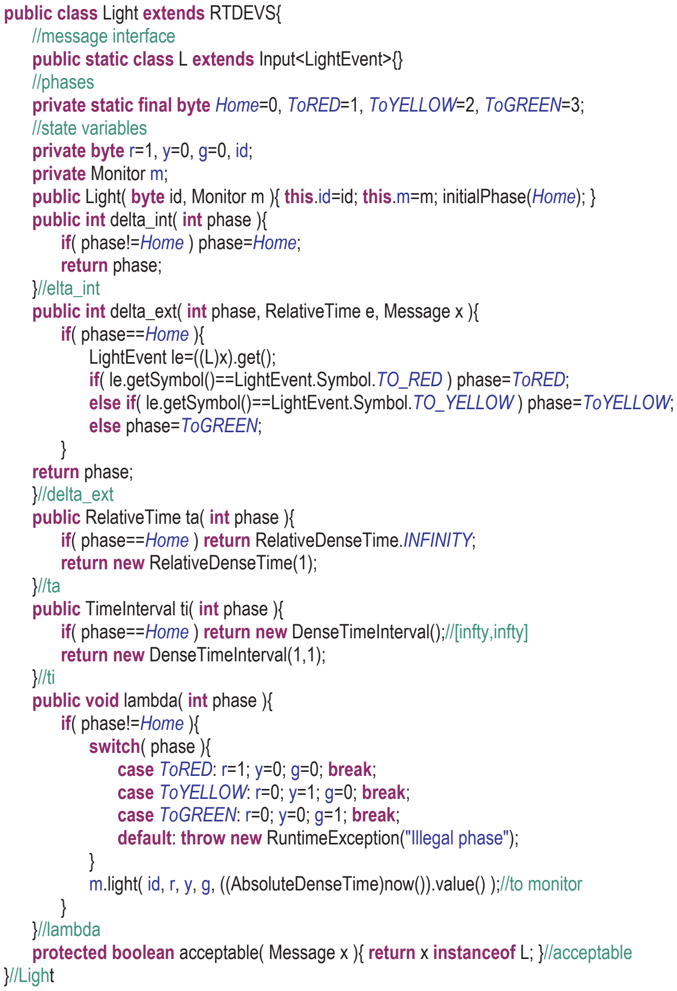
```
public class LightEvent {
    public static enum Symbol{ TO_RED, TO_YELLOW, TO_GREEN };
    private Symbol symbol;
    public Symbol getSymbol(){ return symbol; }
    public void setSymbol( Symbol symbol ){ this.symbol=symbol; }
}//LightEvent
```

Fig. 9. Class of light events

user defined class which specifies the data/control symbols which can flow through the port. `Input` is a subclass of `Output`. Each component exports its input port types. Output ports are created by a configurer (e.g. the `main()` method) and passed to relevant components e.g. at construction time. The configurer is also in charge of linking matching ports for establishing a coupled model. Programming style is exemplified by showing details of the Light atomic component. Light events were modelled as instances of the `LightEvent` class (Fig. 9). The Light component, shaped for prototyping and simulation purposes, is illustrated in Fig. 10.

For components with non punctual time intervals (e.g. Ambulance and Controller) the `ta()` method returns a number uniformly distributed in the time interval of current phase.

Java TLC model was executed using dense time and the `RTDEVS_Simulation` control engine which mimics the RT-DEVS operational semantics. `RTDEVS_Simulation` receives the (`AbsoluteDenseTime`) simulation time limit (e.g. $10^7$) and a simulation clock (here a `SimulationDenseTimeClock`). `RTDEVS` maintains a priority queue of timers ranked by ascending fire times (absolutized `ta` values). The engine fires most imminent



```
public class Light extends RTDEVS{
    //message interface
    public static class L extends Input<LightEvent>{}
    //phases
    private static final byte Home=0, ToRED=1, ToYELLOW=2, ToGREEN=3;
    //state variables
    private byte r=1, y=0, g=0, id;
    private Monitor m;
    public Light( byte id, Monitor m ){ this.id=id; this.m=m; initialPhase(Home); }
    public int delta_int( int phase ){
        if( phase!=Home ) phase=Home;
        return phase;
    }//elta_int
    public int delta_ext( int phase, RelativeTime e, Message x ){
        if( phase==Home ){
            LightEvent le=((L)x).get();
            if( le.getSymbol()==LightEvent.Symbol.TO_RED ) phase=ToRED;
            else if( le.getSymbol()==LightEvent.Symbol.TO_YELLOW ) phase=ToYELLOW;
            else phase=ToGREEN;
        }
    return phase;
    }//delta_ext
    public RelativeTime ta( int phase ){
        if( phase==Home ) return RelativeDenseTime.INFINITY;
        return new RelativeDenseTime(1);
    }//ta
    public TimeInterval ti( int phase ){
        if( phase==Home ) return new DenseTimeInterval();//[infty,infty]
        return new DenseTimeInterval(1,1);
    }//ti
    public void lambda( int phase ){
        if( phase!=Home ){
            switch( phase ){
                case ToRED: r=1; y=0; g=0; break;
                case ToYELLOW: r=0; y=1; g=0; break;
                case ToGREEN: r=0; y=0; g=1; break;
                default: throw new RuntimeException("Illegal phase");
            }
            m.light( id, r, y, g, ((AbsoluteDenseTime)now()).value() );//to monitor
        }
    }//lambda
    protected boolean acceptable( Message x ){ return x instanceof L; }//acceptable
}//Light
```

Fig. 10. Class Light of the TLC

internal transitions one at a time and updates the simulation clock to the fire time accordingly. The output function then sends synchronously its message to the coupled component. In the case the partner component is not ready for synchronization, the sent message is simply lost. During simulation, a `Monitor` object (transducer) gets informed of event occurrences and checks system properties (e.g. it counts the number of times the bad state green-green of the two lights is reached, and measures the maximal time distance between the occurrence time of the green light in the arriving direction of the ambulance, and that of the immediately preceding before event, etc.). Also under simulation, the TLC was found to be temporally correct.

For real-time execution, RT-DEVS naturally requires a multi-processor implementation (each component runs on its own processor, as was assumed by temporal analysis). The `ta()` function is no longer useful. The `activity()` method should be programmed with the (sub)algorithms to be carried out in each phase of the component. All other methods remain unchanged. Of course, a real-time executive has to possibly compensate for violations of activity durations. An activity can terminate earlier than its lower bound duration or after its upper bound. In the first case the engine can delay the firing of the internal transition until the real time clock reaches the lower bound. In the latter case activity interruption and concepts of adaptive scheduling and imprecise computation [13] could help. As a particular scenario, an RT-DEVS model could be analyzed and executed on a single processor, by ensuring atomicity and mutual exclusion of activities.

## VI. Conclusion

This paper reports about specification, analysis and Java implementation of RT-DEVS systems operated under model continuity. Model checking is enabled by a translation onto timed automata of UPPAAL. For large models an achieved discrete-event simulation tool can be exploited. Java implementations rely on a minimal, efficient and customizable agent framework [9], [10].

On-going and future work is directed at:

- experimenting with real-time executives using the Real-time Specification for Java platform [14]
- extending the approach to the distributed context using standard middleware like HLA/RTI or real-time CORBA
- building development tools for visual modelling, prototyping/simulation, and automatic generation of Java code and UPPAAL XML code.

*Abstract*—**The paper presents features and implementation of a shared redundant approach to increase the reliability of networked control systems. Common approaches based on redundant components in control system use passive or active redundancy. We deal with quasi-redundant subsystems (shared redundancy) whereas basic features are introduced in the paper. This type of redundancy offers several important advantages such as minimizing the number of components as well as increasing the reliability. The example of a four-rotor mini-helicopter is presented in order to show reliability improving without using any additional redundant components. The main aim of this paper is to show the influence of the load increasing following different scenarios. The results could help to determine the applications where quasi-redundant subsystems are a good solution to remain in a significant reliability level even if critical failure appears.**

**Keywords: Shared redundancy, Dependability, Networked control systems**

## I. Introduction

To BE able to obtain relevant results of reliability evaluations for complex systems, it is necessary to describe the maximum of specific dependencies within the studied system and their influences on the system reliability. Different methods or approaches for control systems' reliability improvement are developed in order to be applied to specific subsystems or to deal with dependencies among subsystems. A classical technique consists in designing a fault-tolerant control [12] where the main aim is to propose a robust control algorithm. Guenab and others in [4] deal with this approach and reconfiguration strategy in complex systems, too.

On the other side is the design of reliable control architectures. Probably the most used technique is to consider the redundant components which enlarge the system structure and its complexity too. Active and passive redundancy is the simplest way how to improve dependability attributes of the systems such as reliability, maintainability, availability, etc [8]. However, as it was mentioned the control structure turns to be more complex due to an increasing number of components as well as the number of possible dependencies among components.

The paper introduces complex networked control architecture based on cascade control structure. The cascade structure was chosen purposely due to its advantages. This structure is widely used in industrial applications thanks to positive results for quality of control which are already described and generally known [2]. On the other side it offers some possibilities of system reliability improvement. There are potentially redundant components such as controllers (primary, secondary). If more than one network is implemented we could consider them as potentially redundant subsystems too. Finally if the physical system allows it, it is possible to take profit from sensors. The cascade structure and other features are introduced in more details in the third part.

The paper is organised as follows. After bringing closer the research background, the shared redundancy is introduced. The controllers and networks are presented in more details in order to show some dependencies which could be appeared when a shared redundancy approach is implemented. In the next part are presented networked topologies considered as cascade control (CC) structure of the 4-rotor mini-helicopter (drone) model [3]. Using Petri nets were prepared the models of the introduced quasi-redundant components as well as drone's control structure. A simple model of the two quasi-redundant subsystems is evaluated. Finally, are proposed the simulation results of the mentioned simple two components model as well as the model of the complex drone's structure with short conclusion.

## II. Research Background

Control architecture design approach was taken into account by Wysocki, Debouk and Nouri [13]. They present shared redundancy as parts of systems (subsystems) which could replace another subsystem in case of its failure. This feature is conditioned with the same or similar function of the subsystem. Wysocki et al. introduce the shared redundant architecture in four different examples illustrated on "X-by-Wire" systems used in automotive applications. Presented results shown advantages of this approach in control architecture design.

The shared redundancy approach involves the problematic of a *Load Sharing* [1]. Thus, some of the components take part of the load of the failed components in order to let the system in functional mode. Consideration of the load sharing

978-83-60810-14-9/08/$25.00 © 2008 IEEE

in mechanical components is presented by Pozsgai and others in [11]. Pozsgai and others analyze this type of systems and offer mathematical formalism for simple system 1-out-of-2 and 1-out-of-3. Also there are some mathematical studies [1] of several phenomena appeared on this field of research. Bebbington and others in [1] analyze several parameters of systems such as survival probability of load shared subsystems.

## III. Shared Redundancy

Specific kind of redundant subsystems which have similar features such as active redundancy however gives us some additional advantages which will be introduced in further text. This kind of spares represents another type of redundant components which are not primary determined as redundant but they are able to replace some other subsystem if it is urgently required. This type of redundancy is referred as *shared redundancy* [13] or *quasi-redundancy* [6]. Due to its important advantages it is useful to describe this kind of spares in order to show several non-considered and non-evaluated dependencies which could have an influence to the system reliability. Identification and description of this influence should not be ignored in order to obtain relevant results of the reliability estimation of the systems which involve this kind of spares.

As it was abovementioned, the *shared redundancy* (SR) mentioned by Wysocki and others in [13] is in further text taken into account in the same meaning as a *quasi-redundant* (QR) component. Thus, quasi-redundant components are the parts of the system which follow their primary mission when the entire system is in functional state. However, when some parts of the system fail then this function could be replaced by another part which follows the same or a similar mission, thus by quasi-redundant part. The quasi-redundant components are not primary determined as active redundant subsystem because each one has its own mission which must be accomplished. Only in case of failure it could be used. In NCS appears the question of logical reconfiguration of the system when the data flow must be changed in order to replace the functionality of a subsystem by another one. For example, some new node will lose the network connection and system has to avoid the state when packets are sent to node which does not exist. Thus, the main features of the shared redundancy could be summarized as follows:

> *"Quasi-redundant component is not considered as primary redundant component such as the active or the passive redundant components."*

Generally in networked control systems, three kinds of quasi-redundant components (subsystems) could be considered:

- QR controllers.
- QR networks.
- QR sensors.

Hence, a necessary but not sufficient condition is that a control structure where SR could be considered has to be composed at least of two abovementioned subsystems (controllers, networks, actuators). The subsystems should have similar functionality or construction in order to be able to replace the mission of another component. In case of quasi-redundant components there are several limitations. In order to take profit of quasi-redundant networks, it is necessary to connect all nodes in all considered QR networks. Thus, in case of different networks the components should have implemented all necessary communication interfaces. In case of QR controllers the hardware performance has to allow implementing more than one control task.

Third mentioned components are sensors. Consideration of the sensors as QR components has important physical limitations. In order to be able to replace a sensor for measuring a physical value $X$ by another one for measuring $Y$ it is necessary to use "multi-functional" smart sensors. *We can suppose that some combination of the physical values can not be measured by using one sensor due to inability to implement required functionality in one hardware component.*

Other limitation is the distance between failed sensor and its QR sensor which could have a significant influence to the possibility of its replacing. Generally, implementation of the QR sensors within control system structure could be more difficult than the application of the SR approach on controllers or networks.

There are several naturally suitable control structures which could implement the shared redundancy approach without other modifications such as cascade control structure (Fig. 1). This structure is often used in industrial applications thanks to its important features which improve the quality of control. With using cascade control structure there are several constraints [13]. The main condition requires that controlled system must contain subsystem (secondary subsystem FS(s) – Fig. 1) that directly affect to primary system FP(s). Thus, cascade structure composes of two independent controllers which could be used in order to implement the shared redundant approach.

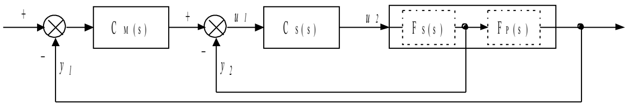

Fig. 1 Main structure of the cascade control

Usually for secondary subsystems there is a condition of faster dynamics than primary process. This condition must not be fulfilled [13] however, some modifications of conventional cascade structure (Fig. 1) and control laws must be provided.

### I. Quasi-redundant controllers

In previous text, several suitable control structures were briefly introduced. As was shown the controllers covered by these structures could be considered as quasi-redundant components by default. Thus, the hardware of both components could be shared in order to implement shared redundant approach.

Suppose the networked cascade control system shown in figure 2. The system is composed of five main components (Sensor $S_1$, $S_2$, controllers $C_1$, $C_2$ and actuator A) and two networks. The communication flow among components is determined by its cascade control structure. Thus, sensor $S_1$ sends a measured value to controller $C_1$ (*Master*), the controller $C_2$ (*Slave*) receives the values from the sensor $S_2$ as well as the controller $C_1$ in order to compute an actuating value for the actuator A.

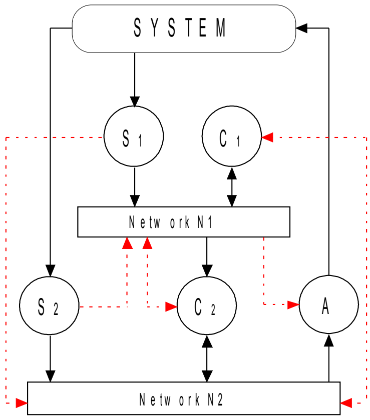

Fig. 2 NCCS with two networks and alternative network connections

Each part of the system (components and networks) presents independent subsystem. However, when quasi-redundant components are considered the system is not already composed of the independent components. Depending on the performance parameters of the used hardware equipment in the control loop, a specific influence on the system reliability should be taken into account. Thus some dependencies should not be ignored in the dependability analysis. In the NCCS shown in figure 2 we could consider controllers $C_1$ and $C_2$ as the quasi redundant subsystems (components). Both QR controllers have the primary mission which must be followed. Thus, controller $C_1$ controls outer control loop and controller $C_2$ stabilizes inner control loop. However in case of failure of one of them, we could consider the second one as some kind of spare.

As was abovementioned, the controllers follow their primary mission stabilization or performance optimization of the controlled system. Therefore, in regard to the similar hardware it allows sharing the computing capacity and executes different tasks. Thus, in order to implement SR approach both controllers *have to encapsulate both control tasks* – for the outer and the inner control loop (see the cascade control structure in figure 1).

In non-failure mode the primary task is executed in both controllers. However, in case of controller's failure (primary or secondary) non-failed controller starts execute both tasks and computes actuating value for primary as well as secondary subsystem. In this case we can suppose two scenarios.

The first one supposes that the controller is able to execute all the necessary tasks within the required sample periods (Fig. 3a). Thus, no delays or other undesirable consequences are expected. In this case the behavior of the quasi-redundant component is similar as in case of the active redundant components. Thus, in case of failure of one of the components, the second takes care about its mission until its failure.

Figure 3b shows a second case when time to execute both necessary tasks is greater than the required sampling period. Thus, the controller will cause the delays which have significant influence to the system stability [5] [7]. Therefore, this delay could be known that allows its partially compensating by using several methods [10]. Thus, we can suppose that system destabilization will not occur immediately after the first delay and we are able to compensate it for some time interval. Thus, quasi-redundant controller does not fail immediately but its reliability decreased.

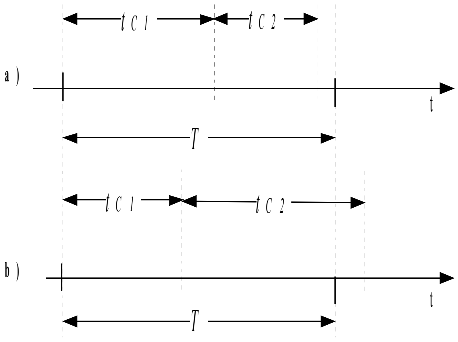

Fig. 3 Possible scenarios for quasi-redundant controllers

There are several situations when this scenario could be considered. In critical systems where failure of an important component could cause undesired damage or other dangerous consequences the shared redundancy approach could helps to allocate some time interval in order to take the system in a safe state. Thus, SR approach can be a significant technique how to save the system before damage.

### *II. Quasi-redundant networks*

The second part of the NCS which could be taken into account as an SR subsystem are networks. Suppose a system with two networks (Fig. 2) where all components could communicate (connect) on these networks ($N_1$ and $N_2$) if is it needed. In this case we can apply SR approach on this system.

Considered functionality of the quasi redundant networks is as follows. Both networks transmit required data - network $N_1$ transmit data from $S_1$ to $C_1$ and from $C_1$ to $C_2$ such as network $N_2$ from $S_2$ to $C_2$ and from $C_2$ to A. Thus both networks are active and allocated during the system mission. The same as in case of QR controllers, when one network has failed the second one can take its load after a system reconfiguration. Thus, all required data are sent through the second network. Hence, two similar scenarios as with controller task execution could be described. The amount of transmitted data on network with specified bit rate has logically influence on the probability of failure of the network (of course this depends on the network type and other parameters mentioned). This influence could be ignored when network performance parameters are sufficient. However, we can suppose that probability of network failure is increasing simultaneously with increasing network loading.

The characteristic between network loading and its bit rate depends on the network type and have to be measured in real network conditions in order to determine the type of dependency – linear or nonlinear.

Not only the network bit rate can be important however other network limitations such as maximal number of nodes connected to network, etc. All limits of the QR subsystems can create dependencies with direct influence on the system reliability. Primary, we could consider these dependencies as undesirable but in case of critical failures this SR approach gives some time to save the system.

When NCS with SR approach are analyzed this characteristic should be included in prepared model and further evaluated in order to determine its influence to the reliability of the whole NCS.

### *III. Different scenarios in shared redundancy*

When certain dependencies are ignored we could regard on the control system with QR components as control structure with active redundant components. However, there are several important scenarios when the reliability of the system could be decreased in order to prevent dangerous consequences or other undesirable events.

These scenarios could appear when some conditions could not be fulfilled (insufficient execution time or network bit rate) but the system need some time in order to take a safe state. Hence, it is necessary to identify and describe the influence of these dependencies which leads to more relevant results. Thus, prevent from too pessimistic or too optimistic results of the reliability analysis of the considered systems. The dependencies could be distinguished as follows:

- active redundant dependency,
- single step change of the nominal failure rate $\lambda_n \in \langle 0;1 \rangle$ - increased once by constant value – step load change,
- time depend change of the nominal failure rate $\lambda_n$ - functional dependency –the load of the subsystem is changed with time passed from speared subsystem failure,
    - linear,
    - nonlinear.

We suppose the presumption that destabilization of the system does not occur immediately after the first delay on the network caused by insufficient controller's hardware or network's parameters. Thus, quasi-redundant controller does not fail immediately but in this case its failure rate increases which correspond consequently to a decreased reliability.

Thus, in case of the active redundant dependency we suppose that quasi-redundant subsystem has sufficient capacities in order to follow its primary mission as well as the mission of the failed subsystem (or subsystems).

Single step change of the nominal failure rate of the subsystem is considered in case of subsystems where the failure rate of the quasi-redundant subsystem is changed (increased) once by constant value (Fig. 4) during its life time. Thus, the new increased failure rate $\lambda$' remains constant during further life time of the subsystem. For example, let's suppose a NCS with two Ethernet networks where one of them has failed and consequently the system is reconfigured and all nodes (components) start to communicate through the non-failed network which has sufficient bit rate capacity in order to transmit all required data. However, the amount of data has been increased which consequently increases the probability of packets' collisions. Thus, probability of the failure (failure rate) has been increased up to new value $\lambda$'.

A third case considers the change of the nominal failure rate $\lambda_n$ which depends on the time passed from the moment of the failure until current time of the working of the quasi-redundant subsystem which encapsulates the executing necessary tasks (own tasks as well as tasks of the failed subsystem). Thus, a functional dependency has to be considered. This dependency of the change of the failure rate $\lambda_n$ could be described by linear or nonlinear dependency / function. We could take previous example of the system with two networks. However, in this case the bit rate of the second (non-failed) network is not sufficient. Consequently delays in data transmission as well as other consequential undesirable problems such as system destabilization might be caused. We can suppose that the non-failed network will fail in some time. Thus, the nominal failure rate $\lambda_n$ of the second network is now time dependent and is linearly or nonlinearly increased until system failure. Mentioned examples with related equations are further discussed in more details.

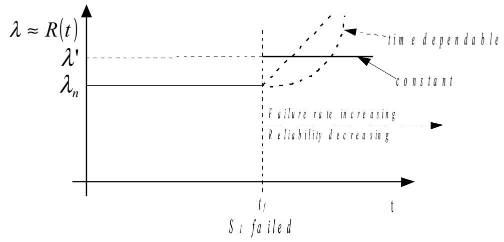

Fig. 4 Possible failure rate curves for subsystem S2 during its mission

Let's suppose that the reliability of the system $R(t)$, probability of the failure during time interval <0; $t$>, is characterized by a nominal failure rate $\lambda_n \in \langle 0;1 \rangle$ . Let's suppose a system with two subsystems $S_1$ and $S_2$ (such as networks in abovementioned examples) whereas the subsystem $S_1$ will fail as first and then quasi-redundant subsystem $S_2$ will follow both missions ($S_1$ and $S_2$). In figure 4 are shown two above mentioned scenarios when the nominal failure rate $\lambda_n$ of the subsystem is increased by a constant value or by value which could be described as linear or nonlinear function (functional dependencies).

At first increasing the failure rate $\lambda_n$ one time by constant value (see Fig. 4) will be dealt. It corresponds with the reliability reduction of the quasi-redundant subsystem $S_2$ by increasing the failure rate, during its mission, from its nominal value $\lambda_n$ up to new $\lambda$'. Consequently, the system will follow its primary mission thanks to QR subsystem $S_2$ but its failure rate is already increased and consequently the probability of failure of $S_2$ is higher. The difference between nominal $\lambda_n$ and increased $\lambda$' failure rate will be called *decrease factor* $d_R$. Thus, mentioned constant value is characterized by decrease factor $d_R$ of QR subsystem and new changed failure rate $\lambda$' at fail time $t_f$ is given by followed simple formula

$$\lambda' = \lambda_n + d_R \tag{1}$$

Failure rate increases only one time by the specified value and QR subsystem $S_2$ with new constant failure rate $\lambda$' will follow both mission of its own mission and mission of the failed subsystem $S_1$.

The second case shown in figure 3 considers reliability reduction where the failure rate $\lambda_n$ is increased during the working of the subsystem $S_2$ by a specified *decrease factor*. This change of the nominal failure rate depends on time whereas with time extending the failure rate of the $S_2$ is got near to 1 (system failed). Thus, a *decrease function* $f_{dr}(t)$ is represented by linear or nonlinear characteristic and depends on real subsystem which is considered as quasi-redundant. Thus, increased failure rate $\lambda$' of the subsystem $S_2$ depends on time $t$ and is given by following formula:

$$\lambda'(t) = \lambda_n + f_{dR}(t) \, . \tag{2}$$

As it was mentioned, the decrease function $f_{dr}(t)$ can be represented by a simple linear function, for example,

$$\lambda'(t) = \lambda_n + d_R 10^{-3}(t + 1 - t_f) \tag{3}$$

where $t$+1 allows change the nominal failure rate $\lambda_n$ at the moment of the failure at time $t_f$.

On the other side a nonlinear exponential function can be considered as follows:

$$\lambda'(t) = \lambda_n + e^{d_R(t-t_f)} \tag{4}$$

where $\lambda$' is the value of the increased failure rate, $\lambda_n$ is the nominal failure rate of the component, $t_f$ is the time of the failure of the component, $d_R$ is the decrease factor which has a direct influence on the increased failure rate.

### *IV. Application to a mini-drone helicopter*

The NCC structure is applied for the control of a four rotors mini-helicopter (Drone, Fig. 5). The proposed control structure for this real model is as follows. The NCC architecture is composed of one primary controller (Master) and one secondary controller (Slave), thirteen sensors, four actuators and two communication networks.

The Master is designed for attitude stabilization (control) through Slave controller for angular velocity control for each propeller. The aim of the control is to stabilize coordinates of the helicopter [11].

The controllers are used as quasi-redundant components within presented networked cascade control system (further only NCCS). They use the same control algorithm (propeller's angular velocity control) but with different input data (set point, system output, etc.)

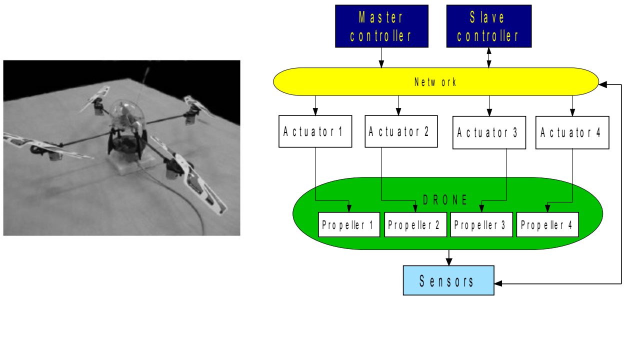

Fig. 5 Cascade control structure of mini-helicopter with one network

Hence, in case of failure one of them could retransmit all required data to another one, whereas pre-programmed control algorithm should compute the actuating value. Thus, failed controller is replaced by second one which start to compute actuating value.

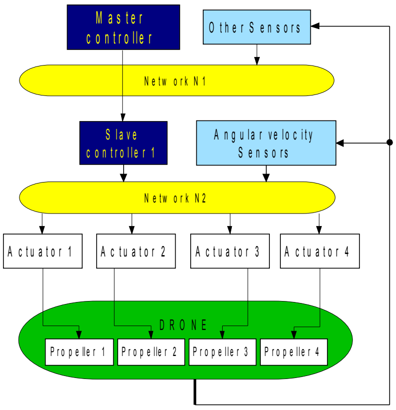

Fig. 6 Cascade control structure of mini-helicopter with two networks

Other quasi-redundant parts of this control structure are networks (Fig. 6). The same as in case of controllers, one of the networks can compensate another one after system reconfiguration. Usually, two networks are primary designed due to reduction amount of transmitted data. However, in case of network failure all data could be retransmitted through second one.

Described approach for subsystem's failure compensation by using the shared redundancy requires logical reconfiguration of the NCCS. Thus, in case of failure the hardware configuration is non-touched but communication ways must be changed in order to transmit the data to non-failed component or through non-failed network.

## IV. Simulation and Results

All presented networked control architectures (Fig. 5, 6) were modelled by using Petri nets. This tool was chosen thanks to its ability to model different types of complex systems and dependencies within them. To provide the reliability analysis the Monte Carlo simulation (further only MCS) method was used. The multiple simulations of the modelled architecture [ 12] are provided to obtain the reliability behavior the basic two quasi-redundant components (for example two controllers in CCS structure).

Model of the system covers the simulation of the random events of the basic components of the system such as sensors, controllers and actuators as well as the network's random failures. Software used for model preparation is CPN Tools which allow multiple simulation of the model in order to obtain statistically representative sample of the necessary data to determine the reliability behaviour of the studied model.

As was mentioned, the simulation of the simple two quasi-redundant components with all considered changes of the failure rate (single, linear, nonlinear) was provided. Thus, new failure rate $\lambda$' of the non-failed component is computed by using equation (1), (3) and (4).

TABLE IV.
MTTFF OF SIMULATED CONTROL STRUCTURES WITH DIFFERENT DECREASE FACTORS

| Decrease factor – $d_R$ | MTTFF - Drone (Fig. 5) | MTTFF -Drone (Fig. 6) |
|---|---|---|
| 0 | 55 (+11%) | 58 (+22%) |
| $2.10^{-3}$ | 54 (+9%) | 56 (+17%) |
| $10^{-2}$ | 53 (+7%) | 54 (+13%) |
| $59.10^{-2}$ | 50.5 (+2%) | 49 (+3%) |
| 0.999 | 49.6 | 47.6 |

This change could be called as single change because the component's failure rate is changed only once during QR component's life time. Both components has equal nominal failure rate $\lambda_n = 0.001$.

Few examples of the influence of the single step change of the failure rate by the specified decrease factor $d_R$ to the reliability behaviour are shown in figure 7. We can see there are five curves. Two non-dashed curves show studied system as system with two active redundant components (thus, $d_R$ is equal to zero – first curve from the top) and as system without redundant components (thus, system composes of two independent components without redundant relation – first curve from the bottom). These two curves determine borders where reliability of the studied system can be changed depending on value of the decrease factor $d_R$.

As we can see from figure 7, single increasing of the nominal failure rate $\lambda_n$ of the non-failed components by the same value as was nominal failure rate $\lambda_n$ up to $\lambda' = 0.002$ ($d_R = 0.001$) cause significant reduction of the reliability.

In tables I, are shown several values of life time (parameter MTTFF) for this studied system. Each table (Table I, II, III) shows the life time of the studied components as active redundant subsystems ($d_R = 0$) and as independent subsystems ($d_R = 0.999$). From value of the decrease factor $d_R = 0.01$ the life time of the system significantly improves (18% and more). The results of the linear and nonlinear failure rate increasing are shown in tables II and III. In all tables are noted the percentual value of the increased life time corresponding to the decrease factor.

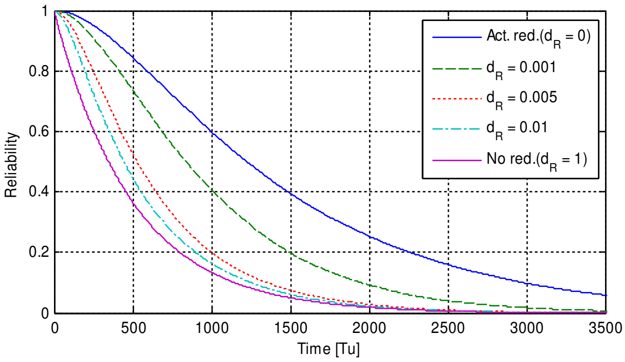

Fig. 7 Influence of the increased failure rate of the component by constant decrease factor $d_R$ to reliability of the system composed of two quasi-redundant components

Table IV shows the MTTFF parameters of both complex mini-helicopter structures. In the first drone structure (Fig. 5) two quasi-redundant controllers are considered. In the second structure (Fig. 6) two groups of quasi-redundant subsystems are considered and simulated – the controllers and the networks.

In all simulated systems was observed the influence of the single step of the failure rate by a value specified by the decrease factor $d_R$. The same as in tables I – III, there are shown the life time of system corresponding to different decrease factors $2.10^{-3}$, $10^{-2}$, $59.10^{-3}$. We can see that increasing the component's nominal failure rate $\lambda_n$ by decrease factor equal to $59.10^{-3}$, which represents approximately 59 times higher failure rate, has a significant influence to decreasing the life time of the system. The results are a little bit better than in the case of the system

TABLE I.
MTTFF OF THE TWO QUASI-REDUNDANT WITH SINGLE STEP CHANGE OF THE FAILURE RATE

| $\lambda_n = 10^{-3}$ | Act. red. $d_R = 0$<br>($\lambda' = 10^{-3}$) | $d_R = 0.001$<br>($\lambda' = 0.002$) | $d_R = 0.005$<br>($\lambda' = 0.006$) | $d_R = 0.01$<br>($\lambda' = 0.011$) | $d_R = 0.1$<br>($\lambda' = 0.101$) | No red. $d_R = 0.999$<br>($\lambda' = 1$) |
|---|---|---|---|---|---|---|
| MTTFF [*Tu*] | 1503 (+300%) | 1002 (+200%) | 667 (+34%) | 589 (+18%) | 509 (+2%) | 499 |

TABLE II.
MTTFF OF THE TWO QUASI-REDUNDANT WITH LINEAR INCREASING OF THE FAILURE RATE

| $\lambda_n = 10^{-3}$ | Active red.<br>$d_R = 0$ | $d_R = 10^{-3}$ | $d_R = 10^{-2}$ | $d_R = 10^{-1}$ | No redundancy |
|---|---|---|---|---|---|
| MTTFF [*Tu*] | 1503 (+300%) | 1153 (+231%) | 812 (+63%) | 611 (+22%) | 499 |

TABLE III.
MTTFF OF THE TWO QUASI-REDUNDANT WITH EXPONENTIAL INCREASING OF THE FAILURE RATE

| $\lambda_n = 10^{-3}$ | Active red.<br>$d_R = 0$ | $d_R = 10^{-3}$ | $d_R = 10^{-2}$ | $d_R = 10^{-1}$ | No redundancy |
|---|---|---|---|---|---|
| MTTFF [Tu] | 1503 (+300%) | 902 (+80%) | 676 (+35%) | 537 (+8%) | 499 |

without redundant components ( $d_R = 0.999$), but we could say that they are almost the same.

The drone's structure composes of twenty (twenty-one – structure with two networks) components – thirteen sensors (3 gyrometers, 3 magnetometers, 3 accelerometers, 4 rotors' angular velocity sensors), two controllers, four actuators and one (two) networks. Due to high ratio of the independent components and shared redundant components within drone's structure (18 independent and 2 quasi-redundant – Fig. 5) there is a difference between life times for minimal and maximal $d_R$ is significantly smaller (about 11% and 22%) than in case of basic two components subsystem (Table I, II, III).

The Mean Time Before First system's Failure is significantly longer in case of basic two component subsystem than in drone's cases. As it was mentioned above this is caused by the difference in complexity between basic and drone's NCC architecture. In case of comparison between two drones structures (Fig. 5, 6) the results are better for architecture with two networks which is composed of two quasi-redundant subsystems – controllers (Master, Slave) and networks when the decrease factor is smaller than $59.10^{-3}$ . The increasing of the nominal failure rate by the decrease factor greater than $59.10^{-3}$ significantly decreases the life time of the drone. On the other side, even if the controller loading will change its failure rate approximatelly ten times ( $d_R = 10^{-2}$ ) the system's life time is about 7% longer than in case of the system without shared redundant approach implementation.

## V. Conclusion

The paper shows the influence of additional reliability decreasing of the quasi-redundant component to entire reliability of the studied system. Description of this dependency is getting closer to show the behavior of the system reliability when shared redundancy approach is implemented . The results shown in tables I – III could be very helpful in order to approximate the life time of the quasi-redundant subsystem under different conditions of the failure rate increasing. Presented cascade control architecture suitable for shared redundancy approach implementation could be applied to similar systems. For example, Steer-by-Wire control [9] of two front wheels in a car, etc. In addition the paper has shown the conventional cascade control structure within conditions of networked control systems as naturally suitable to profit from quasi-redundant subsystems as networks, controllers and potentially sensors if physical process allows it. Despite of some constraints for using this type of control, cascade architecture is widely used in industrial control applications. Hence, only the reconfiguration algorithm should be implemented to take profit from quasi-redundant subsystems.

The main advantages of the quasi-redundant components could be summarized as follows:

- The system is composed only of necessary components (parts) for following the primary mission of the system whereas higher system reliability is ensured without using any additional active redundant components.
- Following the first point we could suppose less number of components used for saving the control mission. Thus, economic aspect could be significant.
- Prevention of the system's critical failure when QR subsystem has no sufficient hardware capacities.

# Runtime resource assurance and adaptation with Qinna framework: a case study

Laure Gonnord*, Jean-Philippe Babau
CITI / INSA-Lyon
F-69621 Villeurbanne Cedex – France
Email: {Laure.Gonnord, Jean-Philippe.Babau}@insa-lyon.fr

***Abstract*—Even if hardware improvements have increased the performance of embedded systems in the last years, resource problems are still acute. The persisting problem is the constantly growing complexity of systems. New devices for service such as PDAs or smartphones increase the need for flexible and adaptive open software. Component-based software engineering tries to address these problems and one key point for development is the Quality of Service (QoS) coming from resource constraints. In this paper, we recall the concepts behind Qinna, a component-based QoS Architecture, which was designed to manage QoS issues, and we illustrate the developpement of a image viewer application whithin this framework. We focus on the general developpement methodology of resource-aware applications with Qinna framework, from the specification of resource constraints to the use of generic Qinna's algorithms for negociating QoS contracts at runtime.**

## I. Introduction

THE STUDY takes place in the context of embedded handled systems (personal digital assistants, mobile phones) whose main characteristic is the use of limited resources (CPU, memory).

In order to develop multimedia software on such systems where the quality of the resource (network, battery) can vary during use, the developer needs tools to:

- easily add/remove functionality (services) during compilation or at runtime;
- adapt component functionality to resources, namely propose "degraded" modes where resources are low;
- evaluate the software's performances: quality of provided services, consumption rate *for some scenarios*.

In this context, component-based software engineering appears as a promising solution for the development of such kinds of systems. Indeed it offers an easier way to build complex systems from base components ([1]), and thus we are able to design resource components like others. The main advantages are the re-usability of code and also the flexibility of such systems.

The Qinna framework ([2], [3]) was designed to handle the specification and management of resource constraints problems during the component-based system development. Variability is encoded into discrete implementation levels and links between them. We can also encode quantity of resource constraints. Qinna provides algorithms to ensure resource constraints and dynamically adapt the implementation levels according to resource availability *at runtime*.

In this paper, we present a case study using Qinna as proof of concept. In Section II we present the main characteristics of the case study which is an image remote viewer. In Section III we recall Qinna's main concepts, as introduced in [2] and formalize them in a more generic way. We give an overview of Qinna's C++ implementation (Section IV), and then provide the general implementation steps to develop a resource-aware application with Qinna (Section V). We illustrate in the particular case of the remote viewer application in Section VI.

## II. Specification of the remote viewer

Our case study is a remote viewer application whose high level specification follows:

- The system is composed of a mobile phone and a remote server. The application allows the downloading and the visualization of remote images via a wireless link.
- The remote directory is reached via a ftp connection. After connection, two buttons "Next" and "Previous" are used to display images one by one. Locally, some images are stored in a buffer. To provide a better quality of service, some images are downloaded in advance, while the oldest ones are removed from the photo memory.
- The application must manage different qualities of services for the resources: shortage of bandwidth and memory, or disconnections of the ftp server. When needed it can download images in lower quality (in size or image compression rate).
- Different storage policies are possible, and there are many parameters which can be modified; like the size of the buffer, or the number of images that are downloaded each time. We want to evaluate which policy is the best *according to a given scenario*.

We aim to use Qinna for two main objectives: maintenance of the application with respect to the different qualities of service, and also the evaluation of the influence of the parameters on the non-functional behavior (timing performance and resource usage) of the application.

## III. Description of the Qinna framework

### A. Qinna's main concepts

The framework designed in [2] and [3] has the following characteristics:

[*] This work has been partially supported by the REVE project of the French National Agency for Research (ANR)

- Both the application pieces of code and the resource are components. The resource services are enclosed in components like `Memory`, `CPU`, `Thread`.
- The variation of quality of the provided services are encoded by the notion of *implementation level*. The code used to provide the service is thus different according to the current implementation level.
- The link between the implementation levels is made through an explicit relation between the implementation level of the provided service and the implementation levels of the services it requires. For instance, the developer can express that a video component provides an image with highest quality when it has enough memory and sufficient bandwidth.
- All the calls to a "variable function" are made through an existing contract that is negotiated. This negotiation is made automatically through the Qinna components. A *contract* for a service at some objective implementation level is made only if all its requirements can be reserved at the corresponding implementation levels and also satisfy some constraints called Quality of resource constraints (QoR). If it not the case, the negotiation fails.

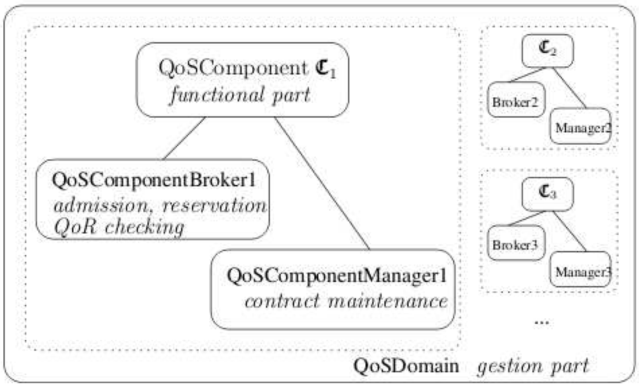

Fig. 1. Architecture example

These characteristics are implemented through new components which are illustrated in Figure 1: to each application component (or group of components) which provide one or more variable service Qinna associates a *QoSComponent* $\mathfrak{C}_i$. The variability of a variable service is made through the use of a corresponding `implementation level` variable. Then, two new components are introduced by Qinna to manage the resource issues of the instances of this *QoSComponent*:

- a *QoSComponentBroker* which goal is to realize the admission of a component. The Broker decides whether or not a new instance can be created, and if a service call can be performed w.r.t. qthe uantity of resource constraints (QoR).
- a *QoSComponentManager* which manages the adaptation for the services provided by the component. It contains a mapping table which encode the relationship between the implementation levels of each of these services and their requirements.

At last, Qinna provides a single component named *QoSDomain* for the whole architecture. It manages all the service requests inside and outside the application. The client of a service asks the Domain for reservation of some implementation level and is eventually returned a contract if all constraints are satisfied. Then, after each service request, the Domain makes an acknowledgment only of the corresponding contract is still valid.

### B. Quantity of Resource constraints in Qinna

A Quantity of resource constraint (QRC) is a quantitative constraint on a component $\mathfrak{C}$ and the service $(s_i)$ it proposes. QRCs are for instance formula on the total instance of a given component type, of the total amount of resource (memory, CPU) allocated to a given component. They are two types of constraints, depending on their purpose:

- Component type constraints (CTC) express properties of components of the same type and their provided services.
- Component instance constraints (CIC) express properties of a particular instance of a component.

The management of these constraints is automatically done at runtime, if the developer implements them in the following way:

- In the `QoSComponent`, for each service, implement the two functions: `testCIC` and `updateCIC`. The former decides whether or not the call to the service can be performed, and the later updates variables after the function call. In addition, there must be an initialization of the CICs formulas at the creation of each instance.
- Similarly, in the `QoSComponentBroker`, for each provided service, implement the two functions `testCTC` and `updateCTC`.

Then, Qinna maintains resource constraints at runtime through the following procedure:

- When the Broker for $\mathfrak{C}$ is created, the parameters used in `testCTC` are set.
- The creation of an instance of $\mathfrak{C}$ is made by the Broker iff $CTC_{compo}(\mathfrak{C})$ is true. During the creation, the CIC parameters are set.
- The $CIC(s_i)$ and $CTC(s_i)$ decision procedures are invoked at each function call. A negative answer to one of these decision procedures will cause the failure of the current *contract*. We will detail the notion of contract in Section III-D.

### C. QoS Linking constraints

Unlike quality of resource constraints, linking constraints express the relationship between components, in terms of quality of service. For instance, the following property is a linking constraint: " to provide the `getImages` at a "good" level of quality, the `ImageBuffer` component requires a "big" amount of memory and a "fast" network". This relationship between the different QoS of client and server services are called QoS Linking Service Constraints (QLSC).

**Implementation Level**To all provided services that can vary according to the desired QoS we associate an *implementation* *level*. This implementation level (IL) encodes which part of implementation to choose when supplying the service. These implementation levels are totally ordered for a given service. As these implementation levels are finitely many, we can restrict ourselves to the case of positive integers and suppose that implementation level $0$ is the "best" level, $1$ gives a lesser quality of service, and so on.

We assume that required services for a given service doesn't change according to the implementation level, that is, the call graph of a given service is always the same. However, the arguments of the required services calls may change.

**Linking constraints expression** Let us consider a component $\mathfrak{C}$ which provides a service $s$ that requires $r_1$ and $r_2$ services. Qinna permits to link the different implementation levels between callers and callees. The relationship between the different implementation levels can be viewed as a function which associates to each implementation level of $s$ an implementation level for $r_1$ and for $r_2$:

$$QLSC_s : \left| \begin{array}{ccc} \mathbb{N} & \longrightarrow & \mathbb{N}^2 \\ IL & \longmapsto & (IL_1, IL_2) \end{array} \right.$$

Thus, as soon as an implementation level is set for the $s$ service, the implementation level of all required services (and all the implementation levels in the call tree) are set. This has a consequence not only on the code of all the involved services but on the arguments of the service calls as well.

Therefore, if a user asks for the service $s$ at some implementation level, the request may fail due to some behavioral constraint. That's why every request for a service must be negotiated and the notion of contract will be accurate to implement a set of a satisfactory implementation levels for (a set of) future calls.

**Implementation of linking constraints in Qinna** The links between the provided QoS and the QoS of the required services are made through a table whose lines encode the tuples of linked implementation levels: $(IL_s, IL_{r_1}, IL_{r_2})$. This "mapping" table is encoded in the QoSManager. The natural order of the lines of the table is used to determine which tuple to consider if the current negotiation fails.

Now we have all the elements to define the notion of contract.

### D. Qinna's contracts

Qinna provides the notion of *contract* to ensure both behavioral constraints and linking constraints.

When a service call is made at some implementation level, all the subservices implementation level are fixed implicitly through the linking constraints. As all the implementation levels for a same service are ordered, the objective is to find the best implementation level that is feasible (w.r.t. the behavioral constraints of all the components and service involved in the call tree).

**Contract Negotiation** All service calls in Qinna are made after negotiation. The user (at toplevel) of the service asks for the service at some interval of "satisfactory" implementation levels. Qinna then is able to find the best implementation level in this interval that respects all the behavioral constraints (the behavioral constraints of all the services involved in the call tree). If there is no intersection between feasible and satisfactory implementation levels, no contract is built. In the other case, a contract is made for the specific service. A contract is thus a tuple $(id, s_i, IL, [IL_{min}, IL_{max}], imp)$ denoting respectively its identifiant number, the referred service, the current implementation level, the interval of satisfactory implementation levels, and the *importance* of the contract. This last variable is used to sort the list of all current contracts and is used for degradation (see next paragraph).

After contract initialization, all the service calls must respect the terms of the contract. In the other case, there will be some renegotiation.

**Contract Maintenance and Degradation** After each service call the decision procedure for behavioral constraints are updated. After that, a contract may not be valid anymore. As all service calls are made through the Brokers by the Domain, the Domain is automatically notified of a contract failure. In this case, the Domain tries to degrade the contract of least importance (which may be not the same as the current one). This degradation has consequences on the resource and thus can permit other service calls inside the first contract.

Basically, degrading a contract consists in setting a lesser implementation level among the satisfactory ones, but which is still feasible. If it is not possible, the contract is stopped.

**Use of services** Each call to a service at toplevel as consequences on the contract which has been negociated for him. We suppose that a contract is made before the first invocation of the desired service. The verification could automatically be done with Qinna, but is not not yet implemented. All the notifications of failures are logged for the developer.

## IV. Qinna's components implementation in C++

We implemented in C++ the Qinna components and algorithms. These components are provided through classes which we detail in this section.

### A. Qinna's components for the management of services

**QoSComponent** The QoSComponent class provides generic constructors and destructors, and contains a private structure to save the current implementation levels of the component provided service. All QoS components will inherit from this class.

**QoSBroker**The QoSBroker class contains a private structure to save the references to all the corresponding components it is responsible for. It provides the two functions `Free(QoSComponent* refQc)` and `Reserve(...)`. As `testCIC` and `updateCIC` functions signature depends of each component/service, these functions will be provided in each instance of QoSBroker.

**QoSManager** The QoSManager class contains all information for the service provided by its associated component. It provide the following public functions:

- `bool SetServiceInfos(int idserv, QoSComponent *compo, int nbreq, int nbmap)` initializes the manager for the *idserv* service, provided by **compo*, with *nbreq* required services and *nbmap* different implementation levels. Return `true` if successful, `false` otherwise.
- `bool AddLevQoSReq(int idserv, int lv, int irq, int lrq)` adds the tuple $(lv, irq, lrq)$ (the $lv$ implementation level for $idserv$ is linked to the $lrq$ implementation level for $irq$ service) in the mapping table for $idserv$.
- `int Reserve(int idserv, int lv)` is used for the reservation of the $idserv$ service at level $il$. It returns the local number of (sub) contract of the Manager or $0$ if the reservation has failed (due to resource constraints).

**QoSDomain** The QoSDomain class provides functions for managing contracts at toplevel:

- `bool AddService(int service, int nbRq, int nbMp, QoSManager *qm)` adds the service $service$ with $nbRq$ required services and $nbMp$ implementation levels, with associated manager $*qm$.
- `int Reserve(QoSComponent *compo,int ns , int lv, int imp)` is used for reservation of the service $ns$ provided by the component $*compo$ at level $lv$ and importance $imp$. it returns the number of contract (in domain) if successful, $0$ otherwise.
- `bool Free(int id)` frees the contract number $id$ (of domain).

**ManagerContract** This class provides a generic structure for a subcontract which encodes a tuple of the form $< id, lv, *rq, v >$ where $id$ is the contract number, $lv$ the current level, $rq$ is the component that provides the service and $v$ is a C++-vector that encode the levels of the required services. This class provides access functions to these variables and a function to change the implementation level.

**DomainContract** This class provides a structure for contracts at toplevel. A Domain contract is a tuple of the form $< di, i, lv, *rq >$ where $di$ is the global identifier of the contract, $*rq$ is the manager associated to the component that provides the service, $i$ is the local number of subcontract for the manager, and $lv$ is the current level of the service.

### *B. Basic resource components*

In the call graph of one service, leaves are physical resources (Memory, CPU, Network). As all resources must be encapsulated inside components, we need to encapsulate the base functions into QoSComponents. For instance, the `Memory` component must be encoded as a wrapper around the `malloc` function, and the associated broker basically implements the CIC functions which decide if the global amount of allocated memory is reached or not.

Sometimes, the basic functions are encapsulated in higher level components. For instance, a high level library might provide a `DisplayImage` function which makes an explicit call to `malloc`, but this call is hidden by the use of the library. In this particular case, the management of basic resource functions can be done in two different but equivalent ways:

- the creation of a “phantom” Memory component which provides the two services `amalloc` (for abstract malloc) and `afree`. Each time the developer makes a call to an “implicit” resource function (*i.e.* when the called function needs a significant amount of memory, like `DisplayImage`), he has to call `Memory.amallloc`. The Qinna’s C++ implementation provides some basic components like Memory, Network and CPU and their associated brokers.
- the creation of QoSComponent around the library function `DisplayImage` which is responsible (through its broker) for the global amount of “quantity of resource” used for the `DisplayImage` function.

Both solutions need a precise knowledge of the libraries functions w.r.t the resource consumption. We assume that the developer has this knowledge since he designs a resource-aware application. In our case study we used the first solution.

## V. Methodology to use Qinna

We suppose that in the application all resources, including hardware resources (Memory, CPU) or software ones (viewer, buffer), are encoded by components. Here are the main steps for integrating Qinna into an existing application designed in C++:

1) **Identify the variable services** which are functions whose call may fail due to some resource reasons. They are of two types:
   - simple functions like `Memory.malloc` whose code does not vary. They have a unique implementation level.
   - “adaptive” functions whose code can vary according to implementation levels.

   The first step is thus to identify the services whose quality vary and associate to each of this services a *unique* key, and if the code vary, clearly identify the variant code through a code of the form:

```
switch(implLevel)
   {
    case 0 :
       ...
   }
```

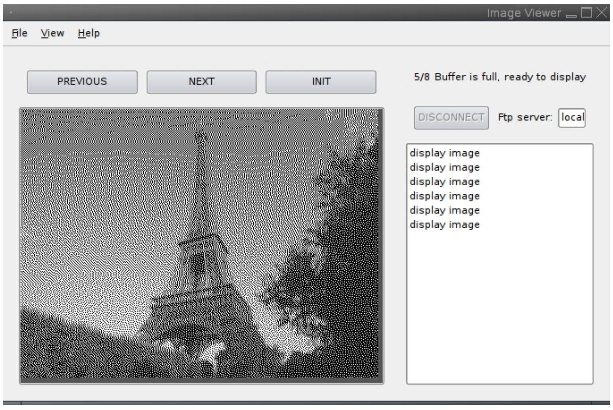
   where implLevel is the associated (variable) attribute of the host component for this service. We must identify which variable services are required for each provided service, and the relationship between the different implementation levels.

2) **Create Qinna components**. First, cut the source code into QoSComponents that can provide one or more QoSservices. As the QoS negotiation will only be made between QoSComponents of different types, this split will have many consequences on the QoS management. For each QoSComponentC (which inherits from the `QoSComponent` class), the designer must encode two classes: `QoSBrokerC` and `QoSManagerC` which respectively inherit from the `QoSBroker` and `QoSManager` generic classes. For the whole application, the designer will directly use the `QoSDomain` generic class.
3) **Implement Quality of Resource constraints**. These constraints are set in two different ways:
   - The type constraints (CTC) for component $C$ implementation is composed of additional functions in $QoSBrokerC$ : `initCTC` which is executed at the creation of the Broker, and which sets the decision procedures parameters ; a `testCTC` function to determine whether a new instance can be created or not ; an `updateCTC` to save modifications of the resources after the creation. For each provided QoS service $s_i$, we add to new functions: `testCTC(idsi)` which is executed before the call of a service and tells if the service can be done, and `updateCTC(idsi)` to be executed after the call.
   - The instance constraints (CIC) for $C$ are also composed of three functions to encode in the $QoSComponentC$: `setCIC` to set the resources constants, `testCTC(idsi)` which is used to decide if a service of identifiant `ids` can be called, and `updateCTC(idsi)` to update the resource constraints after a call to the $s_i$ function.
4) **Implement the linking constraints**. The links between required services and provided service via implementation levels are set by the invocation of the `SetService` and `AddLevQoSReq` functions of the managers. These functions will be invoked at toplevel.
5) **Modify the main file to initialize Qinna components at toplevel**. Here are the main steps:
   - For each base resource (CPU, Memory, ...)
     a) Invoke the constructor for the associated Broker. The constructor's arguments must contain the initialization of internal variables for type constraints (the total amount of memory for example).
     b) Create the associated Manager with the Broker as argument.
     c) Register the QoS services inside the Manager with call to the `SetServiceInfos` function.
     d) Create QoSComponents instances via the use of the `Broker.reserve(...)` function. The arguments can be a certain amount of resource used by the component.
   - For all the other QoSComponents, the required components first:
     a) Create the associated Broker and Manager.
     b) Set the services information.
     c) If a service requires another service of another component, use the function `Manager.AddReq` to link the required manager. Then use `Manager.AddLevQoSReq` to set the linking constraints.
     d) Create QoSComponent instances by invoking the corresponding reservation function (`Broker.Reserve`).
   - Create the QoSDomain and add the services that are used at toplevel (`Domain.AddService`)
   - Reserve services via the QoSDomain and save the contracts' numbers.

## VI. Viewer Implementation using Qinna

This case study is a proof of concept for using Qinna. For this specific application, we want to use Qinna for two objectives:

- the maintenance of the application with respect to the different qualities of service,
- the evaluation of the influence of the parameters on the non-functional behavior (timing performance and resource usage)



5/8 Buffer is full, ready to display

Ftp server: local

display image

display image
display image
display image
display image

Fig. 2. Screenshot of the viewer application

### A. The functional part

The functional part of the viewer is developed with Qt[1] (a C++ library which provides graphical components and implementations of the ftp protocol). Figure 3 describes the main parts of the standalone application. We chose to make the downloading part via the ftp protocol. The wireless part is not encoded.

- The `FtpClient` class makes a connection to an existing ftp server and has a list of all distant images. It provides a `getSome` function to enable the downloading of many files at once.
- The `ImageBuffer` class is responsible for the management of downloaded files in a local directory. As

[1] http://trolltech.com/products/qt/

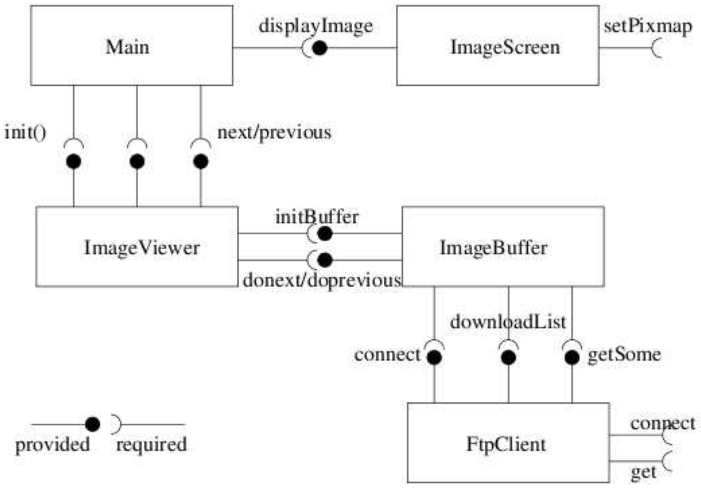

Fig. 3. Functional view of the application

the specification says, this buffer has a limited size and different policy for downloading images. The class provides the two functions donext and doprevious which are asynchronous functions. A signal is thrown if/when the desired image is ready to be displayed. It eventually downloads future images in current directory.

- The ImageViewer class is a high level component to make the interface between the ftp and buffer classes to the graphics components.
- The ImageScreen class is responsible for the display of the image in a graphic component named QPixmap.
- The main class provides all the graphics components for the Graphical User Interface.

### B. Integration of Qinna

Now that we have the functional part of the application, we add the following resource components: Memory, and Network which are QoSComponents that provide variable services. We only focus on these two basic resources. The Network component is only linked to the FtpClient, whereas Memory will be shared between all components. For Memory, the only variable service is amalloc which can fail if the global amount of dedicated memory is reached ; this function has only one implementation level. For Network, the provided function get can fail if there is too much activity on network (notion of bandwidth).

Then we follow the above methodology in the particular case of our remote viewer.

**Identification of the variable services (step 1)**

Now as the variable services for low level components have been identified, we list the following adaptive services for the functional part:

- ImageScreen.displayImage varies among memory, it has three implementation levels which correspond to the quality of the displayed image. We add calls to Memory.amalloc function to simulate the use of Memory.
- Ftpclient.getsome's implementation varies among available memory and the current bandwidth of network. If there is not enough memory or network, it adapts the policy of the downloads. It has three implementation levels. We add calls to Network.bandwidth to simulate the network resources that are needed to download files.
- ImageBuffer.donext/previous varies among available memory: if there is not enough memory the image is saved with high compression.

**Creation of the QoSComponents (step 2)**

The resource components are QoSComponents. Then, the three components ImageScreen, FtpClient and ImageBuffer are QoSComponents which provide each one variable service. Imageviewer and Main are QoSComponents as well. Figure 4 represents now the structure of the application at this step.

For the sake of simplicity, we only share Memory into two parts, a part for ImageBuffer and the other part for imageBuffer. That means that each of these components have their own amount of memory.

**Resource constraints (steps 3 and 4)**

The quantity of resource constraints we have fixed are classical ones (bounds for the memory instances, unique instantiation for the imageScreen component, no more than 80 percent of bandwidth for the ftpClient, etc). The QLSC are very similar to those described in [2] for a videogame application. Here we show how we have implemented some of these constraints in our application.

- *Quantity of resource constraints* The imageScreen component is responsible for the unique service display_image (display the image on the graphic video widget). Here are some behavioral constraints we implemented for this component:
  - There is only one instance of the component once.
  - The display function can only display images with size lesser or equal to $1200 * 800$.
  - There is only one call to the display function once.

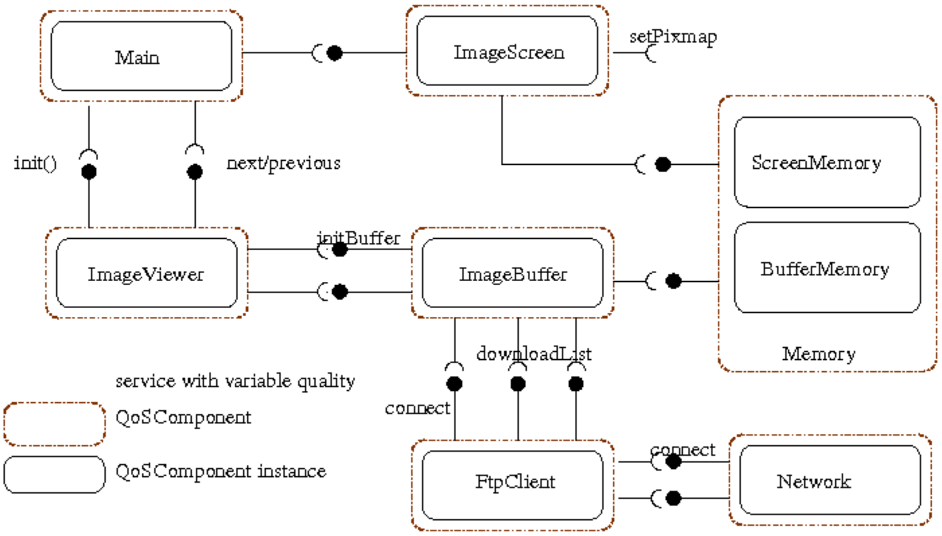

Fig. 4. Application with Qinna

These type constraints are easily implemented in the associated `imageScreenBroker` in the following way: the constraint "maximum of instance" requires two private attributes `nbinstance` and `nbinstancemax` which are declared and initialized at the creation of the Broker with values $0$ and $1$. Then the reservation of a new `imageScreen` by the Broker is done after checking whether or not $nbinstance + 1 \leq nbinstancemax$. If all checks are true, it reserves the instance and increments `nbinstance`.
The checking of memory is done by setting the global amount of memory for `ImageBuffer` and `imageBuffer` in local variables which are set to $0$ at the beginning of each contract, and updated each time the function `amalloc` is called.
These constraints are rather simple but we can imagine more complex ones, provided they can be checked with bounded complexity (this is a constraint coming from the fact the Qinna components will also be embedded).

- *QoS Linking constraints*
To illustrate the difference between quality of resource constraints and linking constraints, we show here the constraints for the `FtpClient.getSome`:
  - The implementation level $0$ corresponds to $3$ successive downloads with the `Network.get` function. The function has a unique implementation level but each call to it is made with $60$ as argument, to model the fact it requires $60\%$ of the total bandwidth. These three calls are made through the use of the `Thread.thread` with implementation level $0$ (quick thread, no active wait).
  - The implementation level $1$ corresponds to $2$ calls to the `get` function with $40\%$ of bandwidth each time. These two calls are made through the use of the `Thread.thread` with implementation level $1$ (middle thread, few active wait).
  - The implementation level $2$ corresponds to $1$ call to the `get` function with $20\%$ bandwidth. This call is made through the use of the `Thread.thread` with implementation level $2$ (more active wait).

Thus if the available bandwidth is too low, a negotiation or an existing contract will fail because of the resource constraints. The creation of the contract may fail because a thread cannot be provided at the desired implementation level.

**Modification of toplevel (step 5)** This part is straightforward. The only choices we have to make are the relative amount of resource (Memory, Network) which are allocated to each QoSComponents. The test scenario is detailed in section VI-D.

### C. Some statistics

The viewer is written in 4350 lines of code, the functional part taking roughly 1800 lines. The other lines are Qinna's generic components (1650 loc.), 600 lines of code for the new components (imagescreenBroker, imageScreenManager *etc.*) and 300 lines of code for the test scenarios. The binary is also much bigger  4.7Mbytes versus 2Mbytes without Qinna.

Thus Qinna is costly, but all the supplementary lines of code do not need to be rewritten, because:

- Generic Qinna components, algorithms, and the basic resource components are provided with Qinna.
- The decision functions for Quality of service constraints could be automatically generated or be provided as a "library of common constraints".
- The initialization at toplevel could be computed-aided through user-friendly tables.

We think that the cost of Qinna in terms of binary code can be strongly reduced by avoiding the existing redundancy in our current implementation.

Moreover, Qinna's implementation can be viewed as a prototype to evaluate the resource use and the quality of service management. After a preliminary phase with the whole implementation used to find the best linking constraints, we can imagine an optimized compilation through glue code which neither includes brokers nor managers.

### D. Results

We realized a scenario with a new component whose only objective is to use the basic resources Memory and Network. This `TestC` component provides only the `foobar` function at toplevel. This function has two implementation levels, and requires two functions: `ScreenMemory.amalloc` and `Network.get`. The whole application provides four functions at toplevel: `TestC.foobar`, `ImageViewer.donext` (and `doprevious`) and `ImageScreen.displayimage`. Three contracts are negotiated, in the following importance order: `foobar` first, then `donext` and `doprevious`, then `displayimage`. We made the three contracts and download and visualize images at the highest qualities, but at some point the foobar function causes the degradation of the contract for displayimage, and the images are then shown in a degraded version, like the Eiffel tower on Figure 2.

The gap between the characteristics of the contract and the effective resource usage can be make through the use of log functions provided by the Qinna implementation.

## VII. Related works

Other works also propose to use a development framework to handle resource variability. In [4] and [5], the author propose a model-based framework for developping self-adaptative programs. This approach uses high-level specifications based on temporal logic formula to generate program monitors. At runtime, these monitors catch the system events and activates the reconfiguration. This approach is similar to us except that it mainly deals with hybrid automata and there is no notion of contract degradation nor generic algorithm for negociation.

The expression and maintenance of resource constraints is also considered as a fundamental issue, so much work deals with this subject. In [6], the author use a probabilistic approach to evaluate the resource consumed by the program paths. Some other works in the domain of verification try to prove conformance of one program to some specification : in [7], for instance, the authors use synchronous observers to encode and verify logical time contracts. At last, the QML language ([8],[9]) is now well used to express QoS properties. This last approach is complementary to our one since it provides a language which could be compiled into source code for QoSComponents or Brokers.

## VIII. Conclusion and future work

In this paper, we have presented a case study using the software architecture Qinna which was designed to handle resource constraints during the development and the execution of embedded programs. We focused mainly on the development part, by giving a general development scheme to use Qinna, and illustrating it on a case study. The resulting application is a resource-aware application, whose resources constraints are guaranteed at runtime, and whose adaptation to variability of service is automatically done by the Qinna components, through the notion of contracts. At last, we are able to evaluate at runtime the threshold between contractualised resource and the real amount of resource effectively used.

This work has shown the effectivity of Qinna with respect to the programming effort, and the performance of the modified application.

Future work include some improvements of Qinna's C++ components, mainly on data structures, in order to decrease the global cost of Qinna in terms of binary size, and more specific and detailed resource components, in order to better fit to the platform specifications.

From the theoretical point of view, there is also a need for a way to manage the linking constraints. The developer has still to link the implementation levels of required and provided services, and the order between all implementations levels is fixed by him as well. The tuning of all these links can only be done though simulation yet. We think that some methods like controller synthesis ([10]) could be used to discover the/a optimal order and linking relations w.r.t. some constraints such as "minimal variability", "best reactivity" *etc.*.

Finally, some theoretical work would be necessary in order to use Qinna as a prediction tool, and provide an efficient compilation into "glue code".

***Abstract*—A current trend in learning programs, even at high-degree studies, is applying the concepts of "learning by projects". In this context, the LEGO® MINDSTORMS® NXT modular robot appears as a simple, flexible and attractive educational platform to achieve the referred challenge in many domains of information technologies, especially in real-time control. The project team can operate with the real system (e.g. constructed robot) to realize a number of particular tasks. The ready-to-use embedded platform and dual microcontrollers architecture represents actual trends in the modern control systems designs. The open hardware and software architecture gives unlimited possibility to handle all devices connected to the main control brick and write effective control algorithms.**

**The proposed rescue robot project is a good example of the simple system where, a number of real-time control problems can be analyzed. The project on this scale requires detailed planning, cooperation in teams, extensive literature survey, and comprehensive software design. That is exactly, what we need for "learning by projects" concept.**

## I. Introduction

A current trend in learning curricula, especially at engineering studies, is applying the concepts of "learning by experiments" or "learning by projects" [1]. The method gives the students the opportunity to get familiar with some practical problems that faces project development teams and organizations in real situations. It was found, that learning achievements resulting from the application of a collaborative work methodology based on the "learning by projects" are much higher [2].

This concept was also proposed for ILERT (International Learning Environment for Real-Time Software Intensive Control System) EU/US project [3]. This study leads to establishing a methodology for a multinational, engineering program, producing graduates capable of working efficiently in multidisciplinary teams engaged in international collaboration on industrial projects. One important output the proposed study is creation of an interdisciplinary specialization in Real-Time Software-Intensive Control (RSIC). As a part of the pilot implementation phase of ILERT project selected courses were introduced as a RSIC curriculum units, acceptable for engineering programs in four partner organizations.

During the research phase of the ILERT we did an intensive literature study demonstrating, that several technical universities have practically implemented robotic design and control experiments with the LEGO MINDSTORMS kits [4], [5]. The LEGO kits give the students a rich and flexible material, which they can use in their design of their robotics projects. The LEGO ability to link directly with Simulink® and access the MATLAB® toolboxes has classified this robot kits as an "open" laboratory. The LEGO MINDSTORMS NXT design is based on the advanced 32-bit ARM7 microcontroller, which can be programmed with the LabView based block-oriented language. However, many other programming tools and languages applicable for real-time LEGO robot control experiments are available in the Internet. The published hardware [9] and software [10] documentation makes the LEGO® MINDSTORMS® NXT system open for any kind of modifications and new applications. Several authors are replacing the operating system of the MINDSTORMS microcontroller with a real-time operating system suitable for C/C++ or similar applications. Most popular is NXC language [17], which supports all of the commands provided by the ARM7 microcontroller. This upgrade might be advantageous for some real-time control applications. The "upgraded" LEGO MINDSTORMS experiment can teach students the importance of real-time computing, periodic tasks development, timers and tradeoffs involving embedded processor size and cost versus performance relations within the context of control systems.

## II. Teaching requirements

From educational point of view, if control aspects are the key element of the curricula, student are expected to design control algorithms based on the mathematical model, simulate how the controlled system works and then implement the controller for the robot during the limited time of a regular academic course. In this case integration of real-time environment with rapid prototyping platforms such as MATLAB/ Simulink or LabView is essential.

If other topics of real-time control system must be covered, for example, task scheduling, resource management, real-time communication or fault-tolerance then text based or object oriented languages are preferable.

This work was supported by the AGH research grant

It is also important to demonstrate  to the students how to fulfill the needs for embedded systems, e.g. how to minimize the application memory requirements. It will be also valuable, if the real-time system monitoring tools provide on-line facilities for measuring execution times.

Working with communication algorithms the LEGO MINDSTORMS built-in Bluetooth media or IEEE 802.11 extension can be explored. The communication tasks can be focused on information interchange between two or more robots and host PC. The PC can support a higher level control algorithms or just to be used for monitoring and data acquisition purposes.

## III. Real-time operating systems for LEGO® MINDSTORMS® NXT

The NXT-G standard graphical programming environment for LMNXT is useful only for very beginning  experiments with robots. Its limited performance does not allow to create and diagnose in real-time the specific algorithms. To improve the performance of robot control a number of software tools were developed and are available [8]. The programming environments available for the LEGO® MINDSTORMS NXT robot and representing real-time features are listed in Table 1. Two most popular solutions for academia and teaching purposes are: LEGO MINDSTORMS Toolkit for LabView and Embedded Coder Robot NXT - based on the graphical environment. Both of them need the licensed software and a number of toolboxes installed. The LabView can operate with a standard LEGO firmware while MATLAB requires the replacement by the leJOS system.

Text programming solutions are represented by NXC and leJOS – both of them are free and open source solutions. The NXC (Not Exactly C) is a text language for MINDSTORMS® NXT robot microcontroller programming with multitasking features, based on standard LEGO firmware [6].

With free programming environment IDE [17] it is possible to create complex and advanced data acquisition and control algorithms operating in real-time, including file management and Bluetooth communication features implementation.

Using text language the programming skills of students together with their understanding of data precision, time dependencies and I/O devices access methods to can be improved.

The leJOS is a Java-based replacement firmware for the LEGO MINDSTORMS RCX microcontroller [14]. The leJOS environment is based on object oriented language (Java) and has the following features: preemptive threads (tasks), arrays including multi-dimensional, recursion, synchronization, exceptions. Java variable types includes Float, Long, and String.

The nxtOSEK [13] (previous name – up to June 2008 was leJOS OSEK) is a hybrid of existing two open source projects (leJOS NXJ and TOPPERS OSEK):

- leJOS NXJ is a API device for NXT sensors, motors, and other external devices [14],
- TOPPERS OSEK provides real-time multitasking features proven in automotive industry [16]. OSEK was originally designed for embedded real-time control systems which are used in real cars [15].

The nxtOSEK is focused on real-time control applications for LEGO MINDSTORMS RCX, thus user-friendly GUI/file system was out of target. Additionally, one can use a graphical modeling, simulation, and code generation environment which is called Embedded Coder Robot NXT - specific MATLAB/Simulink Toolbox.

A unique feature of nxtOSEK application is that users do not need to apply time wait API, which is frequently used by other NXT programming languages to execute control algorithm at desired timing. The nxtOSEK provides accurate preemptive and periodical/event driven task scheduling.

An interesting programming interface, based on client/server architecture , is URBI (Universal Real-time Behavior Interface) [7]. This scripting language can be interfaced with several popular programming languages (C++, Java, MATLAB,...) and OS (Windows, Mac OSX, Linux).

Table I.
Selected programming tools for LEGO MINDSTORMS NXT

| | **LabVIEW Toolkit** | **Matlab/ Simulink** | **NXC** | **RobotC** | **leJOS NXJ** | **nxtOSEK** | **URBI** |
|---|---|---|---|---|---|---|---|
| Programming | Graph | Graph | Text | Text | Text | Text | Text |
| Syntax | NI blocks | Simulink blocks, C | Like C | C | Java | C/C++ | Like C/C++ |
| Firmware | Standard | Repl. | Standard | Repl. | Repl. | Repl. | Standard |
| License | LabView | Matlab/Simulink | Freeware | Yes | Open source | Open source | Open source |
| Events | No | Yes | No | Yes | Java events | Yes (OSEK RTOS) | Yes |
| Multithreading | Yes | Yes | Yes | Yes | Yes | Yes | Yes |
| Bluetooth communication: Brick to PC | Yes | Yes | Yes | Yes | Yes | Yes | n.a. |
| BluetoothBrick to Brick | Yes | Yes | Yes | Yes | Yes | Not yet | n.a. |
| Floating point | No | No | No | Yes | Yes | Yes | Yes |

The URBI language uses an C++ like syntax. It allows to obtain parallel execution of commands, event programming, command tagging, dynamic variables. With the event feature a user can react on sensor inputs or create individual events and emit them ones or periodically.

## IV. Example: NXC – based system for robot DC motor control

The demo LEGO MINDSTORMS NXT robot has been developed for RSIC teaching purposes. The robot uses two drives for movement and one for area scanning with distance and light sensor.

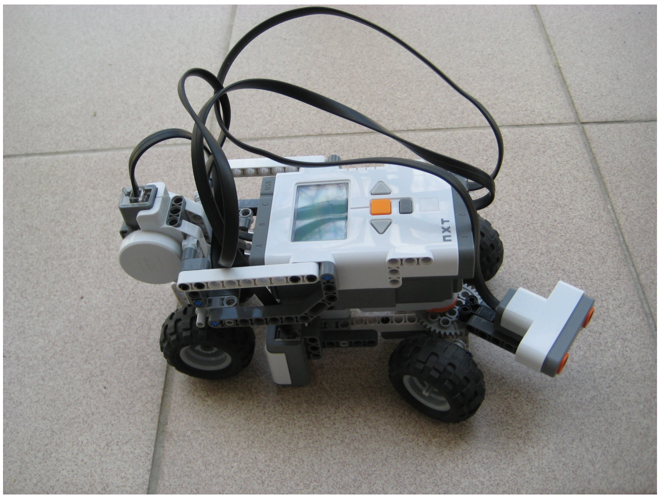

Fig 1. Sinusoid

The problem of target search in the maze was defined as a practical example (“rescue problem”). One can imagine a few algorithms  solving this problem. The basic problem of the proposed robot is  accurate and precise motor control. The error in the motor control can affect the correct navigation and robot movements. From the practical point of view, it is not so important for rescue operation in the maze that the robot moves, but how precise it operates and what is the accuracy of the controlled devices. Thus, the tasks execution details and precision of the robot controller are important.

The aim of this part of the project was to analyze the motor control using two tasks dedicated to motor PID controller and motor encoder measurements. Before the any multitasking operation is started it is required to initialize semaphores, files, read timer values and start simultaneous task execution. The aims of these two tasks were as follows:

- TASK 1 – “Motor control”: to read Tick Counter and Log data to file, start Motor PID control, set semaphore when PID control loop terminates, read Tick Counter and Log data to file,
- TASK 2 - “Encoder Means”: to read Tick Counter and Log data to file, read motor rotations and speed and log them to file, till semaphore is inactive, read Tick Counter and Log data to file (Fig.2).

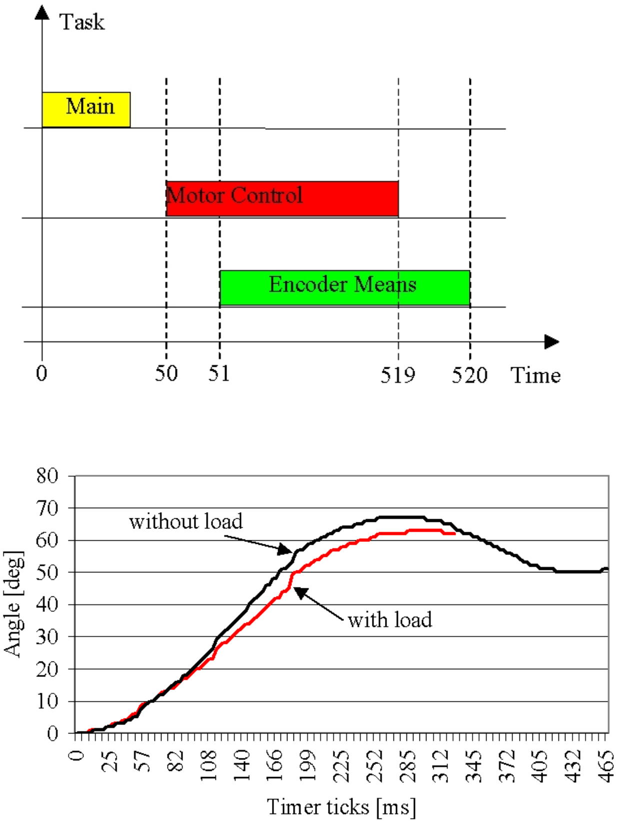

Fig. 2. Motor control in real-time with dual tasks: a) task schedule, b) measured rotor position

The control task was to set the desired angle of the motor axis (45 degrees) using 75% of the total motor power and setting the PID controller parameters. The realized experiments and logged data with a time resolution of 1ms show how the particular tasks are executed. The tasks time diagrams (Fig. 2a) show the execution sequence and confirm the data log time slots. The motor position time diagrams demonstrate the difference in the PID control quality due to the motor load. The steady-state error shows the regulation mismatch and the length of the logged data sequence points the time when the control task has been finished.

The realized testing program written in NXC shows its possibilities for real-time control education. Working with motor control problem students can analyze performance of the built-in, firmware digital PID controller or prepare a custom version of control algorithm. Running two (or more) tasks in the concurrent mode and logging time slots, the scheduling and tasks execution subroutines can be traced. The running tasks can be analyzed in the case of start-up, progress and terminate action.

## V. Conclusions

The idea of open hardware and software solutions for LEGO® MINDSTORMS® NXT offers an unlimited number of application in the field of control education. If focusing of the real-time aspects, the text-based languages are required to demonstrate a full control over the executed code.

Analyzing several solutions it seems that the NXC and nxtOSEK are the best candidates to support real-time control experiments. The simplicity of NXC allows to start immediately with programming, while to start nxtOSEK a number of software replacements is required.

At this moment there are some limitations of Bluetooth communication using nxtOSEK, but hopefully this task will be extended soon. The presented simple example shows that it not so easy to obtain a precise and perfect results of the low level task. One can enjoy with working robot, but the important question facing the students is: does we have a full control providing a repetitive behavior of the robot?

## Acknowledgment

The authors gratefully acknowledge the initial work done by their students K. Balwierz, D. Bieniek J. Blicharski and Ł. Łucek during the first stage of the project.

***Abstract*—A safety shell pattern was defined based on a reconfiguration management pattern, and inspired by the architectural specifications in Specification PEARL. It is meant to be used for real-time applications to be developed with UML-RT as described. The implementation of the safety shell features as defined by in [8], namely its timing and state guards as well as I/O protection and exception handling mechanisms, is explained. The pattern is parameterised by defining the properties of its components as well as by defining the mapping between software and hardware architectures. Initial and alternative execution scenarios as well as the method for switching between them are defined. The goal pursued with the safety shell is to obtain clearly specified operation scenarios with well defined transitions between them. To achieve safe and timely operation, the pattern must provide safety shell mechanisms for an application designed, i.e., enable its predictable deterministic and temporally predictable operation now and in the future.**

## I. Introduction

PREDICTABILITY, dependability and timeliness are major pre-conditions for real-time applications to be safe. Hence, in order to be able to effectively address safety, it should be sustained throughout the entire life-cycle of an application – from design via implementation to upgrades and maintenance. Therefore, it appeared sensible to build a design pattern that would enable designers to address most safety issues and build safe and persistent applications. Kornecky and Zalewski [8] have defined a "safety shell" for real-time applications to be composed of several "guards", each one protecting a certain part of an application. Thus, the input/output needs to be protected from tampering as well as by range checking to sustain the environmental parameters of the application. Then, exception-handling mechanisms should protect the application from malicious consequences of unforeseen situations, by offering mechanisms that bring it back to normal operation. Finally, the operation should be monitored and safeguarded in its state and time spaces in order to prevent the application from leaving its specified execution and temporal frameworks. Since all mechanisms mentioned foresee different scenarios for initialisation, phases of normal operation and of various exception modes, enabling dynamic re-configurations on the application level is crucial to enable these features.

In the development of embedded real-time systems, management of dynamic (re-) configuration has systematically been addressed by hardware/software co-design methods (cp., e.g., [9, 11, 13]). Besides defining diverse (dynamic) operation scenarios, two main goals have been targeted by this approach:

1) achieving fault tolerance by system design (cp. [3, 6]),
2) fast scenario switching (e.g., in industrial automation and telecommunication systems [1, 4, 5, 11]).

## II. Design for Safety

When designing a real-time system, generally three viewpoints must be considered:

1) the external (functional) one, which represents the inputs/outputs and usage scenarios,
2) the internal (behavioural) one, which deals with the definition of usage scenarios, and
3) the definition of system structure – hardware and software architectures together with the mapping of software components onto hardware components and the definition of configurations and re-configuration scenarios.

During re-configuration, application data must remain consistent and real-time constraints must be satisfied. In order to be able to achieve this, these issues must be addressed at multiple levels. At the lowest level, the hardware must be reconfigurable. Software-programmable hardware components support this inherently, since their functions can be changed by their memory contents. Internal hardware structures are designed to restrict dangerous conditions that could damage hardware. At the next higher level, the internal states of the software must be managed under changing tasking. Operating systems support flexible implementations of multiple tasks on single processors in form of time-sharing and/or multitasking. On the top level, one wants to define operation scenarios – configurations – for an application, which enable it to adapt to varying conditions in the environment on one hand, and to respond to changing operational modes by switching between operation scenarios in a safe and predictable manner on the other. Typically, these configurations cannot be managed by operating systems, since groups of processes and possibly also hardware components are involved. Hence, their management is usually placed on the application or middleware level, since it requires the observation of and actions based on the system state. Generally, by this approach, low-level efficiency and hard real-time properties are difficult to achieve. Because of this, we chose to distribute re-configuration management to all three levels – hardware, middleware, and software. With this in

978-83-60810-14-9/08/$25.00 © 2008 IEEE

mind, the hardware/software co-design profile and pattern for real-time application design in UML based on the specification language Specification PEARL (S-PEARL) (cp. [2]) have been developed. While in the profile the constructs of S-PEARL are introduced with their properties, behaviour and interconnections, the configuration management pattern provides the mapping of software to hardware components, and a foundation on which to build custom real-time applications. The latter's approach is followed in extending and parameterising the configuration management pattern with safety features. The pattern and its safety-oriented use are presented throughout this article with the goal to construct a safety shell (cp. [7, 8]) for a designed application.

### A. Configuration Management Pattern

The configuration management pattern was constructed by combining a set of UML-RT [12] stereotypes [10], which represent S-PEARL constructs (see Fig. 1) as a coherent whole. They constitute building blocks at the three levels of architectural modeling: (1) hardware architecture, (2) software architecture, and (3) software-to-hardware mapping. A hardware architecture is composed of processing nodes, termed "stations", whose descriptions also mention their components with their properties. A software architecture is organised in the form of "collections" of "modules", comprising program "tasks", functions and procedures of the application software. The "collection" is the unit of software to be mapped onto "stations", i.e., at any time there is exactly one collection assigned to run on a station. Thus, the "collection" is also the unit of dynamic re-configuration. Each of these constructs has its specific attributes, which pertain to all objects of this type (such as properties, relations, and initialisation). They are layered on three levels of abstraction (see Fig. 2):

1) station level, where a mapping of collection configurations to stations is established;
2) configuration level, where collections grouped into scenarios, named "configurations", are managed by a "reconfiguration manager"; and
3) collection level, where the tasks, which may be grouped into modules (UML packages), are managed by their collections according to their scheduling parameters.

Each collection belongs to a configuration and is mapped to a station. Configuration management is responsible for the co-operation among collections and possible dynamical re-configurations, which depend on the state changes of the station they are residing on. A detailed description of its safety-oriented use is presented in the sequel.

## III. Introducing a Safety Shell

A safety shell is responsible for guarding the main process termed "Primary control" (see Fig. 3) by providing it with additional functionality which keeps the possible sources of error to a minimum. In order to be effective, these functions have to be integrated into or built around an application. In our case, the second variant was chosen by implementing a pattern, which forms the "backbone" of an application, requiring it to be formed in a specific manner in order to function in the safety shell's environment. The configuration management pattern has the structure and functions needed to fulfill the rôle of a safety shell in terms of guarding a system in such a way that it always remains in a foreseen state and time frame of operation. In the sequel, the functions of the four protective mechanisms are described, and it is explained in which manner and to which degree they safeguard an application's execution.

Fig. 1. S-PEARL constructs and their UML (-RT) stereotypes

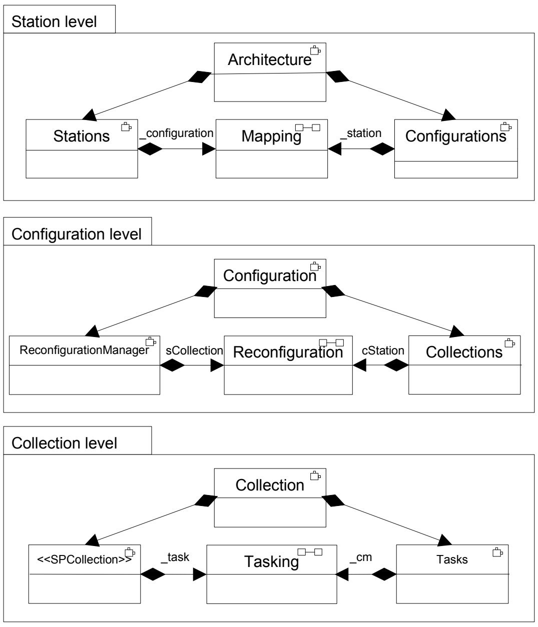

Fig. 2. Levels of configuration management

### A. Protected Input/Output

Protected input/output refers to well defined interfaces with the environment. By well defined we mean stable physical connections and sound protocols with integrated error checking and correction techniques. Usually, the possible problems originate from data overruns or malicious data. By themselves, the device drivers of interfaces can only correct a part of these problems associated with data formats and protocols. They could, however, also detect overruns or out-of-scope data, prevent recurring corruption of data, and signal possible errors. In our implementation of I/O *ports* (see Fig. 4), an important

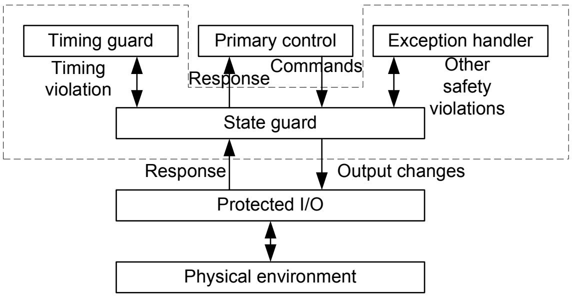

Fig. 3. Safety shell scheme

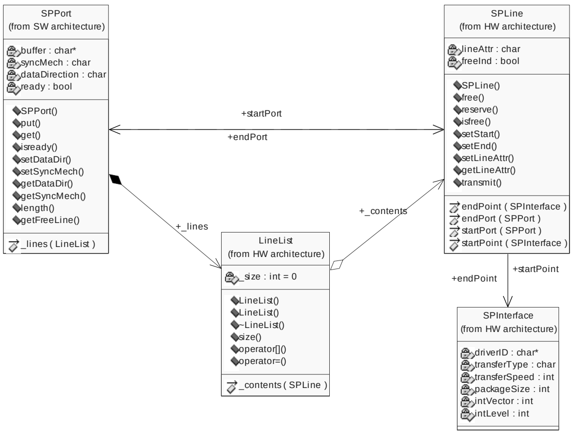

Fig. 4. Safeguarded port-to-port communications

safety-related feature is present, namely, routing parameters. Where stable line connections are of utmost importance, they are usually designed redundantly, being doubled, tripled, or with one of the *lines* representing a slower yet reliable (e.g., wireless) connection. In our routing parameters we can determine the lines which can/must be used, and/or assign a preferred line, being the fastest or most trusted one. If a line is not or becomes unavailable, the protocol automatically searches for the next available line. On the application level, it is important to have uniform interfaces between software components possibly executing at different processing nodes, which is also achieved by "port-to-port" communication. The lower levels are suppressed on the application level, however the parameterisation of the connection lines between ports and device drivers is made transparent by the S-PEARL profile, and enables complete oversight down to the physical level.

### B. State Guard

There should be a predefined scenario for each possible state a system can find itself in ("state guard"). The problem decomposition enables considering loosely coupled interdependent processing nodes, which ensure local predictability, and have well defined global interconnections that form an integral part of each scenario. Due to a possible state explosion during execution, it is impossible to (pre-) determine all global states a system can assume and define scenarios for them. Since scenarios are defined for each station separately (e.g., see Fig. 5), this problem becomes easier to tackle. There exists a limited number of states, only, and as global interconnections are (re-) connected during re-configuration, the global implications are unproblematic. Hence, besides *fault containment*, this makes designing distributed real-time applications easier, and the systems designed more robust. A rigorously designed application structure, in which the execution of a collection of tasks is associated with an exactly pre-determined state, and a simple and well defined station state changing mechanism prevent the transition to an undefined state, herewith implementing the state guard function. The same holds for tasks, where an exactly defined activity structure does not only prevent transitions to an undefined state by exception handling, but also supports safe-guarded execution of temporally sensitive operations (see Fig. 6).

```
// "initial_load_statement"
void init() {
  reconfigure(0); // '0' is the initial state
}

// "reconfiguration_statement"
void reconfigure(char s) {
  if (sreg!=s) { // sreg is the station state register
    switch (sreg) {
      case -1: // initially it is undefined
        break;
      default: // upon state change the current collection is unloaded
        sCollection.unload().sendAt(sreg);
        break;
    }
    switch (s) {
      case -1: // if there is no valid state, nothing is loaded
        break;
      default: // the collection associated with the new state is loaded
        sCollection.load().sendAt(s);
        break;
    }
  }
  sreg=s;
}
```

Fig. 5. Safeguarded state transitions within a station (configuration)

### C. Timing Guard

Timeliness, being a critical property of real-time systems, is of utmost importance for applications and, hence, it is vital that its "backbone" does not introduce any significant delays into execution. Due to this and to ensure observability, the service algorithms of the pattern have been kept simple. They introduce no unbounded delays into scenario switching. This was one of the pre-dispositions while designing them, and is as important for safety as for timeliness of operation. Since some operations such as scheduling, message transmission, or task activation still require some time, however, the operating system overhead shall not introduce any unbounded delays either and, moreover, the service times of operating system calls have to be incorporated into task/operation execution times. Hence, the execution of an underlying real-time operating system has also to be temporally predictable in order to enable timeliness. In our implementation this was accomplished by a small custom real-time operating system (RTOS) kernel, which could be substituted with a fully functional off-the-shelf RTOS, keeping in mind the restriction on bounded and

```
void taskmain()
{
      if (_start_state) {
            aState=choose_start();
            _start_state=false;
            _timeout=false;
      }
      switch (aState) {
            case ith_state: {
                  if (_timeout) {
                        /* timeout action */
                  }
                  else {
                        _timeout=true; /* watchdog start*/
                        maxT.informIn(RTTimespec(timeout,0));
                        /* activity */
                        aState= ith_next();
                        maxT.cancelTimer();
                        _timeout=false; /* watchdog end*/
                  }
                  break;
            }
            case end_state: {
                  /* activity*/
                  _start_state=true;
                  _timeout=false;
                  break;
            }
            otherwise:
                  break;
      }
}
```

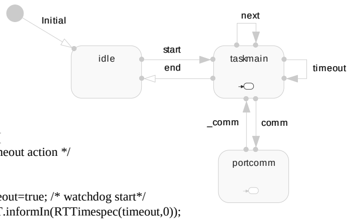

Fig. 6. Temporally safeguarded execution of task activities

predictable system call service times. Temporal monitoring of atomic activities such as executions of task operations is possible by introducing timers into them and, in this sense, prohibit any unreasonably long executions of atomic activities (e.g., by using a watchdog mechanism – "time guard" – see Fig. 6). Here it is also possible (for any activity – task state) to define a time-out action, which is executed in response to a possible time-out condition.

### D. Exception Handler

Since tasks can be re-scheduled at pre-emption points, only, and tasking operations are defined for active tasks, it is sensible to limit their duration. In case of violating an execution time frame, a pre-defined scenario could be activated representing, for instance, *graceful degradation*. To further support *fault-tolerant* operation, however, it would be desirable to additionally check the correctness of other vital operation parameters, too, and by doing so implementing other features of the – "exception handler" – as well. This may introduce additional overhead, but as long as the execution times remain predictable and in the foreseen time frames, this is not a problem. Exception handling is, in part, already present in the safeguarded I/O operations. As already mentioned, the port-to-port communication protocol also enables line replication, thus allowing for "no single point of failure" planning. Range and other error checking mechanisms could be implemented to ensure *fail-safe* operation using well known mechanisms in the same manner as we implemented the time-out handling by introducing, e.g., pre-/post-condition checking of the (critical) tasks' activities. To support *reversion modes*, several collections with the same functionality may be defined within the same configuration to be activated depending on the different operational modes. The "context" of a configuration could be maintained as a list of "collection contexts" or – as in our case – in the form of procedures to (re-) establish collections. They can be (re-) established while (re-) loading and (re-) connecting their ports when desired/needed. The choice to (re-) start or continue a collection execution depends on the nature of the application and is, hence, left to the designer. Although typically one would continue from a state-switching condition, it is not always desirable or even dangerous to do so. In most cases, a collection is only re-loaded if its initial pre-conditions and environment state have been re-established. The "collection context" itself consists of its task control block (TCB) table as well as the lists of currently active tasks and ports. All of these would need to be re-established when re-loading a collection for execution continuation.

## IV. Conclusion

With the help of the safety shell features of the S-PEARL configuration management pattern presented, distributed real-time application programs designed with UML-RT can run with safe, predictable behaviour and re-configuration support. Besides the structure of the applications, the configuration management pattern also defines uniform interfaces and protocols for intra- and inter-component/-node communication using pre-defined port/interface definitions. In (hard) real-time systems, it shall provide the necessary support for deterministic and dependable dynamic system re-configuration. The safety shell features are enabled by the pattern, but the selection and usage of the mentioned mechanisms remain the responsibility of a real-time application's designer, since no two safety critical real-time applications are equal.

*Abstract* — **This paper addresses the problem of educating software engineering professionals who can efficiently and effectively develop real-time software intensive control systems in the global community. A framework for developing curricula that support such education is presented. The curriculum framework is based on the work of two education projects: the ILERT (International Learning Environment for Real-Time Software Intensive Control System) project, and the software engineering efforts of the ACM/IEEE-CS Joint Task Force on Computing Curricula. The authors describe a curriculum framework that integrates principles, content, and organization from the two projects, and which satisfies the intent and requirement of both projects.**

## I. Introduction

THE development of software for real-time, embedded, safety-critical systems (such as for controlling and supporting systems in aviation and space, medicine and health, and atomic energy) is a complex and challenging problem. The health, safety, welfare, and productivity of the public and the world economy increasingly depend on software-intensive systems – the dependability of these systems is paramount. Unfortunately, software developers do not consistently provide safe, secure, and reliable systems; such systems are often of poor quality, and cost and schedule overruns are common. There has been significant improvement in software development methods and practices in the last twenty years. The application of software engineering best practices to such development has proven the value of such practices [1]-[3]. In order to enhance such capabilities for software engineering professionals there have been numerous calls to improve software engineering education, especially in the area of real-time embedded systems [4]-[6].

The last twenty years have also witnessed significant advancements in the state of computer science education (and in allied fields such as computer engineering, information systems, and software engineering). The Association for Computing Machinery (ACM), the IEEE Computer Society (IEEE-CS), and CSAB (which determines criteria for accreditation of programs in computer science and software engineering) have provided encouragement, support, and guidance in developing quality curricula that are viable and dynamic. Degree programs have moved from language- and coding-centered curricula to those that emphasize theory, abstraction, and design. To address the problems in software development the ACM/IEEE-CS Joint Task Force on Computing Curricula has produced guidelines for curricula in computer engineering, computer science, information systems, information technology, and software engineering. The software engineering guidelines, SE2004 ( *Software Engineering 2004, Curriculum Guidelines for Undergraduate Degree Programs in Software Engineering* ) [7], provide information and guidance on various curriculum issues: objectives, content, organization, courses, and pedagogy.

More recently the ILERT (International Learning Environment for Real-Time Software Intensive Control System) project [8] has been involved in the creation of an international curriculum framework centered on RSIC (Real-Time Software-Intensive Control) systems. The ILERT study explores a mechanism for involving students from multilingual, geographically separated institutions in a coordinated educational experience. The ultimate objective is the creation of a RSIC curriculum model, which can be used by engineering schools both in the USA and the EU.

The purpose of this paper is to discuss how the work of the ILERT project might be used to develop an SE2004 software engineering curriculum which satisfies the RSIC framework. In the following sections we provide additional detail about ILERT, the SE2004 guide, and the RSIC curriculum framework. Then, this material is integrated to outline a curriculum which satisfies both the SE2004 and the RSIC frameworks.

## II. The Ilert Project

The analysis, design, implementation, administration, and assessment of international curricula will become increasingly important in the global community of the 21st century. In support of this critical issue, the European Commission and the US Department of Education have funded the ATLANTIS initiative to promote collaboration in higher education between European and American universities. One American (Embry-Riddle Aeronautical University, Daytona Beach, FL) and three European Universities (AGH Univer-

978-83-60810-14-9/08/$25.00 © 2008 IEEE

sity of Science and Technology, Krakow, Poland; Brno University of Technology, Czech Republic; and The University of Grenoble, France) are currently working on the framework of a new common curriculum in real time-software systems. This two-year project "Toward International Learning Environment for Real-Time Software Intensive Control Systems" (EC grant: 2006-4563/006 001, US grant: P116J060005, http://www.ilert.agh.edu.pl) was launched in January 2007. Project work is concerned with program objectives and outcomes, curriculum content and pedagogy, program administration (academic credit, course schedules, exchange of students and staff, etc.), and program assessment and accreditation. Thus far, the project has produced the following deliverables:

- An analysis of industry requirements for graduates in the RSIC domain
- An identification of the RSIC learning objectives and student outcomes
- An analysis of European Credit Transfer System (ECTS) and the mechanism of credit transfer at U.S. Colleges and Universities
- An identification of activities and data for program assessment and evaluation, and those issues and elements required to consider program accreditation
- A description of an international, interdisciplinary RSIC curriculum framework
- A preliminary design for a selected unit supporting the proposed RSIC curriculum.

For the analysis of industry requirements, a survey of USA and European industry engaged in real-time software-intensive control systems was conducted [9]. The survey consisted of two parts: General Skills and Attitudes (10 items), and Technical Knowledge Areas (15 items). For example, one of the Technical Items was "Knowledge of software design and development concepts, methods and tools". Respondents were ask to select "Essential, Important, Unrelated, or Unimportant", with a possibility to provide comment.

Survey results from 43 companies were analyzed and summarized. In the General Skills part, the highest rated skills as follows:

- Work as a part of a multidisciplinary team
- Analyze, understand and define the problem

For the Technical Knowledge part, the following were rated the highest:

- Software design and development concepts, methods and tools
- System specification and design methods

Project work continues on experimental concurrent delivery of the designed RSIC unit at the four partner sites. Finally, the project will provide reflection on a process and methodology for creation of multidisciplinary, transatlantic engineering programs, including guidelines for extension of the approach to other engineering disciplines.

## III. The RSIC Curriculum Framework

This section provides information on the organization and content of the RSIC curriculum framework. The framework is a high-level curriculum specification that is detailed enough to guide the development of a RSIC program, which supports the RSIC objectives and outcomes, and yet is flexible enough to account for specializations, constraints, and requirements of various programs, institutions, and regions.

Table I.
RSIC Components

| **Software Engineering (SoftEng-)** |
|---|
| Software engineering concepts and practices, software lifecycle models, project management, software processes, software construction methods and practices, software modeling and formal representation; software requirements; software architectural and module design; testing and quality assurance; software maintenance; and notations and tools. |
| **Digital Systems (DigSys-)** |
| Digital system concepts/operation, design of combinatorial/sequential circuits, concepts and operation of microcontrollers/microprocessors, assembly language, rudimentary interfacing and exception handling, large scale integration devices and tools, interfacing, advanced memory management, fault tolerant hardware. |
| **Computer Control (CompCtrl)** |
| Concepts of feedback control, time and frequency domains, continuous and discrete models of dynamical systems, state analysis, stability, controllability and observability, controller design, implementing control algorithms in real-time, integrated control design and implementation use of analysis and design tools. |
| **Real-Time Systems (RTSys)** |
| Timing and dependability properties of software intensive systems, RTOS concepts and applications, concurrency, synchronization and communication, scheduling, reliability and safety, etc. |
| **Networking (Network)** |
| Data communication, network topology, analysis and design, information security, algorithms, encryption, bus architectures, wireless, etc. distributed control and monitoring |
| **System Engineering (SysEng)** |
| System engineering concepts, principles, and practices; system engineering processes (technical and management); system requirements, system design, system integration, and system testing; special emphasis on the development of a RSIC system and the integration of RSIC system elements. |

The basic organizational unit for the framework is a RSIC "component". A RSIC component is a curriculum unit which covers theory, knowledge and practice which supports the RSIC curriculum objective and outcomes. Table I describes the RSIC components in six identified RSIC areas: Software Engineering, Digital Systems, Computer Control, Real-Time Systems, Networking, and Systems Engineering.

The RSIC Curriculum Framework does not specify the way in which component topics might be formed into modules or courses. Component topics might be focused in one or two courses, or spread among several courses, along with other non-RSIC topics. Depending on the course rigor and the required prerequisite knowledge, the material can be at either a basic or an advanced level. The curriculum framework includes more detailed specifications of each component: prerequisite knowledge, component learning objectives, information about required facilities and equipment, and guidelines and suggestions for course design and delivery. Table II is an example of one such component specification. The full details of each competent specification will be included in the final ILLERT project report.

The RSIC curriculum framework also makes recommendations about non-RSIC courses or units that should be part of a RSIC program, as prerequisite courses or to supplement the components as part of a full degree program. The recommendations call for courses in the following areas:

- Mathematics (Differential and Integral Calculus, Differential Equations, Discrete Mathematics, Statistics, Linear Algebra)
- Physics (mechanics, E&M, thermo, fluids)
- Electrical Engineering (circuit analysis, basic electronics)

Table II.
Software Engineering

| | |
|---|---|
| **Description** | Software engineering concepts and practices, software lifecycle models, project management, software processes, software construction methods and practices. |
| **Prerequisite Knowledge** | Ability to design, implement and test small programs (100 lines of code), written in a commonly used high-level programming language. |
| **Learning Outcomes** | Upon completion of this component, students should be able to<br>• Describe the major problems in the development of a large, complex software system.<br>• Describe and discuss issues, principles, methods and technology associated with software engineering theory and practices (e.g., planning, requirements analysis, design, coding, testing, quality assurance, risk assessment, and configuration management).<br>• Working as part of a team, use a defined software development process to develop a high-quality modest sized software product (1000 lines of code).<br>• Describe issues, principles, methods and technology associated with the use of formal modeling in software engineering.<br>• Describe, discuss, and apply the commonly accepted principles of software quality assurance (reviews, inspections and testing).<br>• Apply requirements engineering principles of elicitation, analysis, and modeling to the development of a requirements specification.<br>• Describe and analyze different software architectures views and styles.<br>• Describe and discuss the structured and object-oriented design methodologies.<br>• Describe and discuss the principles, methods and practices of software evolution.<br>• Show capability with various software engineering tools used for formal software modeling, requirements engineering and software design. |
| **Facilities and Equipment** | No special equipment or laboratory is required for this component.<br>Students will need access to a computer system equipped with a program development environment (such as Eclipse).<br>There may be a need for process, management and formal modeling tools; but, typically word processors, spreadsheets and simple scheduling tools should be sufficient. |
| **Guidelines and Suggestions** | The emphasis in this component is for students to know and understand how large complex systems should be developed, not, at this point, to be able to develop such systems. For instance, they should understand and be able to describe and discuss the activities and practices that take place in each software development life-cycle phase; they should understand the importance of requirements and the problems that ensue if requirements are not properly elicited and specified; they should understand the various elements of project management; they should come to realize that testing is not the only way to ensure quality; they should come to see software development as an engineering discipline; and they should understand the importance of discipline and process to the development of software.<br>Case studies are particularly helpful in teaching software engineering principles – when students study examples of actual requirements, design, test and planning documents, they better understanding the nature of software engineering and what it takes to develop high-quality software products. There are many introductory software engineering textbooks that contain such examples (Pressman, Somerville, Lethbridge, Pfleeger)<br>This component should include a software team project. It is extremely important that the software product developed be modest in scope and functionality. The purpose of the project is for students to learn about working as part of the team, to experience the software-life cycle, to see how to assure quality, to use planning and process procedures, to document the team's work, and to appreciate the difficulty of developing a high-quality software product. The emphasis should be on teamwork, quality and process.<br>This component is intended to provide more in-depth coverage of software engineering topics than the Basic Level component. However, the coverage still must be at a level that can be covered in one or two courses. It is not intended that there would be an in-depth study of each of the separate areas of formal modeling, requirements, architecture and design, and quality and testing. Such in-depth coverage would require three or four course of study.<br>A development project could involve the creation of a requirements and architecture specification for a software system with more complexity than the Basic level team project.<br>This component would benefit from the use of case study documents (requirements, architecture, module design, code, test plans, project plans, etc.) for a reasonably complex system. Analysis and maintenance problems focused on the case study documents would be helpful in achieving the component learning outcomes. |

- Introduction to Computer Science with Programming

## IV. THE SE 2004 CURRICULUM FRAMEWORK

The software engineering guidelines document, SE2004 [7], provides a comprehensive and detailed set of material to support the development of an undergraduate curriculum in software engineering. Specifically it includes chapters on the following:

- The Software Engineering Discipline
- Guiding Principles
- Overview of Software Engineering Education Knowledge (SEEK)
- Guidelines for SE Curriculum Design and Delivery
- Courses and Course Sequences
- Adaptation to Alternative Environments
- Program Implementation and Assessment

The SEEK describes the body of knowledge that is appropriate for an undergraduate program in software engineering. It designates “core” material which SE2004 recommends is necessary for anyone to obtain an undergraduate degree in the field. It designates Bloom’s levels for the knowledge units [10] and makes a time allocation of “contact” hours. Table III lists the knowledge areas that make up the SEEK and indicates the minimum total time recommended for each area. The SE2004 contains a more detailed description of the content and organization of each area.

In addition to the core materials, undergraduates are encouraged to specialize in some area related to software engineering application. The following specialties are presented in the SE 2004 volume:

a) Network-centric systems
b) Information systems and data processing
c) Financial and e-commerce systems
d) Scientific systems
e) Telecommunications systems
f) Fault tolerant and survivable systems
g) Highly secure systems
h) Safety critical systems
i) Embedded and real-time systems
j) Biomedical systems
k) Avionics and vehicular systems
l) Industrial process control systems

TABLE IV.
SE2004 CORE COURSES

| Number | Title |
|---|---|
| SE101 | Software Engineering and Computing I |
| SE102 | Software Engineering and Computing II |
| SE103 | Software Engineering and Computing III |
| SE211 | Software Construction |
| SE212 | Software Engineering Approach to Human Computer Interaction |
| SE311 | Software Design and Architecture |
| SE321 | Software Quality Assurance and Testing |
| SE322 | Software Requirements Analysis |
| SE323 | Software Project Management |
| SE400 | Software Engineering Capstone Project |

Of these, several certainly correlate strongly with the RCIS components. This provides the motivation and rationale for proposing a framework for an SE 2004 RSIC curriculum.SE2004 also includes a set of courses and their descriptions which, when grouped together, provide for a set of courses which cover the SEEK core knowledge. Table IV describes one such set of courses.

Courses SE101, SE102 and SE103 provide an overview of software engineering with topics typically included in introductory courses in computer science, low level design, and programming. Each course, except for SE400, was envisioned to be offered over approximately 14 weeks, with 3 contact hours per week. SE400 covers a full academic year of work. Other schedules and timelines are possible. SE2004 provides detailed descriptions of each course.

In addition, SE2004 contains several models (or patterns) of how the courses could be arranged into a full three or four year curriculum. The models include three-year and four-year patterns, with versions for North America, Europe, Japan, Australia, and Israel, Table V depicts a four year “North American” curriculum pattern. In addition to the SE core courses in Table V (shaded gray), the SE2004 also contains course descriptions for supporting courses such as Discrete Math I and II, Data Structures and Algorithms, Database Systems, Computer Architecture, Operating Systems and Networking, etc.

## V. A COMBINED SE 2004-RSIC CURRICULUM

In this section we present a curriculum that incorporates the RSIC requirements within the SE2004 requirements. Table VI outlines a four year RSIC-SE2004 curriculum. It represents a modification of Table V: all of the software engineering core courses were retained; and technical electives and science electives items were replaced with courses which

TABLE V
SE2004 NORTH AMERICAN CURRICULUM PATTERN

| Year 1 | | Year 2 | | Year 3 | | Year 4 | |
|---|---|---|---|---|---|---|---|
| **Sem 1A** | **Sem 1B** | **Sem 2A** | **Sem 2B** | **Sem 3A** | **Sem 3B** | **Sem 4A** | **Sem 4B** |
| SE101 | SE102 | SE 200 | SE 211 | SE 212 | SE 311 | SE400 | SE400 |
| Dis Math I | Dis Math II | Data Str & Alg | Database | SE 321 | SE 322 | SE 323 | Tech Elect |
| Calc 1 | Calc 2 | Physics 1 | Physics 2 | Comp Arch | Prof SE Practice | OS & Network | Tech Elect |
| Gen Ed | Gen Ed | Gen Ed | Statistics | Sci Elect | Tech Elect | Eng Econ | Open Elect |
| Gen Ed | Gen Ed | Gen Ed | Sci Elect | Sci Elect | Gen Ed | Gen Ed | Open Elect |

cover the RSIC curriculum components.

The courses in bold type in Table VI represent courses that directly address the requirements of the RSIC components: for example, **DigSys-1** and **DigSys-2** would cover the Digital Systems Component. Notice that **SoftEng** is designated in several courses. This was necessary in order to cover all the RSIC SE advanced topics. Due to the nature of this specific SE program, such topics would be covered in more depth than strictly required by the RSIC Framework. In addition, a number of course were added in order to support prerequisite requirements for RSIC courses: differential equations, electrical engineering and linear algebra.

The course “Prof **RSIC** Practice” is a replacement for the course NT291 (Professional Software Engineering Practice - knowledge, skills, and attitudes that software engineers must possess to practice software engineering in a professional, responsible, and ethical manner.). The RSIC course would contain much of the material from NT291; however, it would also furnish students with material and activities that support two of the non-technical RSIC curriculum outcomes:

- An ability to work effectively in an international environment
- An understanding of the impact of engineering solutions in a global and societal context

One other important item in Table VI is that **SysEng** was designated as part of the SE400. SE400 is a capstone project course and it is envisioned that the project will be a real-time software intensive control system. It relies on and will bring together the knowledge and practices learned by students in the other RSIC courses. Although students will have been introduced to some system concepts in other courses, SE400 is the ideal place to focus on system issues: requirements require system level decisions about allocation and specification; the system architecture will involve software and hardware subsystems and components; systems quality assurance measures will have to be instituted; and the procedures and activities’ involved in system integration will be critical.

Although Table VI provides an outline of a RSIC-SE400 curriculum, much more analysis and detail is needed to support implementation of such a curriculum. However, it is the hope of the authors that this paper, along with the other work of the ILERT project, will motivate and support faculty who wish to create and implement educational programs which will improve the development of RSIC systems.

## VI.CONCLUSION

Creation of RSIC systems engages a large variety of engineering disciplines. Due to worldwide implementation of such systems, a well prepared workforce of scientists and engineers is required. They must be able to work cooperatively in multi-disciplinary and international settings. The software intensive nature of RSIC systems require engineers who understand and can use the software engineering knowledge and practices required to build such systems. The authors feel that the RSIC-SE2004 the potential to have broad impact on the future of engineering education and on the efficient and effective development of RSIC systems.

In addition, the process and format of the RSIC-SE2004

TABLE VI

***Abstract*—The explosion of capabilities and new products within the sphere of Information Technology (IT) has fostered widespread, overly optimistic opinions regarding the industry, based on common but unjustified assumptions of quality and correctness of software. These assumptions are encouraged by software producers and vendors, who at this late date have not succeeded in finding a way to overcome the lack of an automated, mathematically sound way to develop correct systems from requirements. NASA faces this dilemma as it envisages advanced mission concepts that involve large swarms of small spacecraft that will engage cooperatively to achieve science goals. Such missions entail levels of complexity that beg for new methods for system development far beyond today’s methods, which are inadequate for ensuring correct behavior of large numbers of interacting intelligent mission elements. New system development techniques recently devised through NASA-led research will offer some innovative approaches to achieving correctness in complex system development, including autonomous swarm missions that exhibit emergent behavior, as well as general software products created by the computing industry.**

## I. Introduction

SOFTWARE has become pervasive. We encounter it in our everyday lives: the average electric razor contains the equivalent of more than 100,000 lines of code, several high-end cars contain more software than the onboard systems of the Space Shuttle. We are reliant on software for our transportation and entertainment, to wash our clothes and cook our meals, and to keep us in touch with the outside world via the Internet and our mobile phones.

The Information Technology industry, driven by software development, has made remarkable advances. In just over half a century, it has developed into a trillion-dollar-per-year industry, continually breaking its own records [17], [27].

Some breathtaking statistics have been reported for the hardware and software industries [16], [46]:

- The Price-to-Performance ratio halves every 18 months, with a 100-fold increase in performance every decade.
- Performance progress in the next 18 months will equal *all* progress made to date.
- New storage available equals the sum of all previously available storage *ever*.
- New processing capability equals the sum of all previous processing power.

Simultaneously, a number of flawed assumptions have arisen regarding the way we build both software and hardware systems [38], [46], which include:

- Human beings can achieve perfection; they can avoid making mistakes during installation, maintenance and upgrades.
- Software will eventually be bug-free; the focus of companies has been to hire better programmers, and the focus of universities is to better train software engineers in development lifecycle models.
- Mean-time between failure (MTBF) is already very large (approximately 100 years) and will continue to increase.
- Maintenance costs are a function of the purchase price

of hardware; and, as such, decreasing hardware costs (price/performance) results in decreases in maintenance costs.

## II. Software Problems

With the situation stated this way, many flawed assumptions regarding the IT industry come into view. The situation is even worse if we focus primarily on software. The Computing industry has failed to avoid software-related catastrophes. Notable examples include:

- Therac-25, where cancer patients were given lethal doses of radiation during radiation therapy [33].
- Ariane 5, where it was assumed that the same launch software used in the prior version (Ariane 4) could be reused. The result was the loss of the rocket within seconds of launch [34].
- The Mars Polar Lander, where failure to initialize a variable resulted in the craft crash landing on the Martian surface, instead of reverse thrusting and landing softly [29].

Progress in software regularly lags behind hardware. In the last decade, for example, two highly software-intensive applications, namely Internet communications and mobile phone technology, have suffered reduced availability and increased *down time*, while their hardware counterparts, computer hardware and telephony systems, have continued to improve. Figure 1 illustrates this trend [17].

### A. An Historic Problem

The realization that software development has lagged greatly behind hardware is hardly a new one [6], nor is the realization that our software development processes have some severe deficiencies.

Brooks, in a widely quoted and much-referenced article [7], warns of complacency in software development. He stresses that, unlike hardware development, we cannot expect to achieve great advances in productivity in software development unless we concentrate on more appropriate development methods. He highlights how software systems can suddenly turn from being well-behaved to behaving erratically and uncontrollably, with unanticipated delays and increased costs. Brooks sees software systems as “werewolves” and rightly points out that there is no single technique, no Silver Bullet, capable of slaying such monsters [6].

On the contrary, more and more complex systems are run on highly distributed, heterogeneous networks, subject to strict performance, fault tolerance, and security constraints, all of which may conflict. Many engineering disciplines must contribute to the development of complex systems in an attempt to satisfy all of these requirements. No single technique is adequate to address all issues of complex system development; rather, different techniques must be applied at different stages of development (and throughout the development process) to ensure unambiguous requirements statements, precise specifications that are amenable to analysis and evaluation, implementations that satisfy the requirements and various (often conflicting) goals, re-use, re-engineering and reverse engineering of legacy code, appropriate integration with existing systems, ease-of-use, predictability, dependability, maintainability, fault tolerance, etc. [6].

Brooks [7] differentiates between the *essence* (that is, problems that are necessarily inherent in the nature of software) and *accidents* (that is, problems that are secondary and caused by current development environments and techniques). He points out the great need for appropriate means of coming to grips with the conceptual difficulties of software development—that is, for appropriate emphasis on specification and design, rather than on coding and testing.

In his article [7], he highlights some successes that have been achieved in gaining improvements in productivity, but points out that these address problems in the current development process, rather than the problems inherent in software itself. In this category, he includes: the advent of high-level programming languages, time-sharing, and unified programming environments. Object-oriented programming, techniques from artificial intelligence, expert systems, automatic programming, program verification, and the advent of workstations, he sees as non-bullets, as they will not help in slaying the werewolf.

He sees software reuse, rapid prototyping, incremental development, and the employment of top-class designers as potential starting points for the Silver Bullet, but warns that none in itself is sufficient.

Brooks’ article has been very influential, and remains one of the classics of software engineering. His viewpoint has been criticized, however, as being overly pessimistic and for failing to acknowledge some promising developments [6].

Harel, in an equally influential paper, written as a rebuttal to Brooks [19], points to developments in Computer-Aided Software Engineering (CASE) and visual formalisms [18] as potential *bullets*. Harel’s view is far more optimistic. He writes five years after Brooks, and has seen the developments in that period. The last forty years of system development have been equally difficult, according to Harel, and, using a conceptual vanilla framework, the development community has devised means of overcoming many difficulties. As we address more complex systems, Harel argues that we must devise similar frameworks that are applicable to the classes of system we are developing.

Harel, along with many others, including the authors of this paper, believes that appropriate techniques for modeling must have a rigorous mathematical semantics, and appropriate means for representing constructs. This differs greatly from Brooks, who sees representational issues as mainly *accidental*.

## III. New Challenges for Software Engineering

Clearly there have been significant advances in software engineering tools, techniques, and methods, since the time of Brooks' and Harel's papers. In many cases, however, the advantages of these developments have been mitigated by corresponding increases in demand for greater, more complex functionality, stricter constraints on performance and reaction times, and attempts to increase productivity and reduce costs, while simultaneously pushing systems requirements to their limits. NASA, for example, continues to build more and more complex systems, with impressive functionality, and increasingly autonomous behavior. In the main, this is essential. NASA missions are pursuing scientific discovery in ways that require autonomous systems. While manned exploration missions are clearly in NASA's future (such as the Exploration Initiative's plans to return to the moon and put Man on Mars), several current and future NASA missions, for reasons that we will explain below, necessitate autonomous behavior by unmanned spacecraft.

We will describe some of the challenges for software engineering emerging from new classes of complex systems being developed by NASA and others. We will discuss these in Section III-A with reference to a NASA concept mission that is exemplary of many of these new systems. Then, in Section IV we will present some techniques that we are addressing, which may lead towards a Silver Bullet.

### A. *Challenges of Future NASA Missions*

Future NASA missions will exploit new paradigms for space exploration, heavily focused on the (still) emerging technologies of autonomous and autonomic systems. Traditional missions, reliant on one large spacecraft, are being superceded or complemented by missions that involve several smaller spacecraft operating in collaboration, analogous to swarms in nature. This offers several advantages: the ability to send spacecraft to explore regions of space where traditional craft simply would be impractical, increased spatial distribution of observations, greater redundancy, and, consequently, greater protection of assets, and reduced costs and risk, to name but a few. Planned missions entail the use of several unmanned autonomous vehicles (UAVs) flying approximately one meter above the surface of Mars, covering as much of the surface of Mars in seconds as the now famous Mars rovers did in their entire time on the planet; the use of armies of tetrahedral walkers to explore the Mars and Lunar surface; constellations of satellites flying in formation; and the use of miniaturized pico-class spacecraft to explore the asteroid belt.

These new approaches to exploration missions simultaneously pose many challenges. The missions will be unmanned and necessarily highly autonomous. They will also exhibit all of the classic properties of autonomic systems, being self-protecting, self-healing, self-configuring, and self-optimizing. Many of these missions will be sent to parts of the solar system where manned missions are simply not possible, and to where the round-trip delay for communications to spacecraft exceeds 40 minutes, meaning that the decisions on responses to problems and undesirable situations must be made *in situ* rather than from ground control on Earth.

Verification and Validation (V&V) for complex systems still poses a largely unmet challenge in the field of Computing, yet the challenge is magnified with increasing degrees of system autonomy. It is an even greater open question as to the extent to which V&V is feasible when the system possesses the ability to adapt and learn, particularly in environments that are dynamic and not specially constrained. Reliance on testing as the primary approach to V&V becomes untenable as systems move towards higher levels of complexity, autonomy, and adaptability in such environments. Swarm missions will fall into this category, and an early concern in the design and development of swarms will be the problem of predicting, or at least bounding, and controlling emergent behavior.

The result is that formal specification techniques and formal verification will play vital roles in the future development of NASA space exploration missions. The role of formal methods will be in the specification and analysis of forthcoming missions, enabling software assurance and proof of correctness of the behavior of these systems, whether or not this behavior is emergent (as a result of composing a number of interacting entities, producing behavior that was not foreseen). Formally derived models may also be used as the basis for automating the generation of much of the code for the mission. To address the challenge in verifying the above missions, a NASA project, Formal Approaches to Swarm Technology (FAST), is investigating the requirements of appropriate formal methods for use in such missions, and is beginning to apply these techniques to specifying and verifying parts of a future NASA swarm-based mission.

### B. *ANTS: A NASA Concept Mission*

The Autonomous Nano-Technology Swarm (ANTS) mission will involve the launch of a swarm of autonomous pico-class (approximately 1kg) spacecraft that will explore the asteroid belt for asteroids with certain characteristics. Figure 2 gives an overview of the ANTS mission [47]. In this mission, a transport ship, launched from Earth, will travel to a point in space where gravitational forces on small objects (such as pico-class spacecraft) are all but negligible. Objects that remain near such a point (termed a Lagrangian point) are in a stable orbit about the Sun and will have a fixed geometrical relationship to the Sun-Earth system. From the transport ship positioned at such a point, 1000 spacecraft that have been assembled en route from Earth will be launched into the asteroid belt.

Because of their small size, each ANTS spacecraft will carry just one specialized instrument for collecting a specific type of data from asteroids in the belt. As a result, spacecraft

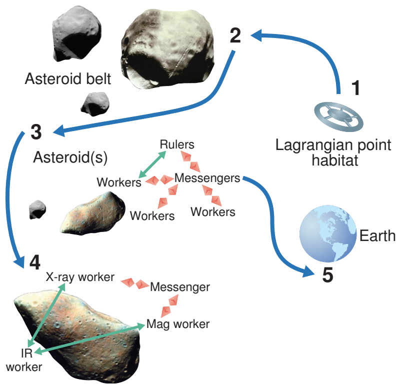

Fig. 2. NASA's Autonomous Nano Technology Swarm (ANTS) mission scenario.

must cooperate and coordinate using a hierarchical social behavior analogous to colonies or swarms of insects, with some spacecraft directing others. To implement this mission, a heuristic approach is being considered that provides for a social structure to the swarm based on the above hierarchy. Artificial intelligence technologies such as genetic algorithms, neural nets, fuzzy logic and on-board planners are being investigated to assist the mission to maintain a high level of autonomy. Crucial to the mission will be the ability to modify its operations autonomously to reflect the changing nature of the mission and the distance and low-bandwidth communications back to Earth.

Approximately 80 percent of the spacecraft will be workers that will carry the specialized instruments (e.g., a magnetometer, x-ray, gamma-ray, visible/IR, neutral mass spectrometer) and will obtain specific types of data. Some will be coordinators (called rulers) that have rules that decide the types of asteroids and data the mission is interested in, and that will coordinate the efforts of the workers. The third type of spacecraft are messengers that will coordinate communication between the rulers and workers, and communications with the Earth ground station, including requests for replacement spacecraft with specialized instruments as these are required. The swarm will form sub-swarms under the direction of a ruler, which contains models of the types of science that it wants to perform. The ruler will coordinate workers each of which uses its individual instrument to collect data on specific asteroids and feed this information back to the ruler who will determine which asteroids are worth examining further. If the data matches the profile of a type of asteroid that is of interest, an imaging spacecraft will be sent to the asteroid to ascertain the exact location and to create a rough model to be used by other spacecraft for maneuvering around the asteroid. Other teams of spacecraft will then coordinate to finish the mapping of the asteroid to form a complete model.

### C. Problematic Issues

*1) Size and Complexity:* While the use of a swarm of miniature spacecraft is essential for the success of ANTS, it simultaneously poses several problems in terms of adding significantly to the complexity of the mission.

The mission will launch 1000 pico-class spacecraft, many of which possibly will be destroyed by collisions with asteroids, since the craft, having no means of maneuvering other than solar sails, will be very limited in their collision-avoidance capabilities. The several hundred surviving spacecraft must be organized into effective groups that will collect science data and make decisions as to which asteroids warrant further investigation. These surviving spacecraft effectively form a wireless sensor network [23] tens of millions of miles from Earth. The overhead for communications is clearly significant.

To keep the spacecraft small, each craft only carries a single instrument. That is why several craft must coordinate to investigate particular asteroids and collect different types of science data. Again, while miniaturization is important, the use of such a scheme has a major drawback: we have no *a priori* knowledge as to which instruments will be lost during normal operations (where we expect to regularly lose craft due to collisions).

The need to identify lost capabilities and instruments, and then replace them, presents an extremely complex problem. In the case of lost messengers and rulers, other craft may be *promoted* to replace them. It is merely the software that differentiates messengers and rulers from other workers, so mobile code serves to overcome this problem. When an instrument is lost, however, we have a rather different problem. A worker with a damaged instrument can be reserved for use as a ruler, and another spacecraft with an identical instrument can replace it.

An alternative would be add more features (instruments) into each spacecraft, but this would increase both their size (a problem in such a constrained environment) and their power requirements. The addition of features, of course, also increases complexity, as identified by Lawson [32].

*2) Emergent Behavior:* In swarm-based systems, interacting agents (often homogeneous or near homogeneous agents) are developed to take advantage of their emergent behavior. Each of the agents is given certain parameters that it tries to maximize. Bonabeau et al. [4], who studied self-organization in social insects, state that "complex collective behaviors may emerge from interactions among individuals that exhibit simple behaviors" and describe emergent behavior as "a set of dynamical mechanisms whereby structures appear at the global level of a system from interactions among its lower-level components."

Intelligent swarms [3] use swarms of simple intelligent agents. Swarms have no central controller: they are self-organizing based on the emergent behaviors of the simple interactions. There is no external force directing their behavior and no one agent has a global view of the intended macroscopic behavior. Though current NASA swarm missions differ from true swarms as described above, they do have many of the same attributes and may exhibit emergent behavior. In addition, there are a number of US government projects that are looking at true swarms to accomplish complex missions.

*3) Autonomy:* Autonomous operation is essential for the success of the ANTS mission concept.

Round trip communications delays of up to 40 minutes, and limited bandwidth on communications with Earth, mean that effective control from the ground station is impossible. Ground controllers would not be able to react sufficiently quickly during encounters with asteroids to avoid collisions with asteroids and even other ANTS spacecraft. Moreover, the delay in sending instructions to the spacecraft would be so great that situations would likely have changed dramatically by the time the instructions were received.

But autonomy implies absence of centralized control. Individual ANTS spacecraft will operate autonomously as part of a subgroup under the direction of that subgroup's *ruler*. That ruler will itself autonomously make decisions regarding asteroids of interest, and formulate plans for continuing the mission of collecting science data. The success of the mission is predicated on the validity of the plans generated by the rulers, and requires that the rulers generate sensible plans that will collect valid science data, and then make valid informed decisions.

That autonomy is possible is not in doubt. What is in doubt is that autonomous systems can be relied upon to operate correctly, in particular in the absence of a full and complete specification of what is required of the system.

*4) Testing and Verification:* As can be seen from the brief exposition above, ANTS is a highly complex system that poses many significant challenges. Not least amongst these are the complex interactions between heterogeneous components, the need for continuous re-planning, re-configuration, and re-optimization, the need for autonomous operation without intervention from Earth, and the need for assurance of the correct operation of the mission.

As mission software becomes increasingly more complex, it also becomes more difficult to test and find errors. Race conditions in these systems can rarely be found by inputting sample data and checking whether the results are correct. These types of errors are time-based and only occur when processes send or receive data at particular times, or in a particular sequence, or after learning occurs. To find these errors, the software processes involved have to be executed in all possible combinations of states (state space) that the processes could collectively be in. Because the state space is exponential (and sometimes factorial) to the number of states, it becomes untestable with a relatively small number of processes. Traditionally, to get around the state explosion problem, testers have artificially reduced the number of states of the system and approximated the underlying software using models.

One of the most challenging aspects of using swarms is how to verify that the emergent behavior of such systems will be proper and that no undesirable behaviors will occur. In addition to emergent behavior in swarms, there are also a large number of concurrent interactions between the agents that make up the swarms. These interactions can also contain errors, such as race conditions, that are very difficult to ascertain until they occur. Once they do occur, it can also be very difficult to recreate the errors since they are usually data and time dependent.

As part of the FAST project, NASA is investigating the use of formal methods and formal techniques for verification and validation of these classes of mission, and is beginning to apply these techniques to specifying and verifying parts of the ANTS concept mission. The role of formal methods will be in the specification and analysis of forthcoming missions, while offering the ability to perform software assurance and proof of correctness of the behavior of the swarm, whether this behavior is emergent or not.

## IV. Some Potentially Useful Techniques

### A. Autonomicity

Autonomy may be considered as bestowing the properties of self-governance and self-direction, i.e., control over one's goals [15], [26], [43]. Autonomicity is having the ability to self-manage through properties such as self-configuring, self-healing, self-optimizing, and self-protecting. These are achieved through other self-properties such as self-awareness (including environment awareness), self-monitoring, and self-adjusting [45].

Increasingly, self-management is seen as the only viable way forward to cope with the ever increasing complexity of systems. From one perspective, self-management may be considered a specialism of self-governance, i.e., autonomy where the goals/tasks are specific to management roles [46]. Yet from the wider context, an autonomic element (AE), consisting of an autonomic manager and managed component, may still have its own specific goals, but also the additional responsibility of management tasks particular to the wider system environment.

It is envisaged that in an autonomic environment the AEs communicate to ensure a managed environment that is reliable and fault tolerant and meets high level specified policies (where a policy consists of a set of behavioral constraints or preferences that influences the decisions made by an autonomic manager [10]) with an overarching vision of system-wide policy-based self-management. This may result in AEs monitoring or *watching out for* other AEs. In terms of autonomy and the concern of undesirable emergent behavior, an environment that dynamically and continuously monitors can assist in detecting race conditions and reconfiguring to avoid damage (self-protecting, self-healing, self-configuring, etc.). As such, autonomicity becoming mainstream in the industry can only assist in improving techniques, tools, and processes for autonomy [44].

### B. Hybrid Formal Methods

The majority of formal notations currently available were developed in the 1970s and 1980s and reflect the types of distributed systems being developed at that time. Current distributed systems are evolving and may not be able to be specified in the same way that past systems have been developed. Because of this, it appears that many people are combining formal methods into integrated approaches to address some of the new features of distributed systems (e.g., mobile agents, swarms, and emergent behavior).

Integrated approaches have been very popular in specifying concurrent and agent-based systems. Integrated approaches often combine a process algebra or logic-based approach with a model-based approach. The process algebra or logic-based approach allows for easy specification of concurrent systems, while the model-based approach provides strength in specifying the algorithmic part of a system.

Some recent hybrid approaches include:

- CSP-OZ, a combination of CSP and Object-Z [11]
- Object-Z and Statecharts [8]
- Timed Communicating Object Z [13]
- Temporal B [5]
- Temporal Petri Nets (Temporal Logic and Petri Nets) [1]
- ZCCS, a combination of Z and CCS [14]

These and new hybrid formal methods are being investigated to address swarm and other complex NASA missions [41].

### *C. Automatic Programming*

For many years, automatic programming has referred, primarily, to the use of very high-level languages to describe solutions to problems, which could then be translated down and expressed as code in more traditional (lower level) programming languages. Parnas [36] implies that the term is glamorous, rather than having any real meaning, precisely because it is the solution that is being specified rather than the problem that must be solved. Brooks [7] supports this view, and equally criticizes the field of visual programming, arguing that it will never produce anything of value.

Writing just five years after Brooks, Harel [19] disagrees, faulting Brooks for failing to recognize advances in *visual formalisms*. Now, writing almost two decades after Brooks, we argue that automatic code generation is not only a viable option, it is essential to the development of the classes of complex system we are discussing here, and as exemplified by ANTS.

Autonomous and autonomic systems, exhibiting complex emergent behavior, cannot, in general, be fully specified at the outset. The roles and behaviors of the system will vary greatly over time. While we may try to write specifications that constrain the system, it is clear that not all behavior can be specified in advance. Consequently, the classes of system we are discussing will often require that code is generated, or modified, during execution. As a result, the classes of system we are describing here will *require* automatic code generation.

Several tools already exist that successfully generate code from a given model. Unfortunately, many of these tools have been shown to generate code, portions of which are never executed, or portions of which cannot be justified from either the requirements or the model. Moreover, existing tools do not and cannot overcome the fundamental inadequacy of all currently available automated development approaches, which is that they include no means to establish a provable equivalence between the requirements stated at the outset and either the model or the code they generate.

Traditional approaches to automatic code generation, including those embodied in commercial products such as Matlab [35], in system development toolsets such as the B-Toolkit [31] or the VDM++ toolkit [28], or in academic research projects, presuppose the existence of an explicit (formal) model of reality that can be used as the basis for subsequent code generation. While such an approach is reasonable, the advantages and disadvantages of the various modeling approaches used in computing are well known and certain models can serve well to highlight certain issues while suppressing other less relevant details [37]. It is clear that the converse is also true. Certain models of reality, while successfully detailing many of the issues of interest to developers, can fail to capture some important issues, or perhaps even the most important issues.

That is why, we believe, future approaches to automatic code generation must be based on Formal Requirements-Based Programming [39].

### *D. Formal Requirements Based Programming*

Requirements-Based Programming refers to the development of complex software (and other) systems, where each stage of the development is fully traceable back to the requirements given at the outset. In essence, Requirements-Based Programming takes Model-Based Development and adds a *front end* [40].

The difference is that Model-Based Development holds that emphasis should be placed on building a model of the system with such high quality that automatic code generation is viable. While this has worked well, and made automatic code generation feasible, there is still the large *analysis-specification* gap that remains unaddressed. Requirements-Based Programming addresses that issue and ensures that there is a direct mapping from requirements to design, and that this design (model) may then be used as the basis for automatic code generation.

There have been calls for the community to address Requirements-Based Programming, as it offers perhaps the most promising approach to achieving *correct* systems [20]. Although the use of Requirements-Based Programming does not specifically presuppose the existence of an underlying formalism, the realization that proof of correctness is not possible without formalism [2] certainly implies that Requirements-Based Programming should be formal.

In fact, Formal Requirements-Based Programming, coupled with a graphical representation for system requirements (e.g., UML use cases) possesses the features and advantages of a visual formalism described by Harel [18].

*1) R2D2C:* R2D2C, or Requirements-to-Design-to-Code [22], [39], is a NASA patent-pending approach to Requirements-Based Programming.

In R2D2C, engineers (or others) may write specifications as scenarios in constrained (domain-specific) natural language, or in a range of other notations (including UML use cases). These will be used to derive a formal model (Figure 3) that is

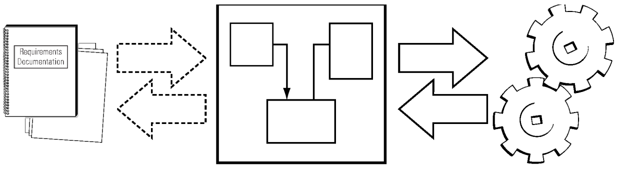

Fig. 3. The R2D2C approach, generating a formal model from requirements and producing code from the formal model, with automatic reverse engineering.

guaranteed to be equivalent to the requirements stated at the outset, and which will subsequently be used as a basis for code generation. The formal model can be expressed using a variety of formal methods. Currently we are using CSP, Hoare's language of Communicating Sequential Processes [24], [25], which is suitable for various types of analysis and investigation, and as the basis for fully formal implementations as well as for use in automated test case generation, etc.

R2D2C is unique in that it allows for full formal development from the outset, and maintains mathematical soundness through all phases of the development process, from requirements through to automatic code generation. The approach may also be used for reverse engineering, that is, in retrieving models and formal specifications from existing code, as shown in Figure 3. The approach can also be used to "paraphrase" (in natural language, etc.) formal descriptions of existing systems. In addition, the approach is not limited to generating high-level code. It may also be used to generate business processes and procedures, and we have been experimenting with using it to generate instructions for robotic devices that were to be used on the Hubble Robotic Servicing Mission (HRSM), which, at the time of writing, has not received a final go-ahead. We are also experimenting with using it as a basis for an expert system verification tool, and as a means of capturing domain knowledge for expert systems.

*2) R2D2C Technical Approach:* The R2D2C approach involves a number of phases, which are reflected in the system architecture described in Figure 4. The following describes each of these phases.

D1 Scenarios Capture: Engineers, end users, and others write scenarios describing intended system operation. The input scenarios may be represented in a constrained natural language using a syntax-directed editor, or may be represented in other textual or graphical forms.

D2 Traces Generation: Traces and sequences of atomic events are derived from the scenarios defined in phase D1.

D3 Model Inference: A formal model, or formal specification, expressed in CSP is inferred by an automatic theorem prover — in this case, ACL2 [30] — using the traces derived in phase D2. A deep[1] embedding of the laws of concurrency [21] in the theorem prover gives it sufficient knowledge of concurrency and of CSP to perform the inference. The embedding will be the topic of a future paper.

D4 Analysis: Based on the formal model, various analyses can be performed, using currently available commercial or public domain tools, and specialized tools that are planned for development. Because of the nature of CSP, the model may be analyzed at different levels of abstraction using a variety of possible implementation environments. This will be the subject of a future paper.

D5 Code Generation: The techniques of automatic code generation from a suitable model are reasonably well understood. The present modeling approach is suitable for the application of existing code generation techniques, whether using a tool specifically developed for the purpose, or existing tools such as FDR [12], or converting to other notations suitable for code generation (e.g., converting CSP to B [9]) and then using the code generating capabilities of the B Toolkit.

*3) Advantages of the R2D2C Approach:* We have not yet had an opportunity to apply R2D2C to ANTS, although that is certainly our plan.

In addition to applying it to the HRSM procedures [39], we have applied R2D2C to LOGOS, a NASA prototype Lights-Out Ground Operating System, that exhibits both autonomous and autonomic properties [48], [49]. We illustrate the use of a prototype tool to apply R2D2C to LOGOS in [40], and describe our success with the approach.

Here, we summarize some benefits of using R2D2C, and hence of using Formal Requirements-Based Programming in system development. It is our contention that R2D2C, and other approaches that similarly provide mathematical soundness throughout the development lifecycle, will:

- Dramatically increase assurance of system success by ensuring
    - completeness and consistency of requirements
    - that implementations are true to the requirements
    - that automatically coded systems are bug-free; and that
    - that implementation behavior is as expected
- Decrease costs and schedule impacts of ultra-high dependability systems through automated development
- Decrease re-engineering costs and delays

### *E. Tool Support*

John Rushby [42] argues that tools are not the *most* important thing about formal methods, they are the *only* important thing about formal methods. Although we can sympathize, we do not support such an extreme viewpoint. Formal methods would not be practical without suitable representation notations, proof systems (whether automated and supported by tools, or not), a user community, and evidence of successful application.

We do agree, however, that tool support is vital, and not just for formal methods. Structured design methods *took off* when they were *standardized*, in the guise of UML. But

[1] "Deep" in the sense that the embedding is semantic rather than merely syntactic.

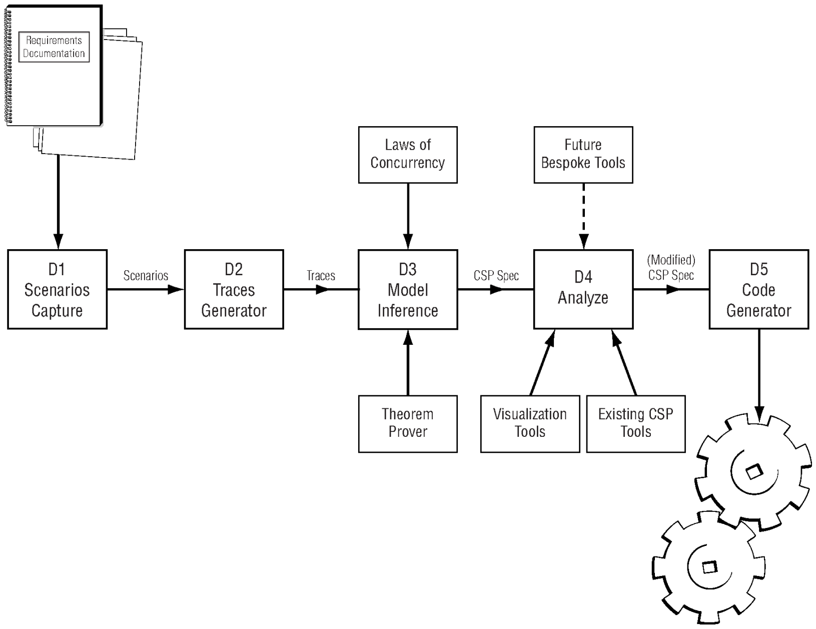

Fig. 4. The entire process with D1 thru D5 illustrating the development approach.

it is only with the advent of tool support for UML that they became popular. The situation is analogous to high-level programming languages: while the community was well convinced of their benefits, it was only with the availability of commercial compilers that they became widely used.

Tools are emerging for the development of complex agent-based systems such as Java-based Aglets and tools for autonomic systems. For automatic code generation and Formal Requirements-Based Programming to be practical, the development community will need commercial-quality tools.

## V. Conclusion

The computing industry thrives on the assumption in the marketplace that software is reliable and correct, but many examples from experience over the decades cast doubt on the validity of this assumption. There is no automated, general purpose method for building correct systems that fully meet all customer requirements. This represents a major gap that has yet to be fully addressed by the software engineering community. Requirements-based programming has been described along with new automated techniques recently devised at NASA for ensuring correctness of the system model with respect to the requirements, as a possible way to close this gap.

In future mission concepts that involve advanced architectures and capabilities — such as swarm missions whose individual elements not only can learn from experience but also must pursue science goals cooperatively — NASA faces system development challenges that cannot be met with techniques currently available in the computing industry. The challenges boil down to building reliability and correctness into mission systems, where complexity, autonomous operation, machine adaptation, dangerous environments, and remoteness combine to push such missions far into uncharted territory in systems engineering. With approaches such as autonomic computing and automated requirements-based programming, NASA will have greater possibilities for achieving success with these advanced mission concepts.

***Abstract*—This paper describes the design and implementation of a small real time operating system (OS) called *Minos* and its application in an onboard active safety project for General Aviation. The focus of the operating system is predictability, stability, safety and simplicity. We introduce fault tolerance aspects in software by the concept of a very fast reboot procedure and by an error correcting flight data memory (FDM). In addition, fault tolerance is supported by custom designed hardware.**

## I. Introduction

WE DEVELOPED Minos in the context of a European Union Research project called *Onbass* [1]. The following quote of the Onbass homepage gives an overview of the project goals:

> The final goal of the project is to design, develop, test and validate an on-board active real-time data processing system that will monitor flight related parameters and react in the case of a proliferation of risk to the aircraft or its occupants. The system will recognise undesirable trends or patterns in data relating to the various aircraft agents (aircraft, systems, pilot) by analyzing and comparing current flight data against previously accumulated aircraft-specific behavioral data. As a result, timely interventions could be made in order to eliminate the associated risk(s) or to minimise the severity of the corresponding effects. In addition, the system will offer invaluable and comprehensive data for post-flight analysis upon which aviation safety bodies could base and/or redesign safety policies and procedures.

The interested reader may refer to [2]–[4] for further information about the application side of the Onbass project, the theory of Active Safety and its implementation.

In this paper we shall describe the operating system developed during the project, with an emphasis on two fault tolerance aspects: a.) recovering from memory faults mainly caused by radiation and b.) reliably recording flight data in a *Flight Data Memory* (FDM). A FDM is a reliable persistent storage system for flight data such as heading, temperature, engine information, etc. recorded in real time during the flight.

The main concept used to increase dependability [5] in our project is managed redundancy. Duplication of the main memory (see chapter II) and of the flight data memory (see chapter VI) lead to a substantially higher level of reliability.

## II. The Hardware Platform

The hardware platform was custom designed and built for this project by IRoC Technology in Grenoble, France, according to the requirements given by the Onbass project specification. The FPGA implementation [6] features a CPU, synthesised from a standard (non fault tolerant) ARM7TDMI IP core by Actel, a fault tolerant main memory (RAM) and a fault tolerant ROM.

Fault tolerant RAM and ROM provide safeguards against both temporary and permanent errors. Temporary errors, for example bit flips, are mainly induced by radiation such as alpha particles, neutrons or heavy ions that are generated by solar winds or by other cosmic radiation. At sea level, these events happen rarely because most of the radiation is filtered by the earths atmosphere. However, at typical flight altitude (10km above sea level) or in deep space several hundred or thousand kilometers above ground, experiments have shown [7] that such events occur as frequently as 5.55 times per megabyte RAM per day in average. ROM is much less susceptible to such events, but they can still occur.

Permanent errors on the other hand affect both, RAM and ROM equally. Such errors usually manifest themselves as failures of parts of or the entire physical memory chip. In the former case, only certain regions are affected, in the latter case the whole chip fails.

If a temporary fault occurs, the system should recover as quickly as possible and continue its operation from the most recent consistent state. In the case of a permanent error, the system is supposed to still continue its operation, possibly in a degraded mode, after signalling the failure to the runtime and application.

The following sections describe the strategies chosen for dealing with the two types of error just described.

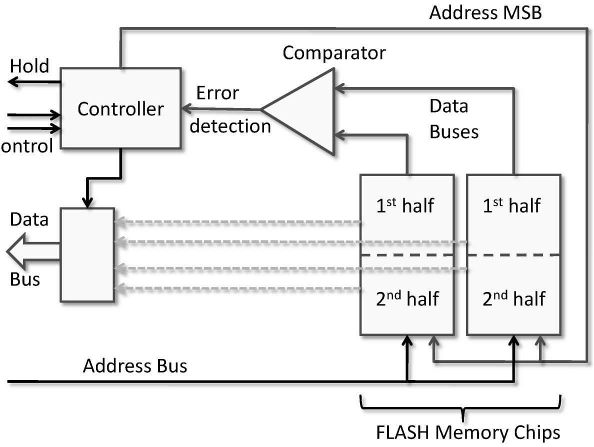

Fig. 1. ROM Implementation (Picture courtesy of IRoC Technology)

**Memory Subsystem:** As a first precaution, static RAM was chosen instead of dynamic RAM as it is faster and more resilient to temporary errors. Physical duplication of memory chips combined with a CRC mechanism provides immunity against a complete failure of any single memory chip. Read/ write operations are always performed simultaneously on two memory chips and, if one of them fails, the error is immediately flagged to the OS.

Furthermore, a word-based error detection mechanism was implemented. A 36-bit wide version of SRAM was chosen, where the 4 extra bits per word are used to store a hardware-generated *Cyclic Redundancy Check* (CRC). At each read operation, the data of both memory chips involved is compared against each other. If the comparison fails, the CRC is used to determine the faulty chip, and its partner chip is used to automatically correct the faulty memory location. As these operations are integrated into the memory controller, the comparison can be done without performance penalty, and the correction in case of a mismatch requires just one additional memory access (one CPU cycle). Counters of all corrected and uncorrected errors are provided to the runtime for further analysis or logging.

Triplicated memory was considered an alternative to the duplication but an unimproved level of protection regarding temporary faults, longer Mean Time To Failure (MTTF), lower hardware costs and lower heat dissipation favoured the chosen approach.

**Flash Memory:** The binary image of the OS is stored in flash-memory (ROM). The system ROM is physically duplicated but, as it is less susceptible to external influences, no extra bits for error detection are provided. Instead, two instances of the OS image are stored on each ROM chip, one in the first half of the address space and one (in reverse bit order) in the second half, as shown in Figure 1. This procedure can be justified in our case by the extremely small size of the OS image.

In order to understand how error detection/ correction in ROM works, we first remember that ROM chips are actually 16 bit wide[1], so that two corresponding 16 bit entities from the two ROM chips fit in one 32 bit word. At boot time, the hardware controller uses this fact for error detection when copying the binary OS image wordwise from ROM into RAM. If the two 16 bit entities in a word do not match, the image stored in the lower ROM part is considered corrupted, and the correct data has to be retrieved from the upper ROM part. As this procedure is only initiated once at boot up, the additional overhead is negligible.

Calculations [6] showed that the system just described not only features up to 99% mitigation efficiency regarding to non-permanent (transient) errors but it also enjoys twice as long Maintainance Free Operating Periods (MFOPs) if compared with a non-redundant implementation. Both, a more extensive reliability analysis and more implementation details, are given in [6].

## III. The Programming Language Oberon

The programming language used in the Onbass project is *Oberon 07* [8], [9], a modular descendant of Pascal and Modula-2. Oberon 07 is a simple and safe variant of *Oberon* [10] for embedded systems. For example, the option of in-line assembler code has been removed completely from the language and replaced with a set of safer and more structured custom built-in functions [8]. Oberon07 also provides a mechanism for accelerated calls and execution of ”leaf” procedures that do not contain (further) procedure calls. Parameters and local variables in leaf procedures are allocated in registers (instead of on the stack) whenever possible. The Oberon language is especially suitable for safety critical applications as it is completely type safe and allows no unsafe operations such as type conversions, etc. except in explicitly marked sections for kernel code.

## IV. The Applications

Before explaining the design of the Operating System, we would like to give a short overview of the Onbass applications that were supposed to run on the system. This gives an idea about the requirements:

**Flight Data Acquisition** The Onbass system is installed in a general aviation airplane such as a Piper Lance and directly connected to the onboard air data computer that delivers a set of sensor data to the Onbass system up to eight times per second.

**Black Box Recording** After the data acquisition, the raw black box data is stored in the flight data memory (see chapter VI) for later analysis or recovery.

**Data Parsing** Next, the acquired data is parsed and validated according to the air data computer specification.

**Flight Mode Detection** The current flight mode (take off, cruise, etc) is then evaluated. This is especially important, as the valid airplane constraints such as speed, vertical speed, etc. heavily depend on the flight mode.

[1] ROM chips use an interlaced addressing scheme, where the first 16 bits in address space belong to the first chip, the second 16 bit belong to the second chip, the third 16 bit to the first chip again, etc.

**Airplane safety checks** A set of rules is applied to the current airplane flight state to validate the operation of the airplane in terms of safety. In case of detected deviations, a warning is displayed to user via the web interface.

**Web Server** A web server is used to display system information such as configuration options, warnings, etc. via a separate computer to the pilot.

**Replay** For post flight analysis, the system can be configured to load the flight data from the FDM and and use it as data input for the application instead of acquiring the data from the air data computer.

**Supportive tasks** Various other tasks are required to support the system such as additional logging, polling driver tasks for UART and MMC etc.

The whole flight data acquisition and analysis must obviously be performed in real time and must be finished before the next flight data set arrives. This imposes requirements on the real time capabilities of the system.

## V. The Design of Minos

As a starting point for the runtime system we chose *HelyOS* [11], an embedded operating system for the control of autonomously operating model helicopters developed at ETH Zurich.

We did a substantial rewriting of HelyOS and customised it towards our specific needs as it was too limiting. The resulting system is called *Minos* and enjoys the following qualities:

- Very small, simple and efficient
- Suitable for safety critical applications
- Predictable in terms of task execution time
- Easily portable to other platforms
- Highly configurable at boot time
- Fast boot up time

In the next few chapters we shall give a short introduction to the key concepts of the Minos design.

### A. Fast Boot Up

Special attention was given to system boot up time. A hardware watchdog is used to detect ”stuck” programs caused by a malfunction of either hardware or software. As soon as the watchdog detects a timed-out activity of any kind, the OS and the applications are restarted and brought into the most recent consistent state. This is quite easily possible in this case because all the relevant data has by been stored in the flight data memory by concept IV. In order to achieve a minimum downtime it is important to implement an ultra fast boot up mechanism that, in our case, takes less than 0.5 seconds. Unavoidably this requirement has an impact on various subsystems such as the flight data memory (see chapter VI).

### B. Memory Management

Sytems of the Oberon family [12], [13] traditionally use a completely type-safe ”managed” runtime including garbage collection. However, it is widely known that garbage collection introduces unpredictable latencies in the execution of application programs and garbage collectors for real time systems are complex and difficult to design and implement. As a consequence, other traditional garbage collector based systems, i.e. Java, propose in their real time variants (Real Time Java [14]) the addition of memory outside the scope of the garbage collector for time critical software parts.

As explicit memory allocation and deallocation is inherently unsafe and therefore incompatible with safety-critical applications, the only viable option is not to generate garbage at all. We use a closed system approach that still allows applications to allocate dynamic memory but at initialisation time only. An additional benefit of closed systems is that they can never run out of memory.

Unavoidably however, there is a price to pay for such simplicity. It is the need for compensatory support for application programming. For example, it is impossible for Minos to permanently keep a dynamic metadata structure for files in memory. Instead, metadata needs to be consistently stored in flash memory, and sector caches are taken from a preallocated buffer pool. As the pool is only used internally by the filesystem and as blocks are automatically recycled when the buffer pool is empty, no ”out of memory” situations can ever occur.

### C. Interrupt Handling

The interrupt handling scheme in Minos is again kept simple. At boot time, the kernel installs a single, general interrupt handler that is responsible for dispatching all signalled interrupts. Device drivers register their own handler in the kernel, where only one handler per interrupt source is currently supported. Interrupt handlers are non interruptable, and their processing time must be kept in limits in order not to compromise realtime guarantees. In the case of multiple interrupts pending, the kernel calls the handlers in the order of ascending interrupt numbers.

### D. Task Model

*Original Tasking Scheme:*
HelyOS uses an ingeniously simple, preemptive tasking scheme that is characterised by the following principles. First, the scheme distinguishes four priorities corresponding to four different task types: Interrupt handlers, high priority periodic tasks running at period $s$, low priority periodic tasks running at period $l = k * s$ with fixed $k$, and background tasks.

Second, HelyOS uses the following scheduling policy:

- Interrupt handlers have highest priority and preempt all other tasks.
- High priority periodic tasks preempt low priority tasks and background tasks but no interrupts.
- Low priority periodic tasks preempt background tasks but no others.
- Background tasks do not preempt any tasks.

An interesting consequence of this scheduling policy is the fact that each task must run to completion before any other task of the same priority can start its execution, with the immensely beneficial implication that a single stack is sufficient in principle for implementing the entire scheduling scheme.

*Modified Tasking Scheme:*
The scheduling policy just described is not powerful enough for our application. In particular, the restriction to merely two types of periodical tasks corresponding to two fixed periods is too rigid. However, in the interest of avoiding the full complexity of managing multiple stacks and of mastering an intricate synchronisation mechanism, we refrained from switching to a fully general model. Instead, we generalised the HelyOS model appropriately. The most important modification is a new strategy oriented towards ”earliest deadline” scheduling. Both a period and a priority number are preassigned to each task, where the period corresponds to the ”earliest deadline” and the priority number is used to resolve ties. A priority number is also preassigned to background tasks, but of no period of course.

Minos Scheduling Principles:

- Interrupt handlers have highest priority and preempt all other tasks.
- Periodic tasks are scheduled according to their deadline as derived from their period. If two tasks have the same period, the execution order is defined by their priority.
- Background tasks are scheduled according to their priority.
- Tasks can only be preempted by tasks with a shorter deadline.

A consequence of this scheme is the fact that the use of periodic tasks for polling external events is inappropriate, and that interrupts must be used instead. The reason is that a delay in the order of the period (currently 5 ms, but this could be easily changed) is often unacceptable. However, this scheme is still suitable in our case because we are not primarily interested in very fast reaction times but in a predictable behavior in terms of both time and order of execution.

If a deadline was missed, then an optional delegate provided by the task object is called. The delegate is responsible for taking recovery actions such as, in the simplest case, merely logging the problem. The next execution of this task is then skipped to give the system time to recover. Note that such a behavior is also necessary to prevent possible stack overflows.

Another nice consequence of our simple tasking model is that accessing shared data often needs no synchronisation as the tasks are serialised implicitly. This is notably the case if data structures are shared among tasks of the same period and background tasks only. In the (rarely occurring) other cases where a locking mechanism is required, we use a global system lock that simply disables all interrupts (including timer interrupt).

Figure 2 illustrates this tasking scheme. After background task A runs to completion, task B is automatically executed. At this time, neither a periodic task nor an interrupt is pending. At time 50, periodic tasks P and Q are both due, whereas Q has the smaller period and therefore shorter deadline than P. The task B is preempted and Q executed. When Q finishes, P is automatically invoked because periodic tasks have higher priority than background tasks. At time 63, an interrupt is signaled by the hardware and the respective interrupt handler is called immediately. P is resumed as soon as the interrupt handler has finished its task. When P finishes executing, neither a periodic task nor an interrupt is pending and background task B is resumed.

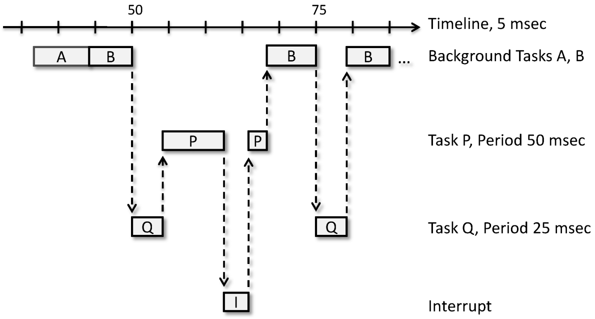

Fig. 2. Scheduling example

A question naturally arising here is if priority inversion is possible that is if a scenario can be found where some high priority task needs access to a shared resource that is locked by a low priority task so that intervening medium priority tasks can effectively block the execution of the high priority task. In our tasking model, the only synchronisation primitive provided is the global lock. When a task acquires this lock, the task is implicitly set to highest priority (priority ceiling) and the scheduling mechanism is disabled while the lock is held. Because it is impossible that any task holding the global lock is interrupted by another task, priority inversion is impossible.

The scheduler itself runs in linear time (linear in the number $O(n)$ of tasks as the due time has to be calculated for each task), and it is thus easy to calculate an upper bound for the scheduler execution time.

Our tasking model (see section V-E) pays out in a very efficient task switching algorithm. In fact, the switch from the task scheduler to any other task is synchronous and amounts to just a procedure call (delegate), and the return to the scheduler simply corresponds to the return from the procedure. Only interrupts are asynchronous and therefore require saving of registers on the stack.

### E. *Stack Management*

The stack management is equally simple. We use a fixed number of separate stacks, one for interrupts, one for periodic tasks and one for background tasks respectively. In principle, one stack would suffice because each task either runs to completion or is preempted by a task of a higher priority, which in turn runs to completion, so that each preempted task finds a clean stack when resumed. However, using a fixed number of separate stacks simplifies the handling of traps.

### F. *Boot Configuration Procedure*

A particular requirement in our project specification is full configurability of the system at boot time. In the interest of readability, flexibility and ease of configuration, we chose an

XML [15] approach. For each hardware component and each software component, a separate XML section is provided, and a complete set of default settings for all core components is hardcoded into the program and activated at run time before the XML configuration parser is invoked. This serves the purpose of putting the system into a consistent working state even before the configuration file has been read.

Due to the restricted policy of allocating dynamic memory, we implemented a considerably simplified SAX [16] based parser that itself does not rely on heap memory. As the system must be able to operate independently of any external host computer, the configuration file can alternatively be stored in flash memory in the device itself or downloaded from a host terminal at boot time.

The initialization procedure resulting from all these constraints looks like this:

1) Kernel initialisation, platform setup.
2) Hardware configuration and initialisation by default settings.
3) Mounting of RAM and ROM disc.
4) Acquisition of XML configuration file either by loading it from the ROM disk or by downloading it via a serial connection from a host computer.
5) Processing of the ”autostart” section in the XML file. Can execute any arbitrary command but is especially used to register XML handler plug-ins for the configuration process.
6) The XML parser scans through the rest of the XML file and calls the appropriate plug-ins if one is registered.
7) Enter main command loop.

The configuration scheme described above proved to be extremely powerful and flexible. The only negative aspect is the strict top-down parsing order imposed by SAX, which sometimes leads to clumsy configuration clauses.

### G. Modular System Structure

As shown in figure 3, Minos is a fully modular and hierarchically structured system. For the sake of better readability, the (optional) boot configuration mechanism and the XML parser are omitted in the figure. The RAM disk is modelled as a *volume object* for filesystem containers. Other examples of volume objects are ROM disks and Flash disks. Again in the interest of readability, the dependencies on modules *Log* and *SerialLog* are also omitted.

**SYSTEM** This is a pseudo module provided by the Oberon compiler; it provides potentially unsafe functionality required for low level system programming such as memory mapped input/ output. Utmost care must be exercised in code that uses features from module SYSTEM because such code must be considered as potentially unsafe.

**Platform** Platform specific information such as memory layout, interrupt numbers and memory mapped I/O registers. By merely replacing the implementation of this module, Minos can be adapted to a variety of processors of the same architecture, including for example the Marvell PXA255 and the Marvell PXA270.

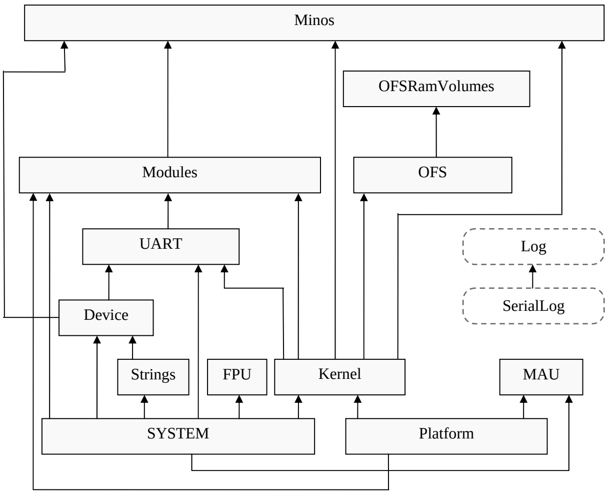

Fig. 3. Core system modules

**MAU** Memory Allocation Unit, provides the implementation of the memory allocation logic. This module is referenced by the compiler and should not be used directly.

**FPU** Floating Point Emulation. This Module implements runtime support for basic Math operations on floating point numbers as well as for integer division. It is used by the compiler rather than by applications.

**Strings** Basic functionality for copy, search, add, etc. operations on strings. This module is added to the kernel for reuse to avoid code duplication.

**Kernel** The Kernel provides platform-specific tasks such as system initialisation, interrupt handling, timers, etc. It is highly unportable and must be adapted to every platform individually.

**Device** An abstract Character Device used as an abstract interface by plug-in device drivers. It allows the dynamic addition or change of input/ output devices such as (real or virtual) serial ports at runtime.

**Uart** UART device driver, implements a Device.Device plug-in object.

**Log** An abstract logging device that can be used to display log output on different devices such as serial port or Web browser.

**SerialLog** Log over the serial connection. A concrete implementation of module Log.

**OFS** Oberon File System. Provides file operations such as creating, deleting, reading or writing files. It also implements the Oberon File System that is based on the notion of volumes, where a volume is an abstract file system container that provides read/ write access to blocks of fixed size.

**OFSRamVolumes** RAM Disk support. Implements a volume declared as an abstract object in OFS

**Modules** Dynamic module loader. Allows to dynamically download, link and execute modules at runtime.

**Minos** Implements the scheduler and the trap handler and offers user interface commands to be activated via a remote terminal.

The set of modules presented here is a basic and self-contained subset of all Minos modules. The modular concept allows software developers to seamlesly add new functionality to the system at any time by simply linking the appropriate modules to the current image. Minos also allows modules to be downloaded, linked and executed dynamically at runtime. This is very convenient for prototyping, testing and debugging. For example, a flexible testing environment can be built by merely flashing to ROM a version of the basic Minos runtime that automatically downloads application code at boot time.

The size of the full operating system including all the above listed modules, the XML configuration parser and the boot configuration mechanism is ca. 100 Kbytes. This is less than half the size of a comparable commercial system such as, for example, VxWorks by Wind River (Size of VxWorks 6.2 without XML parser is about 250 Kbytes Basic OS profile [17]).

## VI. Flight Data Memory

### A. Introduction

An avionics Flight Data Memory (FDM), also called a ”black box”, is an extremely robust and reliable flight data recorder that is typically used in aircrafts for post flight/ post disaster analysis. The current trend in General Avionics goes towards declaring FDM mandatory even in small aircrafts [18]. FDMs often get their input streamed down from an air data computer (ADC) that, in turn, collects the data from a variety of sensors across the airplane. Optionally, FDMs can also be connected to other input sources.

Streams of sensor data like heading, height, fuel flow, etc. must be recorded reliably on long life and non-volatile medium such as flash memory or special magnetic tape [18]. Data redundancy schemes such as CRC-32 [19] for error detection, or Reed Solomon for error detection and correction are commonly used to further enhance the reliability of the FDM. Our own choice in Onbass was using CRC-32 for error detection and data duplication on two separate multimedia cards (MMC) for error correction.

The FDM in Onbass was designed with the following requirements in mind:

- Simple design
- Fast data storage and retrieval
- Minimum 15 years life time
- Fast recovery after unexpected reboot & transparent flight resuming
- Transparent MMC device recovery in case of faulty read or write operation
- Small memory footprint
- Support for replaying stored flights
- Human decipherable format
- Space efficiency

### B. MMC vs Compact Flash

We had to decide between multimedia cards (MMC) [20] and compact flash cards (CF) [21]. MMC has the advantage of physical compactness and of a low pin count (7 pins), whereas CF comes with a built in wear-leveling algorithm but has a high pin count (50 pins). We decided in favor of a low pin count because physical connections are arguably the most critical components in any system from a reliability point of view.

### C. Flash Properties and Limitations

Flash memory is organised in blocks (usually 512 bytes) and in *erase units* consisting of a number of adjacent blocks (usually 32 or 64 [22]. Reads and writes are performed blockwise, and writes must be made only to previously erased blocks. Blocks can either be erased automatically or manually, where the former option is more comfortable while the latter is faster. The number of erases per unit before ”wearing out” is limited, typically to some number between 10000 and 100000. In the interest of longevity of the flash card, the use of a ”wear leveling” strategy is highly advisable. Wear-leveling means that erase cycles and write cycles are evenly distributed across the memory chip. Traditional file systems are unsuitable for flash cards because they exhibit *hot spots* such as meta data fields that are frequently updated.

### D. Analysis and Design Considerations

In Onbass we can take advantage of the fact that the size of records to be stored is fixed (flight data frame plus warnings). As mentioned above, the use of a standard file system is unsuitable as it typically exhibits hot spots. Much of the research [23] into overcoming this problem introduces some virtual-to-physical block number mapping. Two kinds of data structures are typically suggested for this purpose. *Direct maps* map a logical block number (index $i$) to its physical sector number. Unfortunately, such data structures have typically a footprint in the order of several megabytes [24]. *Inverse maps* store in location $i$ the virtual block number corresponding to sector $i$. These maps are usually stored on the flash disk itself and are mainly used for regenerating the direct map at boot time. However, after an unexpected reboot, it would take considerable time to rebuild the direct and indirect maps, which is incompatible with the request of a fast reboot time. Also, many of these algorithms are patented.

While algorithms based on virtual block mapping can greatly extend the lifetime of flash memory, this comes at the price of increased complexity, of a large memory footprint, and of a garbage collection mechanism for reclaiming invalid sectors. As this is again incompatible with realtime constraints, it is not an option in our case.

Another approach is the use of a log structured file system such as *JFFS* [25]. Log structured file systems do not structurally separate metadata and payload data but instead maintain a comprehensive log of all performed operations in chronological order. While wear leveling is implicit in such systems, they still suffer from the garbage collection problem, which again disqualifies them for the use in our project.

We should also remember that one of the Onbass requirements (see chapter VI-A) is readability of the data recorded in an FDM without the help of a software decoder. A FDM must

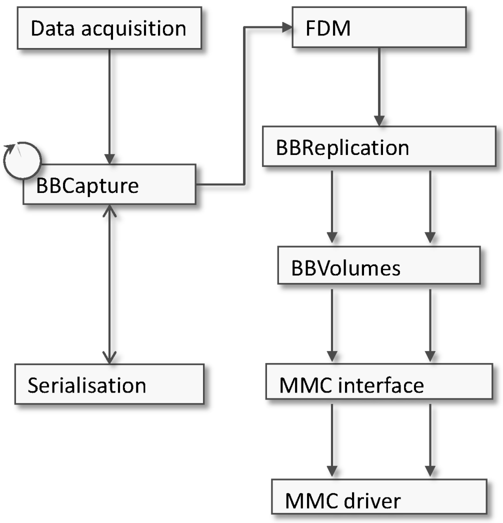

Fig. 4. FDM Implementation Overview

by law be fully recoverable from scratch. This requirement de facto excludes any sophisticated allocation scheme because recovering data without decoder software would either be impossible at all or at least take considerable efforts.

Therefore, we refrained from using such advanced storing schemata and decided in favor of a simple circular buffer structure, where each flight data record occupies the same number of flash card blocks. Whenever a new erase unit is entered, an erase operation is performed as a preparation for subsequent writing. The obvious drawback of this scheme is internal fragmentation if the size of a data element is not an exact multiple of the elementary block size. We considered this as acceptable in particular because more sensor data will have to be stored in the future, which reduces the fragmentation overhead.

### E. *Implementation*

In addition to the actual flight data, some metadata is recorded on the FDM: The FDM header occupies one erase block and describes the current contents of the FDM. It contains a fingerprint, the number of flights currently stored in the FDM, the flight numbers of the oldest and newest flights currently stored in the FDM, and a list of flight indexes. A flight index in turn points to the first and the last header block of the corresponding flight. Flight header blocks again contain a fingerprint (for the support of a scavenging process), the flight number, the starting time of the flight and the date.

During flight recording, the pointer to the last block of the current flight index is declared invalid before the flight has properly been closed. This allows the system to detect unexpected reboots and, as each flight data block is stamped with the corresponding flight number, to use a binary search procedure for locating the most recently recorded flight data block.

Prior to writing, the FDM software must check whether the next sector is free or the start of the oldest flight in the circular buffer. In the latter case, the FDM software deletes the oldest flight and continues recording.

### F. *Module View*

Figure 4 shows the implementation of the FDM as a layered modular system.

**Flight Data Memory (FDM)** This module provides an API for starting and ending the recording of flight data, for storing and retrieving flight data frames and for performing other administrative tasks.

The standard procedure to initialise the flight data memory is registering the FDM module with the XML configuration mechanism by calling the *Install* procedure and then configuring the flight data memory according to the specification in the XML configuration file. A replay mode (replay of a stored flight) can also be enabled via the configuration file.

**BBCapture** This module is responsible for acquiring the flight data from the application and for periodically storing it. For this purpose, *BBCapture* installs a periodic task.

**Serialisation** The *Serialisation* module is responsible for serialising flight data frames into a contiguous data stream to be fed to the FDM.

**BBReplication** This layer partly implements the error detection/correction algorithms. In detail, the module is responsible for computing the CRC-32 for each block. The CRC-32 is automatically generated during write operations and automatically checked during read operations. All read/ write operations are performed sequentially on two configurable partitions on two distinct flash cards. At each read operation, data integrity is checked automatically. If a faulty CRC-32 is detected, the healthy copy is used to fix the data by merely rewriting the faulty block and an error indication is returned. If one of the flash cards fails permanently, the system still continues to record data on the healthy card, and a log message plus an appropriate status code are generated to indicate the failure.

**BBVolumes** Flash disks usually come with a standard partition table and thereby support the coexistence of an FDM and standard file systems on the same disk. *BBVolumes* implements a disk volume object that represents a logical volume, in our case a partition, and extends its functionality with the ability of erasing erase units on the flash disk.

In case of a malfunctioning MMC controller or card, both, the controller and the cards are automatically reset and the failing operation is retried. If it fails again, an error code is returned to indicate the failure.

**MMC Interface / MMC Driver** These two modules implement the multimedia card driver, an interface for reading, writing and erasing blocks and some administrative support such as acquiring cards.

## VII. Conclusion and Future Work

We have built a small and highly reliable realtime operating system that is targeted at safety-critical applications such as the onboard monitoring purpose specified by the Onbass project specification. In numerous real and simulated flight trials (with simulated hazards), the system has proved to operate correctly and reliably. However, some scenarios pushed the system to its limits, especially the MMC subsystem. Because recording of flight data is of prime importance in Onbass, it is performed by a periodic real time task. This is possible because writing a disk sector usually takes less than 500 usec. However, in case of any failure, the MMC specification defines a default timeout value of 250 msec [22], which easily goes beyond the time limit of the corresponding periodic task. Our system proved to work reliably even in such cases but only thanks to the low system load. It is advisable to extend the tasking mechanism by an option of suspending a task while waiting for some hardware event. Alternatively, accesses to the MMC controller could be encapsulated in a separate periodically polling task. However, this would lead to a degradation of the sequential read/ write performance as the maximum throughput would be limited by the minimum polling period of the task.

The FDM has proved to work reliably as well. Tests performed by intentional modifications of the stored flight data on one or both of the MMC cards showed that all tested inconsistencies (data errors) are reliably detected and (where possible) fixed. A potential improvement in terms of wear leveling could be achieved by periodically moving the FDM header (which is a hot spot) across the medium. Adding spare sectors or entire erase units for a potential replacement of blocks with permanent errors could also improve the lifetime of the system.

## ACKNOWLEDGMENT

The authors would like to thank Felix Friedrich and Florian Negele for their help in designing and implementing the system and for the many hours of intense collaboration and discussions. Many thanks also go to Brian Kirk and to Igor Schagaev for their inspiration and all the contiguous critical and constructive discussions.

***Abstract*—Hardware simulation is an important part of the design of embedded and/or real-time systems. It can be used to compute the Worst Case Execution Time (WCET) and to provide a mean to run software when final hardware is not yet available. Building a simulator is a long and difficult task, especially when the architecture of processor is complex. This task can be alleviated by using a Hardware Architecture Description Language and generating the simulator. In this article we focus on a technique to generate an automata based simulator from the description of the pipeline. The description is transformed into an automaton and a set of resources which, in turn, are transformed into a simulator. The goal is to obtain a cycle-accurate simulator to verify timing characteristics of embedded real-time systems. An experiment compares an Instruction Set Simulator with and without the automaton based cycle-accurate simulator.**

## I. Introduction

SIMULATION of the hardware platform takes place in the final stage of development. It can be used for 2 tasks. The first task is the evaluation of the Worst Case Execution Time (WCET) to compute the schedulability of the application [9]. The second task is the test of the application using scenarios before final testing on the real hardware platform. This test is useful because simulation allows an easy analysis of the execution. In both cases, a cycle accurate model of the hardware platform must be used to insure that timings of the simulation are as close as possible to timings of the execution on the real platform.

A common approach for the hardware modelling [5] is based on an hardware centric view; in this approach, the processor is usually modelled by a set of functional blocks. The blocks communicate and synchronise with each other in order to handle the pipeline hazards. A pipeline can be modelled with this approach by designing a functional block for each stage of the pipeline (a SystemC [8] module for instance). This approach is very useful in the design process as it allows synthesis generation. However, simulators that are generated from these kind of models are slow because of the block synchronisation cost. In our approach, we propose to use an Architecture Description Language (ADL) to describe the pipeline and the instruction set of the target architecture. The goal of the pipeline description is to focus on the effects of dependencies and device usage on the timing. This description is transformed into a finite state automaton, which is then transformed into the simulator source code by adding the instruction behaviour (see figure 1). The aim of the automaton is to provide a faster—yet accurate—simulator because hazards of the pipeline are not computed at execution time but at generation time instead. This paper focuses on pipeline modelling and does present the pipeline description in our ADL: HARMLESS [7] (Hardware ARchitecture Modelling Language for Embedded Software Simulation) but the method presented may be extended to include the modelling of other parts of the architecture like branch prediction or cache memories.

## II. Related work

Pipeline and resource scheduling have been studied widely in instruction schedulers, that are used by compilers to exploit the instruction level parallelism and to minimise the program execution time. In [12], Müller proposes to use one or more finite state automata to model the pipeline and build a simulator. Then the simulator is used by the instruction scheduler to compute the execution time of instruction sequences. The automata can be quite large and minimisation techniques may be used to alleviate them. In [13], Proebsting and Fraser use the same approach but a different algorithm which produces directly a minimal automaton. In [1], Bala and Rubin improve the algorithm on [12] and [13] by allowing to replace instructions in already scheduled sequences and present the BuildForwardFSA algorithm which is used to build the automaton. In these works, only structural hazards are taken into account. It makes sense for instruction schedulers.

Other works have been done to build simulator for WCET analysis using an ADL. In [10], Li and al. use the EXPRESSION ADL to build an *executions graph* and express pipeline hazards. The hazards are resolved at run-time. In [14], Tavares and al. use a minimal ADL to generate a model based on Proebsting and Fraser work.

In [2], another kind of pipeline modelling using coloured Petri Nets is presented, but functional behaviour is not taken into account. The simulator cannot execute a real binary code.

In the work presented hereafter, we extend the BuildForwardFSA algorithm to take into account the data hazards (data

dependency), the control hazards and the resources which can be held by external hardware devices that are not modelled using one automaton.

The paper is organised as follow: Section III presents how the pipeline is modelled. The two kind of resources and their usage are described. Instruction classes are introduced. Section IV explains the automaton generation algorithm. In section V, a brief description of HARMLESS ADL with a focus on pipeline description, is given. Section VI presents examples. Section VII presents the simulation result provided by our approach. Section VIII explains the relation between simulation and WCET. At last, section IX concludes this paper.

## III. Pipeline modelling

Sequential pipelines are considered in this paper (i.e. there are no pipelines working in parallel nor forking pipelines). An automaton is used to model the pipeline behaviour where a state of the automaton represents the pipeline state at a particular time (see figure 2).

At each clock cycle, the pipeline goes from one state to another according to hazards. They are classified into three categories:

- *Structural hazards* are the result of a lack of hardware resource;
- *Data hazards* are the result of a data dependancy between instructions;
- *Control hazards* that occurs when a branch is taken in the program.

Control hazard are resolved in the simulator at runtime: instructions that are in the delay slot of a branch instruction are dynamically replaced by NOP instructions, if the branch is found to be taken. Constraints resulting from structural and data hazards are used to generate this automaton and modelled using *resources*.

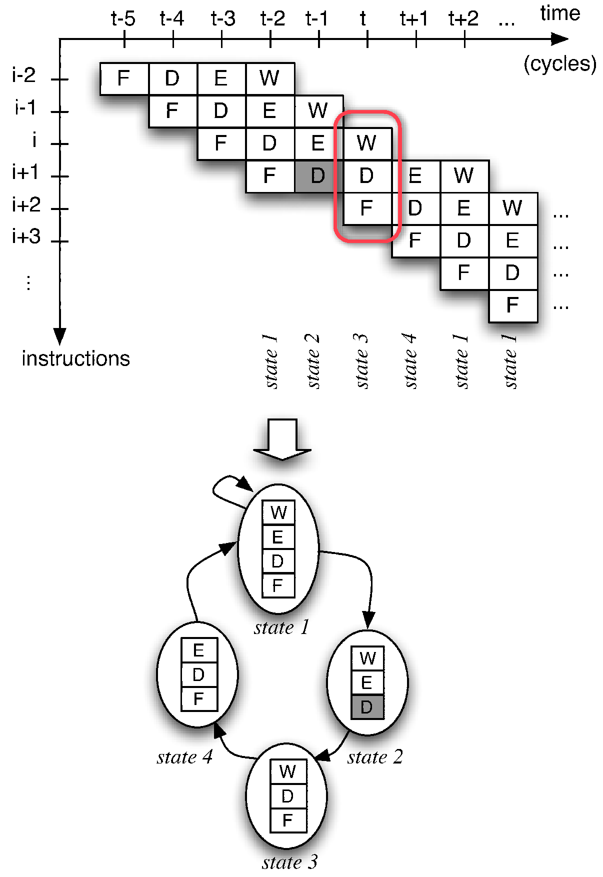

Fig. 2. A state of the automaton represents the state of the pipeline at a given time. In this example with a 4-stages pipeline, three instructions are in the pipeline at time *t*, and the 'D' stage was stalled at time *t-1*. The automaton highlights the pipeline sequence, assuming that there is only one instruction type (this restriction is only made for clarity reason).

### A. Resources

*Resources* are defined as a mechanism to describe temporal constraints in the pipeline. They are used to take into account *structural hazards* and *data hazards* in the pipeline.

Two types of resources are defined, *internal* and *external* resources, that model constraints respectively statically and dynamically.

*1) Internal resources:* can be compared to "resources" in [12]. They model structural hazards.

As the pipeline state is known (*i.e.* the instructions are defined for each stage of the pipeline), then the state of each *internal resource* is fully defined (taken or available). In that case, when the automaton is built (and then the simulator), constraints described by *internal resources* are directly resolved when the set of next states is built.

Internal resources are designed to describe structural hazards inside a pipeline. As these resources are taken into account at build time (*static* approach), no computation overhead is required to check for this type of constraint at runtime.

For example, each pipeline stage is modelled by an internal resource. Each instruction that enters in a stage takes the associated resource, and releases that resource when it leaves. The resulting constraint is that each pipeline stage gets at most one instruction. Another example of internal resource is presented in section VI.

*2) External resources:* represent resources that are *shared* with other hardware components such as timers or memory controllers. It is an extension of internal resources to take into account resources that must be managed *dynamically* (*i.e.* during the simulation). For instance, in the case of a memory controller, the pipeline is locked if it performs a request whereas the controller is busy. Otherwise, the pipeline stage that requests the memory access takes the resource.

If an external resource can be taken by instructions in more than one pipeline stage, a priority is set between stages. For example, at least two pipeline stages may compete for a memory access using a single pipelined micro-controller without instruction cache nor data cache.

One interesting property of the external resources is that it allows to check for data hazards. An external resource is used, associated to a *data dependancy controller*. In this section, we suppose that the first stages of the pipeline are a `fetch` stage, followed by a `decode` stage that reads operands.

The data dependancy controller works as presented in algorithm 1 when instructions in the pipeline are executed. An instruction that is in the `Fetch` stage sends a *request* to the controller to check if all of the operands, that will be taken in the next stage (`Decode`), are available. If at least one of the register is busy (because it is used by one or more instructions in the pipeline), the request fails and the associated external resource is set to `busy`.

When the transition's condition is evaluated to get the next automaton state, the transition associated with this new condition (the transition's condition depends of the state of external resources) will lead to a state that inserts a stall in the pipeline. It allows the instruction that is in the `fetch` stage to wait for its operands, and resolves the data dependancy.

**Algorithm 1**: Instructions and data dependancy controller interaction during simulation.

```
if there is an instruction in the fetch stage and the instruction
will need operands in the decode stage then
    - The instruction sends a request to the controller;
    if at least one register is busy then
        - the request fails: the external resource associated is
        set to busy;
    else
        - the request success: the external resource associated
        is set to available;
else
    - the request success: the external resource associated is set
    to available;
```

### B. Instruction class

To reduce the automaton state space, instructions that use the same resources (internal and external) are grouped to build ***instruction classes***.

The number of instruction classes is limited to $2^{R_{ext}+R_{int}}$ ($R_{ext}$ and $R_{int}$ are the number of respectively external and internal resources in the system), but this maximum is not reached because some resources are shared by all instructions, like pipeline stages, which leads to get a lower number of instruction classes.

## IV. Generating the finite automaton

The automaton represents all the possible simulation scenarios of the pipeline. A state of the automaton represents a state of the pipeline, which is defined as the list of all pair (*instruction classes, pipeline stage*) in the pipeline at a given time. For a system with $c$ *instruction classes*, there are $c + 1$ possible cases for each pipeline stage $s$ of the pipeline (each instruction class or a stall). The automaton is *finite* because it has at most $(c + 1)^s$ states. The initial state is the one that represents an empty pipeline. A transition is taken at each clock cycle and its condition depends *only* on:

- the state of the external resources (taken or available);
- the *instruction class* of the next instruction that can be fetched in the pipeline.

Internal resources are already resolved in the generated automaton and does not appear in the transition's condition. Other instructions in the pipeline are already known for a given automaton state, thus only the next instruction that will be fetched is necessary. This transition's condition is called *basic* condition. As many different conditions can appear to go from one state to another one, the transition's condition is a disjunction of *basic* conditions.

The number of possible transitions is limited to at most $c \times 2^{R_{ext}}$ *for each state* ($c$ is the number of *instruction classes* and $R_{ext}$ is the number of external resources in the system). It implies that there are at most $(c + 2)^s \times 2^{R_{ext}}$ transitions for the whole automaton.

The automaton generator algorithm is presented in algorithm 2 and is based on a breadth-first exploration graph to prevent stack problems. The basic idea of the algorithm is that from the initial state, it computes all the possible basic conditions. From the current state, each possible transition is taken to get the set of next automaton states. The algorithm is then reiterated for each state that have not been processed.

**Algorithm 2**: Generation of the automaton pipeline model.

```
- Create a list that contains the initial automaton state;
- Create an automaton, with the initial automaton state;
while list is not empty do
    - Get an automaton state in the list (start state);
    - Generate all the possible basic conditions (combinations
    of external resources, combined with the instruction class
    of the next instruction fetched);
    for each basic condition do
        - Get the next automaton state (this is a deterministic
        automaton), using the basic condition and the start
        state;
        if the state is not yet included in the automaton then
            - Add the new automaton state (target state) in the
            list;
            - Add the new automaton state in the automaton;
        if the transition does not exist then
            - Create a transition, with an empty condition;
        - Update the transition's condition, by adding a basic
        condition (disjunct);
    - Remove automaton start state from the list;
```

The central function of this algorithm is the one that can *get the next automaton state*, when a basic condition is known. From a generic pipeline model, this function computes the next state of an automaton, taking into account all the constraints brought by resources (internal and external). A pipeline is modelled as an ordered list of pipeline stages, where each pipeline stage is an internal resource. In the algorithm 3, the pipeline stages in the loop are taken from the last to the first, because the pipeline stage that follows the current one must be empty to get a new instruction.

This algorithm allows to detect sink states in the automaton (not shown in the algorithm 3, for clarity reason). A sink state corresponds to a wrong pipeline description.

***Combinatorial explosion*** The increase in complexity of the pipeline to model leads to get a combinatorial explosion. As presented above, the automaton is limited to $(c+1)^s$ states and $(c+2)^s \times 2^{R_{ext}}$ transitions. The maximum size of the automaton increases exponentially with the pipeline depth and the number of external resources, and in a polynomial way with the number of instruction classes. We can discern three types of processors:

- short pipelines (5-6 stages) that can be found in simple processors, generally used in embedded systems (4 stages on the Infineon C167). There is no combinatorial explosion due to the short pipeline;
- processors with a single deep pipeline, called super-pipelines (8 stages with the MIPS R4000). There have both a deep pipeline and many instruction classes. To reduce the complexity of the automaton, These long pipelines can be cut in two parts to genarate two smaller automata that are synchronized using an external resources;
- processors with a pipeline that has many branches: each branch of pipeline may be modelled by a separate automaton as introduced in [12]. Instruction are dispatched among different branches, thus each branch has less instruction classes. This kind of processor can be modelled with several automata. Splitting a complex pipeline into different branches will be studied in future work.

**Algorithm 3**: Function that *gets the next automaton state*, from a given state, with a known basic condition.

```
for each pipeline stage, from the last to the first do
    if there is an instruction class in the current stage then
        if resources required by the instruction class can be
        taken in the next pipeline stage then
            - Instruction class releases resources in the current
            pipeline stage;
            if there is a next pipeline stage then
                - Instruction class is moved in the next
                pipeline stage;
                - Resources required in the next pipeline stage
                are taken;
            - Instruction class is removed from the current
            stage;
```

## V. A brief description of HARMLESS

The HARMLESS ADL allows to describe a hardware architecture using different parts:

- the instruction set;
- the hardware components used by the instructions like memory, registers, ALU, ...;
- the micro-architecture;
- the pipeline;
- the peripherals like timers, input/output, ...

A `component`, in HARMLESS ADL, allows the functional description of a hardware component. It may contain one or many methods. A `method` allows an instruction to access a function offered by a component.

The micro-architecture is described in an `architecture` section. It forms the interface between a set of hardware components and the definition of the pipeline. It allows to express hardware constraints having consequences on the temporal sequence of the simulator. It may contain many `device`s to control the concurrency between instructions to access the same component. Every device in the architecture is related to one component. The different methods of a component can be accessed by a `port` that allows to control the competition during access to one or many methods. A port may be private to the micro-architecture or shared (ie the port is not exclusively used by the micro-architecture). The next section shows two examples that illustrate these notions.

## VI. Experiment

Two examples are presented in this section. The first one is a very simple example which leads to a very small automaton. The second one is a more complex example with a 6 pipeline stages inspired by a DLX simple pipelined architecture [6], using the Freescale XGate instruction set [4].

### A. A simple example

Let's consider an example with a 2 stages pipeline, with only 1 instruction (Nop), 1 component (the Memory) and one temporal constraint (the memory access in the fetch stage). Using the HARMLESS ADL, this pipeline can be described as follow:

```
architecture Generic {
   device mem : Memory {
      shared port fetch : getValue;
   }
}

pipeline pFE  maps to Generic {
   stage F {
       mem : fetch;
   }
   stage E {
   }
}
```

In the description above, two objects are declared: the `architecture` named `Generic` and the `pipeline` named `pFE`.

the architecture contains one device (`mem`) to control the concurrency to access the Memory component. In this description: at a given time, the method `getValue`, that get the instruction code from the memory, can be accessed one time using the `fetch` port. We suppose this access can be made concurrently by other bus masters. So the port is `shared`.

The pipeline `pFE` is mapped to the `Generic` architecture. The 2 stages of pipeline are listed. In stage `F`, an instruction can use the `fetch` port.

A shared port is translated to an external resource `M`. When `M` is available the Memory can be accessed through the `fetch` port. Since there is only one instruction in this example, there is only one instruction class. The instruction class depends on the external resource `M` to enter in stage `F`.

This description leads to generate the 4 states automaton shown in figure 3. For each state, the pipeline state is defined at a given time: 'N' represents an instruction class and '-' represents an empty stage. A transition's condition is composed of an instruction that could be fetched, and the state of the external resource. 'M' and '/M' mean that the external resource is respectively available or busy. An 'X' for the instruction class or an external resource means that the parameter is irrelevant for the transition's condition.

The initial state, on the left, represents an empty pipeline. At the next clock cycle, two transitions may be taken. In both transition's conditions, the instruction class is irrelevant (as there is only one). A transition is taken depending on the state of the external resource. If the resource is busy (transition labelled `X,/M`), the memory controller access is not allowed and no instruction can be fetched, the pipeline remains in the same state. If the external resource is available, an instruction of class 'N' is fetched. The new state of the pipeline is `N-`.

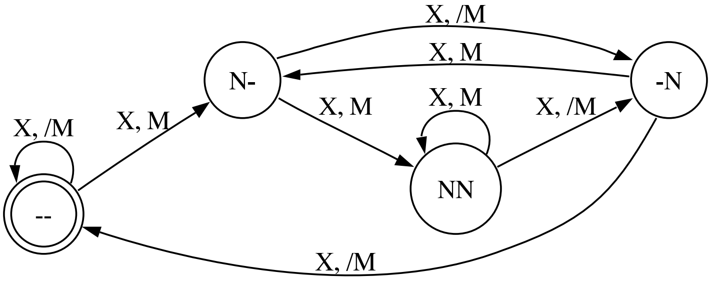

Fig. 3. 4 states automaton generated for the very simple example.

### B. A more realistic example

The second example is more realistic and considers a pipeline with 6 stages. The pipeline is composed of a `Fetch` stage to get the instruction code in memory, a `Decode` stage which decodes the instruction, reads operands and performs branch instructions, 2 `Execute` stages, a `Memory` access stage and a `WriteBack` stage that performs write accesses on the register bank. 88 instructions are available in this example.

The concurrency constraints are:

- the registers file is able to perform 3 reads and 2 writes in parallel;
- an Harvard architecture (separate program and data memories) is used;
- the computation in the ALU requires 2 stages and is not pipelined;

Using the HARMLESS ADL, this 6 stages pipeline can be described as follow:

```
architecture Generic {
   device gpr : GPR {
      port rs1 : read;
      port rs2 : read;
      port rs3 : read;
      port rd1 : write;
      port rd2 : write;
   }
   device alu : ALU {
      port all;
   }
   device mem : Memory {
      shared port fetch : read;
      shared port loadStore : read or write;
   }
   device fetcher : FETCHER {
      port branch : branch;
   }
}
```

```
pipeline pFDEAMWB maps to Generic {
   stage Fetch {
      MEM : fetch;
   }
   stage Decode {
      fetcher : branch;
      gpr : rs1, rs2, rs3, rd1, rd2;
   }
   stage Execute1 {
      alu  release in Execute2 : all;
   }
   stage Execute2 {
   }
   stage Memory {
      mem : loadStore;
   }
   stage WriteBack {
      gpr : rd;
   }
}
```

In the same way, this description declares two objects : `architecture` and `pipeline`. In the `architecture`, many devices are declared. Port `loadStore` allows the access to 2 methods. the keyword 'or' is equivalent to the exclusive or. `loadStore` allows to access the method `read` or `write`. At a given time, if an instruction uses `read` in a stage of pipeline, the second method `write` becomes inaccessible, and the associated resource is set to busy.

Sometimes, using any method of a component makes it unavailable. Instead of forcing the user to give the list of all methods, an empty list is interpreted as a all methods list. Here the `alu` device uses this scheme.

When using a port in a pipeline stage, it is implicitly taken at the start of the stage and released at the end. If a port needs to be held for more than one stage, the stage where it is released is explicitly given. Here port `all` of `alu` is taken in the `Execute1` stage and released in the `Execute2` stage.

As in the previous example, shared ports `loadStore` and `fetch` are translated to external resources. One is associated with the data memory controller. The other one is associated to the program memory controller. A third external resource is used to check for data dependancies during the simulation (see section III-A2).

Other ports may or may not have an associated internal resource. For instance, the `gpr` device offers enough ports to satisfy the needs of the instruction set. So no internal resource is used to constrain the accesses to GPR's methods.

Instruction classes group instructions that use the same resources (internal or external) as presented in section III-B. In this example, 10 resources are used:

- 6 internal resources for the pipeline stages;
- 1 internal resource for the ALU management: `alu`;
- 2 external resources for the memory accesses: `fetch` and `loadStore`;
- 1 external resource to check data dependancies: `dataDep`.

As each instruction depends on the `fetch` resource and the pipeline stages, only three resources can differentiate instructions: there may be a maximum of $2^3 = 8$ instruction classes. We can notice that an architecture without the ALU structural constraint, the maximum of instruction classes would be reduced to $4$. Instructions used in the example (a Fibonacci sequence) are displayed in table I. It uses 5 instruction classes. The 3 remaining instruction classes correspond to impossible configurations.

TABLE I
INSTRUCTIONS USED IN THE EXAMPLE WITH THE XGATE. INSTRUCTIONS THAT USES THE SAME RESOURCES ARE IN THE SAME INSTRUCTION CLASS.

| **opcode** | **Alu** | **loadStore** | **dataDep** | **Inst. class** |
|---|---|---|---|---|
| LDW (load) | | X | X | 1 |
| STW (store) | | X | X | 1 |
| LDH (load) | | X | | 2 |
| LDL (load) | | X | | 2 |
| MOV | | | X | 3 |
| BGT (branch) | | | X | 3 |
| BRA (branch) | | | | 4 |
| ADDL | X | | X | 5 |
| ADD | X | | X | 5 |
| CMP | X | | X | 5 |

This example is executed on an Intel Core 2 Duo @ 2.4 GHz processor with 2 GB RAM. The results are the following: 21.3 s are required to compute the whole simulator. This elapsed time is split in 7.7 s to generate the automaton from the pipeline description, 3.1 s to generate C++ files from the automaton and 10.6 s to compile the C++ files (using GCC 4.0). About 30 MB of RAM are required to generate the automaton. The generated automaton has 43 200 states and 325 180 transitions. 2 030 401 pipeline states were calculated and the generated C++ files represent 4.7 MB in 79 800 lines of code. The simulator generation is fast enough to model realistic processors.

## VII. SIMULATION RESULT

We present in this section the simulation result provided by our tool from the example presented in section VI-B:

- each line represents an instruction that is executed in the pipeline. The instruction that follows a branch instruction (`-`) points out that it is a dummy instruction that is fetched before the branch detection in the decode stage (1). No behaviour is associated with the instruction because the branch instruction is taken;
- each column represents one processor cycle. Numbers from 0 (`Fetch`) to 5 (`Write Back`) represent the pipeline stage number in which the instruction is.

From this short example, we can get both the *functional behaviour* (registers and memory are updated for each instruction) and the *temporal behaviour*. This short example of temporal behaviour shows that:

```
MOV R6,R0         012345
LDL R6,#0x2c       012345
CMP R6,R7           0    12345
BGT 1                    0  12345
-                           012345
MOV R6,R7                    012345
LDW R2,(R5,R6+)               0    12345
LDW R3,(R5,R6+)                    0    12345
ADD R4,R2,R3                            0    12345
STW R4,(R5,R6)                               0    12345
ADDL R7,#0x2                                      012345
BRA -12                                            012345
```

Fig. 4. Execution trace produced by the generated simulator on the Fibonacci sequence

- the four instructions LDW (x2), ADD and STW are data dependent, and only one instruction is executed at each time in the pipeline. No bypass circuitry is included in our description;
- the BGT instruction (line 4) is delayed for 2 cycles because it needs the ALU result from the previous instruction (comparison);

The temporal behaviour is required to compute the WCET of real time applications.

## VIII. From simulation to WCET

The automaton sequencing is directly linked to the processor clock. Thus, the time required to execute an instruction block depends directly on the number of transitions that are taken during the simulation. This property can be integrated in a static WCET approach, for instance using an Implicit Path Enumeration Technique (IPET) approach [11]. In that case, the simulator has in charge to give the execution time of basic blocks on which the IPET algorithm is based to determine the WCET. Additionally, it can give the pipeline state after the execution of the basic block, directly obtained from the last automaton state. Our tool is being integrated with the OTAWA tool [3]: Otawa is a Framework for Experimenting WCET Computations.

On the real example presented in the previous section, it takes 23.9 s to simulate 100 million instructions (requiring 270 million cycles), on an Intel Core 2 duo@2.4GHz. This cycle accurate simulation tool is fast enough to be integrated in such static WCET analysis tools. As a comparison, the Instruction Set Simulator required 6.3 s for the same scenario, but without any temporal information. So the increase factor for computing timing properties is less than 4.

We have focus our study in the pipeline modelling, but other components may significantly influence computation timings, such as caches (branch, instructions or data). Additional delays (that model a cache miss) can be taken into account using external resources, see section III-A2

## IX. Conclusion

This paper has presented the method used in HARMLESS to generate a Cycle Accurate Simulator from the description of a pipeline and its hazards. The method uses an improved version of the BuildForwardFSA algorithm to handle the data and control hazards as well as the concurrent accesses to devices that are not managed statically by the automaton. This improvement is done by using external resources at the cost of a larger automaton. The results look promising. By adding cycle-accurate pipeline simulation to an Instruction Set Simulator, the simulation time is only increased by a factor less than 4. Another important part of this work is the design of an Architecture Description Language HARMLESS [7]. A small part of this language is briefly presented here.. It is a very important part because it considerably simplify the design of a simulator - and so the execution time computation - for a particular target processor. Future work will focus on the minimisation of the automaton, the use of multiple automata to reduce the global size of the tables, and to model and simulate superscalar processors. How to model dynamic superscalar processors, including speculative execution is also planned.

*Abstract*—**This paper presents an overview and the role of certification in safety-critical computer systems focusing on software and hardware use in the domain of civil aviation. It discusses certification activities according to RTCA DO-178B "Software Considerations in Airborne Systems and Equipment Certification" and RTCA DO-254 "Design Assurance Guidance for Airborne Electronic Hardware." Specifically, certification issues in real-time operating systems, programming languages, software development tools, complex electronic hardware and tool qualification are discussed. Results of an independent industry survey done by the authors are also presented.**

## I. Introduction

CERTIFICATION is the hot issue in many industries that rely on the use of computers and software in embedded systems that control safety-critical equipment. The term "certification" in software engineering is typically associated with three meanings: certifying product, process, or personnel. Product and process certification are the most challenging in developing software for real-time safety critical systems, such as flight control and traffic control, road vehicles, railway interchanges, nuclear facilities, medical equipment and implanted devices, etc. These are systems that operate under strict timing requirements and may cause significant damage or loss of life, if not operating properly. Therefore, the society has to protect itself, and governments and engineering societies initiated establishing standards and guidelines for computer system developers to follow them in designing such systems in several regulated industries, including aerospace, avionics, automotive, medical, nuclear, railways, and others.

Consequently, the U.S. government and international agencies that regulate respective industries have issued a number of standards, guidelines, and reports related to certification and/or other aspects of software assurance, such as licensing, qualification, or validation, in their specific areas of interest. Two such guidance documents for civil aviation, DO-178B [1] and DO-254 [2], developed by RTCA, Inc., describe the conditions for assurance in designing software and electronic hardware in airborne systems. The guidelines are adopted by the U.S. Federal Aviation Administration (FAA) and the European EUROCAE, as mandatory for design and implementation of airborne systems.

In this paper we present an overview of current practices in civil aviation industry and discuss issues related to certification of software and hardware to meet the guidance requirements. Section 2 discusses the role of guidance in certification, and sections 3 and 4 review the certification issues according to DO-178B and DO-254, respectively. Section 5 provides some conclusions.

## II. The Role of Standards in Certification

The RTCA, Inc., previously known as the Radio-Telecommunication Committee for Aviation, is a non-profit corporation formed to advance the art and science of aviation and aviation electronic systems for the benefit of the public. The main RTCA function is to act as a Federal Advisory Committee to develop consensus-based recommendations on aviation issues, which are used as the foundation for Federal Aviation Administration Technical Standard Orders controlling the certification of aviation systems.

In 1980, the RTCA, convened a special committee (SC-145) to establish guidelines for developing airborne systems and equipment. They produced a report, "Software Considerations in Airborne Systems and Equipment Certification," which was subsequently approved by the RTCA Executive Committee and published in January 1982 as the RTCA document DO-178. After gaining further experience in airborne system certification, the RTCA decided to revise the previous document. Another committee (SC-152) drafted DO-178A, which was published in 1985. Due to rapid advances in technology, the RTCA established a new committee (SC-167) in 1989. Its goal was to update, as needed, DO-178A. SC-167 focused on five major areas: (1) Documentation Integration and Production, (2) System Issues, (3) Software Development, (4) Software Verification, and (5) Software Configuration Management and Software Quality Assurance. The resulting document, DO-178B, provides guidelines for these areas [1].

RTCA/EUROCAE DO-254/ED-80 [2] was released in 2000, addressing design assurance for complex electronic hardware. The guidance is applicable to a wide range of hardware devices, ranging from integrated technology hybrid and multi-chip components, to custom programmable micro-coded components, to circuit board assemblies (CBA), to en-

The presented work was supported in part by the Aviation Airworthiness Center of Excellence under contract DTFACT-07-C-00010 sponsored by the FAA. Findings contained herein are not necessarily those of the FAA.

tire line replaceable unit (LRU). This guidance also addresses the issue of COTS components. The document's appendices provide guidance for data to be submitted, including: independence and control data category based on the assigned assurance level, description of the functional failure path analysis (FFPA) method applicable to hardware with Design Assurance Levels (DAL) A and B, and discussion of additional assurance techniques, such as formal methods to support and verify analysis results.

## III. Software Certification according to DO-178B

There are three essential categories of software that impact the certification process, due to their different functionality: real-time operating systems, programming languages (with their compilers), and development tools.

### *A. Real-Time Operating Systems*

There is an evident trend to adopt the Real-Time Operating System (RTOS) kernels to increasing scrutiny of regulatory demands. The vendors have quickly "jumped on the bandwagon" and attempted to comply with requirements of DO-178B, claiming certifiability. This includes VxWorks from Wind River Systems [3-5], as well as LynxOS from LynuxWorks, Integrity from Green Hills Software, Linux and RTLinux, RTEMS and microC.

Romanski reports [3] on certification attempts of VxWorks that started in 1999. At the start of the project, the specifications, documentation, and source code were all analyzed to determine which features need to be removed or changed to support the certification. The analysis showed that the core OS could be certified and many of the support libraries could be included as well, with some restrictions, for example on memory allocation/deallocation functions. The process was largely automated, with a database and CD-ROM materials deliverable to the auditors. Further, Fachet [4] reports on the VxWorks certification process to meet the criteria of IEC 61508, and Parkinson and Kinnan [5] describe the entire development platform for a specific version of the kernel VxWorks 653 to be used in the integrated modular avionics.

Not much information, except articles in trade magazines, is available on other real-time kernels. Applying the definition of certification as "procedure by which a third-party gives written assurance that a product, process or service conforms to specified requirements", Moraes et al. [6] use the risk assessment technique FMEA (Failure Mode and Effect Analysis) to create a metric and analyze data for two kernels RTLinux and RTEMS. The analysis shows that if the threshold to certify the software is set to an estimated risk lower than 2.5%, only RTEMS would be certified.

Interestingly, a well described process of selecting an RTOS according to DO-178B guidelines [7] led to a choice of microC/OS kernel, a relatively unknown although well documented RTOS, available for many years but not much advertised. Verification of this RTOS has been contracted to an independent organization and all requirements-based tests have been completed in 2003.

### *B. Programming Languages*

A similar trend among vendors is visible in the area of programming languages and compilers. In an earlier article, Halang and Zalewski [8] present an overview of programming languages for use in safety-related applications up to 2002, focusing on PEARL, originated and predominantly used in Germany. Their observation with respect to DO-178B and other standards is that " because verification is the main prerequisite to enable the certification of larger software-based solutions, only serious improvements aiming to support the process of program verification will be a step in the right direction."

There are essentially three contenders among languages used in safety-critical systems: Ada, C/C++ and Java, for which DO-178B certifiability is claimed. Due to limited space, we only address Ada and C/C++. The most advanced in this respect seems to be Ada, whose certification attempts go back to the eighties, with roots in compiler validation [9].

*Ada and Compiler Certification.* Santhanam [10] answers the question, what does it mean to qualify a compiler tool suite per DO-178B requirements, and lists the requirements on the object code and the development process, estimating the overwhelming cost of providing evidence. Therefore, defensive techniques are advocated, to assure confidence in the compiler correctness with the use of assertions, optimizations turned off, no suppression of run-time checks, avoidance of nested subprograms, etc.

Features of the object model of Ada 2005 are claimed to be "well suited for applications that have to meet certification at various levels" [11]. It meets the safety requirement, which means that programmers are able "to write programs with high assurance that their execution does not introduce hazards" [12], in order "to allow the system to be certified against safety standards", such as DO-178B. However, the common opinion, expressed by the same authors, who actually developed compilers, is that compilers "are far too complex to be themselves certified" [11]-[12].

One version of Ada, which makes use of its severely limited subset, named SPARK, seems to have gained some popularity in safety-critical applications, because of the existence of its formal definition. Amey et al. [13] report on multiple applications of SPARK in industry, including one to the DO-178B Level A.

*The C/C++ Certification Issues.* In the C/C++ world, there have not been many reports on the successful uses of these languages in safety-critical applications that would pass or be aimed at any certification efforts. The languages are being widely criticized for having features not necessarily suitable for safety-critical systems.

Hatton [14] gave an overview of safer C subsets and MISRA C, in particular, following his crusade towards make C a safer language. His premise was that "C is the perfect language for non-controversial safer subsetting as it is known to suffer from a number of potential fault modes and the fault modes are very well understood in general." He analyzed the standards with respect to style related rules, divided further into rules based on "folklore" and those based on known failures. He observes "MISRA C does not address all known fault modes, and does not incorporate the full range of analysis checks that it might."

Despite the enormous popularity of C++, the number of C++ applications in avionics is relatively low, perhaps due to the multitude of known language problems. Subbiah and Nagaraj [15] report on the issues with C++ certification for avionics systems, focusing on structural coverage, whose intent is "to ensure that all output of the compiler is tested during the execution of the requirement-based tests, so as to preclude the possibility that some instruction or data item produced by the compiler is first depended upon during operation.“

*C.Software Development Tools*

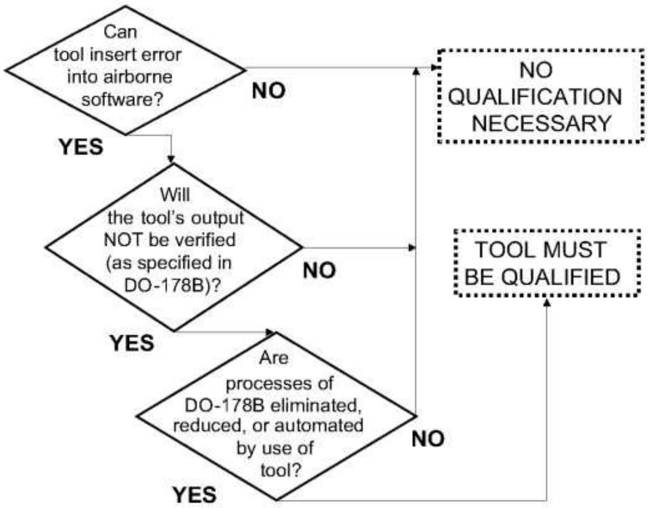
Regarding the use of tools, the FAA recently released a comprehensive report by the current authors on " Assessment of Software Development Tools for Saf ety-Critical Real-Time Systems" [16], which has been summarized in [17] and briefed in [18] regarding tool qualification. The experimental part of this work involved collecting data from the usage of six software design tools (as opposed to verification tools [19]), in a small-scale software development project, regarding four software quality criteria. Assuming these criteria were direct metrics of quality, the following specific measures to evaluate them were defined and used in the experiments:

- usability measured as development effort (in hours)
- functionality measured via the questionnaire (on a 0–5 point scale)
- efficiency measured as code size (in Lines of Code, (LOC))
- traceability measured by manual tracking (in number of defects).
- collection and analysis of results.

Since then, a good number of articles have been written on tool verification, qualification and certification attempts. Regarding software, the tool qualification process must address the requirements of the DO-178B. In particular, the decision must be made, whether tool qualification is necessary (see Fig. 1).

A tool is categorized as the development tool, if it can insert an error in the airborne system, or as the verification tool, if it may only fail to detect an error. In the following, we try to cover issues related to software verification tools.

For verification tool qualification, several interesting papers have been published in the last few years. As Dewar and Brosgol [20] point out in their discussion of static analysis tools for safety certification, a tool as fundamental as the compiler can be certainly treated as a development tool, but also as a verification tool, since compilers "often perform much more extensive tasks of program analysis." As a perfect counterexample they refer to the Spark's Examiner, which is not a usual kind of compiler, because it does not generate code at all. It is only used for checking the program, nevertheless is a part of a software development process. Furthermore, they ask the question should the tools "be certified with the same rigorous approach that is used for safety-critical applications?" Their answer is that this is not practical, and they support this view by stating that even "the compilers themselves are out of reach for formal safety certification, because of their inherent complexity."



Can tool insert error into airborne software?
NO
YES
NO QUALIFICATION NECESSARY
Will the tool's output NOT be verified (as specified in DO-178B)?
NO
YES
TOOL MUST BE QUALIFIED
Are processes of DO-178B eliminated, reduced, or automated by use of tool?
NO
YES

Fig. 1 Tool qualification conditions according to DO-178B [1].

Dewar supports this view in another article [21], elaborating more on the tools for static analysis of such properties as schedulability, worst-case timing, freedom from race conditions, freedom from side effects, etc. He also offers his views on the use of testing, object-oriented programming, dynamic dispatching, and other issues in developing safety-critical systems. He elaborates on the role of the Designated Engineering Representatives (DER's), whose job is to work with software development companies and the certification authorities on the qualification and certification issues, stating that DER's "are the *building inspectors* of the software engineering industry."

In another article, Santhanam [22] describes a toolset called Test Set Editor (TSE), which automates the compiler testing process and working in combination with the Excel spreadsheet and the homegrown scripts in Tcl/tk significantly contribute to cost savings in constructing structural tests to satisfy FAA certification requirements.

A recent FAA report [19] provides an overview of the verification tools available up to the time of report's publication. One tool not covered in this report, Astrée, is described in [23]. It is a parametric, abstract interpretation based, static analyzer that aims at proving the absence of run-time errors in safety-critical avionics software written in C. The authors, representing Airbus, claim that they succeeded on using the tool on a real-size program "as is", without altering or adjusting it before the analysis. Other issues addressed with this tool, although not described in the paper, include: assessment of worst-case execution time, safe memory use, and precision and stability of floating-point computations. In all that, automatically generated code should be subjected to the same verification and validation techniques as hand-written code.

It may be also worth noting that all established tool vendors have been addressing the DO-178B issues for some time now. One such interesting example is McCabe Software [24]. Their document provides a summary of McCabe IQ tool functionality and explains how the tool can be used to support the DO-178B guidelines. Several other vendors do the same, and the current list of safety-critical software tools can be found on the web [25].

## IV. Certification According to DO-254

### *A. Circuitry Compliance with DO-254*

General Issues . With the progress of microelectronic technologies, the avionics hardware is typically custom generated using programmable logic devices. Field Programmable Logic Arrays (FPGA) and Application Specific Integrated Circuits (ASIC) are two leading implementation technologies. More often the devices include also components containing Intellectual Property (IP) chips with dedicated algorithms or custom made solutions resembling general purpose embedded microprocessor's functionality. All this caused an emergence of RTCA document DO-254 [2], which deals with safety assurance for hardware used in avionics and can be used for other safety-critical applications.

What also contributed to the origins of DO-254 is the fact that avionics companies and designers, facing the rigors of DO-178B requirements, began moving device functionality from software to hardware [26]. As reported by Cole and Beeby in 2004 [27], "There are several schemes that have been used by some to take advantage of a current loophole that allows airborne software functionality to be embedded in firmware or programmable devices. This loophole affectively sidesteps the need to adhere to DO-178B as a software standard." Thus, a new document was introduced that forms the basis for certification of complex electronic hardware, by identifying design lifecycle process, characterizing the objectives, and offering means of complying with certification requirements. The Advisory Circular published subsequently by the FAA [28] clarifies the applicability of DO-254 to custom microcoded components, such as ASIC, PLD, FPGA, and similar. In this section, we discuss recent approaches to hardware certification according to DO-254 covered in the literature.

Miner et al. [29] considered compliance with DO-254, before even the guidance was officially released. In a joint project with the FAA, NASA Langley was developing hardware to gain understanding of the document and to generate an example for training. A core subsystem of the Scalable Processor-Independent Design for Electromagnetic Resilience (SPIDER) was selected for this case study.

Hilderman and Baghai [26] offer an advice to manufacturers to map their existing development processes to those of DO-254. The strategy they recommend is "to focus on ensuring correctness at the conceptual design stage and then preserve the design integrity" as one proceeds through the development stages. Each individual vendor or designer faces multiple specific design problems that must be addressed to meet the DO-254 requirements. How they proceed depends on the vendor and the type of problem.

In the white paper of the DO-254 Users Group [30], Baghai and Burgaud offer a package including the following items designed to assist in the qualification process:

- The processes documents, that help define, benchmark and improve the industrial design, verification, validation, and quality assurance processes
- The quality assurance checklists, for reviews and audits, ensuring that each project is compliant with the defined industrial process
- The tools for requirements management and traceability, checking compliance of HDL code with coding standards, HDL code verification, and test suite optimization
- The tools integration into the industrial process, until their qualification (interfaces, report generation for a certification audit, trainings, tools assessment, etc.), and the DO-254 TRAINING by consulting partners.

Cole and Beeby [27] studied DO-254 compliance for graphic processors, considered common off-the-shelf components (COTS), and proposed a multiphase approach to meet DO-254 requirements:

- Provision of a DO-254 COTS data pack to support the use of a given electronic part.
- Provision of a DO-254 compliance statement.
- Process improvement and further analysis.
- Ongoing support for new parts and processes.

Glazebook [31] discussed certification according to DO-254 in the British context, especially the 26 data items listed in the standard as the compliance suite, of which four are required for submission: (a) Plan for Hardware Aspects of Certification; (b) Hardware Verification Plan; (c) Top Level Drawings; and (d) Hardware Accomplishment Summary. He made eight recommendations summarized in the paper.

Barco-Siles S.A. [32] report on the way the company deals with increasing demands related to implementing DO254 causing non-negligible cost, but bringing some advantages. The guidance obliges the supplier to analyze in detail processes, methodologies and tools and to apply a rigorous quality assurance. It also allows the supplier to adapt its set of internal processes to the design assurance level targeted, to optimize efforts while requiring the subcontractor to respect a structured development processes. The resulting products have improved quality and the development cycles are optimized. Verification is focused on design errors, and effort and resources are better distributed. Applying the DO254 gives the assurance that the applicant can obtain from the subcontractor a good level of quality, good documentation, and the ability to reuse the design, if necessary.

When the complexity of designs increases, it is more and more difficult to verify the correctness of circuits and thus their compliance with the specifications. As Karlsson and Forsberg point out [33], "…tests and deterministic analysis must demonstrate correct operation under all combinations and permutations of conditions down to the gate level of the device." To comply with the requirements of DO-254 they developed a design strategy that relies on a semi-formal solution, a hybrid of static and dynamic assertion based verification. They believe that by such independent assessment using their method of tool outputs, the tool qualification will become unnecessary.

EDA Industry Views . Chip and board manufacturers are eager to comply with DO-254, due to their concerns about the market share. Since compliance with the guidance is considered a technological advantage, most of the vendors began changing their development processes towards meeting the DO-254 criteria. Several companies announced their readiness to comply with certification requirements.

Mentor Graphics is particularly aggressive in providing compliance of their products with DO-254. Lange and Boer [34] give an overview of functional hardware verification methodologies, as a part of the design process. They observe that the verification techniques that served well the designs 10-15 years ago are no longer adequate due to a tremendous increase in design complexity and integration. As a consequence, design verification has become a limiting factor in safety-critical systems, with respect to such issues as: complexity, concurrency and metastability. Latest verification techniques are described that handle problems such as state explosion, design traceability and the effectiveness of coverage.

Advanced Verification Methodology (AVM), consisting of constraint random test generation, a total coverage model, design intent specification, and formal model checking, described in [35], has been used on a practical design of FPGA based DMA engine at Rockwell-Collins. The approach based on an open source Transaction Level Modeling (TLM) class library, is vendor neutral and supports SystemVerilog and SystemC standard languages. Due to the open source nature AVM allows code inspections that may be required for certification. Although the project has not been fully completed at the time of this writing, it is believed that AVM helps not only demonstrate that the DO-254 guidelines are followed, but also assists in shortening design cycles.

These verification steps/techniques must be performed in concert with the RTL design, ultimately leading to automatic circuit synthesis [36]. Since automatic synthesis and conversion to gate-level designs is often done with optimizations by the hardware design tools, it may be counterproductive in safety-critical designs, which mandate strict adherence to the guidance. DO-254 defines tool qualification, "to ensure that tools used to design and verify hardware perform to an acceptable level of confidence on the target project." The paper comments on three methods of DO-254 allowed tool assessment: relevant history, independent output assessment, and tool qualification. Since proving relevant history and qualifying the tool are both tedious and expensive processes, requiring the submittal of data, which may not be easily available, the paper suggests the product assessment route to demonstrate that "the hardware item must be thoroughly verified against the functional requirements", thus, the independent tool assessment is not necessary. In the opinion of current authors, the tool output is still an abstract entity, not the hardware item yet, and may contain errors that cannot be detected during verification.

Lee and Dewey [37] shed more light on meeting DO-254 guidance in a form acceptable to the DER, by explicitly proposing:

- requirements management and tracking, with the use of such tools as Reqtify or DOORS
- Register Transfer Level (RTL) code validation, with an automated method to measure RTL to a company standard
- verification process assurance, with the use of AVM, and
- producing design documentation, from requirements, to the RTL code, to the bit streams or Graphic Data System (GDS) II file format.

The mindset of the paper is that "DO-254 is not a burden but a set of guides that helps standardize hardware systems assurance, making flight systems safe."

Aldec and Actel, working in alliance, published some information on their efforts towards making their products DO-254 certifiable. Sysenko and Pragasam [38] outlined their process for airborne systems design assurance which relies on the verification methodology called Hardware Embedded Simulation (HES) and follows two traditional steps: RTL simulation and gate-level simulation. It is a hardware-software simulation platform driven by software that facilitates the implementation of the design in a reconfigurable hardware, such as an FPGA, and then verification of the design functions. Earlier, Land and Bryant [39] presented more details on the process, with MIL-STD-1553 bus chip design as an example to comply with DO-254.

Lundquist in his thesis [40] looked at the problems that arise when trying to DO-254 certify system-on-chip solutions. Since more than 700 Actel FPGAs are used in the Airbus A380 commercial airliner, the Actel Fusion FPGA chip with integrated analog and digital functionality was tested according to the verification guidance. The results have shown that a certification procedure for a standard non-embedded FPGA based safety critical system is possible. However, the question of how these embedded chips could pass certification to be used in safety-critical systems has not been answered.

### B. Tool Certification against DO-254

Since the growing complexity of electronics hardware requires the use of automatic software tools, the DO-254 document also includes a section on tool qualification. It distinguishes between design tools, which can introduce errors into the product, and verification tools, which do not introduce errors into the product but may fail detecting errors in the product. The qualification process tool vendors have to comply with is shown in Figure 2.

Several vendors recently began dealing with tool qualification. Aldec [41] used a sample design of a system containing two connected boards: Aldec HES board (HES-3X3000EX) generating stimuli and collecting results for Design Under Test (DUT) and the second user designed board. The verification process contained three independent stages: simulation, verification, and comparison.

Lange [42] addresses circuit metastability in the context of DO-254 tool certification. Metastability describes what happens in digital circuits when the clock and data inputs of a flip-flop change values at approximately the same time. This

8. Tool is design tool A/B?
9. Design tool qualification
no

Fig. 2 Tool assessment and qualification process according to DO-254 [2].

leads to the flip-flop output oscillating and not settling to a value within the appropriate delay window. This happens in designs containing multiple asynchronous clocks, when two or more discrete systems communicate. Metastability is a serious problem in safety-critical designs as it causes intermittent failures. A comprehensive verification solution is offered by Mentor Graphics 0-In Clock Domain Crossing (CDC) tool. The tool provides an added assurance that the design will function correctly within the intended system. If one has a specific requirement from the customer or a DER to verify the clock domain crossings and identify and eliminate instances of metastability, then one has to use one of the tool assessment methods. Again, the one suggested is the Independent Output Assessment.

Another verification tool from Mentor Graphics, ModelSim, is discussed by Lange [43] in a view of meeting the DO-254 guidance. The paper outlines the exact ten steps to go through the DO-254 assessment and qualification process, as presented in Figure 2. The suggested way to proceed with tool assessment is to avoid qualification by using an independent output assessment method (Step 3 in Figure 2).

TNI [44] presents Reqtify, tool supporting requirement traceability, impact analysis and automated documentation generation which a ccording to DO-254 classification is a verification tool. Prior to the use of the tool, a tool assessment should be performed to ensure that the tool is capable of performing the particular verification activity to an acceptable level of confidence. The assessment is limited to those functions of the tool used for a specific hardware life cycle activity, not the entire tool.

Dellacherie et al. [45] describe a static formal approach that could be used, in combination with requirements traceability features, to apply formal methods in the design and verification of hardware controllers to support such protocols as ARINC 429, ARINC 629, MIL-STD-1553B, etc. A tool name imPROVE-HDL, a formal property checker, has been used in the design and verification of airborne electronic hardware. Reqtify tool has been used to track the requirements throughout the verification process and to produce coverage reports. According to the authors, using imPROVE-HDL coupled with Reqtify gives confidence that the designers can assure that their bus controllers meet the guidelines outlined in DO-254.

### *C.Tool Questionnaire*

To identify issues and concerns in tool qualification and certification, and help understand the underlying problems, we conducted a survey to collect data on the experiences and opinions concerning the use of programmable logic tools as applied to design and verification of complex electronic hardware according to the RTCA DO-254 guidelines. The objective was to collect feedback, from industry and certification authorities, on assessment and qualification of these tools.

The questionnaire has been developed and distributed during the 2007 National FAA Software & Complex Electronic Hardware Conference, in New Orleans, Louisiana, in July 2007, attended by over 200 participants. In subsequent months, we have also distributed this questionnaire to the participants of two other professional events. It has been made available via DO-254 Users Group website ( `http://www.do-254.org/?p=tools` ). As a result of these activities a sample of almost forty completely filed responses was received. Even though this may not be a sample fully statistically valid, the collected results make for several interesting observations.

The survey population, by type of the organization, included the majority of respondents from avionics or engine control developers (65%). Over 95% of respondents have technical background (55% bachelor and 45% master degrees) and over 72% have educational background in electronics. While 97% of respondents have more than three years of experience, 59% have more than 12 years. The most frequent respondents' roles relevant to the complex electronics tools include:

- use of the tools for development or verification of systems (62%)
- managing and acting as company's designated engineering representative (26%)
- development of the tools (2%)
- development of components (12%).

The respondents' primary interest was divided between verification (32%), development (27%), hardware (22%) and concept/architecture (18%).

Considering criteria for the selection of tools for use in DO-254 projects (Figure 3), as the most important have been reported the following: the available documentation, ease of qualification, previous tool use, and host platform, followed by the quality of support, tool functionality, tool vendor reputation, and the previous use on airborne project. Selection of a tool for the project is based either on a limited familiarization with the demo version (50%) or an extensive review and test (40%). The approach to review and test the tool by training the personnel and using trial period on a smaller project seems to be prevailing.

For those who have experienced effort to qualify programmable logic tools (only 14% of respondents), the quality of the guidelines is sufficient or appropriate (62%), so is the ease of finding required information (67%), while the increase of workload was deemed negligible or moderate (80%). An interesting observation concerns the scale of safety improvement due to qualification: marginal (43%), moderate (21%), noticeable (7%) and significant (29%). Similarly, the question about errors found in the tools may be a source for concern: no errors (11%), few and minor errors (50%), significant and numerous (17%). Despite all this, the satisfaction level towards programmable logic tools was high: more than 96% of respondents marked their satisfaction level as 4 out of 5.

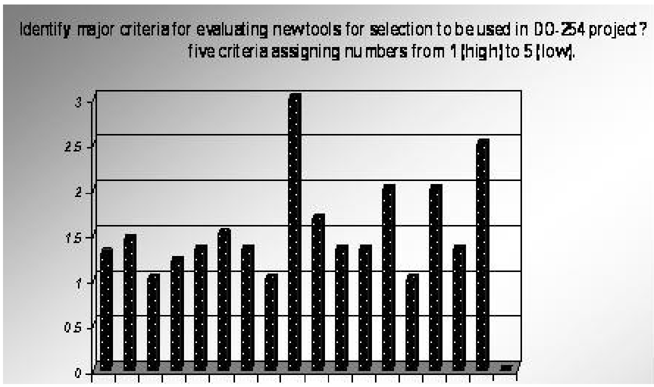

Fig. 3 Tool selection criteria in DO-254 projects (from left to right: vendor reputation, functionality, acquisition cost, compatibility with existing tools, compatibility with development platform, reliability, availability of training, amount of training needed, documentation quality, quality of support, previous familiarity with the tool, performance on internal evaluations, host platform, compatibility with PLDs, previous use on airborne products, tool performance, ease of qualification, other criteria).

Overall, it is obvious that software tools used in design and verification of complex electronics in safety-critical applications should be scrutinized because of concerns that they may introduce design errors leading to accidents. However, the conducted survey indicated that the most important criteria for tool selection are considered to be: available documentation, ease of qualification, and previous tool use, none of which is technical. In this view, work should be done on developing more objective criteria for tool qualification and conducting experiments with tools to identify their most vulnerable functions that may be a source of subsequent design faults and operational errors. Some of the authors specifically point out that the lack of research investment in certification technologies will have a significant impact on levels of autonomous control approaches that can be properly flight certified, and could lead to limiting capability for future autonomous systems.

## V. Summary and Conclusion

The paper makes an attempt to show the role of software certification in development of dependable systems, both from the software and hardware perspective. An important observation is about the increasing role of software tools, which are used to create and verify both software and hardware. An extensive literature review has been presented, focusing on the issues of civil aviation guidance requiring specified level of assurance for the airborne systems, both from the software and hardware perspective.

Both DO-178B and DO-254 guidelines serve industry well and promote rigor and scrutiny required by highly critical systems. However, the relative vagueness of these guidelines causes significant differences in interpretation by industry and should be eliminated. RTCA called a new committee, SC-205, with a charge to revise DO-178B guidance. Possibly, a common ground should be found between RTCA DO-254 and DO-178B guidelines.

***Abstract*—Real-time database management systems (RT-DBMS) are recently subject of an intensive research. Model checking algorithms and verification tools are of great concern as well. In this paper we show some possibilities of using a verification tool Uppaal on some variants of pessimistic concurrency control protocols used in real-time database management systems. We present some possible models of such protocols expressed as nets of timed automata, which are a modeling language of Uppaal.**

## I. Introduction

MANY real-time applications need to store some data in a database. It is possible to use traditional database management systems (DBMS). But they are not able to guarantee any bounds on a response time. This is the reason why so-called real-time database management systems (RTDBMS) emerged.

Research in RTDBMS focused on evolution of transaction processing algorithms, priority assignment strategies and concurrency control techniques. But the research was based especially on simulation studies. Hence at Technical university of Ostrava, Václav Król, Jindřich Černohorský and Jan Pokorný designed and implemented an experimental real-time database system called V4DB [6], which is suitable for study of real time transaction processing. The system is still in further development but some important results were obtained already.

Formal verification is of great interest recently and finds its way quickly from theoretical papers into a real live. It can prove that a system (or more exactly a model of a system) has a desired behavior. The difference between testing and formal verification is that during testing only some possible computations are chosen. Formal verification can prove correctness of all possible computations. A drawback of formal verification is that for models with high descriptive power are almost all problems undecidable. It is important to find a model with an appropriate descriptive power to capture a behavior of a system, yet with algorithmically decidable verification problems.

In this paper we consider so called model checking (see e.g. [3], [8]). This form of verification uses a model of a system in some formalism and a property expressed usually in the form of formula in some temporal logic. Model checking algorithm checks whether the property holds for the model of a system. There are quite many automated verification tools which implement model checking algorithms. Those tools use different modeling languages or formalisms and different logics.

The idea of the research described in this paper came from authors of V4DB. They were interested in using a verification tool on their system. They would like to verify and compare different variants of algorithms and protocols used in RTDBMS. To our best knowledge, there are only rare attempts of automated formal verification of real-time database system. In fact we know about one paper ([9]) only where authors suggested a new pessimistic protocol and verified it using Uppaal. They presented two small models covering only their protocol.

There is not any verification tool intended directly for real-time database systems. We have chosen the tool Uppaal because it is designed for real-time systems. But, it is supposed to be used on so-called reactive systems, which are quite different from database systems. So we need to solve the problem of modeling data records of the database and some other problems. Then we would like to check some important properties of used protocols and algorithms, for example: absence of a deadlock when using an algorithm which should avoid deadlock in the transaction processing, processing transaction with bigger priority instead of transactions with smaller priority and so on.

Big problem of verification tools is so called state space explosion. Uppaal is not able to manage too detailed models. On the other hand, too simple models can not catch important properties of a real system. So we need to find a suitable level of abstraction.

One of the most important and crucial parts of RTDBMS is concurrency control. There were many different concurrency control protocols suggested. In this paper, we will concentrate on variants of a pessimistic protocol called two-phase-locking (2PL). First variant is basic 2PL protocol, then slightly modified version where deadlines are used to abort waiting transactions and finally 2PL – high priority where a

Author acknowledges the support by the Czech Ministry of Education, Grant No. 1M0567.

transaction with higher priority can restart a transaction with a smaller priority. We will show that it is possible to model those protocols, to some level of abstraction, using modeling language of Uppaal. These examples will show possibilities of modeling other similar pessimistic protocols and even some other parts of RTDBMS. The models are inspired by the RTDBMS system V4DB in some way. V4DB is experimental so it has some simplifications which we can use to obtain simpler models yet with important behavior covered (as V4DB has). But it is possible to use ideas shown in this paper for verification of concurrency control algorithms in general.

We will also mention a few simple formula with an Uppaal's answer to show model checking possibilities on suggested models.

## II. Verification tool Uppaal

Uppaal ([2], [4]) is a verification tool for real-time systems. It is jointly developed by Uppsala University and Aalborg University. It is designed to verify systems that can be modeled as networks of timed automata extended with some further features such as integer variables, structured data types, user defined functions, channel synchronization and so on.

A timed automaton is a finite-state automaton extended with clock variables. A dense-time model, where clock variables have real number values and all clocks progress synchronously, is used. In Uppaal, several such automata working in parallel form a network of timed automata.

An automaton has locations and edges. Each location has an optional name and invariant. An invariant is a conjunction of side-effect free expressions of the form $x < e$ or $x \leq e$ where $x$ is a clock variable and $e$ evaluates to an integer. Each automaton has exactly one initial location.

Particular automata in the network synchronize using channels and values can be passed between them using shared variables. A state of the system is defined by the locations of all automata and the values of clocks and discrete variables. The state can be changed in two ways - passing of time (increasing values of all clocks) and firing an edge of some automaton (possibly synchronizing with another automaton or other automata).

Some locations may be marked as committed. If at least one automaton is in a committed location, time passing is not possible, and the next change of the state must involve an outgoing edge of at least one of the committed locations.

Each edge may have a select, a guard, a synchronization and an assignment. Select gives a possibility to choose non-deterministically a value from some range. Guard is a side-effect free expression that evaluates to a boolean. The guard must be satisfied when the edge is fired. Synchronization label is of the form $Expr!$ or $Expr?$ where $Expr$ evaluates to a channel. An edge with $c!$ synchronizes with another edge (of another automaton in the network) with label $c?$. Both edges have to satisfy all firing conditions before synchronization. There are urgent channels as well – synchronisation through such a channel have to be done in the same time instant when it is enabled (it means, time passing is not allowed if a synchronisation through urgent channel is enabled). An assignment is a comma separated list of expressions with a side-effect. It is used to reset clocks and set values of variables.

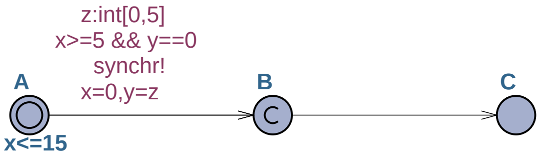

Fig. 1. Graphical representation of a timed automaton in Uppaal

Figure 1 shows how the described notions are represented graphically in Uppaal. There are 3 locations named `A`, `B` and `C`. Location `A` is initial and `B` is committed. Moreover `A` has an invariant `x<=15` with the meaning that the automaton could be in this location only when the value of the clock variable `x` is less or equal 15. The edge between `A` and `B` has the select `z:int[0,5]` – it nondeterministically chooses an integer value from the range 0 to 5 and stores it in variable `z`. This edge also has the guard `x>=5 && y==0`. This means that it can be fired only when the value of the clock variable `x` is greater or equal 5 and the integer variable `y` has the value 0. Data types of variables are defined in a declaration section. Further it has synchronization label `synchr!` and an assignment `x=0, y=z` reseting the clock variable `x` and setting the value of `z` to the integer variable `y`.

Uppaal has some other useful features. Templates are automata with parameters. These parameters are substituted with given arguments in the process declaration. This enables easy construction of several alike automata. Moreover, we can use bounded integer variables (with defined minimal and maximal value), arrays and user defined functions. These are defined in declaration sections. There is one global declaration section where channels, constants, user data types etc. are specified. Each automaton template has own declaration section, where local clocks, variables and functions are specified. And finally, there is a system declaration section, where global variables are declared and automata are created using templates.

Uppaal's query language for requirement specification is based on CTL (Computational Tree Logic, [5]). It consist of path formulae and state formulae. State formulae describe individual states and path formulae quantify over paths or traces of the model.

A state formula is an expression that can be evaluated for a state without looking at the behavior of the model. For example it could be a simple comparison of a variable with a constant `x <= 5`. The syntax of state formulae is similar to the syntax of guards. The only difference is that in a state formula disjunction may be used.

There is a special state formula `deadlock`. It is satisfied in all deadlock states. The state is deadlock if there is not any action transition from the state neither from any of its delay successors.

Path formulae can be classified into *reachability*, *safety* and *liveness*. Reachability formulae ask if a given state formula is satisfied by some reachable state. In Uppaal we use syntax `E<>` $\varphi$ where $\varphi$ is a state formula.

Safety properties are usually of the form: “something bad will never happen”. In Uppaal they are defined positively: “something good is always true”. We use `A[]` $\varphi$ to express, that a state formula $\varphi$ should be true in all reachable states, and `E[]` $\varphi$ to say, that there should exist a maximal path such that $\varphi$ is always true.

There are two types of liveness properties. Simpler is of the form: “something will eventually happen”. We use `A<>` $\varphi$ meaning that a state formula $\varphi$ is eventually satisfied. The other form is: “leads to a response”. The syntax is $\varphi$ `-->` $\psi$ with the meaning that whenever $\varphi$ is satisfied, then eventually $\psi$ will be satisfied.

The simulation and formal verification are possible in Uppaal. The simulation can be random or user assisted. It is more suitable for verification whether the model corresponds with the real system. Formal verification should confirm that the system has desired properties expressed using the query language. There are many options and settings for verification algorithm in Uppaal. For example we can change representation of reachable states in memory. Some of the options lead to less memory consumption, some of them speed up the verification. But improvement in one of these two characteristic leads to a degradation of the other usually.

For more exact definitions of modeling and query languages and verification possibilities of Uppaal see [2].

## III. Pessimistic protocol two-phase-locking

In this section we suggest one model of pessimistic concurrency control protocol. Of course, it is not the only one possible.

Two-phase-locking protocol is based on data locks. Before access to data the transaction must have a lock. All locks granted to a transaction are released after all operations of this transaction are executed. There are two types of locks—for read and write. The first is used for the operation select and the latter for update, delete and insert. Either one write lock or several read locks can be on a particular record (for simplicity, in our model will be only one read lock allowed for one record). If a transaction can not get a lock for a request it is placed in a queue of this record. After an existing lock is released, a new lock is granted to the first transaction in the queue.

The suggested model consists of several timed automata created using two templates. One type of automata represents data records in a database. The template is shown on the Figure 2. Each record automaton has an integer ID stored in `rec_id`. There are three locations corresponding to two types of locks and to an unlocked state. Channels `rd_ch[x]` and `wrt_ch[x]` are used for requests for read and write locks on record $x$. Channel `rls_ch[x]` is for release (unlock) request.

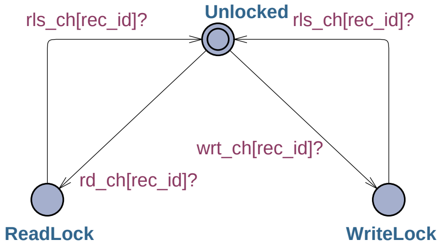

Fig. 2. Automaton representing a record in a database

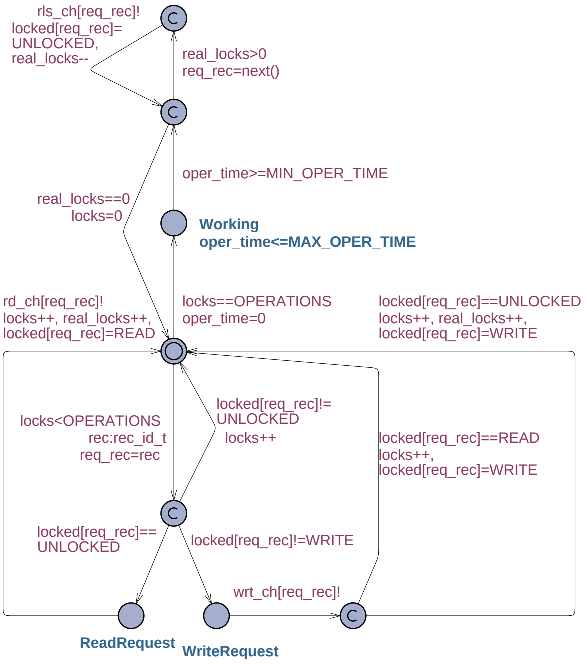

Fig. 3. Transaction automaton for two-phase-locking protocol

The second template shown on the Figure 3 is intended to create automata representing active transactions in the system. In V4DB is a number of active transactions bounded (predispatcher module of RTDBMS holds the queue of incoming transactions and passes them to a dispatcher in such a way that it avoids overloading). So it is possible to represent one active (i.e. currently in execution) transaction as one automaton. After successful end of a transaction the same automaton represents some other transaction.

For simplicity, all transactions are supposed to have the same number of operations (given by a constant `OPERATIONS`). Each operation accesses one record (i.e. needs one lock). A type of operations and an accessed record is for a real RTDBMS in fact random because it is determined outside the RTDBMS. We do not need to model concrete operations, only locks. The record is chosen nondeterministically using select `rec:rec_id_t`. The operation is then immediately (due to a committed location) chosen nondeterministically by using one of three possible edges. If a transaction owns the demanded type of a lock on the accessed record, it does not asks the lock again. If it has only a read lock, it can ask change to a write lock. In the array `locked` is stored the information about owned locks, variable `locks` contains the number of operations for which locks are gained and `real_locks` the number of records locked by this transaction.

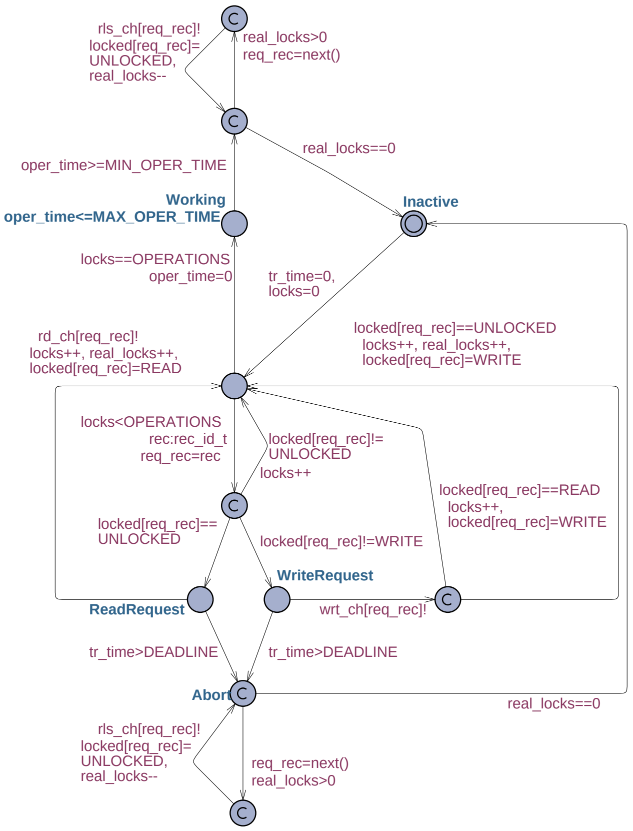

Fig. 4. Transaction automaton for modification of two-phase-locking protocol

If the transaction has all necessary locks, the automaton is in a location `Working`. This represents execution of database operations. The time spent in this location is bounded by constants `MIN_OPER_TIME` and `MAX_OPER_TIME`. After the execution, all locks are released instantly (using committed states and edges between them).

The described model simulates basic variant of 2PL protocol where a deadlock can arise when some transactions wait mutually for locks granted to other transactions. A small modification where transactions exceeding their deadline may be aborted can solve the problem with deadlocks.

## IV. Modification of a model of two-phase-locking protocol

A template for database record automata remains the same as in the previous model (Figure 2). A changed transaction automata template is shown on Figure 4.

There is a clock variable `tr_time` added. It measures time from the beginning of transaction execution. If a transaction is waiting for a lock and it reaches its deadline (for simplicity same for all transactions given by a constant `DEADLINE`), it can be aborted. This means that all locks previously granted to this transaction are released.

We can use Uppaal to verify that this solution is really sufficient to avoid deadlock. For Uppaal, reachability properties are more suitable. So the formula

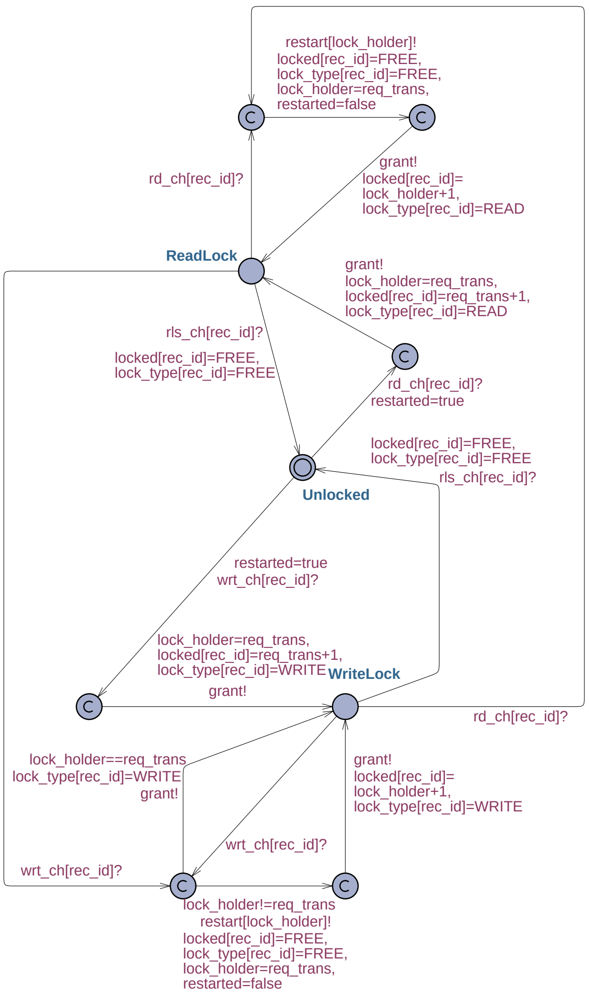

Fig. 5. Automaton representing a record in a database for 2PL-HP protocol

```
E<> deadlock
```

means that deadlock is reachable in the model and this property is not satisfied. Hence it is verified that the system is deadlock-free.

## V. Pessimistic protocol two-phase-locking high-priority

The last modification of our model is for a protocol two-phase-locking high-priority (2PL–HP). If a lock is requested by a transaction with a higher priority the transaction with a lower priority holding this lock may be restarted.

For this model we change both automata templates. A new template for database record automata is depicted on Figure 5.

In the global declarations are defined two arrays – `locked` and `lock_type`. The first one contains information about transactions holding locks for particular records and the latter one contains information about types of particular locks. `lock_holder` is a local variable of one record automaton used for the ID of transaction holding the lock on this record. As almost all is chosen nondeterministically (including the order of activating particular transaction automata), we can model priorities using ID numbers of transaction automata – higher ID means higher priority.

If the automaton is in the location Unlocked, all requests passed through channels rd_ch and wrt_ch are answered immediately through a channel granted and informations about this lock are saved to above mentioned arrays and variable.

If the automaton is in the location WriteLock or ReadLock and a new request arrives, it has to restart a transaction holding the lock (priorities are checked before the request in a transaction automaton). Restarted transaction $x$ is contacted using a channel restart[x]. Then the lock is granted to a requesting transaction using channel grant. If a write lock is requested from the location ReadLock, there is a possibility to grant it without any other activity (except for the change of a type of lock in lock_type array). This is done when requesting transaction (req_trans) is the same as the current holder of the read lock (lock_holder).

The transaction automata template has to be changed as well. The modified version is depicted on the Figure 6.

There are added edges leading to a new location Restart from all locations where an automaton can be during passing of time. All those edges have synchronization label restart[trans_id]. In this way a transaction (with an ID stored in a variable trans_id) can be restarted anytime by a record automaton. In the location Restart all previously gained locks are released and the waiting transaction with higher priority is notified using global boolean variable restarted. A function next() returns the smallest ID number of a record on which is the transaction actually holding a lock.

Requests for locks are guarded. A requested record (specified by the variable req_rec) has to be unlocked or locked by a transaction with smaller priority. It comes handy to use $0$ (constant FREE is defined as $0$) in the array locked[] for unlocked records and ID of transaction automaton (i.e. the priority of transaction) plus one for a lock holder. Than the guard

```
trans_id+1 > locked[req_rec]
```

is true whenever the lock on req_rec is hold by a transaction with a smaller priority or this record is unlocked.d by a transaction with a smaller priority or this record is unlocked.

As in the previous case, although for this model Uppaal can verify that it is deadlock-free. We can use the same formula

```
E<> deadlock
```

and the answer is negative (i.e. no deadlock is reachable).

Furthermore we can check e.g. if the transaction with the highest priority could be possibly restarted. The number of transaction automata is given using a constant TRANSACTIONS. Hence the greatest ID number (this means priority too) is TRANSACTIONS-1. The formula is

```
E<> Transaction(TRANSACTIONS-1).Restart
```

and it is not satisfied, i.e. this transaction could not be restarted. For all other transactions $x$ the formula

```
E<> Transaction(x).Restart
```

is satisfied.

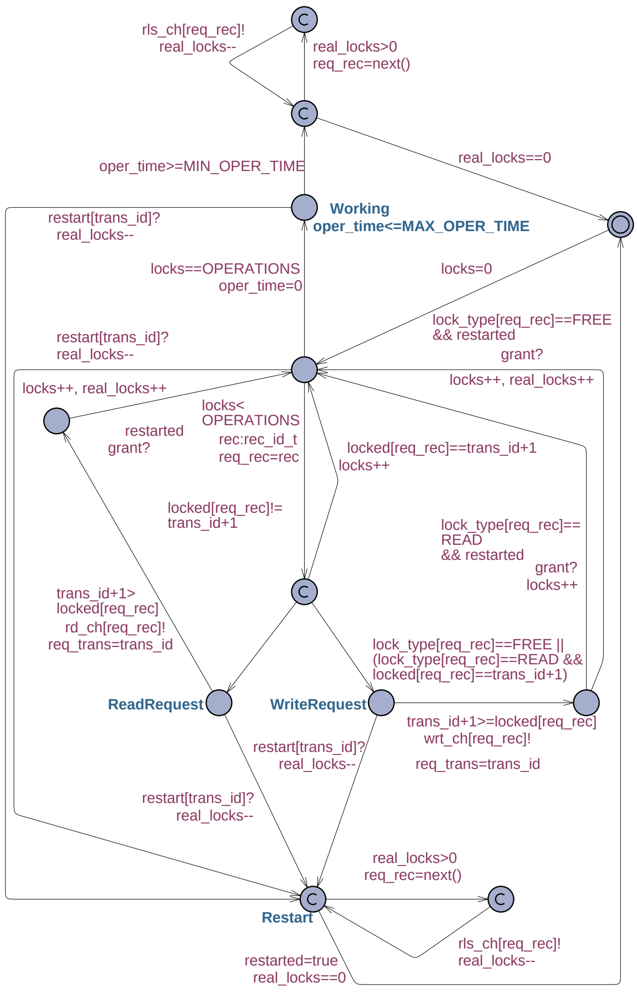

Fig. 6. Transaction automaton for 2PL-HP protocol

## VI. Conclusion

In the previous sections, several timed automata were shown. They form models of three variants of pessimistic concurrency control protocols used in real-time database management systems. Of course, this were not the only possible models. The purpose was to show that some important aspects of the real-time database system such as a concurrency control can be modeled using such a relatively simple model as nets of timed automata are. The models can be extended in many different ways to capture more behavior of those protocols and thus allow many properties to be described as a formula in the logic of Uppaal and then checked using its verification algorithms. Even on presented models (without any extensions or modifications) different properties have been checked and some simple samples of them were presented in this paper.

Some properties can not be expressed using Uppaal's modification of CTL. The possible solution to this problem is to try some other verification tool with other query language.

Other parts of real-time database system or other concurrency control protocols can be modeled too. For example priority assignment algorithms have significant influence on performance database management system. This is our potential future work.

***Abstract*—The increase of railway traffic efficiency and flexibility requires new real-time scheduling and control methods. New charter trains have to be added continuously without disturbing the other (periodic) train moves or decreasing the safety conditions. A distributed method to schedule new trains such that their real-time constraints are fulfilled is presented. The trains have timelines to meet and hence the deadlines are extracted taking into account the included laxity. The trains have pre-established routes specifying the stations and required arrival times. The paths containing the block sections from one station to another are dynamically allocated without leading to deadlocks.**

## I. Introduction

### A. Justification of the Problem

RAILWAY networks can solve many of the transportation problems raised by modern society. Railway traffic improvements involve higher flexibility, speed and density. Besides the regular trains (with fixed routes and timetables), new charter trains have to be dynamically accepted without losing the safety and disturbing the other train schedules.

Early conventional railway traffic control has been focused on safety and scheduling train arrival times such that they can be met. Train traffic was of very low density and its efficiency was based on long trains. To avoid train delays, their rates were low and the train speeds were much under their capacities so that the timetable could be fulfilled. Such systems were inflexible and the railway resources were underused.

Railway traffic is described as an emerging network embedded real-time application with long and short reaction time magnitudes. The long durations of event reactions allow the usage of expensive scheduling algorithms that are not accepted in many distributed real-time control applications. The short reaction times involve decisions to be taken under corresponding time constraints.

The railway traffic control system is a dynamic one that operates in an environment with dynamically uncertain properties that include transient and resource overloads, arbitrary arrivals, arbitrary failures and decrease of traffic parameters.

Unlike classical real-time control applications that usually concern only the response times to meet the deadlines, railway traffic involves the reasoning about end-to-end timelines and the reaction to events such that the global traffic system fulfills the time requirements. Despite many uncertainties, the control system is expected to guaranty that all the trains behave according to timelines.

Due to the large dimension of railway networks, the centralized control is not appropriate in the current circumstances because of the need of safety, the communication delays, the complexity of the system and the difficulties to get the right control decisions in time. These are the main reasons for developing autonomous decentralized control systems for railway traffic.

Global train traffic planning is a possible approach of the current problems. A set of trains with their routes and initial departure times is given. The feasible solution provides the train arrival and departure times at the railway stations contained in the given routes. The solution is usually obtained through large system simulation and use of the minimization of different criteria. At this level, train traffic control refers to sending signals such that all the train timetables are fulfilled in all the railway stations.

A train traveling from one point to another involves some dependent real-time activities. The train crossing an interlocking performs an activity directly controlled by the control system. The traveling from one interlocking to another is usually free movement. Some traffic lights can be added to split the long track lines into smaller block sections to increase the track utilization. In this case, a safe policy requires that each block section contains only one train at a time and between each pair of trains a non occupied block section is compulsory. Using Global Positioning System (GPS) and the wireless communication some moving block sections can be implemented. This can lead to higher track utilization, but traffic safety is based on GPS and wireless communication system reliability.

Traffic system goals are:

- to minimize traffic cost;
- to maximize traffic system throughput
- to fulfill train timing requirements;
- to guaranty system safety;
- to minimize fault effects on train schedules and
- to sustain railway maintenance.

### B. Related Work

The basic principles of railway traffic control are given in [1]. These include the interlocking usage, resource management and dividing the railway network into different parts. The assessment of scheduling is performed by the capability of the schedule to meet the needs of customers and the capabilities of the trains to recover the delays according to their timetables.

The train deviations from the scheduled timetable should be removed during the operation [2].

New trends of train traffic control and management started since 1997 [3]. An autonomous decentralized train control and management system is proposed to attain both the real-time properties for train control such as the real-time traffic and non-real-time properties for train management.

A single delayed train can cause a domino effect of secondary delays over the entire network, which is the main concern of planners and dispatchers [4].

Train scheduling implementations are:

- *off-line scheduling* when all the train arrival times and departure times are calculated before the train starts. The trains behave exactly as they were planned. No unexpected event happens and no new train can appear.
- *on-line scheduling* when the scheduling is performed during the train traffic operation. Some trains have variable delays, unexpected events happen, and new train scheduling requests are required and accepted during the operation.

Some train scheduling approaches are based on:

- distributed artificial intelligence (using trackside intelligent controllers [5]). This kind of allocation of function can optimize the use of resources, reduce complexity and enhance the reliability and availability of the traffic system.
- heuristics methods (as genetic algorithms [6] or ant colony systems [7]). The NP-hard problem complexity with respect to the number of conflicts in the schedule is avoided by generating random solutions and guiding the search.
- auction-based [8]. Each train is represented by an agent that bids for right to travel through a network from its source to destination.
- interactive scheduling [9]. Interactive applications are used to assist planners in adding new trains on a complex railway network. It includes many trains whose timetables cannot be modified because they are already in circulation.

An improvement can be obtained using the GPS and wireless communication between train engine and local control center [10]. Some distributed signal control systems based on the Internet technology are also used [11].

Formal development and verification of a distributed railway control system are performed applying a series of refinement and verification steps [12].

The distributed train scheduling problem has some similarities with distributed software job scheduling [13], [14]. Both have to fulfill real-time constraints relative to finishing time, communication requests and resource management. The concept of collaborative scheduling is also applicable. The problem of the railway interlocking scheduling has some common features with independent scheduling of each node of a distributed software system. Each node constructs its local schedule using only local information. The lack of global information makes it impossible for a node to make a globally optimal decision. Thus it is possible for a node to make a scheduling decision that is locally optimal in terms of the utility that can be accrued to the node, but compromises global optimality. The collaborative scheduling is a paradigm for systems that can withstand its large overhead.

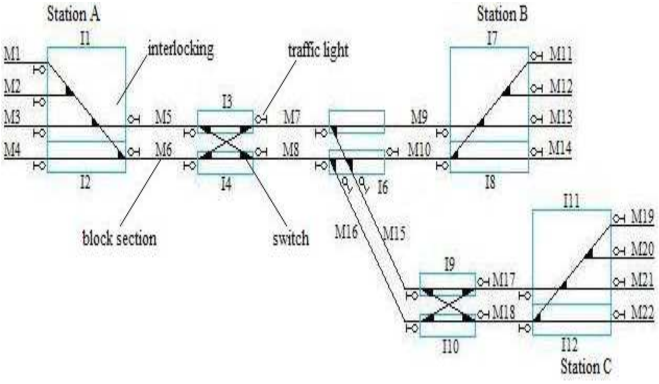

Fig. 1. The railway network structure

## II. Structure and Objectives

### A. Railway Structure

Figure 1 represents a railway network between three stations. On the graph are represented the traffic lights and the switch points. The interlockings are marked by I1, , I12. M1,, M22 denote the block sections controlled by managers. The train movements are controlled by traffic lights and switch points.

An *interlocking* is an arrangement of neighbor interconnected sets of (switch) points and (traffic light) signals such the train movements through them is performed in a proper and safe sequence.

Generally, a *train schedule* is a designation of train description, day, route, speed, arrival and departure times of a train. The train schedule also contains the station dwell times. Some other train stops are required if the necessary track lines are not available when the trains reach the interlocking.

Figure 2 shows a train trajectory with a variable laxity. The notations are:

- *ea* for earliest arrival time;
- *la* for latest arrival time;
- *er* for earliest release (exit) time and
- *lr* for latest release (exit) time.

The objective is to schedule the train move such that it arrives at the next (destination) point between earliest and latest arrival time.

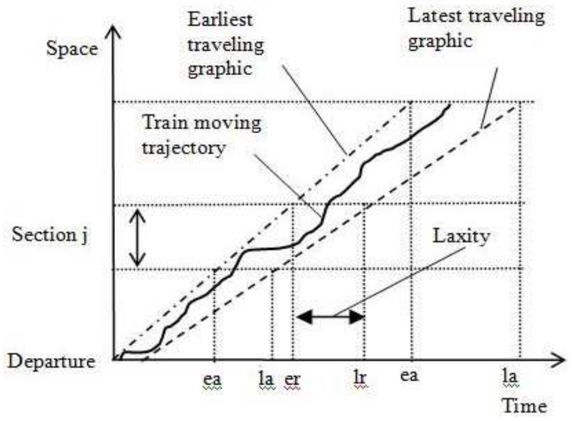

Fig. 2. Train traveling diagram with variable laxity time

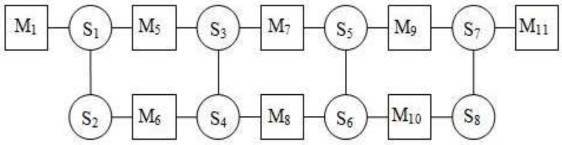

Fig. 3. Distributed scheduling structure

The control decisions take as a target to lead the train such that it reaches the earliest arrival time. The performance evaluation of the system behavior considers that the control fulfills the requirements if all the trains arrive before their specified latest arrival times. If the laxity time is not consumed during a block section or in front of a switch it is added and available to the next sections.

A similar case can be constructed such that the laxity time remains fixed on each section. The train move on a section has to recover the laxity time consumed on the previous one.

In both cases of policy decisions, the laxity time provides the deadline of train behavior together with the earliest arrival time.

### B. *Traffic Control Objectives*

The current study refers to finding a train path starting at a given time, the schedule and the control between two neighbor stations such that the global planned times are fulfilled. This means to find a path from one railway station platform (or block section) to the neighbor railway station platform and the necessary resources (block sections and interlockings). The train traffic control between the neighbor stations means to apply the schedule on-line. The traffic light and switch (point) signals are applied according to the trains current positions and schedules.

## III. Distributed Scheduling

### A. *Architecture of Distributed Scheduler*

Figure 3 represents the software components involved by a train traveling path scheduling. The section managers are denoted with $M_1, \ldots, M_{11}$. $S_1, \ldots, S_8$ represent the interlocking schedulers.

The distributed scheduling is performed by collaboration of train agents, interlocking schedulers and block section managers. The agents have information about the possible paths and expected timetables. For some (charter) trains an acceptable solution is such that the mentioned trains reach the destination as soon as possible.

The interlocking schedulers allocate their resources on-line when the trains approach the interlocking; meanwhile the block section managers allocate the resources off-line (before the trains start their travel from one station to another). An agent asks a scheduler to reserve its controlled interlocking for a specified duration during a given time interval. The scheduler grants it only if the requested task does not delay unacceptably the already scheduled trains, such that the last ones miss their deadlines.

### B. *Agent Behavior*

The train agent's goal is to get a path that fulfills the timing requirements from a railway station platform or block section to another neighbor station.

The agent has to solve a local problem defined by the current train position, departure time, next station block section and arrival time. The planned duration has included, besides the necessary moving time, a laxity time used to compensate the waiting (delay) times involved by crossing of interlockings.

There are two train agent behaviors (approaches):

- In the first one the train agent asks all the schedulers and managers of the possible paths (*listOfPaths*) from the departure station to the neighbor station to accept the train moves. The train agent chooses the best schedule analyzing the schedulers and managers responses.
- In the second one the train agent demands the move specifying the train parameters only to the first scheduler. This is responsible further on to get all the possible paths from departure to neighbor destination. The train agent gets the possible schedules and chooses the best of them. It announces the neighbor scheduler about the chosen path. The neighbor scheduler announces further its neighbor involved components in the path about the firm reservation.

The first approach involves a transaction where the train agent (algorithm) takes a list of possible paths, the start time and the laxity. Using the schedulers and the managers it fills the list of paths with times. Finally, it chooses the best path and announces the scheduling participants about that.

The following notations are added:

- *is* for train input speed at the arrival time at the entrance in the interlocking;
- *os* for train output speed at the exit from the interlocking;
- *st* for train start time;
- *Lx* for laxity time;
- *C* for train worst case crossing time of the interlocking;
- *dd* for absolute deadline.

*Agent algorithm* (first approach):

```
input: trainParameters, trainRoute, Lx;
input: currentStation, listOfPaths;
input: listOfSchedules;
output: trainSchedule;
Initialization: listOfSchedules = extend(listOfPaths);
currentSection=getCurrentSection();
ea=st; la=st+Lx;
is=0;
for all paths from listOfPaths do
    choose an unvisited path;
    while (next) choose the next component as next; do
        (er,lr,os)=next.request(trainParameters,ea,la,Lx, is);
        if (er==0) then break;
        else ea= er; la=lr; is=os; fill in the listOfSchedule;
    end while;
end for;
choose the bestPath from the listOfSchedule;
notify all the participants;
return bestPath as the train schedule;
```

The laxity of traveling from one station to the neighbor station is distributed uniformly to all the paths sections. During traveling from one section to another, if the laxity was not consumed it can be added to the next section.

### C. Scheduler Behavior

Each interlocking is controlled by a scheduler. This can respond to another software component if a new train $T_k$ can be scheduled during a given time interval $[T_k.ea, T_k.la]$ (where ea is the earliest arrival time and la is the latest arrival time of the train $T_k$ at the entrance of the interlocking) without unacceptably delaying the already scheduled trains. If any train is scheduled such that the finishing time of crossing the interlocking is longer than the deadline, then the schedule of the train set is not feasible. A new train can be added to be moved through interlocking only if the schedule of the all train sets with the arrival time intervals overlapping is feasible.

The train $T_k.dd$ deadline of crossing through interlocking is given by:

$$T_k.dd = T_k.ea + T_k.Lx \tag{1}$$

*1) Feasibility analysis:* The worst case for the feasibility analysis is when all the trains of a set arrive simultaneously as close as possible to their deadlines.

Let $t_x$ be the latest time when the trains of a given set can arrive at the same time.

$$t_x = \sup_t \bigcap_k T_k.AI \tag{2}$$

where $T_k.AI = [T_k.ea, T_k.la]$ is the arrival time interval of the train $T_k$ at the entrance of an interlocking. The time $t_x$ is the latest arrival time of any train contained in the intersection of arrival intervals of the considered set.

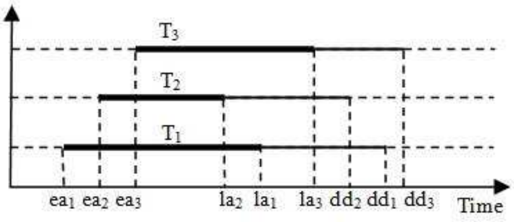

Fig. 4. Train arrival intervals

Figure 4 shows the arrival intervals of three trains $(T_1, T_2, T_3)$ with overlapping arrival time intervals. For this example $t_x = la_2$.

Jackson's rule states: ”Given a set of n independent tasks, any algorithm that executes the tasks in order of nondecreasing deadlines is optimal with respect to minimizing of the maximum lateness [15].”

The feasibility test is:

$$\forall i = 1, ..., n; \sum_{k=1}^{n} T_k.C \leq T_i.dd \tag{3}$$

The previous formula is used off-line to feasibility test analysis. This test has to be applied for all train sets that overlap with the new train added to schedule.

The scheduler uses for on-line traffic control the earliest deadline first (EDF) algorithm. That means if more than one train arrives at the same time, the train with the earliest deadline gets first the right to cross the interlocking. Taking into account that the train deadlines are fixed, the algorithm can be applied on-line using fixed priorities.

The list *scheduledQueue* contains elements with the attributes: *trainIdentifier* $T_i, T_i.ea, T_i.la, T_i.dd, T_i.C.$

For evaluation of the worst loading of an interlocking by a train set with the overlapping arrival intervals, the following formula can be used:

$$load = \frac{\sum\limits_{k=1}^{n} T_k.C}{\sum\limits_{k=1}^{n} (T_k.dd - t_x)} \tag{4}$$

For the reason of robustness a path with smaller load factors of the contained interlockings is preferred. On the other side, if the load is small, there is a greater possibility to obtain a feasible scheduling if a new train agent demands the move through interlocking.

*2) Scheduller Algorithm:* The following notations are added:

- *Cmin* for the minimum crossing time of the interlocking;
- *Cmax* for the maximum crossing time.

*Scheduler grant algorithm of an interlocking:*

```
input: trainParameters;
input: ea, la, Lx, is;
input: scheduledQueue;
input: interlockingParameters;
```

```
output: er, lr, os;
output: feasibility, load;
Initialization: load=0; lr=0;
calculate the best case crossing time Cmin using
  trainParameters and interlockingParameters;
er = ea + Cmin;
calculate the worst case crossing time Cmax and os
  as the maximum speed at the exit of the interlocking
  using trainParameters and interlockingParameters;
find all the train sets with arrival intervals that
  overlap with the arrival interval of the new train;
for all train sets do
    calculate the worst case arrival time $t_x$ of the
      trainSet using formula (2);
    dl =add the worst case crossing time Cmax of
      all trains from trainSet;
    temp = la + Cmax + dl;
    if the formulae (3) are fulfilled with C = Cmax
        then feasibility = true;
        else feasibility = false; break;
    ld = $(\Sigma_i T_i.C)/(\Sigma_i (T_i.dd - t_x)$;//formula (4)
    if (load $\prec$ ld) then load=ld;
    if (lr $\prec$ temp) then lr = temp;
end for;
return er, lr, os, feasibility, load;
```

### D. The Scheduling Improvement

In the presented scheduling algorithm, if a train with lower priority arrives with a very short duration earlier than a train with higher priority, the first one gets the right of crossing. This is inconvenient if the train global priorities express the operator's desires that some trains have to use the interlocking before the others when they arrive almost in the same time.

An algorithm improvement can be: if a lower priority train arrives before a higher priority train, and the first train cannot cross the interlocking before the higher priority train arrival, but the first one can be delayed without missing the timing constraint, the interlocking has to be blocked until the higher priority train arrives and then the EDF algorithm is applied.

An oracle construction can be performed based on GPS or installing detectors on the block sections and estimating the arrival time at the interlocking based on the train current speed. That leads to know in advance the train arrival times during a specified period of time.

Let $T_i.at$ be the arrival time of the train $T_i$ and $B$ the blocking time of the interlocking until the higher priority train arrives. The test of scheduling feasibility is:

$$\forall i = 1, ..., n; T_i.at + B + \sum_{k=1}^{n} T_k.C \leq T_i.dd \qquad (5)$$

The trains can accept different blocking times given by the formula:

$$B_i = T_i.at - T_i.at - \sum_{k=1}^{n} T_k.C \qquad (6)$$

TABLE I
BLOCK SECTION - STATE TABLE

| Time | Solicitor | State |
|---|---|---|
| 0 | $Train_x$ | occupied |
| 1 | $Train_y$ | reserved |
| 2 | $Train_y$ | reserved |
| 3 | - | free |
| 4 | $Train_z$ | requested |
| 5 | $Train_z$ | requested |
| ... | ... | ... |

This acceptable blocking time depends on the train arrival time and its deadline.

Trains with higher priorities usually have higher speed and the proposed improvement involves that a higher priority train can cross the interlocking without waiting. That makes possible that a higher priority train needs shorter laxity time such that the feasibility scheduling test to be fulfilled. This improvement can be used to diminish the unexpected delay of a train due to some faults.

### E. Manager Behavior

The resource manager has the task to reserve on the train agent's request the block section and to maintain the current state of the resource. A block section could have the following state: free, requested, reserved and occupied in every minute. The manager gets information from sensors about occupancy and clearance of the section. The section state is updated at every minute.

The resource manager keeps the Block Section - State Table with reserved periods of the resources for each train.

The train agent asks the reservation calling the method:
*request(trainParameters, ea, la, Lx, is)*

The manager has information about section length and maximum accepted speed. It calculates the necessary time to move from one end to another and reserves an extra *Lx* time. If it is not able to perform the reservation, the manager reserves zero length time intervals.

*Manager request algorithm:*

```
input: trainParameters;
input: ea, la, Lx, is;
input: sectionSpeed, sectionLength;
output: er, lr, os;
determine the train speed sp;
calculate the moving time mt;
er = ea + mt;
lr = mt + Lx; // calculate the later release of the resource
if(the resource is free between ea and lr) then
    mark on the Block Section State Table the attempt of
      reservation for trainID;
    return er, lr, os=sp;// respond with the latest
      // release time and the output speed;
else return er=lr=0, os=is;
```

Agent confirmation call is performed by the method:
*confirm(trainID, ea, lr)*

That reserves firmly the necessary resources and releases the resources attempted to be acquired, but not necessary for the chosen path.

## IV. Implementation and Tests

Two approaches were used to test the scheduling algorithms. One uses the implementation of the proposed algorithms (based on real-time scheduler) and the other uses an implementation based on genetic algorithm. Both approaches use the same railway network model and have the same set of trains already scheduled. A new train schedule is required. Meanwhile the real-time scheduler uses the earliest arrival time as a target and the deadlines only for scheduling feasibility test; the evolutionary system has the goal to obtain the shortest traveling times having the arrival times between earliest arrival times and deadlines.

### *A. Genetic Algorithm for Train Traffic Scheduling*

A *path* from a platform (or a block section) of station A to a platform (or a block section) of station B consists of a sequence of linked elements (interlockings and block sections) used by a train for moving from departure to destination.

The solving of the *scheduling problem* using a *genetic algorithm* has the goal to find the best path and the train speeds on the contained (path) elements. As a consequence, a solution is a pair *(path, set of speeds)*.

A *train schedule* (departure time, path, set of speeds) is *viable* if the train reaches the destination and its trajectory does not overlap any time and any element of the trajectory of any other train from the given train set.

A *train schedule is better* than any other if, starting at departure time and following the solution (path, set of speeds), the train reaches the destination at a time closer to arrival time (if there is given an arrival time), or earlier (if no arrival time is specified) than the time obtained with other solutions.

Between two stations there are a limited number of paths.

*1) Individual coding:* An individual codifies all the paths from departure to destination and the train average speeds on all involved elements. This codification is implemented on a matrix with the number of lines equal with the number of possible paths, and the number of columns equal with the maximum number of elements of any of the paths from departure to destination. As a consequence, each matrix line corresponds to a path. The elements of the line describe the train average speeds on the path elements. Due to the possibility that the path element numbers differ from one path to another, some elements on the right-side of the matrix could not correspond to real train speeds.

*2) Individual evaluation:* Using the train departure time, departure block section and individual codification, the train *traffic simulator* determines for each path of an individual the arrival times. The railway net traffic could contain other trains already scheduled and their schedules are not acceptable to be modified. If the trajectory of an already scheduled train overlaps at the same time the trajectory of the train attempted to be scheduled, the value of the fitness function corresponding to this path is drastically penalized. The evaluation of an individual is given by the *fitness function* that in this case is the weighted sum of the schedules (path, set of speeds) evaluations.

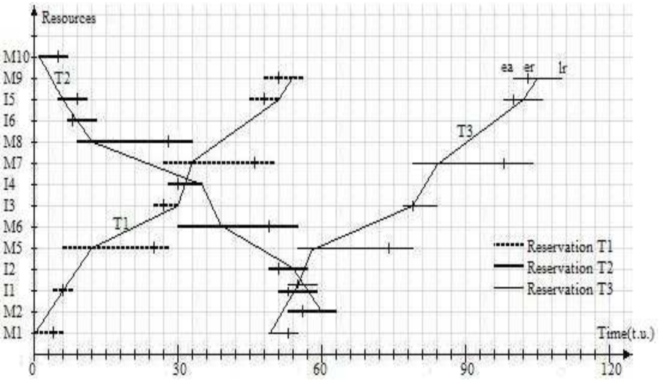

Fig. 5. Example of scheduling

*3) New individual creation:* The solution search using the genetic algorithms is performed by individual creation and evaluation. A new individual creation is obtained by:

- *Mutation.* An individual line (i.e. a path) and an element (i.e. the train speed on an element) of it are randomly chosen. The value of the element is randomly modified taking into account the specified speed limits.
- *Crossover.* Two individuals are chosen. A randomly chosen matrix column is used to cut the individuals' matrices in two parts. Two new individuals are constructed using parts from different matrices.

*4) Individual's selections:* Genetic algorithms work with populations of individuals. The selection of individuals that survive from one generation to another is obtained using the fitness function. The individuals with higher values of fitness functions have higher chances to survive.

The *solution of the scheduling problem* is chosen by taking from all the individuals the best value of the pair (path, set of speeds).

### *B. Solution Comparison*

The solutions obtained using the distributed scheduling algorithms and the genetic algorithm are represented in Figure 5.

The solution given by the genetic algorithm for the traveling of three trains is represented by continuous lines. On the figure are also drawn the block section reservations provided by the real-time scheduler. Each horizontal line describes the mentioned values of *ea*, *er*, and *lr*. The interlocking *I1* is concurrently demanded by two trains (T2 and T3). The genetic algorithm solution avoids the simultaneous use of the interlocking by delaying the T2 train.

## V. Conclusion

The proposed scheduling method does not lead to deadlock due to advance resource reservation. Comparing the performance of the proposed real-time scheduling algorithms with the genetic algorithm performance, the first is lower but needs much smaller computation power (memory and time). The proposed method can provide deterministic time to get the solutions. It also has the advantage to be finally applied on-line and so it is able to diminish the variations of the train arrival times. The proposed method can be used to design the railway networks such that to be capable of providing a specified throughput with real-time features.

***Abstract*—Nowadays developments in Wireless Sensor and Actuators Networks (WSAN) applications are determined by the fulfillment of constraints imposed by the application. For this reason, in this work a characterization of WSAN applications in health, environmental, agricultural and industrial sectors are presented. A case study for detecting heart arrhythmias in non-critical patients during rehabilitation sessions in confined spaces is presented, and finally an architecture for the network and nodes in these applications is proposed.**

## I. Introduction

Currently, there is a great interest in developing applications for monitoring, diagnosis and control in the medical, environmental, agricultural and industrial sectors, to improve social and environmental conditions of society, and increasing quality and productivity in industrial processes. The development of Wireless Sensor and Actuators Networks (WSAN) applications will contribute significantly to solve these problems, and facilitate the creation of new applications.

Some applications which can be developed using WSAN are:

- Medical Sector: economic and portable systems, to monitoring, recording and analyzing physiological variables, from which it is possible to indicate the status of a patient and detect the presence or risk of developing a disease. As well, developing systems for the detection and analysis of trends in the daily behavior of patients, contributing to timely detect the presence of a health problem, and provid ing an economically viable solution to patient care in societies where the old population is great.
- Environmental Sector: continuous systems monitoring of species in dangerous extinction, monitoring and detection of forest fire systems, etc.
- Agricultural sector: detection systems, microclimates monitoring and pest control, to reduce the use of agrochemicals and make an optimal control of pests; optimal use of water in irrigation systems, etc.
- Industry: economic systems and easy installation for monitoring, diagnosis and control of plants and industrial processes.

Some of the currently technological challenges in WSAN development are [1], [2], [3], [4], [5]:

- It is necessary to develop detailed models of the system components (hardware and software tasks, task scheduler, medium access control and routing protocols), in languages that allow correct specifications and the subsequent analysis of information processing, reachability, security, and minimum response time application, enabling analysis of end to end deadline in real time applications.
- Task scheduler and medium access control and routing protocols proposed in this area are mostly focused on the optimization of a single critical parameter of the application, which often affects considerably the performance of the others. Therefore it is necessary to create new cooperation forms between these levels of the application architecture, in order to take the most appropriate decisions for the system reconfiguration in relation to the application's quality of service (QoS). Additionally, current proposals consider QoS parameters directly linked to conventional parameters of the operation and communication between computers but not to particular application requirements, so do not allow achieving optimal performance in applications.
- It is necessary to develop analysis strategies for performance and stability of signal processing and control algorithms in this area, in order to guide the design towards a co-design methodology to develop the processing algorithm and the implementation of computer architecture, allowing to compensate the sampling period changes and jitter effects, and optimize other parameters such as power consumption.

The previous paragraphs show how these developments are determined by the fulfillment of constraints imposed by the application, such as energy consumption, limited computing power, coverage of large areas and real time deadlines, etc. For these reasons, in this work a characterization of WSAN applications for health, environmental, agricultural and industrial sectors is presented; then a case for detecting heart arrhythmias in non-critical patients during rehabilitation sessions in confined spaces is presented, finally an architecture for the network and nodes in these applications is proposed.

The article is organized as follows, section 2 shows a classification and characterization of applications in health, environmental, agricultural and industrial sectors, section 3 presents the case analyzed, in section 4 a proposal for the nodes architecture is presented, the network architecture and its simulation results are presented in section 5, finally in section 6 the conclusions and future work are presented.

This work is partially supported by the CYTED D2ARS Project

## II. Classification of Applications

During the classification was detected that different application sectors share similar characteristics from a technological point of view, for this reason the classification and characterization was developed in five types of application rather by sectors [6], [7], [8], [9], [10], [11], [12], [13], [14].

- Type 1 applications are characterized by measuring sampling periods from one second to few hours, and no strict deadlines for the generation of the algorithms results. Additionally, these applications, developed in open spaces, must cover large areas and it is necessary to synchronize measurements in different nodes. Agricultural and environmental applications, designated to measure, record and to analyze environmental variables, primarily belong to this category.

The energy sensors autonomy expects for each node varies from days to months; in some applications, in places without access to conventional energy sources, nodes are equipped with energy transducers like solar cells, which supply energy to the nodes batteries.

- Type 2 applications are developed in confined spaces and have greater computing capacity demanding than applications type 1, although there is not strict response time, either. Because they are in confined spaces and nodes are fixed, there are no restrictions on energy consumption since they can use conventional energy sources; however, the use of wireless networks is justified since it facilitates the installation, adaptability and portability of implementation, in addition to the lower costs of implementation.

Such applications are fined mainly in industrial and agricultural sectors. The sampling periods range from one millisecond, for implementation of diagnostic algorithms, until a second for monitoring and supervision tasks. The diagnostic algorithms do not require continuous operation; therefore the samples can be stored before being processed.

- Type 3 applications. In this category, in addition to measuring and processing data requirements similar to those in applications type 2, grouped applications are required to process images and they are developed in open spaces, some of which are in the agricultural sector for the detection of pests, and environmental sector aimed at detecting fires.

Some of the nodes are mobile and require few hours' energy autonomy, and then restrictions in terms of power consumption are large. At the same time it is also necessary for synchronization of the nodes. While, because of the algorithms used for image processing, the computing capacity, memory size and communication bandwidth requirements are greater than applications type 2.

- Type 4 applications. These applications differ from applications type 3 because they are developed in confined spaces, then the network's coverage is not demanding; energy sensors autonomy expected are also higher, becoming close to one week. Grouped healthcare applications to the detection of diseases are in this category with body area networks (BAN).
- Type 5 applications. In these applications a sample data should be sent every sampling period, and then sampling periods are limited by the minimum interframes time space of data communication protocols. For this category, a range of sampling periods between 50 milliseconds and a few seconds has been selected.

In this category are the applications of industrial control process, which are developed in confined spaces, so the distance between nodes is not big, and there are not restrictions on energy consumption. The deadlines for generating actions are less than or equal to a sampling period, and it is necessary to guarantee end to end deadline. If these constraints are not fulfilled, the control system performance can be degraded significantly, even generating instability in the system, therefore, it is important to synchronize the activities of the nodes that are integrated in the control loop. In addition, to improve the control system performance, it is important to limit the variability in the task jitter.

Table 1 summarizes the characteristics of the applications described. As a strategy to increase reliability in the presence of faults, and optimizing the applications QoS, this proposal also has considered the migration of components between the nodes, which will be reflected in the architecture of the network and nodes .

## III. Arrhythmia Detection Algorithm

Actually cardiovascular problems have the highest mortality rate from natural causes in the world. The great interest in developing devices for clinical detection and continuous monitoring of such diseases, is based on these activities are limited by the information type and the moment that it is caught, so transitional abnormalities can not be always monitored. However, many of the symptoms associated with cardiovascular diseases are related to transient episodes rather

Table 1
Analysis of requirements for each application type

| **Application** | **Computing capacity** | **Memory size** | **Communication bandwidth** | **Location** | **Node Mobility** | **Real-Time** | **Network's coverage** | **Energy autonomy** | **Synchronization** |
|---|---|---|---|---|---|---|---|---|---|
| **Type 1** | Low performance | Low | < 256 kbps | Yes | No | Only measurement | Open space 10 km | Months | Yes |
| **Type 2** | Low performance | Medium | < 256 kbps | Yes | No | Only measurement | Confine space 100 m | There isn't restriction | Yes |
| **Type 3** | High performance | High | 1 Mbps | Yes | Yes | Only measurement | Open space 10 km | Hours | Yes |
| **Type 4** | High performance | Medium | < 256 kbps | Yes | Yes | Only measurement | Confine space 1 km | Days | Yes |
| **Type 5** | Low performance | Low | < 256 kbps | No | No | End to end and Minimum jitter variability | Confine space 100m | There isn't restriction | Yes |

than continuing abnormalities, such as transient surges in blood pressure, arrhythmias, and so on. These abnormalities can not be predicted therefore a controlled supervision analysis is discarded. The reliable and timely detection of these episodes can improve the quality of life of patients and reduce the therapies cost. For this reason in this work a WSAN architecture to address such problems is proposed, this application belong s to type 4 described in paragraph 2.

As an example, the detection of arrhythmias using data from electrocardiogram (ECG) measure, in patients who are moving during a rehabilitation activity in a confined space of 100m x 100m, as a rehabilitation center, was analyzed. The sampling period was selected from the ECG frequency spectrum, which, according to the American Heart Association, has 100Hz harmonics. The greatest amount of relevant information for monitoring and detection of arrhythmias is between 0.5Hz and 50Hz.

When analyzing the ECG frequency spectrum can be established that the relevant components of the signal (QRS complex and waves P and T) are up to 35Hz. Applying the sampling theorem a minimum sampling period of 14ms approximately is necessary, but for practical purposes a period of 3ms was selected.

For the detection and analysis of ECG the Pan and Tompkins algorithm was selected, [15]. The results of this algorithm are used by a maximums detection algorithm, which identifies the time when segments of the ECG wave were presented, figure 1. Subsequently the analysis of the separation time between two R waves, the duration of the QRS segment and the energy of the wave R is developed, which allows detecting the presence of arrhythmias [16].

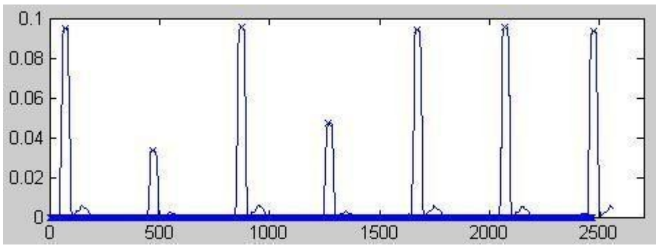

Figure 1 Results of maximums detection algorithm

## IV. Architecture Node

The proposed generic architecture for the network nodes in applications type 4 is presented in figure 2. Its characteristics are:

- The architecture enables the hardware and software components co-design. This feature will allow optimizing the development of distributed application components required for its implementation in hardware and software, getting a balance between cost, power consumption and processing time
- There are fixed and mobile nodes. The latter are linked to the sub-network that guarantees them the best QoS ( $QoS_{sn}$ ) during its movement (less saturated sub-networks).
- Communication between the nodes and local coordinators is done through wireless networks.
- Use an EDF scheduler and dynamic scaling voltage and frequency techniques of the processor to optimize the power consumption [17]. This allows fulfilling the application deadlines, which is supported on statics utilization rate tables for each operating frequency, and periods of execution for each task.
- Update its QoS indexes ( $QoS_{n}$ ); using these indexes and its neighboring ones it is possible to request to another node in its sub-network the migration, creation or destruction of components (some of which are clones of others).

To select a set of architectures for an adequate performance of these applications, the performance of the arrhythmia detection algorithm, presented in section 3, was analyzed on four types of processors currently used to implement nodes in sensor networks: ARM7TDMI, MSP430, PIC18 and MC9S08GB60.

For the analysis , the same operation velocity for each processor was used, 8MIPS. The time necessary to develop the Pan and Tompkins algorithm is presented in Table 2, which was estimated considering the sum of the values of individual functions (derivative, quadratic function and integrator window) in each architecture.

The results show that the ARM architecture requires a lower percentage of utilization, while the PIC architecture needs the highest utilization percentage.

It also was related consumed power by each architecture in active mode ($P_A$) with the respective percentage of utilization

TABLE 2
COMPUTING TIME TO DEVELOP THE PAN AND TOMPKINS ALGORITHM

| Processor | Derivative | Quadratic function | Integrator window | Total computing time | Period [µs] | Percentage of utilization (U) |
|---|---|---|---|---|---|---|
| **LPC2124 – ARM** | 70.2 µs | 142 µs | 280.5 µs | 492.7 µs | 3000 | 16.4% |
| **MSP430F1611** | 191.9 µs | 162.5 µs | 697.8 µs | 1052.2 µs | 3000 | 35% |
| **PIC18F458** | 406.2 µs | 209 µs | 1083.7 µs | 1698.9 µs | 3000 | 56.6% |
| **MC9S08GB60** | 497.2 µs | 332 µs | 707.35 µs | 1536.55 µs | 3000 | 51.3% |

during the implementation of the algorithm, table 3. It can be seen as the ARM7 architecture has a closer performance to the architecture MC9S08GB60; then these two architectures are appropriate for the implementation of the case proposed. The MSP430 architecture presented the best indicator.

TABLE 3
INDICATOR $P_A$*U

| | Utilization percentage (U) | Active Power ($P_A$) [mW] | $P_A$ *U |
|---|---|---|---|

## V. NETWORK ARCHITECTURE FOR CONFINED SPACES HEALTHCARE APPLICATIONS

In figure 3, a generic architecture for network applications type 4, which integrates different types of nodes, is proposed. The approach of a cooperation plan between architecture levels of the application, in order to take the most appropriate decisions for the reconfiguration of the system in relation to the application QoS, can be appreciated. General goals of the architecture are:

- Minimize latencies.
- Optimize power consumption.

The Main Coordinator is responsible for coordinating the complete application. It will have a fixed location, and communication with local coordinators will be supported through wireless or wired links. It develops the following functions:

- Send sync hronization signals to the local coordinators of the sub-networks.

Local Coordinator control s the activity inside the sub-network and develop s some information processing activities, whose architecture is presented in figure 4 and its features are:

- It has a fixed location.
- Sends synchronization signals to nodes in its sub-network.

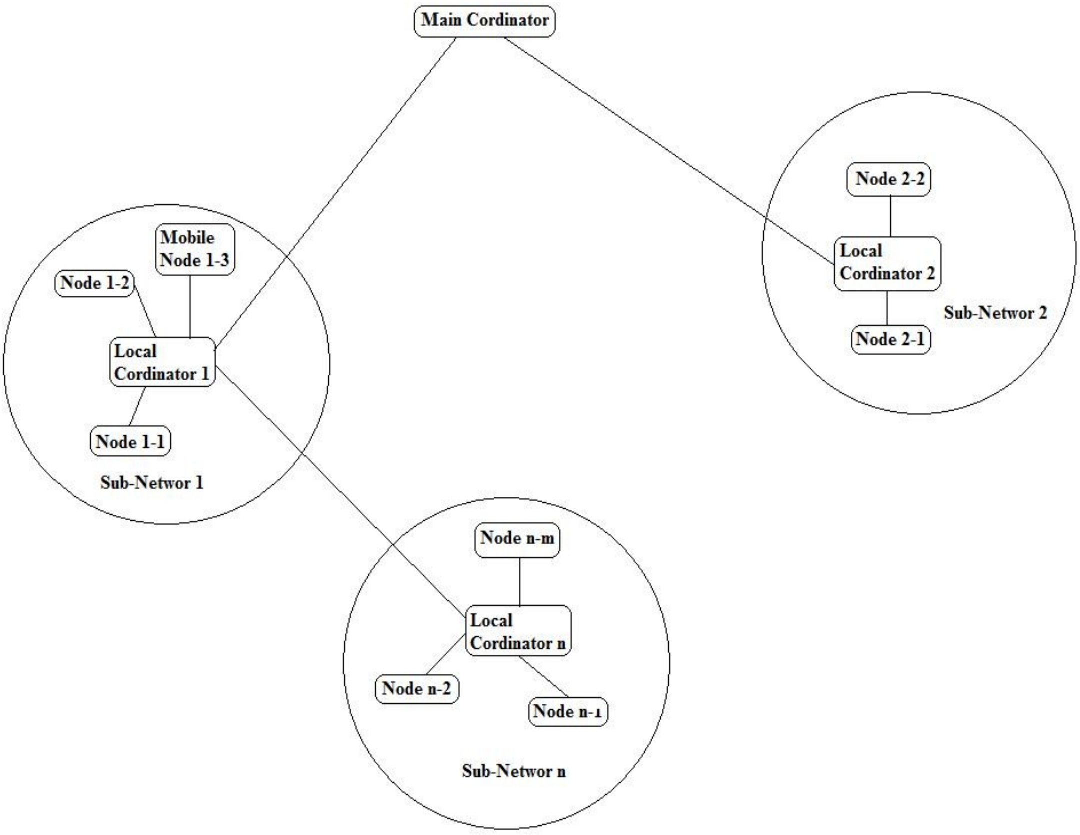

Figure 3 Network architecture

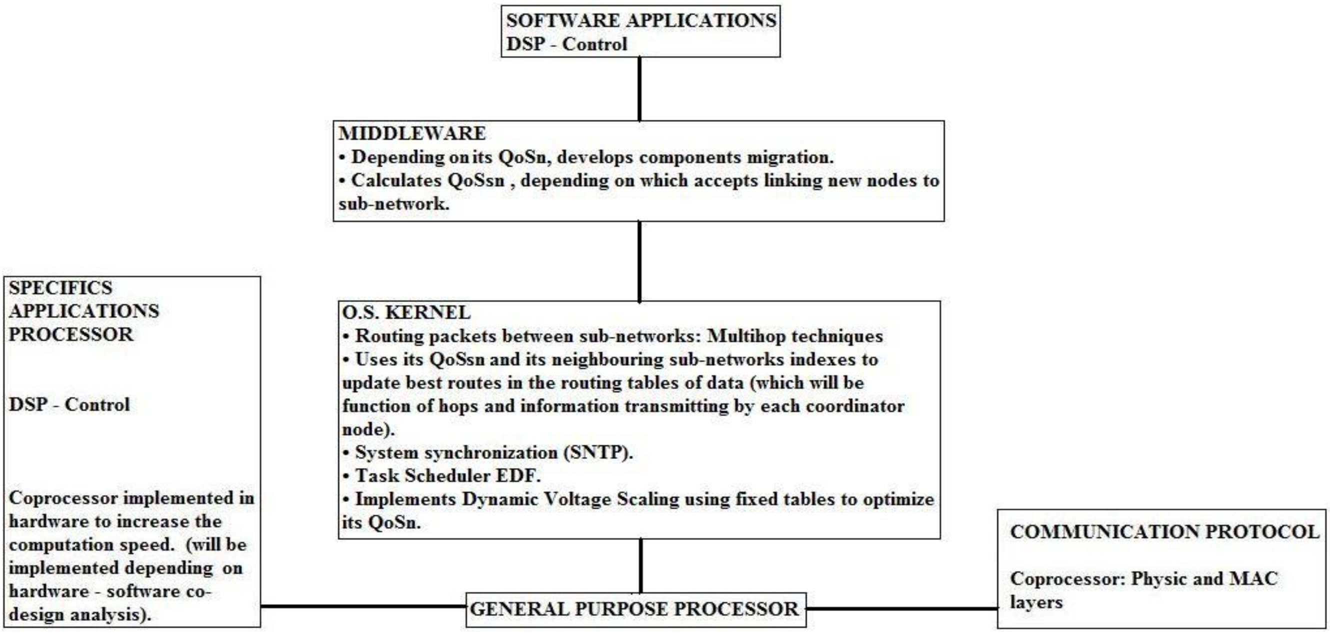

SOFTWARE APPLICATIONS
DSP - Control
MIDDLEWARE
• Depending on its QoSn, develops components migration.
• Calculates QoSsn , depending on which accepts linking new nodes to sub-network.
SPECIFICS APPLICATIONS PROCESSOR

O.S. KERNEL
• Routing packets between sub-networks: Multihop techniques
• Uses its QoSsn and its neighbouring sub-networks indexes to update best routes in the routing tables of data (which will be function of hops and information transmitting by each coordinator node).
• System synchronization (SNTP).
• Task Scheduler EDF.
• Implements Dynamic Voltage Scaling using fixed tables to optimize its QoSn.
COMMUNICATION PROTOCOL
Coprocessor: Physic and MAC layers
GENERAL PURPOSE PROCESSOR

Figure 4 Sub-network coordinator architecture

- Develops routing packets between sub-networks using multihop techniques.
- Distributes QoS indexes of nodes which belong to its sub-network ( $QoS_n$ ) .
- Calculates its sub-network QoS index ( $QoS_{sn}$ = f(quantity of information to be transmitted)), and distributes this value and its neighboring sub-networks indexes (those reached in a single communication hop) between nodes in its sub-network. Depending on which:
  - Accepts linking new nodes to sub-network.
  - Updates best routes in the routing tables of data (which will be function of hops and the utilization percentage -information transmitting- of each router node).

As a first approximation to the proposed architecture, we examined the performance of the case analyzed on the IEEE 802.15.4 protocol. Considerations for the proposed solution to the case are:

- Transmission of the analysis results, from nodes located on each patient to a main node, every 3 s. The data frame consists of 2 Bytes, which contain patient codes and the type of arrhythmia detected.
- After each sending the sender node waits for an acknowledgement (ACK) from next node in the routing path. If there isn't an answer before 100ms the node sends again the information. If after 25 attempts there i s no answer this node change s to a mistake state.
- The communication protocol selected is IEEE 802.15.4. The node distribution is shown in figure 5, which allows cover ing all possible locations of patients considering the specifications of the devices selected to implement the physical layer, CC2420, whose characteristics are:
  - Coverage radio of 30m, and 100m without obstacles.
  - Frequency range of 2.4 - 2.4835 GHz.
  - Supports data transfer rates of 250 kbps.

In the case a network as presented in figure 6 was proposed. It consists of 3 fixed nodes which have no restrictions on power consumption, will receive reports from five patients and rout e the messages to the main node. The fixed devices have fixed identifiers 0, 1 and 2; the main node has the 0 identifier, and devices on every patient have identifiers from 3 to 7.

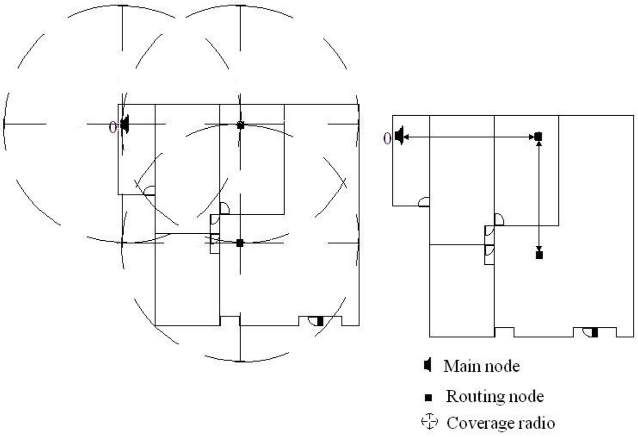

Figure 5 Distribution nodes for case and their coverage

The routing is developed through 1, 2 and 0 nodes, 0 is the network coordinator, each of these nodes form ing a sub-network together with patients, figure 6. The mobile nodes leave and enter the sub-networks continuously changing the configuration and network structures.

The simulation was developed in the TOSSIM tool, and the TelosB platform was selected, including the CC2420 transceiver. Because the characteristics given of the case, with fixed nodes to implement the routing protocols, a routing fixed table algorithm was implemented, it is presented in table 4.

Table 5 Time in sending 2 Bytes from all patients to the main node

| Sender node | Receiver node | Time (s) | Source node | Receiver node | Time (s) |
|---|---|---|---|---|---|
| 6 | 2 | 78.309 | **0** | **1(ack)** $_1$ - 5 ends | .613 |

| 7 | 2 Rtx $_2$ | .535 | **2** | **1 Rtx moving 3** $_2$ | .929 |
| **2** | **4(ack)** | .547 | **1** | **2 (ack)** | .949 |
| **2** | **1 (moving frame from 4)** | .581 | **1** | **0 (moving frame from 3)** | .979 |
| **1** | **0 (moving frame from 5)** | .589 | **0** | **1 (ack)** $_1$ - 3 ends | 79.013 |

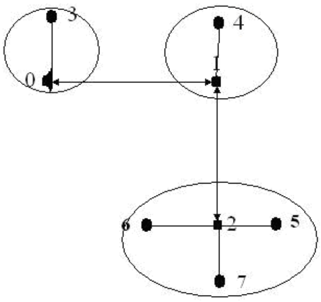

Figure 6 Network structure for case

Table 4 Routing Table

| Source node | Destination node |
|---|---|
| 2 | 1 |
| 1 | 0 |
| 0 | |

In the simulation was considered the most critical case, wh ere all mobiles nodes are connected all time to the farthest sub-network from the main node.

Times obtained in sending 2 Bytes from all patients to the main node (node 0), are presented in table 5. The data$_1$ indicate that transmitting the message from a mobile node to the main node was over; the data$_2$ indicate that the corresponding node has not received the ACK. Times obtained demonstrated that it is possible to fulfill the constraint of 3s, for the transmission of patient status from a mobile node to the main node, which was imposed by the case analyzed.

## VI. Conclusions and Future Work

From the study it can be concluded that developments on specific technologies and applications in this area are still emerging, and developing them will enable the growing of great social impact new applications.

The proposed architecture considers the constraints of application field, allowing to find optimal solutions to the challenges in network and nodes designing, and will facilitate the development and validation of applications. It makes possible too the cooperation between levels of the network architecture to choose between different operations modes depending on QoS indexes.

It is noted as the routing algorithm based on fixed tables supported by IEEE 802.15.4, fulfils the time requirements of these applications. Also as MSP430 architecture presents a good performance for the implementation of the case considered.

The future work proposed is the performance analysis of different task schedulers and routing protocols on the presented architecture, and a cooperation strategy between them to minimize power consumption.

***Abstract* - Service-oriented architectures (SOA) become more and more important in connecting devices with each other. The main advantages of Service-oriented architectures are a higher abstraction level and interoperability of devices. In this area, Web services have become an important standard for communication between devices. However, this upcoming technology is only available on devices with sufficient resources. Therefore, embedded devices are often excluded from the deployment of Web services due to a lack of computing power and memory. Furthermore, embedded devices often require real-time capabilities for communication and process control. This paper presents a new table driven approach to handle real-time capable Web services communication, on embedded hardware through the Devices Profile for Web Services.**

## I. Introduction

THE usage of a standardized device-centric SOA is a possible way to fulfill interoperability requirements in future networked embedded systems. Technologies like UPnP (Universal Plug and Play), DPWS (Devices Profile for Web Services), REST (Representational state transfer) and Web services are used to realize a so called SODA (Service-oriented device architectures) [23]. While UPnP, DLNA and related technologies are established in networked home and small office environments, DPWS is widely used in the automation industry at device level [24] and it has been shown that they are also applicable for Enterprise integration [22, 26].

Besides the advantages of SODA, additional resources are required to host a necessary software stack. There are SODA toolkits available for resource-constrained devices like UPnP stacks or DPWS toolkits [WS4D, SOA4D]. However, additional effort is necessary for deeply embedded devices and for embedded real-time systems especially. Deeply embedded devices are small microcontrollers with only a few kB of memory and RAM (e.g. MSP430, ARM7). These devices cannot be applied to huge operating systems. But they are essential because as they combine price, low power properties, size and build-in hardware modules.

In this Paper a new approach is presented, which can be applied to deeply embedded devices and serve real-time and specification compliant DPWS requests.

## II. Web services in Device Controlling Systems

The World Wide Web Consortium (W3C) specifies the Web services standard [11]. UPnP is a popular specification in the home domain. Due to the lack of security mechanisms and the missing service proxy it is limited to small networks (see [2]). Web services are more important when using larger networks. This client-to-server interaction uses SOAP [10] for the transport layer and Extensible Markup Language (XML) for the data representation [1, 13]. On the other hand, the Web services protocols need much computing power and memory, in order to enable a device-to-device communication. Therefore, a consortium lead by Microsoft has defined DPWS [4]. DPWS uses several Web services protocols, while keeping aspect of resource constrained devices. In comparison to standard Web services, DPWS is able to discover devices at run time dynamically, without a global service registry (UDDI). The included WS-Eventing [5] specification also enables clients to subscribe for events on a device. The device sends a notification to the client, whenever an event occurs. State changes not have to be polled by the client. DPWS is integrated in the Microsoft operating system Vista. For many companies, this is the reason for developing new interfaces for their products based on these protocols.

In specific scenarios, communication proxies are necessary because of the low memory and computing power of deeply embedded devices. With the new implemented approach, Web services become also available on deeply embedded devices. Both deeply embedded devices and devices that are more powerful will be enabled to communicate and interact with each other. This substitutes the communication proxies.

Through linking the devices to a higher level of communication, devices no longer rely on specific transfer technologies like Ethernet. All devices in an ensemble are connected via services. This services based architecture is already used in upper layers. Services based communication becomes available on lower layers nearest to the physical tier. This allows a higher abstraction level of process structures. The first step to allow this is the creation of a SODA framework that fulfills the requirements of deeply embedded devices.

## III. Requirements for a Light Weight SODA

High-level communication on resource constrained embedded devices can result in an overall performance degradation. In a previous paper [6] we have presented different challenges which have to be met in order to realize DPWS communication with real-time characteristics.

This work was partly supported by the ITEA LOMS project.

Firstly, as a basis an underlying real-time operating system must exist, ensuring the scheduling of the different tasks in the right order and in specific time slots. Secondly, the physical network has to provide real-time characteristics. The major challenge in DPWS with respect to the underlying network, is the binding of DPWS and SOAP. SOAP is bound to the Hypertext Transfer Protocol (HTTP) for transmission. HTTP is bound to the Transmission Control Protocol (TCP) [8] (see Figure 1). The TCP-standard includes non-deterministic parts concerning a resend algorithm in case of an error. Furthermore, the Medium Access Control (MAC) to the physical tier has to grant access to the data channel for predictable time slots. For example, Ethernet cannot fulfill this requirement.

As shown in Figure 1, it is possible to use SOAP-over-UDP. But in accordance to the DPWS specification, a device must support at least one HTTP interface [4].

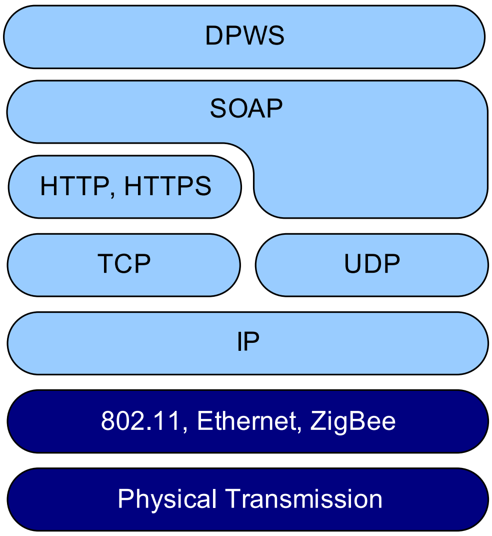

Figure 1. DPWS protocol stack

In Prüter et al. Xenomai [9] is used as operating system and RTNet [12] is used to grant network access with real-time characteristics. RTNet relies on the User Datagram Protocol (UDP) instead of TCP and uses Time Division Multiple Access (TDMA) for Medium Access Control (MAC). The usage of UDP demands SOAP-over-UDP at the same time. At least two interfaces have to be implemented: A non real-time, DPWS compliant HTTP/TCP interface and a real-time UDP interface. The disadvantage of using a special network stack including a special MAC, also implies building up a separate network. In this network, all participating notes have to conform to the MAC and used protocols.

For deeply embedded devices, various real-time operating systems exist. FreeRTOS[19] is a mini real-time kernel for miscellaneous hardware platforms like ARM7, ARM9, AVR, x86, MSP430 etc. Unfortunately, no useful real-time network stack and operating system combination is currently available for these kinds of deeply embedded devices. Therefore, this paper concentrates on the possibilities to provide real-time characteristics in the upper layers being on the top of TCP/IP.

The binding of DPWS and TCP through HTTP causes different challenges in granting real-time characteristic for DPWS communication and is still an ongoing work in our research group. It is not possible to reach deterministic characteristics without specific real-time operating systems and network stacks. A real-time operating system grants access to peripheries for predictable time slots and execution of tasks in the right order. The arising high level communication may not interfere with the real-time process controlling. The underlying real-time operating system takes care of correct thread management and correct scheduling of the real-time and non real-time tasks. Tasks on the controller, competing with the communication, are prioritized by the operating system.

In order to provide Web services on microcontrollers, different challenges have to be met. Figure 2 shows the single parts, which have to be realized.

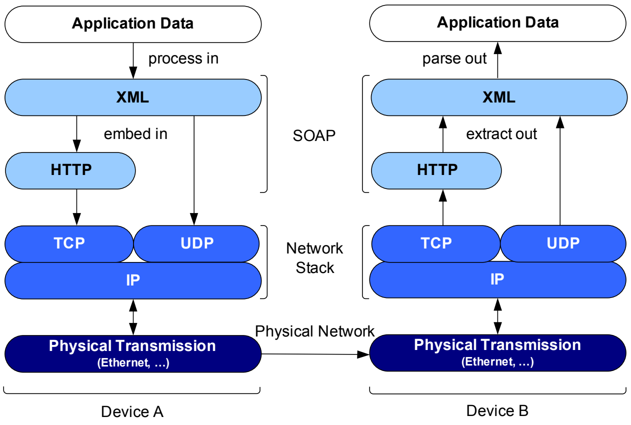

Figure 2. Modules to be implemented

### *A. Network Stack*

The network stack, responsible for the right addressing and the way of exchanging data, is the first module, which have to be realized. Dunkels has developed uIP and lwIP, two standard compliant TCP/IP stacks for 8 Bit controller architectures ([13, 14, 15]). uIP fulfills all minimum requirements for TCP/IP data transmissions. The major focuses are minimal code size, memory and computing power usage on the controller, without losing standard conformance. lwIP also fulfills non mandatory features of TCP/IP. Both implementations are designed to run on 8-bit architectures with and without an operating system. The differences between both stacks are shown in the following table.

DPWS utilizes WS-Discovery for automatic discovery of devices and is based on IP Multicast. Multicast applications use the connectionless and unreliable User Datagram Protocol (UDP) in order to achieve multicast communications. uIP is able to send UDP Multicast messages, but is not able to join multicast groups and receive multicast messages [15]. In contrast to uIP, the lwIP implementation supports all necessary UDP and Multicast features. The above mentioned FreeRTOS can use the lwIP stack for networking. This combines the advantages of a compatible, lightweight network stack and the usage of an embedded real-time operating system.

Table 1.
uIP vs. lwIP

| Feature | uIP | lwIP |
|---|---|---|
| IP and TCP checksums | X | X |
| IP fragment reassembly | X | |
| IP options | | X |
| Multiple Interfaces | | X |
| **UDP** | | **X** |
| Multiple TCP connections | X | X |
| TCP options | X | X |
| Variable TCP MSS | X | X |
| RTT estimation | X | X |
| TCP flow control | X | X |
| Sliding TCP window | | X |
| TCP congestion control | Not needed | X |
| Out-of-sequence TCP data | | X |
| TCP urgent data | X | X |
| Data buffered for rexmit | | X |

### *B. SOAP*

Upon the network stack, HTTP communication protocol is used. The payload is embedded in XML structures and sent via HTTP.

Because DPWS requires a small part of the HTTP functionality only, it is not necessary to implement a full functional HTTP stack. All DPWS messages are using the POST method of HTTP for delivering.

In contrast, the XML processing and parsing draws more attention. On deeply embedded devices, with only few kB of memory, the code size and the RAM usage have to be reduced. The WS-Discovery and WS-Metadata messages exceed the Maximum Transmission Unit (MTU) of most network technologies, including Ethernet. This supports the decision for lwIP in favour of uIP. The uIP implementation only uses one single global buffer for sending and receiving messages. The application first has to process the message in the buffer, before it can be overwritten [15]. In case of a complete XML message, the whole file has to be available before a useful parsing can be processed. Additional, computing power is restricted to resource constrained devices. With respect to the overall performance of the communication task, it is difficult to work through and parse the whole message as a nested XML file. Therefore, our research group has developed and implemented a new approach to handle HTTP and XML analysis. This new approach is described in the next section.

## IV. New Table Driven Approach

A complete implementation of SODA for deeply embedded systems, like wireless sensor network nodes with limited processing power and memory, is a significant challenge. All modules that are mentioned in section III like network stack, SOAP, HTTP and DPWS have to be implemented.

We have analyzed different setups with DPWS compliant implementations to identify which parts of DPWS could be omitted to reduce necessary resources. In most scenarios, only few types of messages have to be processed. After discovery and metadata exchange, the devices and their addresses are known and the services can be invoked. Only a few parts change within the exchanged messages. Major parts of the messages stay unchanged. Every time a service is called, almost the same message has to be parsed and almost the same message has to be build.

With all exchanged messages from the analysis of different scenarios tables are generate. The tables contain all appropriated incoming and outgoing messages. The new implemented table driven approach is able to answer every request with the right answer by referring to these tables. In section the dynamic changing parts of the different messages are shown.

This new table driven implementation is not based on SOAP and HTTP. Instead, we are using an approach basing on a simple string comparison of incoming messages in this new implementation. The messages are interpreted as simple text messages and not as SOAP Envelopes being embedded in HTTP. The relevance of the received strings from HTTP and SOAP protocols are unknown for the table driven device. The device is able to send specific response with the correctly adapted dynamic changing sections. The overhead for parsing and building always the same message is reduced by this approach. Thereby memory usage and computation time are decreased in comparison to a traditional implementation.

With respect to a real-time capable communication, the treatment of the messages as strings and not as specific protocols is useful. The parsing as a string is independent of the depth of the nesting of XML structures. The necessary time, to parse the message as a string, is predictable. XML Schema, which is required by DPWS, cannot fulfill these requirements.

## V. Mobile Robots as Test Bench

We verified our solution in a real world scenario. An external PC and an overhead camera control a team of five autonomous robots. The robots are coordinated via DPWS interfaces. The robots receive commands from a central server. The commands have to be executed in predicted timeslots to prevent collisions and enable accurate movement of the robots. The whole setup is shown in Figure 3.

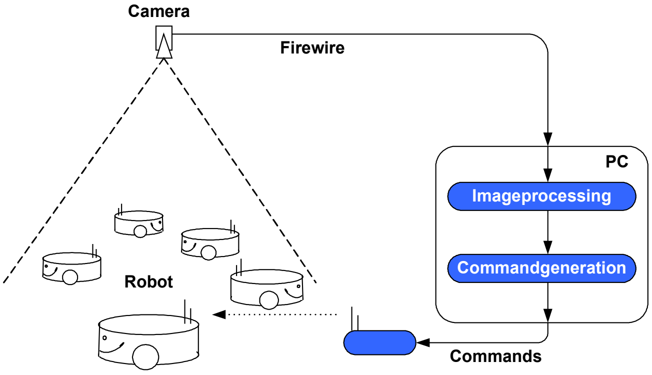

Figure 3. Robot Scenario

The team behavior of the robots is controlled by a central server which uses one or more cameras mounted above the ground. Image processing software on the PC extracts the position of all robots in the field. On the PC even the commands for the robots are calculated. These commands consist of global coordinates of the robot positions and the target positions. These commands are sent with a high transmission rate to the robots. The robots use global coordinates to update their own local and imprecise coordinate tracking. The robots need this global updates in regular periods, otherwise a correct controlling cannot be granted. These real-time requirements for controlling the robots with a parallel running communication system make the robot scenario an ideal test bench for our implementations.

### *A. Robot Hardware*

To control the robots we use two controller boards alternatively: an embedded Linux board and an ARM7 controller board. The embedded Linux board is the Cool Mote Master (CMM) from LiPPERT. It is equipped with an AMD Alchemy AU 1550 processor [17]. This board is designed as a gateway node for sensor networks. The CMM is already equipped with an 802.15.4 compliant transceiver. We have extended the board with additional Bluetooth and Wi-Fi (IEEE 802.11) interfaces [18]. Thereby, the board has three different radio technologies for networking beside Ethernet.

The ARM7 board is a SAM7-EX256 evaluation board from Olimex . This board is applied with an Atmel ARM7 controller with 256 kB memory and 64 kB RAM. The board already provides an Ethernet interface, which was used for testing. The controller is running with a clock rate of 55MHz. It is possible to schedule the lwIP stack and the implemented table driven device in different tasks with the help of FreeRTOS.

The implementations are evaluated on a standard PC and on these boards. An overview of used hardware is provided in Table 2 . The network devices are configured in a way, that all of them can handle IP traffic.

Table 2.
Used hardware for testing the new table driven approach

| | PC | CMM | SAM-7 |
|---|---|---|---|
| CPU | Intel Pentium4 | AlchemyAU 1550 | Atmel ARM7 |

| Network interfaces | Ethernet | Ethernet,<br>802.11g,<br>802.15.4,<br>Bluetooth | Ethernet |

## VI. Implementation

Our research group has implemented the WS4D-gSOAP toolkit[7]. This is a software solution, which includes a DPWS stack and software tools for creating of own Web services based on DPWS. This toolkit uses gSOAP [20] for SOAP functionalities and extends gSOAP with an implementation of the DPWS specification. This traditional implementation will be used as benchmark for the new table driven approach.

In the first step a service is created with the existing WS4D toolkit that provides all necessary commands for the robots in our mobile robot scenario. The external PC calls a hosted service on the robots. The service is called every time when new commands have to be send to the robots. The new commands are embedded in the request. The service answers with a response, including a performance parameter of the robot.

In the second step, the exchanged messages are analyzed according to the DPWS specification. All possible outgoing and incoming messages for the mobile robot scenario are generated.

In the third step, a completely new device is implemented. The structures and contents of the possible messages are deposited in the new implemented device as strings. This device does not support any dynamic SOAP or HTTP functionalities. The new table driven approach does not parse the whole incoming message as XML file. Every received message is analyzed with an elementary string compare. Thereby the type of the message is figured out. If the message type is known, the device answers with the right message. The answer is already deposited in the implemented device as a string also. In the answer, only parts required by the DPWS specification and the payload are changed.

During the implementation of the table driven device, we have taken care that system functions are not called in critical sections. For example, the memory management is provided by the task itself. The task allocates a pool of memory when it is started and then organizes the memory itself. Furthermore, the different threads for the network stack and the threads handling the messages are analyzed to be scheduled in the right order and with correct priorities.

### *A.Message Exchange*

Figure 4 gives an overview of exchanged messages in the mobile robot scenario. When starting the device, it announces itself with a *Hello SOAP Envelope*. Within this message only the wsa:MessageID and the wsd:XAddrs, the IP address, are dynamically and has to be adapted. Furthermore, the MessageNumber and the InstanceID has to be correct.

When a client was not started, as the device announces itself with a *Hello* , the client asks with a *Probe* for available devices. The answer is a *Probe Match* , where the wsa:RelatesTo has to fit to the wsa:MessageID of the *Probe* and the wsa:MessageID has to be dynamic. Here, also the MessageNumber and the InstanceID has to be incremented.

When the devices and their addresses are known, the client will ask for the hosted services on the device in the next step. Therefore, a *GetMetadata Device* is send to the hosting service, which is at least a service that announces the available hosted services. The *GetMetadata* message is the first one that is sent via HTTP. Within the HTTP header, the content length, the length of the message, and the IP address has to be adopted. The address only has to be changed, if it was not known at compile time. This applies to all IP addresses in the scenario. In the *GetMetadata Device* message, the wsa:To entry has to match to the address of the device, detected through the *Probe* . The device answers with a *GetMetadata Device Response* message. In this message the wsa:RelatesTo has to match the wsa:MessageID of *the GetMetadata Device*.

When the client knows available hosted services, the specific hosted service, that the client is looking for, is asked for the usage interface with a *GetMetadata Service* . The *GetMetadata Service Response* refers to the *GetMetadata Service* through the wsa:RelatesTo section.

Figure 4. Message Exchange[1]

After the metadata exchange is complete, the client knows how to interact with the specific service and the service usage starts. The client invokes the service with a message, where wsa:To and wsa:MessageID has to be correct. In the *Service Usage Request* , the coordinates of the mobile robot scenario are integrated. The service answers with the *Service Usage Response* . Therein, the reference to the request is given through the wsa:RelatesTo section. In our special mobile robot scenario, the response also contains the mrs:ProcessingTime section. In this section, the service informs the service user about the time, the application needs to process the new coordinates and is a performance parameter for the mobile robot.

An overview about the dynamic parts of the different messages is given in Table 3 .

The overall size for the exchanged messages is 12.839 Bytes. The overall number of Bytes that can change is 588. Only 4.6% of the overall exchanged bytes are dynamic in the mobile robot scenario.

## VII. Measurements/Comparison

In this section, the performances of the original WS4D toolkit and the new table driven approach are compared.

Table 3. Overview Exchanged Messages

| MessageType | Changingparts | Dynamic Bytes |
|---|---|---|
| Hello | wsa:MessageID | 36 |
| | wsd:XAddrs(IP) | max.17[2,3] |
| | wsd:AppSequenceMessageNumber | approx.2 |
| | wsd:AppSequence InstanceId | 10 |
| Probe | wsa:MessageID | 36 |
| ProbeMatch | wsa:MessageID | 36 |
| | wsa:RelatesTo | 36 |
| | wsd:AppSequenceMessageNumber | approx.2 |
| | wsd:AppSequence InstanceId | 10 |
| GetMetada Device | HTTP content-length | max.5 |
| | HTTP host | max.17[2,3] |

| | mrs:ProcessingTime[4] | 3 |

### *A. Devices Sizes*

The WS4D toolkit implementation of the DPWS device needs 794 kB of disk space when compiled for Linux on a x86 architecture. The table driven device implementation has a 16 kB footprint when compiled for a standard x86 PC running with Linux. The table driven device does not contain the independent lwIP stack in this x86 implementation. Both implementations for a x86 PC running with Linux are using the BSD Socket API to handle the network traffic. The same implementation of the new table driven approach ported to the SAM7-EX256 board running with FreeRTOS 5.0 has a 13 kB footprint without network interface. As network stack the independent lwIP stack in Version 1.3 is applied to the board. Therefore, the stack was ported to FreeRTOS 5.0.

[1] number of Bytes may vary because of different IP addresses and payload e.g.

[2] depends on IP Address and Port number

[3] if not known at compile time

[42] depends on IP Address and Port number

[3] if not known at compile time

Payload

The required disk space for the different parts on the SAM7 board is shown in Table 4. The overall memory being used on the board, including FreeRTOS, lwIP and the device needs 146 kB.

Table 4.
Footprint of SAM7 Implementation with FreerRTOS and lwIP

| Module | Footprint |
|---|---|
| static DPWS device | 13 kB |
| lwIP 1.3 | 77 kB |
| FreeRTOS including Debug Tasks | 56 kB |

### B. Time Responds

Also some timing measurements have been done in order to have an objective comparison for the new static approach. Therefore, the overall time was measured that is required from sending the message to receiving the response on the client side. Through this method the overall performance and the maximum number of requests per second can be determined which can be served.

These measurements are done for a standard PC and the SAM7 board. On both devices a 100 MB/s Ethernet interface is applied, which has been used for the measurements. On the SAM7 boards, an independent thread simulated an additional CPU load. This CPU load thread was scheduled with different priorities. As requesting client a standard PC (2x3,5 GHz with 1 GB RAM) was used in all cases.

The following Table 5 shows the times measured for the different implementations of DPWS server/device. The values are the average over 1000 requests, send directly successive.

Table 5.
Respond time and processed requests per second

| Device System | Response time | Requests per sec |
|---|---|---|
| Standard PC<br>WS4D toolkit | 1,05 ms | 952 |
| Standard PC<br>Table Driven DPWS | 0,9 ms | 1111 |
| SAM7-EX256<br>Table Driven DPWS | 18,6 ms | 53 |
| SAM7-EX256<br>Table Driven DPWS<br>CPU load thread lower priority then lwIP and DPWS tasks | 18,6 ms | 53 |
| SAM7-EX256<br>Table Driven DPWS<br>CPU load thread same priority like lwIP and DPWS tasks | 30,2 ms | 33 |

On the PC, the new implemented approach provides a faster overall processing. The time responds on the real-time operating system of the SAM7 board, depend on given priorities for the different competing tasks. As long as the CPU load task has a lower priority than the DPWS and the lwIP tasks, no effect to the average times could be measured.

## VIII. Conclusion

The new table driven approach allows the usage of Web services on deeply embedded devices. Furthermore, the implemented services can grant real-time capabilities. Thus, the deeply embedded devices can be integrated in enterprise service structures. The created service interfaces can be reused in different application. The connectivity between such large numbers of embedded devices normally needs proxy concepts with static structures. Now, these proxies are no longer required. The devices can be directly accessed by a high level process logic. Furthermore, the validation and certification become cheaper because of the slim implementation and reusability of the interfaces.

The measurements show that the size of a device can be reduced by the factor of about 50. At the same time, the time responds can be improved. Through the implementation in different threads, the time responds of the new implemented static approach is independent from other competing tasks. However, this assumes an underlying real-time operating system.

The optimization of the footprint and dynamic memory usage are a main focuses for the future work. Future work will also research on a completely specification compliant implementation. Therefore, the specification has to be analyzed in detail and all possible messages, even for error cases, have to be discovered and integrated into the static device.

*Abstract* — **This paper compares task jitter measurement performed under RTLinux and RTX hard real-time operating systems. Both the operating environments represent Hardware Abstraction Layer extensions to general-purpose operating systems, and make possible to create a real-time system according to the POSIX 1003.13 PSE 54 profile (multipurpose system). The paper is focused on discussion of experimental results, obtained on PC hardware, and their interpretation.**

## I. Introduction: Applicability of general-purpose operating systems in control systems

REAL-TIME task is a task, which meets prescribed deadline. Control system is a computer system, which physically realizes real-time tasks. The physical realization of the real-time task is not ideal, but it shows latencies and jitters.

Operating system and hardware support the real-time tasks with standardized means, which have non-zero and variable overhead. Kernel latency is defined as a delay between scheduled and actual execution of a task (e.g. between scheduled and actual instance starting time) [5]. The kernel latency is not stable, but it shows a jitter. Jitter is defined as a variable deviation from ideal timing event. The causes of jitter encompass code branching into paths with different execution times, variable delays implied whenever variable amount of code or data is stored in or read from caches and buffers, as well as noise and electromagnetic interference.

The substance of jitter can be seen in a need for parallel processing, which in turn stems from inevitable conflict between predictability and unpredictability. The control system has to be predictable and deterministic as much as possible. Control systems are intended to communicate with technology, as well as with people managing the technology (at least an emergency stop pushbutton is provided). Seen from this viewpoint, control system shall be appropriately flexible. As the result, a control system design represents a compromise between stability and adaptability.

It is possible to design a control system on two computers, one designed to meet technology demands, and the other designed to meet the user interface demands, but there is also the possibility to realize such system on one computer only. Computer system of this scope is standardized in the POSIX 1003.13 standard, as the PSE 54 profile (multipurpose system). PSE 54 - sized solutions are often preferred for their challenging possibility to use a broad range of standardized and low-cost hardware components, primarily intended for general-purpose computers, but on the other hand, they can involve lack of predictability typical for general-purpose (non real-time) systems.

Traditional general-purpose kernel provides full range of API services specified in the POSIX 1003.1 standard, and because of that, it cannot guarantee appropriately deterministic behavior, required in most real-time and technology control applications. Basic approaches to make such architecture more real-time one include

- low-latency kernel,
- preemptible kernel,
- hardware abstraction layer (HAL).

Low-latency kernel represents a traditional approach. The low-latency kernel is monolithic (i.e. it cannot be preempted by task), but its design minimizes latencies and jitters of the kernel API services typically used in real-time applications.

Preemptible kernel can be preempted by task. Preemptivity by task means, that a task can preempt the kernel just servicing another task, and enter the kernel instead. This type of premptivity is called reentrancy. However, at least some parts of a kernel (scheduling, interrupt service mechanism) cannot be made reentrant. Moreover, the idea of a preemptible kernel itself does not imply, that the kernel is deterministically preemptible, i.e. its jitters are acceptably stable.

Last but not least, hardware abstraction layers can be applied. A hardware abstraction layer receives timer interrupt and sends a virtual (software) interrupt to the general-purpose operating system kernel, thus providing a virtual (slower) clock for the general-purpose operating system. This can be seen as a cycle stealing. In the free time, real-time tasks can be run. Obviously, latencies and jitters of the HAL layer must be kept low enough by design.

## II. RTLinux and RTX basics

Both the RTLinux and RTX represent real-time Hardware Abstraction Layers. RTLinux is the product of the FSMLabs, Inc., designed for the Linux operating environment, while RTX is the product of the Citrix Systems Inc. (Ardence), and is designed to run under the Windows operating system.

### *A. RTLinux*

RTLinux microkernel (fig. 1a) implements a Hardware Abstraction Layer inserted between hardware and Linux kernel. Both the RTLinux microkernel and the Linux kernel have to communicate mutually, thus it is necessary to make certain modifications into the Linux kernel. The modifications include

- modification of macros for disabling and enabling interrupts in order to use internal HAL signals (software interrupts) instead of using cli and sti assembler instructions,
- modification of interrupt handlers, in order to use signals instead of direct Interrupt Controller access,
- modification of device drivers in order to prevent them from using sti/cli assembler instructions directly as well.

Within a RTLinux thread, time is measured with resolution that depends on hardware. On the Pentium 4 platform, the time resolution is equal to 32 ns.

[1] and [4] discuss the overall architecture more deeply. Basic resources used for interprocess synchronization and IPC communication in the RTLinux/Linux environment are semaphores, mutexes, shared memory pools, and real-time data pipes, which are more complex structures combining buffers and mutexes. Moreover, many A/D cards are controlled by direct access to registers, thus direct I/O access is an important feature.

### *B. RTX*

RTX microkernel is similar to RTLinux kernel in functionality, but different in realization (fig. 1b). It supports real-time tasks, which are called RTSS threads. The Windows kernel is a proprietary solution, and its source code is not freely available to the public. Fortunately, two possible access paths to its modification exist. The first customizable part is the Windows HAL, and the second one is a device driver [2]. Basically, it is necessary to modify the Windows HAL for three purposes:

- to add interrupt isolation between Windows kernel and RTSS threads,
- to implement high-speed clocks and timers,
- to implement shutdown handlers.

The two interconnection points between Windows kernel and RTX microkernel mentioned above make possible to realize connection between RTX microkernel and Windows kernel, providing the same functionality as the interface between RTLinux microkernel and the Linux kernel (fig. 1b), [2, fig. 1]. The communication interface between Windows and RTX kernels implements a low-latency client-server mechanism, which includes both buffers and Service Request Interrupts (SRI) [2].

Due to the communication interface, subset of Windows API services is callable from within a RTSS thread. It includes APIs for storing data to file, thus real-time pipes are not available in the API services set. However, we can reasonably suppose, that similar IPC mechanisms are necessary to provide similar functionality, no matter whether they are hidden for the programmer. Some of Windows APIs available from RTSS threads are listed as non-deterministic, i.e. they can cause significant jitter when called from a RTSS thread. High-speed (and high resolution) clocks are needed for real-time precise timer realization. Within a RTSS thread, time is measured with 100 ns step and resolution.

Shutdown handler is a mechanism delivering more robustness to the real-time RTSS subsystem when the Windows subsystem is crashed or regularly shut down.

It can be summarized, that following differences from RTLinux exist:

- no real-time pipes or their equivalents are available in the API service set,
- it is possible to call a subset of Windows API services directly from the RTX (RTSS) real-time task,
- time is measured with 100 ns resolution,
- interrupts to the Windows kernel are masked while the RTX (RTSS) real-time task runs,
- a real-time interrupt routine has two mandatory parts, which can be used as upper and bottom ISR part,
- it is possible to implement a shutdown handler as the last resort resource.

## III. Applied measurement method

The measurement method applied is described in [3] and more deeply in [4]. Based on RTLinux resource analysis, following important RTLinux characteristics have been identified:

- precision of scheduler (measured as task starting time jitter),
- interrupt latency time,
- execution time of typically used API services, e.g.
  - pipe write and read operations,
  - shared memory write and read operations,
  - thread switching time
- I/O port read and write access time.

The I/O access is also included, because it characterizes hardware, and presents the basic method of communication with both sensors and actuators.

A generalized application has been written, which uses the above-mentioned RTLinux key resources. The application is called RT-golem, and its design is described in [3] and [4].

As RTLinux and RTX operating environments are functionally similar and their key resources are merely the same, it can be supposed, that similar design can be used for jitter measurement under the RTX operating environment too.

The RT-golem is written in C language, thus it should be portable. But, both the environments contain non-portable extensions, and as a result, the design had to be partially re-written. The RT-golem re-written for the RTX environment is called Win-golem.

The measurement method is realized in measurement architecture. The measurement architecture includes both software (measurement and workload tasks and operating system), which all is a mere design abstraction, and hardware, which presents its physical realization. Nonetheless, we should note, that the border between software and hardware design is rather fuzzy, and many non-trivial resources formerly realized in software design are recently applied in hardware design too.

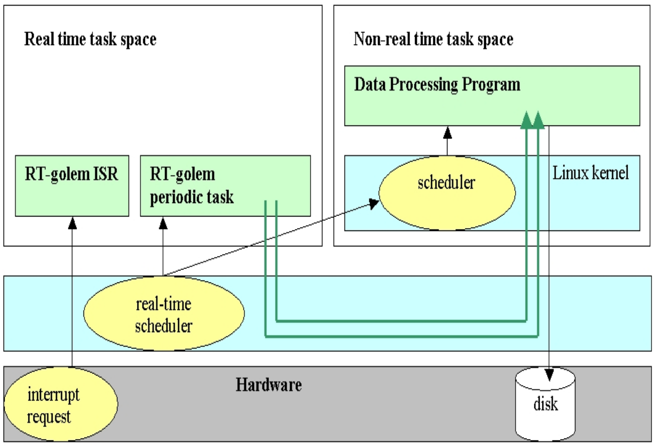

Fig. 1a RT-golem architecture

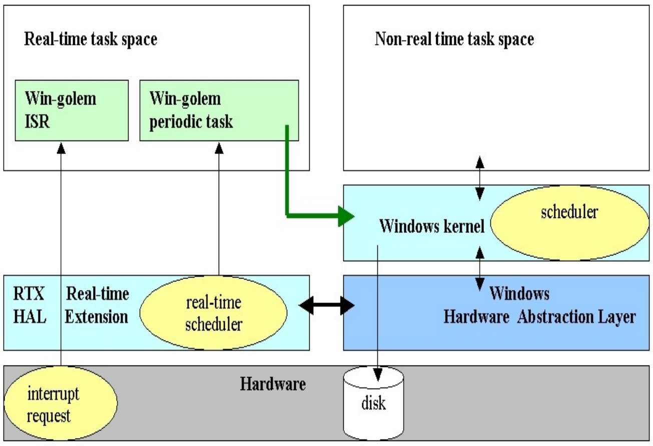

Fig. 1b Win-golem architecture

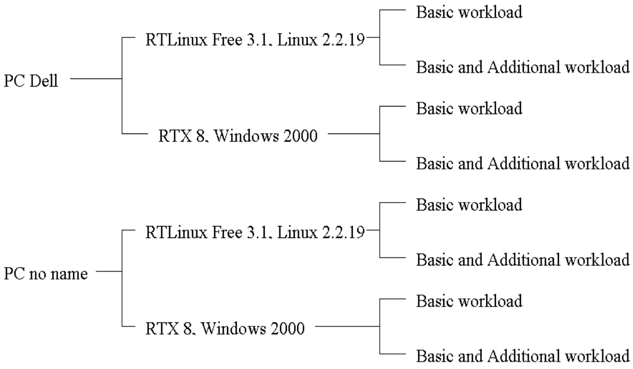
## IV. Experimental setup

Series of measurements have been performed. It has been measured on different hardware (PC Dell, PC no name), under different operating environments (RTLinux Free v. 3.1, RTX v. 8) and under different workload (basic workload only, basic workload and additional workload). Experimental setup configuration chart is given in Figure 1, while hardware configurations are presented in Table 1.



PC Dell
RTLinux Free 3.1, Linux 2.2.19
Basic workload
Basic and Additional workload
RTX 8, Windows 2000
Basic workload
Basic and Additional workload
PC no name
RTLinux Free 3.1, Linux 2.2.19
Basic workload
Basic and Additional workload
RTX 8, Windows 2000
Basic workload
Basic and Additional workload

Fig. 2 Experimental setup configuration chart

Basic workload means a workload caused by the operating system kernel (kernel overhead), daemons normally needed and running, and the measurement task. Additional workload is presented with a shell script copying short files (bash or command.com) in a loop.

## V. EXPERIMENTAL RESULTS

Representative selection of results is presented further. The series of graphs, presented in fig. 3 through 6, and in figures 9 and 10, show the task instance starting (or finishing) times comparison. These graphs are completed with statistical data evaluation graphs (fig. 7 and 8), which show mean vs. median comparison and standard deviation vs. interquartile range comparison on the PC Dell platform.

The task instance starting time is calculated from the previous task instance starting time (as in [3]). This means, the starting time delay impacts two adjacent values. First, the difference between the correct and delayed instance is longer, which causes the spike up on the graph, and then, the difference between the delayed and next correct instance is shorter, which causes the spike down. If both spikes are symmetrical, the second value is okay. Finishing time is calculated from task instance starting time [3]. Spikes on the relative starting time graphs below oscillate around 1 msec, because they show scheduling jitter, i.e. a difference of the actual relative starting time from the nominal value, which is 1 msec.

## VI. CONCLUSION

It can be concluded from the presented experimental results, that the measured task starting time jitter (kernel jitter, [5]) is significantly lesser on the RTX-based measurement architectures, than on the RTLinux Free-based architectures (fig. 3, 5, 9). The median of task finishing time is approximately the same within the applied range of test architectures and workloads. Under RTLinux Free, the port write time median value is ca. 15% less than the port read time median value, but under RTX both medians are the same (fig. 7). As with the task starting time, task finishing time shows significantly lesser jitter on the RTX-based architectures (fig. 4, 6, 8, 10).

Using the RTLinux Free operating system, it has been observed (on graphs presented above and in [2], [3], and [4]), that most of the jitter instances are near the best-case values, but sometimes significantly higher spikes occur. These spikes can form typical patterns (measurement of task relative starting time, left graphs on fig. 3, 4, 9), or can be observed randomly (left graphs on fig. 6, 7, 10), but in any case their amplitude is typical for the underlying hardware. However, with the RTX and Windows system, the spikes are significantly less (fig. 3, right graph), or none at all.

It can be supposed, that the significant worst-case jitter spikes observed in experiments with RTLinux Free are caused by cache writing and flushing effects (in accordance with [2]). As the measurements are performed on the top of the hardware and software stack, and the virtual resources presented to the measurement task by the operating system API services are quite distant to the resources presented to the operating system by the hardware (more precisely, by the part of the operating system realized in hardware), it is not possible to validate such hypothesis by methods described here. However, the absence of this phenomenon on both test hardware with RTX operating system can imply, that the RTX microkernel prevents the hardware from flushing the cache freely. Moreover, some further tracks can be given. [2] notes video drivers as most cache demanding part of Windows operating system, and in the RTX platform evaluation kit, video is used as a workload. Video is a real-time task as well as a RTX microkernel task. Thus, the conflict between video and RTX microkernel can be seen as the conflict between two real-time cache-demanding tasks, which can lead to swapping the RTX code out of the cache.

Unfortunately, the RTX microkernel source code is not freely available, and it is not possible to verify the tracks given above with the code analysis. However, the measurement results as well as the tracks given above can suggest, that the mechanism of locking the real-time code in the hardware cache is worthy to be studied and implemented.

# Multilevel Localization for Mobile Sensor Network Platforms

Jae Young Park, Ha Yoon Song
Department of Computer Engineering, Hongik University, Seoul, Korea
pjyooungs@hotmail.com, hayoon@wow.hongik.ac.kr

***Abstract*—For a set of Mobile Sensor Network, a precise localization is required in order to maximize the utilization of Mobile Sensor Network. As well, mobile robots also need a precise localization mechanism for the same reason. In this paper, we showed a combination of various localization mechanisms. Localization can be classified in three big categories: long distance localization with low accuracy, medium distance localization with medium accuracy, and short distance localization with high accuracy. In order to present localization methods, traditional map building technologies such as grid maps or topological maps can be used. We implemented mobile sensor vehicles and composed mobile sensor network with them. Each mobile sensor vehicles act as a mobile sensor node with the facilities such as autonomous driving, obstacle detection and avoidance, map building, communication via wireless network, image processing and extensibility of multiple heterogeneous sensors. For localization, each mobile sensor vehicle has abilities of the location awareness by mobility trajectory based localization, RSSI based localization and computer vision based localization. With this set of mobile sensor network, we have the possibility to demonstrate various localization mechanisms and their effectiveness. In this paper, the preliminary result of sensor mobility trail based localization and RSSI based localization will be presented.**

## I. Introduction

THE researches on Mobile Sensor Network (MSN) have been plenty worldwide. For MSN, there could be a lot of valuable application with attached sensors as well as capabilities such as locomotion, environmental information sensing, dead-reckoning, and so on. For such applications, usual requirements have been acknowledged with localization of each sensor node and formation of the whole sensor network. In this research, we are going to discuss about a Mobile Sensor Vehicle (MSV) which can compose MSN. We will discuss a construction of MSN as well as required functionalities of each MSN.

This paper is organized as follows. In section II we will discuss localization method that have been researched. The following section III we will analyze the requirement for MSV, the hardware design of MSV, and equipments for localization, and we will discuss software capabilities of MSV software and will show software components to fully control our MSV including software for MSN itself, monitoring program, map building features, and other related topics. In section IV, our approach and methodology for mobility trajectory based localization for medium distance localization will be discussed. Section V we will demonstrate one of the localization feature of our MSV. RSSI (Radio Signal Strength Identification) based localization will be presented based on 802.11 devices with software modification. We will show the merits and demerits of RSSI based localization. Finally section VI will conclude this paper with possible future research topics.

## II. Related Work

There have been a lot of researches regarding mobile sensor localization. In this section, we will discuss past researches concentrating RSSI based localization, and dead-reckoning based localization. This works are not restricted on mobile sensors only but also related to robot technology.

### A. RSSI based Localization

Radio Signal Strength Identification is one of the known solutions for distance measure. It requires wireless network device for mobile sensors and extra features.

We use 802. 11 network devices which have wide popularity. In addition we need communication between mobile sensors thus 802.11 networking devices are popular solutions for us. RSSI features for 802.11 device networks are required features in order to implement physical layer of CSMA/CA networking [12]. However RSSI based distance measure is very prone to radio signal attenuation and thus has low accuracy. And it has some restriction that once it is a data transfer modes, it cannot switched to API mode instantly. It implies the restricted realtimness for RSSI based localization. There are no defined standards for 802.11 RSSI and manufactures of 802.11 device usually provide their arbitrary method [11]. This is another restriction.

In this paper, we will demonstrate our MSV successfully does long distance, low accurate localization only with commercial 802.11 devices and networking software embedded on MSVs.

### B. Computer Vision Based Approach

There are very few researches on localizations by use of computer vision technology. There have been the previous results regarding mobile sensor vehicle control, obstacle detection and so on.

Matsummoto et al. [13] used multiple camera in order to control mobile robots. In their research, cameras are installed on their working space instead of mobile vehicle itself. Their whole system is consisted of mobile robots and multiple cameras and this helps the search of proper path of robots.

This work was supported by 2006 Hongik University Research Fund.

Their initial experiments were done with 3 pan-tilt cameras. Keyes et al. [14] researched various camera options such as lens type, camera type, camera locations and so on. They also used multiple cameras to obtain more precise information. In this paper we will provide MSV with multiple cameras in order to accomplish short distance, high accurate localization.

### C. Autonomous Driving Robot and dead-reckoning

This sort of localization is usually due to military area. For example DARPA, USA invests on unmanned vehicle, and their aim is about 30% of army vehicle without human on board controller. Stanley by Stanford university [15], which earned first prize in competitions, are equipped with GPS, 6 DOF gyroscope and can calculate the speed of driving wheels. Those sensors information can be combined to locate the position of their unmanned vehicle. They used computer vision system with stereo camera and single camera, and laser distance meter, radar in order to get environmental information. Sandstorm from CMU [16] is equipped with laser distance meter as a major sensor. Topographical model can be obtained by laser lines and the speed of car can be calculated by the density of laser line. Gimbal on their vehicle can install long distance laser scanner with seven laser sensors. Shoulder-mounted sensors can calculate height information of topography. Two scanners on bumpers can obtain obstacle information. Long distance obstacles can be identified by radar.

Our MSV are equipped with RSSI devices, stereo cameras and other sensors for dead-reckoning. Apart from the examples of locomotive robots, these equipments are for accurate localization.

## III. Mobile Sensor Vehicle

We developed MSV in order to experiment our localization method in real environment. Various versions of MSV are designed and implemented. The localization functions implemented on MSV are as follows:

- Long distance low accuracy localization by RSSI
- Medium distance medium accuracy localization by dead-reckoning tracking
- Short distance high accuracy localization by Stereo camera with computer vision.

In the following subsection we will discuss hardware and software of MSV respectively.

### A. Hardware

MSV is actually a mobile sensor node for MSN. Each MSV can move autonomously and can identify obstacles. They can communicate each other by 802.11 networking devices. The chassis of MSV are composed of aluminum composite with high durability and lightweight. The main driving mechanism is caterpillar composed of three wheels, L-type rubber belt, gears as shown in figure 1. The adoption of caterpillar is for minimization of driving errors. There are a lot of rooms to install additional sensor hardware. With digital compass equipped on the top of MSV, the accurate vehicle location can be sensored. This angular information can help exact localization of MSVs. The design concepts of MSV are as follows.

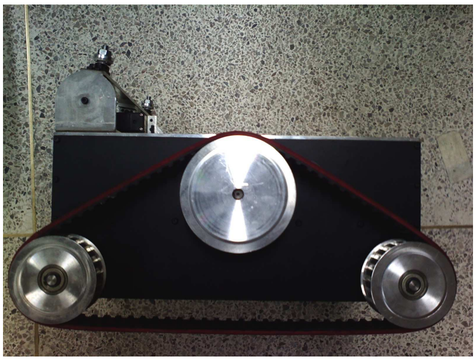

Fig. 1. Driving Mechanism Outlook

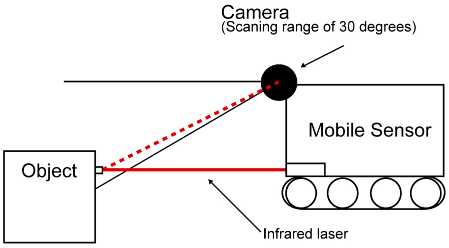

Fig. 2. Obstacle Detection Mechanism

- Autonomous mobility
- Extensibility of equipped sensors
- precise movement and mobility trail

And MSV characteristics as a node of mobile sensor network are as follows:

- Self identification and colleague identification
- Wireless communication
- Computing power

For autonomous driving, MSV must identify obstacles and avoid them. We use an infrared laser and cameras with infrared filter. IR laser is constantly lighting in parallel to round. Camera looks down grounds in a degree of 30 which is determined by experiments. The concept of this obstacle detections is depicted in figure 2. Obstacle reflects IR laser and sensed by camera [3], [5]. The obstacles with reflected IR will be detected as white lines. For short distance obstacles within the dead angle of camera, ultrasonic sensors are located under the MSV and in front of MSV. For computer vision based localization, MSVs are equipped with stereo eyes as shown in figure 3. Three servo motors can control two cameras independently. This stereo camera system can be used not only for localization but also for obstacle detection with diminished dead angle. There are three infrared LEDs mounted in the front of MSV. These LEDs are for computer vision based localization.

Fig. 4. Hardware Structure

For hardware construction, we need micro controller unit, a serial communication port, a PWM port, an interrupt port in order to control motors and communicate with sensors. Figure 4 shows the conceptual structure of MSV hardware.

### B. Software

Software for MSV operations are required in a form of embedded software. Figure 5 shows required facility and their structure for MSV software.

Total part of software can be divided into five categories. One of the role of software is to convert sensor information into driving information. Information for driving can be obtained via serial communication from T-board (MCU) with driving information and angular information.

The location of MSV is constantly updated with the moving distance and updated angle. Camera class provides obstacle information as well as basic information for map building. Map building class builds a map with the information from T-board class and camera class. These maps are required for autonomous locomotion and localization. Network class provides networking functionalities between MSVs.

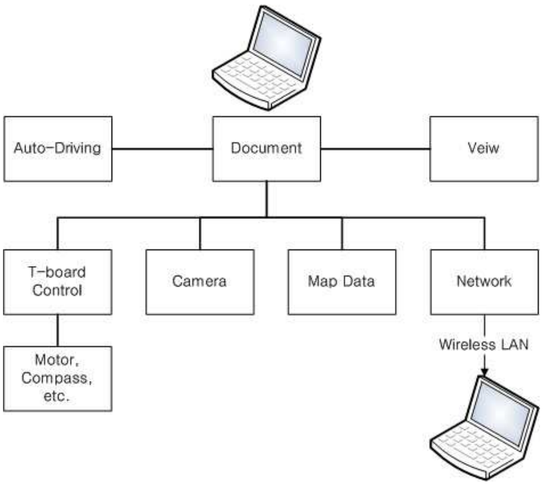

Fig. 5. Software Structure

*1) Core Software:* We implement core software based on multi threads. There is document class, which provides organic data flow between classes. Thus the major role of MSV software is as follows.

- Autonomous driving
- Motor control and driving distance identification
- Communication with MCU (T-board)
- Obstacle detection
- Map building
- Internetworking
- User interface dialog (Monitoring Program)

*2) Monitoring Program:* Monitoring program is a user interface between MSV and user. Monitoring program shows MSV condition, camera view, driving information, map built, and other sensor information. It also provides manual operation functionality of MSV. Figure 6 shows outlook of monitoring program. A mouse click on local map can drive MSV into dedicated location on the map.

Subdialog box in figure 7 shows the map built during the navigation of each MSV. It shows a result of localization based on dead-reckoning.

*3) Map Building:* Map building is one of the core parts of localization. The result of localization must be presented on local map and therefore be transferred to global map. MSVs communicate with each other in order to combine local maps into global maps. The following information will be shown on a map.

- White : Untapped territory
- Red : Territory with obstacle
- Blue : Territory with MSV
- Green : Tapped territory
- Undefined : Totally unknown territory

For map building we must consider relative coordinate and absolute coordinate. For example, obstacle information identified by MSV is in a form of relative coordinate. In relative coordinates, the very front of MSV is in angle 0 as shown in figure 8. This coordinate must be transformed into

Fig. 9. Absolute Coordinate

absolute coordinate as shown in figure 9 and therefore can be a part of map.

Local map is usually in a form of grid map. However in case of global map with huge capacities, grid map is very inefficient. Therefore we will use topological map for global map as presented by Kuipers and Bynn [4]. Thrun [6] presented a hybrid approach of both maps and we will consider it as our ultimate format of global map. Table I compares advantages and disadvantages of grid and topological map.

## IV. Sensor Mobility Trail based localization

### A. Dead-Reckoning

For the medium distance localization, we decided to utilize mobility trail. We define the range of medium distance between 4 meters and 40 meters since our vision based short distance localization covers within the range of 5 meters and RSSI based long distance localization is effective outside the range of 30 meters. Our aim is to trail the mobility of MSV and to record the trail on the local map with reasonable accuracy for medium distance localization. Every driving mechanism for mobile sensors or even mobile robots has mechanical errors and it is impossible to avoid such errors practically. We can summarize the cause of driving errors as followings:

- The difference between the sizes of two (left and right) wheel
- The distortion of wheel radius, i.e. the distance between average radius and nominal radius
- The wheel misalignment
- The uncertainty about the effective wheelbase
- The restricted resolution of driving motors (usually step motors)

Usually those errors are cumulated and final result will be void without proper error correction technique. However, in order to cope with those location errors due to mechanical errors, a method of dead-reckoning have been widely used and we also adopt such technique as well. Dead-reckoning is a methodology that calculates the moving distance of two wheels of MSV and derive the relative location from the origin of MSV.

Among the various versions of Dead-reckoning techniques, we used UMBmark technique from University of Michi-

TABLE I
COMPARISON BETWEEN GRID MAP AND TOPOLOGICAL MAP

| MAPS | Grid MAP | Topological MAP |
|---|---|---|
| Advantages | • precise presentation of geography of environment<br>• ease of algorithm design : environmental modeling, path finding, localization by map-matching | • simple presentation of environment and simple path planning<br>• tolerance of low accuracy mobile sensors<br>• natural interface to users |
| Disadvantages | • difficulty in path planning<br>• requirement of large memory and computation<br>• poor interface to symbolic problem solver | • impossibility of large map building with inaccurate, partial information<br>• difficulties in map-matching : difficulties in calculation of pivot sensor value<br>• difficulties in dealing complex environment |

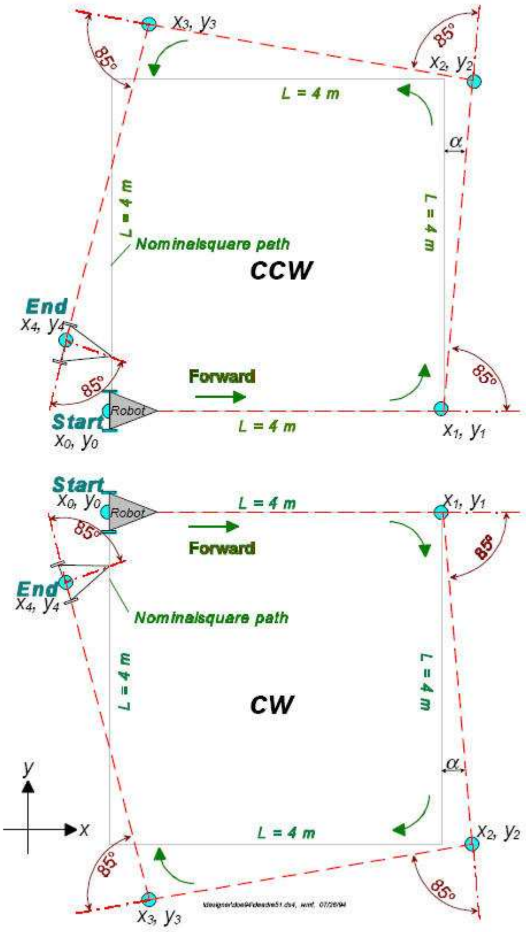

Fig. 10. Rotational Angle Error

gan [2]. UMBmark analyzes driving mechanism errors and minimized the effect of driving errors. UMBmark analyzes the result of MSV driving in a certain distance and compensates mechanical errors of MSV driving mechanism. The driving results of rectangular course, both in clockwise(CW) and counter-clockwise(CCW), and then analyzed.

Two error characteristics are classified in Rotation angle error and Wheel mismatch error. Rotational angle errors are for the difference between actual wheel sizes and theoretical design sizes of wheels. Due to rotational angle errors, CCW driving after CW driving shows larger errors as usual. For example, actual wheel size bigger than designed wheel size results in insufficient rotation at corners and then rotational angle errors are cumulated for the whole driving. The following equation summarizes the rotational angle error which is depicted in figure 10.

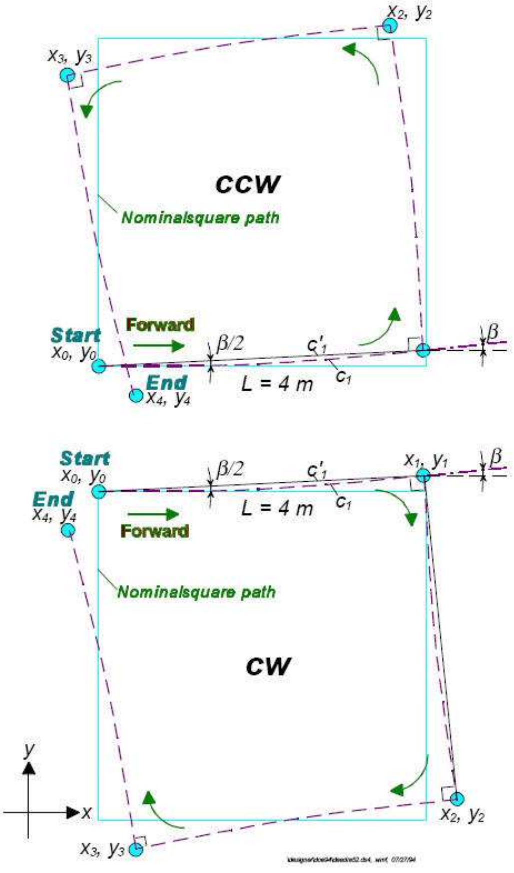

Fig. 11. Wheel Mismatch Error

$$E_d = \frac{D_R}{D_L}$$

where $D_R$ is diameter of left wheel and $D_R$ is diameter of right wheel. In short, $E_d$ is a ration between diameters of left wheel and right wheel.

Wheel mismatch errors are from wheelbase mismatch. This error causes skews in straight driving. With wheel mismatch error, the error characteristics of CW driving is opposite to CCW driving. The following equation summarizes the wheel size error which is depicted in figure 11.

$$E_b = \frac{90°}{90° - \alpha}$$

where $\alpha$ is a value of rotational angle error. $E_b$ stands for a ration between ideal and practical errors in rotation, i.e. wheel base error.

Equations above and figures 10 and 11 have been reprinted from [2].

Mechanical errors are systematical errors and therefore can be predicted and analyzed, while non-mechanical errors cannot be predicted because non-mechanical errors are due to the driving environment. Non-mechanical errors are classified as follows:

- Uneven driving floor or ground
- Unpredicted obstacle on driving course
- Slipping while driving

We applied UMBmark to our MSV and the following subsection shows the result.

### B. Driving Error Correction of MSV

We composed a set of experiment for MSV driving in order to apply UMBmark. The driving experiments have been made on the flat and usual floor with the rectangular driving course of 4 × 4 meters. As shown in figures 10 and 11, both CW and CCW driving have been made and error values have been measured. These error values are incorporated in our software system and MPU controllers.

With the following equations from [2] we can find the error value for error correction.

$$b_{actual} = E_b \times b_{nominal}$$

where $b_{actual}$ is an actual wheelbase and $b_{nominal}$ is a measured wheelbase.

$$\Delta U_{L,R} = c_{L,R} \times c_m \times N_{L,R}$$

Where U is actual driving distance, N is the number of pulses of the encoder, and $c_m$ is the coefficient to convert pulse per centimeters.

Our experimental result with driving location correction by UMBmark dead-reckoning mechanism is shown in figure 12. Circled dotes are result from CCW driving and rectangular dotes are from CW driving. Empty dotes are of uncorrected driving results while filled dotes are of driving results with UMBmark in 16 meter driving experiment. Note that the origin of MSV (starting point) at the coordinate (0,0) are at the upper right part of the figure. Without dead-reckoning technology, MSV returns to erroneous point than the origin point, at the left part of the figure. This MSV tends to show more errors with CW driving. With the application of UMBmark technique, we achieved faithful result within 10 centimeters of error range in total. Directional errors are within the range of 3 centimeters from the origin. Since our approach is for mechanical driving errors, non-mechanical errors can be avoided and thus we will introduce real-time correction of driving with the help of digital compass for the future researches. Thus it is possible to mention that the trail of MSV in figure 7 is in the correct location within the errors of 10cm in our experimental environments.

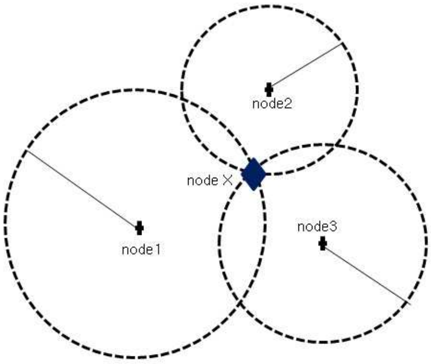

Fig. 13. Triangulation With RSSI Measurement

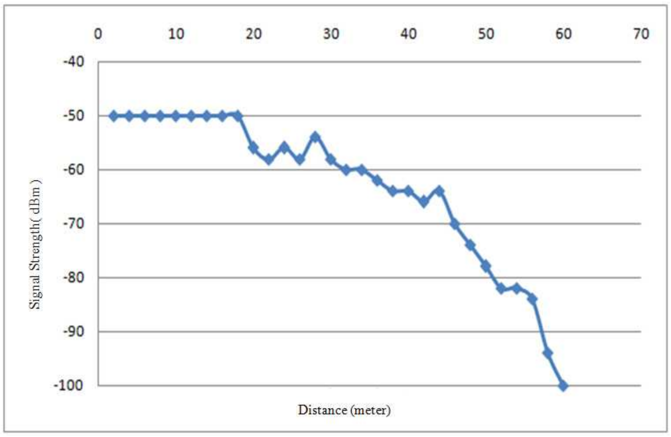

Fig. 14. RSSI values According To Distance

## V. RSSI BASED LOCALIZATION

Our MSV are equipped with homogeneous 802.11 networking devices with RSSI facilities. With distance information we can do triangulation with at least three nodes and one anchor. Our monitoring station with monitoring program can act as an anchor. The 802.11 networking devices can be switched to AP (Access Point) mode so that each MSN can act as AP. With software modification that utilizes 802.11 device RSSI features, we can achieve RSSI based localization for our MSN.

The unit of RSSI is in dBm (-50dBm $\sim$ -100dBm) and it designates distances between specified MSVs. As already mentioned, the RSSI value is very affective by environments, and we obtain error rate of 10 $\sim$ 15% in specific distance. The RSSI value is very sensitive with hardware vendor and the direction of AP [7]. Our experimental environment is as follows.

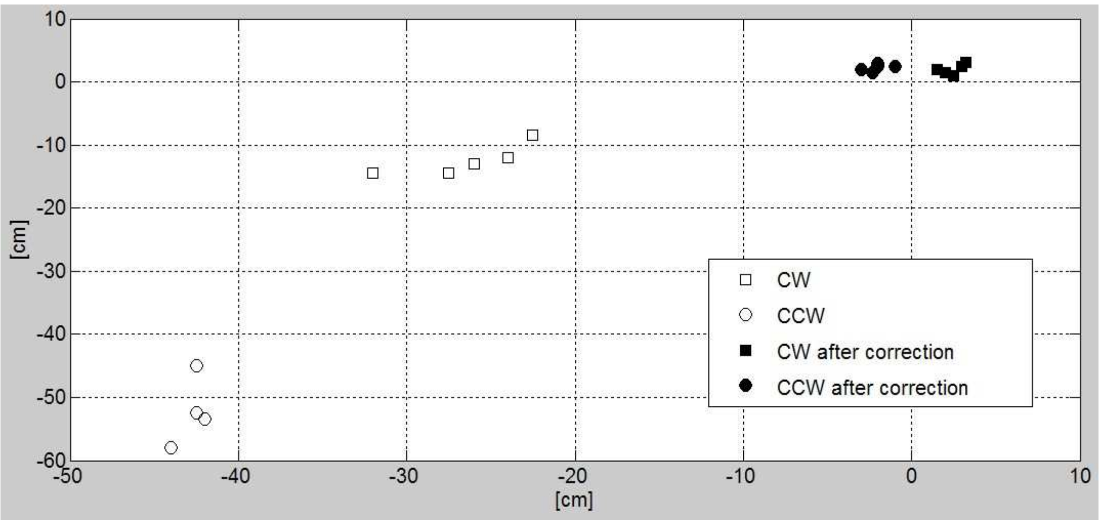

Fig. 12. Result of UMBmark

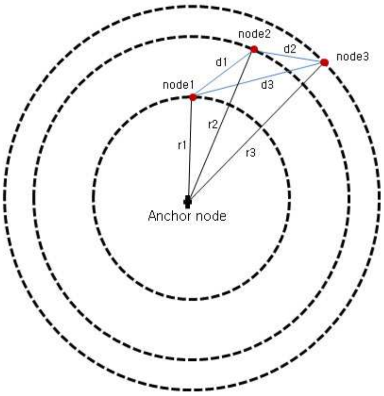

Fig. 15. Relation Between One Fixed Anchor And Mobile Sensor Vehicles

- Wide open area
- Intel Wireless LAN 2100 3B Mini PC Adapter
- WRAPI software model [11]
- One fixed anchor as monitoring station

For the calibration of our RSSI device, a set of experiment has been conducted and the results are shown in figure 14.

We can find within the distance of 20 meter, RSSI is no more useful for distance measure since the signal strength is too high. Our experiments shows RSSI based localization is useful more than 35m distance. The values are within error range of 15% by experiment. This is the main reason why we choose RSSI based localization for long distance, low accuracy localization.

From the distance information from RSSI sensing, we can do triangulation as shown in figure 13. For actual implementation, we have one fixed anchor and can do more precise localization with a known anchor coordinate as shown in figure 15. The figures show three mobile nodes one anchor node. The distance obtained from circle $r1, r2, r3$ can be obtained from RSSI values. Thus with this environment we can triangulate the coordinate node $X$ from the intersection of circles drawn by node 1, node 2, and node 3 [9][10].

Thus from the distance which can be obtained from RSSI values, let the distance be d$i$ from radius of circle r$i$ The following algorithm 1 shows a procedure to find coordinates of each MSV with provided distance information by RSSI.

Figure 16 shows a final result in RSSI based localization. The x-axis stands for actual distance between MSVs and y-axis shows a distance calculated by algorithm 1. As we predicted the RSSI based localization is useful with the distance more than 30 meters. On the range where RSSI based localization is effective, we can see errors between actual distance and calculated distance. We believe it is tolerable since we have another method of localization with more accuracy within the distance of 30 meters. Of course, the distance information is not a sufficient condition for localization. The other information of direction of MSV can be obtained by digital compass on each MSV. Thus we implemented long distance, low accuracy localization.

## VI. Conclusions

For the localization methodologies for mobile sensor network, we proposed three different categories of localization methodology. In addition for the experiment, we implemented mobile sensor vehicle as a node of mobile sensor network. We showed brief description of mobile sensor vehicle including hardware and software functionalities. The driving mechanism hardware and software cooperate with each other and naturally achieve localization based on dead-reckoning, which is a medium distance and medium accuracy localization. The result of localization can be presented on local maps and eventually be merger into global maps. In addition we showed RSSI based localization. The long distance, low accuracy localization can be implemented by 802.11 networking devices

}}}}}}
```

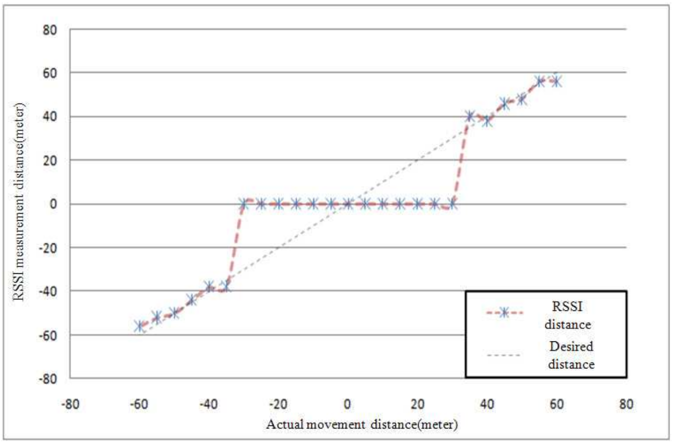

Fig. 16. Actual and RSSI based Distance

and algorithms based on triangulation. For short range, high accuracy localization, a stereo camera system is utilized. The detailed result of this computer vision based approach can be found in [18]. From these three levels of localization, we believe that we implemented useful localization system and will do more research using this platform. For example multiple MSV can cooperate and communicate each other and then a formation based on localization can be made. Also, a digital compass is also equipped in each MSV. Our medium accuracy localization can be more precise with more error correction mechanism with digital compasses.

# A Component-based Approach to Verification of Embedded Control Systems using TLA$^+$

Ondrej Rysavy and Jaroslav Rab

Faculty of Information Technology
Brno University of Technology
Brno, Czech Republic
Email: {rysavy,rabj}@fit.vutbr.cz

***Abstract*—The method for writing TLA$^+$specifications that obey formal model called Masaccio is presented in this paper. The specifications consist of components, which are built from atomic components by parallel and serial compositions. Using a simple example, it is illustrated how to write specifications of atomic components and components those are products of parallel or serial compositions. The specifications have standard form of TLA$^+$specifications hence they are amenable to automatic verification using the TLA$^+$model-checker.**

## I. Introduction

SOFTWARE running in embedded systems necessary acquires some properties of the physical world. Usually, these properties form a part of non-functional aspects in system requirements [1]. To model embedded software, these aspects must be considered by a specification method otherwise the model of a system easily diverges from the reality and becomes inapplicable in further refinement and analysis. Constructing large systems relies on effective and systematic application of modular approach. A large class of entities playing the role of building blocks that can be composed have been defined, most notably, classes for object-oriented program construction, components in hardware design, procedures and modules in procedural programming, and active objects and actors for reactive programming [2].

This paper deals with a method based on a formalism called Temporal Logic of Actions [3] that enables to describe embedded control software in a modular manner and apply an automatized model-checker tool to verify required properties of a specification. The main contribution of this paper lies in demonstration of how the TLA$^+$specifications whose interpretation is that of a formal model called Masaccio[4] can be written in a systematic way. The formal model permits to construct a hierarchical definition of components that are built from atomic components using operations of parallel composition, serial composition, renaming of variables, renaming of locations, hiding of variables, and hiding of locations. As the resulting TLA$^+$specifications have the form of a conjunction of initial predicate and next-state actions, they are readily explorable by the TLA$^+$explicit model-checker.

## II. Component Model

This section gives a brief overview of a formal model for embedded components as defined by Henzinger in [4]. In this paper, only discrete components are considered, although the proposed approach relies on the language that can be applied to hybrid systems [5] as well.

A fundamental entity of the model is a component. The component structures the system into architectural units that interact through defined interfaces. It is possible to structure components into a hierarchy that can be arbitrary nested to simplify the system design. The component $A$ consists of definition of interface and internal behavior. An interface defines disjoint sets of input variables, $V_A^{in}$, output variables, $V_A^{out}$, and a set of public locations, $L_A^{intf}$. An execution of the component consists of a finite sequence of jumps. A jump is a pair $(p, q) \in [V_A^{in,out}] \times [V_A^{in,out}]^1$. An observation $p$ is called the source of jump $(p, q)$ and an observation $q$ is called the sink of jump $(p, q)$. A jump $v$ is successive to jump $u$ if the source of jump $v$ is equal to the sink of jump $u$. Formally, an execution of $A$ is a pair $(a, w)$ or a triple $(a, w, b)$, where $a, b \in L_A^{intf}$ are interface locations and $w = w_0 \dots w_n$ is a nonempty, finite sequence of jumps of $A$ such that every jump $w_i$, for $1 \leq i \leq n$ is successive to the immediately preceding step $w_{i-1}$. We write $E_A$ for the set of executions of the component $A$.

*An atomic component* is the simplest form of components found in Masaccio. The behavior of the component is solely specified by its jump action. The interface of atomic component exploits input variables read by the component and output variables controlled by the component. The component $A(J)$ has two interface locations, $from$ and $to$; that is, $L_{A(J)}^{intf} = \{from, to\}$. The entry condition of $from$ is the projection of the jump predicate to the unprimed I/O variables. The entry condition of *to* is unsatisfiable.

Two components $A$ and $B$ can be combined to form a *parallel composition* $C = A \otimes B$ if the output variables of $A$ and $B$ are disjoint and for each interface location $a$ common to both $A$ and $B$, the entry conditions of $a$ are equivalent in $A$ and in $B$. The input variables of component

[1] The research has been supported by the Czech Ministry of Education in the frame of Research Intentions MSM 0021630528, and by the Grant Agency of the Czech Republic through the grants GACR 201/07/P544 and GACR 102/08/1429.

[1] $[V_A^{in,out}]$ stands for a set of all possible assigments of values into input and output variables of a component.

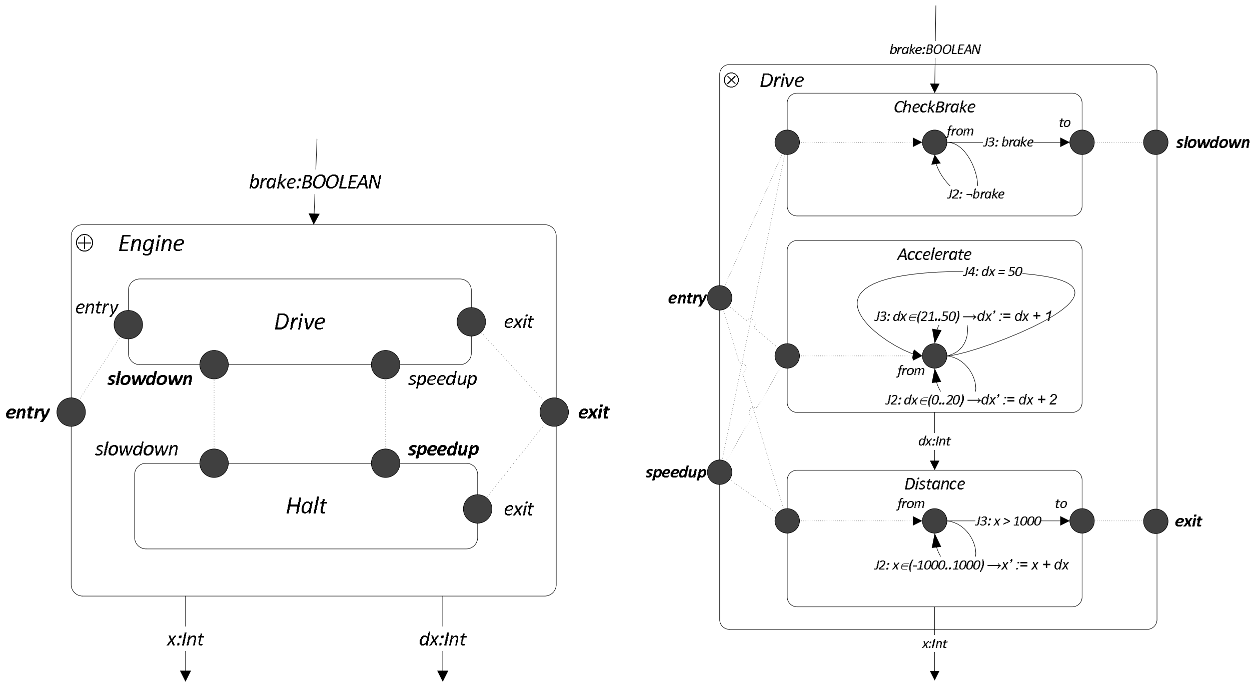

Fig. 1. The components Engine and Drive

$V_C^{in} = (V_A^{in} \setminus V_B^{out}) \cup (V_B^{in} \setminus V_A^{out})$. The output variables of the component are $V_C^{out} = V_A^{out} \cup V_B^{out}$. The interface locations of $A \otimes B$ are the interface locations of $A$ together with the interface locations of $B$. An interface location $a$ that is common to $A$ and $B$ and its entry conditions agree in both components has this entry condition also in $A \otimes B$. Other interface locations cannot be used to entry the component.

The definition of parallel composition specifies that each jump is done in synchronous manner in both subcomponents. Moreover, if one component reaches the exit interface location then the execution in the other component must be terminated. If both components reach their exit locations one is chosen nondeterministically. As the consequence of these properties, parallel composition operation is associative and commutative.

Two components $A$ and $B$ can be composed in series to form a *serial composition* $C = A \oplus B$ if the set of output variables are identical; that is, $V_A^{out} = V_B^{out}$. The input variables of composed component is $V^{in} = V_A^{in} \cup V_B^{in}$. The interface locations of $A \oplus B$ are the interface locations of $A$ together with the interface locations of $B$. If $a$ is an interface location of both $A$ and $B$, then the entry condition of $a$ in $A \oplus B$ is the disjunction of the entry conditions of $a$ in the subcomponents $A$ and $B$.

The set of execution of the component $C = A \oplus B$ contains 1) the pair $(a, w)$ iff either $(a, w|_A)$ is an execution of $A$, or $(a, w|_B)$ is an execution of $B$, 2) the triple $(a, w, b)$ iff either $(a, w|_A, b)$ is an execution of $A$, or $(a, w|_A, b)$ is an execution of $B$. The operator of serial composition is associative, commutative, and idempotent.

To support these two compositional operations, the renaming and hiding operations are defined for variables and locations. The renaming operation maps variables and locations of different names to each other that allows for sharing data and control between components. Hiding makes variables or locations internal to the component, which is useful when a complex behavior is modeled inside the component.

## III. TLA$^+$

Temporal Logic of Actions (TLA) is a variant of linear-time temporal logic. It was developed by Lamport [3] primarily for specifying distributed algorithms, but several works shown that the area of application is much broader. The system of TLA+ extends TLA with data structures allowing for easier description of complex specification patterns. TLA+ specifications are organized into modules. Modules can contain declarations, definitions, and assertions by means of logical formulas. The declarations consist of constants and variables. Constants can be uninterpreted until an automated verification procedure is used to verify the properties of the specification. Variables keep the state of the system, they can change in the system and the specification is expressed in terms of transition formulas that assert the values of the variables as observed in different states of the system that are related by the system transitions. The overall specification is given by the temporal formula defined as a conjunction of the form $I \wedge \Box[N]_v \wedge L$, where I is the initial condition, N is the next-state relation (composed from transition formulas), and L is a conjunction of fairness properties, each concerning a disjunct of the next-state relation. Transition formulas, also called actions, are ordinary formulas of untyped first-order logic defined on a denumerable set of variables, partitioned into sets of flexible and rigid variables. Moreover, a set of primed flexible variables, in the

```

Fig. 2. The TLA$^+$ specification of component Accelerate

form of $v'$, is defined. Transition formulas then can contain all these kinds of variables to express a relation between two consecutive states. The generation of a transition system for the purpose of model checking verification or for the simulation is governed by the enabled transition formulas. The formula $\Box[N]_v$ admits system transitions that leave a set of variables v unchanged. This is known as stuttering, which is a key concept of TLA that enables the refinement and compositional specifications. The initial condition and next-state relation specify the possible behaviour of the system. Fairness conditions strengthen the specification by asserting that given actions must occur. The TLA+ does not formally distinguish between a system specification and a property. Both are expressed as formulas of temporal logic and connected by implication $S \implies F$, where S is a specification and F is a property. Confirming the validity of this implication stands for showing that the specification S has the property F. The TLA+ is accompanied with a set of tools. One of such tool, the TLA+ model checker, TLC, is state-of-the-art model analyzer that can compute and explore the state space of finite instances of TLA+ models. The input to TLC consists of specification file describing the model and configuration file, which defines the finite-state instance of the model to be analysed. An execution of TLC produces a result that gives answer to the model correctness. In case of finding a problem, this is reported with a state-sequence demonstrating the trace in the model that leads to the problematic state. Inevitably, the TLC suffers the problem of state space explosion that is, nevertheless, partially addressed by a technique known as symmetry reduction allowing for verification of moderate size system specifications.

## IV. Specification of Components

Using a simple example as required by space constraints, this section explains the construction of TLA$^+$specifications that corresponds to Masaccio embedded components.

An example represents a specification of component $Engine$ taken from [4]. This component is a part of a complex specification that models the control of a railway crossing. In particular, the $Engine$ component controls acceleration and deceleration of a train that is moving in a near distance to the railway crossing. Although this example is rather trivial, it is sufficient to demonstrate basic principles of the specification method as it contains both parallel and serial compositions.

The component $Engine$ and its subcomponents are visually modeled in figure 1. Components are represented by rectangles. Input and output variables are represented by arrows connected to component boundaries. Locations are represented by solid discs. Jump actions are represented by arrows. A jump is labeled with condition predicate and action predicate, which computes new values of output variables.

Component $Engine$ consists of a serial composition of two subcompoments, namely, $Drive$ and $Halt$. An entry location is directly connected with one of the locations of $Drive$ component. There is one exit location that is accessible from both subcomponents. Other interface locations, namely $slowdown$ and $speedup$, serve for passing the control flow between $Drive$ and $Halt$ components. The component interacts with the environment by reading input variable $brake$ and controlling output variables $x$ and $dx$. These variables are also available to both subcomponents.

Component $Drive$ governs train acceleration. The component is a parallel composition of three atomic components: $CheckBrake$, $Accelerate$, and $Distance$. Input variable $brake$ determines whether the train accelerates or decelerates. Its value is observed by $CheckBrake$ component that takes away control from $Drive$ component if variable $brake$ signalizes the application of train's brake. In component $Accelerate$, the actual speed of the train is computed. The train dynamics is simplified by considering that the train accelerates by $1ms^{-2}$ if its velocity is greater $20ms^{-1}$ and by $2ms^{-2}$ if its velocity is

```

Fig. 3. The TLA$^+$ specification of component $Drive$

less than $20ms^{-1}$, respectively. Finally, component $Distance$ is responsible for computing the actual distance from the railway crossing.

Component $Halt$ has similar structure to component $Drive$. It's purpose is to slow the train down as long as input variable $brake$ is set to true. If $brake$ is released it passes the control back to $Drive$ component through location $speedup$.

To show that TLA$^+$ specifications conform to Masaccio interpretation, the interpretation of TLA$^+$ expressions needs to be defined. The following simplified system is used (for complete semantics see e.g. [6]). The TLA$^+$ module is called a standard module if it has the form of conjunction of an initial state predicate and a next-state action predicate. The meaning of a standard TLA$^+$ module $M = \langle V, I, N \rangle$, where $V$ is a finite set of variables, $I$ is an initial predicate, and $N$ is a set of next-state actions, is then defined by valuation function $\mathcal{V}_s(x)$, which assigns a value to each variable $x \in V$ and each state $s$, and model satisfying relation, $s \models_{\mathcal{M}} p$, which asserts that proposition $p$ is true in state $s$ in the model $\mathcal{M}$ of module $M$. A model $\mathcal{M}$ is a graph that consists of a set of nodes $\mathcal{M}_N$ representing states, and a set of edges $\mathcal{M}_E$ representing transitions between states. Obviously, a set of initial states of model $\mathcal{M}$ is defined as all states satisfying the initial predicate; that is, $\mathcal{I} = \{s \in \mathcal{M}_N : s \models_{\mathcal{M}} I\}$. Each next-state action $n$ can be split into a part $n_1$, where only unprimed variables occur, and a part $n_2$, where also primed variables occur. If $s \models_{\mathcal{M}} n_1$ and $r \models_{\mathcal{M}} n_2$ then, necessary, $s, r \in \mathcal{M}_N$ and $\langle s, r \rangle \in \mathcal{M}_E$. Masaccio interpretation is defined in terms of execution traces. Obviously, an execution is a trace that can be generated by traversing a graph $\mathcal{M}$. Formally, a trace $w$ consists of jumps $(p, q)$, such that $p, q \in \mathcal{M}_N$ and $\langle p, q \rangle \in \mathcal{M}_E$.

### A. Specifying atomic components

According to Masaccio semantics, an atomic discrete component $A(J)$ is completely specified by a jump predicate that defines a set of legal jumps $J$. Further, an atomic component has an arbitrary number of input and output variables. In each atomic component, there are only two interface locations, denoted as $from$ and $to$.

The representation of atomic component is straightforward in TLA$^+$ language. In figure 2, TLA$^+$ description of $Accelerate$ component is shown. A set of jumps is a conjunction of three next-state actions. Action $J1$ represents acceleration of a train in lower speeds. Action $J2$ represents acceleration of the train in higher speeds. Finally, action $J3$ specifies that if the train reaches its maximal speed it maintains this speed. In addition to state variable $location$ and controlled variable $dx$, which keeps the actual train's speed, the module declares a boolean variable $clock$, which models the passing of the time. Introducing the system clock is necessary for synchronization of the components. While this simple approach seems to be appropriate in this case, more flexible approach, e.g. [7], might be considered in more involved real-time specifications.

The following definition generalizes atomic component specification rules.

*Definition 1 (atomic component):* An atomic component $A(J)$ is a TLA$^+$ module $M = \langle V, I, N \rangle$ such that:

- it declares a variable for each I/O variable of the atomic component; that is, $\forall v : T \in V^{in,out}_{A(J)} : \exists v \in V$ such that $s \models_{\mathcal{M}} v \in T$ for all $s \in \mathcal{M}_N$.
- it declares a location variable; that is, $location \in V$, and $s \models_{\mathcal{M}} v \in \{from, to\}$ for all $s \in \mathcal{M}_N$.
- the meaning of next-state action $N$ agrees with the predicate $\varphi^{jump}_J$; that is, $(p, q) \models_{\mathcal{M}} N$ if each unprimed variable $x$ from $N$ is assigned the value $\mathcal{V}_p(x)$ and each primed variable $y$ from $N$ is assigned the value $\mathcal{V}_q(y)$.
- the meaning of initial predicate $I$ agrees with the predicate $\varphi^{en}_{A(J)}(from)$; that is $p \models_{\mathcal{M}} I$ for every trace of atomic component $A(J)$ with prefix $(from, (p, q))$ if each variable $x$ from $I$ is assigned the value $\mathcal{V}_p(x)$.

As it can be seen from the TLA$^+$specification in figure 2, the atomic specification contains variable denoted as $clock$. This variable serves to synchronization purposes. It enforces that parallel actions are executed at the same time. Therefore all jumps include the condition stating $clock' = \neg clock$. Except proper actions, there are also specific actions supporting serial compositions as described later in this section. These specific actions violate this condition requiring that the time is stopped; that is, $clock' = clock$.

A component can be entered at location $a$ if an entry condition $\varphi^{en}_A(a)$ is satisfied at $(p, q')$; that is, $(p, q') \models \varphi^{en}_A(a)$. A valid expression of entry condition is similar to next-state relation in TLA. It has form of conjunctions of expressions that can contain unprimed and primed variables. Contrary to TLA, the entry condition is enabled if both unprimed and primed parts are satisfied in $(p, q)$, while the TLA action is enabled if the unprimed part is satisfied in state $p$. This is important for guarantee of the dead-lock free property. As TLC automatically checks whether the given specification is dead-lock free, it is possible to relax the entry condition into its weaker form $p \models \varphi_A^{en}(a)$, which does not contain the primed variables.

### B. Specifying Composition of Components

The component $Drive$ shown in figure 1 is a result of parallel composition of three subcomponents. The corresponding TLA$^+$ specification is given in figure 3. The semantics of parallel composition corresponds to joint-action specification as described by Lamport in [3, p.147]. Its encoding in TLA is straightforward.

The $Drive$ module contains input and output variables $brake$, $x$, $dx$ and also variables $loc1$, $loc2$ and $loc3$ that keeps the state of subcomponents $DriveBrake$, $Accelerate$ and $Distance$, respectively. These location variables are bound to variable $location$ in each component during the component instantiation as declared on lines 5-7. Line 9 defines a collection of initial states of the subcomponents. The initial predicate $Init$ is a conjunction of initial predicates of all subcomponents. Next-state action predicate $Next$ is a conjuction of next-state predicates of subcomponents, which gives the intended execution interpretation of the component; that is, the jumps of subcomponents are executed in parallel and in synchronous manner.

*Definition 2 (parallel composition):* A component $C = A \otimes B$ composed in parallel from subcomponents $A$ and $B$ can be written as TLA$^+$module $M_C = \langle V_C, I_C, N_C \rangle$, where

- $V_C$ is a set of module's variables that includes all input and output variables of the subcomponents and location variables (an implicit renaming of location variables is considered to prevent the slash of their names in module $M_C$); that is $V_C = V_A \cup V_B$.
- $I_C$ is an initial predicate that is a conjunction of initial predicates of both submodules and a component specific constraints; that is $I_C = I_A \wedge I_B \wedge I$.
- $N_C$ is a next-state action predicate that is defined as a conjunction of next-state predicates of both submodules; that is $N_C = N_A \wedge N_B$.

A state space of a composed component is generated according the initial predicates and next-state actions of its subcomponents. The conjunction of next-state actions requires that there are simultaneous jumps in each of the subcomponent. Moreover if one of the subcomponent reaches its end location, which causes that such component has not enabled action, it is not possible to execute any jump in any of the contained components. This configuration is then recognized as the end location of the component.

The serial composition of components requires that only one contained component has control at a time. This needs to be reflected in a location configuration. Therefore a special location, denoted as empty string (""), has been added to represent a state of a component without a control. A component whose location configuration is "" cannot execute any of its jumps. To enable the passing of control between components, specific actions that modify only location variables are added into the specification. Their purpose is similar to that of connector elements that can be found in many architecture description languages, e.g. [8].

The example of a component composed in series is shown in figure 4. The module $Engine$ instantiates two subcomponents, namely $Drive$ and $Halt$. The initial predicate specifies that the component $Drive$ will have control when component $Engine$ is first executed. This means to define valid initial interface location for subcomponent $Drive$, in particular, to assign value $from$ to $dl1$, $dl2$ and $dl3$ variables, and to define that $Halt$ subcomponent is in the idle state that is expressed by assigning "" to variables $hl1$, $hl2$ and $hl3$. To define next-state action predicates we assume that specification of $Halt$ and $Drive$ were both extended with the following definition:

$$Idle \triangleq loc1 = "" \wedge loc2 = "" \wedge loc3 = ""$$

This definition asserts that component is in the idle state. Therefore, action $L1$ and action $L2$ define a behavior of the containing component as an execution of component $Drive$ and component $Halt$, respectively, assuming that a complementing component is being idle during this execution. Finally, two connector actions are necessary to allow switching between $Drive$ and $Halt$ components. In particular, connector $C1$ specifies that if $Drive$ reaches the end location $slowdown$, which is represented by interface locations $dl1 = "from" \wedge dl2 = "to" \wedge dl3 = "to"$, the control is passed to $Halt$ component entering its $slowdown$ location. This location is represented by interface location $hl1 = "from" \wedge hl2 = "to" \wedge hl3 = "to"$. The control is removed from component $Drive$ by assigning $dl1' = "" \wedge dl2' = "" \wedge dl3' = ""$.

*Definition 3 (serial composition):* A component $C$ composed in series from subcomponents $A$ and $B$; that is, $C = A \oplus B$, can be written as TLA$^+$module $M_C = \langle V_C, I_C, N_C \rangle$, where

- $V_C$ is a set of module's variables that includes all input and output variables of the subcomponents and location variables.
- $I_C$ is an initial predicate that is a disjunction of initial predicates of both submodules annotated with control flow information in the form of assertions on interface locations; that is, $I_C = (I_A \wedge L_B) \vee (I_B \wedge L_B)$, where $L_A$ or $L_B$ specifies that control can be assigned to component $A$ or $B$, respectively.
- $N_C$ is a next-state action predicate that is defined as a disjunction of next-state predicates of both submodules and all necessary connectors $C_i$; that is $N_C = N_A \vee N_B \vee C_i$.

Fig. 4. The TLA$^+$ specification of component $Engine$

## V. VERIFICATION USING TLC

In this section, a brief elaboration on results of verification experiments is presented. The TLC tool was used to check the basic properties of specifications composed in the style of Masaccio model.

Each component can be verified using TLC tool separately. Nevertheless, often a component depends on its environment and the environment specification needs to be supplied in order to get a meaningful results. For instance, component $Distance$ that computes a distance according to the actual velocity requires to provide a specification that sets boundaries on the behavior of velocity variable $dx$. Moreover, the dependency among the components can be circular. Therefore to verify a component, a suitable context needs to be provided. The approach used in this paper for verification of the components stems from the assume-guarantee principle that constraints the context of a component. This principle was studied in the frame of Masaccio formalism in [9]. The context does not need to be specified from scratch. Instead, existing specifications of components that form the environment of the component being verified can be turned into a context like specification. Moreover, this context specification can be proved as appropriate if it satisfies a refinement relation. In many cases, it can be checked automatically using TLC tool. Interface refinement is described in [3, p.163] as $LSpec \triangleq \exists \hat{h} : IR \wedge HSpec$, where $\hat{h}$ is a vector of free variables of $HSpec$ and $IR$ is a relation between variables of $\hat{h}$ and lower level variables of $\hat{l}$ of specification $LSpec$.

Verification of component $Engine$ required to compute the state space consisting of 816288 states. TLC completes this task roughly within 30 seconds on a computer with 1.66 GHz processor. It should be noted, that the specification shown in figure 4 was extended with $loop$ action for the sake of TLC verification procedure. The loop action is required to prevent TCL to complain on finding a deadlock state. It just loops forever if the end location of component $Engine$ is reached.

$$\begin{aligned}
loop \quad & \triangleq (hl3 = ”to” \vee dl3 = ”to”) \\
& \wedge \text{UNCHANGED } vars
\end{aligned}$$

The specification sent to TLC for verifying properties was as follows:

$$Spec == Init \wedge \Box[Next \vee loop]_{vars}$$

The verification of component $Near$ (see [4] for its specification) took much longer (approx. 15 minutes) and the state space searched was greater than 7 millions of distinct states. An issue lies in the use of integer variables for meassuring distance and actual speed of the train and the necessity to check whether the property holds for any combination of these values. The solution is to merge concrete values into significant intervals, i.e. for $dx$ there are two such intervals, in particular, $hispeed = (21..50)$ and $lospeed = (0..20)$. Also distance variable $x$ can be defined to be from a set of intervals, e.g. $extdist^+ = (\infty, 5000), fardist^+ = (5000, 1000), neardist^+ = (1000, 0)$.

## VI. Conclusion

In this paper, the overview of the method capable of formal specifying and verifying embedded control systems has been presented. The method is based on the TLA$^+$, which allows to produce clear and simple specifications because of its very expressive language. An accompanying tool, TLC model checker, can be employed to show that the specification exposes intended properties. This method was illustrated on a simple example in this paper. The semantics of specification can be defined in terms of Masaccio interpretation, including serial and parallel component compositions.

In addition to clarification of the basic facts on the method for writing TLA$^+$specifications under Masaccio interpretation, the several topics for future work were revealed during the work on this paper:

- Deeper understanding of the assume-guarantee refinement in the TLA$^+$specification framework is required and the proof that these specifications obey assume-guarantee principle as specified for Masaccio model should be given.
- Specification of hybrid systems as proposed by Masaccio was not addressed in the paper. As shown in [5], TLA$^+$is expressive enough to capture a large class of hybrid system specifications. The question is whether the verification can be adequately supported by the tools available for TLA$^+$.
- As expected and shown by the example, the state explosion is a problem in the case of verification of non-trivial systems. While TLA$^+$model-checker can explore several hundreds of millions of states, there is also possibility to apply state space reduction techniques. The TLC poses symmetry reduction mechanism [3, p.245] that can reduce significantly state space for design that contains multiple same or similar parts.

The formal model and the presented specification and verification method is suitable, in particular, for application to the domain of distributed time-triggered systems [10]. The intention is to integrate this method in a visual modeling framework [11] to enable automatic checking of properties of systems being visually modeled.

***Abstract*—This paper presents the algorithm of stereo-faces detection in video sequences. A Stereo-face is a face of a man presented by set of images obtained from different points of view. Such data can be used for faces structure estimation. Our algorithm is based on computationally effective method of face detection in mono image. Information about face positions is then combined using sparse stereo matching algorithm. Sparse means that stereo correspondence is estimated not for all scene points but only for points of interest. This allows obtaining the low computation cost of algorithm. We use few criteria to estimate correspondence. These are: epipolar constraint, size correspondence, 3D region of interest constraint and histogram correspondence.**

**Object distance estimation method that does not use projective transformations of stereo planes is also considered.**

## I. Introduction

3D FACE modeling is widely used nowadays in data processing systems. These models are applied in such fields as man-computer interface, multimedia applications, biometric identification in surveillance and access control systems. Three-dimensional face recognition became more popular in recent time [1], [2], [3]. Its methods promise to achieve better accuracy in comparison with the more traditional 2D face recognition methods. It is rapidly developed area in computer vision.

Special equipment is usually used to obtain 3D models. It can consist of several video cameras, structured light source, special laser scanners and other. When accuracy of the model is not critical 3D models can be obtained from static images or frames of video sequence [4]. Building such coarse models sometimes requires user assistance [5]. Mentioned approaches allow estimating three-dimensional face structure with appropriate quality but have disadvantages. They can't be used when it is necessary to obtain such models in real time, in uncontrolled conditions and when user assistance is unavailable.

Person identification systems which use 3D face models as biometric feature require high speed of the model estimation and minimum requirements to the object position. Existing systems can not provide such requirements. A lot of cameras of surveillance systems are used in present time. Such equipment can provide obtaining frames with high resolution. They can be used for 3D face estimation and can be done in several ways. The first approach is based on mono view image processing, the second are multi view (stereo) images processing. In the first case frontal face position is strongly required for acceptable model accuracy. Such models can not accurately represent real parameters of the face. A more accurate face model can be obtained using images from different points of view. Stereo reconstruction methods can be used in this case for additional information estimation. Stereo base face detection methods [6] require additional efforts for depth estimation. It also usually need that cameras have parallel optical axes. In other case it will be necessary to perform transformation of the images to a standard parallel stereo view [7].

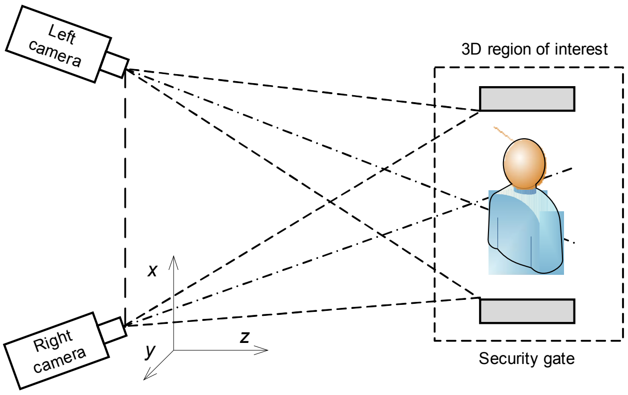

Fig. 1. 3D face processing in security applications

Object detection is usually one of the stages of image processing. We speak about face detection in the case of person identification by portrait. In this paper we present the algorithm of face detection and matching in frames of stereo images sequence. Our goal is to detect and localize stereo-faces of people moving in the field of view of several video cameras (see fig. 1). Stereo-face here is a set of face images obtained from different views. Main requirements are the next: number of faces from 1 to 5; face size not less than 100*100 pixels; and frame size is 1024*768 pixels.

## II. Camera Calibration

Camera calibration in stereo vision classically means computation of relative positions of the camera optical centers. It is not necessary for current task and it is acceptable to compute fundamental matrix that represents epipolar geometry of

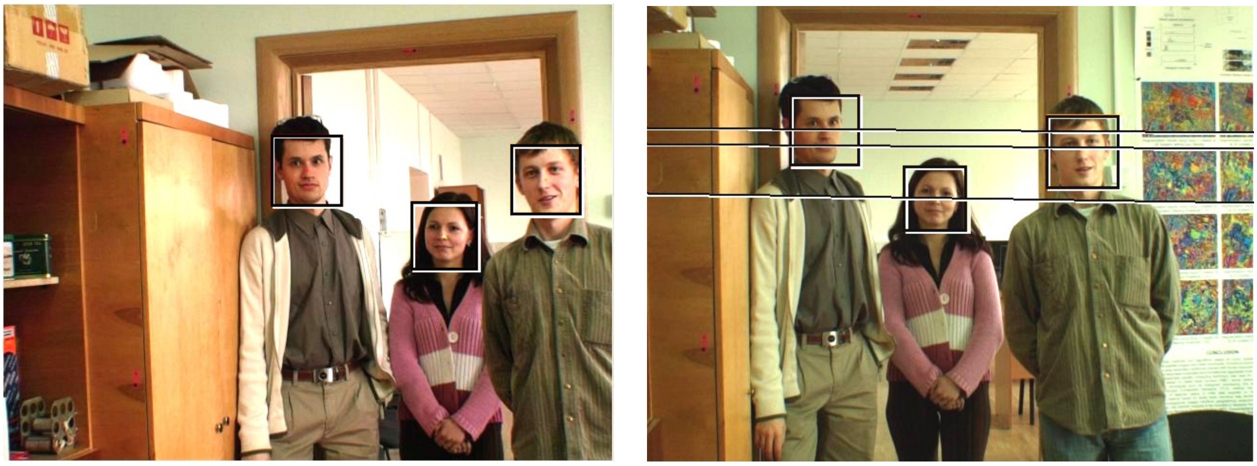

Fig. 2. Stereo frame with detected faces and corresponding epipolar lines.

camera views. The fundamental matrix allows calculating so called epipolar line in one frame that corresponds to given point in another frame. Epipolar geometry greatly reduces search space for points correspondence estimation. We used RANSAC method [8] that is based on eight points algorithm [9] for fundamental matrix estimation.

User has to mark at least eight pairs of correspondent points for calibration. Obtained matrix can be applied for epipolar line estimation by using next relation:

$$l = Fx, \tag{1}$$

where $x$ – given point, $F$ – fundamental matrix and $l$ – sought value.

## III. Stereo-Faces Detection

We use sparse stereo matching algorithm for stereo-faces obtaining. It works with small amount of scene points that leads to fast processing speed. In classical scheme of stereo reconstruction correspondence is estimated for each point of stereo frames. Our algorithm processes only points of interests. These points correspond to human faces found at each view. We use cascade of weak Haar classifiers [10] for face detection in each frame. Fig 1 shows stereo pair example with detected faces and corresponding epilines.

### *A. Matching Algorithm*

Applied approach for face corresponding estimation is based on geometric characteristics analysis, spatial face position and visual correlation. Faces found in each view are characterized by their geometric characteristics and pattern. The algorithm calculates correspondence degree for objects from two frames based on these characteristics. The goal of this procedure is selection of most probable pairs and rejection of faces without pair.

Pair correspondence is defined by multiplication of the set of coefficients. Each coefficient corresponds to some feature correlation:

- K1 – represents the faces positions accuracy in compliance with epipolar geometry;
- K2 – represents face sizes correspondence;
- K3 – represents histogram correspondence of the face areas.

All calculation are performed in the coordinate system of one frame from stereo pair. Algorithm handles only pairs that comply with epipolar constraint. In other words, pair candidates for the face from one view have to lie on correspondent epiline at another view. In fig.2 each man's face in first image has two candidate faces in second image, but woman's face has only one. This constraint allows greatly reducing the amount of false pairs. Then size and position coefficients are calculated.

Coefficient K1 is defined as ratio between distance from face area centre to correspondent epipolar line and minimal face size in pair. It possesses the value 1 when the center of the face coincides with the line and is less than 1 otherwise. Coefficient K2 is defined as ratio between smaller and bigger area sizes. It also is less or equal to 1.

It is necessary to estimate face position in the 3D space for coefficient K3 calculation.

### *B. Histogram matching.*

Coefficients K1 and K2 allow rejecting big amount of false pairs. They are not enough because are based on geometrical features that can be obtained with essential error. That is why histogram matching based coefficient K3 is

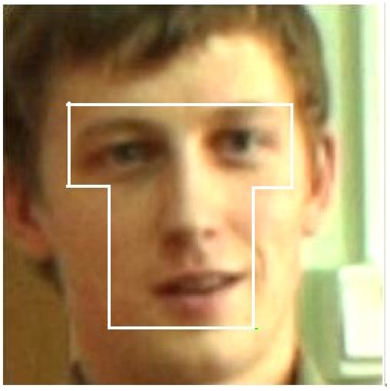

Fig. 3. Histogram area

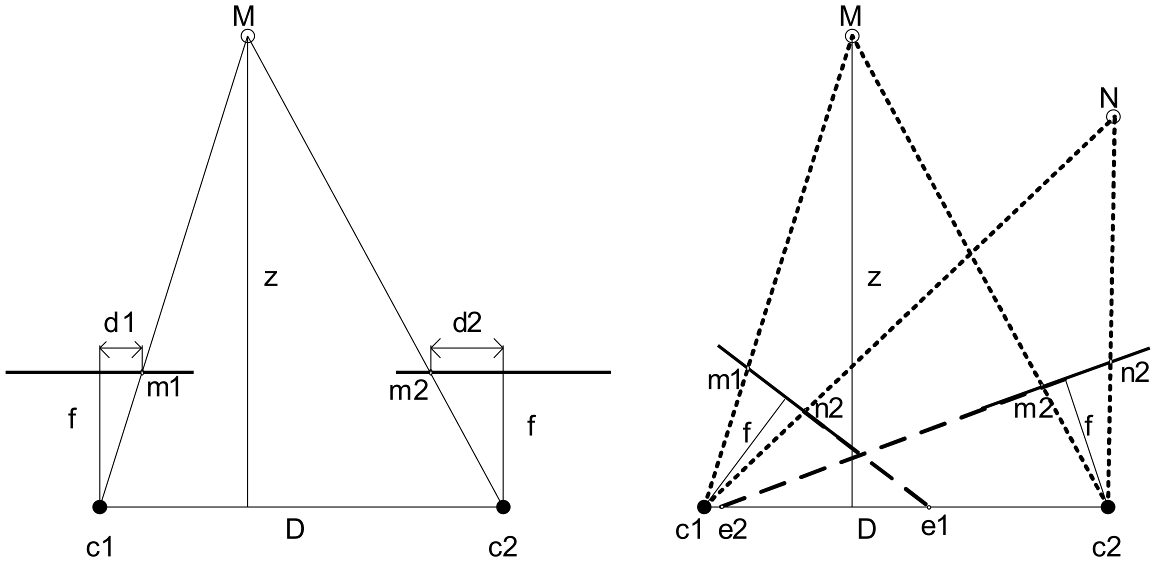

a b

Fig. 4. Stereo geometry a) simple, b) with arbitrary cameras positions.

computed for the rest small amount of possible pairs. Histogram matching is used because of its relative computational simplicity in comparison with other metrics.

Histogram is built not for all face area to avoid influence of background, hair, clothes pieces that can be not presented at both views. Only central part of face area is used where eyes, nose and mouth are apparently situated (see fig. 3). Median filter and area normalization are used to bring histogram to common form.

Sum of Absolute Differences (SAD) and Sum of Squared Differences were used for histogram matching. The SAD applied to three-cannel histograms shows the best result. Error is calculated as square of Euclidian distance between each RGB component's errors. Coefficient K4 then is estimated as:

$$K3 = 1 - histERR\,, \tag{2}$$

where *histERR* is histogram correspondence error.

Hence maximization of the product *K1*K2*K3* gives us the most probable pairs. Pairs formed by faces without right correspondence are ignored by threshold. Such pairs can appear because only one face view can be visible for stereo cameras. The threshold is applied to compound coefficient (the product). Its value was estimated empirically and is equal to 0,3.

## IV. Face 3D Position Estimation.

It is known from stereomerty that distance to object can be estimated by using triangulation. Fig 3a. shows simple stereo system geometry. The indications are: c1 and c2 – camera optical centers, M – point of the scene, m1 and m2 – scene point projections, *f*–focal length of optical system and *D*–distance between optical centers (so called base line). Unknown distance *z* can be found by using next equation:

$$\frac{z}{D} = \frac{f}{d1 + d2}\,, \tag{3}$$

where sum *d1+d2* is disparity of projections' positions.

Real stereo systems rarely have such ideal configuration. Fig.4b represents the geometry of a stereo system with arbitrary cameras position and orientation. Image planes in such system are not parallel to base line. It is necessary to perform projective transformation of each plane in order to use eq. 3 for distance estimation. It leads to additional computational cost.

Optical centers' projections can not be used as reference points for disparity computation in this case. It is seen in fig. 4b that disparity for space points M and N relative to image centers are equal. But these points lie at different distance from base line. It is necessary to choose reference points for disparity computation that allow estimating distance independently from camera configuration. We use epipolar centers as such points. These centers are points where all epipolar lines of respective view come together. The centers are indicated as e1 and e2 at fig. 4b. These points can be calculated by using next equations:

$$\begin{aligned} e_1 F &= 0, \\ e_2 F^T &= 0, \end{aligned} \tag{4}$$

where *F* is fundamental matrix.

Disparity computed relative to epicenters can not be used for real distance calculation but allows estimating its value. Disparity evaluations can have large absolute values. Especially in the case when image plane has very small angle relative to base line. Such values are not informative. We consider the crossing point of cameras' optical centers as zero point (Z=0) to avoid large disparity values. Base disparity *d*0 is calculated for this point. Distance to the object is estimated as difference between the point and base disparities. For example absolute disparities *dm* and *dn* for points M and N at fig. 2b can be estimated as:

$$dm = dist(m1,e1)+dist(m2,e2), \tag{4}$$
$$dn = dist(n1,e1)+dist(n2,e2),$$

where *dist* is distance function between two points. Distance (or depth) evaluation can be computed as *dm-d*0 and *dn-d*0 respectively.

Hence three-dimensional face position accuracy in compliance with 3D region of interest can be computed as:

$$K_{ROI} = 1 - \frac{|d_{face} - d_0|}{\Delta d}, \tag{5}$$

where $\Delta d$ is disparity scattering determined by 3D region of interest.

## V. Position estimation discussion

It seems that the coefficient $K_{ROI}$ can to be used as additional weight for pair correspondence estimation. It means that it can be added to the complex coefficient ($K1*K2*K3*K_{ROI}$). Figure 5 illustrates this idea.

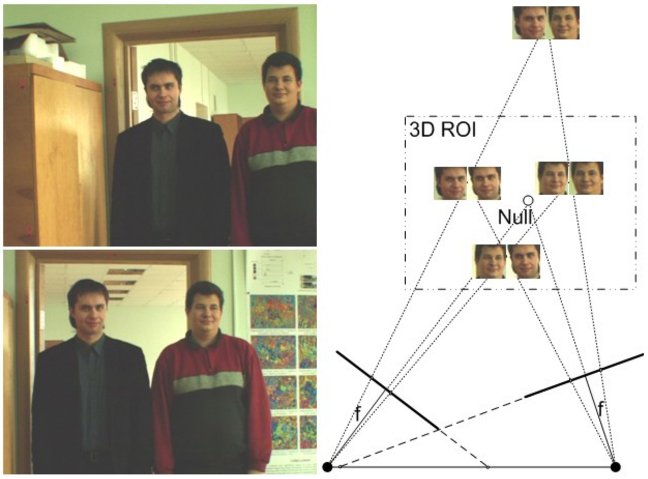

Fig. 5. Peoples stay close to zero point.

Men's stay quite close to zero point inside 3D ROI. False face pairs are located behind and in front of true pair's positions. It means that difference between true face disparity and zero point disparity is less than the same value in false face case. False face means that it is formed by false pair. Coefficient $K_{ROI}$ (5) will be mach less for such pairs than for correct pairs. It allows greatly increasing of the right correspondence rate.

It was good idea, but its application meat problems. Some cases exist then this condition does not help. Figure 6 represent the example then people stay close (at the same distance) to each other but relatively far from zero point.

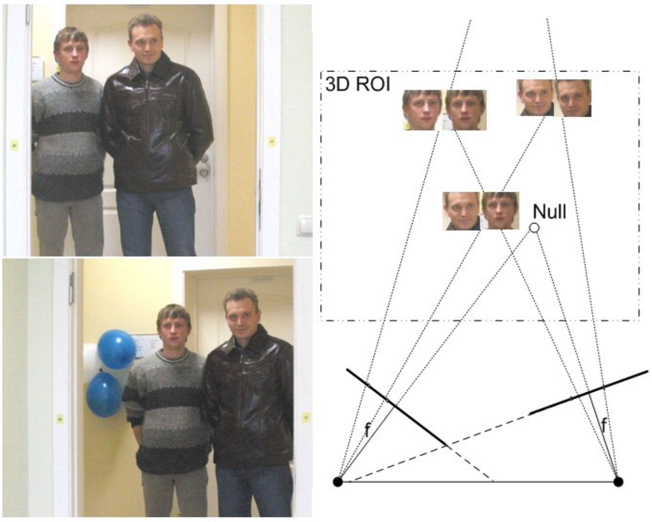

Fig. 6. Peoples stay far behind zero point.

Here false pair has greater weight because it lies closer to zero point. Right and face pairs positions are unpredictable. It is impossible to say even that they always positioned at the same cornets of the quadrilateral (fig. 7).

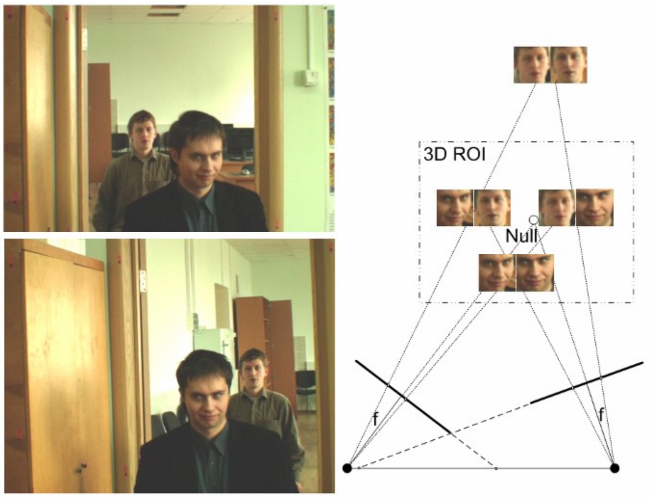

Fig. 7. Peoples stay at the different sides from zero point.

The obstacle problem also leads to unpredictable values of the coefficients for correct and false pairs. We considered different cases of occlusion then a face can close one ore more other faces on different views. We skip its detailed description.

As the result we can say that coefficient $K_{ROI}$ can't be used for correspondence estimation as it was described. But it can be applied for face ranging. It can be usable to process faces with predictable parameters. For example face identification method can be configured to operate with appropriate size faces. This size must correspond to visible face size then corresponding man stay at the zero point distance.

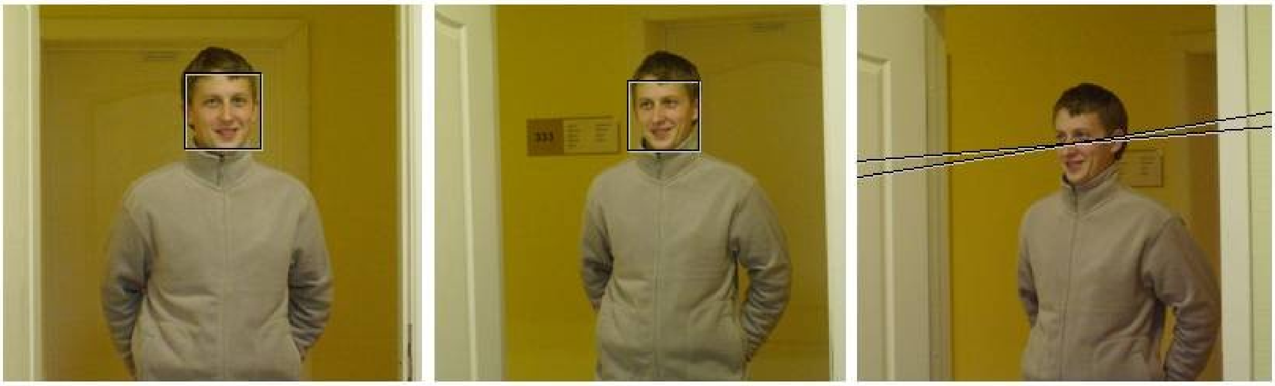

Fig. 8. Missed views estimation based on epipolar geometry.

## VI. Missed Views Estimation

Described algorithm can be used in a system this two and more cameras. The situation then face was not found at all vies is possible. It may be causes by to big angle of the head rotation, occlusions, mistakes and so on. If face was detected at least at two frames its position can be computed at other views based on epipolar geometry.

Position of the missed face view is defined by crossing two ore more epipolar lines which correspond to known views. For example, face was detected at first and second frames (Fig. 8) and they were matched by presented algorithm. It is necessary to compute epipolar line at third frame that correspond to the face at first frame and also epipolar line that correspond to the face at second frame. Face must be positioned on each epipolar line. That's why the crossing is the result (Fig 8. right image).

## VII. Results

The algorithm has been tested with images obtained by stereo device that includes two high resolution cameras. Stereo frames are color images with resolution 1024*768. It was considered that maximum face size is 100*100 pixels. Test set includes 200 stereo pairs and Table 1 represents test results.

The matching accuracy came to 93.5%. Time costs for processing is about 50 ms. per stereo frame. Main part of this processing time employs face detection module. Hence presented algorithm allows face views matching with high processing speed.

Table I.
Algorithm Test Results

| Parameter | Numerical value | Percentage |
|---|---|---|
| Number of faces in left view | 336 | - |
| Number of faces in right view | 372 | - |
| Detected faces (left) | 326 | 97% |
| Detected faces (right) | 366 | 98% |
| Total amount of correct pairs | 306 | - |
| Correctly matched pairs | 286 | **93,5%** |
| False rejections by threshold | 4 | 1,3% |
| False matched pairs | 2 | 0,65% |
| Faces without pair (left) | 30 | 13% |
| Faces without pair (right) | 61 | |

## VIII. Future Work

Described algorithm was developed to be used in biometric identification applications which operate in real time. Several ways to use the results of this algorithm for this purpose exist.

First of all stereo face can be used for best view estimation. 2D face recognition algorithms mostly based on frontal face processing. Information about relative positions of eyes, nose and other feature point can be used for appropriate image selection. Needed information can be obtained using methods of stereo analysis.

From other hand good frontal view can be not represented at frames. It is very probable situation especially if only two cameras are used. In this case stereo face can be used to develop frontal face view.

The most preferable case of stereo face usage is 3D model estimation (Fig. 9). Such techniques are still very computationally expensive and require a lot of efforts to be launched in real time.

## IX. Conclusion

Developed algorithm allows obtaining 3D position of stereo-faces with high computational efficiency. It is based on sparse stereo matching of objects of interest. Fast speed processing was also reached by using distance estimation procedure without projective transformation. It can be used in real time surveillance systems as base for 3D face identification.

Email: i.schagaev@londonmet.ac.uk

*Abstract*—**Generalized algorithm of fault tolerance is presented, using *time*, *structural* and *information* redundancy types. It is shown that algorithm of fault tolerance might be implemented using hardware and software. It is also shown that for the design of efficient fault tolerant system elements must be malfunction tolerant. The advantage of element malfunction tolerance is proven in reliability terms. Reliability analysis of a fault tolerant system is performed with deliberate separation of malfunction and permanent faults. Special function of reliability gain is introduced and used to model system reliability. Maximum reliability of fault tolerant system is achievable with less than a duplication system and depends on malfunction/permanent fault ratio and coverage of faults. System level of fault tolerance prerogative is the reconfiguration from permanent faults.**

## I. Introduction

THE world of applications for fault tolerant systems is expanding beyond our imagination. Areas where we need them most are called embedded systems. The principal features of on-board systems as well as embedded safety critical systems are Fault Tolerance (FT) and Real Time (RT) response. They both are reflected in the main system components: hardware (HW) and system software (SSW). The process of FT system design consists of two mutually dependent sequences of HW and SSW development, using different redundancy types [1]. The design of the FT system assumes that the required specification is already known, including faults that system should tolerate [2],[14],[25].

FT system design required objectives are: performance, reliability and low power consumption (the latter especially for spaceborne computers). All of them are achievable in combination by means of a careful and balanced introduction and monitoring of hardware and system software features. Achieving reliability assumes either using of multiple unreliable components [3], or higher reliability components, or application of various types of internal redundancy to maximize efficiency of the solution [4],[5].

The term *fault tolerant system* needs a rigorous definition; at the same time it must be differentiated from such terms as *graceful degradation* and *fail-stop systems* . Avizienis [6-10], Laprie [9,11-12] and Siewiorek [14] proposed that a system be called *fault tolerant* (FTS) if it recovers itself to full performance or at least continues with sufficient specified functions and required features.

The *gracefully degradable system* (GDS) is the system that can recover itself and continue functioning in degraded mode after occurrence of a fault [12] . In turn, if a system can stop itself correctly once a fault has been detected in acceptable state it is called a *fail-stop system* (FSS) [13].

The most critical reliability requirements for on-board applications are MTTF (Mean Time To Failure) 10-25 years and system availability not less than 0.99 over the whole life cycle of the system, typical for aircraft, satellites, gas pipelines, etc.

## II. Generalized Algorithm of Fault Tolerance

Several authors [2],[5] proposed to consider fault tolerance as a process of several steps for: proving that the appeared fault did not damage hardware, determination of type of fault (malfunction or permanent), checking the consistency of software state, detecting of correct states and further recovery from the correct state.

This process was called a Generalized Algorithm of Fault Tolerance (GAFT). The *information* , *time* and *structural* types of system redundancy enable to complete these steps of the process of fault tolerance. Combination of GAFT and possible redundancy types forms a matrix shown in Table 1. All steps of GAFT are implemented by SSW and HW. Steps {A,…,G} vs. redundancy types form a framework for the classification, design and analysis of implemented FT computer systems. According to Table 1, a system is called *fault tolerant* if it implements GAFT, i.e. every row (line) was visited and the algorithm is completed. There is no doubt that the algorithm can be completed differently, using different redundancy types at each step. This shows that fault tolerant systems may differ in:

- The time taken to implement various steps
- Types of redundancy used
- Types of faults which might be tolerated.

The taxonomy of Table 1 might be used for comparison of various design solutions of FT systems. The other interesting property of this taxonomy is an evaluation of efficiency of redundancy in implementation of various steps of GAFT. Therefore, this taxonomy might provide analytic evaluation and assist in selection of the most efficient solution for the

This work has been done as a part in the ONBASS (On Board Active Safety System) Project No. 160045, funded by the EC.

implementation of on-board system from the alternative approaches.

TABLE I.
GAFT VS. REDUNDANCY TYPES

| Steps | Redundancytypes | | | | | |
|---|---|---|---|---|---|---|
| | hw | | | sw | | |
| | i | s | t | i | s | t |
| A.Provetheabsenceof fault, ELSE | | | | | | |
| B.Determinetypeof fault | | | | | | |

| D.Reconfigurehardware | | | | | | |
| E.Proveconsistencyof softwareELSE | | | | | | |
| F.Locatefaultystates | | | | | | |
| G.Recoversoftware | | | | | | |

Description of a fault tolerant system proposed initially for on-board systems [5] is more rigorous. It applies an algorithmic definition of the feature of *fault tolerance* using GAFT. In other words, GAFT introduces FT not as a feature but as *a process*.

We consider a system as *fault tolerant if and only if* it implements GAFT transparently for an application. On-board system's main function is the implementation of control algorithms; we call it "process one" or $P_1$ [15]. Thus the functional definition of fault tolerance for control computers is the following: if the system provides for an application ("process one") full functionality and can transparently for the application recover itself from a predefined set of faults, this system will be *fault tolerant* .

The transparency of fault tolerance for the applications (for on board computers) means that GAFT is completed within a defined time (between sequential data outputs or inputs; in practice it is about 10-125 milliseconds). In short, the system is fault tolerant if it provides failure-free-mode for the implementation of the process $P_1$ . Again, it is assumed that the performed recovery is transparent for the application.

## III. TIME REDUNDANCY AND FAULT TOLERANCE

The GAFT implementation varies in terms of redundancy types used and, therefore, the time to complete. In terms of time slot which is required to implement FT of the system, different levels of granularity of SW might be used: instruction, procedure, module, task and system, as presented in Fig. 1.

At the *instruction level* scheme, SSW assumes an elimination of a fault appearing and its influence within the instruction execution. For example, the triplicate memory voter masks the faults of one memory element and therefore, this fault is tolerated at the *instruction level* .

In turn, the techniques such as microinstruction or instruction repetition can be considered as implementation of instruction level FT for the processor. From the system point of view an implementation of fault tolerance at the *instruction level* has a serious and undisputable advantage: fault checking, detection and recovery can be completely transparent to the system software.

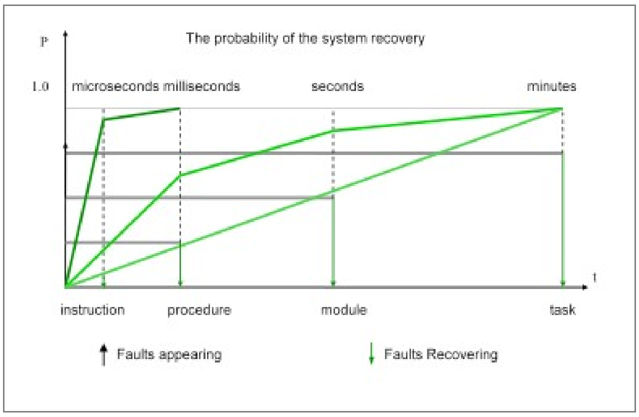

Fig. 1 Levels of implementation of fault tolerance

At the *procedure level* an implementation of fault tolerance assumes that a fault and its influence is tolerated and eliminated within the scope of a procedure execution. For example, the techniques such as *recovery blocks* (wrongly known as recovery points) [16],[17],[18],[19] can be considered as procedure- oriented scheme. This approach requires system software support (compiler level and run-time system) and might be efficient if and only structural programming approach is used (known after [20]).

The analysis of efficiency of procedure level approach together with aspects of implementation was done in [21]-[23]. There is no doubt that the state of the program must be conserved/re-generated to recover from a hardware fault. For this scheme the volume of the information required to restore the system after fault is much larger (and has significant software overheads).

For the *module level* scheme a module tolerates influence of a fault. For example, module restart or run of a simplified alternative module [10] might be used. Module recovery reduces the probability to restart the task or the whole system. The same comments apply for the procedure scheme.

At the *Task level* a fault and its influence is eliminated by restart of a task after reconfiguration of hardware.

Initialization of this scheme of GAFT implementation might also use time redundancy available within task execution. Clearly this option has the highest software, state space and time overheads for implementing fault tolerance. This level requires system software (operating system) support for HW fault tolerance. Details of the SSW features to support hardware fault tolerance for parallel FT systems are discussed in [24].

*System level* of fault tolerance assumes automatic or manual (when the control process allows it) restart of the system after fault and performing of control function after full restart of the system. Automatic restart has to be supported by system software using automatic hardware testing and software restart schemes.

## IV. PERFORMANCE OF FT SYSTEMS

The time impact of implementing GAFT at each of these levels is different, as well as is the delays caused by their use. The current embedded system practice indicates the following order of magnitudes for timing:

- microseconds for the instruction level
- milliseconds for the procedure level
- hundreds of milliseconds for the module level
- tens of seconds at the task level
- ten of minutes to hours at the system level.

The various schemes of GAFT implementation have different overheads, capabilities for tolerating of various classes of faults, power consumption overheads and affiliated system costs. For the instruction level scheme the concrete hardware support is required. For example, duplicate or triplicate hardware modules could result in serious overhead in power consumption and size. Some better solution was recently found as well (http://www.itacsltd.com).

However, not all hardware sub-systems need necessarily be designed in this way. For example, a cost benefit analysis (where 'cost' infers financial, power consumption, chip area, time delays, etc.) might indicate that it is worthwhile to have the processor and system RAM fault tolerance, achieving fault tolerance of the rest of the system using procedure or module schemes.

The *procedure* and *module level* schemes require much less hardware support but, of course, have a larger timing and software-coding overhead. For the *module* and the *task level* schemes with no extra hardware, system software support for fault tolerance is actually incomplete, as any *permanent* hardware fault would cause the system stop and loss of the control application. If the system requires reboot to recover then it is resilient to *malfunctions* (transient faults), not the permanent faults.

Depending on the level employed in the implementation of fault tolerance, systems differ in time required of achieving it (see the thick lines in Fig. 1). Note that different fault types might be tolerated by different schemes applied in combination; in other words, levels of implementation of fault tolerance are not mutually exclusive.

A good fault tolerant system tolerates the vast majority of malfunctions within the *instruction* execution making them invisible in terms of other instructions (and software) . The malfunctions with longer time range might be detected and recovered differently, for example, at the procedural or task level.

The complexity of GAFT implementation also differs in the types of fault that have to be tolerated. Even knowing that the ratio of malfunctions is the order of magnitude higher than permanent faults, it is necessary to implement the special schemes for re-configurability and recoverability of the hardware to eliminate an impact of *permanent faults* on the system.

At the other extreme, the system could tolerate the vast majority of *malfunctions* at the task level using SW. The operating system support or even user support also might be used to tolerate hardware faults. From the user's viewpoint even 'WINTEL' systems (Windows/Inter based) might be considered as fault tolerant as long as scheduled application was completed and results delivered on time. In this case, the fault tolerance was achieved by means of maintenance of hardware and involvement of system engineers to fix the fault 'in time'.

Most WINTEL systems assume system reboot and restart of the applications is an acceptable way of operation. Practical experience of real-time systems confirms that this is not the case, at least for systems that must run continuously for more than a few hours.

## V. Reliability Evaluation for Fault Tolerance

From the classic reliability point of view any extra redundancy of hardware reduces the absolute reliability of the system [26]. At the same time, a reliability of the system might be increased if introduced redundancy is able to tolerate faults of the main part of the system by means of GAFT and itself contributes less in the system fault ratio.

Thus, part of the problem – the decreasing reliability of the system caused by hardware redundancy at some point becomes part of solution. GAFT implementation breaks down to two processes for checking (P2) and recovery (P3), while process (P1) is application execution [15]. Clearly, there are design tradeoffs to be made to achieve the optimum operational reliability and redundancy types used.

Reliability analysis [27] introduces a reliability value for each element (hardware redundancy) and assumes a Poisson failure rate $\lambda$ . This makes possible to calculate the overall reliability as a function of time for the whole system, if the structure of the system is known.

Hardware redundancy used at the various steps of GAFT degrades in reliability over time; thus achievable performance and reliability and their degradation within life cycle of the RT system are dependent. Therefore, an analysis of the surface shape and evaluation of performance and reliability degradation caused by the redundancies used should be performed for every fault tolerant system. Fig.2 presents qualitatively a slope where a fault tolerant system should be located, between the plane of requirements and curves of reliability and performance degradation.

Furthermore, the introduction of the cost to implement each proposed solution makes it possible to summarize the system overheads required to implement fault tolerance. There is no doubt, a quantitative evaluation of reliability, performance and cost overheads within one framework might be extremely efficient for justification of the design decisions and comparison of different approaches in implementation of fault tolerance.

There is a correspondence between reliability of FT systems and steps of GAFT related to the malfunction tolerance. The next sections analyze this correspondence.

### *A.Impact on Reliability of Malfunction Tolerance*

Let's denote a rate of permanent fault for the system without redundancy as $\boldsymbol{\lambda}_{pfl}$ , the malfunction rate as $\boldsymbol{k}\,\boldsymbol{\lambda}_{pfl}$ . For modern technologies $\boldsymbol{k}$ varies from $10^{3}$ to $10^{5}$ (the latter applies to aeronautics). The probability of operation without permanent fault within time gap [0,T) and mean time to failure are determined by formulas (1).

$$P_{1}(t) = e^{-((1+k)\,\lambda\, pf1)t}$$

$$\mathrm{MTTF}_1 = 1/(1+k)\lambda_{pfl} \qquad (1)$$

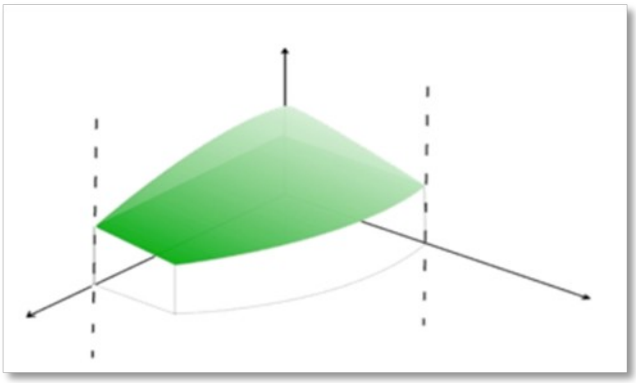

Fig. 2 Performance/reliability dependence

Fig. 3 presents a reliability degradation of the device without implementation of the fault detection and fault recovery). Introduction of the checking of hardware condition requires a hardware support.

In reliability terms, extra hardware has an extra rate of permanent and intermittent faults d λ pf1 and d λ if1 respectively, and reliability of the system with an implemented checking process is equal

$$P_{1+checking}(t) = e^{-((1+d)\ \lambda\ pf1+ (1+d)\ \lambda\ if1)t} \qquad (2)$$

where ***d*** is a share of the hardware redundancy required to implement the checking process. Redundancy for checking (detection) d varies in different hardware schemes. The maximum redundancy to provide checking is 100%, or d=1, when duplication of the hardware is used to compare outputs.

Maximum power of fault detection is a privilege of the duplication approach. Assume the same coefficient k of malfunction/permanent fault ratio

$$P_{1+checking}(t) = e^{-((1+d)+k)\lambda\ pf^{*}t}$$

$$MTTF_2 = 1/(1+d)+k)\lambda_{pf1} \qquad (3)$$

Introduction of checking schemes makes the only difference in system reliability analysis by a guarantee that the appeared hardware fault (assuming the chosen fault type) is detectable. In other words, checking justifies reliability by transition of an observer from a random world into the world of conditional probabilities. Conditional probability describes a reliability of the system provided that fault of a chosen class did not happen.

So far, we assumed that our system has hardware to detect chosen and representative class of faults and that faults do not have latency period (a natural assumption for processors, cache memory and immune systems).

In contrast to detection, a recoverability of the system after intermittent faults requires more efforts and redundancy use, let's denote it r. Then the redundancy of hardware descends even more – the lowest curve of Fig 3.

$$P_3 = e^{-(1+d+r)(\lambda\ pf1)t} \qquad (4)$$

$$\mathrm{MTTF}_3 = 1/(1+d+r)(1+k)\lambda_{pf1}t$$

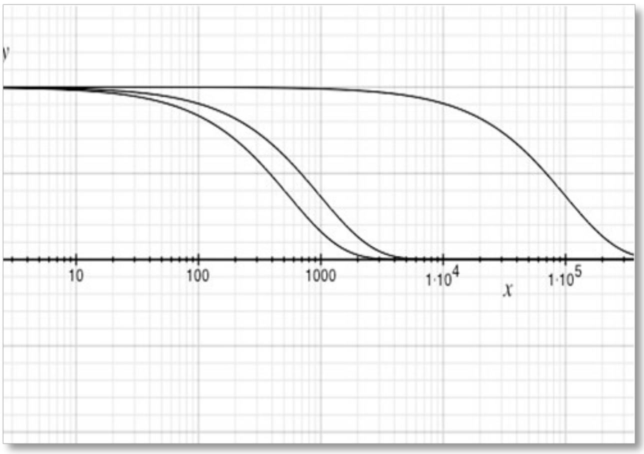

Fig. 3 R(t) with malfunction and checking

On the other hand, reliability might be increased, as long as malfunctions are tolerated. In the equations (4), a coefficient k of malfunction impact might be reduced, say, α times. Then

$$P_{1+checkingandrecovery} = e^{-(1+d+r)(1+\alpha k)(\lambda pf1)t} \qquad (5)$$

$$\mathrm{MTTF}_4 = 1/(1+d+r)(1+\alpha\, k)\lambda_{pf1}t$$

The role of α defines a reliability gain that might be achieved by elimination of malfunctions. It is worth to analyze α a bit more.

### *B. Success Function*

Let us define a success function of the malfunction reductions as SF. It is a well known fact that a double system covers all possible faults by comparison and while checking of the element is implemented it can recover from malfunctions [21]. Thus, a form of SF is defined by two values: initial and maximal. When no redundancy is used (x=0), a probability of recovery from malfunction is zero, SF→0. (Compare: if you don't pay for people healthcare then people will die from any disease…). In turn, using the known fact that 100% redundancy guarantees full success of system operation (including fault detection and complete recovery) one is able to write that SF →1.

A function SF=x*e1-x satisfies both initial conditions. Denoting coefficient alpha α as malfunctions reduction leads to:

$$\alpha = 1- c^{*}(x^{*}e^{\ 1-x}) \qquad \mathbf{(6)}$$

where ***c*** is a coverage of faults and directly depends on redundancy spent on detection c = f(d,λ) - the more we know the better, but at the cost.

Compare finally MTTF2 and MTTF1 (for the systems with malfunction elimination and without, respectively) calling it efficiency. Y axis denotes times of improvement, while X axis presents amount of redundancy involved:

$$E = (1+k)/[(1+d+r)(1+(1-c^{*}x^{*}e^{1-x})k)] \qquad (7)$$

Figure 4 shows that higher coverage of fault and ability to tolerate malfunctions makes an element almost 3 times more efficient in comparison with a standard element. The gain will be much higher when a real malfunction to permanent fault ratio (100:1 or 1000:1) is applied.

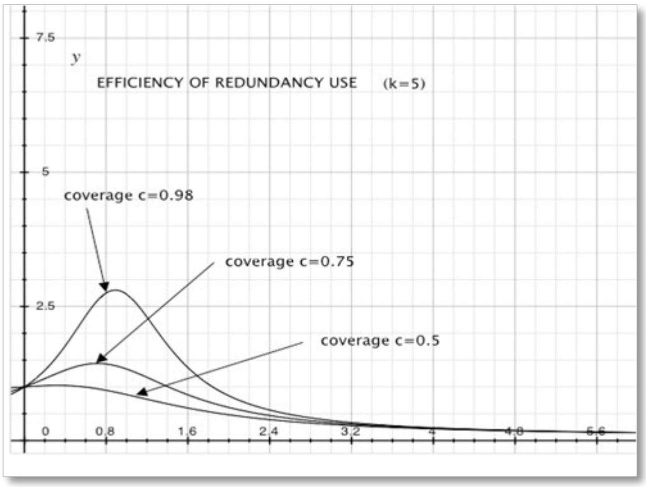

Fig. 4 Efficiency of redundancy

The estimation presented in Fig 4 does not separate use of redundancy between checking and recovery processes. This is a subject of further research; but the key outcomes are obvious and summarized below.

## VI. Conclusion

Design of fault tolerant systems should be revisited: malfunctions must be tolerated at the element level, leaving permanent fault handling to the system level. There is an optimum in redundancy level spent on fault tolerance; this optimum is achieved with less than 100% redundancy. Efficiency of fault tolerance implementation in reliability terms depends on coverage of faults.

# Rapid Control Prototyping with Scilab/Scicos/RTAI for PC-based and ARM-based Platforms

Skiba Grzegorz, Żabiński Tomasz, Bożek Andrzej
Rzeszów University of Technology
Email: skiba.g@gmail.com, tomz@prz-rzeszow.pl, bozekand@op.pl

*Abstract*—**This document describes three didactic systems with a Rapid Control Prototyping (RCP) suite based on Scilab/ Scicos and a PC computer. Servomechanisms with wire signal transmission and PID as well as a fuzzy controller are presented. The servomechanism with wireless signal transmission is also described. As the RCP suite based on Scilab/Scicos/RTAI was successfully used in the servo controller development on a PC platform, the concept of a tool-chain for RCP on an embedded platform with ARM processor is discussed. The TS-7300 embedded system with RTAI real-time operating system is described. The changes in Scilab/Scicos needed to interface the generated controller code to TS-7300 are presented. The didactic use and a possible commercial use of the tool-chain is indicated. The didactic use is focused on controllers tuning, friction and long delays influence on servomechanism control and embedded control systems development.**

## I. Introduction

Rapid Control Prototyping (RCP) gives a possibility for quick and convenient control strategy verification and iterative controller development. RCP involves a controller simulated in real-time, coupled with a real plant via hardware input/output devices. Nowadays RCP has become a crucial method in developing and testing control strategies within time acceptable by the market. It is also a very popular technology in scientific and didactic laboratories.

RCP requires two components: a Computer-Aided Control System Design (CACSD) software and a hardware with a hard real-time operating system. CACSD includes a broad range of computational tools and environments for: control systems design, real-time simulation, data acquisition and visualization. CACSD should support all the phases of the control system development namely specification, modeling, identification, controller design, simulation, implementation and verification [1], [2]. The most significant element of CACSD in supporting implementation is an integrated code generator which allows a direct creation of a controller code from e.g. a graphical schema. One of the most popular RCP systems is based on the Matlab/Simulink/RTW (Realtime-Workshop) suite [3] which enables creation and compilation of a controller code for different targets. The Matlab/Simulink/RTW commercial product is very popular at universities and in industries. The main advantage of the suite is its convenience and accurate graphical interface. The main drawback is given by its cost. An interesting alternative to Matlab/Simulink/RTW is the free and open-source Scilab/Scicos/RTAICodeGen suite [4]. The alternative is based on Scilab/Scicos, Linux RTAI and RTAI-Lab. The RCP open source environments are especially desirable for didactic purposes because of their low cost. The RCP tool-chain based on RTAI-Lab has been successfully used in Department of Computer and Control Engineering at the Rzeszów University of Technology. The tool-chain is used in Mechatronics, Control Theory, Embedded Systems and Real-Time Control courses. Additionally the tool-chain is also used by students and researchers who engage in the creation of control systems.

This paper describes the existing laboratory equipment for servo control with wire or wireless signal transmission. The examples of using PID and Fuzzy Model Reference Learning Controller (FMRLC) for a servo control are also briefly described in the paper.

The paper is organized as follows: in Section II the Scilab/ Scicos/RTAICodeGen suite is described; in Section III three different didactic control systems for servomechanisms are presented; in Section IV an idea of the RCP tool-chain for embedded system as well as the architecture of TS-7300 em bedded platform with ARM9 processor and FPGA chip is briefly described; and finally in Section V the main results are briefly discussed.

## II. Scilab/Scicos/ RTAICodeGen suite

Scilab is a scientific software for numerical computations. It has been developed since 1990 by scientists from INRIA (Institut National de Recherche on Informatique et on Au tomatique) [5] and ENPC (École Nationale des ponts et chaussée) [6]. Scilab provides a rich set of functions for sci entific applications and engineering [7].

Scicos is a Scilab toolbox which allows a graphical design of a control system. The design and simulation of a control schema can be realized directly from the Scicos graphical interface in a comparable manner to Simulink.

Linux RTAI is a hard real-time extension of the Linux Operating System. RTAI has been developed since 1999 by the researches from the DIAPM (Dipartimento di Ingegneria Aerospaziale del Politecnico di Milano) [8].

The RTAI environment has been extended to include a code generator called RTAICodeGen in order to obtain com patibility with RTAI for a hard real-time code from Scicos schemas.

RTAI-Lab is a tool included in an RTAI distribution which provides a framework for designing, building, running and monitoring RTAI-based controllers and real-time simulators. The controllers can be coded manually in languages akin to C/C++ or generated automatically by Scilab/ Scicos/ RTAICodeGen or by Matlab/Simulink/RTW. The RTAI-Lab framework contains block library that allows the interaction of Scicos schem a s with a data acquisition hardware. Drivers for acquisition hardware are provided by the COMEDI project [9] or can be implemented by the user [4]. *Xrtailab* the GUI application included in RTAI-Lab is used for the purpose of data acquisition and monitoring and so as to change controller parameters on the fly.

The generated controller typically runs as a user space hard real-time application on a standard PC computer [1], [10]. Nowadays it is a typical way of using the RCP suit based on Scilab/Scicos and RTAI. As RTAI supports the following hardware architectures:

- x86 and x86_64
- PowerPC
- ARM (some subarchitectures)

it would be convenient to use the RCP suite for Rapid Control Prototyping on a destination embedded hardware [11].

Section IV briefly describes the way to obtain the RCP tool-chain for the TS-7300 embedded system with the AR M920T processor.

## III. Control of a DC servo motor in Scilab/Scicos/RTAI-Lab

Three didactic servo control systems developed in Department of Computer and Control Engineering are described in this section. The systems are used for didactic purposes in courses of Mechatronics and Control Theory.

### *A. Plant description*

The plant includes a DC servo motor from Pittman, an HP incremental encoder, an MSA-12-80 power amplifier in current mode from Galil and a KR33 linear stage with a ball screw from THK (Fig. 1).

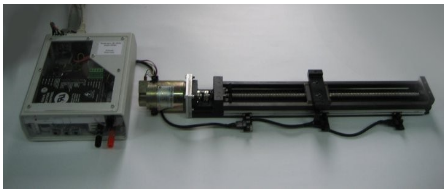

Fig. 1. Laboratory servomechanism

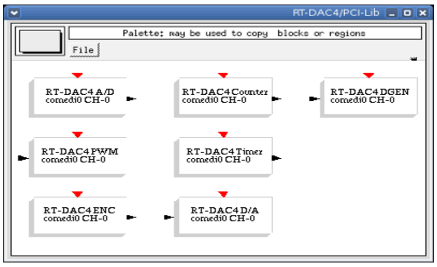
For RCP purposes a general PC computer equipped with Linux RTAI as real-time operating system is used. For wire signal transmission the input/output board RT-DAC4-PCI [12] from Inteco is used. The driver for RT-DAC4-PCI card was developed using COMEDI specification [4]. In wireless communication two transmission modules are used: one connected to the power module and the second connected to the PC computer via the RS232 interface. The transmission modules were constructed using ADuC7128 controllers and TLX2401 radio modules [10].

### *B. DC servo control with wire signal transmission and PID controller*

In order to use the RT-DAC4-PCI card in real-time experiments the driver and communication blocks for Scicos were developed [4]. The blocks for: A/D and D/A conversion, PWM outputs and encoder counters were developed (Fig. 2).



RT-DAC4/PCI-Lib

RT-DAC4 D/A comedi0 CH-0

Fig. 2. Communication blocks for RT-DAC4-PCI and Scicos

Control system structure with PID digital controller is presented on Fig. 3.

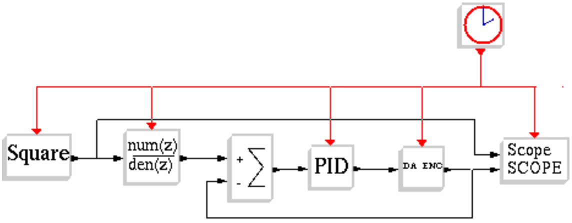

Fig. 3. Control system structure for DC servo control with PID discrete controller

The block DA-ENC includes the D/A conversion block and the encoder counter interface block which provides communication with the real plant (Fig. 4).

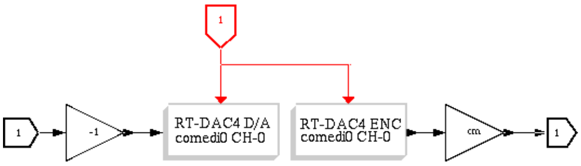

Fig. 4. DA-ENC block internal structure

The PID block internal structure is presented on Fig. 5.

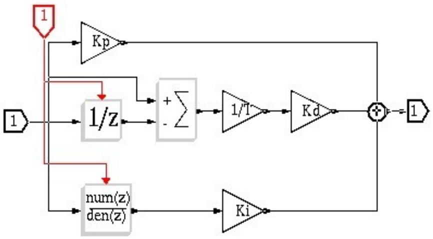

Fig. 5. Discrete PID controller structure

The system is mainly used for didactic purposes. The students perform identification procedure of the real-plant model and perform PD and PID controllers tuning. Many different experiments are performed in order to test the step response parameters and the influence of friction on servomechanism systems e.g. steady-state errors, hunting and stick-slip.

A plant model given by a double integrator transfer function is identified via a step response real-time experiment conducted using Scicos schema. The Scilab *datafit* function is used to fit the model to the experimental data. The PD and PID controller is tuned using root-locus design method. In this case, two design data, i.e. gain of the drive treated as double integrator and required settling time, are only needed [13]. The results of servomechanism real-time step response experiment are presented on Fig. 6.

Fig. 6. Servomechanism real-time step response experiment with PID controller - *xrtailab*

The obtained results are similar to the ones which use the RCP suite based on Matlab/Simulink/RTW and RT-CON [12].

### C. DC servo control with wire signal transmission and FMRLC controller

A more sophisticated controller for a servomechanism with Fuzzy Model Reference Learning Controller (FMRLC) [14] is also used by the students [4]. The control system consists of the reference model, fuzzy Takagi-Sugeno controller under learning process, fuzzy inverse model, learning mechanism and knowledge-base (Fig. 7). The two inputs to the fuzzy PD controller are the error *e* and change in error *de* (Fig. 7). On the basis of the internal knowledge the controller produces control signal *u* which is fed to the plant (power amplifier). The fuzzy controller is continuously taught during the control process by a fuzzy inverse model, learning mechanism and knowledge base. The learning goal is to keep a plant output ($y$) as close as possible to the reference model response ($y_m$). Only the consequents of the controller rules are changed, fuzzy sets remain unchanged.

The Scicos control schema with FMRLC controller is shown on Fig. 8.

The FMRLC block was developed in C language as a computational function for Scicos [4], [7].

The system is used for didactic and research purposes. The students perform experiments with different configurations of FMRLC e.g. simple fuzzy controller in control loop and complete FMRLC structure.

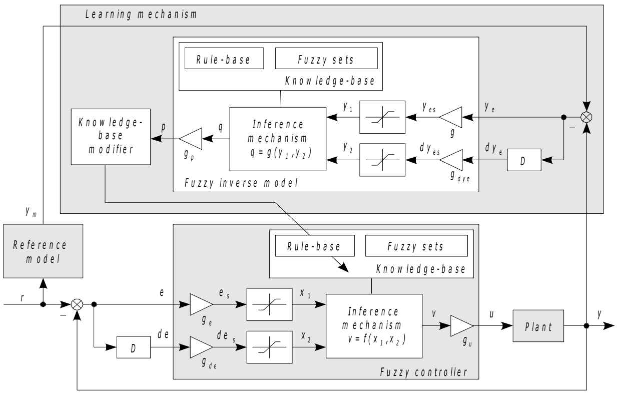

Fig. 7. FMRLC structure [14]

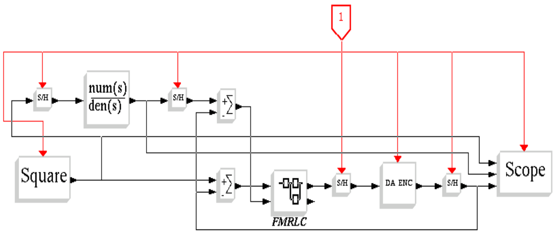

Fig. 8. Scicos schema with FMRLC

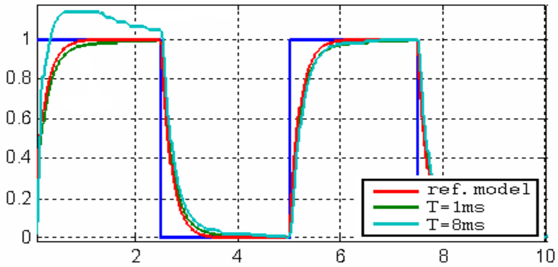

Fig. 9. Servomechanism real-time step response experiment with full FMRLC configuration

On Fig. 9 demonstrative results of the experiments are presented.

For different control periods $T$ the servomechanism gives different results (Fig. 9). As it is shown on Fig. 9 the system response with $T$=1 ms is very close to the model reference response. It must be emphasized that FMRLC rapidly gains the knowledge of how to control the plant. At the beginning of the experiments all the rules consequents were set to zero.

### D. DC servo control with wireless signal transmission

The third example of using Scilab/Scicos/RTAICodeGen, RTAI and RTAI-Lab for servo control is described in this section. Unlike the already described systems this one uses wireless transmission (Fig. 10) between a controller and an object.

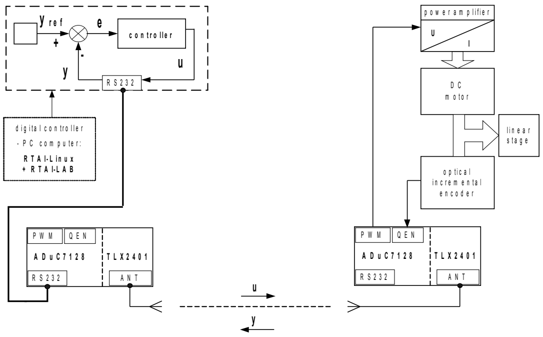

Fig. 10 . Structure of servomechanism with wireless signal transmis sion

In the system, instead of the RT-DAC4/PCI card, transmission via the RS232 interface and two modules with the ADuC7128 controllers and the TLX2401 radio modules are used. The modules make bidirectional wireless transmission possible for PWM control signal, position measurements and additional information. The structure of the communication frames can be freely arranged by the module software. Special blocks were created for Scicos, designed for a real-time communication via the RS323 interface and signal multiplexing/demultiplexing. These blocks allow the integration of the developed hardware with the RCP software environment. The real plant with transmission modules is presented on Fig. 11.

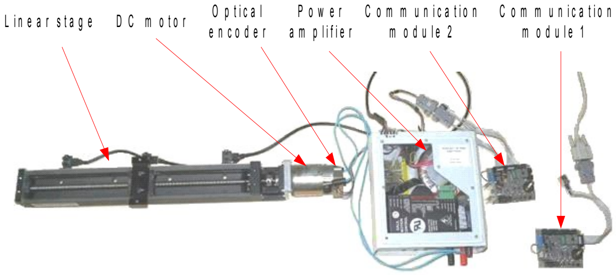

Fig. 11. Servomechanism with wireless signal transmission

The system was primarily designed as a didactic equipment used to test control algorithms in case of long delays or data loss. A few simple solutions are tested by students:

1. Keeping the last control value active until the next one arrives (zero order hold) versus resetting (setting to zero) control while data does not arrive.
2. Extension control period over many communication periods.
3. Using predictive control calculation based on object model equation on the controller side.

The example of Scicos schema for the control system with the PID discrete controller and anti-wind-up system is shown on Fig. 12. The control period for control loop is 3 ms and there is a possibility to count the number of lost data packets.

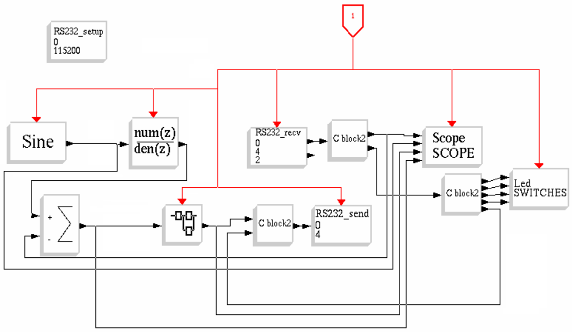

Fig. 12. Scicos schema for wireless servomechanism with PID controller

On Fig. 13 the demonstrative results of the experiments are shown. The reference model response reflects the desired response shape obtained from a simulation model without wireless communication. Remote plant responses were registered in the case of approximately 25% and 75% loss of data packets during the experiment. The level of the data loss was tuned by modifying the distance between the modules and placing barriers on waves propagation way. The degradation of responses quality according to higher number of lost packets is observed.

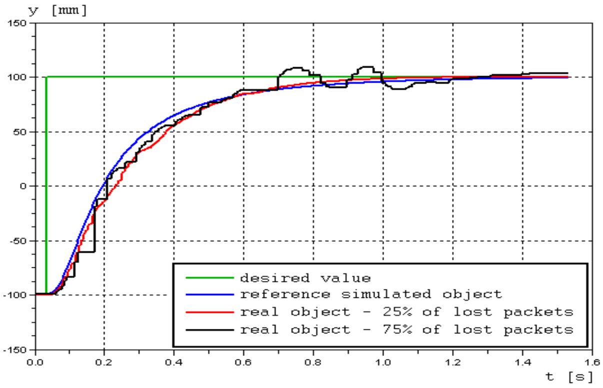

Fig. 13. Wireless servomechanism real-time step response experiment with PID controller

The remote communication module can also simulate object transfer function. There are a few advantages of this solution for students, e.g.:

1. It is possible to control objects that are not physically available in the laboratory.
2. Object model can be precisely defined and is not disrupted by unmodeled real plant dynamics. It allows students to concentrate on long delays or data loss compensation.

The transfer function given for a simulated object can be expressed in *s* or *z* domain. If the transfer function is given in *s* domain it is converted to *z* domain in the Scicos context script (automated action) applying a bilinear transformation. Finally, coefficients of the transfer function are inserted into a specially designed Scicos block ( `ControlSetup` ) that sends them to the remote communication module when the controller application starts. The process was automated as much as possible using the RCP environment. Only information that must be directly given by a student (object transfer function and controller diagram) is inputted manually.

Fig. 14 presents the demonstrative results of the system step response with a remote simulated object given by the transfer function $G(s)=\frac{36}{s^2-36}$ .

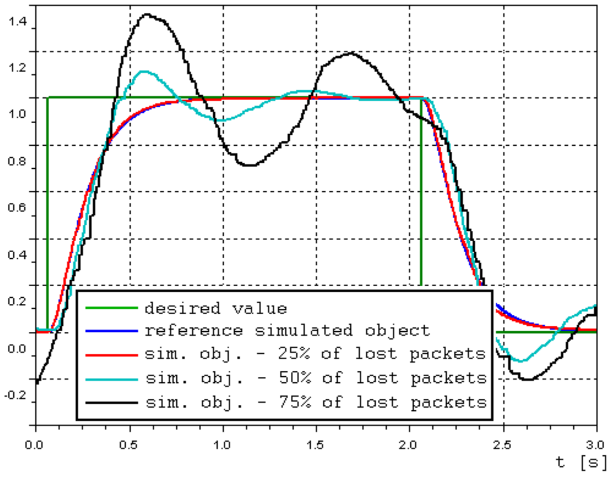

Fig. 14. The system step response with the remote simulated object

The three examples described in this section show the possibility of using Scilab/Scicos and RTAI for educational purposes. The mechatronics group in the Division of Informatics and Control at the Rzeszów University of Technology has the experience in using the Matlab/Simulink/RTW suit [15]–[17] as well as Scilab/Scicos/RTAI [4], [10]. Positive experience in using Scilab/Scicos/RTAI generated the definition of a new research goal. The goal is to build tool-chain for RCP on destination embedded hardware TS-7300 with the ARM9 processor and the FPGA chip.

## IV. RCP TOOL-CHAIN IDEA FOR EMBEDDED SYSTEM

### A. *Tool-chain idea*

Typical use of the Scilab/Scicos/RTAI suit involves a PC computer as a hardware platform in order to develop, run and test controllers. The goal defined in the mechatronics group in the Division of Informatics and Control assumes developing RCP tool-chain for embedded platform TS-7300. PC computer will be used as a platform for: developing controllers in Scilab/Scicos, cross-compiling controller code for embedded target, data acquisition and visualization. The executable controller code will be automatically deployed and run on the embedded platform. The GUI interface will be used on a PC computer for visualization and data acquisition. The sequence of actions taken up when tool-chain will be used is presented on Fig. 15.

PWM

Fig. 15. Tool-chain for embedded system

In order to obtain remote GUI interface, middle-ware layer based on UDP [2] is going to be used.

To achieve the goal the following main problems are de fined to be solve:

1. Recompilation of the RTAI kernel in order to enable floating point operations in real-time tasks. TS-7300 is equipped with MaverickCrunch math co-processor.
2. Modification of automatic code generator in order to support network communication between *xrtailab* and real-time tasks without *net-rpc* mechanism which is not available for the ARM platform.
3. Developing Scicos blocks for input/output operations using encoder counters and PWM outputs implemented in the FPGA chip.

Embedded platforms are considered to be more proper for a real-time control than general PC machines. Therefore, the RCP for embedded system can be used for didactic and in dustrial purposes.

The created tool-chain will be used for developing control systems for CNC machines and laboratory robots. The CNC machine control system based on RT-Linux [18] will be exchanged with newly developed system using the tool-chain. The tool-chain will be also used for didactic purposes i n courses of Embedded Systems and Real-Time Control.

### B. *The TS-7300 embedded platform*

The embedded platform consists of the TS-7300 Single Board Computer (Fig. 16) equipped with the RTAI real-time operating system.

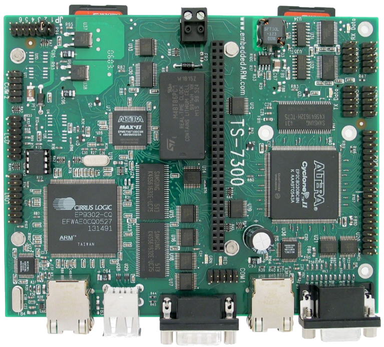

Fig. 16. TS-7300 Single Board Computer

The TS-7300 embedded system is a multipurpose board with a Cirrus Logic EP9302 200MHz processor. EP9302 features an advanced ARM920T processor designed with a memory management unit (MMU) that allows the support of high level operating systems such as Linux with a real-time extension. The modern processor connected via Wishbone, an open source hardware high-speed bus with Altera FPGA increases the flexibility of the system. The FPGA allows the development of user defined logic which can perform common controller tasks that are difficult, CPU intensive, or impossible to accomplish in software with regular DIO/GPIO hardware and the facilities of the processor. The TS-7300 provides up to 35 DIO lines connected directly to the FPGA through DIO header which can be used as a interface for control applications. In order to create servo controller, a student has to change the default FPGA configuration by implementing encoder counters and PWM generators. Peripherals such as SD Card flash socket, VGA controller, 2 USB ports, 10/100 Ethernet ports, RS232 serial ports are also included on the board.

In order to operate on the board it is possible to connect a mouse, keyboard and a monitor to USB and VGA connectors. The board can be used with additional laptop and SSH via Ethernet. For files transfer SCP software can be employed.

In order to adapt TS-7300 for servo control purposes as well as for cooperation with the Scilab/Scicos/RTAI suite the following problems were solved:

1. A cross-compiler for the embedded platform was developed. The created cross-compiler supports C, C++ and Fortran programming languages. The support for Fortran is required for automatic code generation from Scicos schemas. The cross-compiler delivered with TS-7300 does not support Fortran.
2. The RTAI kernel delivered with TS-7300 was modified in order to allow running real-time tasks in a user mode. In the original version of kernel delivered with TS-7300 a real-time task running in user mode caused system crash.
3. Encoder counters and PWM outputs have been implemented using Verilog language and Quartus II software tool in FPGA chip.

The tool-chain will let students to graphically design control structure, simulate system with plant model, deploy controller code into embedded system, run and test system for real-plant control.

## V. Conclusion

Scilab/Scicos/RTAI is low cost, high quality and an open source Rapid Prototyping System. The system can be used on courses of Control Theory, Embedded Systems, Real-Time Control and Mechatronics as an alternative to Matlab/Simulink. The system can be also applied in control system development for embedded platforms with ARM processors. It seems that the number of embedded industrial applications developed using Scilab/Scicos/RTAI should rapidly grow in the nearest future. According to the above mentioned expec tation teaching students applying Scilab/Scicos/RTAI in the development of embedded control systems is indispensable.

*Abstract*—**This paper presents development of the hardware and software for the low cost avionic system of ultralight airplanes. There are shown three levels of a hardware and software system design. As far as the software is concerned, we focused on changeover from non real-time operating system (embedded Linux) to the real-time embedded platform (QNX). We discussed the problems that led to operating system change. Various advantages and disadvantages of both operating systems are presented in this contribution. Concerning the hardware we concentrated on the development of the avionic control, monitoring and display modules that are a components of the dash board. The paper has been focusing on safety and reliability in the ultralight aviation and what can be improved or extended by the real-time operating system.**

## I. Introduction

THIS paper shows dependence hardware and software reliability. The control and monitoring system for ultralight or sport airplane has to be stable in an extreme situation as well as in a daily routine. When one designs your own hardware and software architecture one has to keep in mind the hazard states that can occur in many cases. In the aviation industry the safety and reliability are very important goals. But the other aspect is a product price. It means that hardware for double or triple protection is too expensive for the customer so we have to presume that hardware will work reliably at all times. This is the same case of our system that is why we focus on software architecture development in this article. The embedded Linux as main operating system has been implemented in our embedded system. The basic problem are drivers that have to be certificated and be very safe as all operating system. On the Linux platform it is difficult to ensure that drivers do not corrupt the kernel because both run within the same address space as the OS kernel. Therefore we were looking for a new software architecture solution. As the ideal answer it resulted in QNX real-time platform with client-server architecture where drivers are independent on the kernel (microkernel) that only implements the core services, like threads, signals, message passing, synchronization, scheduling and timer services. There are other possible real-time operating system of course that are very often use in the avionic systems, for example VxWorks from Wind River or Integrity from Green Hills but the problem for the low cost product is license price of the RTOS. When the run-time license price of RTOS is over the client limits there is no way how to use them. Especially Integrity software is very powerful system for developing purpose on the different platforms and has a very nice debugging tools.

## II. RTOS Selection

The right choice of a software system architecture is important for following development of all stuff. Due to the lack of our experiences and that requirements on the system where growing up during developing period, it caused that we had to try three different architectures.

### *A. Embedded uClinux*

The first platform was the embedded uClinux based on microprocessor ColdFire MCF5329 from Freescale. This solution had shown us that graphic hardware is not powerful enough as we supposed and the lack of MMU was the huge problem as well. [3] On the other hand the advantage of this solution is quick access to memory and integrated CAN hardware device on the developing board. The address space

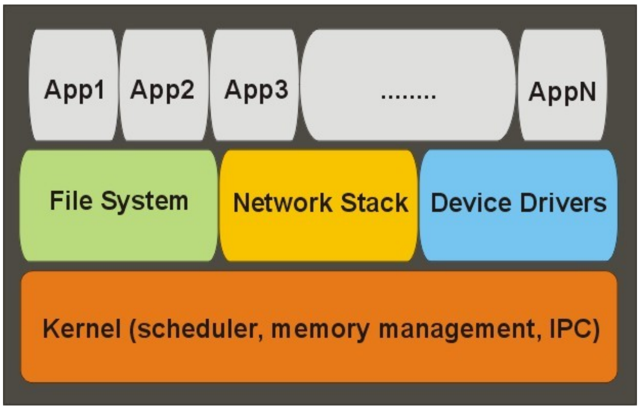

Fig 1. Architecture of uClinux - traditional for old RTOS

This work is supported by grant of the Grant Agency of the Czech Republic GA102/08/1429 - Safety and security of networked embedded system applications

is common for the kernel  as well as for the user application which decreased safety and reliability of the entire control system but it is real-time in nature because there is no overhead of system calls, message passing, or copying of data. The uClinux architecture (flat addressing model) is shown on the  Figure 1.

### B. *Embedded Linux*

The embedded Linux architecture was chosen as the next platform for avionic system. This architecture is based on monolithic kernel that has distinction between the user and kernel space. [5] Any fault in the application will not cause system crash. The system has run on ARM processor PXA 270 from Intel and ARM processor PXA 320 from Marvell. The  both processors are very powerful but there is a lack of floating point instructions set that is very important for graphic operations. The next problem that was mentioned above is incorrectly written driver or module that can cause the system to crash. [6] The embedded Linux architecture is shown on Figure 2.

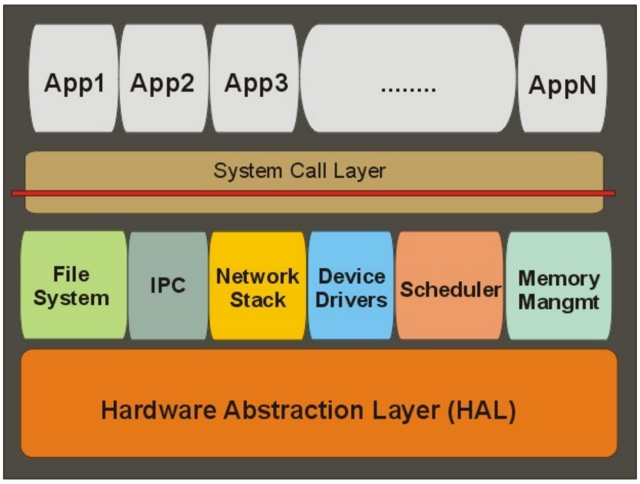

Fig 2. Architecture of embedded Linux

### C. *QNX Neutrino real-time OS V 6.3*

The embedded Linux has worked without problems but there was demand on system to be high reliable and safe. The embedded Linux was sufficient for the monitoring of avionic values but for the control activity it was worse. We had to ensure time death line for the control process activity and graphic smooth step to the next frame on LCD display. There were requirements to isolate graphic process from control process but in monolithic kernel architecture the graphic driver could corrupt all system. [4] So the next logical step was to use microkernel to realize mentioned requirement. The basic principle of microkernel architecture is that each of kernel subsystem (network stack, file system, scheduler, etc.) has private address space similar to application. This way offers complete memory protection, not only for user applications, but also for OS components. This architecture provides maximum modularity and relies on robust message passing schema. The QNX microkernel architecture is shown on Figure 3. [11]

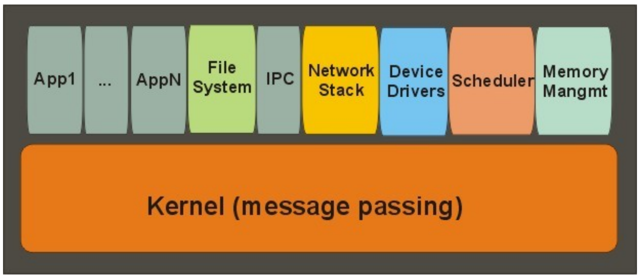

Fig 3. Architecture of QNX microkernel

Due to the lack of floating point instructions set we needed to use another processor that supports FPU and QNX RTOS. We decided to use ARM microprocessor iMX31 from Freescale but parallel solution stop on ARM processor PXA 270 with QNX RTOS. Unfortunately for the ARM microprocessor PXA 320 was not QNX BSP available.

## III. Software Architecture

The reliability is main goal in the process control of the most industrial or others systems. As we presented in software architecture part, there are many reasons, why divide all control and monitoring system into the smaller software distributed units – processes.

The client-server architecture brings features that  are able to guarantee more stability of the whole system. The failure of one part of the system (process) causes crash of any other one. The interprocess communication is based on robust message passing. The processes are separate according its functionality and hardware requirement. It means that each process uses one specific driver. Every individual process runs in independent address space.

There are five basic process groups. The first one is the motor control group that is responsible for everything what is connected with plane control. We measure avionic sensors inputs that are needed for autopilot control, maximum and minimum plane speed, etc.

The second group takes care of communication with other hardware parts. We are using CAN communication protocol and CAN driver where each hardware device is CAN node. [2] There is possible to use serial communication RS232 or USB as special process as well but for another purpose.

The third big group is SCADA system. The SCADA system or we can say graphic tasks that are responsible for monitoring and display avionic values in continuous time (it depend on processor time scheduling). Graphic process is very demanding on time of the processor so the priority level are low but have to ensure specific frame count per second.

The fourth group is IO device control for other purpose. We use GPIO driver for pins states monitoring. Each pin has special function where the most of them are used as button, trimer or switch. We use GPIO-event handling mechanism for pin state tracking.

The fifth group and the last process group is audio device group that is responsible for voice transmitting into the central communication system. There is audio system for warning and critical errors as well. The audio system can be used for other purpose it is up to client additional extension. The

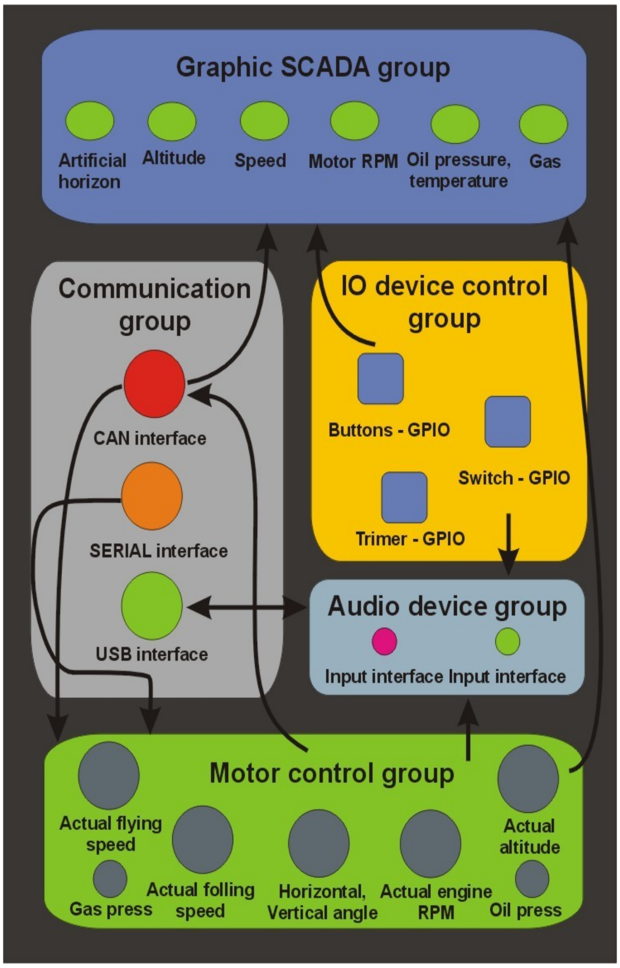

Fig 4. Architecture of process control

following schema on the Figure 4 shows process structure. The communication group allows data for other process groups from sensors and actuators. The motor control group uses communication group for engine values control. The communication unit has to be one of the most reliable part of the control and monitoring system.

## IV. Critical System Control

The basic critical processes of the aviation control have to meet the following criteria. The plane take-off speed as well as landing speed has to meet the required characteristics. These values are measured with sensors which are build-in the hardware board. The measurements are completed by the pressure difference against the surrounding environment. All data which have been gained from the sensors are used for the rotation engine process. The measurement of the stalling speed is a very important to prevent the uncontrolled plane fall /accident/ and jet-engine failure which is closely connected with this event. The measurement of the vertical and horizontal plane heeling is the next critical process. Exceeding the allowed plane heeling can result in stability loss of the airplane. To make the jet-engine work sufficiently the pressure in the gas and oil tank must be sustained. Other important flying data are information about a plane position. The position is shown through GPS system. All above mentioned processes must run in the independent address space so that the safety of the system is sustained.

The driver design is very important for communication and stable control of the application. The critical data goes through CAN interface which gives or receives information for engine control and fly control. The CAN driver is connection between module control node (present in next chapter) and motor control process group. The next sophisticated driver which is used for SCADA system is framebuffer driver. This driver has to be very efficient and quick. The visualization system was extended by OpenGL ES 2D driver [12]

## V. Hardware Architecture for Avionic Systems

The avionic system is distributed into the independent modules that measure specific values on mechanical parts of the airplane. The hardware solution is a configurable according type of airplane. The highest layer is graphic user module that represents received data on the LCD display. The sense of monitoring system is offer customers same facilities as have pilots in the professional aircrafts and make aviation more easier using low cost embedded electronic system.

The real-time embedded control system is designed with a modular structure. [4] This structure supports a flexible configuration. In terms of user requirements, the control system can be configured in different sizes and options. [8] The s everal modules with different options were designed. All modules are connected to an industrial bus – so each module is the bus node. Except the GPS module that is connected directly to the main control module.

This architecture supports a future expansion. In terms of user requirements it is possible to design new modules. The new module node will be connected to the bus. The new module can work to satisfy a user after upgrading of the firmware in the main control mode. This way it is possible to connect a maximal 30 modules - nodes. The block diagram of a desk control and monitoring system with today's full configuration of prototype is shown on the Figure 5.

The monitoring and control modules are connected together by using an industrial bus [2]. This bus has to be highly reliable and have enough speed. Depending on these two main requirements a CAN bus was selected. The main reason is that the CAN has an extremely low probability of non-detected error. The versatility of the CAN system has proven itself useful in other applications, including industrial automation as well, anywhere that a network is needed to allow controllers to communicate. A CAN bus is given the international standard ISO11898 which uses the first two layers of ISO/OSI model (CAN-CIA 2005). The CAN is a multi-master protocol. When a CAN message is transmitted over the network all nodes connected to the network will receive the message. [7] Any node can begin transmitting at any time the bus is free of traffic and all nodes will listen to the message. Each node may employ a filtering scheme that allows it to process only relevant information. Each message has either an 11 bit identifier or 29 bit identifier which will define which node will receive the message, error checking bits, 8 bytes of data and priority information. If two nodes try transmitting a message at the same time, the node with the higher identifier (lower priority) loses control of the bus as soon as another node exerts a dominant bit on the bus. It ensures that the message with the highest priority will be transmitted on the first try.

**Designed modules are the following:**

- Main control module
- User interface (LCD display) module
- Motor measuring values module
- Advanced avionic data module
- Black-Box module

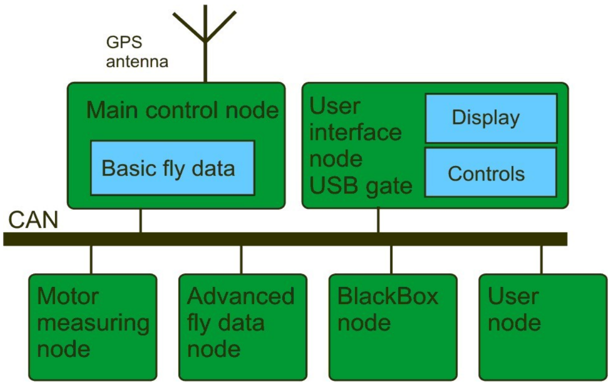

Fig 5. Block diagram of the control and monitoring system

### A. Main control module

The main control node serves as master for all other nodes. (Figure 6) [1] The requesting values from other nodes are compared with given limits and stored in the local memory. The main module decides what will be displayed and sends information to the user interface module by the CAN bus. The main control module contains a real time clock and data flash memory for storing measured values and statistics. For a measuring of the basic values the main module is equipped by sensors.

### B. Engine monitoring and control module

The engine monitoring and control module supports the complete monitoring and control of all necessary engine data. It collects all possible temperatures, pressures and the diagnostics of the engine. The basic motion control values and critical avionic data are already connected to the main control module.

### C. Avionic monitoring module

The advanced avionic data are supported by this module, for example a magnetic compass. This module only increase basic monitoring and control data that are supported in the main control module. It is up to client requirement.

### D. Black-Box module

The black-box module controls all traffic on the CAN bus. It reads data from CAN messages and stores data in the local memory. The black-box module is equipped with its own RTC timer and stores time together with the CAN data. There is no other connection to this module with such high reliability. [10]

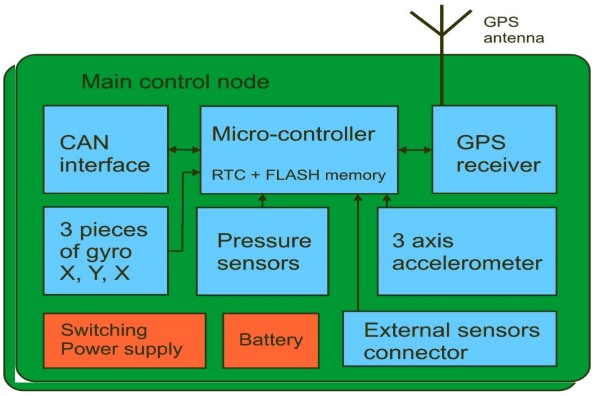

Fig 6. Main control node block diagram

### E. Development kits

There were three development kits used during the whole evolution. The first development kit that has been used comes from the world-wide known company – Freescale. This development kit is based on 32.bit microprocessors ColdFire family. This microprocessor runs on frequency 240 MHz and integrates display controller and other useful interfaces. [9] The second development kit that has been chosen comes from the Toradex company and integrates ARM microprocessor Intel PXA270 (Marvell PXA320) runs on frequency 520MHz respective for PXA320 on frequency 806MHz. There is an integrated display driver and CAN driver as well as other interfaces. [10] The third development kit that has been tested comes from company Logic PD. There is Freescale ARM microprocessor i.MX31 as SOM module integrated. This microprocessor runs on frequency 532MHz and integrates display controller and floating point unit as well.

### F. Prototype hardware development solution

The prototyping is the long process of improvements and cost lot of money and time. We have focused on finishing development on the ARM processors (Intel, Marvell and Freescale). The prototype board is designed for SOM module with processor PXA270 and PXA320. We are planning to design a new prototype board for SOM module based on processor iMX31. There is possibility to use other SOM modules for our prototype board as PXA300 or PXA255 as well.

These SOM module are intended for graphic processing of avionic data. The measurement and control module is based on 16.bit processor HCS12 from Freescale. There is not any RTOS integrated within. A lot of main control functions have been moved to SOM module (PXA270, iMX31) with RTOS QNX. The prototype implements interfaces as CAN, RS232, USB, GPIO. The standard interfaces like SERIAL and USB are supported by QNX BSP package but CAN and GPIO drivers have been developed by our software team to ensure drivers stability and reliability. We have chosen standard CAN controller SJA1000 produced by the Philips company. The GPIO driver has been implemented using older

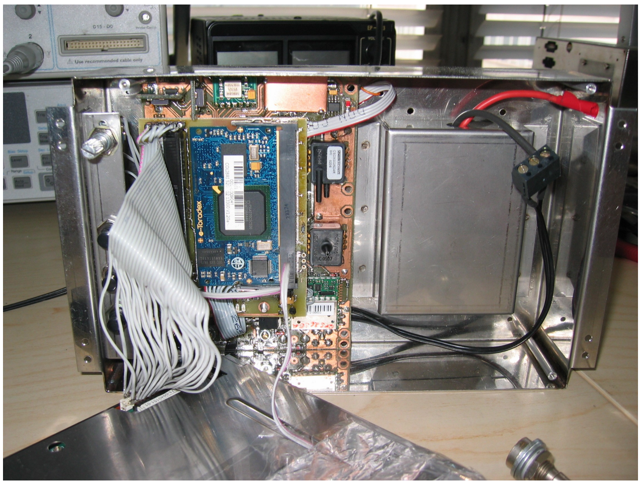

Fig 7. Prototype hardware realization

version where only address mapping had to be modified. The avionic system has three level of power supply. The first is standard supply from airplane battery that is recharged during a flight. When, due to some reasons or troubles this source is out of order, there are two batteries backup system. At the moment only one is embedded inside the box. The power supply for this prototype solution is 12V DC. The same power supply is used for LCD TFT display as well. The LCD TFT display has external backlight unit for better graphics recognition. The most energy from the power conception is consumed by the backlight module and LCD TFT display nearly more then 80% by the whole system. An extra extension can be reconfigured by the jumpers on the prototype board. Following Figure 7 and Figure 8 shows prototype realization.

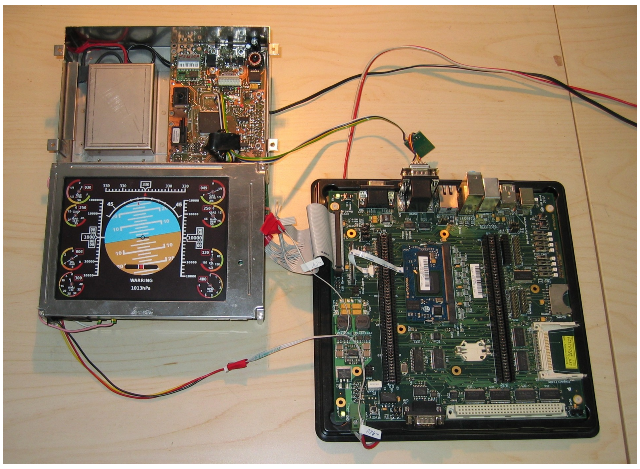

Fig 8. Prototype hardware realization with development kit

## VI. Graphic System Design

The graphic system design for the embedded system is usually quite difficult to meet optimal parameters for the mobile devices. The prototype solution that we proposed is embedded in the global avionic system and runs continuously during the flight. There is a big problem how to ensure low power consumption when you have to supply backlight module and LCD display. We can control backlight using software settings but this is not a cellphone where it is possible to switch off display when not used. But there are special cases when the backlight is switch off. For example when main power supply has to be replaced by battery and system controls backlight directly.

The PXA processors 270 and 320 lack of floating point unit and there is only floating point emulation that is very slow. The graphic operations base on emulation floating point are five times slower then on a fixed math primer. The fixed mathematics operations have been based on 16.bits integer scale what is sufficient for a precision of our application. The graphics rendering process takes a lot of processor time. So we decided to integrate graphic acceleration chip 2700G5 by the Intel company. The graphic acceleration has increased  the whole graphic process more then 100 times. The new processor PXA320 has integrated 2D graphics accelerator inside but the stable driver is not available yet. On the other hand the processor iMX31 by the Freescale company support 3D acceleration using their integrated chip inside and the driver is available for Linux and for QNX as well . The graphic library that has been used is OpenGL for embedded systems. There were only 2D graphic operations use in our system application. This OpenGL commands have to meet the avionic standards according OpenGL SC (Safety Critical for Avionics). The special example of 2D object rotation based on OpenGL is the gyro-horizon.[12]

## VI. Conclusion

The main goal of this paper is to show development and realization of the low cost avionic control and monitoring system for ultralight planes. We discussed safety and reliability of the control processes. In the step by step procedure we described software development process as well as hardware development process. The whole system was presented as distributed control system that consists of a few modules interconnected using CAN bus interface. We presented makeover from common operating system Linux to real-time operating system QNX.

***Abstract*—Upon first consideration, the Self-Managing Systems (and specifically Autonomic Systems) paradigm may seem to add too much additional functionality and overhead for systems that require strict real-time behavior. From our experience, not only does the Real-Time Systems area benefit from autonomicity, but the autonomic systems initiative requires the expertise of the RTS community in order to achieve its overarching vision. We briefly highlight some of the design considerations we have taken in incorporating self-management into Real-Time Systems.**

## I. Introduction

"AUTONOMIC Computing" is the term coined, initially by DARPA under the Autonomic Information Assurance program [13], and subsequently by IBM in their call to industry in 2001 [2]. The approach takes inspiration from the human and mammalian nervous systems in attempting to develop systems that are self-managing and ultimately self-governing [1].

We have argued in a previous article [3] that computer-based systems should be autonomic. We stand by that belief, in particular as software becomes more complex with greater expectations in terms of functionality, performance and real-time behavior. In our previous article [3], we were addressing a particular audience, viz. members of the IEEE Technical Committee on Engineering Computer-Based Systems (TC-ECBS). To that community, "computer-based systems" typically means embedded systems involving both hardware and software.

Such systems, like real-time systems, often have strict constraints in terms of performance and timing requirements. The addition of concepts from Autonomic Computing (AC) might at a first glance seem to add complexity rather than reduce it, something that real-time systems can generally ill-afford. We believe, however, that Autonomic Computing has much to offer in terms of reducing complexity, and our work over the last number of years has looked at how we might exploit AC and other biologically-inspired techniques in classes of systems that would otherwise be infeasible.

We believe that Autonomic Computing is not achievable without real-time systems (in particular at lower, implementation levels). Simultaneously, we believe that real-time systems can benefit much from AC, without significant overhead, and that future advancements necessitate that we move towards self-managing real-time systems.

## II. Self-Managing Systems

The vision of achieving self-management in our computing and communications systems has come to light under many similar initiatives—Autonomic Computing, Autonomic Communications, Organic Computing, Adaptive Infrastructure, N1, Dynamic System Initiative, Adaptive Network Care, Proactive Computing, Self-Organizing Systems, Self-*, Selfware, Biologically-Inspired Computing [5].

Although these different initiatives may have different academic specialties at their base, or were initiated by different industrial organizations, often they are inspired by self-management as exhibited in Biology and Nature. The IEEE has formalized the community as a Technical Committee on "Autonomous and Autonomic Systems" to underscore the strategic aims of developing next generation self- organizing and self-managing computing and communications infrastructures and systems.

### A. *Autonomic Computing*

The Autonomic Computing (AC) initiative focuses on managing complexity with self-managing systems, taking inspiration from the human autonomic nervous system (ANS) [1]-[5].

The ANS is that part of the nervous system that controls the vegetative functions of the body, such as circulation of the blood, intestinal activity, and secretion and production of chemical "messengers" (hormones) that circulate in the blood. The sympathetic nervous system (SyNS) supports "fight or flight", providing various protection mechanisms to ensure the safety and well-being of the body. The parasympathetic nervous system (PaNS) supports " rest and digest ", ensuring that the body performs necessary functions for long-term health.

The general properties of an autonomic (self- managing) system can be summarized by four objectives: being self-configuring, self-healing, self-optimizing and self-protecting, and four attributes: self-awareness, self-situated, self-monitoring and self-adjusting [7]. Essentially, the objectives represent broad system requirements, while the attributes identify basic implementation mechanisms.

Self-configuring represents a system's ability to re-adjust itself automatically; this may simply be in support of changing circumstances, or to assist in self-healing, self-optimization or self-protection.

Self-healing, in reactive mode, is a mechanism concerned with ensuring effective recovery when a fault occurs, identifying the fault, and then, where possible, repairing it. In proactive mode, it monitors vital signs in an attempt to predict and avoid "health" problems (reaching undesirable situations).

Self-optimization means that a system is aware of its ideal performance, can measure its current performance against that ideal, and has defined policies for attempting improvements. It may also react to policy changes within the system as indicated by the users. A self-protecting system will defend itself from accidental or malicious external attack. This necessitates awareness of potential threats and a means of handling those threats.

In achieving such self-managing objectives, a system must be aware of its internal state (self-aware) and current external operating conditions (self-situated). Changing circumstances are detected through self-monitoring and adaptations are made accordingly (self-adjusting).

As such, a system must have knowledge of its avail able resources, its components, their desired performance characteristics, their current status, and the status of inter-connections with other systems, along with rules and policies for how these may be adjusted. Such ability to operate in a heterogeneous environment will require the use of open standards to enable global understanding and communication with other systems.

These mechanisms are not independent entities. For instance, if an attack is successful, this will necessitate self-healing actions, and a mix of self-configuration and self-optimization, in the first instance to ensure dependability and continued operation of the system, and later to increase self-protection against similar future attacks. Finally, these self-mechanisms should ensure that there is minimal disruption to users, avoiding significant delays in processing.

The Autonomic Systems architecture essentially consists of cooperating autonomic elements made up of the component that is required to be managed, and the autonomic manager [11, 12]. It is assumed that an autonomic manager (AM) is responsible for a managed component (MC) within a self-contained autonomic element (AE). This autonomic manager may be designed as part of the component or provided externally to the component, as an agent for instance. To achieve a self-managing system these AEs will cooperate with remote autonomic managers through virtual, peer-to-peer, client-server or grid configurations.

### B. *Aims of AC*

If we consider the eight overriding objectives set out by IBM in 2001 in their call to the industry [2], some of these will seem, to the real-time systems (RTS) researcher or practitioner, characteristics that are common to real-time systems or that at least very desirable:

1. To be autonomic, a computing system needs to "know itself"—and comprise components that also possess a system identity.
2. An Autonomic Computing System must configure and reconfigure itself under varying and unpredictable conditions.
3. An Autonomic Computing system never settles for the status quo—it always looks for ways to optimize its workings.
4. An Autonomic Computing system must perform something akin to healing—it must be able to recover from routine and extraordinary events that might cause some of its parts to malfunction.
5. A virtual world is no less dangerous than the physical one, so an Autonomic Computing system must be an expert in self-protection.
6. An Autonomic Computing system knows its environment and the context surrounding its activity, and acts accordingly.
7. An Autonomic Computing system cannot exist in a hermetic environment.
8. *Perhaps* most critical for the user, an Autonomic Computing system will anticipate the optimized resources needed while keeping its complexity hidden.

This list of eight requirements, set out in [2] and [4], point to the fact that to qualify as an Autonomic System (AS), a system has to have a degree of self-awareness and familiarization with the components that compose it. It must know their capabilities, if it is to be able to adapt to its environment successfully, analogous to the way that dynamic scheduling requires a knowledge of tasks, their periods and deadlines.

An AS must be able to adapt to unpredictable conditions and adjust itself as necessary. This is something that is done, almost routinely, in an RTS. Real-Time Systems are constantly evolving. Their role is to adapt to changing environmental circumstances or new inputs. The role of scheduling is to optimize the use of resources and to make efficient use of available processing power. An effective RTS is performing this role.

A key focus of the list of essentials given above, is a move towards management and reduction of inherent complexity. Complexity is a major issue for any large-scale system. RTS have the added difficulty of having to meet strict timing-constraints and inputs from many sources, all of which need to be met.

But surely adding self-managing abilities to an already complex system, such as exhibited by an RTS, is only adding to adherent complexity? The overhead of self-management essentially adds an overhead to any system. Many RTSs are already pushing the limits of their schedules and adding any additional overhead is impossible.

It is our contention, however, that sometimes adding this overhead is justified. There are classes of systems for which self-management, and even self-government, is essential, for which timing constraints could not be met otherwise and for which the overhead of AC is more than repaid by a corresponding reduction in complexity.

### C. *Implementing AC*

It will be obvious to any practitioner that to hand over control to the system that was previously held by a human, in principle will add additional functionality, complexity and processing overhead to the system. Also experience from AI, Expert Systems, and Machine Learning problems will have shown many how slow decision-making systems can be. As such, it is vital to develop key principles and engineering techniques for how self-management systems should be created.

If we reconsider the meaning of the actual terms "Autonomic" and "Autonomous" [6]:

***au·to·nom·ic*** (àwtə nómmik)
*adj.*

1. Physiology.
   - a. Of, relating to, or controlled by the autonomic nervous system.
   - b. Occurring involuntarily; automatic: an autonomic reflex.
2. Resulting from internal stimuli; spontaneous.

***au·ton·o·mic·i·ty.*** (àwtə nóm i síttee)
*n.*

1. The state of being autonomic.

***au·ton·o·mous*** (aw tónnəməs)
*adj.*

1. Not controlled by others or by outside forces; independent: an autonomous judiciary; an autonomous division of a corporate conglomerate.
2. Independent in mind or judgment; self-directed.
3. 
   - a. Independent of the laws of another state or government; self-governing.
   - b. Of or relating to a self-governing entity: an autonomous legislature.
   - c. Self-governing with respect to local or internal affairs: an autonomous region of a country.
4. Autonomic.

[From Greek autonomos: *auto-*, auto- + nomos , *law*]

A difference stands out: "Autonomic" is very much concerned with spontaneous, reflex reactions while "Autonomous" is a slower, high level conscious decision-making process.

The basic principles of Autonomic and Autonomous systems can be incorporated into the design of a system to ensure that the correct response rate is achieved where it is needed. This has resulted in us considering a simple three tiered abstract architecture in our designs of self-managing systems:

- Autonomous Layer
- Selfware Layer
- Autonomic Layer

The *Autonomic Layer* is the bottom tier, closest to the hardware, and operates with immediate reaction to situations to ensure that system operations are maintained.

The *Selfware Layer* incorporates day-to-day operations of self-managing activity as and when needed, and as and when the system has the processing capacity available.

The *Autonomous Layer* is the top tier where high-level strategic objectives of the system are directed and satisfied over time. This often includes reflection.

As such, a key element that we have included in our work in designing AS is that of the *Autonomic Reflex,* borrowed from embedded and real-time systems and extended to include active system health telemetry.

### *D. Reflex Reactions*

Essentially, the aim of Autonomic C omputing is to create robust, dependable self-managing systems [8] in an attempt to deal with complexity.

At the heart of the architecture of any autonomic system are sensors and effectors. A control loop is created by monitoring behavior through sensors, comparing this with expectations (knowledge, as in historical and current data, rules and beliefs), planning what action is necessary (if any), and then executing that action through effectors. The closed loop of feedback control provides the basic backbone structure for each system component. There are two conceptual control loops in an Autonomic Element—one for self-awareness and another for self-situation (environmental awareness and context-awareness).

IBM represents this self-monitor/self-adjuster control loop as the monitor, analyze, plan and execute (MAPE) control loop. The monitor-and-analyze parts of the structure process information from the sensors to provide both self-awareness and an awareness of the external environment. The plan-and-execute parts decide on the necessary self-management behavior that will be executed through the effectors. The MAPE components use the correlations, rules, beliefs, expectations, histories, and other information known to the autonomic element, or available to it through the knowledge repository within the AM.

The autonomic environment requires that autonomic elements and, in particular, autonomic managers communicate with one another concerning self-* activities, in order to ensure th e robustness of the environment [9, 10]. It is our belief that the autonomic manager communications (AM ⇔ AM) must also include a reflex signal.

To facilitate this, fault-tolerant mechanisms such as a heart-beat monitor ('I am alive' signals) and pulse monitor (urgency/reflex signals) may be included within the autonomic element [9, 10]. See Figure 1 for an illustration of our autonomic environment.

The notion behind the pulse monitor (PBM) is to provide an early warning of an undesirable condition so that preparations can be made to handle the processing load of diagnosis and planning a response, including diversion of load. Together with other forms of communications it creates dynamics of autonomic responses [11] — the introduction of multiple loops of control, some slow and precise, others fast and possibly imprecise, fitting with the biological metaphors of reflex and healing [9].

This refle x component may be used to safeguard the autonomic element by communicating its health to another AE. The component may also be utilized to communicate environmental health information. For instance, in the situation where each PC in a LAN is equipped with an autonomic manager, rather than each of the individual PCs monitoring the same environment, a few PCs (likely the pillow queen—the least busy machines) may take on this role and alert the others via a change in pulse to indicate changing circumstances.

Figure 1: An Autonomic Environment

An important aspect concerning the reflex reaction and the pulse monitor is the minimization of data sent—essentially only a "signal" is transmitted. Strictly speaking, this is not mandatory; more information may be sent, yet the additional information must not compromise the reflex reaction and the required real-time response of the system. For instance, in the absence of bandwidth concerns, information that can be acted upon quickly and not incur processing delays could be sent. The important aspect is that the information must be in a form that can be acted upon immediately and not involve processing delays (such as is the case of event correlation).

Just as the beat of the heart has a double beat (lu b-dub) the autonomic element's pulse monitor may have a double beat encoded as described above, a self health/urgency measure and an environment health/urgency measure. These match directly with the two control loops within the AE, and the self-awareness and environment awareness properties.

Another extension we have been working on is the adaptive pulse monitor; where the rate of the pulse adapts not only when alerting other self-managing components about concerns (increase in pulse rate) but to take into consideration bandwidth concerns. In particular, under fault conditions there is often a cascade and flood of event and alarm messages on the network, and we must actively reduce alerting so that achieving autonomicity is not making the situation worse.

## III. A Self-Managing RTS Example

### IV. *NASA Missions*

NASA missions require the use of complex hardware and software systems, and embedded systems, often with hard real -time requirements [3]. Most missions involve significant degrees of autonomous behavior, often over significant periods of time. There are missions which are intended only to survive for a short period, and others which will continue for decades, with periodic updates to both hardware and software. Some of these updates are pre-planned; others, such as with the Hubble Space Telescope, were not planned but now will be undertaken (with updates performed either by astronauts or via a robotic arm).

While missions typically have human monitors, many missions involve very little human intervention, and then often only in extreme circumstances. It has been argued that NASA systems should be autonomic [9, 14], and that all autonomous systems should be autonomic by necessity. Indeed, the trend is in that direction in forthcoming NASA missions.

We take as our example, a NASA concept mission, ANTS, which has been identified [15] as a prime example of an autonomic system.

#### 1) *ANTS*

ANTS is a concept mission that involves the use of intelligent swarms of spacecraft. From a suitable point in space (called a Lagrangian), 1000 small spacecraft will be launched towards the asteroid belt.

As many as 60% to 70% of these will be destroyed immediately on reaching the asteroid belt. Those that survive will coordinate into groups, under the control of a leader, which will make decisions for future investigations of particular asteroids based on the results returned to it by individual craft which are equipped with various types of instruments

*a) Self-configuring*

ANTS will continue to prospect thousands of asteroids per year with large but limited resources. It is estimated that there will be approximately one month of optimal science operations at each asteroid prospected. A full suite of scientific instruments will be deployed at each asteroid. ANTS resources will be configured and re-configured to support concurrent operations at hundreds of asteroids over a period of time.

The overall ANTS mission architecture calls for specialized spacecraft that support division of labor (rulers, messengers) and optimal operations by specialists (workers). A major feature of the architecture is support for cooperation among the spacecraft to achieve mission goals. The architecture supports swarm-level mission-directed behaviors, subswarm levels for regional coverage and resource-sharing, team/worker groups for coordinated science operations and individual autonomous behaviors. These organizational levels are not static but evolve and self-configure as the need arises. As asteroids of interest are identified, appropriate teams of spacecraft are configured to realize optimal science operations at the asteroids. When the science operations are completed, the team disperses for possible reconfiguration at another asteroid site. This process of configuring and reconfiguring continues throughout the life of the ANTS mission.

Reconfiguring may also be required as the result of a failure, such as the loss of, or damage to, a worker due to collision with an asteroid (in which case the role may be assumed by another worker, which will be allocated the task and resources of the original).

*b) Self-healing*

ANTS is self-healing not only in that it can recover from mistakes, but self-healing in that it can recover from failure, including damage from outside forces. In the case of ANTS, these are non-malicious sources: collision with an asteroid, or another spacecraft, etc.

ANTS mission self-healing scenarios span the range from negligible to severe. A negligible example would be where an instrument is damaged due to a collision or is malfunctioning. In such a scenario, the self-healing behavior would be the simple action of deleting the instrument from the list of functioning instruments. A severe example would arise when the team loses so many workers it can no longer conduct science operations. In this case, the self-healing behavior would include advising the mission control center and requesting the launch of replacement spacecraft, which would be incorporated into the team, which in turn would initiate necessary self-configuration and self-optimization.

Individual ANTS spacecraft will have self-healing capabilities also. For example, an individual may have the capability of detecting corrupted code (software), causing it to request a copy of the affected software from another individual in the team, enabling the corrupted spacecraft to restore itself to a known operational state.

*c) Self - optimizing*

Optimization of ANTS is performed at the individual level as well as at the system level.

Optimization at the ruler level is primarily through learning. Over time, rulers will collect data on different types of asteroids and will be able to determine which asteroids are of interest, and which are too difficult to orbit or collect data from. This provides optimization in that the system will not waste time on asteroids that are not of interest, or endanger spacecraft examining asteroids that are too dangerous to orbit.

Optimization for messengers is achieved through positioning, in that messengers may constantly adjust their positioning in order to provide reliable communications between rulers and workers, as well as with mission control back on Earth.

Optimization at the worker level is again achieved through learning, as workers may automatically skip over asteroids that it can determine will not be of interest.

*d) Self - protecting*

The significant causes of failure in ANTS will be collisions (with both asteroids and other spacecraft), and solar storms.

Collision avoidance through maneuvering is a major challenge for the ANTS mission, and is still under development. Clearly there will be opportunity for individual ANTS spacecraft to coordinate with other spacecraft to adjust their orbits and trajectories as appropriate. Avoiding asteroids is a more significant problem due to the highly dynamic trajectories of the objects in the asteroid belt. Significant planning will be required to avoid putting spacecraft in the path of asteroids and other spacecraft.

In addition, charged particles from solar storms could subject spacecraft to degradation of sensors and electronic components. The increased solar wind from solar storms could also affect the orbits and trajectories of the ANTS individuals and thereby could jeopardize the mission. One possible self-protection mechanism would involve a capability of the ruler to receive a warning message from the mission control center on Earth. An alternative mechanism would be to provide the ruler with a solar storm sensing capability through on-board, direct observation of the solar disk. When the ruler recognizes that a solar storm threat exists, the ruler would invoke its goal to protect the mission from harm from the effects of the solar storm, and issue instructions for each spacecraft to "fold" the solar sail (panel) is uses to charge its power sources.

*e) Self - aware*

Clearly, the above properties require the ANTS mission to be both aware of its environment and self -aware.

The system must be aware of the positions and trajectories of other spacecraft in the mission, of positions of asteroids and their trajectories, as well as of the status of instruments and solar sails.

### *V. Real Time Issues*

The swarm-based concepts of ANTS (or its submission, PAM—Prospecting Asteroid Mission—as described above) enable exploration missions that never before would be possible. Such concept missions are clearly real-time systems. ANTS must be survivable in a harsh environment (space) over multiple years. The mission must be able to protect itself and to recover from collisions, threats from solar storms, and other problematic issues.

This must all be considered in the context of significant transmission delays. Round-trip delays between Earth and the asteroid belt exceed 40 minutes. The result is that exceptional events cannot be dealt with from Earth. Even anticipated events cannot be dealt with from Earth, as catastrophic damage could have occurred before ground control had even received notification.

The result is that the system must be self-managing. In order for its real-time behavior to be realized, the mission must exhibit the properties of an Autonomic System, which (as we pointed out in Section II.A) are desirable properties of a RTS in any case.

## VI. Conclusion

What is clear, is that applications based on such paradigms as we have described, and many envisioned for the future (and certainly not limited to the aerospace or space exploration domain) will be far too complex for humans to address all issues. Moreover, many issues will not be foreseeable, and much behavior will require hard real-time deadlines that can never be met with more traditional approaches.

While there is an overhead to achieving autonomicity, we believe that this overhead comes with significant benefit for RTS. We do not believe that it is too "costly" 1 for Real-Time Systems, but rather than in the future it will prove to be essential for developing effective RTS. Simultaneously, Autonomic Computing, and related areas, draw on much of the excellent research produced by the RTS community, a significant proportion of which was essential in making the AC initiative feasible.

In short: we believe we are moving swiftly towards a time when it will be imperative to have self-managing Real-Time Systems.

## Acknowledgment

This work was supported in part by Science Foundation Ireland grant 03/CE2/I303_1 to Lero—the Irish Software Engineering Research Centre (www.lero.ie).

This research is partly supported at University of Ulster by the Computer Science Research Institute (CSRI) and the Centre for Software Process Technologies (CSPT) which is funded by Invest NI through the Centres of Excellence Programme, under the EU Peace II initiative.

Several of the technologies described in this paper were developed with NASA and are patent-pending and assigned to the United States Government.

***Abstract*—A prototype environment called CPDev for programming small distributed control-and-measurement systems in Structured Text (ST) language of IEC 61131-3 standard is presented. The environment consists of a compiler, simulator and configurer of hardware resources, including communications. Programming a mini-DCS (*Distributed Control System*) from LUMEL Zielona Góra is the first application of CPDev.**

## I. Introduction

DOMESTIC control-and-measurement industry manufactures transmitters, actuators, drives, PID (*Proportional-Integral-Derivative*) and PLC (*Programmable Logic*) controllers, recorders, etc. Connected into distributed systems, they are used for automation of small and medium scale plants. However, engineering tools used for programming such devices are rather simple and do not correspond to IEC 61131-3 standard [2] (Polish law since 2004).

This paper presents current state of work on engineering environment called CPDev (*Control Program Developer*) for programming small control-and-measurement devices and distributed mini-systems according to the IEC standard (digits dropped for brevity). First implementation involves instruments from LUMEL Zielona Góra [7]. Initial information on CPDev was presented at the previous IMCSIT conference [5]. Similar environments have been described in [1], [6].

The CPDev environment (called also package) consists of three programs executed by PC and one by the controller. At the PC side we have:

- CPDev compiler of ST language,
- CPSim software simulator,
- CPCon configurer of hardware resources.

The programs exchange data through files in appropriate formats. The CPDev compiler generates an universal code executed by virtual machine VM at the controller side. The machine operates as an interpreter. The code is a list of primitive instructions of the virtual machine language called VMASM assembler. VMASM is not related to any particular processor, however it is close to somewhat extended typical assemblers. In this way, portability of the compiled code for different hardware platforms is provided. On the contrary, other solutions are usually built around the concept of translating IEC language programs into C code [6].

Basic characteristics of VMASM and virtual machine are given in [5]. CPSim simulator also involves the machine (in this case at the PC side).

Fig. 1. User interface in CPDev environment

The CPDev package is developed in C# language of .NET Framework. The virtual machine is written in ANSI C and compiled with appriopriate, platform-dependent compilers e.g. avr-gcc in case of the LUMEL's mini-DCS. Other languages and programming environments are also used in specific cases.

The implementation of CPDev components was supported by lexical diagrams (compiler), object-oriented modelling techniques (programming environment) and coloured Petri nets (communication subsystem), see [5], [9].

## II. A program in ST language

Main window of user interface in the CPDev environment is shown in Fig. 1. It consists of three areas:

- tree of project structure, on the left,
- program in ST language, center,
- message list, bottom.

Tree of the START_STOP project shown in the figure includes Program Organization Unit (POU) with the program PRG_START_STOP, five global variables from START to PUMP, task TSK_START_STOP, and two standard function blocks TON and TOF from IEC_61131 library.

The PRG_START_STOP program seen in the main area is written according to ST language rules. The first part involves declarations of instances DELAY_ON, DELAY_OFF of the function blocks TON and TOF. Declarations of the global variables (EXTERNAL) are the second part, and four instructions of the program body, the third one. The instructions correspond to FBD (*Function Block Diagram*) shown in Fig. 2. So one can expect that certain MOTOR is turned on immediately after pressing a button START and a PUMP five seconds later. Pressing STOP or activation of an ALARM sensor triggers similar turn off sequence.

## III. Global variables and task

Global variables can be declared in CPDev either using individual windows or collectively at a variable list. The list for the START_STOP project is shown in Fig. 3.

The addresses specify *directly represented variables* [2], [3] and denote relative location in controller memory (keyword AT declares the address in individual window). Here these addresses are called *local*. Variables without addresses (not used in this project) are located automatically by the compiler.

Window with declaration of the TSK_START_STOP task is shown in Fig. 4. A task can be executed once, cyclically or continuously (triggered immediately after completing, as in small PLCs). There is no limit on the number of programs assigned to a task, however a program can be assigned only once.

Text of the project represented by the tree is kept in an XML text file. Compilation is executed by calling `Project->Build` from the main menu. Messages appear in the lower area of the interface display (Fig. 1). If there are no mistakes, the compiled project is stored in two files. The first one contains universal executable code in binary format for the virtual machine. The second one contains mnemonic code [5], together with some information for simulator and hardware configurer (variable names, etc.).

## IV. Functions and libraries

The CPDev compiler provides most of standard functions defined in IEC standard. Six groups of them followed by examples are listed below:

- type conversions: INT_TO_REAL, TIME_TO_DINT, TRUNC,
- numerical functions: ADD, SUB, MUL, DIV, SQRT, ABS, LN,
- Boolean and bit shift functions: AND, OR, NOT, SHL, ROR,

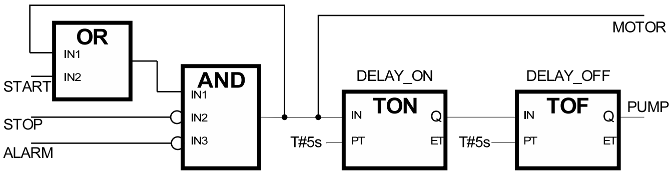

Fig. 2. START_STOP system for control of a motor and pump (with delay of 5 seconds)

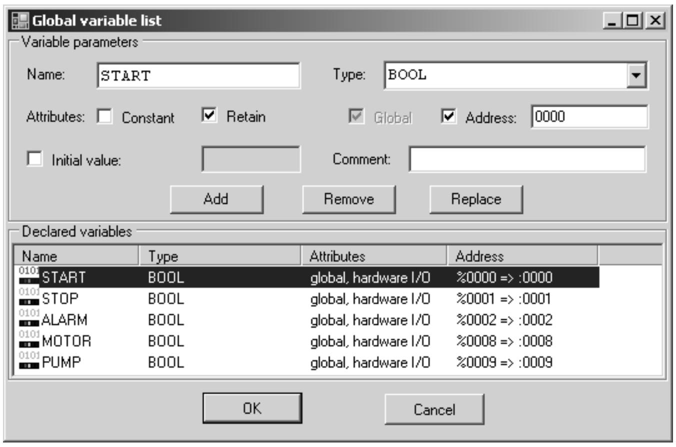


Variable parameters

Name: START Type: BOOL

Attributes: □ Constant ☑ Retain ☑ Global ☑ Address: 0000

□ Initial value: Comment:

Declared variables

| Name | Type | Attributes | Address |
|---|---|---|---|
| START | BOOL | global, hardware I/O | %0000 => :0000 |
| STOP | BOOL | global, hardware I/O | %0001 => :0001 |
| ALARM | BOOL | global, hardware I/O | %0002 => :0002 |
| MOTOR | BOOL | global, hardware I/O | %0008 => :0008 |
| PUMP | BOOL | global, hardware I/O | %0009 => :0009 |

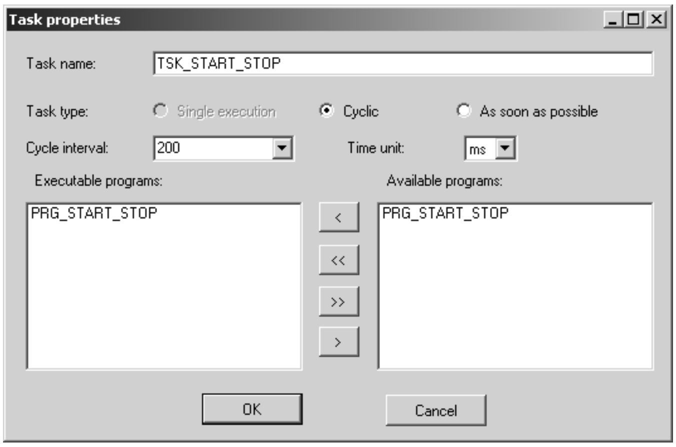
Fig. 3. Global variable list for the START_STOP project.

- selection and comparison functions: SEL, MAX, LIMIT, MUX, GE, EQ, LT,
- character string functions: LEN, LEFT, CONCAT, INSERT,
- functions of time data types: ADD, SUB, MUL, DIV (IEC uses the same names as for numerical functions).

Selector SEL, limiter LIMIT and multiplexer MUX from selection and comparison group are particularly useful. Variables of any numerical type, i.e. INT, DINT, UINT and REAL (called ANY_NUM in IEC [2], [3]) are arguments in most of relevant functions.

Typical program in ST language is a list of function block calls, where inputs to successive blocks are outputs from previous ones (see Fig. 2). So far the CPDev package provides three libraries:

- IEC_61131 standard library,
- Basic_blocks library with simple blocks supplementing the standard,
- Complex_blocks library for continuous regulation and sequential control.



Task name: TSK_START_STOP

Task type: ○ Single execution ● Cyclic ○ As soon as possible

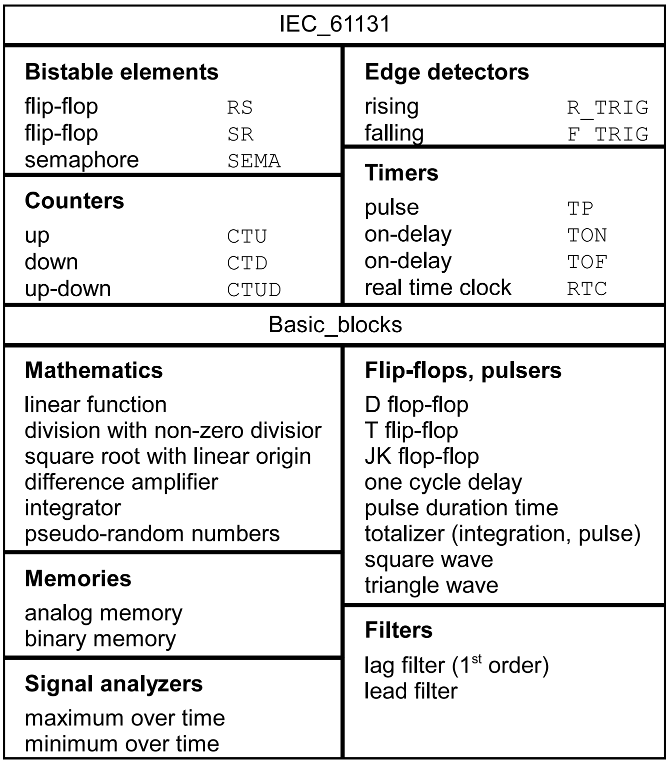
Cycle interval: 200 Time unit: ms

Executable programs: PRG_START_STOP

Available programs: PRG_START_STOP

Fig. 4. Declaration of TSK_START_STOP task

TABLE I
BLOCKS FROM IEC_61131 AND BASIC_BLOCKS LIBRARIES



| IEC_61131 | | | |
|---|---|---|---|
| **Bistable elements** | | **Edge detectors** | |
| flip-flop | RS | rising | R_TRIG |
| flip-flop | SR | falling | F_TRIG |
| semaphore | SEMA | **Timers** | |
| **Counters** | | pulse | TP |
| up | CTU | on-delay | TON |
| down | CTD | on-delay | TOF |
| up-down | CTUD | real time clock | RTC |
| **Basic_blocks** | | | |
| **Mathematics** | | **Flip-flops, pulsers** | |
| linear function | | D flop-flop | |
| division with non-zero divisior | | T flip-flop | |
| square root with linear origin | | JK flop-flop | |
| difference amplifier | | one cycle delay | |
| integrator | | pulse duration time | |
| pseudo-random numbers | | totalizer (integration, pulse) | |
| **Memories** | | square wave | |
| analog memory | | triangle wave | |
| binary memory | | **Filters** | |
| **Signal analyzers** | | lag filter (1$^{st}$ order) | |
| maximum over time | | lead filter | |
| minimum over time | | | |

Table I lists blocks form the first and second libraries. Blocks such as PID controller, servo positioner, multi-step sequencer, dosing block, etc., belong to the third library.

The user can develop functions, function blocks and programs, and store them in his libraries. Tables of single-size are available only.

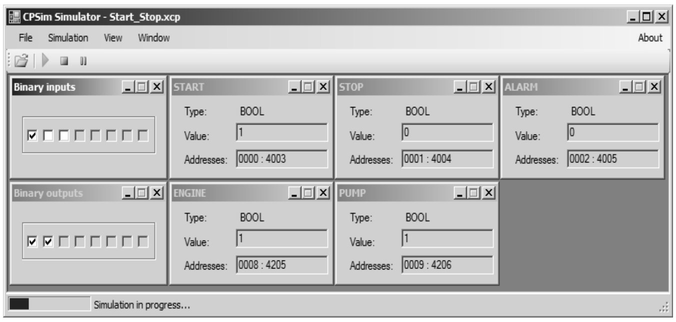
## V. CPSIM SIMULATOR

The compiled project may be verified by simulation before downloading into the controller. The CPSim simulator can be used in two ways:

- before configuration of hardware resources (simulation of the algorithm),
- after configuration of the resources (simulation of the whole system).

The first way involves logic layer of the CPDev environment. PC computer operates as a virtual machine executing universal code. The second way requires configuration of hardware resources, so it is application dependent. The CPCon configurer generates hardware allocation map (see below) that assigns local addresses to physical ones and specifies conversion of ST data formats into formats accepted by hardware. The objective is to bring simulation close to the hardware level, so CPSim uses both the code and the map. Simulation window of the START_STOP project is shown in Fig. 5. The two faceplates on the left present values of three inputs and two outputs (TRUE is marked). The user can select faceplates, arrange them on the screen and assign variables. Simulated values can be set both in group and in individual faceplates.

So far the window of Fig. 5 is used for simulation only. In future it will be also employed for on-line tests (*commissioning*).



CPSim Simulator - Start_Stop.xcp

Binary inputs: ☑ ☐ ☐ ☐ ☐ ☐ ☐ ☐

START — Type: BOOL — Value: 1 — Addresses: 0000 : 4003

STOP — Type: BOOL — Value: 0 — Addresses: 0001 : 4004

Binary outputs: ☑ ☑ ☐ ☐ ☐ ☐ ☐ ☐

ENGINE — Type: BOOL — Value: 1 — Addresses: 0008 : 4205

PUMP — Type: BOOL — Value: 1 — Addresses: 0009 : 4206

Simulation in progress...

Fig. 5. Simulation of the START_STOP project

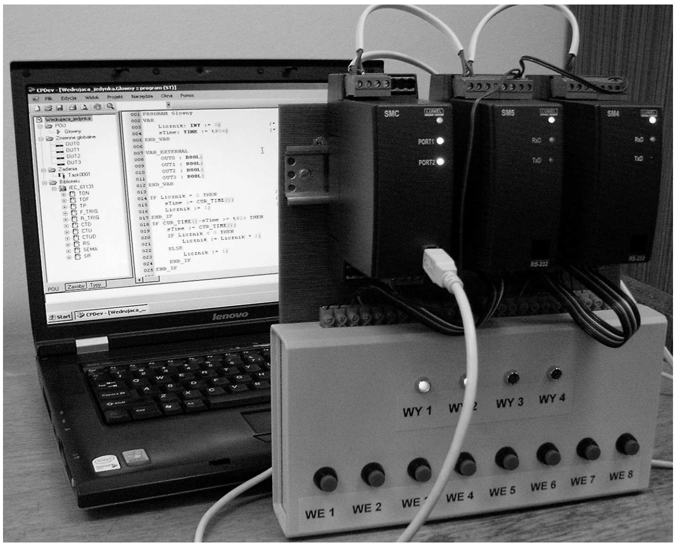

Fig. 6. Test set-up of mini-DCS system with SMC controller and SM I/O modules

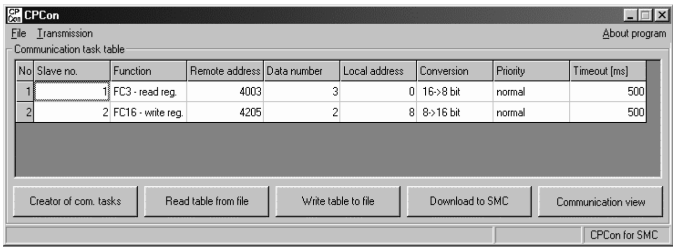
## VI. CPCON CONFIGURER AND MINI-DCS

The CPCon configurer defines hardware resources for particular application. The example considered here involves mini-DCS with SMC programmable controller, I/O modules of SM series and eventually other devices from LUMEL Zielona Góra [7]. Modbus RTU protocol is employed [4] on both sides of the SMC.

Fig. 6 shows test realization of the system with SMC controller (on the left), SM5 binary input module (middle), and SM4 binary output module (on the right). The console with pushbuttons and LEDs (below) is used for testing. The PC runs first the CPDev package and a SCADA (*Supervisory Control And Data Acquisition*) system later. PC and SMC are connected via USB channel configured as a virtual serial port.

The CPCon configurer functions are as follows:

- configuration of a communication between SMC and SM I/O modules,



Communication task table

| No | Slave no. | Function | Remote address | Data number | Local address | Conversion | Priority | Timeout [ms] |
|---|---|---|---|---|---|---|---|---|
| 1 | 1 | FC3 - read reg. | 4003 | 3 | 0 | 16->8 bit | normal | 500 |
| 2 | 2 | FC16 - write reg. | 4205 | 2 | 8 | 8->16 bit | normal | 500 |

Fig. 7. Communication configuration of the START_STOP project.

- creation of file with hardware resource allocation map,
- downloading the files with executable code and map to the SMC.

Recall that having the map the CPSim can be used in the second simulation mode.

Main window of the CPCon configurer is shown in Fig. 7. The Transmission slot sets speed, parity and stop bits for PC↔SMC and SMC↔SM communications. Communication task table determines what question↔answer and command↔acknowledgment transactions take place between SMC controller (*master*) and SM modules (*slaves*). The transactions are called *communication tasks* and represented by the rows of the table. The DCS system is configured by filling the rows, either directly in the table or interactively through a few windows of Creator of com. tasks (bottom).

The first row specifies communication between SMC and SM5 binary input module (remote). SM5 is connected to pushbuttons in the console (Fig. 6) which, in case of the START_STOP project, set the variables START, STOP and ALARM (Figs. 1, 2). In SMC these variables have consecutive addresses beginning from 0000 (Fig. 3). SM5 places the inputs in consecutive 16-bit registers beginning from 4003. So all variables can be read in a single Modbus transaction with the code FC3 (read group of registers [4]). However, since BOOL occupies single byte in CPDev, the interface of the virtual machine has to perform 16→8 bit conversion.

Communication tasks are handled by SMC during pauses that remain before end of the cycle, after execution of the program. Single transaction takes 10 to 30 ms, depending on speed (max. 115.2 kbit/s). If the pause is large, the task can be executed a few times. It has been assumed that the task with NORMAL priority is executed twice slower than the task with HIGH priority, and the task with LOW priority three times slower. As seen in Fig. 7, the communication with SM5 module has NORMAL priority. The Timeout within which transaction must be completed is 500 ms.

Second row of the Communication task table defines communication with the SM4 binary output module. SM4 controls the console LEDs. Two consecutive variables, MOTOR and PUMP, the first one with the local address 0008, are sent to SM4 by single message with the code FC16 to remote addresses beginning from 4205 (write group of registers). This time 8→16 bit conversion is needed.

## VII. Conclusions

CPDev environment for programming industrial controllers and other control-and-measurement devices according to IEC 61131-3 standard has been presented. The environment consists of ST language compiler, project simulator, and configurer of hardware resources, including communications. The user can program his own function blocks and create libraries. Mini-DCS control-and-measurement system form LUMEL is the first application of the package.

Programs written in the future in other IEC languages, first of all in FBD, will also be compiled to the VMASM code and executed by the virtual machine. Appriopriate compilers are under development. XML format for data exchange between languages has already been defined by PLCOpen [1], [8].

# Web-based Laboratories: How Does That Affect Pedagogy? Thoughts for a Panel Discussion

Janusz Zalewski
Department of Computer Science
Florida Gulf Coast University
Fort Myers, FL 33965-6565, USA
zalewski@fgcu.edu

***Abstract* — The author presents a few questions for discussion at the Panel on web-based laboratories. The key issue is whether and how such laboratories can enhance the pedagogy. Is this only a technological trend or are there real values in creating online labs for real-time systems education? Answers to sample questions from the literature are reviewed.**

## I. Introduction

WEB-BASED or online laboratories are a very hot issue in contemporary education in all engineering and science disciplines. They are considered to be the technology alternative and complementary to traditionally organized hands-on labs, where students have direct physical contact with equipment to conduct experiments, as well as to simulation labs, where experiments are modeled using computer software and access is provided either directly in the lab or virtually via the Internet.

While web-based labs are a very attractive option to pursue, especially in cases with expensive lab equipment, when only a few institutions can afford it, or in cases when non-traditional students have difficulties meeting the time frame the labs are offered, there are still several issues related to pedagogy, whether lab experiments conducted via the web have intrinsic value and provide the level of education and experiences comparable with traditionally conducted labs. These issues are of concern to faculty teaching courses with such labs as well as to the institutions hosting these labs, since the investment of time and resources in creating and maintaining web-based labs is significant and needs to be justified in a longer term.

The objective of this panel session is to review some of the existing approaches to offering web-based laboratories and discuss issues affecting the pedagogy of such labs. The discussion is based on the most recent publications on web-based labs reviewed by the panel proponent. A summary of the issues related to pedagogy raised in some of these publications is presented below.

## II. Questions Related to Pedagogy

Serious publications on web-based laboratories began to appear in the early 2000's [1]-[3]. They represented an overall trend in transitioning to intercontinental learning [4]-[5] and concerned a variety of disciplines, from sciences [6] to engineering [7]-[9]. More recently, a proliferation of papers on remote, web-based labs is observed. They report on developments not only in disciplines traditionally considered the most advanced in remote experimentation, such as control engineering and robotics [10]-[12], but also in electronics, in courses using FPGA's [13] and PLC's [14], optical circuits [15] and antennas [16], as well as in physics [17], chemical engineering [18], materials research [19] and energy research [20]. Some authors propose generic labs [21], as well as try to analyze the phenomenon in comparison to hands-on and simulation labs [22]. No major work however, to the author's knowledge, has been done in bringing computer science or software engineering labs to the web.

### A. Four Basic Questions

In this view, the author believes that some basic questions need to be asked, first, regarding the existence or necessity of building such labs. Assuming the basic architecture of a web-based lab, as illustrated in Fig. 1, the following four questions come to mind:

Q1) What is the place of a web-based lab in a Computer Science or a Software Engineering program or a course?

Q2) Once the lab is in place, for conducting computer science or software engineering experiments in a web based lab: is there an ideal model?

Q3) Developing software for remote equipment: how does a web-based lab help?

Q4) Is there really an intellectual value added to a course with remote web-based laboratories?

My understanding of these four questions is as follows: Q1 is setting the stage for the discussion, formulates the requirements for a lab, Q2 and Q3 are meant to discuss the practice of remote labs, and Q4 is meant to stimulate the participants to derive some conclusions.

This work was supported in part by a grant from the National Science Foundation, Award No. DUE-0632729. Findings and opinions contained herein are not necessarily those of the NSF.

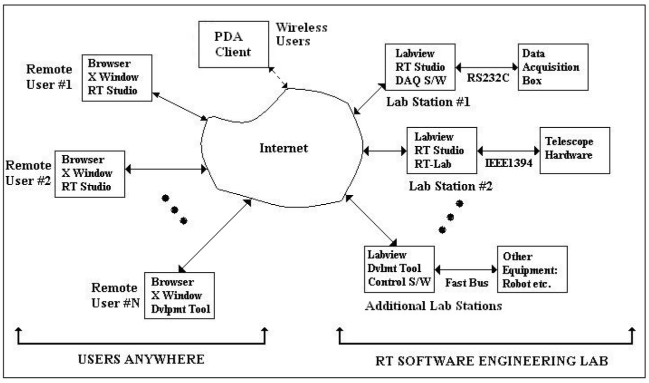

Fig. 1 System architecture of a typical web-based lab.

### B. Addressing the Pedagogy

Educators who have already implemented web-based labs often present their views on educational values of such labs and the challenges they are facing. Ma and Nickerson [22] review a number of early decade publications on web-based labs and mention several advantages such labs might bring to the table:

- sharing expensive experimental devices with a pool of schools
- increasing the availability of devices over time and their accessibility from different locations
- increasing the number of students that have lab access
- increasing student motivation and interest in conducting experiments.

Schools that started building and offering online labs first, offer a number of interesting observations what such labs can bring to pedagogy [21]:

- web labs enhanced conceptual learning, stimulated higher-order thinking, and reinforced individual styles of learning in multiple ways
- web labs allowed students to control their own learning process, while enabling faculty to maintain factual rigor and coherence throughout the course.

Among the challenges, ones the most frequently listed include: providing extended technical support, merit-based assistance to students in extended hours, and practical cost to maintain such labs.

## III. Summary and Conclusion

Being an important new lab component of any course, in addition to hands-on and simulation labs, web-based labs are still facing multiple challenges. It is an open question whether they increase an educational value of a course. It is also unclear whether they have a chance one day to replace traditional labs, filled with instrumentation and operated like a shop. One thing remains certain, however, as the world of technology clearly moves towards operating devices remotely, student experience with remote control of equipment will become invaluable on the job. It is hoped that some of the questions asked in this note will be answered in the discussion.

# Improving Energy-Efficient Real-Time Scheduling by Exploiting Code Instrumentation

Thorsten Zitterell and Christoph Scholl
Albert-Ludwigs-University, Freiburg im Breisgau, Germany
{tzittere|scholl}@informatik.uni-freiburg.de

***Abstract*—Dynamic Frequency and Voltage Scaling is a promising technique to save energy in real-time systems. In this work we present a novel light-weight energy-efficient EDF scheduler designed for processors with discrete frequencies which performs on-line intra- and inter-task frequency scaling at the same time. An intra-task scheduling scheme based on cycle counters of a processor allows the application of our approach to shared code of library functions and to task setups where only sparse intra-task information is available. Our ‘Intra-Task Characteristics Aware EDF’ (ItcaEDF) scheduler which aims to run with a low frequency by eliminating idle time and inter- and intra-task slack times was evaluated in an compiler, WCET analysis, and simulation framework. Our experiments show that state-of-the-art intra-task as well as inter-task frequency scaling approaches are clearly outperformed by our approach.**

## I. Introduction

REAL-TIME systems like mobile multimedia devices have to meet high demands which are often competing. They require high performance under real-time constraints (for audio en-/decoding, e.g.), but also have to deal with limited resources like energy. Dynamic Voltage and Frequency Scaling (DVS/DFS) is an effective instrument to control the trade-off between system performance and energy-efficiency. Here, the operating system or the applications can decide whether the system should run at a higher frequency for higher performance but also with more power consumption – or at a lower frequency to save energy. When the timing behavior of real-time systems is specified by deadlines for individual tasks in the system, DFS (Dynamic Frequency Scaling) algorithms try to decrease the processor frequency under the constraint that deadlines are still guaranteed.

The concept of Dynamic Voltage and Frequency Scaling which changes the supply voltage and the processor frequency during run time has been proposed in many publications, e.g., [1], [2], [3], [4], [5], [6], [7], as a technique to reduce energy consumption for systems with and without real-time constraints. Existing approaches to DVS can be divided into inter-task voltage scheduling and intra-task voltage scheduling.

Approaches to *inter-task* voltage scaling make use of the fact that computation times of tasks are usually not fixed due to different execution paths during run time. Whereas standard scheduling approaches for real-time systems are based on fixed worst-case execution times for the tasks, inter-task voltage scaling makes use of ‘inter-task slack times’, which occur when a task instance terminates earlier than expected for the worst-case. For instance, Lee and Shin [8] adjusted the EDF scheduler [9] to the voltage scaling context. They presented an energy-efficient on-line EDF algorithm which requires only constant time for each context switch. In their approach voltage scaling is only performed when a task starts or resumes after another task which leaves some ‘inter-task slack time’ to the following task. [8] assumes a processor model which is able to provide a continuous spectrum of frequencies (limited by a maximum frequency $f_{max}$).

Whereas in many cases inter-task voltage scaling approaches succeed in reducing energy consumption, there are application scenarios where inter-task voltage scaling is less effective: Since voltage scaling can be applied only between two activations of different tasks, the granularity of inter-task voltage scaling may not be high enough, especially when the system consists of a small number of relatively long-running tasks (with one task as an extreme case).

In contrast to inter-task voltage scaling, *intra-task* voltage scaling algorithms perform voltage scaling during the execution of single tasks (and not between two activations of different tasks). Typically, there are many points in the program for a single task where frequency scaling is performed in case that execution time was saved (relative to the worst-case execution time). In that way, slack time for downsizing the processor frequency can be used much earlier than by inter-task voltage scaling and at a higher granularity. Compared to inter-task methods this may potentially lead to a more homogeneous distribution of used processor frequencies and thus to higher energy savings.[1] In [10] control flow analysis determines execution paths in a program whose traversal will save cycles and result in earlier task termination. Depending on the number of saved cycles the executable code is instrumented at *Voltage Scaling Edges (VSEs)*. Voltage scaling edges are restricted to branches in the control flow. At each edge the processor frequency is decreased by a given factor and the system can save energy. The basic concept has been further optimized by identifying earlier voltage scaling points using data flow information of the program [11] and by using profile information to estimate probabilities of branches [12].

[1] Idle times, which indicate a non-optimal voltage scaling strategy, can not always be avoided by inter-task methods: In the extreme case, the slack produced by a task running much shorter than the worst case execution time can not be used by other tasks, since no instances of other tasks have been released at the finishing time of that task (even if processor utilization is maximal assuming worst-case timing).

The intra-task algorithms mentioned above concentrate on single-task environments and they consider processors with a continuous frequency range. Thus, these algorithms are able to enforce that a task's execution completes exactly at its deadline, provided that there is a frequency scaling point at each branch in the control flow. However, this is not a realistic scenario:

- Usually, processors do not offer a continuous frequency range, but a set of discrete frequencies. On processors with discrete frequencies the frequency required by the intra-task algorithm may not be available and the processor has to run at some higher speed, thus the task may finish *before* its deadline.
- Moreover, in real applications it does not make sense to place a frequency scaling point at *every* branch in the control flow because of the overhead both for frequency scaling itself and for computing saved cycles and scaling factors at run time. For that reason an additional slack may occur.
- Finally, there may also be other reasons for the situation that a task is not able to keep account of every cycle it has saved compared to worst-case estimations during worst-case execution time (WCET) analysis: Especially for more complex architectures including caches and pipelines the execution times really needed may be smaller than the WCET assumptions, though tasks fail to detect these saved cycles at frequency scaling points.

Based on these observations the idea of our approach was to combine the advantages of inter-task and intra-task frequency scaling in an on-line real-time scheduler. More precisely, we propose a multi-level approach to DFS for a set of periodic tasks: The first level tries to eliminate idle times in case that the processor is not fully utilized. The optimal frequency for the task set is dynamically recalculated whenever tasks are created or removed. Whereas the first level is only based on worst-case execution times, the second and the third level take into account that the actual computation times are often much lower that the worst-case times: At level two we perform intra-task frequency scaling for each task individually. Finally, slack times produced by intra-task frequency scaling are used by inter-task frequency scaling at level three.

The idea of combining intra- and inter-task frequency scheduling has already been previously followed by Seo et al. [13], but in a completely different context: Seo et al. consider a fixed and finite set of aperiodic tasks (potentially including task dependencies) and they compute an optimal schedule using an off-line algorithm. Preemption is not allowed in their model, i.e., the schedule consists of starting times $s_i$ and ending times $e_i$ for each task $\tau_i$. Intra-task scheduling is then based on branching probabilities and for a task $\tau_i$ it computes (under the assumption of a continuous frequency range) a frequency distribution which minimizes the average case energy consumption provided that the execution time will be exactly $e_i - s_i$.

In contrast, our approach handles *dynamic* sets of *periodic* tasks which are scheduled by an *on-line* algorithm. Moreover, our scheduler allows *preemption* and voltage scaling is performed for processors with a *discrete set of frequencies*. The contributions of our paper are as follows:

- We make intra-task frequency scaling applicable in a multi-task environment and we make use of it in a tight interaction with inter-task scheduling. We provide an online algorithm suitable for dynamically changing sets of periodic tasks and we support preemptive task execution.
- Thereby, we provide a simplified scheme for computing information necessary for rescaling in the intra-task context. This scheme is based on a cycle counter in the processor hardware and it makes it possible to directly instrument different execution paths within (nested) loops.
- Our scheme for code instrumentation is also suitable for shared code in libraries used by different tasks.
- We provide a method based on a realistic processor model with a set of discrete frequencies instead of a continuous range of frequencies. The method can directly be integrated into an operating system if overhead for context switches and for frequency scaling is considered according to Section III-F.

The paper is organized as follows. We first give some preliminaries and definitions for inter- and intra-task real-time scheduling in Section II. Section III presents the concepts and implementation of our three-level approach. Experimental results are described in Section IV. Finally, Section V concludes the paper.

## II. Preliminaries

### A. Processor and Hardware Model

The processor model used in this paper provides $m$ different operating configurations $S = \{s_1, ..., s_m\}$ with $s_i = (f_i, v_i)$. Each pair $(f_i, v_i)$ consists of a frequency $f_i$ and a voltage $v_i$ with $f_i < f_j$ for $1 \leq i < j \leq m$. Therefore, the minimum and maximum possible frequencies are $f_1$ and $f_m$, respectively. The hardware also provides a cycle counter $\check{C}_{CLK}$ which is automatically incremented during task execution and a frequency-independent clock providing the real time $t$.

### B. Energy Model

In order to evaluate the energy-efficiency of our scheduler, we use the assumptions that the power consumption in CMOS circuits scales quadratically to the supply voltage ($P \propto f \cdot v^2$) [14]. Therefore, we compute the (dynamic) energy consumption $E$ of the system by $E = const \cdot \sum_{s_i \in S} c_{f_i} \cdot v_i^2$ provided that $c_{f_i}$ cycles have been executed at frequency $f_i$ or voltage $v_i$, respectively.

### C. Earliest Deadline First

An Earliest Deadline First (EDF) scheduler [9] always executes the task with the earliest deadline. A task $\tau_i$ is specified by its computation cycles $\check{C}_i$ and its period $T_i$. The symbol ˇ will be used to denote variables containing cycle-based values. Thus, a task set is specified by $\Gamma = \{\tau_i(\check{C}_i, T_i), i = 1, .., n\}$.

```

 2:    // max. 3 iterations
 3:    if cond1 then
 4:       $b_1$;
 5:    end if
 6:    $b_2$;
 7: end while
 8: if cond2 then
 9:    $b_3$;
10: end if
11: $b_4$;
```

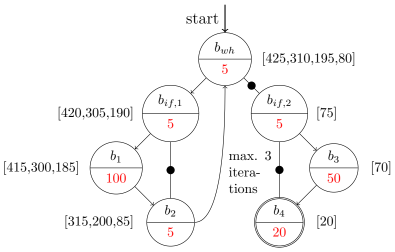

Fig. 1. Example code and corresponding Control Flow Graph (CFG) with timing information: The nodes represent basic blocks including their execution cycles. The values in brackets next to each node give the remaining worst-case execution cycles for each loop iteration.

We assume that the relative deadline $D_i$ of a task is the same as the period $T_i$, the absolute deadline $d_i$ for a task instance increments with $T_i$ for each instance.

In real-time systems, the worst-case execution cycles $\check{C}_i$ of a task $\tau_i$ for a specific processor *internally* depends on the task code and can be determined by static code analysis, for example. However, the period $T_i$ of a task is *externally* specified by the system designer for a task function. Moreover, the worst-case computation time $C_i$ of a task $\tau_i$ can be *derived* from the computation cycles $\check{C}_i$ if the execution frequency $f$ of the processor is known: $C_i = \check{C}_i \cdot f^{-1}$. The worst-case finishing (ending) time is $e_i$, e.g., a task which is activated at $t_{start}$ has an absolute completion time $e_i = t_{start} + C_i$ if it is not preempted.

The utilization factor $U$ of a processor under a given set $\Gamma$ of $n$ independent periodic tasks is defined as $U = \sum_{i=1}^{n} \frac{C_i}{T_i}$. Such a task set is schedulable with EDF if and only if $U \leq 1$.

### D. Intra-task scheduling

Intra-task scheduling aims to save power by lowering the processor frequency and simultaneously by eliminating internal task slack times. Such slack times always occur whenever there is a branching in the control flow of a task and the actual execution path involves fewer cycles than the worst-case execution path. In the following, we will give a brief overview of intra-task voltage scaling based on [10].

Consider the example code and corresponding *Control Flow Graph* (CFG) in Figure 1. Each node represents a basic block. The nodes include the number of cycles for the execution of the corresponding blocks. The values in brackets indicate the remaining worst-case execution cycles when entering a specific block. Multiple values refer to nodes which can be executed several times, i.e., which are part of a loop.

In the case that condition *cond* is not true, block $b_{if,2}$ will be directly executed after block $b_{wh}$. If this situation occurs before any execution of the `while`-loop, the remaining worst-case execution cycles ($\check{C}_{RWEC}$) after block $b_{wh}$ decrease from $\check{C}_{RWEC}(b_{if,1}) = 425 - 5 = 420$ to $\check{C}_{RWEC}(b_{if,2}) = 75$ cycles. The frequency within the task can be reduced by the scaling factor $\beta(b_{wh} \rightarrow b_{if,2}) = \frac{75}{420}$, because the current frequency was chosen in a way that the execution of 420 cycles will be finished in time, but only 75 cycles are needed. Now the processor frequency $S(b_{if,2})$ at block $b_{if,2}$ is updated according to $S(b_{if,2}) = S(b_{wh}) \cdot \beta(b_{wh} \rightarrow b_{if,2})$.

However, this scaling factor changes, if the `while`-loop is executed 1,2 or at most 3 times. As this information is not known in advance, the authors in [10] use so-called L-Type Voltage Scaling Edges (VSE) which calculate the scaling factor $\beta(b_{wh} \rightarrow b_{if,2})$ during run time depending on the number of loop iterations.

A second type are B-Type VSEs and they are used for `if`-statements (line 8 in our example code). As the number of saved cycles does not depend on loop iterations the scaling factor is $\beta(b_{if,2} \rightarrow b_4) = \frac{20}{70}$. Here, we only need 20 cycles, but remaining 70 cycles were in the budget of the task. Note that this simple scheme for B-Type VSEs can not be used, if we consider branches within loops (line 3, e.g.). In that case the number of remaining cycles depends on the iteration count of the outer loop and the scaling factor $\beta(b_{if,1} \rightarrow b_2)$ has to be dynamically computed at run time. (The scaling factor is equal to $\frac{315}{415}$, $\frac{200}{300}$, or $\frac{85}{185}$, depending on whether the loop is iterated for the first, second, or third time). Of course, the computation of the right scaling factor becomes even more involved if the branch is within a larger number of nested loops.

In contrast, our scheduler accepts relative information about the number of saved cycles in order to simplify frequency scaling. As we will describe in more detail in Section III-B1a, our scheme not only simplifies the instrumentation of code, but also makes instrumentation of shared code possible. This scheme is used in an overall approach which integrates intra-task frequency scaling and inter-task frequency scaling for preemptive environments with a dynamic number of tasks and a processor model with discrete frequencies.

## III. Energy-Efficient Intra- and Inter-task Frequency Scaling

Our method for real-time scheduling which is presented in this section aims at obtaining a homogeneous distribution of processor frequencies at a level which is as low as possible and thus minimizes energy consumption. In order to guarantee temporal constraints, the utilization of idle times, intra- and inter-task slack times has to be performed without violating deadlines of tasks.

### A. Idle-time Elimination

For EDF, a real-time schedule contains idle times iff $U < 1$. These idle times can be minimized if a processor is run with a lower frequency $f_\alpha$ (and indirectly with lower voltage and power consumption). Schedulability is still guaranteed when executing all $n$ tasks with a frequency $f_\alpha$ according to

$$\sum_{i=1}^{n} \frac{\check{C}_i / f_\alpha}{T_i} = 1 \Leftrightarrow f_\alpha = \sum_{i=1}^{n} \frac{\check{C}_i}{T_i}.$$

The frequency $f_\alpha$ is the lowest frequency to run the processor without violating real-time constraints provided that computation cycles $\check{C}_i$ are fixed to their worst-case estimation. However, computation cycles of task execution are not constant – they can be reduced by branching conditions or premature abort of loops during run time. In that case we can decrease the processor frequency even more in order to execute less cycles in the same time according to the intra- and inter-task slack-time elimination scheme as described below.

### B. Intra-Task Slack-time Elimination

In Section II-D, we have given a brief introduction to intra-task frequency scaling. In our work the intra-task frequency scaling is supported by the operating system which takes slack times into account for processors with discrete frequencies. Our approach differs from [10] with respect to three issues:

- We use a simplified scheme for computing remaining worst-case execution cycles. This scheme is based on an estimation of worst-case execution cycles for the task as a whole (by static analysis), relative information about saved execution cycles within the control flow, and a cycle counter of the processor. This scheme has the additional advantage that our method is suitable for shared code in libraries used by different tasks.
- The computation of frequencies is not based on scaling factors which take into account the previous estimation for worst-case remaining cycles and a new estimation due to saved cycles (as in [10]), but it is changed in order to be able to make use of inter-task slack time and of intra-task slack time which remain due to a discrete set of processor frequencies.
- The computation of worst-case remaining execution cycles $\check{R}_i$ of a task $\tau_i$, the computation of new processor frequencies, and the according change of frequencies can be seamlessly integrated into an operating system.

*1) Keeping track of remaining worst-case execution cycles:* As a basis for frequency rescaling we need an estimation of worst-case remaining execution cycles $\check{R}_i$ of tasks $\tau_i$. As described in Sect. II-D the computation of worst-case remaining execution cycles $\check{R}_i$ or the scaling factor, respectively, as given in [10] may need rather involved computations at run time. Especially if a frequency scaling point is located in several nested loops, an estimation of worst-case remaining execution cycles $\check{R}_i$ will need the current number of iterations for each of the outer loops which were performed so far (in order to be able to compute the worst-case remaining iteration counts based on the respective maximal iteration counts).

Our scheme for computing remaining worst-case execution cycles is much simpler: It starts with an estimation of worst-case execution cycles for the task as a whole which is obtained by static analysis. In order to keep track of the remaining worst-case execution cycles $\check{R}_i$, the processor has to provide a cycle counter $\check{C}_{CLK}$ which is incremented during program execution. For each task $\tau_i$, the operating system then maintains a task-specific cycle counter $\check{C}_{act,i}$ derived from $\check{C}_{CLK}$. Based on the initial number of worst-case execution cycles for $\tau_i$, the number of cycles used for $\tau_i$, and the number of cycles saved in $\tau_i$ (compared to the worst-case estimation), the remaining worst-case execution cycles $\check{R}_i$ are computed. The number of cycles saved in $\tau_i$ is updated at frequency scaling points by additional code as will be described below.

In more detail, the counter $\check{C}_{act,i}$ is reset to 0 whenever $\check{R}_i$ is updated (see also Section III-E). This happens in the following three cases: 1.) A task $\tau_i$ is activated – here, $\check{R}_i$ is initialized to $\check{C}_i$. 2.) A task $\tau_i$ is preempted. Assume that $\tau_i$ has already executed $\check{C}_{act,i}$ cycles since the last update, then the remaining cycles are updated with $\check{R}_i \leftarrow \check{R}_i - \check{C}_{act,i}$. 3.) Information on saved cycles is evaluated during task execution. Here, the remaining execution cycles $\check{R}_i$ are updated at Frequency Scaling Points (FSP).

*a) R-type Frequency Scaling Points:* We call the Frequency Scaling Points (FSPs) mentioned above R-type FSPs, because they give relative information about saved cycles in the control flow. Consider that the executed task traverses the edge $b_{if,1} \rightarrow b_2$ in Figure 1. The block $b_1$ would be omitted in this case and 100 cycles are saved. Such relative information is independent of the number of (potentially nested) loop iterations performed so far. Whenever a task $\tau_i$ reaches a R-type FSP which saves $\check{C}^R$ cycles, it updates the remaining cycles $\check{R}_i$:

$$\check{R}_i \leftarrow \check{R}_i - \check{C}_{act,i} - \check{C}^R \quad \text{if R-type FSP}$$

It is easy to see that the scheme based on cycle counters and relative information can be implemented with low overhead for computing the remaining worst-case execution cycles. Another key advantage consists in the fact that it is *suitable for shared code* in libraries used by different tasks. In this case absolute information about remaining worst-case execution cycles can not be written into the shared code, because the information differs depending on the context in which the shared code is used. Thus, the annotation scheme from [10] is not applicable. In our scheme shared code contains only relative information about saved cycles and the remaining worst-case execution cycles are computed based on this as described above.

*b) A-type Frequency Scaling Points:* For completeness, we mention a further optimization for special cases within non-shared code. For these cases we introduce A-type FSPs which keep absolute information about remaining worst-case execution cycles. Consider the edge $b_{wh} \rightarrow b_{if,2}$ in Figure 1. Here, the number of remaining cycles can directly be determined (75 cycles). An A-type FSP can only be used if the corresponding edge is not located inside a loop or inside shared code. The absolute number of remaining worst-case execution cycles is directly updated by

$$\check{R}_i \leftarrow \check{C}^A \quad \text{if A-type FSP.}$$

A-type FSPs make sense when $R$-type FSPs do not provide perfect knowledge about saved cycles (e.g., if not all branches in the control flow are annotated with $R$-type FSPs or if worst-case execution time computation is imprecise due to advanced features of processors like caches and pipelines).[2]

[2] For shared code, A-type FSPs can be transformed into R-type FSPs where $\check{C}^R$ is computed depending on the number of saved cycles.

### C. Inter-Task Slack-time Elimination

In the previous Sect. III-A and III-B we determined the frequency $f_\alpha$ to eliminate idle times and explained how the remaining execution cycles $\check{R}_i$ of a task can be updated during run time. Now we will look into the question of how to compute frequencies based on worst-case remaining cycles. To be able to use frequency scaling in a multi-task environment in combination with inter-task frequency scaling we do not use the old estimation for the intra-task scaling factor as a basis for computing the new frequency, but we use a 'remaining time' $t_{remain,i}$ which depends on inter-task slack-time elimination and on effects of intra-task slack-time elimination with discrete frequencies. Here, the lowest possible frequency to run a single task $\tau_i$ with $\check{R}_i$ remaining cycles and a remaining time $t_{remain,i}$ is $f = \check{R}_i / t_{remain,i} = \check{R}_i/(e_i - t)$ with an ending time $e_i$ and the current time $t$.

In order to determine $e_i$ and to consider inter-task slack-time we use the same principle as the EDF based frequency scaling algorithm given in [8]. Whenever the actual completion time of a task is less than its worst-case completion time $e_i$, the additional slack time is implicitly passed to the subsequent task. The (absolute) worst-case completion time $e_i$ can be calculated incrementally whenever a task $\tau_i$ starts, preempts (another task) or resumes at current time $t$. The computation of $e_i$ makes use of execution times $C_i$ which are reserved for tasks $\tau_i$. $C_i$ results from the worst-case execution cycles $\check{C}_i$ by $C_i = \check{C}_i \cdot f_\alpha^{-1}$ where $f_\alpha$ is the frequency determined as described in Sect. III-A. (If all tasks run with frequency $f_\alpha$ and use their worst-case execution cycles, then the processor utilization $U$ exactly equals 1 and EDF scheduling is able to find a feasible schedule.) The absolute worst-case completion times $e_i$ are computed as follows:

$$e_i = \begin{cases} t + C_i & \text{if } \tau_i \text{ preempts task } \tau_j \\ e_i + e_k - t_i^p & \text{if } \tau_i \text{ was preempted at } t_i^p \\ & \text{and resumes after task } \tau_k \\ e_k + C_i & \text{if } \tau_i \text{ starts after } \tau_k \\ & \text{and } d_i \geq d_k \wedge t < e_k \\ t + C_i & \text{otherwise} \end{cases} \quad (1)$$

In cases 2 and 3 this scheme ensures that a possible slack is used by the following task. The difference of $e_i - t$ gives the available time for task $\tau_i$ and thus, the lowest possible frequency is $f = \check{R}_i/(e_i - t)$. The absolute worst-case completion time $e_i$ is used during intra-task slack-time elimination to further decrease the frequency whenever it detects saved cycles at frequency scaling points.

The correctness of the overall approach follows from the correctness of [8] together with the observation that intra-task frequency scaling never increases the computation time of a task $\tau_i$.

### D. Split Frequency Rescaling

In [15], Ishihara and Yasuura considered the problem of minimizing energy consumption for variable voltage processors. They proved that the *two voltages which minimize energy consumption under a time constraint are immediate neighbors to the $v_{ideal}$* – the optimal voltage for a continuous voltage processor. A similar scheme is applied for discrete frequencies in [16], so that a task with a deadline constraint is firstly executed with a lower frequency and later switched to a higher frequency to meet its deadline for the worst-case. In contrast to [16] we also perform splitting at each frequency scaling point. More precisely, we split the time needed to execute the remaining worst-case execution cycles $\check{R} = \check{R}_a + \check{R}_b$ which should be executed with frequency $f$ into two time intervals executed at the largest frequency $f_a \leq f$ and the smallest frequency $f_b \geq f$. We conclude under the constraints $\check{R} = \check{R}_a + \check{R}_b$ and $\check{R} \cdot f^{-1} \geq \check{R}_a \cdot f_a^{-1} + \check{R}_b \cdot f_b^{-1}$ that we have to switch to the higher frequency $f_b$ when the number of remaining execution cycles is

$$\check{R}_b = \left\lceil \check{R} \cdot \frac{f^{-1} - f_a^{-1}}{f_b^{-1} - f_a^{-1}} \right\rceil .$$

Therefore, the tasks starts with $f_a$ and, if there are only $\check{R}_b$ cycles left, the scheduler switches to the higher frequency $f_b$. For a real processor, this frequency switch can be triggered with a previously set timer.

Note that split frequency rescaling aims to eliminate slack times due to discrete frequencies and – in the ideal case – no inter-task slack should occur. However, this goal can not always be achieved, as the computed ideal frequency can be lower than the lowest available frequency $f_1$ and therefore, a task instance would still produce slack after its completion. Another reason to consider inter-task slack would be the application of this approach for complex architectures, e.g. with caches. Firstly, static analysis tools tend to overestimate worst-case execution times. Secondly, a task can not detect all saved cycles as their number depends on the preceding cache accesses.

### E. Integration into Operating System

There are two procedures which implement our overall approach based on the concepts for idle, intra- and inter-task slack-time elimination. The first procedure is called whenever a new task arrives or is removed from the task set: it verifies if the new task set is feasible ($U \leq 1$) and calculates the frequency $f_\alpha$ and the reserved computation time $C_i = \check{C}_i \cdot f_\alpha^{-1}$ for each task $\tau_i$. The second procedure is given in Algorithm 1 which combines the concepts of inter- and intra-task slack time elimination whenever there is a context switch or program execution reaches a FSP. Essentially, it updates the values for the remaining cycles $\check{R}_i$ and the absolute finishing time $e_i$ of each task $\tau_i$. Please note that for each context switch and each execution at an intra-task frequency scaling point the needed computations can be performed in constant time.

### F. Overhead Considerations

In order to include overhead due to intra-task frequency scaling points and inter-task context switches a fixed number of cycles can be added to the worst-case execution cycles $\check{C}_i$ of a task $\tau_i$ as discussed in the following.

**Algorithm 1** Called on inter- or intra-task scheduling

```
$calculate\_frequency(\tau_i)$
  **if** intra-task scaling of $\tau_i$ **then**
    // task $\tau_i$ saved some cycles at a FSP
    **if** absolute FSP **then**
      $\check{R}_i \leftarrow \check{C}^A$
    **else**
      $\check{R}_i \leftarrow \check{R}_i - \check{C}_{act,i} - \check{C}^R$
    **end if**
  **else if** inter-task scaling of $\tau_i$ **then**
    **if** $\tau_i$ preempts $\tau_j$ **then**
      $e_i \leftarrow t + C_i$
      $\check{R}_i \leftarrow \check{C}_i$
      $\check{R}_j \leftarrow \check{R}_j - \check{C}_{act,j}$ // $\check{C}_{act,j}$ since last switch
    **else if** $r_i$ resumes after some task $\tau_k$ **then**
      $e_i \leftarrow e_i + e_k - t_i^p$ // $\tau_i$ was preempted at $t_i^p$
    **else**
      // $\tau_i$ starts execution after some task $\tau_k$ has finished
      **if** $d_i \geq d_k$ and $t < e_k$ **then**
        $e_i \leftarrow e_k + C_i$
      **else**
        $e_i \leftarrow t + C_i$
      **end if**
      $\check{R}_i \leftarrow \check{C}_i$
    **end if**
  **end if**
  $\check{C}_{act,i} \leftarrow 0$
  $f \leftarrow \frac{\check{R}_i}{e_i - t}$
  determine $\check{R}_{i,b}$ with next lower frequency $f_a$ and higher frequency
  $f_b$ and set timer which switches to frequency $f_b$ when $\check{R}_{i,b}$ cycles
  are left
  $set\_frequency(f_a)$
```

For *inter-task overhead* we consider the worst-case number of cycles $\check{C}_{\text{CS}}$ for a context switch. Each context switch is always connected with an activation or termination of a task, i.e., the overhead can be estimated by $2 \cdot \check{C}_{\text{CS}}$ per task instance. This consideration includes a switch between tasks, a switch from and to a (possibly virtual) idle task, and preemption of a task. Hence, an upper bound for the additional system utilization $U_{\text{CS}}$ can be determined by $U_{\text{CS}} = \frac{2\check{C}_{\text{CS}}}{f_{\text{CS}}} \sum_{i=1}^{n} \frac{1}{T_i}$, assuming that scheduler routines are executed with a frequency of at least $f_{\text{CS}}$.

Of course, tools for WCET estimation are also able to analyze code with intra-task instrumentation and thus, additional cycles for *intra-task overhead* due to frequency scaling points can be determined. However, only conditional branches in the CFG where the overhead for processing a FSP is smaller than the number of saved cycles will be instrumented. This will lead to an incomplete instrumentation in practical applications.

## IV. Experiments

For our experiments we implemented a simulation framework which determines the energy efficiency with different task sets and hardware configurations. In order to evaluate the effectiveness of our approach, we implemented various well-known DVS schedulers, e.g., LaEDF [4] and OLDVS [8], and compared the results to our scheduler implementation ItcaEDF (*Intra-Task Characteristics Aware EDF*). Before we discuss the results in Section IV-C we will give a more detailed description of our simulation framework and system setup.

### A. Simulation Framework

Our experiments were performed with a compiler and simulation framework written in C++. As our approach utilizes intra-task slack due to unused execution paths during program execution, it was not only necessary to model task execution times but also their control flow. To achieve this, task behavior is described in a language based on ANSI C in order to define task behavior including control flow, task semantics and temporal characteristics. Syntax extensions make to possible to specify execution times for statements and to annotate code with *flow facts* like upper bounds for loops. These extensions are used for both integrated path-based WCET analysis and simulation. Finally, in our framework we implement frequency scaling points with a code instrumentation scheme, i.e., after path-based WCET analysis we instrument the task with additional statements giving hints about the number of saved cycles $\check{C}^R$. The number of saved cycles at a FSP is constant for conditional branches in the CFG. For loops, it is dynamically computed depending on the worst-case numbers of iterations and the actual numbers of iterations.

### B. System and Task Setup

In our simulations we use a processor model with four different operating configurations $S = \{(250 \text{ kHz}, 2\,\text{V}), (500 \text{ kHz}, 3\,\text{V}), (750\,\text{kHz}, 4\,\text{V}), (1\,\text{MHz}, 5\,\text{V})\}$. The energy consumption is computed assuming each cycle needs an energy amount proportional to the square of the operating voltage. As we are only interested in the relative energy consumption of the DVS schedulers, we assume that idling the processor consumes no energy as discussed in [4]. In the following we will provide details on how we generated task sets in our implementation.

Firstly, we choose an overall worst-case utilization factor $U \leq 1$. This utilization factor is randomly split under the given number of tasks, so that $U = \sum_{\tau_i \in \Gamma} U_i$ and $\forall \tau_i, \tau_j : \frac{1}{l} \cdot U_j \leq U_i \leq l \cdot U_j$ for a given $l \in \mathbb{R}$. We choose $l = 2$ to avoid exceeding differences in task characteristics. Subsequently, the system determines a period $T_i \in [100\,\text{ms}, 1000\,\text{ms}]$ and computes the worst-case execution time according to $C_i = U_i \cdot T_i$. Finally, this worst-case execution time is realized by a nested loop:

```
**for** $i = 1, .., i_{\text{max}} = b_{\text{outer}}$ **do**
  // randomly determine $j_{\text{max}} \in [b_{\text{inner,min}}, b_{\text{inner,max}}]$
  // automatically inserted intra-task frequency scaling point
  **for** $j = 1, .., j_{\text{max}} \leq b_{\text{inner}}$ **do**
    // computation with fixed number of cycles $\check{C}_{i,\text{loop}}$
  **end for**
**end for**
```

The real worst-case numbers of cycles $\check{C}_{i,\text{loop}}$ needed in the nested loop and the final overall worst-case utilization factor were computed so that $C_i \cdot f_m = b_{\text{inner}} \cdot b_{\text{outer}} \cdot \check{C}_{i,\text{loop}}$.

In this paper we specifically set $b_{\text{outer}} = 5$ and $b_{\text{inner}} = 10$ and therefore, the inner loop including the FSP is executed five times. The values of $b_{\text{inner,min}}$ and $b_{\text{inner,max}}$ were varied to realize different ranges for the actual execution time (AET) to worst-case execution time (WCET) ratio. For example, values of $b_{\text{inner,min}} = 4$ and $b_{\text{inner,max}} = 8$ can be used to force an average fraction of $0.6$ for the actual workload of a task.

### *C. Results*

The simulation results are given in Figure 2 for different task scenarios. Each diagram shows a histogram for the energy efficiency of a specific scheduler. On the x-axis we have the worst-case utilization factor of the corresponding task set and on the y-axis the energy consumption for the different methods as a fraction of the energy consumption for an EDF based execution with the highest possible frequency $f_m$. In the experiments we varied the number of executed tasks $n$ and the 'actual workload'. The 'actual workload' denotes the fraction $c$ of the actual execution time (AET) to the worst-case execution time (WCET) of a task as described above. The diagrams in this paper refer to scheduling with either $n = 2$ or $n = 8$ tasks and an actual workload either in the interval $[0.8, 1.0]$ or $[0.4, 0.8]$.

We separated the results for the different schedulers into two blocks, respectively. Before we discuss the results we will give a short overview of the compared energy-efficient scheduling methods. The first block consists of real-time DVS schedulers known from literature:

- **StaticEDF:** StaticEDF uses a constant frequency depending on the worst-case utilization $U$ of the task set.
- **OrigIntra**: Original Intra-Task DVS which uses fixed ratios for frequency rescaling [10].
- **OLDVS**: Slack passing scheme which gives unused computation to the subsequent task [8].
- **OLDVS*:** Improved OLDVS variant for discrete frequency processors which splits execution time in two parts executed with the next lower and next higher discrete frequency [16].
- **LaEDF**: Speculative Look-ahead EDF scheduler which scales to the lowest possible frequency by deferring as much work as possible after the next deadline [4].

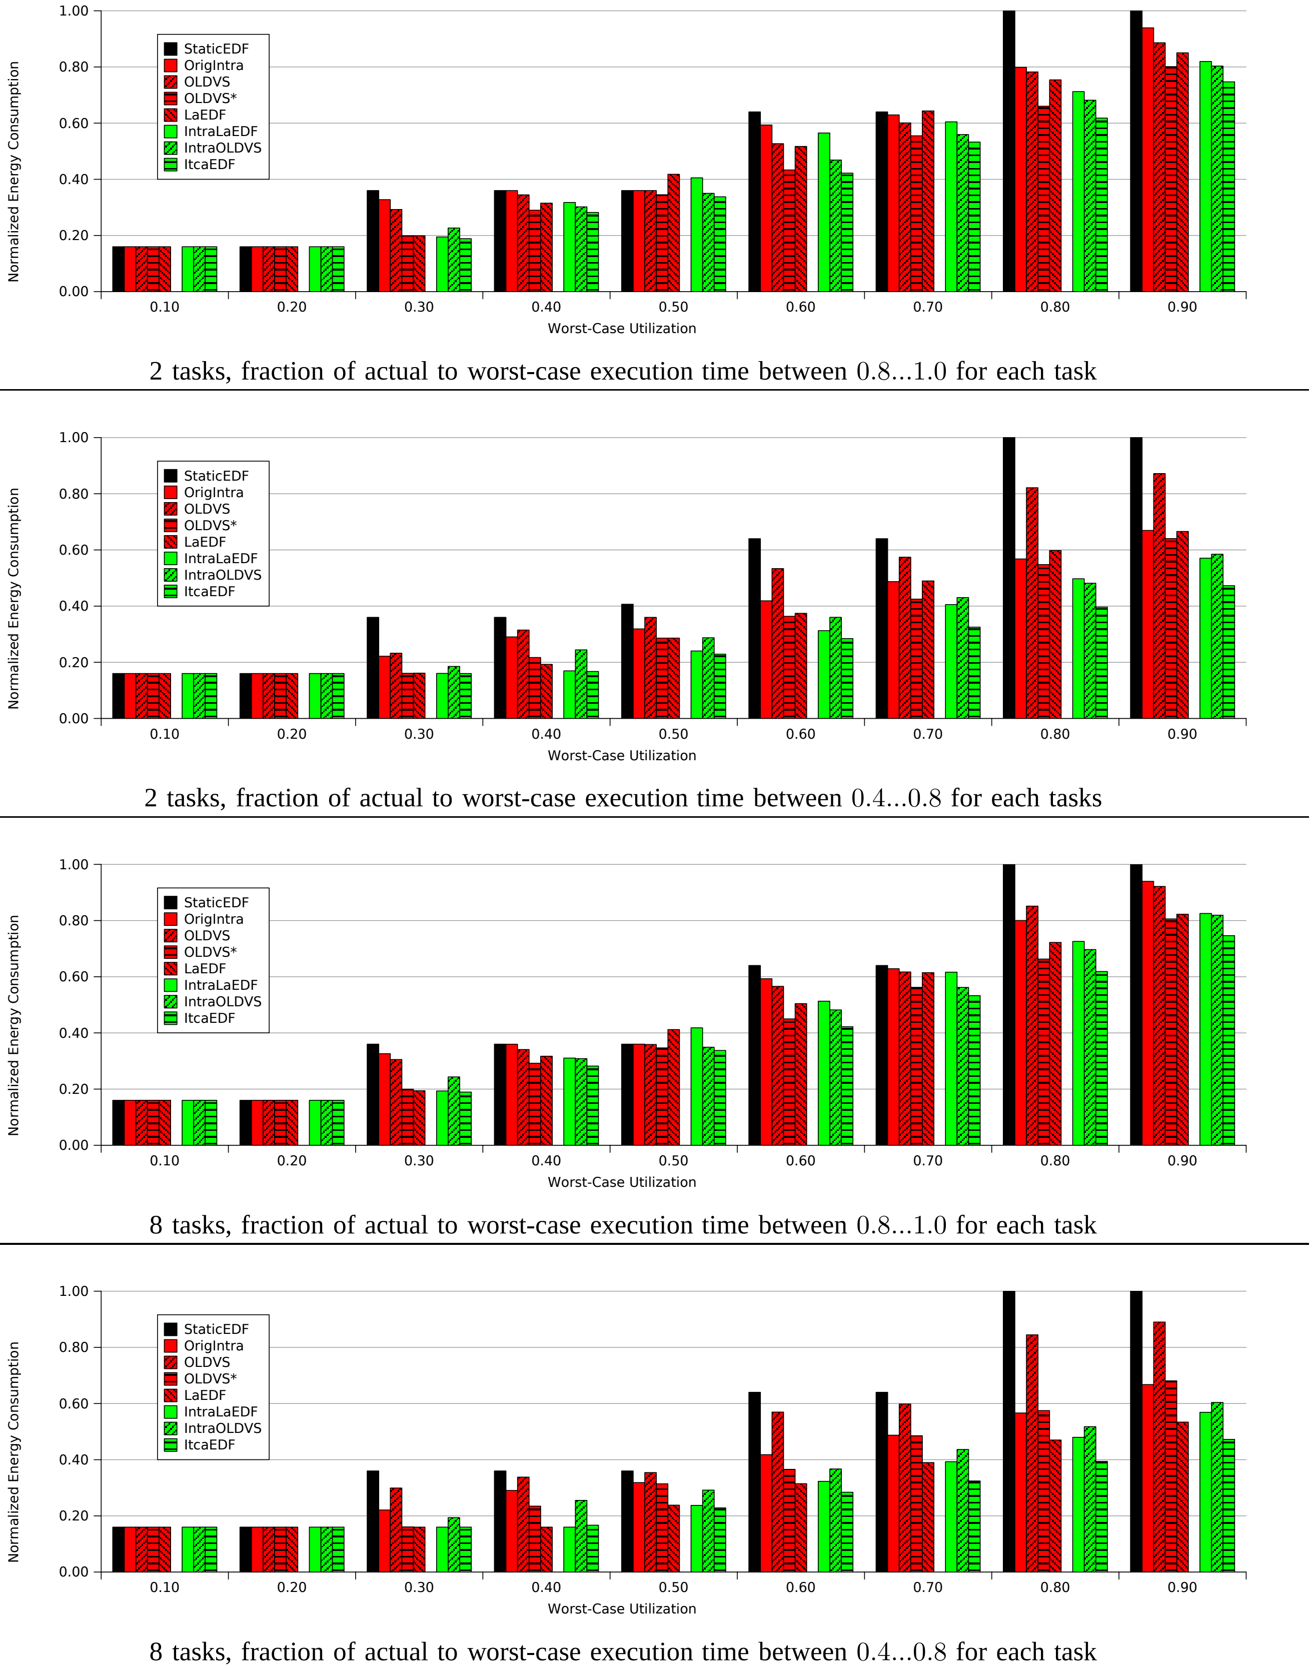
The second block consists of inter-task schedulers which include intra-task voltage scaling according to the scheme presented in this paper. Here, the last method *ItcaEDF* is our proposed approach which outperforms all other DVS schedulers:

- **IntraLaEDF**: Variant of LaEDF combined with our intra-task approach. Rescaling with deferring work after the next deadline is done at each frequency scaling point and at each context switch.
- **IntraOLDVS**: OLDVS combined with our intra-task approach.
- **ItcaEDF (Intra-Task Characteristics Aware EDF)**: The proposed on-line algorithm which integrates our intra-task approach and split frequency rescaling (see Sect. III-D).

In all configurations the minimal energy consumption depends on the lowest available frequency. Therefore for utilization factors smaller than the ratio $f_1/f_m = 0.25$ all frequency scaling techniques gave the same energy consumption as all tasks already start with the lowest possible frequency. The energy consumption increases with higher worst-case utilization factors. As expected, StaticEDF shows a stepwise increase of energy consumption (according to the discrete frequency distribution), because only worst-case execution times and no occurring slack is considered. (Energy consumptions for $U = 0.10, 0.20$, $U = 0.30, 0.40, 0.50$, $U = 0.60, 0.70$, and $U = 0.80, 0.90$, respectively, are identical.)

Considering the first block of schedulers known from literature, neither OrigIntra nor OLDVS show an overall good performance. OrigIntra performs comparatively well when the actual workload is low (see second and fourth histogram), since it is able to rescale with a high granularity at task-internal frequency scaling points. However, OrigIntra shows high energy consumption when the actual workload is large (i.e., not far away from the worst-case workload, see first and third histogram), as the occurring slack for a single task is too small in order to scale to a lower frequency and slack is not accumulated between tasks (since it is not passed to a subsequent task). OLDVS shows only moderate savings compared to StaticEDF, since frequency scaling with slack passing to the subsequent task is performed only at context switches with a lower granularity. The original OLDVS scheduler is improved by the split frequency scaling of OLDVS* which provides a better support for discrete frequencies on the one hand and on the other hand works more optimistically by selecting the lower of the two neighbor frequencies first. The most optimistic (or in other words most aggressive) method is LaEDF which works especially well when the actual workload is low and the number of tasks is high (see fourth diagram). However, when the workload is too high, the speculative scheme of LaEDF (which defers as much work as possible after the next deadline) seems to be too aggressive and the likelihood that, for example, a preempting task has to choose a higher frequency is increased (see first and third diagram). When the number of tasks is low (see first and second diagram) LaEDF also may suffer from the fact that the number of context switches becomes smaller and there are less opportunities for frequency scalings.

Considering the last blocks, our proposed ItcaEDF approach clearly outperforms the other schedulers in all task setups. For instance, considering a worst-case utilization of $U = 0.8$, a AET/WCET ratio between 0.4 and 0.8, and two tasks (see diagram 2), ItcaEDF improved the normalized energy consumption by 28% compared to OLDVS* and 34% compared to LaEDF. Increasing the number of tasks to 8 (see diagram 4) results in a energy reduction of 16% compared to LaEDF and 31% compared to OLDVS*. Apparently, in our scheduler the deep integration of intra-task code instrumentation into inter-task frequency scaling really pays off. The intra-task frequency scaling points both provide timing information to reflect the actual work load of the system more accurately and give a



2 tasks, fraction of actual to worst-case execution time between $0.8 \ldots 1.0$ for each task

2 tasks, fraction of actual to worst-case execution time between $0.4 \ldots 0.8$ for each tasks

8 tasks, fraction of actual to worst-case execution time between $0.8 \ldots 1.0$ for each task

8 tasks, fraction of actual to worst-case execution time between $0.4 \ldots 0.8$ for each task

Fig. 2. Normalized energy consumption under various task characteristics for 2 or 8 tasks and different fractions of utilization

higher granularity for efficient scheduling with DVS. ItcaEDF avoids working too aggressively (as LaEDF in some cases), since the only case of an optimistic frequency selection occurs when a not existing continuous frequency is approximated by two discrete frequencies and the lower one is selected first. However this decision is confirmed by the observation that the need for using the second (higher) frequency is often canceled in the future, when the actual workload is low and additional slack occurs after the frequency splitting.

For completeness, we also considered schedulers where our intra-task code instrumentation scheme is integrated into OLDVS directly (without frequency splitting) and into LaEDF (the corresponding bars in the histograms are labeled IntraOLDVS and IntraLaEDF, respectively). As expected, IntraOLDVS (in comparison to OLDVS) profits from the detection of reduced remaining worst-case execution cycles during task run time, but it is outperformed by ItcaEDF. Somewhat surprisingly, the results for IntraLaEDF show that it is not always a good idea to combine an inter-task scheduler with intra-task code instrumentation: LaEDF can hardly benefit from our code instrumentation approach and sometimes IntraLaEDF displays an even higher energy consumption than LaEDF. Obviously, increasing the aggressiveness of the speculative algorithm by exploiting intra-task characteristics has a negative impact on energy-efficiency.

## V. Conclusions

In this paper, we proposed an energy-efficient real-time scheduler which incorporates cycle-based intra-task and time-based inter-task frequency scaling for the realistic scenario of processors with discrete frequencies and dynamic task sets. A multi-level approach considers idle, intra- and inter-task slack times and scales the processor speed to the lowest possible frequency on context switches and within task execution. We also presented a novel technique to keep track of remaining worst-case execution cycles for intra-task frequency scaling which is based on cycle counters of the hardware and which is suitable for shared code. To evaluate the performance of the on-line scheduler we integrated the algorithms into a compiler and simulation framework. Our experimental results showed that our approach is able to reduce energy consumption of state-of-the-art inter-task DVS schedulers by over 30%.

# 3$^{rd}$ International Workshop on Secure Information Systems

THE SIS workshop is envisioned as a forum to promote the exchange of ideas and results addressing complex security issues that arise in modern information systems. We aim at bringing together a community of security researchers and practitioners working in such divers areas as networking security, antivirus protection, intrusion detection, cryptography, security protocols, and others. We would like to promote an integrated view at the security of information systems.

As information systems evolve, becoming more complex and ubiquitous, issues relating to security, privacy and dependability become more critical. At the same time, the global and distributed character of modern computing - typically involving interconnected heterogeneous execution environments - introduces many new and challenging engineering and scientific problems. Providing protection against increasingly sophisticated attacks requires strengthening the interaction between different security communities, e.g. antivirus and networking. New technologies lead to the emergence of new threats and attack strategies, involving smart mobile devices, peer-to-peer networks, instant messaging, VoIP, mesh networks or even networked consumer devices, such as house appliances or cars. Furthermore, the increasing openness of the communications infrastructure results in novel threats and can jeopardize critical enterprise and public infrastructure, such as industrial automation and process control systems. Not only it is estimated that half of all Web applications and Internet storefronts still contain some security vulnerabilities, but secure commerce applications are also exposed to increasingly elaborate attacks, including spyware, phishing and other social engineering methods.

In order to develop a secure system, security has to be considered in all phases of the lifecycle and adequately addressed in all layers of the system. At the same time, good engineering has to take into account both scientific and economic aspects of every solution: the cost of security has to be carefully measured against its benefits - in particular the expected cost of mitigated risks. Most companies and individuals treat security measures in information system as a necessary, but often uncomfortable, overhead. The increasing penetration of computing in all domains of everyday life means that security of critical business systems is often managed and maintained by personnel who are not knowledgeable in the field. This highlights the importance of usability and ease of configuration of security mechanism and protocols.

Covered topics include (but are not limited to):

- Access control
- Adaptive security
- Cryptography
- Copyright protection
- Cyberforensics
- Honeypots
- Intrusion detection
- Network security
- Privacy
- Secure commerce
- Security exploits
- Security policies
- Security protocols
- Security services
- Security evaluation and prediction
- Software protection
- Trusted computing
- Threat modeling
- Usability and security
- Viruses and worms
- Zero-configuration security mechanisms

***Abstract*—This paper reports our ongoing work to design a *C*ontext-*R*isk-*A*ware *A*ccess *C*ontrol (*CRAAC)* model for Ubiquitous Computing (UbiComp) environments. *CRAAC* is designed to augment flexibility and generality over the current solutions. Risk assessment and authorisation level of assurance play a key role in *CRAAC*. Through risk assessment, resources are classified into groups according to their sensitivity levels and potential impacts should any unauthorised access occurs. The identified risks are mapped onto their required assurance levels, called Object Level of Assurance (*OLoA*). Upon receiving an object access request, the requester's run-time contextual information is assessed to establish a Requester's Level of Assurance (*RLoA*) denoting the level of confidence in identifying that requester. The access request is granted iif *RLoA* ≥ *OLoA*. This paper describes the motivation for, and the design of, the *CRAAC* model, and reports a case study to further illustrate the model.**

## I. Introduction

UBICOMP, sometimes referred to as pervasive computing, envisages a new computational environment in which heterogeneous devices with varying levels of capabilities and sensitivities interact seamlessly to provide smart services. By gathering information about surroundings (contextual data), the environment adaptively and non-intrusively provides context-aware services to users [1]. A context, defined as " *any information that can be used to characterise the situation of an entity* " [2], could relate to users (e.g. a ccess location ) or to systems (e.g. network channel security level).

Context is dynamic, and its values may change from one session to another, and even during the same session. While UbiComp adapts its services to the surrounding context, the security services in the underlying environment should also be adaptive to the relevant context. In Access Control (AC) for example, we emphasis that an AC solution for UbiComp environments should be context-aware; it should react not only to value changes of individual contextual attributes, but also to the composite effect as caused by multiple contextual attributes value changes. It is inappropriate for an AC solution to take multiple contextual attributes directly as additional AC constraints while disregarding their composite effect on the risk level of unauthorised access in the underlying system. Furthermore, users' mobility further exacerbates the AC challenges in such environment. Mobile users with known/unknown devices move in/out of the environment without the protection of infrastructure-based firewalls exposes the environment to more security threats and attacks. An effective UbiComp AC solution should take into account the level of confidence in the entity trying to gain access to sensitive resources as well as the confidence level in the provided contextual information.

To realise this vision of context-aware AC, we have designed the *CRAAC* model, which uses the notion of risks and risk-linked levels of assurance (*LoA*) to govern the AC decisions. Through risk assessment, resources/services are classified into different groups each with a distinctive *OLoA*. In fact, the *OLoA* of a given resource object is determined based on its sensitivity level and the potential harm or impact should any unauthorised access to that object occurs. When an object access request is received, the requester's run-time contextual information is assessed to establish an *RLoA* denoting the confidence level in that requester. The access request is granted iif *RLoA* ≥ *OLoA*.

This idea of using a risk linked *LoA* is inspired by the OMB/NIST e-Authentication Guidelines in [3], [4]. Similar to the OMB/NIST approach, *CRAAC* uses risk assessment to identify the risks for resource objects, and maps the identified risks to appropriate assurance levels (*OLoA)* for that object group. Our work, however, features the following distinct characteristic over the OMB/NIST work. The OMB/NIST work addresses the issue of authentication in the context of electronic transactions in a static environment, whereas our work focuses on context-aware AC in a dynamic UbiComp environment. As a result of this fundamental difference, our work differs from the OMB/NIST effort in the following ways. Firstly, the OMB/NIST guidance only considers issues related to users identification via the use of electronic credentials (e-credentials) that are largely static, whereas we handle a broader range of AC attributes, not only static e-credentials but also dynamic contextual attributes. Secondly, unlike the OMB/NIST work that only considers risk impact as caused by a single attribute (i.e. e-authentication credentials), we consider risk impacts by multiple attributes, as well as their composite effect on the authorisation assurance level. In addition, unlike the OMB approach by

Would like to thank the Faculty of Computers and Information, Cairo University, for its financial support.

which appropriate authentication technologies are chosen and implemented prior run-time to ensure that the underlying system achieves the required level of authentication assurance, *CRAAC* derives an *RLoA* for each requester at run-time based on their real-time dynamic contextual information, then compares this *RLoA* against *OLoA,* an AC threshold for the requested object, to make an AC decision.

The rest of this paper is structured as follows: section II gives an overview of the related work in context-aware AC. Section III describes the *CRAAC* model in detail. A case study is given in section IV. Finally, section V concludes the paper and outlines the future work.

## II. Related Work

The main objective of an AC system is to restrict the actions a legitimate user can perform on a given resource object [5]. Role-Based Access Control (RBAC) [6] is a powerful model to specify and enforce organisational policies in a way that seamlessly maps to an enterprise structure [7]. Instead of assigning access rights to users directly, RBAC assigns access rights to roles that users can have as part of their organisational responsibilities. RBAC is considered as a policy natural authorisation approach particularly suited to large-scaled distributed environments [8]. However, the major weakness of the RBAC model is that it can not capture any security relevant information from its environment due to the subject-centric nature of its roles [8]. As a result, it can not enforce context-aware security policies, and therefore it is not adequate for UbiComp environments. To overcome this weakness, there have been proposals, will be discussed later on, to extend the basic RBAC model to equip it with the context-awareness capability. Those proposals use contextual information directly as additional constraints to govern the AC decision, as depicted by Fig. 1.

One of the earliest proposals is the Generalized Role-Based Access Control (GRBAC) model [9]. It introduced the concept of environment roles to capture contextual information from the underlying access environment. GRBAC, However, requires the use of complex system architecture to support the extended roles [10].

Another notable proposal is the Temporal RBAC (TRBAC) model [11] which extends the traditional RBAC model by introducing a temporal constraint into the AC specification to provide a mechanism to enforce time-dependent AC policies [12]. A subsequent proposal, the Generalized Temporal RBAC (GTRBAC) model [13], further extends the TRBAC model by introducing the notion of an activated role. More precisely, GTRBAC differentiates enabled roles, which subjects can activate, from active roles, which are being activated by at least one subject, for a more fine-grained AC.

The Spatial RBAC (SRBAC) model in [14] introduces a location-dependent constraint. A location space is divided into multiple *zones* , and an access permission is granted if the role condition is satisfied and the user is within the specified *zone* . The SRBAC model, as observed by [15], suffers from a lack of a semantic meaning of the position information, and it does not support the use of geometrically bounded roles.

The Dynamic Role Based Access Control (DRBAC) model [16], specifically designed for AC adaptation in UbiComp environments, is an interesting piece of work. Any change in an access context will be captured by an '*agent*' that will, in turn, trigger an '*event'* to cause a transition between the current role/permissions set to a new role/permissions set. DRBAC is considered as a pioneering effort in achieving context-aware authorisation in UbiComp environments. However, as noted by the authors themselves, implementing DRBAC can significantly increase the complexity of the applications concerned. This is particularly troublesome for the resource-restricted devices typically seen in UbiComp environments.

Young-Gab *et al* in [17] proposed a context-aware AC model which considers location, time, and system resources as AC constraints. The role is activated only if all the constraints are satisfied. The model has failed to consider the potential composite effects of, or the correlations between, these context attributes. In a similar approach, the model in [12] divides the location information in a levelled manner. The work formalised the model and conducted a case study, but again, it only focuses on temporal and spatial context attributes.

The work by G. Motta in [18] focuses on preserving patients' privacy and protecting the confidentiality of the patients' data in smart hospitals. The proposed contextual RBAC model classifies the patients' records based on their sensitivity levels, and an AC decision is made based upon the sensitivity level of the data being requested. The work, however, does not show how to adjust AC decisions in adaptation to the requesters' dynamic changes of the contextual information.

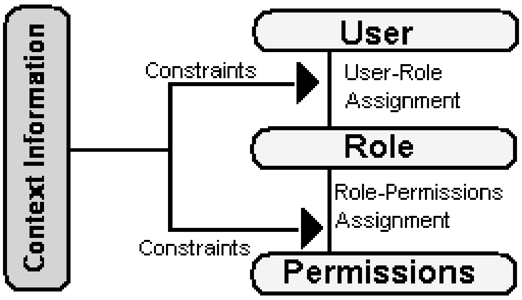

Fig 1. Existing Context-aware RBAC Approaches

A recent published work [19] has tried to address the need for evaluating the effect of multiple contextual attributes on an authorisation decision coherently. The model introduces the notion of risk-aware AC. The context information is used as the input to a risk assessment process to compute a risk value that is then fed into the authorisation decision engine. However, the scope of the risk assessment is quite broad covering confidentiality, integrity and authentication, so the delay incurred in the risk value calculation may be quite large, which may adversely affect the performance of the underlying AC system. Whether this delay would decrease the system ability to promptly adapt its decisions to context changes is yet to be investigated.

From the above discussions, it is clear that more investigation is needed for designing an AC model that could accommodate multiple contextual attributes in a generic and a coherent manner, and adapts its decisions to the dynamic changes of context, while, at the same time, keeping the costs down. The next section describes the design of such a model.

## III. *CRAAC* Model

The *CRAAC* model aims at achieving *context-aware adaptation* (i.e. requirement 1 — capable of capturing, and adapting its decisions to the surrounding information for fine-grained AC), *flexibility* (requirement 2 - flexible enough to accommodate different contextual attributes and should not tie itself to a particular application domain), *extensibility* (requirement 3 - extensible to allow easy addition of new, and removal of obsolete, contextual attributes and any alterations imposed to the architecture as caused by such contextual attribute changes should be refrained within the context management part of the AC system), and *low performance costs* (requirement 4 — performance costs incurred in achieving context-awareness should be kept as low as possible).

### A. Methodology Overview

The architecture of a context-aware AC system should include two major functional blocks, one for the *Context Management (CM)* and the other for AC. *CM* encompasses components for context acquisition, interpretation and representation while *AC* is responsible for making authorisation decisions. *CRAAC* is built on the basic RBAC model. While satisfying the requirements outlined above, the model has the two functional blocks (CM and AC) loosely coupled. That is, any change made to the attributes set managed by the CM block should not lead to changes in AC algorithms and policy representations managed by the AC block, and vice versa. One way to facilitate this loose coupling is to use a generic attribute that, on one hand, can capture the impact on AC as caused by context changes (in CM block), and, on the other hand, to feed that impact into the AC block as an additional AC constraint. In addition, it is desirable to link that attribute value to the resources sensitivity levels. Based upon these considerations, we introduce the notion of authorisation Level of Assurance (*LoA*) and use it as that generic attribute.

In details, resources/services are classified into object groups each with a distinctive *OLoA*. The determination of *OLoA* of an object group can be done via risk assessment for that group. The assessment identifies the risks, assesses their potential impacts, and maps the identified risks to an appropriate assurance level, i.e. *OLoA*. When an object access request is received, the decision engine will compare the *RLoA,* derived based on the requester's contextual information, against the *OLoA* of that object. The request is granted iif $RLoA \geq OLoA$. In fact, the *OLoA* of an object is the minimum authorisation requirement a user has to satisfy to gain access to that object. The more sensitive the object is, and/or the higher the potential impact, the higher the *OLoA*. Consequently, the higher the *RLoA* a requester would have to satisfy before the request can be granted.

One of the challenging tasks for designing this context-aware *LoA* linked AC is how to derive an *RLoA* value for a given access request based upon the requester's real-time contextual information. To achieve this, we need to, firstly, identify a set of contextual attributes that have impacts on the degree of certainty that the access request is from an entity that it claims to be from, secondly, to investigate, analyse, and define the respective assurance levels for these attributes, and thirdly, to devise a method that can derive the *RLoA* value based upon the attributes' LoA. In the remaining part of this section, we are going to address these issues respectively.

### B. Contextual Attributes and their LoA Definitions

There are a number of factors that can increase the risk of unauthorised access, e.g. weak authentication protocol/token, less trustworthy access location, lack of intrusion detection and response systems, unprotected communication channels, … etc. In this paper, the focus is on the authentication token types, the access locations, the channel security, and the ability to respond to intrusion attacks (intrusion response). We name these factors as contextual attributes. At run-time, the risk associated to these attributes, if materialised, may lead to unauthorised information access. In the rest of this section, these attributes will be discussed in details.

#### 1. eToken Attribute

Many factors in an e-authentication process affect the confidence level (i.e. *LoA*) in verifying a claimed identity. These include identity proofing, credentialing, credential management, record keeping, auditing, authentication protocols and token types. The assurance levels of some of these steps are achieved through procedural and process governance, while others may be left to the requesters' decision. For example, a requester may choose to use a particular authentication credential when making an access request. As our focus here is on the derivation of an authentication *LoA* and on linking it to the authorisation decision making, we exclude the procedural factors (i.e. user registration, credential management and storage procedures) from the *LoA* derivation. We rather focus on the types of e-credentials/tokens that are collectively called *eTokens*. Different *eTokens* provide varying degrees of confidence in entity identification and authentication. To quantify that degree of confidence, we introduce the notions of $LoA_{eToken}$.

***Definition 1:*** *$LoA_{eToken}$ refers to the service provider's degree of confidence that an eToken presented by a user is linked to his/her identity.*

The *eToken* types versus their assurance levels have been recommended by NIST [4], as shown in Table I. NIST recognises the token types of hard tokens, soft tokens, one-time password (OTP) device tokens, and user-name/password pairs, and defines four levels of $LoA_{eToken}$.

#### 2. Access Location (ALoc) Attribute

Authentication services are of two main types; one is e-authentication by which a user is identified through the use of an eToken, and the other is physical authentication (p-authentication) by which a user is identified through the use of biometrics, sensors or location based services. *CRAAC* recognises both of these authentication services. This is because, firstly, a combined use of e-authentication and location-based p-authentication not only provides optional services to users, but also offers a more reliable user identification. Secondly, location based services are commonly seen in UbiComp environments, and the access location is an important contextual attribute in such environment. Therefore, in addition to the *eToken* attribute, we introduce another authentication attribute, Access Location (*ALoc*). $LoA_{ALoc}$ in relation to *ALoc* is defined below.

***Definition 2:*** *LoA $_{ALoc}$ refers to the degree of confidence in a claimed a ccess location .*

Depending on the application context, there are various ways to represent the location alternatives [20], [21]. As our As our focus is on the degree of confidence in a claimed location, we use the ‘ *zone* ’ representation method [20], [14] to describe different location alternatives. Table II shows some possible location alternatives versus their likely assurance levels. The table is meant for illustration purpose only, as, unlike the case of *eToken* , *ALoc* attribute does not have any international consensus on their *LoA $_{ALoc}$* .

As outlined above, the two attributes, *eToken* and *ALoc,* both make direct contributions to the overall confidence level in the user identification. For example, as a password token is more vulnerable to guessing attacks than a PKI credential, then using it inside a secure room with a biometric physical authentication facility may be comparable, in terms of authentication assurance level, with a PKI credential used in a public area. To quantify such correlation between the two attributes, we introduce the notion of $LoA_{authN.}$

***Definition 3:*** *LoA $_{authN}$ is the overall confidence level associated with the composite authentication solution consisted of token based e-authentication and location based p-authentication .*

The derivation of $LoA_{authN}$ given $LoA_{eToken}$ and $LoA_{ALoc}$ will be discussed later on.

### 3. *Channel Security (CS) Attribute*

The level of security protection of the channel running between the requester and the service provider may indirectly influence the risk level of unauthorised access. For instance, if a channel is more vulnerable to eavesdropping attacks, some credentials sent over the channel may experience a high risk of being compromised. In addition, the requested data may also experience a high risk of being disclosed to unauthorised entities via channel interceptions. For this reason, we introduce another contextual attribute, Channel Security ( *CS* ) and its *LoA* is defined below.

TABLE I.
TOKEN TYPES VERSUS $\text{LoA}_{\text{eToken}}$ [4]

| Token type | Levels | | | |
|---|---|---|---|---|
| | 1 | 2 | 3 | 4 |
| **Hard token** | √ | √ | √ | √ |
| **One-time password token** | √ | √ | √ | |
| **Soft token** | √ | √ | √ | |
| **Password token** | √ | √ | | |

TABLE II.
LOCATION ALTERNATIVES VERSUS $\text{LoA}_{\text{ALoc}}$

| Alternatives | $\text{LoA}_{\text{ALoc}}$ |
|---|---|
| **Zone-0** | **Level 0**; public area which does not have any provision for p-authentication. |
| **Zone-1** | **Level 1**; semi-public area which uses p-authentication to identify a group of users, e.g. through the use of a shared building key. |
| **Zone-2** | **Level 2**; personal area – access to this zone is controlled by the use of a locker key owned by a single user or a sensor based user identification (e.g. RFID). |
| **Zone-3** | **Level 3**; secured personal area – this zone uses some strong form of physical identification method that is less vulnerable to theft or loss than locker keys, e.g. Biometrics (physical) authentication facility. |
| **Zone-4** | **Level 4**; highly secured personal area – this zone may use multiple physical authentication methods. |

***Definition* 4:** *LoA $_{CS}$ refers to the degree of confidence in the channel (linking requesters and service providers) security .*

Similar to the *ALoc* attribute, the *CS* attribute does not have any international consensus on its assurance level definition. Table III describes an exemplar setting of a 5-level $LoA_{CS}$ mimicking the NIST’s *eToken LoA* definition. The exemplar setting is for a demonstration purpose and to be used later on in section V.

### 4. *Intrusion Response Attribute*

The last contextual attribute addressed by *CRAAC* is the Intrusion Response (*IR*) attribute, and its *LoA* is denoted by $LoA_{IR}$.

***Definition 5:*** *$LoA_{IR}$ refers to the degree of confidence in the ability of the underlying system to detect intrusion attacks and the ability to respond to such attacks*.

Sundaram in [22] divides IDS detection mechanisms into; anomaly, and misuse. An IDS may monitor host computers or network activities. The ability to detect intrusions and to respond promptly to these intrusions varies from an IDS to another. An IDS class may have an associated level of confidence as they vary in capabilities. Again there is no international consensus on the $LoA_{IR}$ definition. Table IV is an exemplar $LoA_{IR}$ setting for illustration purposes and to be used later on in the case study.

Once the AC related attributes are identified, and their assurance levels are specified, the next step is to estimate an overall/aggregate *LoA* value for an access requester based upon the assurance levels of such attributes.

## C. *Requesters’ Aggregate LoA Derivations*

### 1. *Relationships among Multiple Attributes*

As mentioned earlier, the confidence level in identifying a user may be influenced by multiple methods or attributes, either directly (eTokens and Access Location) or indirectly (Channel Security and Intrusion Response). To quantify the confidence level as influenced by the combination of a requester’s multiple contextual attributes, we introduce the notion of an overall (aggregate) assurance level for a requester, *RLoA*.

***Definition* 6*:*** *RLoA refers to an overall LoA in identifying a requester based upon the requester's contextual information associated to multiple contextual attributes (eToken, ALoc, CS, and IR).*

The derivation of *RLoA* depends on the types of the attributes used in the access session, the correlation among the attributes, and the used security policy. Formally, given a set of contextual attributes ($A_1, A_2, ..., A_n$) and their associated assurance levels ($LoA_{A_1}, LoA_{A_2}, ..., LoA_{A_n}$), *RLoA* can be expressed using a generic function, *f*, as:

TABLE III.
LOA ASSOCIATED TO CHANNEL SECURITY ATTRIBUTE

| $LoA_{CS}$ | Descriptions |
|---|---|
| **Level 0** | This attribute is disabled, or not used. |
| **Level 1** | Little or no confidence in channel security. |
| **Level 2** | Some confidence in channel security. |
| **Level 3** | High confidence in channel security . |
| **Level 4** | Very high confidence in channel security. |

TABLE IV.
LOA ASSOCIATED TO INTRUSION RESPONSE ATTRIBUTE

| $LoA_{IR}$ | Descriptions |
|---|---|
| **Level 0** | IDS is disabled or no IDS is installed. |
| **Level 1** | Little or no confidence in the installed IDS. |
| **Level 2** | Some confidence in the installed IDS.. |
| **Level 3** | High confidence in the installed IDS. |
| **Level 4** | Very high confidence in the installed IDS. |

$$RLoA = f(LoA_{A_1}, LoA_{A_2}, \dots, LoA_{A_n}) \qquad (1)$$

The function *f* is determined by the relationship among the multiple attributes. We have identified two types of relationships, one is the *elevating* relationship and the other is the *weakest-link* relationship. In the *elevating* relationship, the combined use of two or more contextual attributes may result in the overall confidence level being higher than that provided by any one of the contextual attributes.

*Elevating* security is used by Microsoft in Windows Server 2003 to enable regular users to install applications even if they do not have the required permissions [23]. In our problem context, attributes, *eToken* and *ALoc*, are in an *elevating* relationship, as it is obvious that a combined use of e-authentication and location-based p-authentication will result in a more reliable user identification, thus a higher *LoA*.

In the *weakest-link* relationship, on the other hand, the value of *RLoA* is equal to the lowest attribute *LoA* value in the attributes set. This is in line with the *weakest-link* principle in system security. For example, attributes, {*eToken*, *ALoc*}, *CS* and *IR*, resembles more the *weakest-link* relationship (here *eToken* and *ALoc* are treated as one whole attribute in terms of *LoA*). This is because, even if the underlying authentication procedure is strong (thus difficult to impersonate), and channel security has a high assurance level (thus difficult to intercept useful information), provided that the service provider's system is easy to break into, there will still be a high risk of compromising server end of the identification and authentication procedure, e.g. by directly attacking credential files stored in the system. This implies the overall assurance level should not be higher than the lowest attribute *LoA* involved.

*2. Converting LoA to Ratings*

Later in this section, when we describe the *RLoA* derivation method, the attributes' *LoA* values (e.g. $LoA_{eToken}$, $LoA_{ALoc}$, $LoA_{CS}$, and $LoA_{IR}$) will need to be converted from levels (or ranks), as shown in Tables I-IV, to values in the real interval [0,1] (i.e. ratings or weights). To accomplish this rank-to-rating conversion of *LoA* values, we employ the Rank Order Centroids (*ROCs*) method, a well-known rank-to-rating (or weight) conversion technique. This subsection focuses on describing the *ROCs* method.

*ROCs* is often used in solving an *MCDA* (Multiple Criteria Decision Analysis) problem. It takes a set of attributes ordered by importance (ranks) and converts them into a set of approximated weights (ratings) as sometimes it may not be realistic to determine the precise weights [24]. *ROCs* originally proposed by Barron in [25] with an appealing theoretical rational for its weights [26]. In addition, the weights are derived by a systematic analysis of implicit information in the ranks which would give more accurate outcome [24].

Using the *ROCs* method, the weights are derived from a simplex $w_1 \geq w_2 \geq .... \geq w_n \geq 0$ restricted to:

$$\sum_{i=1}^{n} w_i = 1 \qquad (2)$$

where *n* is the number of attributes (system cardinality). The vertices of the simplex are $e_1 = (1, 0, ..., 0)$, $e_2 = (1/2, 1/2\ 0, ..., 0)$, $e_3 = (1/3, 1/3, 1/3, 0, ..., 0)$, ........ $e_n = (1/n, 1/n, ..., 1/n)$. The coordinates of the centroids (weights) are calculated by averaging the corresponding coordinates of the defining vertices [24]. In general, the weight of the k$^{th}$ most important attribute is calculated as:

$$(\sum_{i=k}^{n} \frac{1}{i})/n \qquad (3)$$

*ROCs* is a light-weight method for the rank-to-rating conversion as *ROC*-based analysis is straightforward and efficacious [24]. Therefore, it is particularly suited to the UbiComp environment. In addition, the weights can be calculated off-line, and uploaded into a rank-to-weight conversion table as shown in Table V to further reduce run-time overheads incurred in the conversion.

Tables, VI and VII, describe the corresponding $LoA_{eToken}$*, and* $LoA_{ALoc}$ values in ratings converted by *ROCs receptively.*

It is worth noting that level$_4$ in both cases of $LoA_{eToken}$ and $LoA_{ALoc}$ is the most significant level and corresponds to the first rank. The same rule can be applied to convert the *LoA* values from levels to their corresponding ratings for the Channel Security and the Intrusion Response attributes.

### 3. *RLoA Derivation in Elevating Scenarios*

Given that a requester has *n* contextual attributes, ($A_1, A_2, ..., A_n$), and all the attributes are in an *elevating* relationship, and assume that each of the attributes has a confidence value associated to it, ($LoA_{A_1}, LoA_{A_2}, ..., LoA_{A_n}$), then, under the assumption that $LoA_{A_i} > 0$, where $i \in \{1, n\}$, the overall confidence value, *RLoA*, can be calculated (using probability theory) as [27]:

$$RLoA = 1-(1-LoA_{A_1})(1-LoA_{A_2})....(1-LoA_{A_n}) \qquad (4)$$

where $LoA_{A_i}$ is a real value in the interval [0, 1], 1 denoting the highest confidence and 0 the lowest. An advantage of this equation is that an attribute with a higher assurance value would have a higher impact on *RLoA*, and an attribute with a lower assurance value would have a lower impact on the overall assurance value. Applying equation (4) to attributes, *eToken* and *ALoc*, we can calculate $LoA_{authN}$ That is:

$$LoA_{authN} = 1-(1-LoA_{eToken})(1-LoA_{ALoc}) \qquad (5)$$

where the values of $LoA_{eToken}$ and $LoA_{ALoc}$ are given in Tables VI and VII, respectively.

Further applying equations (4) to all the attributes concerned in this section (i.e. *authN, CS and IR)* we obtain an *RLoA* value as:

$$RLoA = 1-(1-LoA_{authN})(1-LoA_{IR})(1-LoA_{CS}) \qquad (6)$$

TABLE V.

|---|---|---|---|---|---|
| 5 | 0.4567 | 0.2567 | 0.1567 | 0.0900 | 0.0400 |

It is worth noting that with the *elevating* method, every attribute component *LoA* contributes towards the overall *RLoA*. As a result, the overall *RLoA* will be greater than the maximum *LoA* value afforded by any one of the contextual attributes involved. In some application scenarios or under a certain system setup, Equation (4) may not always be applicable to the attributes of *CS* and *IR*, i.e. equation (6) may not always be true. In such cases, the *weakest-link* method may be more appropriate.

### 4. *RLoA Derivation in Weakest-Link Scenarios*

When the composite influence of multiple contextual attributes follows the *weakest-link* principle, *RLoA* should then be calculated using the *minimum* function. That is, *RLoA* can be calculated using the following formula:

$$RLoA = min(LoA_{authN}, LoA_{IR}, LoA_{CS}) \qquad (7)$$

where *min* is the minimum function that returns the minimum value of those enclosed in the brackets. Note that the calculation of $LoA_{authN}$ remains the same, as the two attributes, *eToken* and *ALoc*, follow the *elevating* relationship due to its two-factor authentication nature.

## IV. CASE STUDY

In this section, the *CRAAC* model is applied to a real-life context-aware authorisation scenario. The scenario describes a Smart Hospital (SH), where Drs. Alice and Bob work. They both have the same organisational role, and use their wireless devices to access the SH restricted services from anywhere (within the hospital). In detail, Alice uses a PDA while Bob uses a wireless laptop. Assuming the patients' data are divided into four categories, denoted by Types$_{1-4}$, and their respective *OLoA* values are given in Table VIII. Users of these services have subscribed to four contextual attributes, namely, *eToken*, *ALoc*, *CS*, and *IR*. Approximately at the same time, Alice and Bob are seeking access to a *Type$_4$* service. Alice is in *Zone$_4$* (i.e. with $LoA_{ALoc}$ of level$_4$) and uses a user-name/password pair as her authentication token. Bob is in *Zone$_1$* (i.e. with $LoA_{ALoc}$ of level$_1$) and has got a PKI smart card. The installed IDS is of a '*High confidence*' type. As both access requests are made at approximately the same time, the $LoA_{IR}$ value associated to both requests corresponds to level$_3$ (i.e. $LoA_{IR}$ level is 3). However, $LoA_{CS}$ varies from Alice to Pop where Alice uses a channel with $LoA_{CS}$=Level$_1$, Bob is on a Level$_3$ channel protection. Table IX summarises the *LoA* values of all these contextual attributes in both levels and ratings (converted using *ROCs*) for both Alice and Bob.

Now, let us compute the *RLoA* for Alice under the assumption the SH is running a strict security policy, i.e. using the *weakest-link* principle. Applying equations (5) and (7), we have $LoA_{authN}$ = 1-(1- 0.1458) (1- 0.4567) = 0.5359 where *RLoA* = *min* (0.5359, 0.2567, 0.0900) = 0.0900. The authorisation decision engine compares Alice's *RLoA,* just computed, to the service Type$_4$ *OLoA* (0.1458). Obviously, as *OLoA*(Type$_4$) > *RLoA*(Alice), which means the assurance level required by the resource *Type$_4$* is higher than what Alice could achieve via her current context information, and therefore Alice is denied access to Type$_4$ services.

However, if the service provider uses an *elevating* security policy, $LoA_{authN}$ remains the same but the overall *RLoA* would be (using equation (6)): $RLoA = 1 - (1-0.5359)(1-0.2567)(1-0.09)=0.686$. In this case, Alice will be granted access to Type$_4$ services as now $OLoA(Type_4) < RLoA$(Alice).

For Bob's access request, when the *weakest-link* security policy is used, *RLoA* is calculated as 0.2567 that is sufficient to grant Bob the access, as $OLoA(Type_4) < RLoA$(Bob). When the *elevating* policy is used, however, Bob's *RLoA* is 0.7591, which will also enable him to access Type$_4$ services.

As shown, *CRAAC* provides the flexibility to allow a service provider to adapt its AC decisions based on the requester's run-time contextual attribute values and the chosen AC policy model (e.g. the *elevated* or the *weakest-link* policies). For instance, if Alice upgrades her channel access software to use a stronger encryption algorithm and crypto key, she would be able to obtain the access permission even if the SH is running the *weakest-link* AC policy. This is because the associated $LoA_{CS}$ value will be increased to 0.4567 (as a result of the channel security upgrade), and *RLoA* using *min* function would produce 0.2567 which is greater than the *OLoA* required by Type$_4$ services.

TABLE VIII.
OLOA REQUIREMENTS

| Service | OLoA | | Description |
|---|---|---|---|
| | Level | Value | |
| **Type$_1$** | 4 | 0.5208 | Patients' DNA data |
| **Type$_2$** | 1 | 0.0625 | Anonymous patient data |
| **Type$_3$** | 3 | 0.2708 | Patients' profiles |
| **Type$_4$** | 2 | 0.1458 | Statistical results for a group of patients |

TABLE IX.
CASE STUDY ATTRIBUTES LOA VALUES

| Context Attribute | Alice's LoA | | Pop's LoA | |
|---|---|---|---|---|
| | Level | Value | Level | Value |
| **eToken** | 2 | 0.1458 | 4 | 0.5208 |
| **Access Location** | 4 | 0.4567 | 1 | 0.0900 |
| **Channel Security** | 1 | 0.0900 | 3 | 0.2567 |
| **Intrusion Response** | 3 | 0.2567 | 3 | 0.2567 |

## V. CONCLUSION AND FUTURE WORK

In this paper we have introduced a new AC model, *CRAAC*, for achieving fine-grained AC in UbiComp environments. Risk assessment and level of assurance play a key role in the *CRAAC* model. Resources are classified into different groups based upon their sensitivity levels and the potential impacts of unauthorised access. Each group is assigned a distinctive *OLoA* denoting the minimum required authorisation level of assurance for that resource group. Upon receiving an object access request, the requester's run-time contextual information is assessed, and an *RLoA* is derived based upon these contextual information. The access request is granted iif $RLoA \geq OLoA$.

*CRAAC* has a number of major advantages over the existing AC approaches. Rather than directly using context information as additional AC constraints, *CRAAC* uses an abstract parameter, the authorisation *LoA*, to decouple the context management from the AC functional module, thus achieving context-aware AC without loosing generality, extensibility and flexibility. Through identifying and grouping users' contextual attributes in relation to authorisation *LoA*, and quantifying and aggregating the contextual information of these attributes into assurance levels, *CRAAC* achieves context-based *LoA* linked AC that allows different contextual information to be captured, and different *LoA* algorithms to be used without affecting the AC module. In other words, through the use of *LoA*, we can have a generic approach to context-aware AC, which can easily be applied to different application domains.

Future work includes designing the architectural components of the *CRAAC* model, and prototyping and evaluating the model to investigate its efficiency and efficacy.

***Abstract*—Phishing detection systems are principally based on the analysis of data moving from phishers to victims. In this paper we describe a novel approach to detect phishing websites based on analysis of users' online behaviours – i.e., the websites users have visited, and the data users have submitted to those websites. Such user behaviours can not be manipulated freely by attackers; detection based on those data can not only achieve high accuracy, but also is fundamentally resilient against changing deception methods.**

***Index Terms*—Phishing Attacks, Phishing Websites Detection, Identity Theft, User Protection**

## I. Introduction

PHISHING attacks are well-organised and financially motivated crimes which steal users' confidential information and authentication credentials. They not only cause significant financial damage to both individuals and companies/financial organisations, but also damage users' confidence in e–commerce as a whole. According to Gartner analysts, financial losses stemming from phishing attacks have risen to more than 3.2 billion USD with 3.6 million victims in 2007 in US [23], and consumer anxiety about Internet security resulted in a two billion USD loss in e–commerce and banking transactions in 2006 [22].

The scale and sophistication of phishing attacks have been increasing steadily despite numerous countermeasure efforts. The number of reported phishing web sites increased five–fold from 10047 to 55643 in the 10 month period between June 2006 and April 2007 [3]. The real figure may be much higher because many sophisticated phishing attacks (such as context aware phishing attacks, malware based phishing attacks, and real-time man-in-the-middle phishing attacks against one-time passwords [34]) may not all have been captured and reported.

In this paper we present our design, implementation and evaluation of the *user-behaviour* based phishing website detection system (UBPD). UBPD does not aim to replace existing anti-phishing solutions, rather it complements them. It alerts users when they are about to submit credential information to phishing websites(i.e. when other existing countermeasures fail), and protects users as the last line of defence. Its detection algorithm is independent from how phishing attacks are implemented, and it can easily detect sophisticated phishing websites that other techniques find hard to deal with. In contrast to existing detection techniques based only on the incoming data, this technique is much simpler, needs to deal with much less low level technical detail, and is more difficult to bypass by varying spoofing techniques and deception methods.

Note: In the rest of the paper we use 'interact', 'interaction' and 'user-webpage interaction' to refer to the user supplying data to a webpage.

## II. Related Studies

Researchers have studied the characteristics of phishing attacks [29], [30], [38] and have provided models of phishing attacks [4], [10], [18]. Our understanding of human factors in phishing has been improved by works such as[9], [17], [19], [20], [33]. Novel security interfaces, and automated detection systems have also been invented to protect users.

Anti-phishing email filters can fight phishing at the email level, as it is the primary channel for phishers to reach victims. SpamAssassin [2], PILFER [11], and Spamato [5] are typical examples of those systems. They analyse the incoming emails by applying predefined rules and characteristics often found in phishing emails. PHONEY is a phishing email detection system that tries to detect phishing emails by mimicking user responses and providing fake information to suspicious web sites that request critical information. The web sites' responses are forwarded to the decision engine for further analysis [7].

Web Wallet [40] creates a unified interface for authentication. Once it detects a login form, it asks the user to explicitly indicate the intended site to login. If the intention matches the current site, it automatically fills webpage input fields. Otherwise a warning will be presented to the user.

Phishing website filters in Internet Explorer [24], safe browsing in Firefox 2/3 [27], and Netcraft toolbar [28] are all blacklist anti-phishing websites detection systems. They check whether the URL of the current web page matches any identified phishing web sites before rendering the webpage to users.

SpoofGurad[8] is a signature-and-rule based detection system. It analyses the host name, URL, and the images used in the current webpage to detect the phishing websites. CANTINA [41] uses the TF-IDF information retrieval algorithm to retrieve the key words of the current webpage, and uses Google search results to decide whether the current website is phishy.

Ying Pan et al. have invented a phishing website detection system which examines the anomalies in web pages, in particular, the discrepancy between a web site's identity and its structural features and HTTP transactions [31].

## III. Design

### A. Phishing Nature and Detection Philosophy

Phishing websites work by impersonating legitimate websites, and they have a very short life time. On average a phishing website lasts 62 hours, and users rarely visit the phishing website prior to the attack [26].

Secondly, phishing attacks always generate mismatches between a user's perception and the truth. In successful web based phishing attacks, victims have believed they are interacting with websites which belong to legitimate and reputable organisations or individuals. Thus the crucial mismatch that phishers create is one of real *versus* apparent identity.

Phishing attacks can be detected if we can detect such a mismatch. One approach is to predict a user's perception and then compare it with the actual fact understood by the system. CANTINA is an example of this approach [41]. The main issue with this approach is that the data the system relies on is under the control of attackers, and there are so many techniques that attackers can apply to manipulate the data to easily evade the detection. For CANTINA, attackers could use images instead of text in the body of the webpage, they could use iframes to hide a large amount of content from the users while computer programs can still see it; they could use Javascript to change the content of the page after the detection has been done.

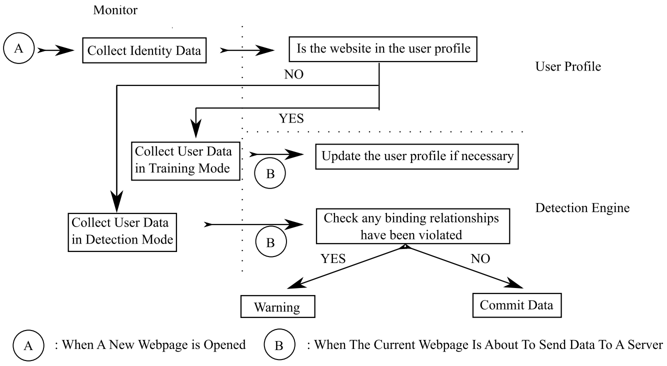
We decide to use another, more reliable, approach. The authentication credentials, which phishers try to elicit, ought to be shared only between users and legitimate organisations. Such (authentication credential, legitimate website) pairs are viewed as the user's *binding relationships*. In legitimate web authentication interactions, the authentication credentials are sent to the website they have been bound to. In a phishing attack the mismatches cause the user to unintentionally break binding relationships by sending credentials to a phishing website. No matter what spoofing techniques or deception methods used, nor how phishing webpages are implemented, the mismatch and violation of the binding relationships always exists. So one can discover the mismatch by detecting violation of users' binding relationships.

Hence phishing websites can be detected when both of the following two conditions are met: 1) the current website has rarely or never been visited before by the user; 2) the data, which the user is about to sumbit, is bound to website other than the current one.

### B. System Design

*1) Overview of the detection work flow:* UBPD has three components:

- **The user profile** contains data to describe the users' binding relationships and the users' personal whitelist. The profile must be constructed before the system can detect phishing websites.



Monitor
A
Collect Identity Data
Is the website in the user profile
User Profile
NO
YES
Collect User Data in Training Mode
B
Update the user profile if necessary
Detection Engine
Collect User Data in Detection Mode
B
Check any binding relationships have been violated
YES
NO
Warning
Commit Data
A : When A New Webpage is Opened
B : When The Current Webpage Is About To Send Data To A Server

Fig. 1. Detection Process Work Flow

- **The monitor** collects the data the user intend to submit and the identity of the destination websites, and activates the detection engine.
- **The detection engine** uses the data provided by the monitor to detect phishing websites and update the user profile if necessary.

UBPD has two working modes: training mode and detection mode. In training mode, UBPD runs quietly in the background, and focuses on learning newly created binding relationships or updating the existing binding relationships. Only in detection mode, UBPD checks whether any of the user's binding relationships would be violated if the user submitted data is sent to the current website. The mode in which UBPD runs is decided by checking whether the webpage belongs to a website

1) whose top level domain[1] is in the user's personal whitelist, or
2) with which the user has shared authentication credentials.

If either is true the system will operate in training mode, otherwise, in detection mode. Phishing webpages will always cause UBPD to run in the detection mode, since they satisfy neither condition.

The detection work flow is shown in Figure 1. Once a user opens a new webpage, the monitor decides in which mode UBPD should be running. Then, according to the working mode the monitor chooses appropriate method to collect the data the user submitted to the current webpage, and sends it to the detection engine once the user initiates data submission. The details of the data collection methods are discussed in section IV. When running in detection mode if the binding relationships are found to be violated, the data the user submitted will not be sent and a warning dialogue will be presented. For the remaining cases, UBPD will allow the data submission.

*2) Creation of the User Profile:* The user profile contains the user's binding relationships and personal whitelist. The binding relationships are represented as a collection of paired records, i.e., $\langle aTopLevelDomain, aSecretDataItem \rangle$. The personal whitelist is a list of top level domains of websites.

[1] Suppose the URL of a webpage is "domain2.domain1.com/files/page1.htm", the top level domain is "domain1.com"

Fig. 2. User Profile Creation

To make sure the binding relationship records are created, UBPD makes it as a mandatory step of UBPD's installation procedure. Having installed the UBPD, when the browser is restarted for the first time, the user is presented with a dialogue, which asks for the websites with which the user has accounts. Then UBPD automatically takes users to those websites, and asks users to fill in the authentication forms on those websites one by one. In addition, UBPD also dynamically modifies each authentication webpages, so that all the buttons on the webpage will be replaced with the 'Train(UBPD)' button. Once a user clicks on it, UBPD creates new binding relationship records in the user profile and then asks whether the user wants to carry on the authentication process (in case it is a multiple step authentication) or go to the next website. A screen shot is shown in Figure 2.

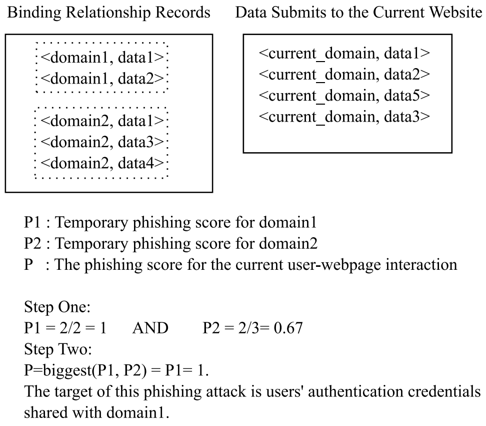
On average users have over 20 web accounts [12]. We do not expect them to train UBPD with all their binding relationships, however, we do expect them to train UBPD with their most valuable binding relationships (such as their online accounts with finanical organisations). Our preliminary evaluations have confirmed that our assumption is valid.

There are two types of binding relationships that UBPD is unaware of: the ones that already exist but users have not trained UBPD with, and the ones that users will create in the future. It is possible that the authentication credentials in these unknown binding relationships have also been used in the binding relationships that UBPD is aware of (as the result of authentication credentials reuse). When this is the case, with the binding relationships records alone UBPD interprets the legitimate use of the unknown binding relationships as a violation of binding relationship, and wrongly raise a phishing attack warning. To avoid such false warnings, the whitelist is automatically created to include the websites that users have already got accounts with but did not make UBPD aware of and the websites they may have account with in future. As stated in section III-B1 if the website with which the user is currently interacting is found to be in the whitelist UBPD will only run in training mode. In the training mode, such reuse of the authentication credentials can only cause UBPD to either create new binding relationships record or update existing ones.

The personal whitelist is constructed by combining a default whitelist with the websites the user has visited more than three times (configurable) according to the user's browsing history. The default whitelist is constructed by identifying the 1000 websites that are most visited in the user's country. This information is obtained from Alexa, a company specialising in providing internet traffic ranking information. The default whitelist could be viewed as a reflection of mass users' online browsing behaviours. These most popular websites are not phishing websites, and users are likely to have binding relationships with them in the future if they do not have already. In this way, websites that users currently have accounts with or are going to have account with are very likely to be included in the whitelist. By default, this whitelist is automatically updated weekly. It is worthy noting that, the whitelist in UBPD is mainly used for reducing false warnings, it is not used as conventional whitelist to decide whether the current website is legitimate or not.

*3) Update of the User Profile:* Besides the manual update by users, when running in the training mode UBPD has an automatic method to update the user profile with the other unknown binding relationships. It detects whether the user is using a web authentication form. This is achieved by analysing the HTML source code, such as the annotation, label, use of certain tags (such as ⟨form⟩) and type of the HTML elements. If the user is using a web authentication form, and the user profile contains no binding relationships with the current website, then UBPD prompts a window to ask the user to update the user profile. If there is an existing binding relationship for the current website, then UBPD will replace the authentication credentials in the binding relationships with the lastest values the user submits. If users have entered the authentication credentials wrongly, those credentials will still be stored, but those wrong values will be corrected, when users relog in with the correct authentication credentials. In future the detection of web authentication page usage can be much simpler and more accurate once web authentication interfaces [15], [35], [37] are standardised. Current authentication form detection is still accurate because it deals with legitimate websites (automated update is carried out only in training mode), and those legitimate websites use standard web forms and will not deliberately disrupt detection.

*4) Phishing Score Calculation:* In detection mode, UBPD decides whether the current webpage is a phishing webpage by calculating phishing scores. The calculation is a two step process. In the first step, for each legitimate website, with which the user has shared authentication credentials, a temporary phishing score is calculated. Each temporary phishing score is the fraction of the authentication credentials associated with a legitimate website that also appear in the data to be submitted to the current webpage. Its value ranges from $0.0$ to $1.0$.



P1 : Temporary phishing score for domain1
P2 : Temporary phishing score for domain2
P : The phishing score for the current user-webpage interaction

Step One:
P1 = 2/2 = 1 AND P2 = 2/3= 0.67
Step Two:
P=biggest(P1, P2) = P1= 1.
The target of this phishing attack is users' authentication credentials shared with domain1.

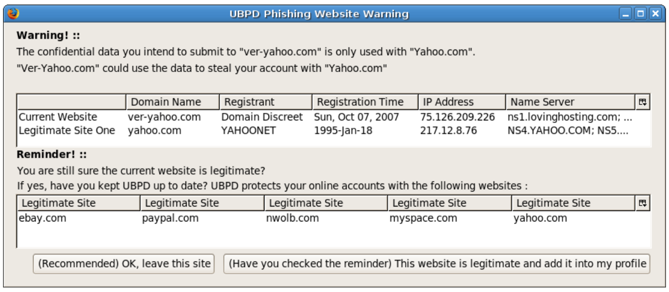
Fig. 3. An Example of How Phishing Score Is Calculated

In the second step, those temporary phishing scores are sorted into descending order. The current webpage's phishing score is the highest score calculated. The legitimate website with the highest temporary phishing score is considered to be the impersonated target of the phishing website. If more than one legitimate website has yielded the highest phishing score (due to the reuse of authentication credentials), they will all be considered as targets. Although it may not be the attacker's intent, the data they get if an attack succeeds can certainly be used to compromise the user's accounts with those legitimate websites. Figure 3 illustrates how a phishing score is calculated in UBPD.

Given our phishing score calculation method, clever attackers may ask the user victims to submit their credential information through a series of webpages, with each phishing webpage asking only for a small part of data stored in the user profile. To handle this fragmentation attack UBPD has a threshold value and cache mechanism. Once the phishing score is above the threshold the current webpage will be considered as a phishing webpage. The system's default threshold is $0.6$. Why we choose $0.6$ is discussed in section V. If the current phishing score is not zero, UBPD also remembers which data has been sent to the current website and will consider it in the next interaction if there is one. Accordingly many fragmentation attacks can be detected.

*5) Reuse:* It is very common that a user shares the same authentication credentials (user names, passwords, etc) with more than one website. The two running modes and the user's personal whitelist are designed to prevent false warnings caused by reuse without compromising detection accuracy.

UBPD detects the violation of binding relationships only when the user is interacting with websites that are neither in the user's whitelists nor which the user has account with. So as long as legitimate websites for which users have used the same authentication credentials are all contained in the user profile, there will be no false phishing warning generated due to the reuse. The method that UBPD uses to create the user profile ensures such legitimate websites are most likely to be included, as those websites are either within the user's browsing history or are popular websites in the user's region. Our preliminary false positive evaluation also confirmed this.



**Warning! ::**
The confidential data you intend to submit to "ver-yahoo.com" is only used with "Yahoo.com".
"Ver-Yahoo.com" could use the data to steal your account with "Yahoo.com"

| | Domain Name | Registrant | Registration Time | IP Address | Name Server |
|---|---|---|---|---|---|
| Current Website | ver-yahoo.com | Domain Discreet | Sun, Oct 07, 2007 | 75.126.209.226 | ns1.lovinghosting.com; ... |
| Legitimate Site One | yahoo.com | YAHOONET | 1995-Jan-18 | 217.12.8.76 | NS4.YAHOO.COM; NS5.... |

**Reminder! ::**
You are still sure the current website is legitimate?
If yes, have you kept UBPD up to date? UBPD protects your online accounts with the following websites :

| Legitimate Site | Legitimate Site | Legitimate Site | Legitimate Site | Legitimate Site |
|---|---|---|---|---|
| ebay.com | paypal.com | nwolb.com | myspace.com | yahoo.com |

(Recommended) OK, leave this site
(Have you checked the reminder) This website is legitimate and add it into my profile

Fig. 4. Phishing Warning Dialogue

*6) Warning Dialogue:* The content of the warning dialog must be suitable for users with very limited knowledge, otherwise, as previous user study [39] found, users may ignore the warning or may not behave as suggested. Figure 4 is a warning dialog example. To make the information easy to understand, the dialogue tells users that the current website, to which they are submitting credentials, is not one of the legitimate websites associated with those authentication credentials. To help users understand the detection result and make a correct decision, UBPD also provides information regarding the differences between the legitimate website and the possible phishing website in five aspects: the domain name, the domain registrant, the domain registration time, name servers, and IP addresses. Users don't need to understand those terms. They only need be able to recognise the difference between values of the five attributes of the legitimate website and the phishing website.

*7) Website Equivalence:* To discover whether the user is about to submit the authentication credentials to entities, with which they have not been bound, UBPD needs to be able to accurately decide whether a given website is equivalent to the website recorded in user's binding relationships. It is much more complicated than just literally comparing two URLs or IP addresses of two websites, because: 1) big organisations often have web sites under different domain names, and users can access their account from any of these domains; 2) the IP address of a website can be different each time if dynamic IP addressing is used; 3) it is hard to avoid 'pharming' attacks, in which the phishing site's URL is identical to legitimate one.

Our system first compares two websites' domain names and IP addresses. When the two domain names and two IP addresses are equal the web sites are assumed to be identical. Otherwise, the system interrogates the WHOIS[2] database and uses the information returned to determine equivalence. When analysing two different IP addresses our system compares the netnames, name servers, and the countries where each IP address is registered. If they are all identical then the two websites are deemed to be identical. This method can

[2] WHOIS is a TCP-based query/response protocol which is widely used for querying a database in order to determine the owner of a domain name, an IP address. RFC 3912 describes the protocol in detail.

also detect pharming attacks, in which both fraudulent and legitimate websites have the same domain name but are hosted on different IP addresses.

This method is not perfect. A more elegant and complete solution would be a mechanism where servers provide security relevant metadata (including the outsourcing information) to the web browser via a standard protocol as suggested by Behera and Agarwal [6]. However, unless it becomes a standard we have to rely on WHOIS. The extended validation certificate [13] can provide information to decide whether two websites belong to the same party, but the problem is the high cost, high entry level and complexity of obtaining such certificates. Many small and medium businesses will not be able to own them; as a result they cannot be used to decide website equivalence in general.

*8) User's Privacy:* Since a user profile contains confidential user information, it is important that it does not add new security risks. We use a one-way secure hash function to hash the confidential data before it is stored. When the system needs to determine the equivalence between the data, the system just needs to compare the hash values.

However, because the domain name of the website is not hashed, if the profile is obtained by attackers they would be able to find out with which websites users have accounts and where users have reused their authentication credentials. This information is helpful for attackers; for example, it can be used to launch context aware phishing attacks against the users. To prevent this, when the system is installed it will randomly generate a secret key, and this key will be used to encrypt and decrypt the domain names.

### C. Implementation

UBPD is implemented as a Firefox add-ons. Most of the detection is implemented using Javascript. The hash function we use is SHA-1[21] and the encryption method we use is Twofish[1]. The hash function and encryption methods can be changed, we choose to use them mainly because there are open source implementations available. The user interface of the system is implemented by using XUL, a technology developed by Mozilla [14]. Although only implemented on Firefox, the detection system can be easily developed to work on other browsers, such as Internet Explorer and Opera.

## IV. Evasion and Countermeasures

### A. Disruption of Data Collection

To accurately detect phishing UBPD needs to be able to work with the exact data the user is submitting to the current webpage. This data can be easily retrieved by accessing the DOM interface, however, the client script language can also manipulate the data before the monitor retrieves it.

In training mode, websites that users are visiting are legitimate, the monitor uses the DOM interface to retrieve the data, as in those cases client scripts manipulation is not an issue. However, in detection mode, when the user is interacting with websites that may be phishing websites, client scripts manipulation is a real threat. The monitor takes hence a different approach. The monitor performs like a keylogger, it collects user data by listening to a user's keystrokes for each element in the webpage. Such key logging is very efficient to run and since UBPD runs in detection mode only occasionally, there is little performance overhead.

### B. Activation of the detection engine & denial of service attack

The detection engine must be activated before the data the user entered has been sent to a remote server. Normally webpages forward the user submitted data using built-in functions, such as the one provided by the standard web form (Almost every legitimate website uses this function to submit the data). So the detection engine is triggered and data submission is suspended when the monitor discovers the use of such functions. This is achieved by listening for 'DOMActivate' [16] events. These events are fired by the browser when such built-in functions have been used. This is the mechanism the monitor uses to activate the detection engine when the system is running in training mode.

However, phishers can use client side scripts to implement these built in functions. For example, by using Javascript they can access the DOM interface to retrieve the data users entered and use AJAX (Asynchronous Javascript And XML) techniques to send the data to the server before the user clicks the submit button. To prevent this evasion, UBPD could monitor the client script function calls when it is running under the detection mode. The function calls should be monitored are 'open()' and 'send()' from the 'xmlhttprequest' API [36]. These are the only two functions that client scripts can use to send data to the server. Once the monitor discovers such function calls, the function is suspended and the detection engine is triggered. Regardless of the data the client scripts would like to send, the detection engine always works on all the data the user has entered to the current webpage. The function call is only resumed if the detection engine thinks the current website is legitimate.

Since the detection engine would be triggered once the 'xmlhttprequest' API has been called, the attackers can issue this function call continously to freeze the browser. To prevent this, the monitor can keep a record of whether there is user input since the last time the detection engined was activated for the same webpage. If there is then the detection engine will be activated, otherwise, not.

We plan to implement such client side scripts function call detection by using the techniques in Venkman (a Firefox JavaScript Debugger Addon) in the next version of UBPD. Nevertheless, if attacked by this evasion technique, at least UBPD would still be able to inform users what they have done, and preserve the evidence for possible analysis. One of the major problem for users is they do not know when they have been attacked and how. It gives users a good chance to reduce the damage caused by the phishing attacks.

## V. Evaluation

We have carried out two experiments to evaluate the effectiveness of UBPD in terms of the two following rates:

TABLE I
CHARACTERISTICS OF USER PROFILE

| | Alice | Bob | Carol | Dave |
|---|---|---|---|---|
| Reuse | No | No | Yes | Yes |
| Uniqueness | Strong | Weak | Strong | Weak |

- **False negative**: The system fails to recognise a phishing attack.
- **False positive**: The system recognises a legitimate website as a phishing website.

In addition we also search for a useful default threshold value (mentioned in section III-B4). For both experiments UBPD was modified to not present the warning dialogue, instead it records the phishing score results as well as the URLs for later analysis.

### A. *False Negative Rate*

From PhishTank[32] and millersmiles[25] we randomly collected 463 recently reported phishing webpages, which target Ebay, Paypal, and Natwest bank. We created four user profiles, which describe four artifical users' binding relationships with the three targeted websites. The four user profiles have different characteristics as shown in Table I. 'Reuse' indicates maximum possible reuse of authentication credentials. In this case the user would have same user name and password for Ebay and Paypal. 'Uniqueness' indicates whether the user would use the exact data they shared with a legitimate website at other places. For example if Bob chooses his email address as password then the uniqueness is weak, because Bob is very likely to tell other websites his email address. If Bob uses some random string as his password, then the uniqueness is strong, because this random string is unlikely to be used with any other websites.

We entered the artifical authentication credentials to each phishing webpages. Regardless of the characteristics of the user profile, the detection result is the same for all four users: 459 pages had a phishing score of 1, and 4 had a phishing score of 0. Thus only four pages evaded detection – a 99.14 percent detection rate. Compared to other existing phishing website detection systems, UBPD's detection rate may not be significantly better. **Its biggest advantage** is that its detection method detects essential characteristics of a phishing attack, namely that phishing web pages request authentication credentials. The details of how users may be manipulated may change with future phishing attacks, but the requesting of such details remains constant. Other detection systems based on the analysis of incoming data will need to adapt and be redesigned for future phishing attacks; UBPD will not.

Detailed analysis confirms that the detection result is determined mainly by the information requested by the phishing webpage. Table II shows the classification of the phishing webpages based on the type of information they requested. 92% of the collected phishing webpages asked only for authentication credentials and 7.14% of the collected phishing webpages asked both for personal and authentication credentials.

TABLE II
STATISTICS OF PHISHING WEBSITES BASED ON THE TYPE OF INFORMATION REQUESTED. AC: AUTHENTICATION CREDENTIALS; PI: PERSONAL INFORMATION

| | Ebay | Paypal | Natwest |
|---|---|---|---|
| AC | 211 | 176 | 39 |
| AC+PI | 22 | 5 | 6 |
| PI | 4 | 0 | 0 |
| Total | 237 | 181 | 45 |

The four phishing web pages that UBPD failed to detect asked only for personal information such as full name, address, telephone number and mother's maiden name. In fact, they can not be detected by UBPD no matter what the threshold value is. However, it is impractical for phishing attacks to ask for personal information without requesting authentication credentials first, because those phishing webpages are not presented to users when a user victim first arrives at the phishing website. Those phishing websites would normally first present the user with a login webpage before directing the user to the webpage that asking for the personal information (none of the four phishing webpages were the landing page of the phishing attacks). Otherwise such practice would be seemed abnormal, and make potential victims very suspicious. As a result, UBPD can detect the phishing attacks and stop users from even reaching the phishing webpages that ask for personal information.

The sample size in this experiment is large and we might have some expectation that this would be reasonably indicative of success rate when deployed 'in the wild'.

### B. *False Positive Rate*

Five volunteers were provided with the information needed to install UBPD on their machine. We did not explictly ask them to train UBPD with all their binding relationships, because we wanted to see how users would train UBPD and what the false positives would be in reality if the user has not properly trained UBPD. At the end of one week, we collected the result log from their machines.

The volunteers were three male and two female science students. They all used Firefox as their main web browser. They were all regular Internet users (in average over three hours per day). As a result the UBPD was activated a large number of times and the interactions that occurred during the experiments covered a wide range of types of interaction. Another reason we chose those volunteers is because they are the most unlikely user group to fall victims to phishing attacks [17] and so we can safely assume they have all interacted with legitimate websites. In total the volunteers interacted with 76 distinct websites, sumbitted data to those websites 2107 times, and UBPD ran in detection mode only 81 times. In fact all the websites volunteers visited were legitimate. On 59 occasions the phishing score was $0$, on five interactions gave a score of $0.25$, on 13 occasions the score was $0.5$, and the score was $1$ on three occasions.

The phishing score was 1 when users interacted with three legitimate websites (the registration webpages of videojug.com and surveys.com, and the authentication webpage of a web forum). We asked the volunteers what data they supplied to those webpages. It seems that the reuse of authentication credentials on creating new accounts is the reason. In this experiment, the warning dialog is not presented, as we did not aim to test usability. But if it does, then the user must make decision to train UBPD to remember these new binding relationships. To avoid the user's confusion about what is the right choice when the warning dialog is presented, the dialog always reminds the user of the legitimate websites UBPD is aware of, and tells the user that if the user is sure the current website is legitimate, and the website is not remembered by UBPD, then they need to update their binding relationships (see the figure 4 in section III-B6). This requires no technical knowledge and should be quite easy to understand. There are only two choices provided by the dialog: to update the profile and submit the data; or donot send the user submitted data and close the phishing webpage. There is no third choice provided by the dialog, in this way we force the user to make the security decision and they can not just ignore the warnings given by the system.

Many websites force users to supply an email address as the user name. As a result, the user's email address is kept in the user profile as part of user's authentication credentials. This email address almost inevitably will be given out to other websites, which are not contained in the user profile, for various reasons such as contact method, activate the newly registered account, etc. Thus even when the user does not intend to give out their credentials, the email address nevertheless is shared and our system simply confirmed that by calculating the phishing score of $0.5$ (which means half of the data the user has shared with a legitimate website was given away to a website that was not in user's profile) on 13 occasions.

For one volunteer five interactions gave a phishing score of $0.25$. The user had an account at a major bank, the authentication credentials for which compromised four data items. One of these was the family name. For other sites not included in the user's profile asking for this information caused our system to identify the sharing of the data.

Based on the figures from both experiments we decided to set the default threshold value to $0.6$. First, it can successfully detect phishing webpages asking for more than half of the credentials the user has shared with a legitimate website (99.14% of the phishing websites in Experiment One can be detected). It also generated few false positives. The false positive rate of the system is $0.0014$ (obtained by dividing the number of false positives generated with the total number of times the UBPD was activated).

Of course this is only a preliminary false positive evaluation, but it still shows the system has a small false positive rate, and it also shows that the reuse of the authentication credentials and partial training are the main cause of the false positives.

## VI. Discussion

### A. Why UBPD is useful

Besides its high detection accuracy, UBPD is useful also because it complements existing detection systems. First UBPD detects phishing websites based on users' behaviours, not the incoming data that attackers can manipulate freely. Violation of the binding relationships cannot be changed no matter what techniques phishers choose to use. As the evaluation proves, UBPD is able to consistently detect phishing webpages regardless of how they are implemented as long as they ask for authentication credentials. In contrast detection systems based on incoming data may find it difficult to deal with novel and sophisticated spoofing techniques. UBPD analyses the identity of websites using both IP addresses and domain names, it can detect pharming attacks, which are undetectable by many existing systems. Being independent of the incoming data means low cost in maintenance, the system does not need updating when attackers vary their techniques, and so we have far fewer evasion techniques to deal with.

Some systems that try to stop phishing attacks from reaching the users (phishing site take down, botnet take down, phishing email filter, etc.), some have tried to detect phishing webpages as soon as users arrive at a new web page (Phishing URL blacklist, netcraft toolbar, spoofguard, CARTINA, etc), and some have tried to provide useful information to help users to detect phishing websites. However, there are no other systems that work at the stage when phishing webpages have somehow penetrated through and users have started to give out information to them. Thus our system plugs a major remaining gap, and it can be easily combined with other phishing detection systems to provide multi-stage protection.

### B. Performance

The two working modes of UBPD reduce the computing complexity. Computing in detection mode is more expensive, but it runs only occasionally (in our second experiment UBPD only in detection mode 81 out of 2107 times). Computing in the detection mode is still light weight for the computing power of an average personal computer (none of the volunteers noticed any delay). As a result, UBPD is efficient to run and adds few delay to the existing user-webpage interaction experience.

### C. Limitations and Future Work

UBPD should be viewed as an initial but promising effort towards detecting phishing by analysing user behaviour. Despite its detection effectiveness, there are some limitations within the implementation and design.

Currently UBPD cannot handle all types of authentication credentials. It can handle static type authentication credentials such as user name, password, security questions, etc, but dynamic authentication credentials shared between users and the legitimate websites cannot be handled by the current implementation (e.g. one-time passwords). In future we will investigate how to handle such credentials.

There is also another method for a phisher to evade detection. Attackers might compromise a website within a user's personal whitelist and host the phishing website under the website's domain (perhaps for several hours to a couple of days). This method is difficult to carry out, and it is unlikely to happen if there are still easier ways to launch phishing attacks.

Detection itself requires little computing time, in fact, retrieving the data from WHOIS database is the most time consuming part. It depends on the type of network the user is using and the workload on the WHOIS database. In future we could add some cache functionality to reduce the number of queries for each detection. Currently the system produces a slight delay because of the WHOIS database query.

Although we have paid attention to the usability design of the system, we have not systematically evaluated it. Further user evaluation will inform development.

## VII. Acknowledgement

I wish to thank all the people helped us, and especially the Engineering and Physical Sciences Research Council(EPSRC) of United Kingdom, without their sponsorship of the project "Defending the weakest link: Intrusion via Social Engineering" the detection method would not be invented.

## VIII. Conclusion

We have used a novel paradigm—analysis of the users' behaviours—to detect phishing websites. We have shown that it is an accurate method, discussed how it has been designed and implemented to be hard to circumvent, and have discussed its unique strength in protecting users from phishing threats. UBPD is not designed to replace existing techniques. Rather it should be used to complement other techniques, to provide better overall protection. We believe our approach fills a significant gap in current anti-phishing technology capability.

*Abstract*—**Peer-to-peer (p2p) networking technology has gained popularity as an efficient mechanism for users to obtain free services without the need for centralized servers. Protecting these networks from intruders and attackers is a real challenge. One of the constant threats on P2P networks is the propagation of active worms. Recent events show that active worms can spread automatically and flood the Internet in a very short period of time. Therefore, P2P systems can be a potential vehicle for active worms to achieve fast worm propagation in the Internet. Nowadays, BitTorrent is becoming more and more popular, mainly due its fair load distribution mechanism. Unfortunately, BitTorrent is particularly vulnerable to topology aware active worms. In this paper we analyze the impact of a new worm propagation threat on BitTorrent . We identify the BitTorrent vulnerabilities it exploits, the characteristics that accelerate and decelerate its propagation, and develop a mathematical model of their propagation. We also provide numerical analysis results. This will help the design of efficient detection and containment systems.**

## I. Introduction

PEER-TO-PEER systems, like eMule, BitTorrent, Skype, and several other similar systems, have became immensely popular since the past few years, primarily because they offered a way for people to get a free service. According to Androutsellis et al. [1] “Peer-to-peer systems are distributed systems consisting of interconnected nodes able to self organize into network topologies with the purpose of sharing resources such as content, CPU cycles, storage and bandwidth, capable of adapting to failures and accommodating transient populations of nodes while maintaining acceptable connectivity and performance, without requiring the intermediation or support of a global centralized server or authority”. Under the hood, these systems represent a paradigm shift from the usual web of client and servers, to a network where every system acts as an equal peer. Moreover, due to the huge number of peers, objects can be widely replicated, therefore increasing the availability of the provided services, despite the lack of centralized infrastructure. This leads to the proliferation of a variety of applications, examples include multicast systems, anonymous communications systems, and web caches. P2P systems consume up to 70 % of the Internet overall traffic[4].

The ease of use, provided services and finally the low price; all contribute in the increasing number of P2P users. However this fact also inspired attackers to attack P2P networks. Making these systems "secure" is a significant challenge. Indeed, a malicious node might give erroneous responses to a request, both at the application level (returning false data to a query, perhaps in an attempt to censor the data) or at the network level (returning false routes, perhaps in an attempt to partition the network). BitTorrent, on the other hand, supplies means of checking the integrity of the data received upon its reception, thus protecting the users from file poisoning and similar attacks. However, BitTorrent fails to prevent attacks that are designed to induce an impact on the network’s infrastructure. These attacks may cause damages of great consequences on the quality of service and the reliability of ISPs. Such attacks are similar to distributed denial of service (DDoS) attacks.

There are several attacks that can be conducted against BitTorrent. Such attacks are like S ybil attacks [6], Eclipse attacks [7], DDoS attacks, or even active worms attacks. Active worms are programs that self-propagate across the Internet by exploiting security flaws in widely-used services [8].

In this paper we analyze the impact of a new worm propagation model on BitTorrent. BitTorrent is particularly vulnerable to topology aware active worms. Topology aware worms use the topologic information found on their victims to find new victims. Such worms are capable of quickly flooding the Internet while escaping current deployed intrusion detection systems. Moreover, in order to boost its initial propagation the worm uses a trackers’ hitlist consisting of the most crowded swarms (*i.e.* groups of BitTorrent users interested in the same content). This mechanism allows the worm to find newer victims even faster than traditional scanning worms. This combination of both scanning strategies (*i.e. the strategy a worm uses to discover new machines to infect*) is fatal, because it provides the worm with certainty, discretion and speed. This combination allows the worm to only attack existing targets, thus saving scanning time and more importantly escaping the current implemented detection systems, since such systems are normally installed on non-attributed addresses.

The possible damages that such worm can causes are huge, our analysis of its propagation shows that it can achieve a 300% increase in its propagation speed in comparison with traditional scanning worms. The purpose of our research is to further investigate this new worm, identify the characteristics that accelerate and decelerate its propagation in BitTorrent, and to develop a mathematical model of their propagation. Such model would be used to compare the worm behavior in different scenarios and thus, better identify its weaknesses and strengths. We believe that our work can provide important guidelines for P2P system design and control to address the concerns of active worms and to develop efficient containment and intrusion detection systems. The rest of the paper is organized as follows. In section 2, we first discuss how the BitTorrent works in practice and then discuss "Tit-for-Tat" algorithm in general. In section 3, we present related and previous research done on P2P worms. In section 4, we explicate the strategy of our developed topology aware worm (the BitTorrent worm). In section 5, we present our model, and provide numerical analysis results. We end up this paper with conclusion and future work in section 6.

## II. BitTorrent

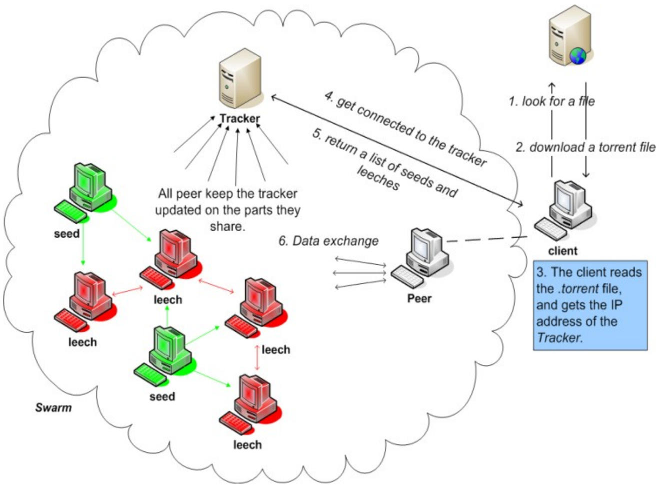
BitTorrent is a P2P protocol for content distribution and replication designed to quickly, efficiently and fairly replicate data [3]. Recent reports have indicated that near 75 % of all the current P2P Internet traffic is due to BitTorrent (see figure 1) [4]. In contrast to other P2P protocols, the BitTorrent protocol does not provide any resource query or lookup functionality, but rather focuses in fair and effective replication and distribution of data. BitTorrent works by groups of users, called *swarms*, with the interest of downloading a single specific file, coordinating and cooperating to speed-up the process.

A *swarm* can be partitioned into two network entities: a *tracker*, and peers [8]:

1. A *tracker* is a centralized software which keeps track of all peers interested in a specific file. Each *swarm* is managed by a *tracker* .
2. The second entity is the set of active peers, which can be further divided into *seeds* and *leeches* . A *seed* is defined as a peer that has already retrieved the entire shared file. Where a *leech* is a downloading peer.

A server, usually a web server is also important for the smooth conduct of BitT*orren*t. The *purpo*se *of th*is server is to provide a *torrent* file for interested clients. The *torrent* file i*s a f*ile that contains the necessary information for the clients to prepare the download and join the *swarms*. The main information in this file is a set of (SHA-1, [9]) hash values, which allows the user to verify the integrity of the received file content. The file stores the address of the *tracker* as well. In this paper, we give enough relevant details to allow us to facilitate the description of the attack.

In figure 1, we illustrate how a client downloads a file from a BitTorrent *swarm*. *Leeches* are represented in a red color, while *seeds* are represented in green. The *tracker* is installed on a machine which is located in a *swarm* represented by a cloud. Let's imagine a scenario, where a client shows an interest in downloading a certain file. The client first searches for the desired file by consulting a known website (see figure 1 step 1). The client would then downloads a *torrent* file which its metadata matches the desired file (see figure 1 step 2). Next, the client will read the content of the torrent file, and get the tracker address (see figure 1 step 3). Once, the client obtains the tracker address, he gets connected to it, announces its will to download the shared file and asks the tracker about other peers (see figure 1 step 4). When asked for peers, a tracker will return a random list of other peers currently in the swarm. As the number of peers in a single swarm may become very large for popular files, the size of the returned list is usually bound; a maximum of 50 peers is typical (see figure 1 step 5) [8]. Once a client has obtained a list of other peers, it will contact them to try to fetch the data it is looking for.



1. look for a file
Tracker
4. get connected to the tracker
5. return a list of seeds and leeches
2. download a torrent file
All peer keep the tracker updated on the parts they share.

Figure 1: How BitTorrent work

The bandwidth being a limited resource, a single client cannot serve every peer interested in pieces it holds at the same time. The maximum number of peers served concurrently (i.e. the number of available slots) is configurable by the user and depends on the available bandwidth. All other peers connected to a client (whether they are interested or not) which are not being served are said to be choked . In consequence, each client implements an algorithm to choose which peers to choke and un-choke among those connected to him over time. The strategy proposed by BitTorrent is named "tit-for-tat", meaning that a client will preferably cooperate with the peers cooperating with him. Practically, this means that each client measures how fast it can download from each peer and, in turn, will serve those from whom it has the better download rates. When a client has finished downloading a file, it no longer has to download from other Peers but it can still share (upload) pieces of the file. In this case the choking algorithm is applied by considering upload rate instead. Peers are selected based on how fast they can receive the upload. This spreads the file faster. Such "seeder" peers that store the whole file are very important to the functioning of a swarm. If a swarm contains no seeders it may lead to a situation in which pieces of the file are missing from the swarm as a whole. In this sense, the system requires some level of altruistic behavior from "seeders". This behavior is encouraged by the matra often repeated on BitTorrent websites: leave your download running for a little while after you have got the entire file [8].

## III. P2P Worms

A computer worm is a program that propagates itself over a network, reproducing itself as it goes [10]. Due to its recursive nature, the spread rate of a worm is very huge and poses a big threat on the Internet infrastructure as a whole. The purpose of a worm is to achieve a high infection rate within the targeted hosts (*i.e.* infects the largest number possible of vulnerable machines). Modern worms may control a substantial portion of the Internet within few minutes. No human mediated response is possible to stop an attack that is so fast. The possible devastating effects on the Internet operation are hard to underestimate. It was reported in the FBI/CSI survey, that in 2007 52% of the detected network attacks were viruses' attacks (worms/spyware). Moreover, they caused damages worth the amount of 8,391,800 USD in the United States alone [11]. Besides the traffic generated by the worm propagation is so huge that it can be considered as a DDoS attack on the whole Internet and could be used to bring down the Internet infrastructure of whole countries. Therefore a huge number of researches were carried out in order to conceive proper detection and containment systems. However, there is a new trend of worms that is emerging and which have a huge destruction potential, such worms are called Peer-to-Peer worms. A P2P worm is a worm that exploits the vulnerabilities of a P2P network in order to propagate itself over the network and accelerate its propagation throughout the Internet. P2P worms could be much faster than the old-fashion worms. Furthermore they are expected to be one of the best facilitators of Internet worm propagation due the following reasons: [8] [6] [12] [13] [14]

*i)* P2P systems have a large number of registered active hosts which easily accelerate Internet worm propag ation, as hosts in P2P systems are real and active;

*ii)* some hosts in P2P systems may have vulnerable network and system environments, e.g., home networks;

*iii)* Hosts in P2P systems maintain a certain number of neighbors for routing purposes. Thus, infected hosts in the P2P system can easily propagate the worm to their neighbors, which continue the worm propagation to other hosts and so on.

*iv)* they are often used to transfer large files,

*v)* the programs often execute on user's desktops rather than servers, and hence are more likely to have access to sensitive files such as passwords, credit card numbers, address books…etc

*vi)* The use of the P2P network often entails the transfer of "grey" content (e.g., pornography, pirated music and videos), arguably making the P2P users less inclined to draw attention to any unusual behavior of the system that they perceive.

In order to identify the characteristics of worms, we need to understand how it propagates itself over a network. A typical worm works as follows: it first scans the Internet to find potential victims (*i.e.* information collection). Once it locates a machine the worm tries to probe it by exploiting a common vulnerability, if successful it transfers a copy of its malicious code to the new victim and so on. The key of a successful worm is its propagation speed rather that the vulnerability it exploits. Since current deployed detection and containment systems are capable of blocking the spread of relatively slow worms, a worm should propagate quickly, regardless the vulnerability it is exploiting, in order to achieve a high infection rate. Choosing an efficient scanning strategy enables the worm to reach a large population in a record time.

Based on the scanning strategies of P2P worms, they could be classified into two broad categories: passive worms and active worms (see figure 5). Passive worms are identical to viruses in the sense that they do not search for new victims, they however await them. On the other hand, active worms search for vulnerable targets. Indeed, active worms are more dangerous and propagate faster than passive worms.

### *A Passive worms:*

A passive worm does not spread in an automated fashion. However, it stays dormant on infected machines, waiting for other vulnerable machines to reach it. Once a connection is established between a vulnerable machine and the infected one, the worm duplicates itself on the other end and infects it. This kind of worms can be developed to exploit the vulnerabilities of any Internet application.

### *B. Active worms:*

Active worms propagate by infecting computer systems and by using infected computers to spread the worms in an automated fashion [12]. We can classify P2P active worms into two categories: *Hitlist worms* which attack a network using a pre-constructed list of potential vulnerable machines; and the *topologic worms* which attack a network based on the topologic information found on their victims.

## IV. The Bittorrent Worm

In this section we will explain a novel propagation strategy of a BitTorrent worm and compare it with previous work.

### *A. Background:*

In a previous study [6], Yu et al. presented a propagation scheme for the Topologic P2P worm. In this strategy, after joining the P2P system at the system's initial time, the infected host immediately initiates an attack against its P2P neighbors with its full attack capacity. If extra attack capacity is available, the infected hosts would randomly attack the Internet. This propagation strategy is unfortunately not realistic, since the worm attacks only its neighbors at the initial instant of its infection, and does not seek future neighbors that will connect to it later. Hence, the worm achieves a low infection rate within the P2P system's peers. Furthermore the authors avoided creating cooperation between infected hosts for simplicity. Therefore, victims could be attacked by different infected hosts, and at multiple times during the attack.

### *B Overview:*

The main idea of our novel propagation model is to increase continuously the number of overlay neighbors of infected peers in order to speed up the topologic worm propagation. Our model uses the concept of *"honey pot"*, where an infected peer advertises itself as a seed in a **popular** swarm. Hence, infected hosts will rapidly attract new victims in the popular swarms. A hit-list of popular swarms is shared among infected peers to increase the number of *"honey pots"*, and thus accelerate the propagation.

### *C. The BitTorrent Worm:*

The BitTorrent Worm (BTW) is a Topology aware worm. Accordingly, like the topologic worms, as soon as a new host is infected by the BTW, it starts attacking its overlay neighbors. If extra attack capacity is available, BTW does not just sit around and waits for new peers to fall in its trap, but goes as far as advertising himself in order to attract new peers. BTW is capable of doing so, by joining new crowded swarms and announcing itself as a *seed*. This is possible since the Tracker does not check the integrity if new comers. Once it joined the swarms, new leeches will automatically try to connect to it. Furthermore, unlike the Topologic worm, BTW does not ignore attacking peers whom will later connect to it. Hence, BTW tends to reach a larger population inside in the BitTorrent network.

Another major limitation of the Traditional Topologic worm was the lack of cooperation between its instances, BTW overrides this constraint by enforcing two levels of cooperation on the infected hosts. The first one is on the *swarm* level and the other one is on the BitTorrent network level. The cooperation on the *swarm* level is achieved upon the time of infection. Once an infected host succeeds in infecting a new victim, it passes a list of the peers it scanned to the victim, so the newly infected host does not waste its attack capacity in re-attacking them. As for the cooperation on BitTorrent level, it is achieved as follows: the attacker builds a Hitlist of trackers responsible for the most crowded swarms and then provided it to the initial worm instance. The worm-infected hosts will continuously join the swarms on the list and start attacking their members. Upon the time of infection, the infected host will communicate half of its list to its victim and so on. Once the Trackers Hitlist exhausted the infected hosts would randomly attack the Internet. The Hitlist should be sorted with regards to the population of swarms to boost the initial propagation of the worm. The detailed algorithm is as follows:

*Algorithm 2:*

```
1. P = 0 // list of peers to infect
   C : attack capacity
   Cr = C // remaining attack capacity
   Cu = 0 //used attack capacity
   i = 0 // last index retrieved in tracker Hitlist

 N = 0 //list of neighbors
2. While (true)
       N = new neighbors
     if  (not empty(N))
        Cu = min (Cr , capacity to attack(N))
        P = peers to attack (Cu)
        startAttack(P)
        Cr = C – Cu
        if (i < HT.length AND Cr > 0)
              join swarm at HT(i)
              i = i +1
     if (Cr > 0)
        randomAttack(1)

startAttack(N)
   for each n in N
       if (n is vulnerable and non-infected)
           I passes HT/2 to n
           I passes the list of the nodes it scanned to n
           // so n does not waste its C scanning them again
           Cr = Cr +1
   end
end startAttack(N)

randomAttack (hosts)
   j = 0
   while ( j < hosts.length)
       randomly choose n
       if (n is vulnerable and non-infected)
            I passes the list of the nodes it scanned to n
           Cr = Cr +1
         j = j+1
   End while
end randomAttack (hosts)
```

In figure 2, we illustrate how BTW propagates through BitTorrent. *Leeches* are represented in a red color, while *seeds* are represented in green and *infected hosts* in black. For the sake of simplicity we consider that the attack capacity of the worm is 5. The attack starts as follows: once the malicious code is installed on initial infected machine *I*, *I* starts attacking its neighbors {1, 2, 3, 4}. (We assume in this example that *I* infects its neighbors orderly). At the time of infection, *I* would pass half of its tracker Hitlist to its victim 1, in order to share its workload with 1. Furthermore *I* would also pass its list of scanned hosts to 1, in order to coordinate their efforts. *I* would repeat the procedure upon the infection of its neighbors 4 and 3. In the other hand, since 2 is not vulnerable, *I* cannot infect it. However, since *I* has already scanned it, *I* would still pass its address to its victims so they do not scan it once more. Since *I* has 4 neighbors only, it uses the remaining of its attack capacity in exploiting its *Trackers Hitlist* (*i.e.* announces itself as a *seed* to the *tracker* of the *swarm* #2 on its *Hitlist*).

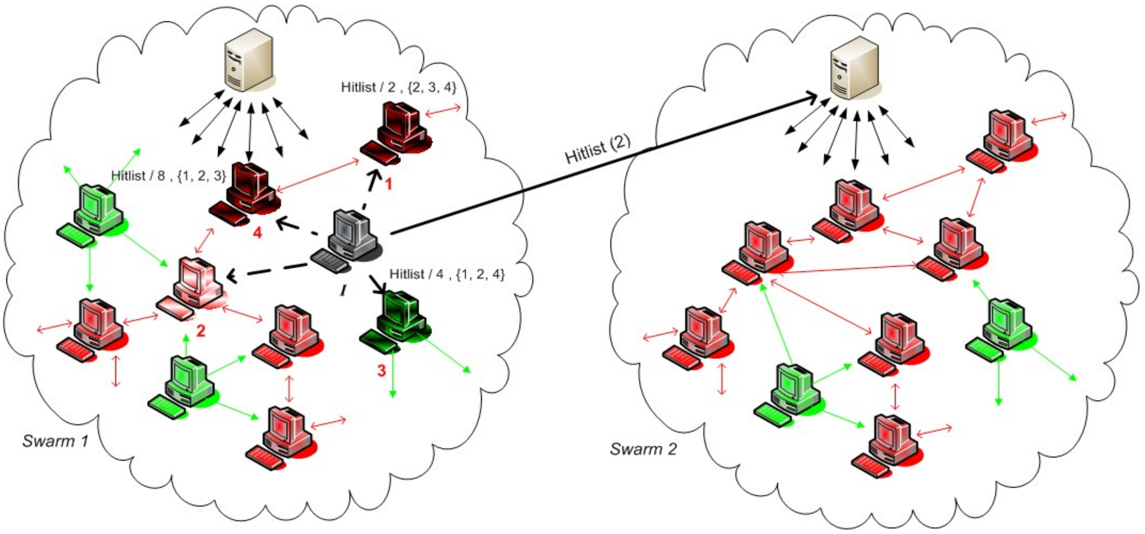

**Figure 2 : BTW attack**

Once *I* advertises itself as a seed in swarm 2, new leeches will automatically try to connect to it. If at instant *t*, a new node connects to *I*, *I* attacks it instantly. Moreover, the previously infected nodes {1, 3, 4} follow the example of *I,* waits for new neighbors, and respectively join swarms from their part of the Hitlist.

## V. Modeling BTW

Modeling worm propagation is very important because it allows us understanding how they evolve; whom they would reach and how long they take to contaminate the network. Moreover, modeling allows us to identify which parameters play a role in their propagation and therefore develop proper and efficient detection and containment mechanisms.

### *A. Parameters*

In order to formally build a model that describes the BTW propagation, we need to identify the different factors play a role in its propagation. After a thorough examination and analysis we identified that the following parameters, which will have an impact on the worm propagation.

*1) Attacker parameters:* The attack capacity of the worm and the system's initial infected worm instances are the most important parameters from the worm attacker perspective. Intuitively, the larger these values are, the faster the propagation is.

*2) P2P system parameters:* For P2P-based systems, the following parameters need to be considered:

*i)* The topology degree of P2P systems: the average nu mber of neighbors connected to each peer.

*ii)* The size of P2P system: defines the number of hosts in a P2P system.

*iii)* The number of peers within a swarm.

*iv)* The vulnerability of P2P systems: measures the vuln erability of P2P hosts. As mentioned before, a host in a P2P system could be used in less protected environments, such as a home environment.

The join and leave rate of BitTorrent peers: defines the number of peers that respectively join and leave BitTo rrent.

*3) The Internet parameters:* these parameters are imposed by the nature of the Internet as well as the presence of detection systems.

The join and leave rate of Internet hosts: defines the number of hosts that respectively join and leave the Internet.

*i)* The average of Internet connection speed.

*ii)* The patch rate, t he rate at which an infected or vulnerable machine becomes invulnerable .

*iii)* The death rate, the rate at which an infection is detected on a machine and eliminated without patching.

### *B. Assumptions*

We assume that the IP system address space is the IP address space of IPv4, thus 2 . In the IPv4 address space, some valid IP addresses are not actively utilized, are non-routable, or are even not applicable to the host (based on previous statistical result [6] , only 24% of available addresses are used by active hosts). We assume that there are two logical systems: a "P2P" system, which represents BitTorrent in the Internet. The other is called "nonP2P" system; it represents the rest of Internet. In both "P2P" system and "nonP2P" system, we assume that a number of hosts are vulnerable. As our analysis considers the average case, we assume that each host in "P2P" or "nonP2P' system has a certain probability to be vulnerable. In this paper, we do not consider the time taken for the infected host to find the vulnerability of victims and assume that the worm infects one victim within one unit time. At the system's initial time, we assume that there are a certain number of infected hosts and infected hosts are already in the "P2P" system. We assume that the join and leave rates are uniform. Furthermore, we assume that the average speed of connection of each peer is 240 kBps [16] , that the size of a BitTorrent packet is 64 kB [15] , and that the number of addresses returned by a tracker upon a request is 50 peers [8].

In table 1, we summarize the different notation used in the description of our model:

TABLE 1:
NOTATIONS IN THIS PAPER

| Parameters | Notations |
|---|---|
| ***T*** | Total IP addresses in the system |
| $S_i$ | Size of “P2P” system at instant *i* |
| $P_v$ | Proportion of vulnerable hosts in the Inte rnet |
| ***C*** | Attack capacity of worm infection host (number of victims being able to be scanned simultaneously) |
| $\lambda_{aP2P}$ | The rate at which a peer joins BitTorrent |
| $\lambda_{lP2P}$ | The rate at which a peer leaves BitTorrent |
| $\lambda_{conn}$ | The number of downloading request r eceived by peer per second. |
| $\lambda_{BTT}$ | The rate at which a peer downloads a Bi tTorrent packet. (i.e. = average connection speed 240 KBps / size of a BitTorrent packet 64KB ) |
| $\lambda_A$ | The rate at which a hosts joins the Internet |
| $\lambda_L$ | The rate at which a hosts leaves the Internet |
| $\lambda_P$ | The rate at which an infected or vulnerable machine becomes invulnerable |
| $\lambda_D$ | The rate at which an infection is detected on a machine and eliminated without patc hing |
| ***V(i,P2P)*** | The number of vulnerable hosts in P2P at the time *i* ( *V* (0, *P2P* ) is the number of vulnerable hosts which can be infected at the system initial time = $S_0$ * $P_v$ ) |
| ***V(i,I)*** | The number of vulnerable hosts in nonP2P at the time *i* ( *V* (0, *I* ) is the number of vulnerable hosts which can be infected at the system initial time = *T* * 0.24 * $P_v$ ) |
| ***I(i,P2P)*** | The number of infected peers in P2P at the time *i* ( *I* (0, *P2P* ) is the number of initial infected hosts in the system.) |
| ***I(i,I)*** | The number of infected peers in nonP2P at the time *i* ( *I* (0, *I* ) is the number of initial infected hosts in the system.) |
| ***I(i,ALL)*** | The total number of infected hosts at the time *i* |
| ***newI(i, P2P)*** | The number of newly infected hosts in P2P added at step *i* ( *newI* (0, *P2P* ) = 0) |
| ***newI(i,I)*** | The number of newly infected hosts in non-P2P added at step *i* ( *newI* (0, *I* ) = 0) |
| ***CacheSize*** | The number of peers a peer can simultaneously upload to. |
| $N_j(i)$ | The number of neighbors , *j* can attack at instant *i* |
| $P_{add}$ | The probability of the address of a peer in BitTorrent is returned by a tracker upon request of resources. |
| $avg_{peers}$ | The average number of peers in a swarm |
| $avg_{leeches}$ | The average number of leeches in a swarm ( $avg_{leeches} = avg_{peers}$ * *0.83 ) [16] |
| ***num*** | The number of peers in a swarm |

*C. Model*

To better understand the characteristics of the BTW spread, we adopt the epidemic dynamic model for disease propagation. In order to make it flexible for analyzing BTW, we use discrete time to conduct recursive analysis and approximate the worm propagation [6] [17]. In what follows, we will calculate the number of infected peers by BTW at instant *i* : *I(i,ALL)*.

***Lemma 1*** **:** The size of BitTorrent evolves as follows:

$$S_{i+1} = S_i * (1 + \lambda_{aP2P} - \lambda_{lP2P}) \tag{1}$$

*Proof* : The size of BitTorrent (1) increments by the number of infected peers which joined BitTorrent at the instant *i* , and decremented by the number of infected peers which left BitTorrent at the instant *i*.

***Lemma 2*** **:** The number of neighbors to scan of each peer in BitTorrent evolves as follows:

```
foreach $I(i+1, P2P)$
    $avg_{leeches} = \frac{V(i,P2P) - I(i,P2P)}{S_i / avg_{peers}}$
    $P_{add} = \frac{50}{avg_{peers}}$
    $\lambda_{conn} = P_{add} * [\lambda_{aP2P} + (avg_{leeches} * \lambda_{BTT})]$
    if ( $C < N_I(i)$ )
        $N_I(i+1) = min(N_I(i) - C + \lambda_{conn}, cache\ size)$
    else
        $N_I(i+1) = min(\lambda_{conn}, cache\ size)$          (2)
```

*Proof* : The number of neighbors $N_I(i+1)$ (2) increases by the number of exchanging request received , and decreases by the number of *peers* the worm scanned at instant *i.* The num ber of neighbors a peer can have in BitTorrent is represented by the size of its uploading\downloading cache (*i.e.* the number of simultaneously maintained connections). The number of downloading request received per second $(\lambda_{conn})$ , is the number of peers which has been redirected by a tracker at instant *i*. In BitTorrent, a *leech* is redirected to another peer upon its request for resources. A *leech* usually asks for resources, when it first joins the swarm, and when it finishes downloading a BitTorrent packet. Hence, $\lambda_{conn}$ is the sum of $\lambda_{aP2P}$ and $avg_{leeches} * \lambda_{BTT}$ multiplied by the probability of being redirected by a tracker upon a request of resources $P_{add}$ .

***Proposition 1*****:** In the ‘P2P’ system, with *V(i,P2P), I(i,P2P),* $S_i$ and $N_I$ ( *i* ) at time *i* , the next tick will have

$$newI(i+1, P2P) = [V(i,P2P) - I(i,P2P)] * \left[1 - \left(1 - \frac{1}{S_i}\right)^{\sum_{j=1}^{I(i,P2P)} \min[N_j(i), C]}\right] \tag{3}$$

*Proof* : The number of newly infected peers in BitTorrent (3): is the number of vulnerable but not infected peers (*i.e.* $[V(i,P2P) - I(i,P2P)]$) by the probability of being scanned by infected peers (*i.e.* $[1 - (1 - 1/T) \wedge \sum_{j=1}^{I(i,P2P)} \min(N_j(i), C)\ ]$ ).

$$I(i+1, P2P) = [I(i,P2P) * (1 - \lambda_{lP2P} - \lambda_P - \lambda_D)] + newI(i+1, P2P) \tag{4}$$

The number of infected peers in BitTorrent (4): is therefore, incremented by the number of newly infected machine in [1], and decremented by the number of patched and detected infected peers, and the number of infected peers which left BitTorrent at the instant *i*.

***Proposition 2*:** In the ‘nonP2P’ system, with *V(i,I), I(i,I)* and $N_I$ ( *i* ) at time *i* , the next tick will have

$$newI(i+1,I) = [V(i,I) - I(i,I)] * \left[1 - \left(1 - \frac{1}{T}\right)^{I(i,ALL)*C - \sum_{j=1}^{I(i,P2P)} \min[N_j(i),C]}\right] \tag{5}$$

*Proof* : The number of newly infected hosts over the Internet and outside BitTorrent (5): is the number of vulnerable but not infected hosts ( *i.e.* $[V(i,I) - I(i,I)]$ ) by the probability of being scanned by infected peers (*i.e.* $[1-(1-1/T)^\wedge I(i,ALL)*C - \sum_{j=1}^{I(i,P2P)} \min(N_j(i),C)]$ ).

$$I(i+1,I) = [I(i,I)*(1-\lambda_L-\lambda_P-\lambda_D)] + newI(i+1,I) \tag{6}$$

The number of infected hosts in the Internet and outside BitTorrent (6): is therefore, incremented by the number of newly infected machine in (5), and decremented by the number of patched and detected infected peers and the number of infected peers which left BitTorrent at the instant *i*.

***Corollary*:** In all the “Internet”, with *I(i,P2P)* and *I(i,I)* at time *i* , the next tick will have

$$I(i+1,ALL) = I(i+1,I) + I(i+1,P2P) \tag{7}$$

The number of infected hosts all over the Internet is (7): the sum of the number of infected peers in BitTorrent (4), and the number of infected hosts outside BitTorrent (6).

## V. Numerical Results

In this section, we evaluate the numerical performance by using models with different parameters for different scenarios. We report the performance results along with observations.

### *A. Simulation Model:*

- *Metrics:* For each of the scenarios, the system attack performance is defined as follows: the time taken *t* (X axis) to infected host number (Y axis). The higher the performance value, the worse is the attack effect.
- *Parameters :* The general system is defined by the tuple: <*A* , *T, C,* $S_0$ , $P_v$ , $\lambda_A$ , $\lambda_L$ , $\lambda_{BTT}$ , $\lambda_P$ , $\lambda_D$ , *I(0,P2P), CacheSize, num* >, representing the system configuration parameters. *A* determines the attack strategy and can be one of < *BTW, Topologic, Random scanning* >. Other parameters are explained in Table 1. As we are only focusing on selected important parameters that are sensitive to BTW, the following parameters are set with constant values ( *T*= $2^{32}$ , *C=6, I(0,P2P) = 5,* $\lambda_{BTT}$ *= 3.75* ) in all our simulations.

### *B. Perfor mance Results:*

In this section, we report the performance results along with observations.

*1) Impact of the attack strategy* : Fig. 3 illu *st* rates the sensitivity of attack performance depend *ing on different attack strateg* ies. The general system is configured as <* , 2, 6 , 1 * *1*, 0.2 , 0.01, 0.01 , 3.75 , 0.00002 , 0.00002 , 5 , 30 , 2000>. We notice that the BTW attack strategy outperforms the tradition *al* Top *ogic at tack str ategy* as well as t *rando* m scanning attack strategy . For example, in the worm fast propagation phase (linear increase – from simulation time 40 to 85), the BTW approach can achieve 300% performance increase over the Topologic attack strategy. The result matches our expectation: achieving a higher infection rate in the P2P system significantly improves the attack performance. From the defense perspective, the BTW attack will be a very challenging issue.

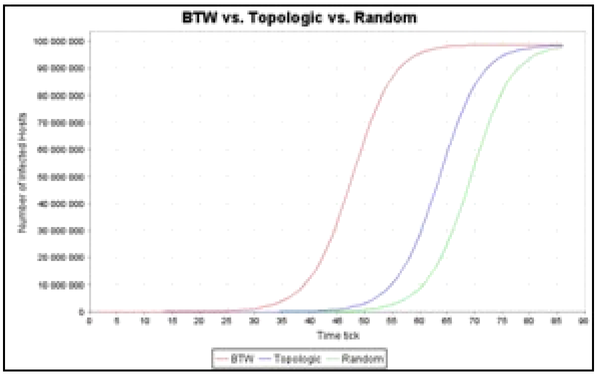

Figure 3. Perormance comparison ofAll Attack St rat egies

*2) The impact of P2P System Size:* Fig. 4 illustrates the sensitivity of BTW performance under different sizes of BitTorrent network. The general system is configured as <BTW, 2, 6, *, 0.2, 0.01, 0.01, 3.75, 0.00002, 0.00002, 5, 30, 2000>. In this figure, the size of BitTorrent varies in $S_0${2* 1, 4* 1, 1* 1}. We notice that increase of BitTorrent network size enhances the attack performance. The result matches previous observations [6] [18]: the larger is the size of the P2P system, the higher is the achieved scan hit probability.

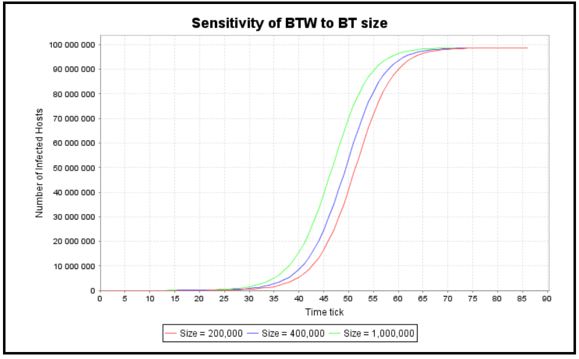

**Figure 4: The Sensitivity of BTW to BitTorrent Size**

*3) The impact of P2P Topology Degree:* Fig. 5 illustrates the sensitivity of BTW performance within the P2P system for different BitTorrent topology degrees. This is represented by the limit of topologic neighbors a peer can have (i.e. cache size).The general system is configured as <BTW, 2, 6, 1* 1, 0.2, 0.01, 0.01, 3.75, 0.00002, 0.00002, 5, *, 2000>. In this figure, the Y axis represents the number of infected peers in BitTorrent. We notice that an increase in topology degree achieves better attack performance. This matches our expectation; a larger topology degree makes more P2P hosts open to BTW and speeds up the worm propagation.

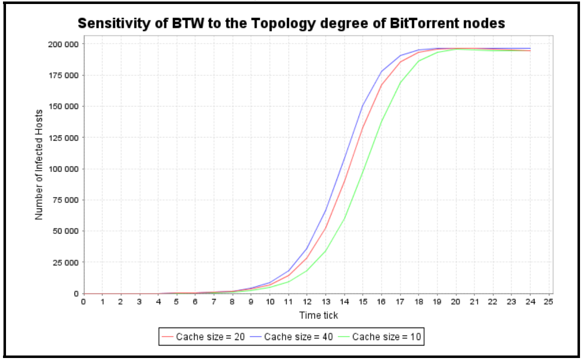

**Figure 5: The Sensitivity of BTW to the Topology degree of BitTorrent nodes**

## VI. CONCLUSION

In this paper we analyzed the impact of a novel worm propagation model on BitTorrent. BitTorrent is particularly vulnerable to topology aware active worms. Topology aware worms use the topologic information hold by their victims to find new victims. Such worms are capable of quickly flooding the Internet while escaping current deployed intrusion detection systems. Moreover, in order to boost its initial propagation the worm uses a trackers' hitlist consisting of the most crowded swarms. This mechanism allows the worm to find newer victims even faster than traditional scanning worms. This combination of both scanning strategies is fatal, because it provides the worm with certainty discretion and speed. Our analysis of this propagation scheme shows that it can achieve a 300% increase in its propagation speed in comparison with traditional scanning worms. W e developed a mathematical model to describe this new propagation strategy, and provided numerical analysis results. We believe that our work provides important guidelines for P2P system design and control that address the concerns of active worms and to develop efficient containment and intrusion detection systems.

***Abstract*—To ensure that safeguards are implemented to protect against a majority of known threats, industry leaders are requiring information processing systems to comply with security standards. The National Institute of Standards and Technology Federal Information Risk Management Framework (RMF) and the associated suite of guidance documents describe the minimum security requirements (controls) for non-national-security federal information systems mandated by the Federal Information Security Management Act (FISMA), enacted into law on December 17, 2002, as Title III of the E-Government Act of 2002. The subjective compliance assessment approach described in the RMF guidance, though thorough and repeatable, lacks the clarity of a standard quantitative metric to describe for an information system the level of compliance with the FISMA-required standard. Given subjective RMF assessment data, this article suggests the use of Pathfinder networks to generate a quantitative metric suitable to measure, manage, and track the status of information system compliance with FISMA.**

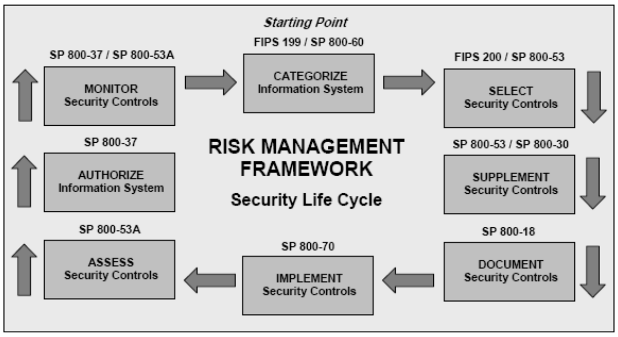

Fig. 1. Risk Management Framework (From [3])

## I. Introduction

TO ENSURE that safeguards are implemented to protect against a majority of known threats, industry leaders are requiring that information processing systems comply with specific security standards. The Federal Information Security Management Act (FISMA) enacted into law on December 17, 2002, as Title III of the E-Government Act of 2002 [1] defined three security objectives for federal government information systems: (1) Confidentiality, to preserve authorized restrictions on access and disclosure, with means for protecting personal privacy and proprietary information; (2) Integrity, to guard against improper information modification or destruction while ensuring information nonrepudiation and authenticity; and (3) Availability, to ensure timely and reliable access to and use of information [2]. To achieve these security objectives, FISMA tasked the National Institute of Standards and Technology (NIST) to develop a set of standards and guidelines, the Federal Information Risk Management Framework (RMF) (Fig. 1), that (1) describe categories for information systems according to risk levels (low, moderate, high), (2) identify types of information systems to be included in each category, and (3) describe a minimum set of security requirements (controls) that must be applied to systems in each category to achieve adequate security [4], [5], [1]. Adequate security is defined by Office of Management and Budget (OMB) Circular A-130 as “security commensurate with the risk and magnitude of harm resulting from the loss, misuse, or unauthorized access to or modification of information” [6]. FISMA also requires an annual assessment of information system compliance with the required standard [7]. With approximately 100 security controls in the low-impact category to over 300 security controls in the high-impact category, the subjective compliance assessment approach described in the RMF guidance, though thorough and repeatable, lacks the clarity of a standard quantitative metric to describe for an information system the level of compliance with the standard. Given the review process outlined by NIST RMF documents, the challenge is to provide a quantitative risk analysis metric adequate to (1) clearly describe the status of compliance with the FISMA-required standard, (2) track progress toward compliance with the FISMA-required standard, (3) direct the allocation of resources required to meet FISMA minimum requirements, and (4) simplify annual report preparation. The authors propose generating a quantitative risk analysis metric at the information system level, using Pathfinder networks (PFNETs), to measure, manage, and track the status of system security compliance with the FISMA-required standard.

Approved for public release; distribution is unlimited.

## II. The RMF

### A. Purpose

The RMF, shown in Fig. 1, describes the steps and related standards and guidelines for implementing the minimum set of controls required to provide adequate security for an information system and the associated information stored, processed, and transmitted by that system. The framework includes guidance for assuring that controls are properly implemented and operating as intended to provide the expected security benefit. The RMF emphasizes the idea that risk management is a continuous process [8], [5].

### B. Federal Information Processing Standard 199

Federal Information Processing Standard (FIPS) 199 [4] addresses the first two FISMA mandates, the definition of information system categories according to risk level and the identification of system types to include in each category. FIPS 199 defines three categories for information systems considering the potential impact to organizations and individuals should a breach of confidentiality, integrity, or availability occur: (1) Low, limited adverse effect, (2) Moderate, serious adverse effect, and (3) High, severe or catastrophic adverse effect. FIPS 199 applies to all federal information systems except those designated as national security as defined in 44 United States Code Section 3542(b)(2).

### C. FIPS 200

FIPS 200 [9] addresses the third FISMA mandate, to develop minimum information security requirements (controls) for information systems in each category as defined by FIPS 199. FIPS 200 went into effect when published, March 2006. Federal agencies are required to be in compliance with the standard no later than 1 year from its effective date. There is no provision under FISMA for waivers to FIPS 200.

### D. FISMA-required System Controls

As required by FIPS 200, NIST Special Publication (SP) 800-53, Recommended Security Controls for Federal Information Systems [3], defines the security controls and provides guidelines for selecting the appropriate set to satisfy the minimum requirement for adequate security given a system category of low, moderate, or high impact. The control sets described in FIPS 200 cover 17 security-related areas (families). As illustrated in Table I, the 17 security control families are organized into three classes – management, operational, and technical – to facilitate the selection and specification of controls when evaluating an information system. Two-character identifiers are assigned to each control family. A number is appended to the family identifier to uniquely identify controls within each family. Appendix D of SP 800-53 identifies three minimum sets (baselines) of security controls that correspond to the low-, moderate-, and high-impact information system categories defined in FIPS 199. Appendix F of SP 800-53 provides a detailed description of each security control and numbered enhancements for each control where applicable. As illustrated in Table II, controls in the Access Control family not used in a particular baseline are marked Not Selected. The numbers in parentheses following the control identifiers indicate the control enhancement that applies. The baselines are intended to be broadly applicable starting points and may require modification to achieve adequate risk mitigation for a given system [3]. Given the repeatable review process outlined by the NIST RMF documents, the challenge is to provide a quantitative risk analysis metric adequate to (1) clearly describe the status of compliance with the FISMA-required standard, (2) track progress toward compliance with the FISMA-required standard, (3) direct the allocation of resources required to meet FISMA minimum requirements, and (4) simplify annual report preparation. The authors propose generating a quantitative risk analysis metric at the information system level, using PFNETs, to measure, manage, and track the status of system security compliance with the FISMA-required standard.

## III. Compliance Measurement Using PFNETS

PFNETs are the result of an effort by Dearholt and Schvaneveldt [10] to develop network models for proximity data [11]. Proximity refers to the measure of relationship (similarity, relatedness, dissimilarity, distance, etc.) between two entities [10]. In networks, proximity measures are represented by distance, with small values representing similarity or a high level of relatedness, and large values representing dissimilarity or a low level of relatedness [10]. Given a dissimilarity matrix resulting from the subjective categorization (mapping) of entities as defined by Dearholt and Schvaneveldt [10], application of the Pathfinder algorithm generates a unique quantitative network representation of the proximity data. Any change in the subjective categorization of entities—in the case of risk analysis, vulnerabilities to threats—changes the resulting network. Our research indicates that the Pathfinder technique may be suitable for generating quantitative network models

of information security standard controls—more accurately, the lack thereof—and information system security controls for comparison using a correlation coefficient ($cc$) formula to determine the status of information system compliance with a specified standard (%*compliant*). Among the successful applications of PFNETs have been in the discovery of salient links between documents to facilitate three-dimensional virtual reality modeling of document relationships [12], in author co-citation analysis to reveal salient linkages between groups of related authors to produce interactive author maps in real-time [13], and in the requirements phase of software development projects to determine stakeholder (users, sponsors, project managers, and developers) understanding/misunderstanding of specified requirements [14]. At a high level, the building of a PFNET involves the following steps [14]:

1) Correlate entities (e.g., vulnerabilities to threats) in an $n \times n$ matrix.
2) Build entity co-occurrence groups from entity correlations.
3) Build similarity matrix from co-occurrence groups.
4) Build dissimilarity matrix from similarity matrix.
5) Apply Pathfinder algorithm to dissimilarity matrix to build PFNET.
6) Build minimum distance matrix from PFNET.
7) Assuming steps 1 through 6 are followed to build two models of the same data entities as perceived by two different stakeholders, use a $cc$ formula to determine the degree of covariance (similarity) between the two models—quantitatively measure the similarity between two perceptions of the relationship between the same set of data entities.

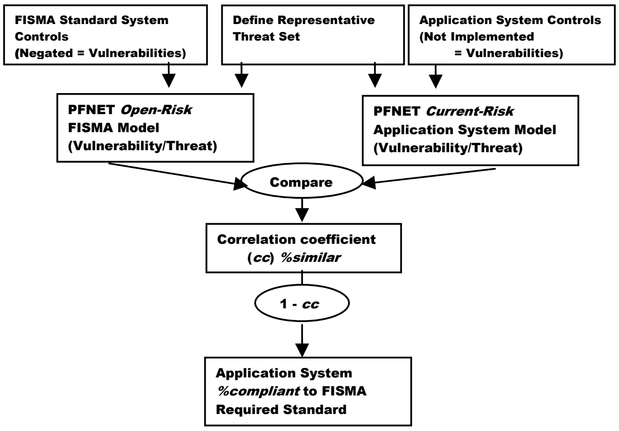
As illustrated in Fig. 2, to generate the proposed %*compliant* metric, the researcher must

- Define a representative threat set where the threat level of detail is dependent on the stakeholder (e.g., system security analyst or FISMA security certifier) requirements.
- Build an *open-risk* PFNET model of the FISMA-required standard security controls. Controls when negated become vulnerabilities. Map all vulnerabilities to threat set. Complete the Pathfinder procedure.
- Build a *current-risk* PFNET model of the information system being evaluated. Map system current vulnerabilities to the threat set—mapping defined by the open-risk model (the standard). Complete the Pathfinder procedure.
- Generate current- and open-risk minimum-distance matrices from the PFNETs generated. Compare the minimum-distance matrices using a $cc$ formula to generate overall %*similar* measures for the models as well as detailed %*similar* measures for each entity within the models.
- Subtract the overall $cc$ %*similar* to open-risk measure from 1 to generate the %*compliant* to *closed-risk* (no vulnerabilities) measure.

Assuming we are evaluating a Financial Management System (FMS) that is web-enabled, intranet accessible, and categorized as moderate impact using the NIST criteria, an example using the Pathfinder technique follows.

### A. Define Representative Threat Set

Table III is a sample list of threats associated with operating the FMS application. The threat categories are taken directly or derived from Ozier [15], Bishop [16], and the Federal Information System Controls Audit Manual (FISCAM) [17].



FISMA Standard System Controls (Negated = Vulnerabilities)
Define Representative Threat Set

PFNET *Open-Risk* FISMA Model (Vulnerability/Threat)
PFNET *Current-Risk* Application System Model (Vulnerability/Threat)
Compare
Correlation coefficient (*cc*) *%similar*
1 - *cc*
Application System *%compliant* to FISMA Required Standard

Fig. 2. Compliance Measurement Using Pathfinder

### B. Build open-risk PFNET Model

Table IV contains a subset of the FISMA-required baseline controls for a moderate-impact system. In Table V, the controls from Table IV are negated to create the vulnerability set for this example. To build the open-risk model (open standard) for evaluating the FMS system, we assume all 20 vulnerabilities (low-level categories) exist by mapping/relating them to the 9 threats (high-level categories) identified in Table III. Vulnerabilities may be mapped to more than one threat. This exercise may be done manually, but could become very tedious as the number of vulnerabilities and threats increases. For this example, a web-based categorization tool written by Kudikyala [18] was used to relate the vulnerabilities to threats resulting in the co-occurrence groups shown in Table VI.

The categorization tool [18] automatically builds an $n \times n$ similarity matrix of distinct entities categorized. For this example, $n$ is the sum of 9 threats and 20 vulnerabilities resulting in a $29 \times 29$ similarity matrix for the open-risk co-occurrence groups. Similarity matrix entries reflect the number of times grouped entities co-occur. For the standard open-risk co-occurrence groups, shown in Table VI, V8 and V4 co-occur 4 times. In the open-risk similarity matrix, the co-occurrence count at entries (V8, V4) and (V4, V8) would be 4.

Higher co-occurrence counts indicate greater similarity. The categorization tool [18] automatically builds a dissimilarity matrix from the similarity matrix of categorized entities. The vulnerability-to-threat relationships in this example are symmetric. Therefore an open-risk dissimilarity matrix (upper triangular portion only) is generated from the open-risk similarity matrix by subtracting each co-occurrence count entry from the maximum co-occurrence count entry plus one to prevent 0-value dissimilarity matrix entries. Lower co-occurrence counts indicate greater similarity.

A Unix-based PFNET generation tool, written by Kurup [19] applying the Dearholt and Schvaneveldt algorithm, was used to generate the open-risk PFNET from the dissimilarity matrix. The tool requires as input the number of nodes ($n = 29$), the upper triangular portion of the dissimilarity matrix, an $r$-metric ($\infty$, input as $-1$), and a $q$ parameter ($n - 1 = 28$). A path will exist between node pair $(i, j)$ in PFNET $(r, q)$ if and only if there is no shorter alternate path between $(i, j)$, where $r$ is the Minkowski $r$-metric calculation of path weight, for paths with number of links $\leq q$.

The distance between two nodes not directly linked is computed using the Minkowski $r$-metric. For path $P$ with weights $w_1, w_2, \ldots, w_k$, the Minkowski distance is [10], [14]

$$w(P) = \left( \sum_{i=1}^{k} w_i^r \right)^{1/r} \qquad \text{where } r \geq 1, w_i \geq 0 \text{ for all } i. \quad (1)$$

When $r = 1$, path weight is calculated by summing the link weights along the path [10], [14]. Calculating path weight this way assumes ratio-scale data where each weight value is presumed to be within a multiplicative constant of the "correct" value [10]. When link values are obtained from empirical data, computing path weight this way may not be justifiable [20]. For generating PFNETs, where only the ordinal relationships between link weights and path weights are important, $r$ should be set to $\infty$ [10]. When $r = \infty$, the path weight is the same as the maximum weight associated with any link along the path [10], [14].

The PFNET generated from the open-risk dissimilarity matrix is a mathematical model of standard open risk.

### C. Build current-risk PFNET Model

Assume these vulnerabilities exist in the FMS system: V4, V6, V7, V8, V9, V10, V11, V12, V13, V14, V15, V16, V17, V18, V19, and V20 (see Table V). To build the current-risk PFNET model, map the FMS vulnerabilities to threats as dictated by the vulnerability mappings in the open-risk standard model to generate the co-occurrence groups shown in Table VII under "FMS System Current Risk." (Note: the Standard Open Risk and FMS System Current Risk co-occurrence groups in Table VII are the initial entries in Table VIII.)

TABLE VII
CO-OCCURRENCE GROUPS

| Standard Open Risk | FMS System Current Risk |
|---|---|
| (T1, V1) | |
| (T2, V1) | |
| (T3, V2) | |
| (T4, V2) | |
| (T5, V18, V17, V10, V8, V4, V3, V1) | (T5, V18, V17, V10, V8, V4) |
| (T6, V18, V10, V8, V4, V3, V1) | (T6, V18, V10, V8, V4) |
| (T7, V20, V19, V10, V8, V4, V3, V1) | (T7, V20, V19, V10, V8, V4) |
| (T8, V15, V14, V13, V12, V3, V1) | (T8, V15, V14, V13, V12) |
| (T9, V16, V11, V9, V8, V7, V6, V5, V4) | (T9, V16, V11, V9, V8, V7, V6, V4) |

Using the procedure described in Section III-B

- A similarity matrix is generated from the FMS system current-risk co-occurrence groups.
- A dissimilarity matrix is generated from the similarity matrix.
- The PFNET algorithm is applied to the dissimilarity matrix to generate the current-risk PFNET model.

The PFNET generated from the current-risk dissimilarity matrix is a mathematical model of the FMS system current risk.

### D. Compare Minimum Distance Matrices

A Unix-based PFNET correlation tool, written by Kudikyala [21], was used to generate minimum distance matrices from the standard open-risk and FMS system current-risk PFNETs using Floyd's algorithm for shortest path [22]. Path distances for the minimum distance matrices are calculated the traditional way, by adding link weights along paths between nodes. The correlation tool was also used to compare the open- and current-risk minimum distance matrices using the $cc$ formula that follows:

$$cc = \frac{\sum (a - \bar{a})(b - \bar{b})}{\sqrt{\sum (a - \bar{a})^2 \sum (b - \bar{b})^2}} \qquad (2)$$

where $a$ is the value of an element in the distance vector of the open-risk minimum distance matrix, $\bar{a}$ is the mean of all the elements in the open-risk distance vector (upper or lower triangular values), $b$ is the value of a corresponding element in the distance vector of the system current-risk minimum distance matrix, and $\bar{b}$ is the mean of all elements in the current-risk distance vector. Normally the $cc$ range is $[-1, +1]$, where $-1$ represents no similarity and $+1$ represents perfect

TABLE VIII
RISK MODEL CO-OCCURRENCE GROUPS

similarity between models [14], [23]. Because of the approach taken in this research to compare current system state to a standard perception of adequate security, the $cc$ range is narrowed from $[-1, +1]$ to $[0, +1]$—no comparison beyond a perfect match.

### *E. Generate %*compliant *Measure*

The correlation tool [21] generates an overall $cc$ value that indicates the degree of covariance (similarity) between the standard open-risk model and the system current-risk model – similarity to unacceptable risk; all vulnerabilities exist. The goal for the FMS system is a $cc$ of $0$, i.e., no similarity to the open-risk model. Subtracting the overall $cc$ value from $1$ yields a value (%*compliant*) that indicates how close the FMS system is to standard compliance as defined by the closed-risk model—no vulnerabilities exist. Comparing the FMS system current-risk model 1 to the open-risk model results in a $cc$ of $0.45$ (see Table IX,“Overall Path Distance $cc$” for FMS 1). The FMS 1 current-risk model in this example exhibits $45$ percent similarity to the open-risk model. Subtracting $0.45$ from $1.0$ (open-risk) yields a value that indicates the FMS system is $55$ percent compliant to closed-risk (see Table IX “%*compliant*” for FMS 1). The more existing vulnerabilities identified in the FMS system, the closer the resulting $cc$ value will be to $1.0$ (open-risk). As vulnerabilities are removed, the $cc$ value moves closer to $0.0$ (closed-risk). Table VIII shows sample FMS risk model co-occurrence groups. The vulnerabilities in bold type are removed in each successive FMS model. For each FMS model, the Pathfinder procedure was applied to generate a minimum distance matrix for comparison with the open-risk model minimum distance matrix. Table IX shows the overall path distance $cc$, node path distance (detailed) $cc$, and %*compliant* values for the FMS models as vulnerabilities are removed and the FMS models are compared with the open-risk model.

Using the distance vectors for each entity in the minimum distance matrices for the open- and current-risk models, detailed $cc$ values are generated that indicate how a single entity in each model relates to all others—how a single entity contributes to the similarity between models. An analysis of the detailed $cc$ values for models compared should provide some insight with regard to choosing an efficient mitigation path to reaching compliance with standard.

## IV. CONCLUSION

Technical Topic Area 3 (TTA 3), Cyber Security Metrics, of the Department of Homeland Security Broad Agency Announcement (BAA), Cyber Security Research and Development (BAA07-09) [24], describes security metrics as “a difficult, long-standing problem.” TTA 3 cites the fact that the security metrics problem is listed on the INFOSEC Research Council (IRC) Hard Problems List [25] as evidence of the importance of research in this area. Good security metrics are required to direct the allocation of security resources to improve the security status of government information systems, to demonstrate compliance with FISMA-required

security control standards, and to simplify the annual FISMA reporting requirement. TTA 3 advises that "the lack of sound and practical security metrics is severely hampering progress both in research and engineering of secure systems" [24].

The proposed approach is unique in that it offers a %*compliant* metric at the information system level. The proposed approach in combination with NIST RMF guidance provides for producing consistent quantitative results. Detailed $cc$ values should indicate vulnerability groups where targeted cost benefit analysis may be applied to determine an effective approach for eliminating vulnerabilities contributing most to the noncompliant state of the system being evaluated. The quantitative %*compliant* metric should allow for the discussion of system compliance with FISMA-required standards in terms easily understood by participants at various levels of an organization without requiring all to have detailed knowledge of the internals of the security standard or the system being evaluated.

***Abstract*—Usually, Intrusion Detection Systems (IDS) work using two methods of identification of attacks: by signatures that are specific defined elements of the network traffic possible to identification and by anomalies being some deviations form of the network behavior assumed as normal. In the both cases one must pre-define the form of the signature (in the first case) and the network's normal behavior (in the second one). In this paper we propose application of Neural Networks (NN) as a tool for application in IDS. Such a method makes possible utilization of the NN learning property to discover new attacks, so (after the training phase) we need not deliver attacks' definitions to the IDS. In the paper, we study usability of several NN architectures to find the most suitable for the IDS application purposes.**

## I.INTRODUCTION

BECAUSE of their generalization feature, neural networks are able to work with imprecise and incomplete data. It means that they can recognize also patterns not presented during a learning phase. That is why the neural networks could be a good solution for detection of a well-known attack, which has been modified by an aggressor in order to pass through the firewall system. In that case, traditional Intrusion Detection Systems, based on the signatures of attacks or expert rules, may not be able to detect the new version of this attack.

In this paper, we focus on three different network architectures: Backpropagation, Radial Basis Function and Self Organizing Map. The result of simulation is the information about the attack detection accuracy, represented as a number of false attacks and not detected attacks in comparison to number of validation vectors for each type of used NN. Performed tests allow us to find drawback of usage of each type of architectures for detection a specific type of the attack. As the input vector, we used data produced by the KDD99 project.

## II.NEURAL NETWORK: A WAY OF WORK

An artificial neural network is a system simulating a work of the neurons in the human brain. In Fig. 1 it is presented the diagram of a neuron's operation.

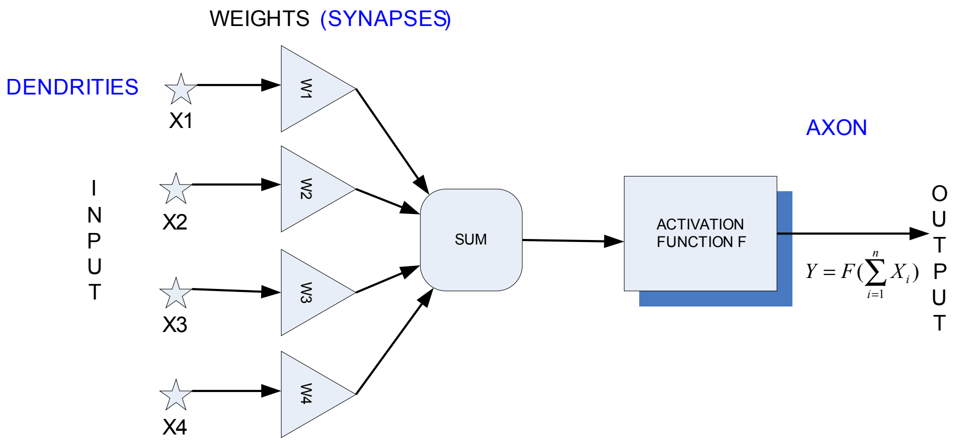

Fig. 1. A scheme of an artificial neuron

This is the work in progress

The neuron consists of some inputs emulating dendrites of the biological neuron, a summation module, an activation function and one output emulating an axon of the biological neuron. The importance of a particular input can be intensified by the weights that simulate biological neuron's synapses. Then, the input signals are multiplied by the values of weights and next the results are added in the summation block. The sum is sent to the activation block where is pro cessed by the activation function. Thus, we obtained neuron's answer for the input signals "x".

### *A. MLP (Multi Layer Perceptron)*

One neuron cannot solve a complex problem that is why the neural network consisted of many neurons is used. One of the most often used architecture is the Multi Layer Perceptron. In such a network, all neurons' outputs of the previous layer are connected with neurons' inputs of the next layer. The MLP architecture consists of one or more hidden layers. A signal is transmitted in the one direction from the input to the output and therefore this architecture is called feedforward. The MLP networks are learned with using the Backward Propagation algorithm (BP). In order to reach better efficient and speed of learning process it arise many types of BP algorithm. In our research we used following variants of the BP algorithm:

- Batch Gradient descent (traingd)
- Batch Gradient descent with momentum (traingdm)
- Levenberg-Marquardt (trainln)
- Resilient Backpropagation (trainrp)
- Conjugate Gradient (traincgf)
- Quasi Newton (trainbfg)
- Quasi Newton 2 (trainoss)

For the simulation procedure, the Matlab toolbox was used. The variants of BP algorithm are followed by the names of the learning Matlab's functions in the bracket.

### *B. Radial Based Function (RBF) Neural Network*

The radial neuron networks in comparison to the MLP where a global approximation is used are working based on the local approximation.

Typically have three layers: an input layer, a hidden layer with a non-linear RBF activation function φ and a linear output layer.

Activation function for the radial neuron network is:

$$\varphi(x) = \exp\left(\frac{\|x - c_i\|^2}{2\sigma_i^2}\right),$$

where C- Center of the function $\sigma$ Spread parameter of the radial function

The argument of radial function φ is the Euclidean distance sample x from center c.

In the RBF network, there are three types of parameters that need to be chosen to adapt the network for a particular task: the center vectors $c_i$ , the output weights $w_i$ , and the RBF spread parameter $\beta_i$.

### *C. SOM (Self Organizing Maps)*

This kind of network is learned without teacher based on the competition rules. On the input of such network learning vector is put and in the next step distance from it to the weight vector is checked. Neuron for its distance is lowest becomes the winner and can modify values of his weights. Depends of the SOM networks architecture the weighs of the winner neuron can be modified (Winner Takes all) or weigh of the winner and neurons from his neighbor (Winner Takes most).

More information about neural network could be found in [2], [7].

## III. KDD99 Input Data

We are using the KDD 99 data set as the input vectors for training and validation of the tested neural network. It was created based on the DARPA (Defense Advanced Research Project Agency) intrusion detection evaluation program. MIT Lincoln Lab that participates in this program has set up simulation of typical LAN network in order to acquire raw TCP dump data [1]. They simulated LAN operated as an normal environment, which was infected by various types of attacks. The raw data set was processed into connection records. For each connection, 41 various features were extracted. Each connection was labeled as normal or under specific type of attack. Four main categories of attacks were simulated:

- **DoS** (Denial of Service): an attacker tries to prevent legitimate users from using a service e.g. TCP SYN Flood, Smurf .
- **Probe:** an attacker tries to find information about the target host. For example: scanning victims in order to get knowledge about available services, using Operating System etc.
- **U2R** (User to Root): an attacker has local account on victim's host and tries to gain the root privileges.
- **R2L** (Remote to Local): an attacker does not have local account on the victim host and try to obtain it.

The KDD data sets are divided into tree subsets: 10%KDD, corrected KDD, whole KDD. Basis characteristic of KDD data sets are shown in Table I. It includes number of

Table I.
KDD99 data subsets

| Dataset | DoS | Probe | U2r | U2l | Normal |
|---|---|---|---|---|---|
| 10%KDD | 391458 | 4107 | 52 | 1126 | 97277 |
| Corrected KDD | 229853 | 4166 | 70 | 16347 | 60593 |
| Whole KDD | 3883370 | 41102 | 52 | 1126 | 972780 |

TABLE II.
DATA SUBSETS FOR TRAINING PROCESS

| Data Set name for training process | Number of normal connection | Number of connection labelled as attack . |
|---|---|---|
| Learn_set | 1000 | 8653 |
| Learn_set_radial_trad | 100 | 1179 |
| Learn_set_radial | 1000 | 1179 |

connections assigned to the particular class (DoS, Probe etc.)..

### A. 10%KDD

The 10%KDD data set is used for the training process of the IDS. It includes connections simulated following 22 types of the attacks: back, buffer_overflow, ftp_write, guess_passwd, imap, ipsweep, land, loadmodule, multihop, neptune, nmap, normal, perl, phf, pod, portsweep, rootkit, satan, smurf, spy, teardrop. The attacks are not represented by the same number of connections. The most of the simulated attacks are of DoS group because of the nature of this type attacks that are using many IP packets in order to block network services.

### B. Corrected KDD

The Corrected KDD data set is used for testing process of IDS. It includes additional 14 types of new attack not presented in 10%KDD and Whole KDD. Thanks to them it is possible to check if tested IDS is able to detect new attack not presented in the training phase.

In our research only 10 %KDD and corrected KDD data set was used.

## IV. TRAINING PROCESS

### A. Process of Selection of the Input Vector

The data set 10% KDD includes the large number of connection. It is influence on the long time of training, high requirements for efficient of using implementation of neural network and hardware on that it is working. That's why in research presented in this publication for training purpose three randomly selected small date set was used. Table II shows how many connections are assigned to the particular training data set.

It was chosen the same number of connections represent each type of attack. In case when number of connections for particular type of attack was lower than assumed number all connections for this group was selected. Because some features of connection (e.g. protocol, flags) were existed as a characters string, it was transformed to numerical representation.

Moreover, for the SOM neural network normalization process of the input data "xi" was performed.

$$x_i^{'} = \frac{x_i}{\sqrt{\sum_{i=1}^{n} x_i^2}} \ .$$

For Radial Neuron network it was noticed that the best results are obtained when the value of features is decreased by dividing it by constant number equal 1000.

For the research purpose three type of neural network architectures were used: MLP (multilayer perceptron), RBF (Radial Basis Function), SOM (Self Organizing Maps).

***Main Assumption for Training Process of MLP***

Number of Epochs = 1000.
MSE (Mean Square error) = 0.01.
Learning rate =1.
Momentum = 0.6.
Activation function =log-signoid.
Number of neurons in hidden layer=5.
Number of neurons in output layer =1.
Updates of weighs – batch mode (after presentation of entire training data set).

Results of the training process show that only the algorithms: **Levenberg-Marquardt and Quasi Newton** achieved to fulfill the above assumption. In other case MLP network cannot reach assumed MSE =0.1 in 1000 Epochs of training process. That is why in the next simulation we focus only on networks that can be trained according our assumptions.

### B. For RBF Network

Implementation from Matlab toolbox was used (newrb**).** At the beginning, a network without radial neurons in the first layer is created. In the next step, the MSE is calculated and a new radial neuron with weighs equals to input vector that caused the max value of MSE is added to the first layer. The last operation is modification of weights of a lineal neuron in the output layer in direction of minimize MSE. All steps are repeated until the assumed MSE is reached.

***Main Assumption for Training Process***

MSE=0.1(because of high calculation power requirements not possible to achieve MSE =0.01 like for MLP)
Spread parameter $\sigma$ = 3
MN (Maximum number of neurons) = 250
DF (Number of neurons to add between displays) = 2
MNE (Number of neurons for that RBF achieved MSE =0.1) = 178
Number of Epochs = 178

### C. For SOM Network

***Main Assumption for Training Process***

Implementation of SOM in Matlab environment was used (function newsom).
Number of Epochs = 1000.
Neighbors topology= hextop
Distance function – mean as a number of links between neurons or steps that must be taken to get neuron under consideration = matlab linkdist.
Ordering Phase learning rate =0.9.

TABLE III.
THE DATA SUBSET FOR TESTING PHASE

| Data Set name for testing process | Number of normal connection | Number of connection labelled as attack . |
|---|---|---|
| Test_set | 60593 | 250436 |
| Test_set_noanomaly | 60593 | 231694 |

TABLE IV.
COMPARISON OF DIFFERENT NETWORK TOPOLOGY TRAINED WITH "LEARN_SET_RADIAL_TRAD" DATA SET

| Neural Network topology | False alarm Number/ Percent of all normal connection | Not detected/ Detection rate | Duration of training |
|---|---|---|---|
| **MLP** learning algorithm<br>**Levenberg-Marquardt** | 31594<br>52% | 382<br>98,5% | About 4 seconds |

| **Radial** | 21938<br>36% | 61568<br>76% | About 2 minutes 20 seconds |
| **SOM** | 19677<br>32% | 40957<br>84% | About 7 minutes |

TABLE V.
RESULTS OF SIMULATION OF MLP NETWORK LEARNED WITH USAGE INPUT DATE SET „LEARN_SET" AND „LEARN_SET_RADIAL"

| Variations of BP algorithm used for training MLP Network | False alarm Number/ Percent of all normal connection | Detection rate |
|---|---|---|
| **MLP** learning algorithm Levenberg-Marquardt<br>**Input data set:** Learn_set, Test_set | 5354<br>8,8% | 19207<br>92% |
| **MLP** learning algorithm Levenberg-Marquardt<br>**Input data set:** Learn_set, Test_noanomaly | 5351<br>8,9% | 4097<br>98% |
| **MLP** learning algorithm Levenberg-Marquardt<br>**Input data set:** Learn_set_radial, Test_set | 10068<br>16,6% | 17139<br>93% |
| **MLP** learning algorithm Quasi Newton<br>**Input data set:** Learn_set, Test_set | 4790<br>7,9% | 10294<br>94% |
| **MLP** learning algorithm Quasi Newton<br>**Input data set:** Learn_set, Test_set_noanomaly | 4790<br>7,9% | 87<br>99,9% |
| **MLP** learning algorithm Quasi Newton<br>**Input data set:** Learn_set_radial, Test_set | 31894<br>52% | 1556<br>99% |
| **MLP** learning algorithm Resilient Backpropagation<br>**Input data set:** Learn_set, Test_set | 4453<br>7,3% | 12877<br>95% |
| **MLP** learning algorithm Resilient Backpropagation<br>**Input data set:** Learn_set, Test_set_noanomaly | 4454<br>7,35% | 2714<br>99% |
| **MLP** learning algorithm Resilient Backpropagation<br>**Input data set:** Learn_set_radial, Test_set | 3564<br>5,9% | 29805<br>88% |

Ordering Phase steps = 1000.
Tuning phase learning rate =0.02.
Tuning phase neighbor distance = 1.

In the ordering phase neighbor distance between two neurons decreases from maximum values to the Tuning phase values, the learning rate decreases from the Ordering phase learning rate to the Tuning phase learning rate. Neuron's weights are expected to order themselves in the input space consistent with the associated neurons position.

In the Tuning phase neighbor distance stay on the same level equal Tuning phase neighbor distance, the learning rate continues to decrease but very slowly. Neuron's weights are expected to spread out ever the input space relatively evenly while retaining their topological order obtained during the ordering phase..

## V. RESULTS OF THE TESTS

The neural networks architectures were tested with using whole date set from the Corrected KDD and with using modified data set that includes only attacks presented during training process. Data sets used for the testing phase were shown in Table III.

In Table IV is presented the comparison of particular neural network architecture learned with input data from „Learn_radial_trad" data set. The evaluation focuses on the value of the detection rate and the false alarm rate for "Test_set" data set. For analysis of neural network answer, it was assumption that value from 0 to 0.5 concerning "normal" and from 0.5 to 1 "attack". The Corrected Data Set used for testing phase includes 311 029 vectors.

High number of false alarms is a result of small number of "normal" connections in the trained data set. It was reduced because of a problem of efficiency of SOM and RBF NN implementation in the Matlab environment.

The MLP network was the most efficient during comparison of different network architecture. That is why in the further research we plan to focus on it. For the training of the MLP network we used an input data set with bigger number of connection (Learn_set, Learn_set_radial). The experiment should show if increasing the number of input patterns improves detection rate and false alarms rate. The results of this test are presented in Table V.

## VI. Conclusions

Usage of neural networks for intrusion detection with the input data from DARPA project was presented in many publication. Unfortunately, in description of simulation process very often is lack of information about assumptions that were made in before. For instance there is no information if the whole tests data set was used in the simulation or only some its subset.

The goal of this research was the comparison of different neural network architectures working with the same assumed parameters and tested with with usage of the whole DARPA tests data set (Corrected KDD). Our research made it possible to formulate precisely general assumptions for making benchmark simulations as well as gave us some conclusions concerning particular NN architectures applied to IDS. The main conclusions are:

- Selection of the input data is a very important issue. Representation of all types of attacks and normal activity should be included in the learning date set.
- Results of simulation show that detection rate was the best for MLP network learned with Backward Propagation Levenberg-Marquardt algorithm
- In the second phase of simulation MLP network number of input vectors are increased because of that summary amount of errors decreases. In particular number of false alarms decreases and numbers of non detected attack a little increases. The reason is that representation of more different type of normal activity was added to input vectors in learning phase.
- The long time is required for the learning phase of SOM and Redial neural network. Moreover, these two neural network architectures need very high CPU performance and Operational Memory (RAM). During tests phase input date set had to be divided into smaller subsets in order to avoid "lack of memory swap" Matlab error.
- MLP required less CPU performance and Operational Memory (RAM). That is why could be tested with using the whole tests data set not divided into smaller subsets.

***Abstract*—The issue of privacy is constantly brought to the spotlight since an ever increasing number of services collects and processes personal information from users. In fact, recent advances in mobile communications, location and sensing technologies and data processing are boosting the deployment of context-aware personalized services and the creation of smart environments but, at the same time, they pose a serious risk on individuals' privacy rights. Being situated in the realms of legal and social studies, the notion of privacy is mainly left, concerning its protection, to legislation and service providers' self-regulation by means of privacy policies. However, all laws and codes of conduct are useless without enforcement. Based on this concept, this paper presents a framework conceived on the basis of privacy legislation. It uses a semantic model for the specification of privacy-aware data access rules and a middleware system which mediates between the service providers and the data sources and caters for the enforcement of the regulatory provisions.**

## I. Introduction

ON *the Internet, nobody knows you are a dog*, according to the famous 1993 Pat Steiner cartoon in The New Yorker, which has been very frequently cited in order to emphasize the potential for anonymity and privacy that the Internet was supposed to offer. However, the reality seems to be rather different; in fact, more than a century after the first essay identifying that privacy as a fundamental human right was endangered by technological advances [1], never before in history the citizens have been more concerned about their personal privacy and the threats by the emerging technologies [2].

The potential impact of contemporary Information and Communication Technologies on the privacy rights of the users is regarded as being among their most evident negative effects. The advances in mobile communications, location estimation and sensing technologies, along with data storage and processing technologies, have expanded the sphere of electronic services' provision and digital facilities from the Web to pervasive smart environments. They create impressive perspectives of rich, highly personalized and coherent services, information and computation ubiquity and, thus, spur an information revolution that brings significant improvements of the citizens' quality of life. On the other hand, they pose serious risks on the privacy rights of the data subjects; the personal data collection scale is augmented, information access, processing, aggregation, combination and linking are facilitated and new, sometimes even more sensitive, types of data are collected. A stream of data about individuals pours into data warehouses, while personal information is increasingly viewed as a valuable financial asset which is a subject of trading.

The service providers usually express their practices by means of privacy policies. Privacy policies concern the formal specification of an organization's business practices regarding the collection and the consequent use of personal data. The privacy policies are supposed to be restricted according to fair information principles and to comply with the relevant legal framework. Privacy legislation dictates how personal data should be treated after their provision by the data subjects to service providers and other processing entities, defining in essence the requirements for the privacy-aware management of personal data through their whole life cycle.

The Platform for Privacy Preferences (P3P) W3C specification [3] has been the first initiative towards this direction, providing a way for a web site to encode its relevant practices and to communicate them to the users that visit the site. Since proposed, P3P has received broad attention from both industry and research community, but it has also been subject of criticism from the current technical work, e.g., [4]. The major issue with P3P is the lack of the mechanisms for the enforcement of the specified privacy policies. In essence, P3P formalizes privacy promises given to the users for fair information practices; nevertheless, after their disclosure to a service provider, there is no guarantee about the fate of a user's personal data. Besides, there are numerous cases where the real practices contradict to well-stated privacy policies, e.g. [5], [6].

The challenge of enforcing a privacy policy has been thoroughly examined and several different solutions have been proposed, e.g., by IBM [7], OASIS [8] and Hewlett Packard [9]. These frameworks mainly focus on enterprise environments and provide the means for the automation of the privacy policies enforcement. The means for achieving this is to apply privacy-aware access control mechanisms which enhance traditional Role-Based Access Control (RBAC) mod els with additional, privacy-related aspects, such as the pur

This work was partially supported by the EU IST project DISCREET.

pose for data collection, retention periods, users' consents, notifications, etc.

However, all these solutions have their weak points. First, although they manage to address the issue of privacy policies internal enforcement within an organization to a great extent, they fail in providing the necessary guarantees for fair information practices to the users. In fact, since an organization possesses some personal data, their use or abuse by means of processing and disclosure are still based on good intents. Misuse may occur by a malicious employee with legitimate access to sensitive data or by any form of direct access to the data that bypasses the privacy protecting system. Second, the privacy policies specified in the context of these frameworks cannot be efficiently audited and verified as far as their regulatory compliance and consistency is concerned. Even an organization with the best intentions may specify a privacy policy that is not legislation-proof. Third, the specification of complex privacy policies and the continuous process of keeping them up-to-date introduce significant economical, operational and administrative overhead to an organization.

In the light of the above issues, this paper proposes a framework for the enforcement of privacy policies by the providers of e-services that are based on the legislation. The main concept behind the framework is the formal and detailed codification and specification of the regulatory provisions by a Privacy Authority into a single privacy policy document and its automatic dissemination to the providers. This unique privacy policy constitutes the technical translation of the privacy principles and regulations and overrides any other privacy policy defined by a provider. For its enforcement, a middleware architecture is introduced, that acts as a three way privacy mediator between the law, the users and the service providers. Its main component is the D-Core Box, a privacy proxy installed at the service provider's premises but totally controlled by the Privacy Authority. The D-Core Box stores any personal data, keeping them separated from the provider. Access to the data is granted based on the legislation originated privacy policy, as well as the relevant preferences expressed by the users via an associated mechanism that the framework offers.

The remainder of this paper is structured as follows. Section II provides some insights on the legal aspects of privacy; it codifies the legal privacy principles that form the requirements for the proposed framework. Section III describes the Ontology of Privacy, the semantic information model that constitutes the basis of the proposed approach, since it contains the rules stemming from the legislation. In Section IV, the means for enabling the users to specify their privacy preferences are outlined. Section V describes the middleware architecture that undertakes the task of enforcing the privacy rules, both regulations- and user- originated. The paper concludes in Section VI.

## II. Personal Data Protection Legislation

The starting point to obtain a formal modeling of the privacy legislation and also to design a technology capable of being privacy compliant and at the same time ensuring enforcement of privacy law provisions is identifying the regulatory requirements to be complied with.

A significant milestone in the privacy literature has been the codification of the fundamental privacy principles by the Organization for Economic Co-operation and Development (OECD), in 1980 [10], as this codification lays out the basis for the protection of privacy. The OECD principles are reflected in the European Directive 95/46/EC [11], which enforces a high standard of data protection and it is the most influential piece of privacy legislation worldwide, affecting many countries outside Europe in enacting similar laws. It is particularized and complemented with reference to the electronic communication sector by the Directives 2002/58/EC [12] and 2006/24/EC [13], which impose explicit obligations on network and service providers to protect the privacy of users' communications. The European Directives constitute the basis for the following summary of the main regulatory data protection requirements to be taken into account for the specification of the proposed framework.

### *A. Regulatory Requirements*

The following requirements are stemming from the European personal data protection legislation:

*Lawfulness of the data processing* : The system should be able to examine whether the data processing complies with applicable laws and regulations.

*Purposes for which data are processed* : The system should provide the means for identifying the data processing purposes, which must be lawful and made explicit to the data subject (namely the subject whose data are processed). Moreover, it should be able to check these purposes to avoid that data processed for a purpose may be further processed for purposes that are incompatible with these for which data have been collected.

*Necessity, adequacy and proportionality of the data processed* : The system should be able to guarantee that only the data functional, necessary, relevant, proportionate and not excessive with regard to the sought processing purpose are processed.

*Quality of the data processed* : The system should provide that the data processed are correct, exact and updated. Inaccurate data must be deleted or rectified; outdated data must be deleted or updated.

*Identifiable data* : The system should provide the means for keeping the data processed in identifiable form only for the time necessary to achieve the sought processing purpose.

*Information to the data subjects; consent and rights of the data subject* : The system should be able to provide for informing the data subject that his data are processed according to applicable data protection legislation. Moreover, the system should guarantee that when requested by applicable data protection legislation, the data subject's consent to the data processing is required, and that the data processing is performed according to the preferences expressed by the data subject. In addition, the system should enable the data subject to exercise the rights acknowledged by applicable data protection legislation in relation to intervention in the data processing (for example the right to access data, to ask for data rectification, erasure, blocking, the right to object the data processing, etc.).

*Data security and confidentiality* : The system should be secure in order to guarantee the confidentiality, integrity, and availability of the data processed. Moreover, the system should provide that the listening, tapping, storage or other kinds of interception or surveillance of communications and the related traffic data may be performed only with the data subject's consent or when allowed by applicable legislation for public interest purposes.

*Traffic data and location data other than traffic data; special categories of data* : The system should be able to guarantee that the processing of special categories of data (for example traffic or other location data, sensitive and judicial data) is performed in compliance with the specific requirements that the applicable data protection legislation sets forth for said categories of data.

*Access limitation* : The system should provide for an authorization procedure that entails differentiated levels of access to the data and for recording the accesses to the data.

*Data storage* : The system should be able to automatically delete (or make anonymous) the data when the pursued processing purpose is reached or in case of elapse of the data retention periods specified under applicable legislation.

*Notification and other authorizations from competent Data Protection Authority* : The system should be able to monitor compliance with the notification requirement and with the provisions on the authorizations of competent Data Protection Authority. Moreover, the system should provide for means that allow communications between the system and the competent Data Protection Authority.

*Supervision and sanctions* : The competent Data Protection Authority should be provided with the means for supervising and controlling all actions of personal data collection and processing.

*Lawful interception* : The competent public authority should be provided with the means to perform interception only when this is allowed by applicable laws and regulations and according to the conditions therein set forth. The necessary "hooks" for the lawful interception should under no circumstance become available to other not authorized third parties.

### B. The Regulations in a Nutshell

From the regulatory requirements presented above, the following facts are extracted:

*The role of the users* : The users are granted certain rights; the right to be informed regarding the collection or processing of personal data, to be asked about their explicit consent, to access their data. Additionally, they should be able to specify their privacy preferences and affect this way the service provision procedure, with respect to privacy.

*The role of the Authorities* : The legislation grants the Data Protection Authorities with certain rights and competences. These include the notification of the Authority, the supervision of the procedures and the means for performing Lawful Interception. That is, the Authority should be able to interact with the system.

*The role of semantics*: The semantics play a very crucial role in what can be characterized as "privacy context". On the one hand, each data item should be treated according to its special type. On the other hand, very important is the purpose for which the data are collected and processed.

*Access control*: The access to the data should be controlled. Beyond the legacy Role-Based Access Control models, decisions concerning access to personal data should take into consideration the semantics characterizing each privacy session.

*Complementary actions*: Access to the data should be accompanied by certain behavioral norms of the system. These include the information of the users or the request for their explicit consent, the notification of the Authorities, the automatic enforcement of data retention periods, as well as the adjustment of the detail level of the data.

*Security*: Naturally, in order for the personal data to be protected, the means for securing their transmission and storage should be taken; security always constitutes the bottom line for privacy protection and this paper takes as granted the availability of the corresponding means.

## III. Semantic Information Model

The modeling of the privacy legislation is achieved using a semantic information model that associates personal data, services and actors with explicitly defined regulatory rules. In that respect, the approach taken is to express any related information by means of an ontology, namely the Ontology of Privacy, which is implemented using the W3C Web Ontology Language (OWL) [14]. The vision is that the ontology should be as detailed as possible in terms of the various types of personal data and the types of services, so that the widest range of services and situations when personal data are involved can be covered. This is similar to what the Common Procurement Vocabulary (CPV) [15] represents for public procurement in Europe; it provides an exhaustive –almost semantic– list of several thousands of products that can constitute subject of public procurement.

In order to associate the personal data with specific processing tasks, the identification of the particular type of each personal data item is necessary. Moreover, in order to define the appropriate rules that will regulate the processing of a personal data item with respect to the purpose for which the information is provided by the user or requested by the service provider, a similar taxonomy of the provided services must be present. These taxonomies constitute separate subgraphs of the ontology. Therefore, the Ontology of Privacy provides a detailed vocabulary of personal data types and services' types, structured in an hierarchical way with well defined inheritance rules, that enables the system to associate all privacy related decisions to semantically specified notions. An equivalent taxonomy is needed for the involved actors; however, here we consider a very simple model, comprised of three actors: the user, the service provider and the Privacy Authority.

Regarding the personal data subgraph, all the types are defined as instances of the `PersonalData` OWL class. Inheritance hierarchies, as well as other relationships between personal data are defined using OWL properties. The first hierarchy specifies the inheritance of characteristics, referring to legislation-originating rules that regulate the collection and processing of personal data. The "root" personal data

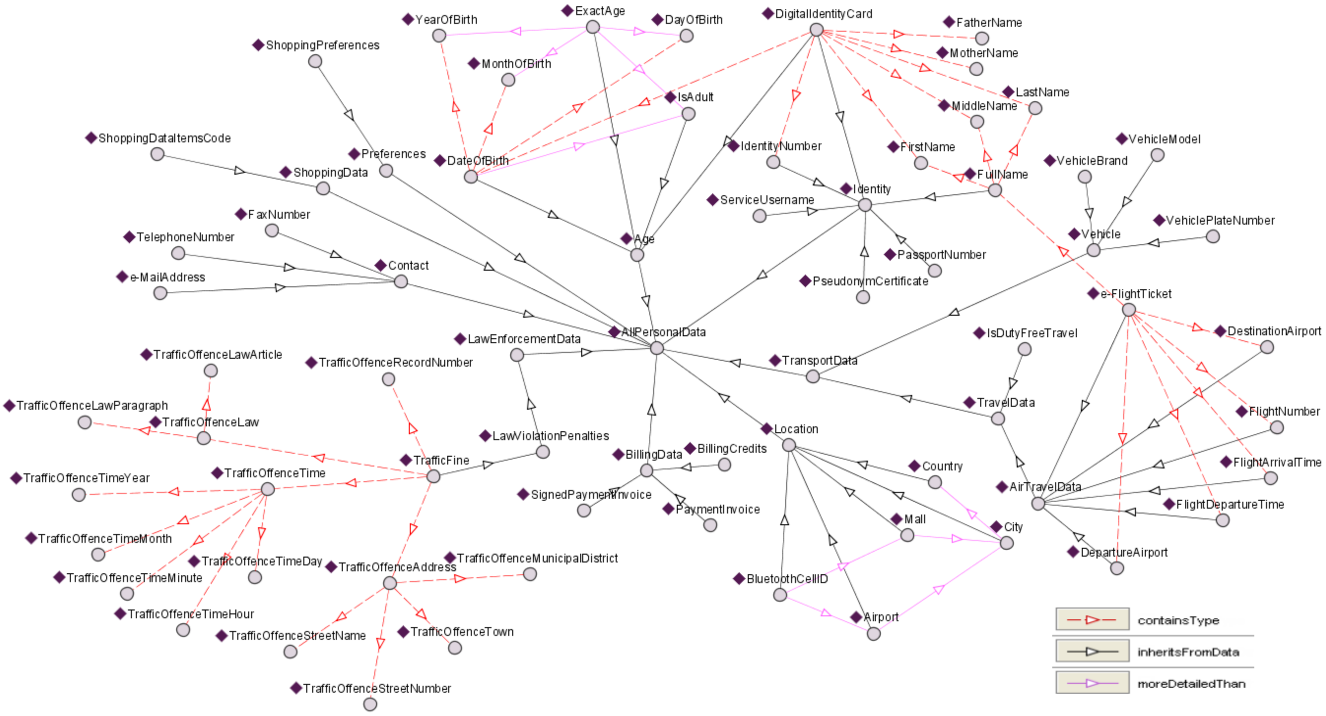

Fig 1: Ontology of Privacy – Personal Data Subgraph

type is the `AllPersonalData` type, from which all the other data types inherit, while "first level" children of `AllPersonalData` type instance include `Age`, `BillingData`, `Contact`, `Identity`, etc. These types constitute general data types, in essence categories of personal data types. This hierarchy is implemented by means of the `inheritsFromData` object OWL property.

The second hierarchy defined inside the `PersonalData` class deals with the detail level of personal data types. For this purpose, two properties are defined, `lessDetailedThan` and `moreDetailedThan`, being the one inverse to the other. In that respect, the `ExactAge` personal data types is `moreDetailedThan` the `YearOfBirth`, while the `Country` is `lessDetailedThan` the `BluetoothCellID`, with respect to the data subject's location.

The last relationship between the instances of the `PersonalData` class is the one that defines complex types resulting from simpler ones. In that respect, the data subject's

Fig 2: Ontology of Privacy – Subgraph of Services

FullName contains the FirstName, LastName and MiddleName data types. The containsType property and its inverse isContainedToType implement the corresponding relationships.

Fig. 1 illustrates part of the personal data subgraph, along with the OWL properties that implement the three types of relationships between the personal data instances, as described above.

The different services' types are organized as a hierarchy that defines inheritance of characteristics. All the defined types constitute instances of the Services OWL class. The "root" service type is the AllServices type, from which all the other services' types inherit, while "first level" children of AllServices type instance include AdultServices, Billing, LawEnforcement, LocationBased, etc. These types constitute general services' types. This hierarchy is implemented by means of the inheritsFromService object OWL property and its inverse one. It is noted that multiple inheritance is possible. As an example, a service can be location-based, while targeting adults; in this case, the service should inherit from both the LocationBased and the AdultServices types. Fig. 2 illustrates part of the services' subgraph; the arks represent inheritance associations, with the source node inheriting from the destination node.

As afore-mentioned, regarding the actors involved in the service provision chain, a very simple model has been considered. So far, the actors that have been defined are the DataSubject, the PrivacyAuthority and the ServiceProvider. However, this assumption can be easily removed with the extension of the Actors class to constitute a very detailed hierarchy of roles and –therefore– render the model fully role-based.

Access control rules are defined as instances of the Rules class of the ontology, in order to regulate the provision of services. Every rule is associated with a {personal data type, service type, actor} triad, using the corresponding refersToData, refersToService and refersToActor OWL object properties, and defines one or more properties that specify the permitted/forbidden actions of the *actor* over the *personal data type*, in the context of the provision of the *service type* under consideration, possibly along with certain complementary actions that must be additionally performed by the system.

With the use of OWL Annotation Properties, every rule contains the following information:

- DisclosureOfData: it defines whether the data of the specified type should be disclosed or not to the specified actor in the context of the provision of the specified service.
- RetentionPeriod: it specifies the period for which the data of the type under consideration should be retained.
- ModificationPermission: it defines if the specified actor should be granted with write/modify rights on the data of the specified type.

While the information above define the "core" of the rule, additional properties specify the complementary actions that should be potentially executed:

- DataSubjectInformation: it refers to the right of the user to be informed when the rule is applied (i.e., when in the context of the specified service, the personal data of the specified type are disclosed to the specified actor, or their modification takes place).
- DataSubjectConsent: it enables the user to be asked about explicit consent, prior enforce the body of the rule.
- AuthorityNotification: it forces the notification of the Authority when the rule is applied.

Finally, a rule may be characterized by certain meta-properties that serve for resolving conflicts between contradictory rules:

- appliesToPersonalDataDescendants: this binary property specifies whether the rule is inherited to the descendants of the specified data type, with respect to the corresponding subgraph of the ontology and the inheritance relationships.
- appliesToServiceDescendants: similarly to the case above, this binary property specifies the inheritance of the rule to the service type descendants.
- appliesToActorDescendants: although redundant since the corresponding actors' subgraph has not been defined yet, it refers to the inheritance of the rule to the descendants of the actor's type.
- OverrideDataSubjectPreferences: in certain cases, the user may have specified privacy preferences that contradict with the rules of the ontology; this property serves for defining which rule dominates over the other.

In Fig. 3, an example of an access control rule is illustrated. What this rule states is that "when the service under consideration is an adult service (AdultServices), and when the service provider (ServiceProvider) requests access to the personal data of IsAdult type (a binary data type, reflecting whether the data subject is an adult or not), the data should be given to the provider, while the data should not be further retained. The rule applies for the descendants of the AdultServices service type, while it does not apply for the descendants of the IsAdult personal data type and of the ServiceProvider actor type."

## IV. Specification of Privacy Preferences

While regulations-originated policies as specified in the Ontology of Privacy may determine the access permission to data up to some extent, the users should be able to determine the fate of their personal data. In that respect, a technical problem to be approached is how to enable the user to that direction, i.e., to control the disclosure, storage and processing of personal information, when the information is traveling through the various system and service components. To face this issue, it is necessary to associate to the data additional information which is communicated and stored with the data and brings information aimed at enforcing the specific treatment desired for the considered data.

Therefore, prior to leaving the user's terminal, the user's personal data are encapsulated into a data structure with the descriptive name Privacy Lock. The purpose behind its use is twofold: to make certain metadata (i.e., the user's preferences) available along with the respective data and to ensure the safe transmission of the data.

In essence, the Privacy Lock constitutes a secure shell that encapsulates the personal data transmitted by the terminal to the D-Core Box and vice versa, along with their metadata into an encrypted and optionally digitally signed object that ensures the safe communication. Moreover, the Privacy Lock can be used for the transmission of metadata solely, that express user preferences as far as either already stored data or data that will be processed in the future are concerned.

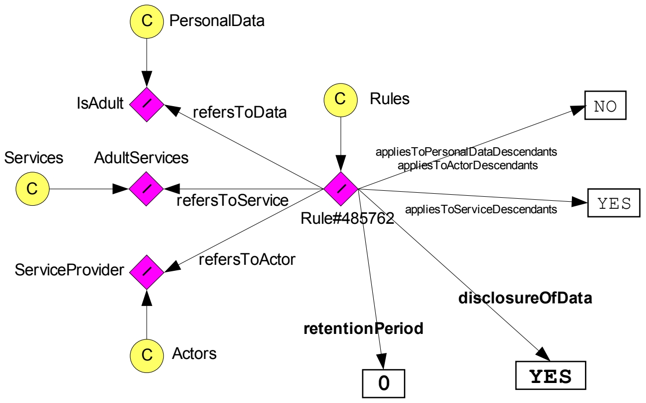

Fig 3: Ontology of Privacy – Example of Access Control Rule

An essential and mandatory attribute that is defined inside the Privacy Lock is the data type, which constitutes a critical parameter for their treatment in terms of disclosure, retention and processing. The type of the data is semantically specified with respect to the personal data subgraph of the Ontology of Privacy.

Apart from reflecting the data type, the metadata assigned to the data define certain properties for {personal data, services} [1] associations. These properties include:

- Whether the data should be disclosed for the provision of a certain service.
- The level of abstraction when the data are disclosed for the provision of a specified service.
- The expression of the user's preference to be informed or asked for consent whenever some processing or disclosure of personal data is about to take place.
- The determination of the desired retention period.
- Issues concerning data and metadata administration and management.

The metadata are formally expressed using a proprietary XML-based language, namely the Discreet Privacy Language (DPL). The DPL is used for the definition of all the necessary elements for the specification of all the afore-described types of metadata. Additionally, it is used for structuring the personal data when communicated from the user's terminal to a D-Core Box and vice-versa into a Privacy Lock, along with their privacy-related metadata.

The DPL's syntax is XML-based and contains the appropriate elements for the specification of the personal data attributes. In that respect, the DPL defines elements for the specification of:

- The personal data types, data items and service types that are regulated by the considered rule.
- Whether the considered rule is inherited by the personal data or service type descendants, with respect to the Ontology of Privacy.
- The rules themselves. The different rules' types defined include the disclosure level along with the corresponding level of precision, the access rights to the personal data, the demand for notifications and consents and the retention/validity period of the data.
- Meta-rules for the resolution of conflicts that naturally occur (e.g., contradictory user and regulations originated rules, rules overriding, etc.).

The detailed description of the DPL is beyond the scope of this paper; the normative definition of the DPL by means of Augmented Backus-Naur Form (ABNF) [16] specification is provided in [17].

## V. Middleware Architecture

The privacy protecting system takes the form of a distributed middleware that regulates the diffusion of personal data from the user towards the service provider, using legislative input. This "privacy broker" is comprised of three high level entities, each assigned to one of the three actors, i.e., the users, the service providers and the Privacy Authority. These entities form a privacy domain, the D-Core, inside which personal data handling is subject to both legislative requirements regarding privacy and user privacy preferences. The high level entities and the privacy domain they define are illustrated in Fig. 4 .

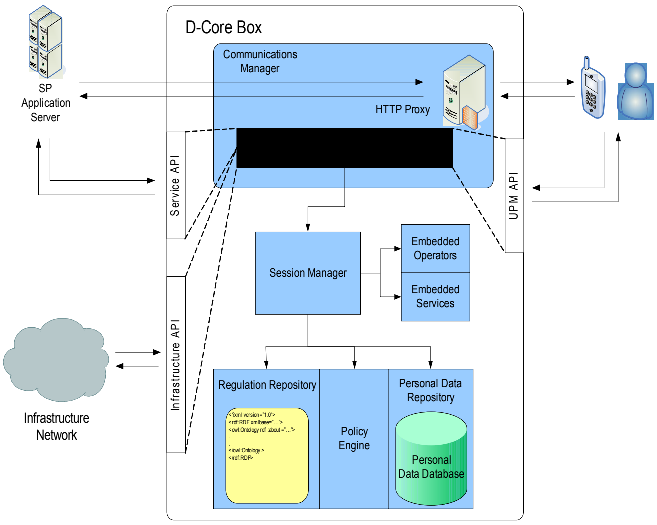
The entity that delivers the core system functionality is the D-Core Box ( Fig. 5 ). This is an intelligent privacy proxy, which, despite the fact that it is logically and physically deployed at the service provider's premises, is being managed by the Privacy Authority and not by the service provider. It constitutes the "edge" module of the D-Core and the border between the service provider's applications and the D-Core.

Any personal data provided by the user to the service provider are stored by the D-Core Box inside the Personal Data Repository. That is, the personal data are kept isolated from the service provider, which has no direct access to them. The storage may be short-time (e.g., immediate service provision) or long-time (e.g., services that require information archives). The data are stored together with the associated privacy preferences of the user, which are either transmitted with the data by means of a Privacy Lock, or defined/updated at any time through the corresponding interface that the D-Core Box offers. The same interface enables user to maintain complete control over the data, i.e., to update or delete them.

[1] It is noted that the metadata specification is actors-unaware; in fact, it is impossible for the user to refer to the internal structure of an organization.

When a service provider submits a request for users' personal data, the request is evaluated by the D-Core Box. All related decisions concerning personal data handling are taken by the Policy Engine which uses two sources of rules. The first source, the Ontology of Privacy is deployed to the D-Core Box by the Privacy Authority and is stored in the Regulations Repository. It provides the legislation-originated rules that are translated internally into a set of concrete DPL rules prior to be provided to the Policy Engine. The second source is the set of user defined privacy preferences which are provided by the Personal Data Repository, expressed as DPL rules. Through this prism, the Policy Engine examines the request and decides about the disclosure of the personal data and the potential execution of associated actions, such as the obfuscation of the data, the information of the user, the request for the user's consent, the notification of the Privacy Authority.

The key idea for the operation of the D-Core Box is to minimize the amount of personal data that are delivered to the application, without degrading the service. Moreover, the data should be disclosed pseudonymized or anonymized. In that respect, data that identify the user should not be disclosed, unless absolutely essential for the provision of the service. Therefore, in order to further minimize the amount of disclosed data, the D-Core Box incorporates modules that execute internally either simple data processing tasks or whole services' parts. These are, respectively, the Embedded Operators and Embedded Services components. Typical Embedded Operators functionalities are the filtering of the data precision prior to their disclosure (e.g., the translation of exact location to more abstract terms, or the transformation of the `ExactAge` data type to the `IsAdult` one.). Embedded Services undertake the execution of standard service components internally, mainly involving data that identify the user (e.g., e-mail sending or service charging mediation). This way, typical processing procedures that concern critical personal data, such as someone's identity or credit card number, are executed inside the D-Core Box and the need for the re spective personal data disclosure is eliminated. The Embedded Operators and Services are invoked by the Session Manager, a “stateful” component of the D-Core Box which orchestrates the functionality of the other components and manages every privacy session.



```
<?xml version="1.0">

<owl:Ontology rdf :about ="...">
.
.
</owl:Ontology >
</rdf:RDF>
```

Fig 5: The D-Core Box

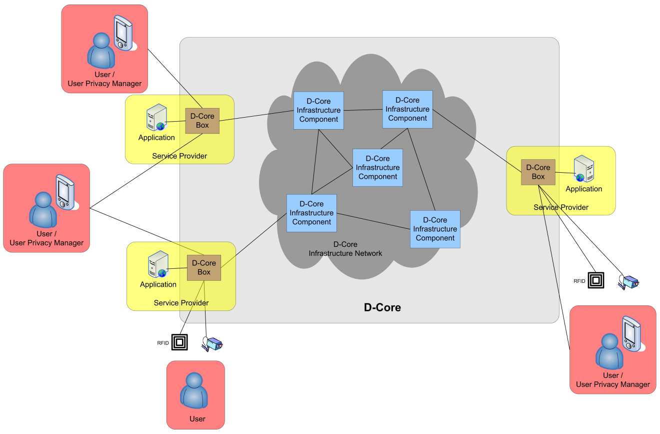

Fig 4: High level entities and the D-Core domain.

The D-Core extends at the user side with the User Privacy Manager (UPM). The UPM is a privacy agent for the user. It manages user identities for different services, it provides a console to edit privacy preferences and UIs to insert/edit personal data inside each identity and it creates Privacy Locks when personal data need to be delivered to the D-Core. The UPM is the peer entity of the D-Core Box for functions like informing the user when a service requests access to a specific personal data type, requesting user permission for this access and when creating and sending Privacy Locks containing personal data along with associated metadata.

The third entity in the D-Core domain is the Infrastructure Network. This is comprised of Infrastructure Components that constitute the Privacy Authority’s entry point to the domain. It provides to the Privacy Authority the means for the management of the Ontology of Privacy, the monitoring, and management of the system and the conduction of Lawful Interception. When the Ontology of Privacy is updated (e.g., due to legislation modification), then the updated version is transmitted through the Infrastructure Network to all the D-Core Boxes in order to consider the new requirements in the subsequent personal data requests. Regarding system management and monitoring, each Infrastructure Component undertakes the administrative responsibility regarding a number of D-Core Boxes and fulfills typical functions like collecting log data, checking status, generating error alarms, etc.

The communication of the D-Core Box with the other components of the D-Core domain as well as the applications is performed through a messaging framework, based on SOAP. The patterns defined for these interactions are presented in detail in [17], along with the detailed specification of the D-Core, its components and the respective interfaces between them and with the providers’ applications.

## VI. Conclusion

In this paper, a framework defining a protection domain for personal data was presented. Conceived on the basis of the legislation provisions, it provides the means for their enforcement and, therefore, the applications' commitment to adhere to privacy requirements. It presents two innovative features.

The first is the formal modeling of the data protection legislation in terms of the Ontology of Privacy. Using the Ontology of Privacy as a powerful tool for expressing the respective notions, a mere dictionary of terms is defined and shared by all system components and actors, starting from a Privacy Authority that specifies and configures the Ontology of Privacy on a constant basis and ending in the data subject and the service providers that make use of it. In that respect, all personal data are semantically marked and their type affects their consequent treatment by all the involved entities. Similarly, the specification of each service type provides the means for disclosure and processing purposes' specification and binding. The policies inside the ontology not only determine the necessity of a personal data type for a service's provision, but also constitute a complete set of regulations that are translated to access rights, services' flows and other rules for the protection of the personal data.

The second contribution of the proposed framework is the explicit separation of the personal data from the service providers' applications. With the mediation of D-Core Box, a service provider cannot gain access to personal data other than the one specified by the legislation and the user's preferences. The incorporation of several privacy-critical processing functionalities in the D-Core Box eliminates further the danger of data misuse.

***Abstract*—The development of the information systems should answer more and more to the problems of federated data sources and the problems with the heterogeneous distributed information systems. The assurance of data access security realized in the cooperative information systems with loose connection among local data sources is hard to achieve mainly for two reasons: the local data sources are heterogeneous (i.e. data, models, access security models, semantics, etc.) and the local autonomy of systems does not allow to create a global integrated security schema.**

**The paper proposes to use one common set of access control concepts to support the access control management in security of heterogeneous information systems. The UML (Unified Modelling Language) concepts can be used to define and implement the most popular access control models, such as DAC, MAC or RBAC. Next, the concepts derived from different models can be joined to use one common approach comprehensible for each administrator of each cooperative information system in the federation.**

## I. Introduction

THE development of the information systems should answer more and more the problems of federated data sources and the problems with the heterogeneous distributed information systems. It is necessary to solve the problems with structured or semantic conflicts on the level of information stored in the systems, to assure the acknowledgment of security constraints defined for the local information sources and to create the control process on the global level of cooperative information systems. We do not solve all these problems in this paper. We only propose to use one common set of access control concepts to support the access control management in the security of heterogeneous information systems. The UML (Unified Modelling Language) [1], [2] concepts can be used to define and implement the most popular access control models, such as DAC (Discretionary Access Control), MAC (Mandatory Access Control) or RBAC (Role-based Access Control) [3], [4], [5], [6]. Next, the concepts derived from different models can be joined to use in the security management one common approach comprehensible for each administrator of each cooperative information system in the federation.

The assurance of the data access security realized in the federated information systems with loose connection among local data sources is hard to achieve mainly for two reasons: the local data sources are heterogeneous (i.e. data, models, access security models, semantics, etc.) and the local autonomy of systems does not allow to create a global integrated security schema. Each of systems, subsystems or applications of the federated information system can be secured by a different security policy, and one common approach joining the concepts from different policies can help in the process of security policy integration on the global level.

The paper is structured as follows: the first part presents the access control in heterogeneous information systems and the creation process of security scheme. The second part deals with the connection of UML concepts with the concepts derived from three types of access control models, i.e. DAC, MAC and the extended RBAC. The third part describes the creation of user profiles based on presented access control models. Finally, the fourth part presents the common access control approach comprehensible for security administrators of each information system in the federation.

## II. Access control in heterogeneous information systems

The security policies of a system generally express the basic choices made by an institution for its own data security. They define the principles on which access is granted or denied. The access control imposes constraints on what a user can do directly, and what the programs executed on behalf of the user are allowed to do. A security access system can be defined by using two parts that cooperate with each other: the security access strategy, which describes all the environments and the specifications of the entire organization on the security level (i.e. organizational and technical aspects), and the access model with:

- a set of concepts to describe objects (data access) and subjects (users),
- a definition of the users' access rights to data,
- an access control policy which describes how users can manipulate data, defines data structure and administers the user' access rights to data.

Two categories of security policies of the information systems can be distinguished: discretionary security policy or mandatory (non-discretionary) security policy. It is possible to find access control models based on these policies:

- *Discretionary Access Control (DAC)* model [3] manages the users' access to the information based on the user' identification and on the rules defined for every user (subject) and object in the system using the access control matrix. For each subject and object in a system there are authorization rules that define the access modes of the subject on the object.
- *Mandatory Access Control (MAC)* model [3] is based on the classification of subjects and objects in the system. Each subject and each object is attached to a security level, which is composed of a classification level and a category. The classification levels are arranged by their sensibility degree: Top Secret, Secret, Confidential and Unclassified. In this model each subject has his own authorization level that allows him the access to the objects starting from the classification level, which has lower or equal range.
- *Role-Based Access Control model (RBAC)* model [4], [5], [6] requires the identification of roles in a system. The role is properly viewed as a semantic structure around which the access control policy is formulated. The role can represent the competency to do a specific task and it can embody the authority and responsibility of the system users. The permissions are associated with roles and the users are assigned to appropriate roles. The roles are created for various job functions in an organization and the users are assigned to roles based on their responsibilities and qualifications. The user playing a role is allowed to execute all access modes to which the role is authorized. The user can take different roles on different occasions.
- *Extended RBAC (eRBAC)* model [7]—each role realizes a specific task in the enterprise process and it contains many functions that the user can take. For each role it is possible to choose the necessary system functions. Thus, a role can be presented as a set of functions that this role can take and apply. Each function can have one or more permissions, and consequently a function can be defined as a set or a sequence of permissions. If an access to an object is required, then the necessary permissions can be assigned to the function to complete the desired job. Specific access rights are necessary to realize a role or a particular function of this role. These rights determine the possibility to execute an application or to access necessary data, and moreover they correspond with these functions. Thus, the specific permissions have to be defined for each function (Fig. 1).

The objectives of the security policy in cooperative information systems are to respect the local security model of each system (each model specifies the security principles of a local system) and to control the indirect security that comes from global cooperation level: a member of a local system may in another local system access only the equivalent information according to his local profile. It is possible to find the situations in which some information systems have to cooperate with each other creating the set of cooperative information systems. Each system can have another security policy for describing the access control rules to access its data. This situation can involve some difficulties and heterogeneities in definition of the global security model. The following types of global security heterogeneities were found [8]:

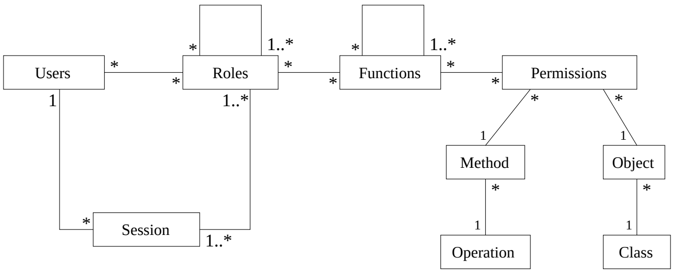

Fig. 1. Extension of the RBAC model

- heterogeneity of the information system security strategies (centralized vs. decentralized authorization, ownership vs. administration paradigm, etc.),
- heterogeneity of security policies between MAC models, DAC models, RBAC models and their extensions,
- different kinds of access rights (positive, negative or mixed), different authorization units (subjects, users, group, roles), different access administration concepts (Grant, Revoke, etc.),
- heterogeneity of security entities: elements of security concept model (databases, domain, types/classes/relations or object, etc.) between local schemes.

This paper deals with the second point—the problem of heterogeneity of security policies. Each system in the federation can use another security policy and in consequence another access control model. The possible solution is to find the common concepts in order to connect all security concepts from different models. It should be possible to present different elements from different access control models using one common approach—the ideas that are universal for all the models. This way, the access control in the heterogeneous information systems can be presented using one common set of concepts in order to manage such system in a common and simpler way.

Two types of actors cooperate in the creation stage of an information system and the security scheme associated with it [9]: the information system developer who knows specifications of an information system that need to be realized and the security administrator who has the knowledge of the general security policy that should be respected on the enterprise level.

The creation process of the security scheme in heterogeneous information systems is proposed as follows (Fig. 2):

- Application developer creates the system application or a set of system applications using the UML concepts. UML is used to define the application Model containing all elements that express the needs of the users.

- Application developer initiates the process of user profile creation (e.g. role engineering for eRBAC model) [10], [9] based on the security rules concerning this application.
- The application Model created by the developer is translated to the concepts of access control models (e.g. DAC, MAC or eRBAC) based on the connection of UML concepts with the concepts of DAC/MAC/eRBAC model (Section 3). Also the process of user profile creation is finished on the developer level (Section 4).
- Security administrator receives the Model containing the lists of access control elements which are presented in a special form, e.g. in the XML files. The administrator finishes the process of user profile creation using the rules of the global security policy (Section 4).
- The application Model together with its associated access control rules (defined by the developer and by the administrator) are transformed to the common access control Model using the common concepts for the heterogeneous security systems (Section 5). The results of this transformation are given in the XML files with its associated DTD files which are legible and comprehensible for each security administrator of each information system in the federation.
- Security administrator(s) can manage the federation of the heterogeneous information systems on the access control level using the common set of concepts.

The next sections presents the theoretical groundwork for the main stages of this process.

## III. Connection of UML concepts with concepts of access control models

The methods of the object-oriented analysis and conception can be considered an evolution of the systemic approach towards greater coherence among the information system objects and their dynamics. The Unified Modelling Language can be mentioned in this category as a standard for the object-oriented modelling in the field of software engineering [1], [2]. It contains a suite of diagrams for requirements, analysis design and implementation phases of the development of systems. Due to the diagrams, it is possible to visualize and manipulate the modelling elements. Out of different types of diagrams defined by the UML and representing different viewpoints of the modelling, three types, i.e. class diagram, use case diagram and interaction diagram, are in the focus of attention of the presented study. The UML has been chosen for the representation of security models because nowadays it is a standard tool, properly reflecting the description of the information system and its needs. UML gives the possibility to present the system using different models. The purpose is to define and implement the access control models, such as DAC, MAC and extended RBAC with the use of UML. To achieve this, the UML concepts and concepts from three models should be joined.

### A. *Concepts of DAC model associated with UML concepts*

The elements of the UML class diagram and interaction diagram, e.g. sequence diagram, can be used to define the concepts of the DAC model (Fig. 3):

- *DAC subject* (user) is found in the instance of actor class from UML class diagram supported eventually by UML constraints,
- *DAC object* defined by UML object,
- *DAC operation* defined by UML operation and furthermore
- user identification can be described by UML constraints.

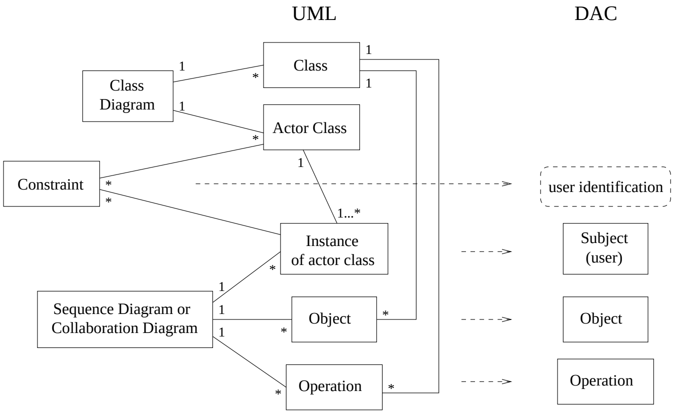

Fig. 3. UML concepts and their relationships with DAC model

### B. *Concepts of MAC model associated with UML concepts*

Similarly, the elements of the UML class diagram and interaction diagram, e.g. sequence diagram, can be used to find the elements of the MAC model (Fig. 4):

- *MAC subject* is defined by the instance of actor class from UML class diagram supported eventually by UML constraints,
- *MAC object* defined by UML object,
- *MAC operation* defined by UML operation and furthermore
- authorization level can be represented by UML stereotypes or element properties,

- security level, i.e. classification level and category, presented by UML element properties or by UML constraints.

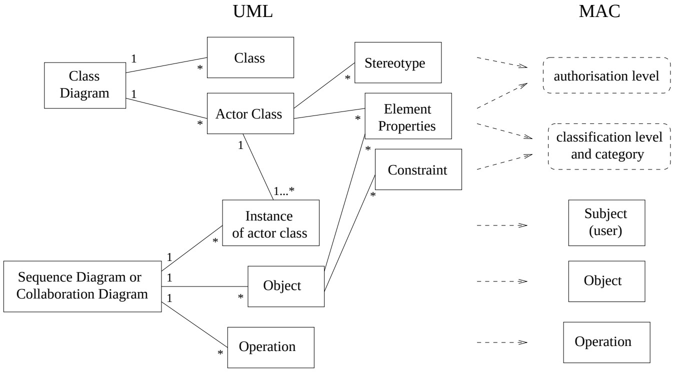

Fig. 4. UML concepts and their relationships with MAC model

### C. Concepts of extended RBAC model associated with UML concepts

Two types of the UML diagrams have been chosen to present and implement the elements of the extended RBAC model: use case diagram and sequence diagram (Fig. 5). The presentation of connections between the UML and the extended RBAC concepts is described widely in [7]:

- *RBAC role* is joined with UML actor,
- *RBAC function* joined with UML use case,
- *RBAC methods* and objects with methods and objects of UML,
- *RBAC permissions* can be found in the interaction diagrams,
- *RBAC constraints* are joined with constraint concept existing in UML [10],
- relations of different types that occur between the elements of the extended RBAC model can be found in the use case diagrams and in the interaction diagrams.

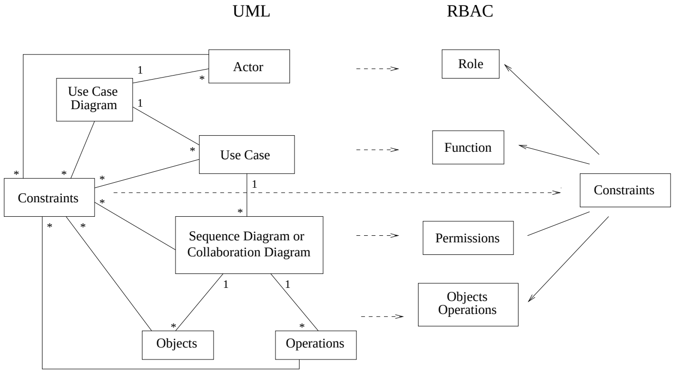

Fig. 5. UML concepts and their relationships with extended RBAC model

## IV. Creation of user profiles based on access control models

System security policies demand that for each user a set of operations that he will be allowed to execute should be clearly defined. Consequently, for each user a set of permissions should be defined. It suffices to specify the permissions for the execution of certain methods on each object accessible for that user. According to the connections between UML and three access control models given above, a definition of user profiles on the developer and administrator levels can be proposed.

### A. DAC model

The authorization rules for the subjects and objects in the DAC model using the UML concepts are defined with the use of class diagram, from which it is possible to obtain the list of system subjects, i.e. system users. The users have the authorizations to realize different operations (i.e. read, write, execute, own) on different objects depending on the definitions of elements situated in the class diagram or in the interaction diagrams in which these subjects participate. These types of UML diagrams allow obtaining the list of objects and the list of operations realized on these objects for each subject in an information system. The user identification is realized by the UML constraints attached to the classes in a class diagram, or to the actors or objects in the interaction diagrams. The notion of ownership policy, characteristic for the DAC model, can be determined with the use of direct or indirect relations between objects in the interaction diagrams or between their classes in the class diagram.

### B. MAC model

The implementation of the MAC model using the UML concepts is realized also with the use of the class diagram and the interaction diagrams, which allow to obtain the list of the system users (i.e. system subjects) and the lists of the system objects on which these users can perform different operations. The characteristic notions for the MAC model, such as authorization level and security level (i.e. classification level and category) can be obtained using the UML extension mechanisms, such as stereotypes, element properties or constraints, defined for the model elements in the class diagram or in the interaction diagram.

Both in the DAC model as well as in the MAC model, the definition of the user's authorizations to execute some operations on different objects (i.e. the definition of the user's permissions) with all the model characteristic notions can be realized by the system developer. The security administrator is responsible for any changes in these definitions that can be made by the new assignments of the information system elements or addition of the new constraints defined for the system elements.

### C. Extended RBAC model

The implementation of the extended RBAC model using the UML concepts is realized with the use of the sequence diagrams, where permissions are assigned to the rights of execution of the methods realized in each use case [7]. The UML meta-model is applied to define the roles of the RBAC model, the functions that are used by these roles to co-operate with the information system and the permissions needed to realize these functions. Owing to the use case diagrams a list of actors co-operating with the information system is obtained. An analysis of these diagrams allows the automatic specification of relations of the following types: R-R (role-role) relation (with the use of the generalization relation between the actors), R-F (role-function) relation (with the use of the association relation between the actors and the use cases) and F-F (function-function) relation (the generalization relation between the use cases). The description of a use case using the interaction diagrams (e.g. sequence diagrams) presents activities needed to realize the functions of a system. Each activity is a definition of execution of a method on an object. Therefore the F-P relations can also be automatically managed. Our definition of a set of roles in an information system with the use of the UML diagrams contains two stages: assignment of a set of privileges (permissions) to the use case in order to define the function and assignment of a set of use cases (functions) to the actor in order to define the role.

In order to create a set of roles assigned to a user profile, users should be assigned to roles. This stage is realized by the security administrator.

## V. Common concepts for heterogeneous information systems

In an information system the access control is responsible for granting direct access to system objects in accordance with the modes and principles defined by protection policies. An access control system defines: the *subjects* (active entities of a system) that access the *information* (passive entities) executing different *actions*, which respect the access rules. The subjects can describe the *users* or the processes that have access to the data stored in a system. The information, i.e. the data, determines the system *objects* on which the actions represented by the most popular *operations*, i.e. read, write, delete, execute, can be performed. Therefore, it is possible to distinguish three main sets of elements describing the access control rules: **subjects**, **objects** and **operations**.

We propose to represent the elements of access control models, i.e. DAC, MAC and eRBAC, using these three sets and additionally the concept of constraints (Fig. 6). A security constraint is an information assigned to the system elements that specifies the conditions to be satisfied so that the security rules and global coherence of a system can be guaranteed [10].

This connection is possible with regards to the features of access control concepts [3] and the concepts of access control models (Section 2). It can be realized by the automatic transformation of XML files, containing the application elements in approach of concepts of access control models (DAC/MAC/eRBAC), to the XML file(s) containing these elements using the common concepts. It is necessary to create the DTD (Data Type Definition) files for these XML files to define their structures. The root elements of DTD files for each access control model are given as follows:

- DTD file for DAC model:
$< !ELEMENT\ DAC(user+, object+, operation+, userIdentification*) >$

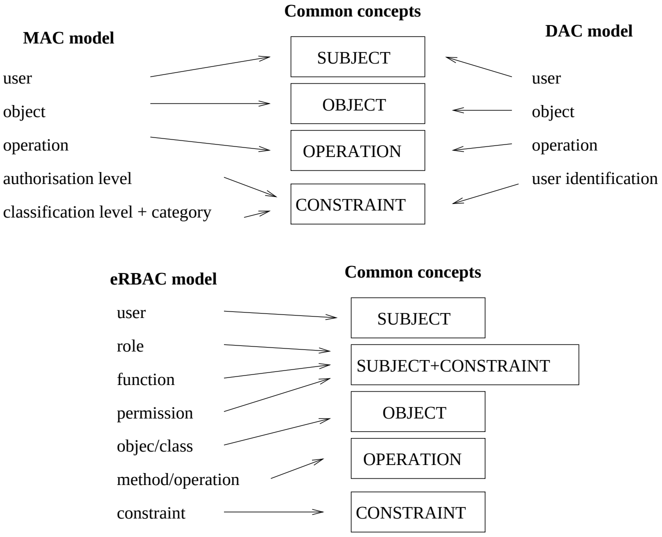

Fig. 6. Common concepts for access control models

- DTD file for MAC model:
$< !ELEMENT\ MAC(user+, object+, operation+, authorizationLevel*, classificationLevel*, category*) >$
- DTD file for eRBAC model:
$< !ELEMENT\ eRBAC(user+, role+, function+, permission+, method+, object+, operation+, class+, constraint*) >$

The root element of DTD file containing the common concepts for describing the security elements of each access control model is as follows:

$< !ELEMENT\ commonModel(subject+, object+, operation+, constraint*) >$

It describes the common concepts of heterogeneous security systems. The XML files based on such DTD file are intended for security administrator(s) to manage the federation of heterogeneous security systems.

## VI. Conclusions

The paper describes the creation and management of security scheme in heterogeneous information systems on the access control level. We propose to use one common set of access control concepts to support the access control management in heterogeneous security systems.

The UML concepts are proposed to support the access control management in the information system security. UML can be used to realize the access control models as DAC, MAC or the extension of the classic RBAC model and next to help in the creation of user profiles based on these access control models. UML, a standard language for object analysis and design nowadays, has been chosen in view of the fact that it enables the complex presentation of the information system and different aspects of information system security. The implementation of access control models is realized using the UML concepts connected earlier with the concepts of these models.

The complexity of the information systems generates the need for new more effective techniques and tools. The object approach and modelling using UML gives the possibility to create the security scheme for the heterogeneous information systems that accepts different access control models, such as DAC, MAC or extended RBAC model.

***Abstract*—With the advent of semantic technology, access control cannot be done in a safe way unless the access decision takes into account the semantic relationships among the entities in a semantic-aware environment. SBAC model considers this issue in its decision making process. However, time plays a crucial role in new computing environments which is not supported in the model. In this paper we introduce the Temporal Semantic Based Access Control model (TSBAC), as an extension of SBAC, which enhances the specification of user-defined authorization rules by constraining time interval and temporal expression over users' history of accesses. A formal semantics for temporal authorizations is provided and conflicting situations (due to the semantic relations of the SBAC model and a sub-interval relation between authorizations) are investigated and resolved in our proposed model. An architecture for the access control system based on the proposed model is presented, and finally, we discuss and evaluate TSBAC.**

## I. Introduction

ACCESS control is a mechanism that allows owners of resources to define, manage and enforce access conditions applicable to each resource [1]. An important requirement, common to many applications, is related to the temporal dimension of access permissions. In these systems, permissions are granted based on previous authorizations given to the users of the system in specific time points (in the past).

Another critical requirement is the possibility of expressing the semantic relationships that usually exist among different authorization elements, i.e. subjects, objects, and actions. To overcome this challenge, our model is constructed based on the SBAC model [2, 3] which is a semantic-based access control model. SBAC authorizes users based on the credentials they offer when requesting an access right. Ontologies are used for modeling entities along with their semantic interrelations in three domains of access control, namely subjects domain, objects domain, and actions domain. To facilitate the propagation of policies in these three domains, different semantic interrelations can be reduced to the subsumption relation.

In this paper we unify the two concepts mentioned previously, that is, we use SBAC (as the base model), and associate a temporal expression with each authorization. Due to the nature of some application domains (such as the banking environment), a real representation of time is required to be used for modeling temporal dependencies between history of accesses. So, in this paper, we use real time operators to impose constraints on elements of History Base. Furthermore, a temporal interval bounds the scope of the temporal expressions (e.g., [1,20] shows that the authorization is valid for time interval starting at ‘1’ and ending at ‘20’). Thus, the main feature provided by TSBAC is the possibility of specifying authorization rules which express temporal dependencies among authorizations. These rules allow derivation of new authorizations based on the presence or absence of other authorizations in specific past time instants (stored in *History Base* in the form of done(t,s,o,a) and denied(t,s,o,a)

A formal semantics is defined for temporal authorizations. The subject of Temporal Authorization Base (TAB) administration and conflicting situations are investigated and resolved. An architecture for the access control system based on TSBAC, and an evaluation is presented.

The rest of this paper is organized as follows: in Section 2 we discuss the related works on this topic. Section 3 gives a brief introduction of the SBAC model and describes the model of time used throughout our work. In section 4, we represent our authorization rules in detail and offer the formal semantics followed by a brief description of administration of the authorization base and conflict resolution in access decision point. Section 5 gives an architecture for the access control system based on the proposed model. In section 6 we give a brief evaluation of our work. Finally, section 7 concludes the paper.

## II. Related Work

Access control systems for protecting Web resources along with credential based approaches for authenticating users have been studied in recent years [1]. With the advent of Semantic Web, new security challenges were imposed to security systems. Bonatti *et al.*, in[4] have discussed open issues in the area of policy for Semantic Web community such as important requirements for access control policies. Developing security annotations to describe security requirements and capabilities of web service providers and requesting agents have been addressed in [5]. A concept level access

978-83-60810-14-9/08/$25.00 © 2008 IEEE

control model which considers some semantic relationships in the level of concepts in the object domain is proposed in [6]. The main work on SBAC, which is the basis of our model, is proposed in [2, 3] by Javanmardi *et al.*. SBAC is based on the OWL ontology language and considers the semantic relationships in the domains of subjects, objects, and actions to make decision about an access request.

The first security policy based on past history of events was introduced as Chinese Wall Security Policy (CWSP) [7]. The objective of CWSP is to prevent information flows which cause conflict of interest for individual consultants. Execution history also plays a role in Schneider's security automata [8] and in the Deeds system of Edjlali [9]. However, such works focus on collecting a selective history of sensitive access requests and use this information to constrain further access requests; for instance, network access may be explicitly forbidden after reading certain files. Another approach which considers the history of control transfers, rather than a history of sensitive requests, is presented in [10].

In a basic authorization model, an authorization is modeled by a triple $(s,o,\pm a)$, interpreted as "subject *s* is (not) authorized to exercise access right *a* on object *o*". Recently, several extensions to this basic authorization model have been suggested. One of them is the temporal extension, which increases the expressive power of the basic authorization model [11-15]. In the model proposed by Bertino *et al.* in [11], an authorization is specified as $(time,auth)$, where $time=(t_b,t_e)$ as the time interval, and $auth=(s,o,m,pn,g)$ as an authorization. Here, $t_b$ and $t_e$ represent the start and end times respectively, during which *auth* is valid; *s* represents the subject, *o* the object, and *m* the privilege; *pn* is a binary parameter indicating whether an authorization is negative or positive, and *g* represents the grantor of the authorization. This model also allows operations *WHENEVER*, *ASLONGAS*, *WHENEVERNOT*, and *UNLESS* on authorizations. For example, *WHENEVER* can be used to express that a subject $s_i$ can gain privilege on object *o* whenever another subject $s_j$ has the same privilege on *o*. Later Bertino *et al.* in [14] extended the temporal authorization model to support periodic authorizations. They completed their research in [16] by presenting a powerful authorization mechanism that provides support for: (1) periodic authorizations (both positive and negative), that is, authorizations that hold only in specific periods of time; (2) user-defined deductive temporal rules, by which new authorizations can be derived from those explicitly specified; (3) a hierarchical organization of subjects and objects, supporting a more adequate representation of their semantics. From the authorizations explicitly specified, additional authorizations are automatically derived by the system based on the defined hierarchies.

## III. Preliminaries

In this section we give a brief introduction of the SBAC model, proposed by Javanmardi *et al.* [2, 3], and introduce the representation of time used throughout this work.

### A. Introduction to SBAC

Fundamentally, SBAC consists of three basic components: Ontology Base, Authorization Base, and Operations. Ontology Base is a set of ontologies: Subjects–Ontology (SO), Objects–Ontology (OO), and Actions–Ontology (AO).

By modeling the access control domains using ontologies, SBAC aims at considering semantic relationships in different levels of ontology to perform inferences to make decision about an access request. Authorization Base is a set of authorization rules in the form of $(s,o,\pm a)$ in which *s* is an entity in SO, *o* is an entity defined in OO, and *a* is an action defined in AO. In the other words, a rule determines whether a subject which presents a credential *s* can have the access right *a* on object *o* or not.

The main feature of the model is reduction of semantic relationships in ontologies to subsumption relation. Given two concepts *C* and *D* and a knowledge base $\Sigma$, $C<D$ denotes that *D* subsumes *C* in $\Sigma$. This reasoning based on subsumption proves that *D* (the subsumer) is more general than *C* (the subsumee).

By reducing all semantic relationships to the subsumption, the following propagation rules are enough:

- *Propagation in subjects domain*: Given $(si,o,\pm a)$, if $sj<si$ then $(sj,o,\pm a)$.
- *Propagation in objects domain*: Given $(s,oi,\pm a)$, if $oj<oi$ then $(s,oj,\pm a)$.
- *Propagation in actions domain*:
  - Given $(s,o,+ai)$, if $aj<ai$ then $(s,o,+aj)$.
  - Given $(s,o,-aj)$, if $aj<ai$ then $(s,o,-ai)$.

### B. Modeling of Time

In this paper, we assume a real representation of time. It is worthwhile to note that, we suppose that the response time of the access control system is trivial and thus we ignore the time duration required by the system to check whether a requested access is granted or denied. This assumption allows us to take an access request time as the access time recorded in the history.

A good representation of time for instantaneous events, if possible, is using an absolute dating system. This involves time stamping each event with an absolute real-time. For instance, a convenient dating scheme could be a tuple consisting of the *year*, *month in the year*, *day in month*, *hour in the day*, *minutes*, and *seconds*. For example, (2008 1 20 10 4 50) would be the 20th day of January 2008, at 10:04 (AM) and 50 seconds. The big advantage of dating schemes is that they provide for constant time algorithms for comparing times and use only linear space in the number of items represented.

Time comparisons are reduced to simple numeric comparisons. Date-based representations are only usable, however, in applications where such information is always known, i.e. applications where every event entered has its absolute date identified. There are many applications where this is a reasonable assumption; for instance, databases of transactions on a single machine, say a central machine maintaining banking records. In addition, with absolute dating, we also have information about the duration of time between events (we simply subtract the date of the later event from the date of the earlier one).

## IV. Temporal Semantic based Access Control Model

In this section we introduce our authorization model, Temporal Semantic based Access Control model (TSBAC), which is an extension of the SBAC model. In TSBAC, we extend the basic authorization model in two directions: adding authorization validation time interval, and associating a temporal expression over a *History Base* (history of users' accesses).

### A. Temporal Authorization Rules with Real Time Scheme

In TSBAC we consider a temporal constraint to be associated with each authorization. This constraint is based on the privileges granted to subjects of the system (on objects), or access requests denied, in a specific real *time point* in the past. These elements of history are stored in *History Base*, in the form of donet,s,o,a and deniedt,s,o,a. We refer to an authorization, together with a temporal constraint and a validation time interval, as a temporal authorization rule. A temporal authorization rule is defined as follows.

**Definition (Temporal Authorization Rule):** A temporal authorization rule is a triple ($[t_s,t_f]$,(s,o,±a),F), where $t_s$∈real-time-sceheme, $t_f$∈real-time-scheme, and $t_s \le t_f$. In this notation, $[t_s,t_f]$ represents the authorization validation time interval, and formula *F* is a temporal constraint which is formally defined as in Table 1.

TABLE 1.
DEFINITION OF TEMPORAL PREDICATE *F*

$$\begin{gathered} A ::= done(s,o,a) | denied(s,o,a) | \\ \sim done(s,o,a) | \sim denied(s,o,a) \\ E ::= prev(A) | past\#(A) | H(A, chunk) | sb\#(A,A) | \\ ab(A,A) | ss(A, chunk) | during(A,A) \\ F ::= true | false | E | {\sim} E | E \wedge E | E \vee E | E \rightarrow E | E \leftrightarrow E \end{gathered}$$

Temporal authorization rule ($[t_s,t_f]$,(s,o,±a),F) states that subject *s* is allowed (or not allowed) to exercise access *a* on object *o* in the interval $[t_s,t_f]$, including time instants $t_s$ and $t_f$, in the case that *F* is evaluated to true.

**Definition (Temporal Authorization Base):** A temporal authorization base (TAB) is a set of temporal authorization rules in the form of ($[t_s,t_f]$,(s,o,±a),F), where $t_s$∈real-time and $t_f$∈real-time.

**Definition (History Base):** A History Base is a set of authorizations and time points, in the form of done(t,s,o,a) which means access *a* has been granted to subject *s* on object *o* at real time point *t,* and denied(t,s,o,a) which means the system has denied access *a* on object *o* at real time point *t* requested by subject *s*.

### B. Informal Meaning of Temporal Authorization Rules

The intuitive meaning of temporal authorization rules is as follows. In these statements *auth* is representative of (s,o, ±a).

- ($[t_s,t_f]$,auth,done(s,o,a)): Authorization *auth* is valid in all time instants *t*, in interval $[t_s,t_f]$, in which done(s,o,a) is evaluated to true. In other words, *auth* is valid at time *t*, if done(t,s,o,a) exists in HB.
- ($[t_s,t_f]$,auth,denied(s,o,a)): Authorization *auth* is valid in all time instants *t*, in interval $[t_s,t_f]$, in which denied(s,o,a) is evaluated to true. In other words, *auth* is valid at time *t*, if denied(t,s,o,a) exists in HB.
- ($[t_s,t_f]$,auth,~done(s,o,a)): Authorization *auth* is valid in all time instants *t*, in interval $[t_s,t_f]$, in which done(s,o,a) is not evaluated to true.
- ($[t_s,t_f]$,auth,~denied(s,o,a)): Authorization *auth* is valid in all time instants *t*, in interval $[t_s,t_f]$, in which denied(s,o,a) is not evaluated to true.
- ($[t_s,t_f]$,auth,prev(A)): Authorization *auth* is valid at the time of request (*t*) in interval $[t_s,t_f]$, if *A* is evaluated to true at the previous moment (t-1). The previous *time point* is determined due to the precision of selected time scheme. For example, if the precision of time is "seconds", the tuple to represent time is of the form of (yyyy dd hh mm ss), so the previous time point is (yyyy dd hh mm (ss-1)). In short, to calculate the previous time point, we simply subtract the numerical representation of time by one. So, PrvTimePoint(yyyy dd hh mm ss)=(yyyy dd hh mm ss)-1 Figure 1 gives a more comprehensible view of the operation of this operator.

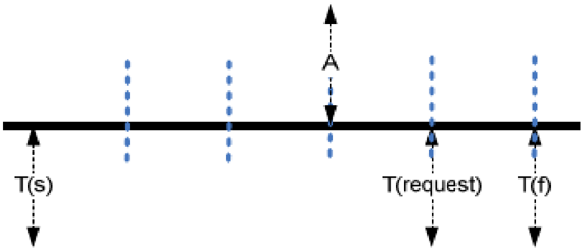

Figure 1. Operation of the *prev* operator on real time axis.

- ($[t_s,t_f]$,auth,past#(A)): Authorization *auth* is valid at the time of request (*t*) in interval $[t_s,t_f]$ if *F* is evaluated to true for # of times from $t_s$ till *t*. 2 gives a more comprehensible view of the operation of this operator.

**Example 1.** Subject $s_1$ is allowed to get another loan (on $Deposit_1$), if he has paid all his (past 36) payments. It is assumed that the date of getting the first loan is 2004/07/01. This rule can be expressed as:

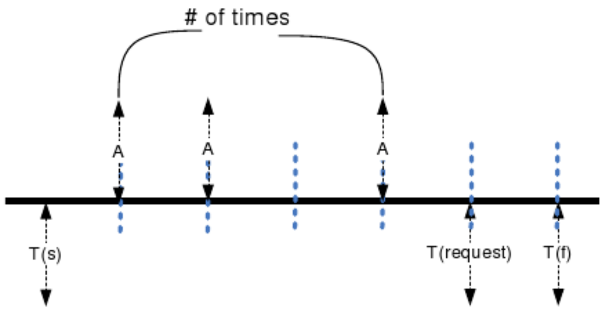

Figure 2. Operation of *past#* operator on real time axis.

$$R:\begin{pmatrix}[2004\ 7\ 1,\infty],(s_1,Deposit_1,+getLoan),\\ past36\big(done(s_1,Deposit_1,payment)\big)\end{pmatrix}.$$

■

- $([t_s,t_f],auth,H(A,chunk))$: Authorization *auth* is valid at the time of request (*t*) in interval $[t_s,t_f]$, if *F* is evaluated to true, at least once in each time interval of length *chunk*, from $t_s$ till *t*. *chunk* is used to reduce the precision of the operator and relax its operation. Figure 3 gives a more comprehensible view of this operator operation.

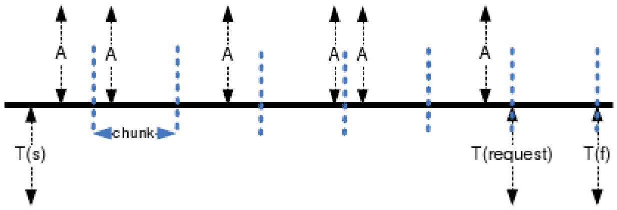

Figure 3. Operation of *H* operator on real time axis.

**Example 2.** Due to insurance rules, everybody can be insured, if he pays for it monthly. This rule for subject $s_1$ that has entered the system since January, 2005 is expressed as: (note that it is assumed a month to be 30 days)

$$R:\begin{pmatrix}[2005\ 1,\infty],(s_1,specialIns,+takeAdvantage),\\ H\big(done(s_1,insDeposit_1,settlement),30\big)\end{pmatrix}.$$

■

All of the operators studied so far, has only one element as their argument. It means that they make their decision (to grant or deny a request) based on presence or absence of just one element in the history base (or first order logic combination of them, but not the temporal relation between two or more of them). In some applications, we need to decide based on the relation between elements of HB. So, TSBAC uses operators that consider the temporal relation between two elements of the history base.

- $([t_s,t_f],auth,sb\#(A_1,A_2))$: Authorization *auth* is valid at the time of request (*t*) in interval $[t_s,t_f]$ if $A_1$ is evaluated to true # of times before the last occurrence of $A_2$, from $t_s$ till *t*. 4 gives a more comprehensible view of the operation of this operator.

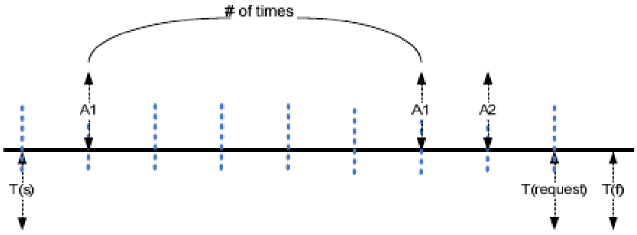

Figure 4. Operation of the *sb#* operator on real time axis

■

- $([t_s,t_f],auth,ab(A_1,A_2))$: Authorization *auth* is valid at the time of request (*t*) in the interval $[t_s,t_f]$ if, if $A_1$ is evaluated to true in $t'\,t_s\le t'\le t$, then there exist a time point $t''$ $t'\le t''\le t$, in which $A_2$ is evaluated to true. In the other words, $A_1$ is evaluated to true in time instants before the evaluation of $A_2$ to true, from $t_s$ till the time of request (*t*). Figure 6 gives a more comprehensible view of the operation of this operator.

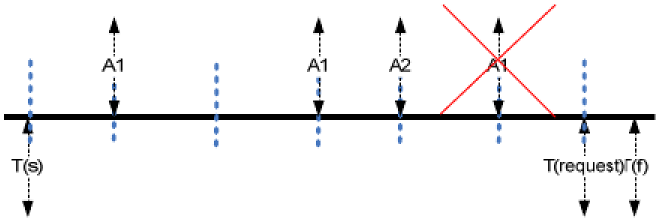

Figure 5. Operation of the *ab* operator on real time axis

**Example 3.** Subject $s_1$ is allowed to get loan on his account (*Account₁*), if he has not withdrawn money from his account since applying for it (that is 2007/01/20). This rule can be expressed as:

$$\begin{pmatrix}[2007\ 20,\infty],(s_1Account_1,+getLoan),\\ ab\begin{pmatrix}\sim done(s_1Account_1,withdraw),\\ done(s_1Account_1,applyForLoan)\end{pmatrix}\end{pmatrix}.$$

■

- $([t_s,t_f],auth,ss(A_1,A_2,chunk))$: Authorization *auth* is valid at the time of request (*t*) in interval $[t_s,t_f]$, if $A_1$ is evaluated to true, at least one time in all time intervals of length chunk, from the first occurrence of $A_2$ in interval $[t_s,t]$. Figure 6 gives a more comprehensible view of the operation of this operator.

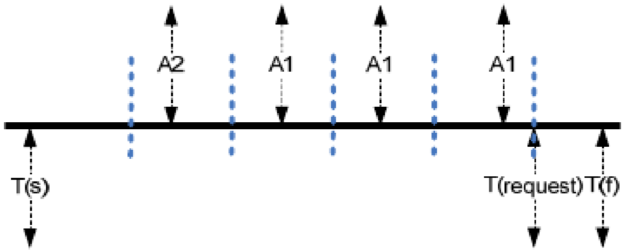

Figure 6. Operation of *ss* operator on real time axis

**Example 4.** Subject s₁ is on the car waiting list, if he paid a prepayment (2006/02/01), and since then he has been paying a defined payment monthly. This rule can be expressed as:

$$\begin{pmatrix} [2006\,31, \infty], (s_1, carWaitingList, +get), \\ ss\begin{pmatrix} done(s_1, Account_1, payment), \\ done(s_1, Account_1, prePayment), 30 \end{pmatrix} \end{pmatrix}.$$

■

- ([t$_s$,t$_f$],auth,during(A$_1$,A$_2$)): Authorization *auth* is valid at the time of request (*t*) in interval [t$_s$,t$_f$] if $A_1$ is not true before the first, or after the last time instant in which $A_2$ is true. Figure 7 gives a more comprehensible view of the operation of this operator.

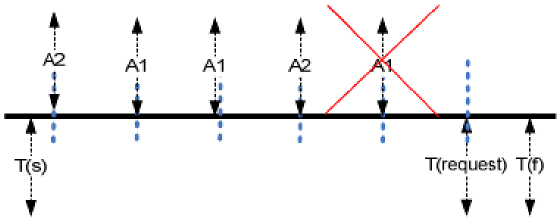

Figure 7. Operation of *during* operator on real time axis

■

- ([t$_s$,t$_f$],auth,~E): Authorization *auth* is valid for each time instant *t* in interval [t$_s$,t$_f$] in which *E* is *not* evaluated to true.
- ([t$_s$,t$_f$],auth,E$_1$∧E$_2$): Authorization *auth* is valid for each time instant *t* in the interval [t$_s$,t$_f$] in which $E_1$ and $E_2$ are both evaluated to true.
- ([t$_s$,t$_f$],auth,E$_1$∨E$_2$): Authorization *auth* is valid for each time instant *t* in the interval [t$_s$,t$_f$] in which $E_1$ or $E_2$ or both of them are evaluated to true.
- ([t$_s$,t$_f$],auth,E$_1$→E$_2$): Authorization *auth* is valid for each time instant *t* in the interval [t$_s$,t$_f$] in which, if $A_1$ is evaluated to true, then $A_2$ is also evaluated to true.
- ([t$_s$,t$_f$],auth,E$_1$↔E$_2$): Authorization *auth* is valid for each time instant *t* in the interval [t$_s$,t$_f$], in which $A_1$ is evaluated to true if and only if $A_2$ is evaluated to true.

### *C. Formal Semantics of Temporal Authorization Rules*

Next we formalize the semantics of authorization rules described so far.

**Definition (Valid Authorization):** an authorization (s,o,±a) is valid at time *t*, if one of the following situations occurred:

1. At time *t*, a temporal authorization rule ([t$_s$,t$_f$],(s,o,±a),F) with t$_s$≤t≤t$_f$ exists in TAB and *F* is evaluated to true based on the elements exist in *History Base* (we define function *f* for performing such an evaluation),
2. There exists a temporal authorization rule ([t$_s$,t$_f$],(s',o',±a'),F) in TAB with t$_s$≤t≤t$_f$ in which *F* is evaluated to true, and (s',o',±a') is derived from (s,o,±a) following the inference rules of SBAC.

- To formalize the semantics of temporal authorization rules, we first define an evaluation function $f_{real}$. This function evaluates the predicate *F* of temporal authorization rules at a real time point *t* and based on the elements stored in *History Base*. The semantics of such an evaluation is given in first order logic and is reported in Table 2. The semantics of a set *X* of temporal authorization rules, denoted by *S(X)*, is the conjunction of the first order formulas corresponding to each element in the set.
- Note that a temporal authorization rule can be removed and therefore not be applicable anymore for the derivation of authorizations. In the formalization we take this possibility into account, by associating with each temporal authorization rule the time $t_d$ at which it is removed. Note that time $t_d$ is not a constant and it is not known from the former. We use it as shorthand for expressing the point up to which a temporal authorization rule is applicable. A function *removed()* can be defined, which, given a temporal authorization rule, *X*, and a time *t* returns *false* if at time *t*, *X* is still present in the TAB, and ,*true*, otherwise. Time $t_d$ is the smallest time *t* for which function *removed(t , X)* returns *true*.

TABLE 2.
FORMAL SEMANTICS OF THE $F_{REAL}$ EVALUATION FUNCTION

$$f_{real}\left(t, t_s, t_f, done(s,o,a)\right) = \begin{cases} true\,, t \in [t_s, t_f] \wedge done(t,s,o,a) \in HB \\ false\,, t \notin [t_s, t_f] \vee done(t,s,o,a) \notin HB \end{cases}$$

$$f_{real}\left(t, t_s, t_f, denied(s,o,a)\right) = \begin{cases} true\,, t \in [t_s, t_f] \wedge denied(t,s,o,a) \in HB \\ false\,, t \notin [t_s, t_f] \vee denied(t,s,o,a) \notin HB \end{cases}$$

$$f_{real}\left(t, t_s, t_f, \sim done(s,o,a)\right) = \begin{cases} true\,, \nexists t, t \in [t_s, t_f] \cdot done(t,s,o,a) \in HB \\ false\,, \exists t, t \in [t_s, t_f] \cdot done(t,s,o,a) \in HB \end{cases}$$

$$f_{real}\left(t, t_s, t_f, \sim denied(s,o,a)\right) = \begin{cases} true\,, \nexists t, t \in [t_s, t_f] \cdot denied(t,s,o,a) \in HB \\ false\,, \exists t, t \in [t_s, t_f] \cdot denied(t,s,o,a) \in HB \end{cases}$$

$$f_{real}\left(t, t_s, t_f, prev(A)\right) = f\left(t-1, t_s, t_f, A\right)$$

$$f_{real}\left(t, t_s, t_f, past\#(A)\right) = \exists t_1, \dots, t_\# \cdot \bigwedge_{k=1}^{\#} f\left(t_k, t_s, t_f, A\right)$$

$$f_{real}\left(t, t_s, t_f, H(A, chunk)\right) = \exists t_0, \dots, t_{\lfloor (t-t_s)/_{chunk} \rfloor - 1} \leq t \cdot \bigwedge_{k=0}^{\lfloor (t-t_s)/_{chunk} \rfloor - 1} f(t_k, t_s + i \times chunk, t_s + (i+1) \times chunk, A)$$

$$f_{real}\left(t, t_s, t_f, sb\#(A_1, A_2)\right) = \exists t_{22} \leq t, \exists t_1, \dots, t_\# \leq t_{22} \cdot f\left(t_{22}, t_s, t_f, A_2\right) \wedge \bigwedge_{k=1}^{\#} f\left(t_k, t_s, t_f, A_1\right)$$

&\qquad\wedge\left(\nexists t_y,t_{max}\le t_y\wedge f\left(t_y,t_s,t_f,A_2\right)\right)\Big)\Big)\\
&\qquad\to\Big(\forall t_1,t_1\le t\\
&\qquad\to\Big(f\left(t_1,t_s,t_f,A_1\right)\to t_{min}\le t_1\\
&\qquad\le t_{max}\Big)\Big)
\end{aligned}
$$

$$
\begin{aligned}
f_{real}\left(t,t_s,t_f,\sim E\right)&=\sim f\left(t,t_s,t_f,E\right)\\
f_{real}\left(t,t_s,t_f,E_1\wedge E_2\right)&=f\left(t,t_s,t_f,E_1\right)\wedge f\left(t,t_s,t_f,E_2\right)\\
f_{real}\left(t,t_s,t_f,E_1\vee E_2\right)&=f\left(t,t_s,t_f,E_1\right)\vee f\left(t,t_s,t_f,E_2\right)
\end{aligned}
$$

$$
\begin{aligned}
&f_{real}\left(t,t_s,t_f,E_1\to E_2\right)\\
&\qquad=f\left(t,t_s,t_f,E_1\right)\wedge\sim f\left(t,t_s,t_f,E_2\right)\\
&f_{real}\left(t,t_s,t_f,E_1\leftrightarrow E_2\right)\\
&\qquad=\left(f\left(t,t_s,t_f,E_1\right)\to f\left(t,t_s,t_f,E_2\right)\right)\\
&\qquad\wedge\left(f\left(t,t_s,t_f,E_2\right)\to f\left(t,t_s,t_f,E_1\right)\right)
\end{aligned}
$$

By the definition of evaluation function freal and by the assumption described above, the semantics of authorization rules are in Table 3 . In the following, grantt,s,o,a denotes subject s is granted to exercise action a on object o and analogously denyt,s,o,a denotes the access request of s for exercising an access a on object o is denied.

$$

### D. Access Control

The centric security mechanism in each system is an access control system. By receiving an access request in such a system, we need to make a decision whether to grant the requested access or deny it. Following the proposed model of temporal authorization in the previous sections, upon receiving an access request sr,or.ar at time *t*, the access control system performs the following steps:

1. Determine the explicit and implicit valid authorization rules in TAB at time *t* (following the definition of valid authorization rules), satisfying the following conditions:
   - $t_s \le t \le min(t_f,t_d)$
   - Temporal predicate *F* is evaluated to true at time *t* (based $f_{real}$ evaluation function).
2. Extract the set of valid authorization rules such as ([$t_s$,$t_f$],(s,o,±a),F) which match the access request. These authorization rules must satisfy, at least, one of the following conditions:
   - s=$s_r$ , o=$o_r$ , a=$a_r$
   - Following the propagation rules of the SBAC model, in the case of a positive action (+a), we have sr<s , or<o , ar<a, and in the case of a negative action (-a), we have sr<s , or<o , a<ar.
3. If there exist just positive valid authorization rule(s) such as ([$t_s$,$t_f$],(s,o,+a),F) in MVA, grant the requested access,
4. If there exist just negative valid authorization rule(s) such as ([$t_s$,$t_f$],(s,o,-a),F) in MVA, deny the access request,
5. If there exist both positive and negative authorization rules in MVA, do conflict resolution and follow the result,
6. If there exists no valid authorization rule, which matches the requested access, follow the default access policy,
7. Record done($s_r$,$o_r$.$a_r$) in the case that the requested access is granted, and denied($s_r$,$o_r$,$a_r$) in the case that the access request is denied.

In this model, the default access policy might be *positive (open)* to grant all undetermined accesses, or *negative (close)* to deny them. The default access policy is determined by the administrator.

### E. Conflict Detection and Resolution

A conflict occurs when two or more access policies cannot be applied in the same time. In access control, due to modal conflict between *matched valid authorizations*, we need a conflict resolution strategy.

#### 1) Conflict Occurrence

In TSBAC, conflict occurs due to semantic relations between entities (in the domains of subjects, objects, or actions) and applying the inference rules of SBAC, or due to sub-interval relationship between the temporal authorization rules of the TSBAC model.

- *Conflict due to semantic relations between the entities*: as mentioned before, in the domains of subjects and objects, the subsumee has all the privileges (positive and negative) of the subsumer, but, in the domain of actions, positive access rights is propagated from subsumer to subsumee, while negative access rights is propagated in the opposite direction (that is from subsumee to subsumer). These semantic relationships and the propagation of negative and positive authorizations between the entities may result in conflicting situations. As an example, consider the following History Base, semantic relation, and authorization rules:

$$\begin{array}{l}
\boldsymbol{HB\ Contains}: \\
done(10, Student, doc_1, read), \\
done(8, Ali, doc_1, write) \\
R_1: \begin{pmatrix} [0,25], (Student, doc_1, +read), \\ prev\big(done(Student, doc_1, read)\big) \end{pmatrix} \\
R_2: \begin{pmatrix} [0,25], (Ali, doc_1, -read), \\ prev\big(done(Student, doc_1, read)\big) \end{pmatrix} \\
\boldsymbol{Subjects\ Ontology}: \\
Ali \prec Student
\end{array}$$

If *Ali* requests a *read* access at time *11* , due to $R_2$ authorization rule, this access is denied, but due to the $R_1$ authorization rule we have Student,doc1,+read , and based on the sample subjects ontology, the *read* access is also granted for *Ali* . So, in this situation we are confronted with a conflicting situation, due to the semantic relationships between the entities.

- *Conflict due to sub-interval relationship between authorization rules*: as an example, consider the following HB, and authorization rules:

$$\begin{array}{l}
\boldsymbol{HB\ Contains}: \\
done(8, Ali, doc_1, read), done(9, Ali, doc_1, read), \\
done(10, Ali, doc_1, read) \\
R_1: \begin{pmatrix} [8,20], (Ali, doc_1, +read), \\ H\big(done(Ali, doc_1, read)\big) \end{pmatrix} \\
R_2: \begin{pmatrix} [0,20], (Ali, doc_1, -read), \\ prev\big(done(Ali, doc_1, read)\big) \end{pmatrix}
\end{array}$$

If *Ali* requests a *read* access at time *11* , due to $R_2$ authorization rule, this access is denied, but is granted due to the $R_1$ authorization rule. So, we are confronted with a conflicting situation based on the sub-interval relationship between $R_1$ and $R_2$.

#### 2) Conflict Resolution

The model supports four predefined strategies for conflict resolution; negative authorization rule takes precedence (NTP) strategy, positive authorization rule takes precedence (PTP) strategy, most specific authorization rule takes precedence, and newer authorization rule takes precedence. Similar to default access policy, the conflict resolution strategy is determined by the administrator.

### F. Temporal Authorization Base Administration

Authorization rules can be changed upon the execution of administrative operations. In this paper, we consider a centralized policy for administration of authorizations where administrative operations can be executed only by the administrator.

Administrative operations allow the administrator to add, remove, or modify (a *remove* operation followed by an *add* operation) temporal authorizations rules. Each temporal authorization rule in the TAB is identified by a unique label assigned by the system at the time of its insertion. The label allows the administrator to refer to a specific temporal authorization rule upon execution of administrative operations. A brief description of the administrative operations is as follows:

*addRule*: To add a new temporal authorization rule. When a new rule is inserted, a label (*rule identifier* or *rid*) is assigned by the system.

*dropRule*: To drop an existing temporal authorization rule. The operation requires as argument, the label of the rule to be removed.

## V. Architecture

In order to guarantee the applicability of the model and usefulness in semantic based and temporal environments, an architecture for the temporal semantic based access control model is proposed.

Several frameworks has been proposed for access control and security in recent years, which, the standard framework of the ITU-T [17] for access control and the standard framework OASIS under the name XACML [18] are the most popular ones. during the design of our model, we have tried to include the elements of both the frameworks mentioned above, especially, the XACML. The major elements of the system are illustrated in .8 The system is composed of a number of *internal* and *external* elements which are described next.

### A. External Entities

The major external entities interacting the system are:

***Subject***: A subject can be a person, a service, or a machine that tries to access resources or objects in a semantic based environment.

***Environment***: The set of *attributes* that are relevant to an *authorization decision* and are independent of a particular *subject, resource*, or *action*.

***Objects and access rights***: entities which provide ontologies in the domains of subject, object, and action. These ontologies and the semantic relations between them are helpful in propagation and inference of new security rules.

### B. Administration Console

This console enables the security administrator to describe meta-policies and also description and administration of the ontologies. The major components of the administration console are as follows:

***Policy Administration Point (PAP)***: The system entity that creates a policy or policy set.

***Ontology manager***: Gathers and updates ontologies in domains of subjects, objects, and actions and also reduces the semantic relations to the subsumption relation.

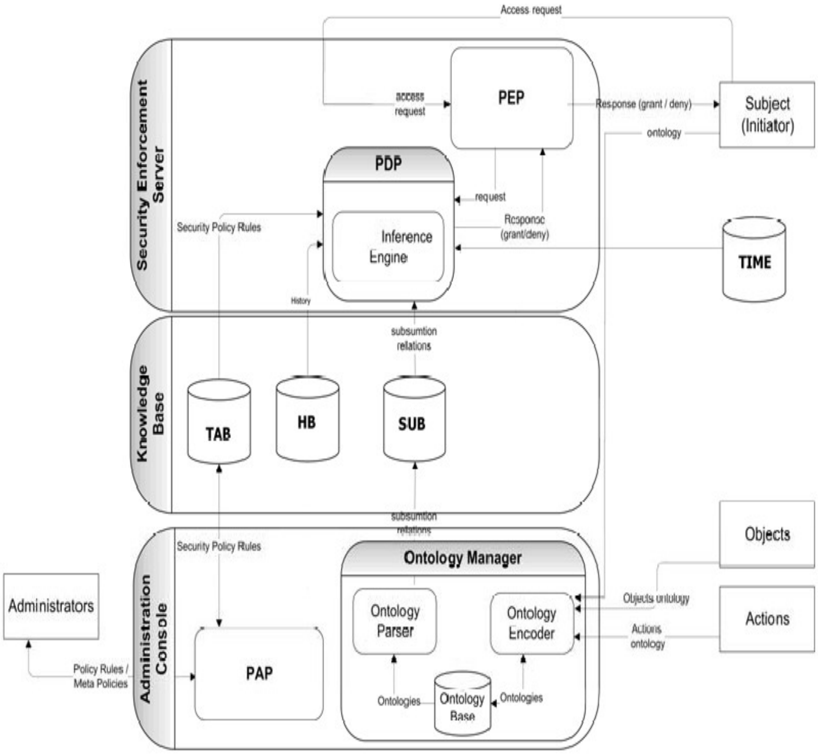

Figure 8. An architecture for an access control system based on TSBAC model

### C. Knowledge Base

As described in the model, the knowledge base is composed of the set of *authorization rules* in TAB, *history of authorizations* (HB), *subsumption relations* between concepts (SUB), and a *time counter* (TIME). Inference of implicit authorization rules is based upon the facts and rules in the knowledge base.

### D. Security Enforcement Server

This element manages inference of the implicit authorization rules and applying them in access control requests. Major sub-elements of this element are as follows:

***Policy Decision Point (PDP)***: The system entity that evaluates *applicable policy* and renders an *authorization decision* by making use of an inference engine, based on facts and rules in the knowledge base.

***Policy Enforcement Point (PEP)***: The system entity that performs access control, by making decision requests and enforcing authorization decisions.

## VI. Discussion and Evaluation

Evaluating authorization models and access control mechanisms, and presenting acceptable criteria in this domain, has been a problem in security and access control zone. Comparing security models with each other, due to differences between them in security definition, seems improper. Security is a comparative quality, and assumptions in security definitions in an environment and security requirements in that environment makes distinctive differences in designing the model. The best way to evaluate a model is to qualitatively scrutiny the model to ensure accordance with security requirements of environment under custody. Moreover, we can take some quantitative criteria into account, but this consideration is possible if an implementation exists for the access control system based on the model.

### A. Qualitative Evaluation of TSBAC Model

In this section, we evaluate TSBAC, regarding requirements of semantic and history based environments.

- Fine-grained and Coarse-grained Authorization: TSBAC allows definition of policies for entities in three domains of access control (namely subjects, objects, and actions), so it provides coarse-grained authorization. Moreover, with the existence of ontology, and possibility of defining entities to the individual level, fine-grained authorization is provided.
- Conditional Authorization: With the existence of temporal operators, TSBAC supports this type of authorization. In this model, due to wide spectrum of temporal operators, and using first order logic operators for combining temporal expressions, conditional authorization is provided, on the basis of existence or nonexistence of specific authorizations in the past.
- Different Policies and Expressing Exceptions: TSBAC provides synthetic policy (including negative and positive authorizations). Moreover, by using ontology in domains of subjects, objects, and actions, and utilizing different authorization propagation methods, expressing exceptions and synthetic policies is possible.

- Conflict Detection and Resolution: Conflict occurrence may be a result of semantic relationships between authorizations, or, sub-interval relations between validity constraint intervals. TSBAC detects these conflicts, and resolves them. Different conflict resolution policies include: denials take precedence, positives take precedence, most specific takes precedence, and newer overrides older.
- Ease of Implementation and Integration with Semantic Web technologies: Security models designed for Semantic Web should be compatible with the technology infrastructure under it. In other words, the implementation of security mechanisms should be possible based on the semantic expression models. SBAC is designed based on the widely accepted semantic web languages, OWL and SWRL; therefore its implementation can be easily achieved by existing tools designed for working with these languages.
- Supporting History-based Information: The main feature of TSBAC is that authorizing an access request is done based on granted or denied access requests (done and denied access requests, which are stored in History Base), or, access requests that have not been done or have not been denied in the system (which can be inferred from History Base). These elements could be combined with temporal operators, or first order logics operators to compose temporal expressions.
- Interoperability : Interoperating across administrative boundaries is achieved through exchanging authorizations for distributing and assembling authorization rules. The ontological modeling of
- Authorization rules in SBAC results in a higher degree of interoperability compared with other approaches to access control. This is because of the nature of ontologies in providing semantic interoperability.
- Generality: Modeling different domains of access control has added a considerable generality to the model. In the subject domain, TSBAC uses credentials which are going to be universally used for user authentication. In the domain of object, different kinds of resources such as web pages or web services can be modeled and can be identified by their URI in authorization rules.

### B. *Quantitative Evaluation of TSBAC*

- Time Complexity: Since every access request is validated at the time of the request, and the process of authorization is based upon searching History Base and evaluating the temporal predicate, due to vast amount of elements of History Base and temporal predicate complexity, access control in TSBAC is time consuming. In some situations, in order to evaluate the temporal predicate, we need to scrutinize the existence of "not-done" or "not denied" requests, and this adds to the time complexity of access control process.

In order to clarify the subjects mentioned above, we give a brief complexity analysis on real time operators (in case of existence of *n* elements in History Base) of the model:

complexityprev=n<br>
complexityH=t-ts/chunk×n<br>
complexitypast#=#×n<br>
complexitysb#=#+1n<br>
complexityab=n<br>
complexityss≤t-ts/chunk×n<br>
complexityduring=n

- Space Complexity: All of the access requests (granted or denied) are stored in History Base. Storing all the requested accesses in the system, gradually, requires a huge amount of storage space. In case of a vast amount of history elements, and thus incapability of keeping all these elements on volatile storage, time complexity of access control process is amplified.

## VII. Conclusions and Future Work

Access control and its requirements in new computing environments, semantic aware access control, and history based access control have been discussed in this paper. Based on the Semantic Based Access Control model (SBAC), and to enhance the capabilities of the model, a semantic aware access control model, which takes the history of accesses of the system into account (TSBAC) is proposed. TSBAC uses the same semantic relationships of the SBAC model, and moreover, it is capable of using temporal relations between authorizations in applying access control. Specifically, TSBAC assigns a temporal expression (over users' history of accesses) to each authorization that expresses the conditions under which the authorization applies. A constraining time interval restricts the interval of validity of the authorization. These authorization rules (which are composed of base authorization of SBAC, constraining time interval, and temporal expression), provides the ability to derive new authorizations based on existence (or non-existence) of other authorizations in the past.

We also proposed formal semantics of our authorization rules. Access control, and conflict detection and resolution presented. An architecture for the access control system based on TSBAC was presented.

Producing preconditions of applying temporal logics operators in Java language, and using these preconditions in CLIPS inference engine in order to apply access control can be considered as some future works.

One of the main deficiencies of TSBAC is the lack of a formal proof for soundness and completeness of temporal operators of the model. On the other hand, a generalized history-based access control model that could be applied to other access control policies (such as RBAC) is one of the important works that could be done.

# Network-level properties of modern anonymity systems

Marta Rybczyńska
Warsaw University of Technology

Email: mrybczyn@elka.pw.edu.pl

***Abstract*—This paper shows the network-level view of the behaviour of two popular and deployed anonymity systems; Tor and JAP (AN.ON). The analysis uses the fact that both of them depend on TCP (Transmission Control Protocol) and shows cases when network conditions may affect the systems' operations. The main topics are: on-off traffic, difference in available bandwidth between peers, and usage of the window mechanism in the TCP. The analysis is divided into two parts: from both the sender's and receiver's point of view. We present the results of experiments made on live systems, showing that the analysed effects may be encountered in practice.**

## I. Introduction

THIS PAPER studies network-level effects on performance and protection given by modern anonymity systems. As the anonymity layer is built on top of the existing network protocols, the interactions between the two may affect the operations of the anonymity system.

We focus on the effects the TCP protocol has on the two most popular and already deployed designs; Tor and JAP. Although a significant amount of effort has been put into researching possible attacks against the protection mechanisms used by those systems, it is not clear which features of the network protocol allow the system to gain better protection, and which should be avoided.

It has been shown that attacks by traffic analysis against Tor are possible, when the attacker modifies the traffic from the sender's side [21]. We check if this works equally well against both Tor and JAP, and look into the limits of such attacks, introduced by the network conditions. We do not limit the analysis to the sender's side only, but also investigate the way the receiver can shape the traffic using the TCP flow control. The analysis and interpretation of results concentrate on the security-related issues, but we also look into possible performance implications when they are clear of issues.

The remainder of this paper is structured as follows: Section 2 reviews the related work and gives the background on Tor and JAP. In Section 3 we show our methodology and setup. The analysis and results are presented in Section 4. We conclude the paper in Section 5.

## II. Background

Modern anonymity systems can be divided into two types. The first type introduces a noticeable delay, even up to days, in exchange for good anonymity of the user messages. Such systems are designed for services like e-mail. Two important examples are Mixminion [6] and Mixmaster [13]. The second group can be used for real-time or nearly real-time applications, like web browsing or remote access. Such systems are designed using client-server or peer-to-peer model. Important examples include Tor [7], JAP (AN.ON) [2], Freedom [3] (all three client-server), and the new I2P system [8] (peer-to-peer).

### A. Tor

Tor is a low-delay, high-bandwidth anonymity system developed for TCP traffic, like web browsing [7]. It includes several extra features, like hidden servers.

The current implementation uses TCP connections between the nodes. It neither supports cover traffic, nor mixing. Congestion control and simple traffic shaping exist. The flows are routed independently through the network. However, multiple requests transmitted between the same two intermediate nodes may be multiplexed and form one connection.

When it comes to the network layer, Tor uses TCP/IP implementation provided by the host operating system. All the processing is done at the user level. From the networking point of view, Tor is a cascade of proxy servers with traffic aggregation.

### B. JAP (AN.ON)

JAP (Java Anon Proxy) is an anonymity system developed at the University of Dresden [10] [11].

It uses a different approach than Tor. Instead of onion routing, it uses a modified version of Chaum mixes. JAP does not form one single network. Instead, users connect to so called cascades. In a cascade, mixes are connected by single connections only, which are used to transfer all the traffic. Additionally, proxy cache servers may be added after the last mix. In practice, JAP uses static cascades. All flows share the same path and are transmitted in a single TCP connection between subsequent nodes (mixes).

From the networking point of view, JAP is, just like Tor, a cascade of proxy servers also implemented as external applications.

### C. Related work

The influence of traffic on the operations of the anonymity systems has been studied mainly in the context of traffic analysis attacks. That class of attacks uses flow properties to match flows before and after the anonymity system.

978-83-60810-14-9/08/$25.00 © 2008 IEEE

In the literature, a statistical approach is often used, as in [5]. Murdoch and Danezis have shown an attack against Tor that marks traffic flows by introducing delays, caused by flooding a node with traffic from an attacker–owned, corrupted node [14]. On the other hand, Wiangsripanawan et al. state that the attack would not work against systems using a different design, like that of Tarzan [19]. Zhu et al. have used a different approach and studied flow correlation attacks for a mix–based system [22]. They propose dummy traffic as a defence.

The problem of timing attacks have been studied in a number of papers [12] [16] [20], showing that numerous properties of the traffic can be observed at the other end of the anonymity system. Shmatikov et al. propose dummy traffic against such attacks [17]. It has also been shown that single flows can be recognised in the aggregated traffic [23]. Yu et al. introduce a flow marking technique where they mark traffic by the changing transfer rate, and detect the introduced pseudo-noise code later [21].

Research on the performance of current designs and reasons for that performance has been much less intensive. Wendolsky et al. measured the delay introduced by Tor and AN.ON (JAP), and report it to be in seconds, rather than milliseconds [18].

## III. Setup and methodology

Our test environment consisted of two computers, controlled by us, and connected to the Internet. One of the machines had a Web server installed, the other one worked as client. The client also used Tor and JAP client software, which was used to connect to the anonymity systems.

During the test we downloaded several files of different sizes, from 40MB to 100KB, from our server to the client, using the two chosen anonymity systems during their normal operations. We did not control any of the nodes, nor interfere with the standard path selection algorithms.

We introduced changes to the traffic sent by the server and received by the client using bandwidth limits by utilising the standard Linux firewall tool iptables/netfilter with additional, custom scripts. We examined the direction from the sender using traffic shaped into bursts with lengths of 60 and 10 seconds, and with a constant limit during experiments performed on the receiver. There were two types of bursts, with the first at 128 kbit/sec and the second at 64 kbit/s. Between bursts, the transmission took place at 32 kbit/sec. Such rates were chosen after initial experiments, showing that JAP allows us to transfer at a maximum rate of 128 kbit/sec. All the traffic was captured for later analysis.

We used unmodified client software and only services available to the general public. It turned out that while huge a majority of Tor connections offered acceptable performance (there were, however, sporadic connection resets and stops of the data flow), JAP showed the performance needed for the experiments only on one cascade; Desden-Dresden. On the other cascades, unexpected connection drops and/or very low bandwidth prevented even short file transfers.

As we did not control the anonymity systems or the behaviour of other users, we could not achieve full stability of the conditions for our measurements. We addressed that issue at different levels. Our transfers were relatively long (from several seconds up to minutes), what allowed us to limit the impact of short disturbances, which were observed in the traffic. Low transfer rates allowed us to perform transfers without interfering with other limits there may be on the path, and without putting significant stress on the anonymity system nodes. Finally, we performed the experiments during the same hours and days of the week.

The later analysis was performed using the recorded traces. We processed the traces to get the number of packets in a one second timeframe. Then we calculated the cross-correlation between both ends. We used the following equation:

$$r(d) = \frac{\sum_i [(x(i) - mx) * (y(i-d) - my)]}{\sqrt{\sum_i (x(i) - mx)^2} \sqrt{\sum_i (y(i-d) - my)^2}} \qquad (1)$$

where $d$ is delay, $r$ is cross–correlation, $x(i)$ and $y(i)$ are the signals, and $i = 0, 1, ..N - 1$. $mx$ and $my$ are the mean values of the $x$ and $y$ signals, respectively. Cross-correlation is often used as a metric in anonymity system evaluation ([22], [12] or [21]), because it gives an attacker a relatively simple and efficient tool to match the sender with the receiver. We used that metric for the same reasons.

## IV. Analysis and results

The analysis is based on TCP properties and on the properties of TCP connection cascades. Similar tests may be performed for any other TCP-based anonymity system.

Figure 1 shows one of our Tor transfers with no modifications from our side, in which a number of interesting facts arise. The first one is the disturbance at approx. 400 seconds from the transfer start, which is clearly visible in both the server and client traffic. Such disturbances can cause attacks to fail and were also observed in the other traces.

It is also worth noting that the number of packets on both pictures differs. The server sends at approx. 20 packets/sec, while the client receives at 40 packets/sec. That fact is easy to explain after realizing that the first picture shows plain a HTTP response, when the second shows the same response, but for packed and encrypted in Tor messages. That is why those pictures, and the ones shown later, should not be compared directly.

Figure 2 shows similar graphs for JAP traffic, with visible bursts on the server side (similar ones appear in all of our transfers) which looks like the expected results of the backward attack. The client traffic does not run at the maximum rate, however, as there are also bursts visible from that side.

### A. Sender side

A number of different modifications to the traffic may be made on the sender side. For instance, the server may limit bandwidth for a single flow. There may also be bursts of traffic as the server switches from one flow to another. Additionally, there may be losses, which cause TCP retransmissions. We

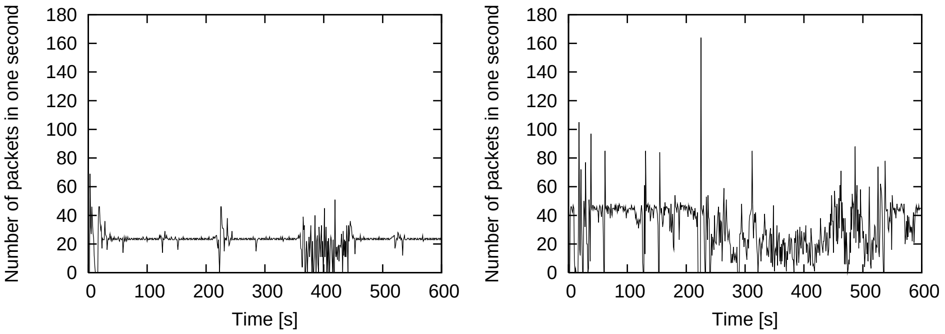

Fig. 1. Traffic flow sent from the server (left) and received by the client (right) during a transfer using Tor, without modifications to the traffic.

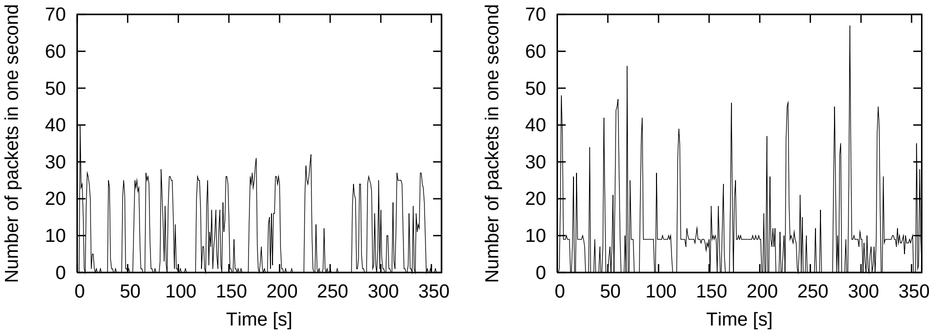

Fig. 2. Traffic flow sent from the server (left) and received by the client (right) during a transfer using JAP, without modifications to the traffic.

wanted to check if and how echos of such events would be visible on the receiver side.

Such echos are likely because of one of the basic features of the TCP protocol [9] [15], namely the fact that the data reaches the receiver application in the same order it was sent, even if it might have reached the node in a different order. It means that if one message is delayed, the data from the later ones would not reach the receiver before the delayed message is received correctly. Given the fact that the path used by the anonymity system consists of several TCP connections, the delays will cumulate.[1] That analysis is correct for both Tor and JAP, as they both use the TCP for transfers between the nodes and between the user and the nodes.

Such properties were already discussed in the context of traffic analysis attacks, as in [14] or [12]. We are not aware, however, of effectiveness tests under real-world conditions.

Figures 3 and 4 show modulated traffic before and after it is transferred, using Tor and JAP, respectively. In both cases the anonymity system did not change the delays and transfer rates to the extent that would make it unrecognisable.

In the tests we introduced a known traffic pattern into the anonymity systems and observed the resulting flow on the receiver side. In the first test, our server was transmitting at 128kbit/sec for 60 seconds, then at 32kbit/sec for 120 seconds, then at 64kbit/sec for 60 seconds and then, finally, at 32kbit/sec again for another 120 seconds. The relatively slow transmission rates were used to limit the possibility of reaching any other limits there might be on the path. The results are presented in Tab. I. Tor traffic obviously shows high correlation. In the case of JAP, the correlation is not that easily seen. However, after calculating cross-correlation between the flows using the equation (1), the values for the corresponding flows are the highest.

TABLE I
CROSS–CORRELATION BETWEEN THE USER AND SERVER SIDE TRAFFIC.

| System | Test | Best correlation |
|---|---|---|
| None | Normal transfer | 0.97 |
| Tor | Long bursts | 0.82 |
| | Short bursts | 0.23 |
| JAP | Long bursts | 0.54 |
| | Short bursts | 0.59 |

TABLE II
CHANGE OF BURST LENGTH AFTER PASSING THROUGH ANONYMITY SYSTEMS (ORIGINAL LENGTH: 60 SAMPLES).

| System | Burst length (before) | | Burst length (after) | |
|---|---|---|---|---|
| | avg. | std. dev. | avg. | std. dev. |
| Tor | 50.0 | 4.1 | 59.4 | 9.3 |
| JAP | 47.9 | 7.0 | 52.7 | 10.1 |

We have also calculated the length of the burst before and after the anonymity system. The results are presented in Table II. In both cases, bursts after the anonymity system are longer

[1] That is independent from packet reordering. The packets will be placed back in the correct order on every anonymity system node during TCP data reassembly, before passing them to the application (anonymity software, in this case).

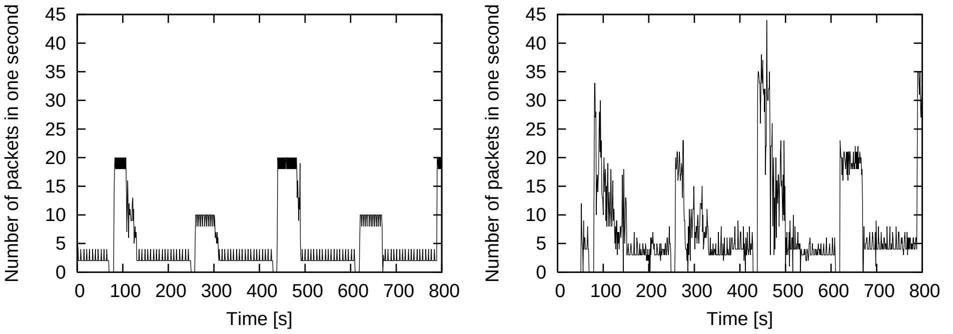

Fig. 3. Traffic flow sent from the server (left) and received by the client (right) during a transfer using Tor, sender–side traffic shaping.

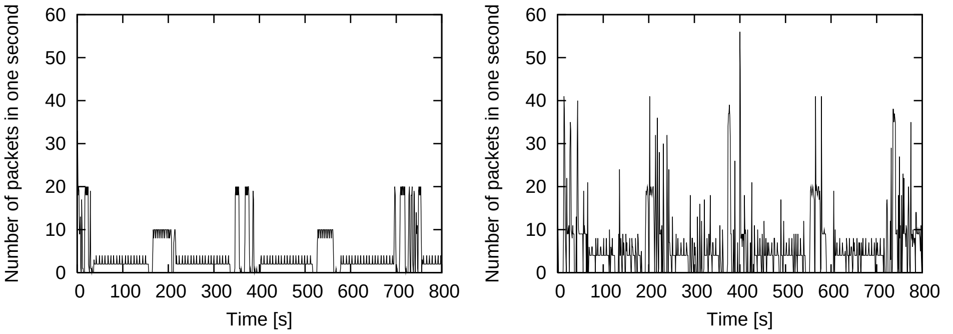

Fig. 4. Traffic flow sent from the server (left) and received by the client (right) during a transfer using JAP, sender–side traffic shaping.

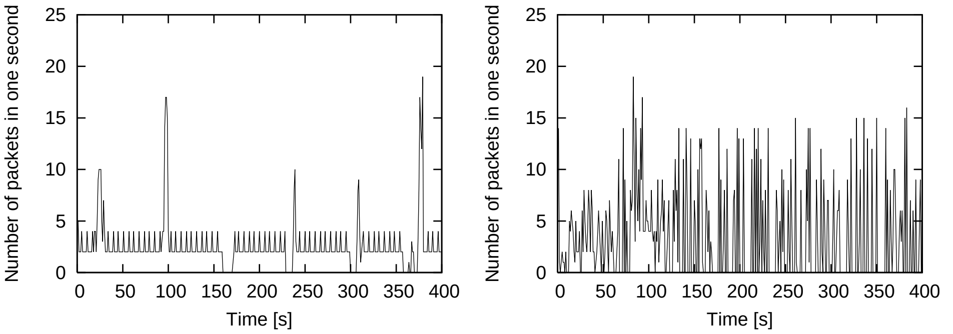

Fig. 5. Traffic flow sent from the server (left) and received by the client (right) during a transfer using Tor, server-side traffic shaping with short bursts.

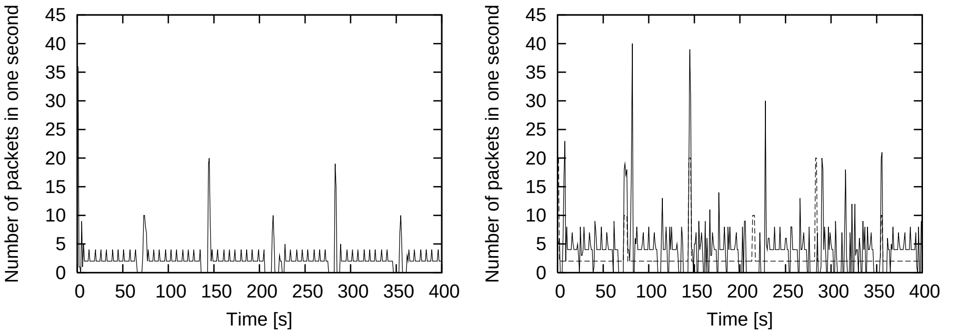

Fig. 6. Traffic flow sent from the server (left) and received by the client (right) during a transfer using JAP, server-side traffic shaping with short bursts.

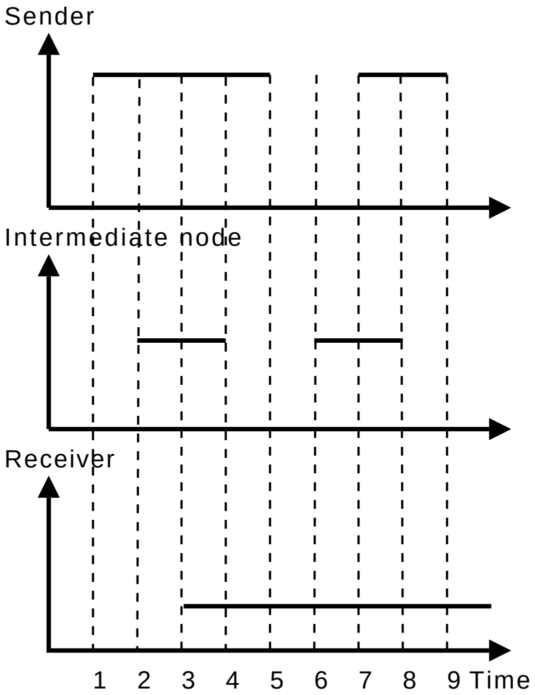

Fig. 7. Application-level view of the traffic in TCP-based anonymity systems as a result of flow control, in the case of differences in available bandwidth, from the sender (S) to the receiver (R) using the intermediate node (IM). Main events: (1) S starts transmitting to IM, (2) IM starts transmitting to R, (3) R starts getting data, (4) IM's transmit buffer full, stops receiving from S, (5) S' transmit buffer full, stops sending, (6) IM re-starts sending to R and receiving from S, (7) S re-starts sending to IM, (8) IM's transmit buffer full again, (9) S' transmit buffer full again.

than before, but the standard deviation also increases.

As the test was successful, we performed another one, using shorter, 10 second bursts. There were two types of bursts: at 128 and 64 kbit/sec. The traffic was then formed at the server, as shown in Figures 6 and 5. It can be noticed that the bursts are actually shorter than 10 seconds, which is an effect of the rate switching.

This time, the Tor traffic shown in Figure 5 did not show similarities to the original. That was also confirmed by low cross-correlation.

The JAP traffic shown in Figure 6, on the other hand, shows some similarities to the original. The cross-correlation test gave values at nearly the same levels as in the previous case of longer bursts.

### B. Receiver side

Conditions on the receiver side can also influence the whole path because of the flow control mechanism in the TCP. The TCP has a window mechanism that allows notifications to the other node, that the transmission should be slowed down or stopped. A window is the number of octets that may be in the network without an acknowledgement. The current value is transmitted as a field in the TCP header [1] [4].

Dividing one TCP connection into multiple ones breaks that end-to-end flow control. The result of this may be seen if the sender transmits at a higher rate than the receiver can receive, and if the rate offered by the anonymity system is enough to handle the traffic without introducing noticeable additional delays or losses.

The situation is depicted in Figure 7. The transmission on the first (receiver) link will take place at the maximum rate (or close to that value). It will be lower, from the beginning, than the transmission rate of the server (events 1-3). That will cause the buffers in the nodes to fill.

When the sending buffer on the first node becomes full, it lowers the window size in the connection with the second node. After some time, the sending buffer on that node will become full. That will stop receiving from the next node (event 4). Finally, window lowering will occur at the last link (between the sender and last node), where it can be observed (event 5). With the maximum rates still at the same level, the transmission from the server will start forming bursts, as the transfers will occur at the maximum rate, but only for short periods of time, when the next node allows it (events 6-9).

Depending on the network configuration, delays, TCP implementation used by the nodes, and their settings, the bursts may be observed sooner or later. Also, the time until the window drops to zero for the first time will vary. In the worst case that includes sending and receiving TCP buffers on all the anonymity system nodes along the path and the buffers in the anonymity software. The bursts may appear earlier if the anonymity protocol has its own window mechanism, for instance.

*Long and short bursts:* We have checked if the effect described above can be observed in practice. Figures 8 and 9 show the results for Tor and JAP, respectively.

In the case of Tor there are bursts visible which are just as we expected (compare the with normal traffic from Figure 1). The time from the transfer start to the moment when the burst appears is much lower than expected, however. That was the reason for another test. The aim was to check more Tor paths and see how long a time was needed for the bursts to appear. We show the results later in this section.

JAP also shows bursts. The client receives at the maximum rate. The bursts do not differ sufficiently from the ones in Figure 2. Even the burst lengths are similar. A different pattern did not emerge even during the longest 12 minutes transfer.

The fact that the test did not work against JAP during our test time, is one of the issues worth noticing. The root cause remains a problem to be considered in the future work. The bursts may finally appear after all the buffers on the path are filled, which may take hours in the case of the slow transfer rates we used.

Our observations show that the transfer rates, even without any modifications, were lower for JAP than Tor. Also, Figure 6 shows no bursts on the server side, that may suggest an external bandwidth limit.

*Filling the buffers of Tor:* We performed additional experiments on Tor, as the amount of data needed to start bursts was much lower than expected. The results we got clearly show that the buffers on the whole path were not full when

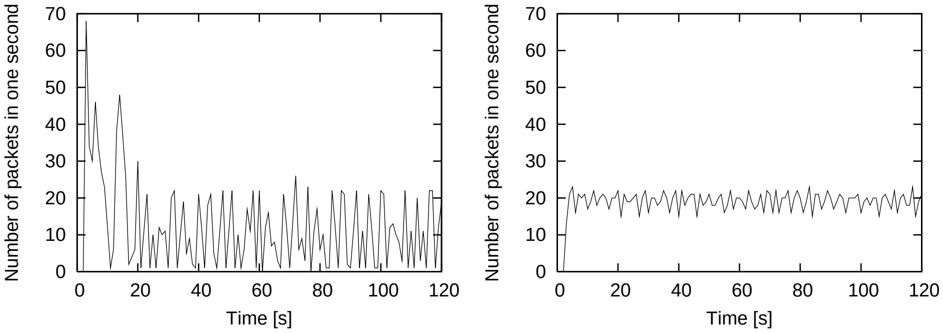

Fig. 8. Traffic flow sent from the server (left) and received by the client (right) during a transfer using Tor with client bandwidth limit at 96kbit/s.

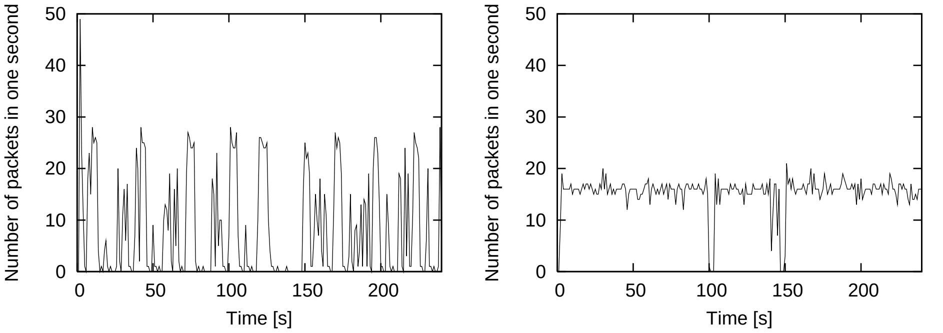

Fig. 9. Traffic flow sent from the the server (left) and received by the client (right) during a transfer using JAP with client bandwidth limit at 96kbit/s.

TABLE III
DELAY TO THE FIRST ZERO WINDOW MESSAGE.

| Amount of bytes transferred | Number of occurrences | Percentage |
|---|---|---|
| less than 100,000 | 4 | 15.4% |
| 100,000 to 200,000 | 2 | 7.7% |
| 200,000 to 300,000 | 0 | 0.0% |
| 300,000 to 400,000 | 3 | 11.5% |
| 400,000 to 500,000 | 6 | 23.1% |
| 500,000 to 600,000 | 2 | 7.7% |
| 600,000 to max | 2 | 7.7% |
| no zero window | 7 | 27.0% |
| Total | 26 | 100.0% |

the traffic pattern started appearing. There should have been a similar test performed for JAP, but only one cascade seemed usable for our research.

Table III shows the results of tests performed using a 630 KB file against different paths through Tor. Every measurement was performed after a Tor restart, and resulted in a different path being used. We show the number of bytes transferred from the connection start to the first packet with zero window size (precisely: a window size lower than 1400 bytes).

We found that there are big differences between the paths. The situation of the window size dropping to zero may appear after less than 100,000 bytes have been transferred, but may not appear in the whole transfer. We looked into the traces in more detail and found a number of interesting facts. There were differences in the initial window. Also, the window size reached close to the beginning of the connection differs between the traces. A large window size appeared in the transmissions with a non-zero window, or in those with a zero window close to the transfer end.

That leads us to the conclusion that the differences are caused by the conditions on the path, including the configuration and operating system of the anonymity system nodes (especially the one closest to the server). It seems that the 'bursty' traffic is not caused by the buffers' overruns on the whole path, but rather as an effect of Tor's internal flow control.

It is also worth noting that if the zero window is reached, the bursts appear regularly for the rest of the transfer.

As the initial window size differs between the nodes, so does the amount of data that may be in transit simultaneously. That may lead to differences in response time, for applications that have such needs.

*Artifacts:* We observed a number of artifacts in the traffic. Examples include: oscillation at 220 sec in Figure 1a, disturbance between 350 and 450 sec in Figure 1 with its' echo in Figure 1, bursts on higher bandwidth transmissions in Figure 4 or oscillations in Figure 9.

While searching for possible explanations, we analysed the source code of the two tested systems. There was no direct answer. However, we have found out that, as data from many flows travel by a single TCP connection between the internal nodes, an retransmission or any other problem will affect performance on multiple streams at the same time. It means that the disturbances may be an effect of interactions with other flows passing through the anonymity systems.

## V. Conclusions

We have shown a number of network-level effects that affect performance of currently deployed, TCP-based anonymity systems. We have also presented results showing that the effects may be visible in practice.

Our research shows that describing the network properties of an anonymity system by using only delay is not enough, and there are more factors to consider. We have also shown how the internal design affects flow characteristics. The results can be interpreted in two ways. The first shows possible performance issues, and the second one possible attacks (as the traffic may be marked from both sides of the connection).

We have shown that both systems do not change the traffic characteristics to the degree that would allow them to hide fast rate changes. Bursts of a length of 60 seconds were recognisable after passing by both systems. Additionally, that was also true for JAP and 10 second bursts. This limits the space for attacks that would watermark the traffic by bandwidth changes, like in [21]. Also, both systems tend to output longer bursts than the input bursts.

It should be noted that receiver behaviour (instead of only sender behaviour) should also be taken into account when modelling anonymity systems using network protocols with flow control like the TCP. When the end-to-end property is broken, characteristic flow bursts may appear on the sender side. How it may be used by an attacker remains a problem for future work to examine. It clearly affects performance, however, and introduces delay when a fast reply is needed. Adding to, or improving application level flow control in anonymity systems, could be a solution to this problem. Such mechanism should be designed to find a compromise between performance and the time of reaction to events from the other peers.

That may also mean that different settings or implementation differences of the network protocols could have a noticeable impact on the anonymity system's performance.

{vertical,giacomaz}@elet.polimi.it

***Abstract*—The early identification of applications through the observation and fast analysis of the associated packet flows is a critical building block of intrusion detection and policy enforcement systems. The simple techniques currently used in practice, such as looking at the transport port numbers or at the application payload, are increasingly less effective for new applications using random port numbers and/or encryption. Therefore, there is increasing interest in machine learning techniques capable of identifying applications by examining features of the associated traffic process such as packet lengths and interarrival times. However, these techniques require that the classification algorithm is trained with examples of the traffic generated by the applications to be identified, possibly on the link where the the classifier will operate. In this paper we provide two new contributions. First, we apply the C4.5 decision tree algorithm to the problem of early application identification (i.e. looking at the first packets of the flow) and show that it has better performance than the algorithms proposed in the literature. Moreover, we evaluate the performance of the classifier when training is performed on a link different from the link where the classifier operates. This is an important issue, as a pre-trained portable classifier would greatly facilitate the deployment and management of the classification infrastructure.**

## I. Introduction

THERE is a constant growth of new Internet applications using either random transport port numbers or reusing well-known ports registered to other applications. For example, peer-to-peer applications do not require the usage of well-known ports and some peer-to-peer applications, such as Skype, use port hopping. Moreover, recent applications frequently tunnel traffic through HTTP connections to seamlessly cross firewalls and NAT boxes. In these cases, the application generating a traffic flow cannot be identified by simply looking at the transport ports.

Therefore, there is a growing interest for alternative classification algorithms relying on features different from transport ports. The most widespread approach relies on the inspection of the packet payload and on the matching with signatures characteristics of the applications to be identified. This solution has the drawback of requiring computationally heavy elaborations that must be made at wire-speed; further it is not effective on cyphered traffic, such as that generated by applications secured through SSL.

Other approaches use the information available in the non-cyphered IP packet header and complement these data with the analysis of statistical properties of the packet flow, considered as a random process. An example of this type of additional metrics is the packet interarrival time. With this approach, each traffic flow is associated with a set of features and, by examining the measured values of these features, a classifier yields the most likely application associated to the flow.

In [1] and [2] the authors use a Bayesian method to classify a traffic flow by using metrics such as flow duration, flow bandwidth, and statistics on packet sizes and interarrival times. The main drawback of this approach is that it is possible to classify only terminated flows. In [3] and [4], the authors introduce the idea of *Early Application Identification* and classify traffic flows by looking only at the lengths of the first packets in a flow; classification is performed by using clustering techniques such as K-means, Hidden Markov Models (HMM) and Gaussian Mixture Models (GMM). The authors of [5] further extend the idea by including packet interarrival times in the feature set and by developing a new classification algorithm based on the Bayesian method. Finally, a preliminary comparison of general-purpose algorithms is given in [6], and the C4.5 algorithm [7] is indicated as one of the best performing. However, in [6] the authors study the classification of terminated flows and early application identification is not considered.

Using Machine Learning techniques for application identification still presents some challenges. In order to train the classifier it is necessary to collect a representative set of flow instances whose applications are known in advance. For example, by using offline payload inspection techniques to label the training data. The main issue with this approach is that the statistical properties of the traffic flows vary from link to link, therefore we expect that, if we train a classifier at a given link and operate it at another link, performance will be worse.

Another problem is that the flow must be observed for some time, in order to collect data enough to categorize it. In the case of early identification a trade-off must be found between speed and accuracy.

This paper presents several contributions along the line of assessing the capability of state-of-the-art Machine Learning techniques for fast traffic classification. The key contributions of the paper are the following.

Work on this paper has been supported by the Italian Ministry of Research project RECIPE

First, we propose the C4.5 algorithm in the context of early application identification and we compare its accuracy to the results reported in [2], [4], and [5] and obtain superior results in terms of both true and false positives.

Second, we observe that the classification performance obtained by observing as few as 5 packets per direction is very similar to the performance obtained by observing all the packets in a flow, provided that suitable features, such as the actual packet lengths, are chosen for classification.

Third, we evaluate the performance of a classifier trained in a WAN link different than the one where it is operated. The performance is worse than using the classifier in the same link, but not to a large extent. Further, there are significant performance differences among protocols; in particular, the classification of HTTP protocol is very robust, whereas the Telnet and FTP traffic flows are more difficult to identify.

The paper is organized as follows. Section II explores the state-of-the-art of traffic classification using Machine Learning techniques. Section III discusses the data and the tools we use in the paper and explains the experimental setup. Section IV reports and discusses the results of our investigation. Finally, the last Section yields our concluding remarks.

## II. Basic Concepts and Related Work

We identify two main application areas of Internet traffic classification: the separation of malicious traffic from good traffic and the identification of the application that generates the packets. Today, deep packet inspection boxes are used for both objectives. For example SNORT [8] for identification of malicious traffic and l7filter [9] for application identification. Both packages perform per-flow classification by comparing the payload of the first packets in the flow with a set of pre-configured signatures, which are generally human-made.

Deep packet inspection is not adequate when traffic is cyphered or when high-speed links are considered, therefore there is a growing research interest for traffic classification considering only packet lengths, interarrival times and any other information available in the protocol headers. One of the first proposals of application identification through the examination of the traffic process is made in [10], where the authors point out that RealAudio traffic exhibits a behavior significantly different from that of telnet, HTTP or FTP traffic, in particular in terms of flow duration and regularity of packet lengths and interarrival times. The authors, however, do not propose a specific classification algorithm.

A more recent work proposes to use clustering techniques for mapping a traffic flow to a QoS class [11]. The authors find that the most significant metrics are the average packet size and the flow duration. The main problem with these metrics is that classification can be performed only when the flow is already finished, limiting the practical utility of this technique.

The authors of [12] apply unsupervised Bayesian techniques to the problem of application identification and use a feature selection technique to to find the optimal set of attributes. The authors find that the most influential attributes are the mean and the variance of the packet lengths, the total amount of traffic in the flow, and the flow duration. Also the mean interarrival time has some influence. As for [11], not all these metrics are suitable for early application identification.

In [1], the authors propose a supervised Bayesian classifier and also use some TCP-specific metrics such as the count of all the packets with the PUSH bit set. However, only semantically complete TCP connections are considered.

Paper [13] proposes how to use behavior analysis to augment the efficacy of automatic classification techniques. Their BLINC framework considers attributes such as the social and functional role of the hosts, which require long observation times to elaborate and, therefore, making BLINC a valuable solution for off-line classification.

In [6], the authors compare the performance of five general purpose supervised Machine Learning algorithms, showing that the C4.5 tree based algorithm provides a good trade-off between classification accuracy and speed. The authors also consider two feature reduction schemes and identify two feature sets that show similar performance. In one feature set packet length statistics are predominant, while in the second feature set there is a balance of packet lengths and interarrival times. The authors of [6] have also developed a set of tools [14] which automates the process of collecting packet traffic, reconstructing the flows, computing metrics and invoking the Machine Learning algorithms.

The authors of [3] study the problem of Early Application Identification and show that it is enough to know the length of the first four or five packets to achieve promising classification results. The authors also compare three supervised clustering techniques.

Finally, the authors of [5] further refine the idea, by considering also packet interarrival times and developing a novel classification algorithm, but do not compare it to other state-of-the-art classification algorithms.

## III. Experimental Setup

In our research work we have set up a laboratory to experiment in practice the classification algorithms. We have used publicly available software and data. Packet traces representative of WAN traffic have been retrieved from the NLANR traffic archive [15]. In particular we have used the `auckland-vi-20010611`, `auckland-vi-20010612`, and `nzix-ii-20000706`. The two `auckland` traces were collected at the same network link; in the paper, we will use the first trace to train the Machine Learning classifier, whereas the second trace will be used to assess the classification performance. We will refer to the first trace as *Samplepoint A (training)* and to the second trace as *Samplepoint A (test)*. The third trace was collected at a different link, and it will be referred to as *Samplepoint B (test)*.

In order to group packets in flows and to elaborate per-flow metrics, we have used the `NetMate`[16] software, extended with the `NetAI`[14] patch. This way, we obtain the features reported in Table I, which we will refer to as the two *Standard* sets. We have isolated the *Standard 2* features because they

TABLE I
THE *Standard* FEATURES

| **Standard 1 features** |
|---|
| Min, max, mean and std. deviation of the packet lengths in the forward direction. |
| Min, max, mean and std. deviation of the packet lengths in the backward direction. |
| Min, max, mean and std. deviation of the packet interarrival times in the forward direction. |
| Min, max, mean and std. deviation of the packet interarrival times in the backward direction. |
| Transport protocol number. |
| Total number of TCP URG and PUSH flags in the forward direction. |
| Total number of TCP URG and PUSH flags in the backward direction. |
| **Standard 2 features** |
| Flow duration. |
| Total number of bytes and of packets in the forward direction. |
| Total number of bytes and of packets in the backward direction. |

TABLE II
THE *Extended* FEATURES

| **Extended 1 features** |
|---|
| Lengths of the first 3 packets in the forward direction |
| Lengths of the first 3 packets in the backward direction |
| Interarrival times of the first 3 packets in the forward direction |
| Interarrival times of the first 3 packets in the backward direction |
| **Extended 2 features** |
| Lengths of the first 5 packets in the forward direction |
| Lengths of the first 5 packets in the backward direction |
| Interarrival times of the first 5 packets in the forward direction |
| Interarrival times of the first 5 packets in the backward direction |

are not meaningful when only the first packets of the flow are considered.

We have also implemented a new patch for NetMate to collect the feature sets proposed in [3] and [5], referred to as the *Extended* feature sets (Table II). These extended sets are the actual packet lengths and the interarrival times of the first packets of the flows. We have grouped the features in two sets of increasing size. The *Extended 1* feature set includes the packet lengths of the first three packets of a flow in each direction and the two interarrival times between them in each direction, for a total of 10 features. The *Extended 2* feature set includes all the packet lengths and interarrival times involving the first 5 packets in a flow.

As a concluding remark, we note that the NetMate software defines a flow as the packets belonging to a single TCP connection, in case TCP is the transport protocol. In case UDP is used, the flow is defined as all the packets with the same IP addresses and UDP port numbers and considered finished when no packets have arrived for 600 s. From all the flows available in the data sets, we have randomly chosen 4000 flows for each of the five application protocols considered in this paper. For some protocols there were fewer flows than required, so we used all the available ones. The total number of flows chosen in each data set is reported in Table III.

TABLE III
SIZE OF THE DATA SETS

| Data Set | Number of Flows | Flows with at least 5 packets per direction |
|---|---|---|
| Samplepoint A (training) | 15606 | 15300 |
| Samplepoint A (test) | 15803 | 15545 |
| Samplepoint B (test) | 13335 | 12788 |

Then, we have processed the selected flows and flow features by using the Weka [17] machine learning suite to train the classifier and perform the validation tests. We have preliminarly evaluated the same algorithms as in [6] and concluded that the C4.5 algorithm [7] gives the best results, so we will show only the results obtained with that algorithm. In fact, the C4.5 algorithm well suits problems in which several attributes assume discrete values and when training data is noisy, which is common in large data sets. To ease a comparison, we performed our assessment by using the same 5 applications as in [6], i.e. FTP-data, Telnet, SMTP, DNS, and HTTP. For the training and for the validation we assumed that the flow category label is the server well-known port number.

## IV. EXPERIMENTAL RESULTS

In this section, we assess the performance of Machine Learning techniques for traffic classification and substantiate the following findings:

- the C4.5 algorithm is superior to the algorithms proposed in [2], [4], and [5];
- the classification accuracy obtained with five packets per direction is similar to the accuracy obtained observing all the packets in the flow even if the trained classifier is used on a different link, but only if the Extended Features are used;
- the performance loss measured when the trained classifier is used on a different link is mainly due to a few protocols, whereas other protocols, in particular HTTP, show minimal performance differences.

### A. C4.5 Algorithm for Early Application Identification

As a first result, we show that the the state-of-the art C4.5 algorithm [7] improves the classification performance over the algorithm proposed in the literature. As performance metrics we use the True Positive Rate and the False Positive Rate, defined as:

$$\mathrm{TPR}(i) = \frac{e_i}{E_i}$$
$$\mathrm{FPR}(i) = \frac{\bar{e}_i}{e_i + \bar{e}_i}$$

where $E_i$ is the number of instances of protocol $i$ in the evaluation set, $e_i$ is the number of instances of protocol $i$ correctly classified as $i$, and $\overline{e_i}$ is the number of instances of other protocols incorrectly classified as $i$.

In Table IV, we compare the True Positive Rates as reported in [2], [4], [5], as well as the test results obtained using the C4.5 classifier trained on the *Samplepoint A (training)* data and tested on the *Samplepoint A (test)* data. In our experiment we used the *Standard-1* plus *Extended-2* feature sets. In Table V, we make a similar comparison considering the False Positive Rates. In reporting results from other papers, we have considered only the classes considered in at least two papers.

TABLE IV
COMPARISON OF THE TRUE POSITIVE RATES

| Protocol | [2] | [4] | [5] | Our solution |
|---|---|---|---|---|
| HTTP | 89.2% | 96.2% | 91.8% | 99.7% |
| SMTP | *97.2% | 90.1% | 94.5% | 98.6% |
| POP3 | *97.2% | 93.4% | 94.6% | N/A |
| FTP | 97.9% | 92.4% | N/A | 94.8% |

*In [2] STMP and POP3 form a single class

TABLE V
COMPARISON OF THE FALSE POSITIVE RATES

| Protocol | [2] | [4] | [5] | Our solution |
|---|---|---|---|---|
| HTTP | 10.4% | 1.3% | 6.4% | 0.1% |
| SMTP | *2.3% | 0.1% | 3.1% | 1.4% |
| POP3 | *2.3% | 0.7% | 3.1% | N/A |
| FTP | 1.8% | 0.4% | N/A | 0.5% |

*In [2] STMP and POP3 form a single class

Our solution shows higher true positive rates than the other solutions for HTTP and SMTP and is inferior to [2] only for the FTP class, where, however, our solution shows a much lower FPR. Our proposal shows false positive rates superior to [2] and [5]. Compared to [4], our solution performs similarly for the FTP class and worse only for the SMTP class, where our solution scores a much higher TPR.

Finding a good trade-off between TPR and FPR is a common challenge when using Machine Learning techniques. In the context of internet traffic classifications for monitoring and security purposes, it is important to achieve a low FPR. From Tables IV and V, we conclude that the C4.5 classifier shows an FPR performance comparable to the best other solution ([4]), but with a higher TPR. Therefore, in the rest of the paper we will consider only the C4.5 algorithm.

### B. Effect of the Observation Horizon and of the Feature Sets

Table VI reports the percentage of incorrectly classified traffic flows for different observation horizons and different feature sets. Results are given for three data sets. The column labeled *Samplepoint A(training)* contains the percentage of flows in the training set equivocated by the classifier, which gives us a lower bound on the classification error that we expect at run time. In all the cases, when we consider at least the first 5 packets per direction, the residual error is lower than 0.3%, and is about 0.5% if we consider only the first 3 packets per direction.

In Table VI the column labeled *Samplepoint A (test)* gives the observed percentage of incorrectly classified packets when the trained classifier is used on a different data set collected on the same WAN network link. Again, when we consider the first 5 or more packets per direction, the error does not change and settles at about 1.5%. On the other hand, if we consider only the first 3 packets, the error is more than 3.5%. This trend is in line with [3] and [5], which indicate in 4 or 5 packets the ideal observation horizon.

The last column gives the classification error when the trained classifier is used with a data set collected on a completely different WAN network link. There are no data in the literature about this problem, but we expect that the different statistics of the collected features hamper the work of the classifier. Results show that the error grows more than 3.5 times, if we consider only the standard set and 3, 5, or 10 packets. Slightly better results are obtained if all the packets of the flow are considered, with an error about 4.5%, which is only 3 times larger than in the *Samplepoint A(test)* case. On the other hand, the Extended Set greatly improves the robustness of the classifier, bringing the error from about 6% down to about 4%, which is about 2.5 times the result obtained in the *Samplepoint A(test)* case and is better than the result obtained with the standard set and observing all the packets in the flow. Further, these apparently non promising results should not make us abandon the idea of using this kind of classifiers because, as we show later, the vast majority of the incorrectly classified packets come from a limited amount of protocols.

TABLE VI
INCORRECTLY CLASSIFIED INSTANCES USING THE *Standard* AND *Extended* FEATURES

| | | Samplepoint | | |
|---|---|---|---|---|
| Packets per direction | Feature set | A (training) | A (test) | B (test) |
| 3 | std1 | 0.48% | 3.52% | 13.54% |
| 3 | std1 + ext1 | 0.44% | 3.22% | 13.06% |
| 5 | std1 | 0.27% | 1.55% | 6.01% |
| 5 | std1 + ext2 | 0.22% | 1.80% | 4.10% |
| 10 | std1 | 0.21% | 1.66% | 6.01% |
| all | std1 + std2 | 0.21% | 1.45% | 4.45% |

TABLE VII
ACCURACY BY CLASS WHEN USING THE *Standard 1* AND *Extended 2* FEATURES

| | Samplepoint A | | Samplepoint B | |
|---|---|---|---|---|
| Class | TPR | FPR | TPR | FPR |
| DNS | 100% | 0.4% | 99% | 0.1% |
| FTP (data) | 95% | 0.5% | 77% | 1.4% |
| Telnet | 92% | 0.1% | 84% | 0.4% |
| SMTP | 98% | 1.4% | 95% | 3.0% |
| HTTP | 99% | 0.1% | 99% | 0.2% |

### C. Per-protocol Classification Accuracy

Finally, Table VII shows the classification performance obtained on test data, broke down by protocol. All the results are obtained considering 5 packets per direction and the *Standard* plus the *Extended 2* metrics. As in the experiment above, the classifier was trained with the *Samplepoint A (training)* dataset and operated with the *Samplepoint A (test)* and *B (test)* datasets.

As already observed in [3] and [5], there are significant performance differences among protocols. Our results, however, shed light on what protocols fingerprints are most likely to be preserved from link to link.

In *Samplepoint A*, the true positives are always reasonably good, with only FTP and Telnet equal to or below 95%. Porting the classifier to *Samplepoint B* worsens the performance of these two protocols, whose TPR drops below 85%, while the other protocols maintain their good performance. Regarding the false positives, the only class with FPR larger than 1% is

SMTP in the *Samplepoint A*, whereas, in the *Samplepoint B* case, both SMTP and FTP have a large FPR.

At the light of these results, we remark that, when porting a trained classifier, those protocols that had a lower TPR tend to decrease their TPR and those protocols that had a higher FPR tend to increase it. However, there can be anomalies, for example in our experiment DNS and FTP had similar FPR in the first link and very different FPR in the second.

## V. Conclusions

In our research work we have experimented, with a thorough laboratory activity, the behavior of machine learning algorithms for the classification of applications by examining the traffic flow process. We have concentrated our attention to the early application identification, therefore, we have examined extended feature sets including lengths and interarrival times of the first few packets of flows and we have matched their performance against that of standard feature sets requiring the examination of the entire traffic flow.

We have examined the behavior of the C4.5 decision tree algorithm with extended feature sets and we have determined, as a novel result, that this algorithm performs very well for early application identification.

We have proceeded by studying a problem so far left open in the related research, that is, the portability of a trained Machine Learning classifier on a link different from that used for training. The possibility of porting pre-trained classifier would be very appealing for practical implementations. We have determined that the performance of a trained classifier moved to another link worsens, but the degradation seems to be concentrated on specific protocols such as FTP and Telnet, while other protocols such as HTTP and DNS are recognized effectively even by a moved classifier.

Our current work concentrates on devising feature sets capable of improving the portability of trained classifiers to different links.

# Workshop on Wireless and Unstructured Networking: Taming the Stray

AS NETWORK customers, operators, and designers strive to bring more productivity and enjoyment into increasingly diverse areas of our lives, be it business and commerce, health services, crisis management, content distribution, or multiuser games, mobile communications and ubiquitous computing are becoming the leading interactivity paradigm. While being thus “condemned” to succeed, they raise at least two main challenges. One is the multitude of standards specifying reliable high-speed wireless networking solutions, and the resultant multitude of heterogeneous technologies that follow (IEEE 802.11, 802.15 and 802.16, Bluetooth, MANET, SANet, Mobile IP, and others). Making them coexist, let alone cooperate, requires integration of many diverse areas of research, such as internetworking, distributed computing, signal processing, networking theory, and economics. Can we venture to predict the outcome? Can we make a case for particular scenarios? Another challenge is the dualism of fixed-infrastructure vs. ad hoc networks. The latter, despite their 20-year presence in academic literature, have been remarkably slow to materialize in the real world. Attempts to blame this on our natural distrust towards systems under distributed control and lacking clear ownership do not sound convincing: P2P technology does away with central administration, yet it has become successful to the point of embarrassing network operators and intellectual property managers. Can ad hoc networks repeat the success of P2P without becoming an embarrassment? The purpose of this workshop is to address questions like the above, to look at wireless networking from a broader perspective, to present ideas and share experience from their verification.

Here is the non-exclusive list of topics:

- routing and location protocols
- MAC schemes
- modeling methodologies for wireless channels
- cross-layer issues
- anonymity and security
- performance studies and comparisons
- mobile applications
- mobility support, handover mechanisms, mobility brokers (MB), MIP
- self-organization
- residential access systems,
- interworking between ad-hoc and fixed/mobile networks
- virtual networks
- ad-hoc networks as part of urban mesh,
- content distribution and multicast overlay
- pricing and incentive arbitration
- software supporting networked applications
- case studies

***Abstract*—We introduce our "holistic" platform for building wireless ad hoc sensor networks and focus on its most representative and essential virtualization component: VUE$^2$ (the Virtual Underlay Emulation Engine). Its role is to provide a vehicle for authoritative emulation of complete networked applications before physically deploying the wireless nodes. The goal is to be able to verify those applications *exhaustively* before programming the hardware, such that no further (field) tests are necessary. We explain how VUE$^2$ achieves this goal owing to several facilitating factors, most notably the powerful programming paradigm adopted in our platform. As implied by the holistic nature of the discussed system, our presentation touches upon operating systems, simulation, network protocols, real-time systems, and programming methodology.**

## I. Introduction

ALTHOUGH simple wireless devices built from low-end components are quite popular these days, one seldom hears about serious wireless networks within this framework. While it is not a big challenge to implement simple broadcasters of short packets, it is quite another issue to turn them into collaborating nodes of a serious ad hoc wireless system. Apparently, many popular ad hoc routing schemes proposed and analyzed in the literature [1]–[6] address devices with a somewhat larger resource base. To make matters worse, some people believe that such devices must be programmed in Java to make serious applications possible [7].

In this context, efforts to introduce an order and methodology into programming small devices often meet with skepticism and shrugs, the common misconception being that one will not have to wait for long before those devices disappear and become superseded by larger ones capable of supporting "serious" programming platforms. This is not true. Despite the ever decreasing cost of microcontrollers, we see absolutely no reduction in the demand for the ones at the lowest end of the spectrum. On the contrary: their low cost and power requirements enable new applications and narrow the gap between the publicized promise of ad hoc wireless sensor networking and the actual state of affairs. Similar to the impossibility of having the three desirable properties of food (cheap, fast, and good tasting) present at the same time, wireless sensor networking has problems being cheap, ad hoc, and useful, all at once.

The goal of our platform is to enable the rapid creation of wireless ad hoc sensor networks using the smallest and cheapest devices available today. In our networks, such devices are capable of ad hoc routing while offering enough processing power to cater to complex applications involving distributed sensing and monitoring. To thoroughly test and evaluate our work, we turn to virtualization.

At the lowest level, virtualization can be accomplished by simulating in software a particular instruction set, i.e., by means of a bytecode interpreter. This approach has been the basis even for commercial grade products, but within the scope of our paper the primary example is Maté [8]. The main shortcomings of such an approach are (a) the interpreter overhead (in terms of both space and time), (b) a lack of back ends for compilation from familiar high-level languages into the invented bytecode format, and (c) the need to define the interaction with peripheral components, e.g., transceivers, in a manner consistent with the invented instruction set. If the virtual machine is fairly well established, e.g., JVM, then one can claim that at least (b) and (c) have been addressed. However, there seems to exist no successful virtual machine geared to sensor devices. For example, even virtual machines intended for small footprint devices (like Dalvik VM [9], part of the Google Android platform [10]) are "heavyweight" for sensor nodes. In addition (as it happens with Dalvik VM), not all of the language libraries are implemented, raising questions on the extent that VMs can be ported to small platforms without compromising fidelity.

On the other end of the spectrum, we find virtualization by means of an API provided by the underlying operating system. The API is accessible using familiar high-level languages like C or C++. One example is the POSIX API. A platform that can provide run-time emulation of an API can be thought of as successfully virtualizing at the level of the API. Unfortunately, commodity OS APIs are very broad, and the abstractions that they promote are expensive to implement on a sensor device. For example, the Berkeley sockets API is a powerful, albeit expensive, way to abstract network communication. Even worse, it is not a useful abstraction for small devices that do not even implement a TCP/IP stack.

We believe that a viable compromise between the two extremes is to introduce a small footprint OS, to specify the API supported by the OS, and to subsequently offer virtualization at the level of that API. Note that in following this approach, we do not need a new toolchain for code production, since we neither have to invent a new higher level language nor do we need to procure a compiler back end for a new (invented) instruction set. In this paper, we focus on the interplay of PicOS (our operating system for tiny microcontrolled devices [11]) and VUE$^2$ (the Virtual Underlay Emulation Engine for realistically simulating networked applications programmed in PicOS).

## II. PicOS

The most serious problem with implementing non-trivial, structured, multitasking software on microcontrollers with limited RAM is minimizing the amount of memory resources needed to sustain a thread. The most troublesome component of the thread footprint is its stack, which must be preallocated to every thread in a safe amount sufficient for its maximum possible need.

PicOS strikes a compromise between the complete lack of threads and overtaxing the tiny amount of RAM with fragmented stack space. A thread contains a number of *checkpoints* that provide preemption opportunities. In the imposed structured organization of a thread, we try to (a) avoid locking the CPU at a single thread for an extensive amount of time and (b) use the checkpoints as a natural and useful element of a thread's specification to enhance its clarity and reduce its structure's complexity. These ideas lie at the heart of PicOS's concept of threads, which are structured like finite state machines (FSMs) and exhibit the dynamics of coroutines [12], [13] with multiple entry points and implicit control transfer.

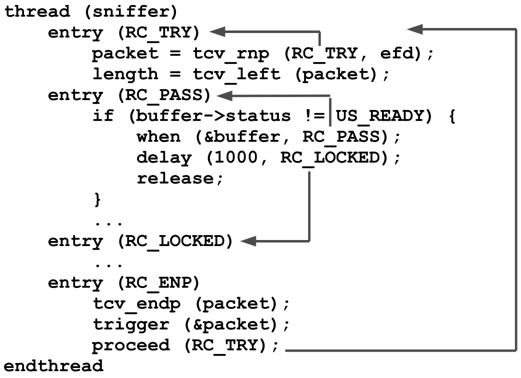
The value of FSM-like programming abstractions is evident to anyone developing networking protocols, as most protocols tend to be described, or even formalized, as communicating FSMs. In addition, programming using a coroutine paradigm is a fairly well-accepted approach and has survived in modern languages (e.g., "stackless" Python [14] and more recently Ruby [15]). The only general criticism coroutines receive is that the lack of arbitrary preemption might allow CPU-bound tasks to monopolize the CPU. This is not a fundamental problem, because a CPU-bound task can be broken down into a sequence of states to allow preemption at state transitions. However, an important element of our view is to use the coroutine paradigm as a means to *discourage* CPU-intensive tasks on sensors. Instead, any tasks of this kind should be either moved to data collectors (i.e., full-scale computers) or delegated to specialized (possibly reconfigurable) hardware.

On a historical note, we arrived at PicOS indirectly as a step in the evolution of our network simulation system SMURPH [16], [17]. As SMURPH underwent a number of enhancements, its capability for rigorous representation of all the relevant engineering problems occurring in detailed protocol design turned it into a specification system. Although oriented towards modeling networks and their protocols, SMURPH became a *de facto* general purpose specification and simulation package for reactive systems [18], [19].

A highly practical project—the development of a low-cost wireless badge—inspired the idea to implement a complete executable environment for microcontrollers based on SMURPH's programming paradigm. After developing a SMURPH model for the badge, the most reliable way of transporting it to the real device was to implement the target microprogram on top of a tiny execution environment mimicking SMURPH's mechanism for multithreading and event handling [11]. Incidentally, that mechanism facilitated a stackless implementation of multithreading. Consequently, the resultant footprint of the complete application was trivially small ($<$ 1 KB of RAM), while the application itself was expressed as a structured and self-documenting program strictly conforming to its SMURPH model.

### A. The anatomy of a PicOS thread

Fig. 1 shows a sample PicOS thread. In this C code, new keywords and constructs are straightforward macros handled by the standard C preprocessor. The `entry` statements mark the different states of the thread's FSM.



```
thread (sniffer)
    entry (RC_TRY)
        packet = tcv_rnp (RC_TRY, efd);
        length = tcv_left (packet);
    entry (RC_PASS)
        if (buffer->status != US_READY) {
            when (&buffer, RC_PASS);
            delay (1000, RC_LOCKED);
            release;
        }
        ...
    entry (RC_LOCKED)
        ...
    entry (RC_ENP)
        tcv_endp (packet);
        trigger (&packet);
        proceed (RC_TRY);
endthread
```

Fig. 1: Code for a sample PicOS thread.

A thread can lose the CPU when (a) it explicitly relinquishes control at the boundary of its current state (e.g., `release`) or (b) a function call blocks (e.g., `tcv_rnp` if no new packets are available). In both cases, the CPU returns to the scheduler, which can then allocate it to another thread. Whenever a thread is assigned the CPU, execution continues in that thread's *current state*.

Before executing `release`, a thread typically issues a number of *wait requests* identifying one or more events to resume it in the future (e.g., `when` for IPC and `delay` for timed events). The collection of wait requests issued by a thread in every state describes the dynamic options for its transition function from that state.

### B. System organization

The organization of PicOS is shown in Fig. 2. VNETI (Versatile NETwork Interface) acts as a layerless networking module, whereby the equivalents of "protocol stacks" are implemented as plug-ins. The set of operations available to plug-ins involve queue manipulations, cloning packets, inserting special packets, and assigning to them the so-called *disposition codes* representing various processing stages. Any protocol can be implemented within this paradigm, with TARP (our Tiny Ad hoc Routing Protocol [20], [21]) being the most prominent example. The modus operandi of VNETI is that packets are *claimed* by the protocol plug-ins as well as the physical interface modules (PHY) at the relevant moments of their life in the module's buffer space. There is no explicit concept of processing hierarchy, e.g., enforcing traditional layers; thus, packets in VNETI are handled "holistically."

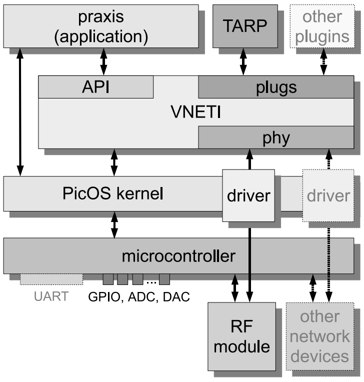


Fig. 2: The structure of PicOS.

All API functions interfacing the application (called the *praxis* in PicOS) to VNETI have the same status as those interfacing the praxis to the kernel, i.e., they are formally system calls. As a thread in PicOS can only be resumed at a state boundary, a potentially blocking system call requires a state argument (e.g., the first argument in the function call `tcv_rnp` in Fig. 1).

## III. VUE$^2$

The close relationship between PicOS and our discrete-time event-driven network simulator named SMURPH [16], [17] makes it possible to automatically transform PicOS praxes into SMURPH models with the intention of executing them virtually. VUE$^2$ implements the PicOS API within SMURPH, and in some cases, it can simply transform PicOS keywords into their SMURPH counterparts. To represent the physical environment of a PicOS praxis, it also provides a collection of event-driven interfaces. This way, a praxis can be compiled and executed in the environment shown in Fig. 3, with all the relevant physical elements of its node replaced by their detailed SMURPH models. Notably, exactly the same source code of VNETI is used in both cases.

### A. Time flow

The fidelity of the emulation environment depends to a great extent on appropriately handling the flow of time, i.e., equating emulated time with real time. In SMURPH, as in all event-driven simulators, the time tags associated with events are purely virtual. The actual (physical) execution time of a SMURPH thread is essentially irrelevant (unless it renders the model execution too long to wait for the results), and all that matters is the abstract delays separating the virtual events. For example, two threads in SMURPH may be semantically equivalent, even though one of them may exhibit a drastically shorter execution time than the other, e.g., due to more careful programming and/or optimization. In PicOS, however, the threads are not (just) models but they run the "real thing." Consequently, the execution time of a thread may directly influence the perceived behavior of the PicOS node. In this context, the following two assumptions made the VUE$^2$ project worthwhile:

1) PicOS programs are reactive, i.e., they are practically never CPU bound. The primary reason why a PicOS thread is making no progress is that it is waiting for a peripheral event rather than the completion of some calculation.
2) If needed (from the viewpoint of model fidelity), an extensive period of CPU activity can be modeled in SMURPH by appropriately (and explicitly) delaying certain state transitions.

In most cases, we can ignore the fact that the execution of a PicOS program takes time at all and only focus on reflecting the accurate behavior of the external events. With this assumption, the job of porting a PicOS praxis to its VUE$^2$ model can be made simple. To further increase the practical value of such a model, SMURPH provides for the so-called *visualization mode* of execution. In that mode, SMURPH tries to map the virtual time of modeled events to real time, such that the user has an impression of talking to a real application. This is only possible if the network size and complexity allow the simulator to catch up with the model execution to real time; otherwise, a suitable slow motion factor can be applied.

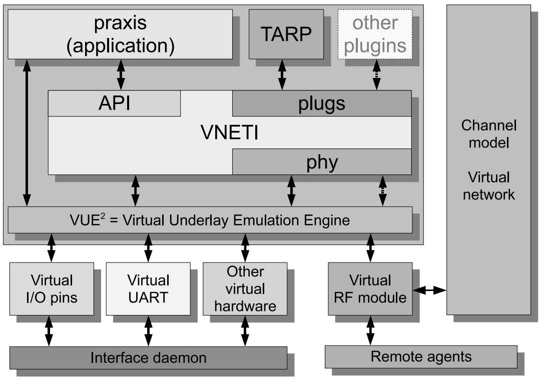

Fig. 3: The structure of a VUE$^2$ model.

### B. Model scope

SMURPH threads are programmed in C++, which we have extended with new keywords and constructs. A special preprocessor (dubbed SMPP) processes the SMURPH source to produce pure C++ code. PicOS praxes are programmed in plain C with the assistance of a few macros (see Fig. 1) expanded by the standard C preprocessor. Putting trivial syntactic issues aside, the most fundamental difference between the two systems is the fact that a SMURPH model must describe the whole network (i.e., a multitude of nodes, each of them running a private copy of the application), while a complete PicOS praxis is a single program that runs on a single device. This difference becomes more pronounced if the network consists of nodes running different praxes, a not uncommon scenario.

We make extensive use of C++ classes to accomplish the conversion from a single-application node to a multi-node (and possibly multi-application) emulator. In the conversion, each PicOS praxis becomes a C++ class. Most of the praxis functions and variables become member functions and attributes of the class, respectively. For truly global (node indifferent) functions and data, the compiler need not associate them with a specific class and can instead keep them global. When the emulator executes and builds the network, it represents each node as an object (i.e., instance of the appropriate class).

Beyond the “adaptation layer” for PicOS praxes, the VUE$^2$ extension to SMURPH implements detailed models for the physical hardware (Section III-C). In terms of communication, SMURPH brings in a powerful generic wireless channel model [22] that provides enough flexibility to implement arbitrarily complex propagation models. All of this potential for modeling allows us to confidently and comprehensively verify applications before uploading the code to physical nodes.

### C. Peripherals

The current version of VUE$^2$ implements detailed models for a significant subset of PicOS-supported peripherals that include serial communications (UART), physical sensors, general-purpose I/O (GPIO), digital-to-analog converters (DACs), analog-to-digital converters (ADCs), and light-emitting diodes (LEDs). Some of these devices, such as the GPIO pins, may require input or produce output. For such devices, VUE$^2$ offers a variety of peripheral-dependent options. In the case of the GPIO pins, the developer can describe their I/O via (a) the initial network description (for input only), (b) external files (to pre-generate/script input and log output), or (c) communication over a network socket. In the third case, VUE$^2$ provides a special program named `udaemon` that allows the developer to interactively read from and write to the peripheral.

The `udaemon` application is a fundamental component in the *interactive* emulation of a wireless sensor node and its peripherals. The initial window in the GUI (Fig. 4, top) allows the user to open peripheral-specific windows for individual emulated nodes. For example, the UART window (Fig. 4, bottom) allows two-way communication with a node over a virtual serial interface. This `udaemon` application provides access to all VUE$^2$-modeled peripherals.

## IV. Application Development

We have used both PicOS and VUE$^2$ together to implement and test a variety of practical wireless network applications such as passively monitoring environmental conditions and actively tracking the movement of indoor objects. In the subsections that follow, we introduce a few of our applications and highlight VUE$^2$’s ability to accommodate their specific (often peripheral-related) virtualization requirements.

### A. EcoNet

The *EcoNet* project, conceived with the Earth Observation Systems Laboratory at the University of Alberta, aims to monitor an environment’s sunlight, temperature, and humidity. Wireless sensor nodes distributed throughout an environment periodically measure these characteristics and then report them to a sink node. In this scenario, a single deployment uses two separate applications: a *collector* to read/transmit sensor values and an *aggregator* to receive sensor values. The collector application uses the PicOS sensor functionality to read the current values from its analog sensors.

During execution, the collector application calls the PicOS function `read_sensor` to obtain the latest values from a device’s sensors. When running on the hardware, PicOS obtains these values using the hardware’s ADC. In the emulator, the user can provide the sensor values graphically on a per-node basis using slider widgets. During an experiment, simply dragging the sliders interactively changes the sensor values visible at a node.

### B. Mousetraps

The *Mousetrap* project, conceived with researchers in the University of Alberta’s biology department, aims to monitor the common live-catching trap. When a rodent enters one of our traps, the movement of the ramp triggers a physical switch that we have added to the trap. The triggering of the switch creates a message that the node sends to its associated sink. In the above network, nodes run a single application that uses PicOS’s pin monitoring/notifier functionality for digital input.

The API for the pin notifier functionality includes functions to enable, disable, and check it. An application that uses it will wait for the predefined event PMON_NOTEVENT. On the actual hardware, this event is implemented through interrupt handlers and some auxiliary functions, e.g., needed for debouncing the switch. In the emulator, we use essentially the same code, and the user can graphically change the value of a monitored input pin using a button in the GUI.

### C. *Tags and Pegs*

The *Tags and Pegs* project at Olsonet aims to locate a sensor-enabled object within a sensor-enabled environment. Nodes in the network periodically broadcast short messages, and then other nodes use received signal strengths to perform localization. This deployment also uses two applications: one for mobile nodes and one for static nodes. To obtain signal strength values, nodes use PicOS's standard packet reception functions.

When the application calls the PicOS function net_rx, the application can retrieve a received packet from VNETI, and at the same time, the corresponding signal strength. In the hardware, the signal strength comes from the radio transceiver. For the emulator, SMURPH's generic wireless model calculates signal strengths for all virtual receptions, and the virtualization of the PicOS API uses these calculated values. From the application's perspective, there is no difference between the hardware and virtual environment.

## V. Case Study: Ping

In this section, we describe a simple *ping* application to illustrate how our platform transforms a single set of source files into code suitable for compilation with both the hardware (PicOS) and the emulator (VUE$^2$). In this example, two nodes run identical copies of the software.[*] When powered on, a node immediately begins to broadcast unaddressed ping packets that contain a locally maintained sequence number. Whenever a node receives such a ping packet, it broadcasts an acknowledgment that contains the received sequence number. Upon receiving an acknowledgement with the last sent sequence number, a node increments its locally maintained sequence number and immediately broadcasts another ping packet. If a ping packet goes unacknowledged, a node retransmits the ping after a predetermined delay.

Before presenting code, the term *thread* (used loosely in Section II) requires some clarification. In the context of the source code, our platform makes a distinction between processes with and without arguments. By doing so, we can improve compatibility between the hardware and emulator targets. We call a process that expects a typed data argument on initialization a strand. Many instances of a strand may exist at any given time, where each operates on its own local (private) data. We call a process that tends to operate on global data and does not accept such an argument a thread. Only one instance of a thread may exist at any given time.

We logically divide the ping application into three processes. In our platform, execution begins at the *thread* root (Fig. 5a, right), which is akin to the function main in a traditional C program. In a *strand* named sender (Fig. 5a, left), we place the code that transmits ping packets. We use a strand so that we can pass it the retransmission delay as an argument (in this case, line 34 sets the delay to about two seconds). Finally, we place the code for packet reception and acknowledgement generation in a *thread* named receiver (not shown).

Consider first the thread named root (Fig. 5a, right). The keyword entry identifies a state boundary and its argument identifies the state name. This thread contains a single state named RS_INIT. The first three lines of this state essentially serve as a constructor to (a) register a physical device with VNETI, (b) register a protocol plug-in with VNETI, and (c) open a session using that device and protocol. After some error handling code, this thread continues to enable the radio's transmitter and receiver along with starting the previously introduced processes sender and receiver.

It is quite possible for a single application to support a variety of different physical radio transceivers. Such a case might arise where a particular deployment's specific characteristics later dictate the best hardware. VNETI's abstractions make this type of flexibility possible. For each supported radio transceiver, the VNETI API provides a single function with the prefix phys_ to register the physical device (e.g., Fig. 5a:25). To support multiple radios, developers can use trivial preprocessor directives (e.g., #if and #endif) to call the appropriate phys_ function. Beyond this initialization stage, most applications require no further changes to switch between different transceivers.

Another noteworthy point is VNETI's protocol plug-in registration using the function tcv_plug(...) (e.g., Fig. 5a:26). By registering the *null* protocol plug-in for the ping application, calls to functions in the VNETI API provide the programmer with a more or less direct connection to the network. The programmer then has much flexibility to manage the packet overhead. Beyond the *null* plug-in, our platform also implements the Tiny Ad hoc Routing Protocol (TARP) to perform the ad hoc routing that we mentioned in our introduction. Given our plug-in oriented approach, users can implement further protocols as desired.

The remaining VNETI API functions begin with the prefix tcv_ and primarily serve as state and buffer management. Table I briefly describes some of the tcv_ functions relevant to the presented code.

In Fig. 5a, left, we present the code for the strand sender. In our platform, we define a number of data types to provide consistent variable sizes between the different targets. The keyword word that appears in the definition of sender identifies the type of its *data* argument (the word type is a 16-bit unsigned value). Later in the strand, the user can access this data argument using the (implicit) variable data. Upon entering the state SN_SEND, code checks whether the node received an acknowledgement for the last ping. If so, it immediately proceeds to send another ping. If not, it (a) sets a timer to delay before rebroadcasting the ping and (b) waits for

    if (last_ack != last_snt) {
      delay ((word)data, SN_NEXT);
      when (&last_ack, SN_SEND);
      release;
    }
    last_snt++;
    proceed (SN_NEXT);
  entry (SN_NEXT)
    x_packet = tcv_wnp (SN_NEXT, sfd,
                        DATA_LENGTH);
    x_packet[0] = 0;
    x_packet[1] = PKT_DAT;
    ((lword*)x_packet)[1] = wtonl (last_snt);
    tcv_endp (x_packet);
  entry (SN_OUT)
    ser_outf (SN_OUT, "SND %lu, len = %d\r\n",
              last_snt, DATA_LENGTH);
    proceed (SN_SEND);
endstrand
```

```
thread (root)
  entry (RS_INIT)
    // setup the radio
    phys_dm2200 (DEV_ID, MAX_LENGTH);
    tcv_plug (DEV_ID, &plug_null);
    sfd = tcv_open (WNONE, DEV_ID, 0);
    if (sfd < 0) {
      diag ("Cannot open tcv interface");
      halt ();
    }
    // start sender
    tcv_control (sfd, PHYSOPT_TXON, NULL);
    runstrand (sender, 2048);
    // start receiver
    tcv_control (sfd, PHYSOPT_RXON, NULL);
    runthread (receiver);
    // done with initialization
    finish;
endthread
```

(a) User-written code for the processes **sender** and **root** prior to preprocessing.

```
int sender (word zz_st, address zz_da) {
  word *data = (word*) zz_da;
  switch (zz_st) {
  case 0:
    if (last_ack != last_snt) {
      delay ((word)data, 10);
      zzz_uwait ((word)(&last_ack),0);
      zz_restart_entry ();
    }
    last_snt++;
    proceed (10);
  case 10:
    x_packet = tcv_wnp (10, sfd, 10);
    x_packet[0] = 0;
    x_packet[1] = 0xABCD;
```

```
    ((lword*)x_packet)[1] =
     ((((last_snt) & 0xffff) << 16) |
     (((last_snt) >> 16) & 0xffff));
    tcv_endp (x_packet);
  case 20:
    ser_outf (20, "SND %lu, len = %d\r\n",
              last_snt, 10);
    proceed (0);
    break;
  default:
    if (zz_st == 0xffff)
      return (0);
    zz_badstate ();
  }
  return 1;
}
```

(b) Preprocessed code for the process **sender** when targeting **PicOS**.

```
void sender::zz_code () {
  switch (TheState) {
  case SN_SEND: __state_label_SN_SEND:
    if ((((PingNode *)TheStation)-> _na_last_ack) != (((PingNode *)TheStation)-> _na_last_snt)) {
      ( ((PicOSNode*)TheStation)->_na_delay ((word)data,SN_NEXT) );
      ( ((PicOSNode*)TheStation)->_na_when (
         ((int)(IPointer)(&(((PingNode *)TheStation)-> _na_last_ack))), SN_SEND) );
      return;
    }
    (((PingNode *)TheStation)-> _na_last_snt)++;
    do { zz_AI_timer.zz_proceed (SN_NEXT); return; } while (0);
  case SN_NEXT: __state_label_SN_NEXT:
    x_packet = ( ((PicOSNode*)TheStation)->_na_tcv_wnp (
                  SN_NEXT,(((PingNode *)TheStation)-> _na_sfd),10) );
    x_packet[0] = 0;
    x_packet[1] = 0xABCD;
    ((lword*)x_packet)[1] = ((((((PingNode *)TheStation)-> _na_last_snt)) & 0xffff) << 16) |
                             (((((PingNode *)TheStation)-> _na_last_snt)) >> 16) & 0xffff));
    ( ((PicOSNode*)TheStation)->_na_tcv_endp (x_packet) );
  case SN_OUT: __state_label_SN_OUT:
    ( ((PicOSNode*)TheStation)->_na_ser_outf (SN_OUT, "SND %lu, len = %d\r\n",
                                              (((PingNode *)TheStation)-> _na_last_snt), 10) );
    do { zz_AI_timer.zz_proceed (SN_SEND); return; } while (0);
  }
}
```

(c) Preprocessed code for the process **sender** when targeting **VUE$^2$**.

Fig. 5: Excerpts from the ping application's source code both before and after preprocessing.

TABLE I: Some of the most common VNETI API functions and their descriptions.

| Function | Description |
|---|---|
| `tcv_plug` | Configures a protocol plug-in for the network interface; in the ping application, the null plug-in provides a more or less direct connection to the network. |
| `tcv_open` | Opens a session and returns a session descriptor (akin to a file descriptor). |
| `tcv_control` | Allows the application to change various parameters associated with the transceiver; in the ping application, we use it to enable the transmit and receive functionality of the radio. |
| `tcv_rnp` | Acquires the next packet queued for reception at the session. |
| `tcv_wnp` | Requests a packet handle from VNETI in order to send a new outgoing packet. |
| `tcv_left` | Determines the length of a packet acquired by `tcv_rnp`. |
| `tcv_endp` | Indicates explicitly the moment when a packet has been processed and is no longer needed. |

a signal (IPC) on the address of `last_ack`. The `receiver` process (not shown) triggers the address of `last_ack` when it receives an expected acknowledgement. By waiting for this signal in `sender`, the application can then immediately advance the sequence number and send out a new ping packet.

The programmer's effort amounts to writing code similar to that presented in Fig. 5a. Note that the context for this code is a single node and it is plain C code, albeit enhanced with new "keywords" to improve clarity and simplify programming that we have implemented as preprocessor macros. Since the code is plain C, compiling for PicOS simply uses the standard C preprocessor and compiler. For VUE$^2$, a specialized preprocessor makes the more complicated transition to C++ code where multiple applications and nodes must operate in a single simulation environment that preserves the state of those individual nodes.

### A. Preprocessing

In Fig. 5b and c, we show the changes made to `sender` by the respective preprocessor to prepare the code for compilation with PicOS and VUE$^2$. In this subsection, we describe some of the changes along with the reasoning behind them.

The first thing to notice is that in both cases the code's general structure remains the same. The user-written finite state machine using our `strand`/`entry` "keywords" becomes a switch on a variable containing the current state. In the PicOS case, the preprocessor substitutes state names with integer constants because the labels are `#define` preprocessor directives. For VUE$^2$, the symbolic names remain because an enumerated type represents states and thus the compiler introduces the integer constants rather than the preprocessor.

In the VUE$^2$ code, notice the appearance of several new variables (i.e., `TheStation` and `TheState`). These variables (and others) arise in the transition from a single-node (hardware) environment to a multi-node (simulated) environment. The simulator represents each node in the network as an object, and the variable `TheStation` points to the node currently being simulated. Another global variable named `TheProcess` identifies the current process (e.g., `sender`) within that node that the simulator is evaluating. Finally, a global variable named `TheState` holds an integer that identifies the current state within that process. At any point, these three variables collectively describe the current state of the simulation.

Notice that all accesses to system calls and node-specific variables within the user's application use the pointer `TheStation` (e.g., Fig. 5c:V04-V07,V10). At different places in the preprocessed code, the single object is typecast to either a `PingNode` or a `PicOSNode`. The derivation of the relevant classes is as follows. SMURPH provides a base class to represent a piece of hardware running in the network named `Station`. VUE$^2$ then introduces the notion of a `PicOSNode` as a specialized type of station and thus derives it from `Station`. At this level, VUE$^2$ defines the PicOS system calls (including those for VNETI) and internal state variables. From here, VUE$^2$ derives a further class that is protocol plug-in specific; it contains the functions and variables necessary to implement the plug-in. In this case, we use the *null* protocol plug-in and thus this further subclass is of the type `NNode`. Note that VUE$^2$ also provides a class `TNode` for nodes that run the *TARP* protocol plug-in. Finally, the class representing the actual application (in this case `PingNode`) inherits from the protocol-specific class (in this case `NNode`) and further defines the processes and variables of the user's application. When starting a simulation, VUE$^2$ builds all of the network nodes using the lowest-level (and most complete class), which in this case is `PingNode`. To see the different typecasts, first look to line V04, which typecasts to `PingNode` when accessing node-private application variables, and then to lines V05 and V06, which typecast to `PicOSNode` for making system calls.

Notice that the C++ version contains additional labels on lines V03, V12, and V20 that begin with the text `__state_label_`. When the simulator comes across the keyword `proceed` (e.g., lines V11 and V23), it saves the next state in the variable `TheState` and then returns control to the scheduler to make the state transition. The scheduler may not immediately return control to the process if other events occur at the same time. When the process does resume, the `switch` statement on the variable `TheState` moves the process into the appropriate state. Sometimes, SMURPH users will want to make a transition that does not involve the scheduler. In these cases, using the command `sameas` (not shown) rather than `proceed` accommodates an immediate transition using the label `__state_label_` along with a `goto` statement. Note that none of the code written for VUE$^2$/PicOS can currently make use of the `sameas` functionality.

Readers may be unfamiliar with the construct

```
do  ... while (0);
```

introduced on lines V11 and V23. It results from a macro expansion of our keyword `proceed`. Essentially, this code is a C idiom to define a macro consisting of multiple statements that has the syntactic rights of a single statement.

In both the PicOS and VUE$^2$ preprocessed code, name mangling occurs. In PicOS, preprocessing appends the characters `zzz_`, `zz_`, or `x_` to functions and variables internal to PicOS in an attempt to avoid conflicts. In VUE$^2$, some similar mangling occurs plus further mangling on node-private variables where the processor appends `_na_` for similar reasons.

## VI. Conclusion

In this paper, we described our "holistic" platform for building wireless ad hoc sensor networks and focused on its most representative and essential component: VUE$^2$ (the Virtual Underlay Emulation Engine). Using it, developers can write applications in C, rather than a new programming language or bytecode, and then easily target to both hardware nodes and our emulator.

Through the development of several applications, we have found that the finite state machine paradigm allows for the natural representation reactive applications. By using VUE$^2$ during the development stage, we can test our applications exhaustively in a virtual environment before investing time to program physical hardware. When we later move our applications to the hardware, they perform within our expectations.

# Wireless Ad hoc Networks: Where Security, Real-time and Lifetime Meet

Zdravko Karakehayov

Technical University of Sofia,
Bulgaria
Department Computer Systems

Email: zgk@tu-sofia.bg

*Abstract*—**This paper deals with the multihop nature of wireless ad hoc networks where security, real-time and lifetime meet. We propose a hierarchical communication model to study how medium access control and network energy signatures provide opportunities for power-efficient partitioning of communication links. We show possibilities to integrate multihop services into routing protocols. At the same time, malicious nodes included in a routing path may misbehave and the paper analyzes vulnerable points in case of communication attacks. The REWARD algorithm for secure routing is used as a main example for corrective actions. Nodes listen to neighbor transmissions to detect black hole attacks. The energy overhead is broken down into static, the additional energy required to watch for attacks, and dynamic, which is application specific. We evaluate the static energy overhead associated with symmetrical routing.**

## I. Introduction

AD HOC networks have a wide spectrum of military and commercial applications. Ad hoc networks are employed in situations where installing an infrastructure is too expensive, too vulnerable or the network is transient. The interaction between the nodes is based on wireless communication. Packets are forwarded in a multihop manner. Nodes have a limited radio footprint and when a node receives a packet it applies a routing algorithm to select a neighbor for forwarding.

There is a class ad hoc networks, sensor networks, where the requirements for lifetime and size of the nodes are driven to extremes. A wireless sensor network consists of a large number of nodes that may be randomly and densely deployed. Sensor nodes are capable of sensing many types of information such as temperature, light, humidity and radiation. Sensor networks must collect data in an area of interest for months or years. Since the energy is a scarce and usually non-renewable resource, the network's functionality must be viewed from a low-power perspective. Sensor network nodes execute three major tasks: sensing, computation and communication.

Communication energy dominates the overall energy budget. The greater than linear relationship between transmit energy and distance promises to reduce the energy cost when the radio link is partitioned. Nodes calculate the distance and tune their transmit power accordingly. Consequently, it would be beneficial to use several hops to reach a node within the transmission radius instead of a direct link. Along with available locations of the nodes, a multihop optimization requires an appropriate power model. For some applications it is not necessary nodes to have real coordinates. Instead, nodes may have virtual coordinates: hop-distances to other nodes.

Moreover, some applications require the network to influence the environment via actuators. Synchronization between input and output demands real-time traffic. Real-time forwarding of packets under multihop communication scheme is a serious challenge. When we factor in security, the outlook becomes even more grim. Packets travel over several nodes and malicious attacks are easy to organize. To detect malicious influence and wage corrective actions the nodes must spend extra energy. Consequently, the multihop nature of ad hoc networks, while beneficial for energy reduction, brings the packets delivery time up. The dynamic nature of the network and the power-efficient partitioning of communication links in particular, often result in unpredictable traffic timing parameters. Enemy nodes included in a routing path may misbehave and any attempt to make the network less vulnerable requires extra energy and affects the lifetime, thus closing the loop.

## II. Related Work

Different MAC protocols are discussed in [1]-[6]. Energy efficiency is the primary goal of the research. While a power saving technique, termed Span [1], dynamically splits the nodes into sleeping nodes and forwarding nodes, S-MAC, a medium access control protocol [2], establishes a low duty cycle operation in all nodes. ExOR, extremely opportunistic routing is a routing method developed to reduce the total number of transmissions taking into account the actual packet propagation [3]. DTA, data transmission algebra, has been developed to generate complex transmission schedules based on collision-free concurrent data transmissions [5]. In related research we proposed ALS-MAC, a medium access control protocol where contention-based advertising slots are mapped to scheduled-based transmission slots [6]. The energy model employed in this paper has been adopted from [7], [8]. Despite there being a plethora of sensing and MAC papers, comparatively little has been published on the companion task of actuation and real-time requirements. Sensor-actuator networks are discussed in [9], [10]. The problem of obtaining virtual coordinates is addressed in [11].

Different aspects of node architectures and capabilities can be found in [12]-[17]. The power reduction methods discussed in [15]-[17] are not confined to computation energy of network nodes. They can be applied, also, in other cases where voltage-scalable or speed-scalable CPUs follow the current requirements and save energy. Another approach to reduce the power consumption is to remove hardware used for localization, such as GPS, and utilize receive signal strength, RSS. The resulting accuracy and impact factors are investigated in [14].

Methods for energy efficient multihop communication are discussed in [18]-[22]. A detailed investigation for simple settings is available in [19]. In related research we studied multihop optimization for non-regular topologies [6], [10]. An Aloha type access control mechanism for large, multihop, wireless networks is defined in [21]. The protocol optimizes the product of the number of simultaneously successful transmissions per unit of space, spatial reuse, by the average range of each transmission.

A review of routing protocols for wireless ad hoc networks is available in [23]. The problem of radio irregularity is discussed in [24]. Later in Section V, we compare distances with the communication range. Due to radio irregularity some neighbors located within the transmission disk may be inaccessible while some remote nodes, outside the disk, will be capable to communicate. Since quite a few processor architectures vie for attention in the realm of sensor networks, target-aware modeling of routing algorithms helps to evaluate important timing properties [25]. Security of wireless sensor networks is in focus in [26]-[31]. Two papers, [22] and [30], emphasize the fact that multiobjective design is needed. Listening to neighbor transmissions to detect black hole attacks is discussed in [32]-[35].

## III. Communication Model

The communication model describes a packet forwarding from a source to a destination. The destination is within the communication range of the source. The communication model, C, has three components: a set of the locations of nodes, L, a medium access control model, M, and an energy model, E.

$$C=\{L, \mathrm{M}, E\} \tag{1}$$

### A.Medium access control model

Medium access control (MAC) mechanism has a significant impact on the energy efficiency [2], [4], [6]. Currently available MAC protocols for wireless sensor networks can be broken down into two major types: contention-based and scheduled-based. While under contention-based protocols nodes compete among each other for channel access, scheduled-based schemes rely on prearranged collision-free links between nodes. There are different methods to assign collision-free links to each node. Links may be assigned as time slots, frequency bands, or spread spectrum codes. However, size and cost constrains may not permit allocating complex radio subsystems for the node architecture. Logically, TDMA scheduling is the most common scheme for the domain of wireless sensor networks. The limited communication range of network nodes provides an extra opportunity for collision-free interaction, space division access [5], [6], [21].

- *Assume scheduled links*

In order to save energy nodes should stay in a sleeping mode as long as possible. Ideally, nodes should have prearranged collision-free links and wake up only to exchange packets. This MAC approach can be termed Assume Scheduled Links, **ASL**. The **ASL** model has two parameters: a packet length in bits, p, and a bit rate, B.

$$\mathrm{M}=\{\mathrm{ASL}, \mathrm{p}, \mathrm{B}\} \tag{2}$$

While **ASL** is a theoretical concept, it helps to outline the floor of the energy required for communication.

- *Beacon Advertise Transmit*

Beacon Advertise Transmit, **BAT**, model is a widespread MAC mechanism [4]. Beacons are employed to synchronize internode communications. A beacon period, $T_B$ , includes two major sections. The period begins with a traffic indication window, $T_A$ . During $T_A$ all nodes are listening and pending packets are advertised. The nodes addressed till the end of $T_A$ send acknowledgements and receive data packets. Data transmissions are followed by acknowledgement frames to confirm successful reception. Fig. 1 illustrates a beacon period.

The **BAT** model has five parameters: $T_A$ , $T_B$ , a data packet length in bits, p, a control packet length in bits, q, and a bit rate, B.

$$M=\{\mathrm{BAT}, \mathrm{T}_A, \mathrm{T}_B, \mathrm{p}, \mathrm{q}, \mathrm{B}\} \tag{3}$$

### B. Energy model

The energy used to send a bit over a distance *d* via radio communication may be written as

$$\mathrm{E}=ad^n+b \tag{4}$$

where *a* is a proportionality constant [7], [8]. The radio parameter *n* is a path loss exponent that describes the rate at which the transmitted power decays with increasing distance. Typically, *n* is between 2 and 4. The *b* constant is associated with specific receivers, CPUs and computational algorithms. Thus the model emerges as

$$E=\{a, n, b, \mathrm{P}_R\} \tag{5}$$

where $P_R$ is the power consumption of a turned on receiver.

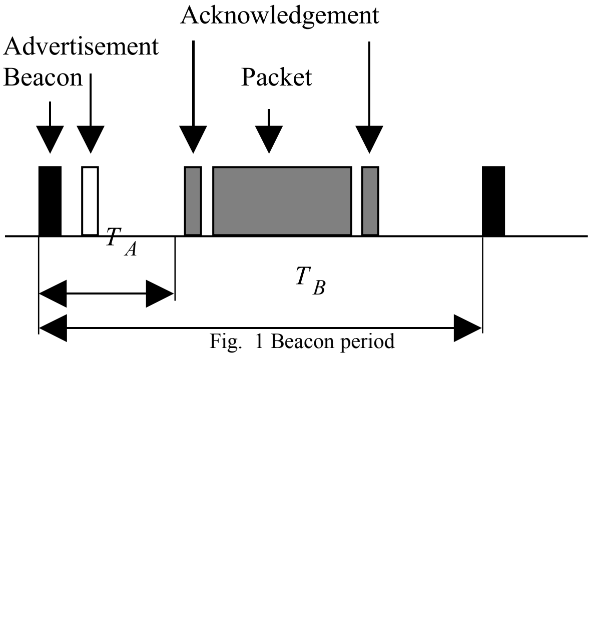

Fig. 1 Beacon period

## IV. Real-Time Behavior

Using the BAT model and counting the beacon periods nodes are in position to calculate the packets delivery time. While this completely applies for destination nodes, intermediate nodes can use the actual packet propagation time and virtual coordinates to foresee the overall delivery time.

In the large, energy versus real-time tradeoffs can be resolved via different values assigned for the beacon period. In the small, at each hop nodes decide whether to include an extra intermediate node for power efficiency or to forward the packet as fast as possible. The local decision is based on the actual propagation of the packet measured in number of beacon periods and the remaining number of hops.

## V. Lifetime

An ad hoc network lifetime can be measured by the time when the first node runs out of energy, or a network can be declared dead when a certain fraction of nodes die. Alternatively, the system lifetime can be measured by application-specific parameters, such as the time until the system can no longer provide acceptable quality of service. Clearly, the higher the energy efficiency is, the longer the network will survive. The energy efficiency can be optimized at three levels.

### *A. Node architecture*

A typical node is built around a low-power microcontroller [12],[13],[15]. Wireless transceivers create physical links between nodes. Hardware provides the following low-power mechanisms. The receiver and transmitter can be individually enabled and disabled. The transmit power can be adjusted gradually. For many applications nodes are capable of determining their coordinates. Voltage-scalable systems may apply dynamic voltage or clock frequency scaling to reduce the power consumption.

### *B. Multihop routing service*

Once the routing protocol has provided the next relay another neighbor can be considered to partition the link. The number of hops is increased to save energy. As an additional benefit, the reduced transmit power allows better spatial reuse. Fig. 2 shows how an intermediate node can be used to break down the link between a source S and a destination D into two hops.

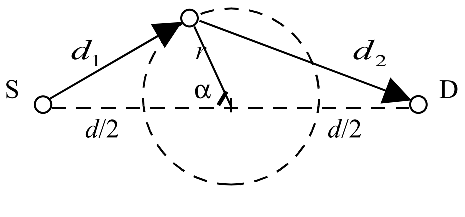

Fig. 2 Routing via an intermediate node

**Theorem 1**. Let $C=\{\{\text{ASL,p,B}\},\{a,4,b,\text{P}_R\}\}$ be the communication model of a wireless ad hoc network. If the distance between the source S and the destination D $d \geq \left((8\text{b}+(\text{p/B})P_R)/7\text{a}\right)^{1/4}$ and the distance between an intermediate node and the halfway point between S and D

$$r \leq (-0.75d^2+0.25(9\text{d}^4-a^{-1}(8\text{b}-7ad^4+(\frac{\text{p}}{\text{B}})P_R))^{\frac{1}{2}})^{\frac{1}{2}},$$

the two-hop communication requires less energy than the direct link.

**Proof.** We must prove when the following inequality holds.

$$ad_1^4+b+ad_2^4+b+2(\text{p/B})P_R \leq ad^4+b+(\text{p/B})P_R \quad (6)$$

Taking into account that

$$d_1=\left(d^2/4-dr\cos\alpha+r^2\right)^{1/2} \quad (7)$$

$$d_2=\left(d^2/4+dr\cos\alpha+r^2\right)^{1/2} \quad (8)$$

We get

$$16ar^4+8ad^2\left(1+2\cos^2\alpha\right)r^2+8\text{b}-7ad^4+(\text{p/B})P_R \leq 0 \quad (9)$$

The inequality has solutions if and only if $d \geq \left((8\text{b}+(\text{p/B})P_R)/7\text{a}\right)^{1/4}$ . Since the threshold value for the distance $r$ will vary with α, we take the worst case, $\cos\alpha=1$ .

Using the quadratic formula,

$$r \leq (-0.75d^2+0.25(9\text{d}^4-a^{-1}(8\text{b}-7ad^4+(\frac{\text{p}}{\text{B}})P_R))^{\frac{1}{2}})^{\frac{1}{2}} \quad (10)$$

□

Fig. 3 shows plots for the radius $r$ compared with half of the distance. This example assumes two bit rates, 1 Mbps and 0.5 Mbps, $a$ = 0.2 fJ/m$^4$, $b$ = 1 nJ, $\text{P}_\text{R}$= 10 mW and p = 128 bit.

**Theorem 2**. Let $C=\{\{\text{BAT,T}_A\text{,T}_B\text{,p,q,B}\},\{a,4,b,\text{P}_R\}\}$ be the communication model of a wireless ad hoc network. Let the average number of neighbors listening to a beacon transmission be D. If the distance between the source S and the destination D

$$d \geq ((b(3\text{q}+p)+P_R B^{-1}(q+p)$$
$$+P_R\text{DT}_A)a^{-1}(3.5625q+0.875\text{p})^{-1})^{1/4}$$

and the distance between the intermediate node and the halfway point between S and D

$$r \leq (-0.25d^2(10.5\text{q}+3\text{p}+0.5\text{q}d)(3\text{q}+p+qd)^{-1}$$
$$+0.5\text{a}^{-1}(3\text{q}+p+qd)^{-1}(0.25a^2d^2(10.5\text{q}+3\text{p}+0.5\text{q}d)^2$$
$$-2\text{a}(3\text{q}+p+qd)(-ad^4(3.5625q+0.875p)$$
$$+b(3\text{q}+p)+P_R B^{-1}(q+p)+P_R\text{DT}_A))^{1/2})^{1/2}$$

the two-hop communication requires less energy than the direct link.

□

The radius $r$ for a given distance $d$ indicates application-specific opportunities for power-efficient partitioning of communication links. Fig. 4 compares **ASL** and **BAT** MAC models for a bit rate of 512 Kbps.

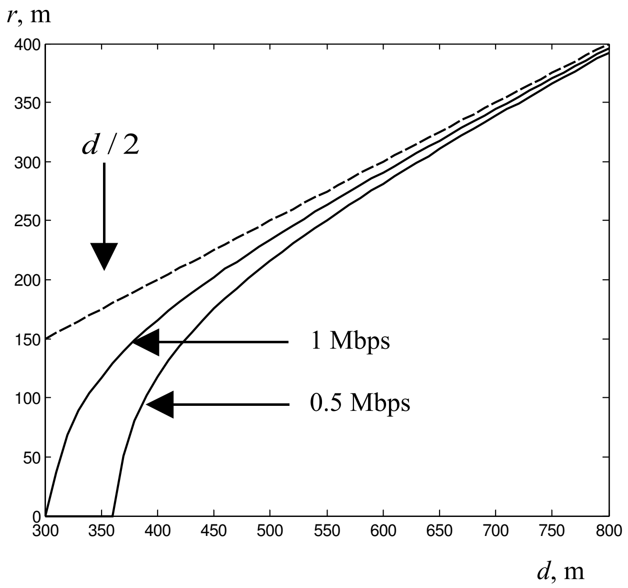

Fig. 3 Radius *r* scales with the distance for two bit rates

### *C.Routing algorithms*

Routing algorithms can be based on two major approaches: topology-based and position-based routing [23]. The topology-based algorithms can be further split into table-driven and demand-driven. The main idea behind the table-driven routing protocols is to create a clear picture of all available routes from each node to every other node in the network. In contrast to the table-driven protocols, the demand-driven algorithms create routes via route discovery procedures only when a necessity arises.

Position-based routing algorithms utilize the physical positions of the participating nodes [19],[21],[23]. Position-based or geographic routing does not require each node to have the locations of all other nodes. Each node keeps track of the coordinates of its neighbors and their neighbors. A greedy routing algorithm based on geographic distance selects the closest to the destination neighbor for the next hop [19].

Assume that the nodes of a wireless ad hoc network are members of the following set $N = \{N_1, N_2, N_3, \dots, N_{n(N)}\}$. The nodes are placed in a rectangular region of *X* by *Y*. The distance between node i and node j is *d*(i,j). The distance between node k and the halfway point between node i and node j is $d(\mathrm{k}, \mathrm{m}_{\mathrm{i,j}})$.

Routing algorithms are employed to determine the next hop of $N_i$, $N_i^{+1}$. The distance between $N_i$ and its next hop $N_i^{+1}$ is *d*(i,+1). Likewise, the distance between $N_k$ and the halfway point between $N_i$ and $N_i^{+1}$ is $d(\mathrm{k}, \mathrm{m}_{\mathrm{i,+1}})$. A statement **power**(*d*(i,j)) in the pseudocode listing adjusts the transmit power according to the distance *d*(i,j). A statement **send** $(\mathrm{N_i} \longrightarrow \mathrm{N_j})$ indicates a packet forwarding from node i toward node j.

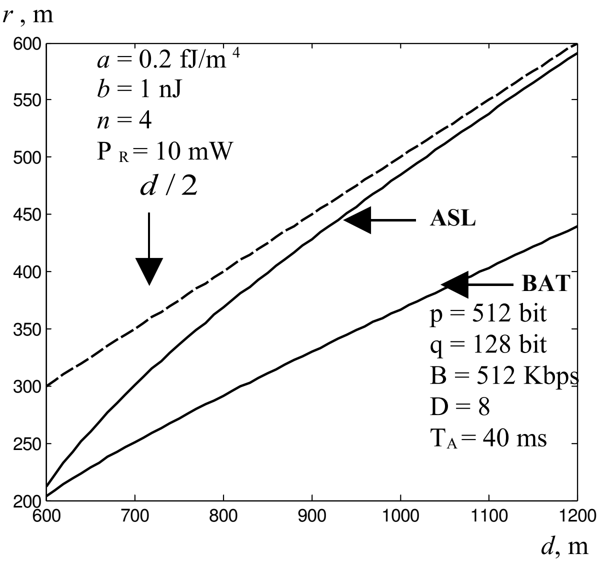

Fig. 4 Radius *r* scales with the distance for two MAC models

**Algorithm 1** $\mathrm{N_i^R} \leftarrow \mathrm{OneHop}(\mathrm{N_i})$

```
$N_i^R = \emptyset$
for $1 \le j \le n(N),\ j \ne i$ do
    if $d(i, j) \le R$
        $N_i^R = N_i^R \cup N_j$
    end if
end for
```

Algorithm 1 describes the procedure to determine the set $\mathrm{N_i^R}$, which includes the one-hop neighbours of $\mathrm{N_i}$. R denotes the communication range.

**Algorithm 2** $\mathrm{N_i^{+1}} \leftarrow \mathrm{NextHop}(\mathrm{N_i}, \mathrm{N_D}, \mathrm{N_i^R})$

```
if $N_D \in N_i^R$
    return $N_D$
end if
$s = (X^2 + Y^2)^{1/2}$
for $1 \le j \le n(N),\ j \ne i$ do
    if $N_j \in N_i^R$ and $d(j, D) < s$
        $N_i^{+1} = N_j,\ s = d(j, D)$
    end if
end for
```

Algorithm 2 applies the greedy routing algorithm to find the next relay of $N_i$.

The multihop service can be integrated into the routing algorithm.

**Algorithm 3** $\mathrm{MultiHop}\left(N_i, N_i^{+1}\right)$

```
do
    MULTI=0
    $d = d(i,+1)$
    $s = \left(X^2 + Y^2\right)^{1/2}$
    for $1 \le j \le n(N),\ j \ne i$ do
        if $d(j, m_{i,+1}) \le MIN(r,s)$
            $s = d(j, m_{i,+1})$ ,    $N_i^{+1} = N_j$ , MULTI=1
        end if
    end for
while MULTI
power $(d(i,+1))$
send $(N_i \to N_i^{+1})$
```

Algorithm 3 applies Theorem 1 or Theorem 2 to partition the communication link until suitable intermediate nodes are found. The procedure results in one forwarding.

**Algorithm 4** $\mathrm{Send}\ (N_S, N_D)$

```
$N_i = N_S$
do
    $\mathrm{NextHop}\left(N_i, N_D, N_i^R\right)$
    $\mathrm{MultiHop}\left(N_i, N_i^{+1}\right)$
while $N_i \ne N_D$
```

Algorithm 4 describes the successive approximation routing. The interaction between the routing procedure and the low-power forwarding is implemented via successive approximations. As soon as the routing algorithm determines the next hop, multihop optimization is applied to select an intermediate node. As soon as the packet is sent to the intermediate node, the routing algorithm is executed again. The multihop service algorithm itself is a successive approximation procedure as well.

In a two-hop distance approach, each node maintains a table of all immediate neighbors as well as each neighbor's neighbors. The number of hops taken into account determines the vulnerability of the routing in case of topology holes. However, considering more hops will require longer execution times. Fig. 5 shows how the transition from a single hop to two hops brings the execution time up. The code has been written in C and compiled for two CPUs: 8051 and Atmel AVR [25].

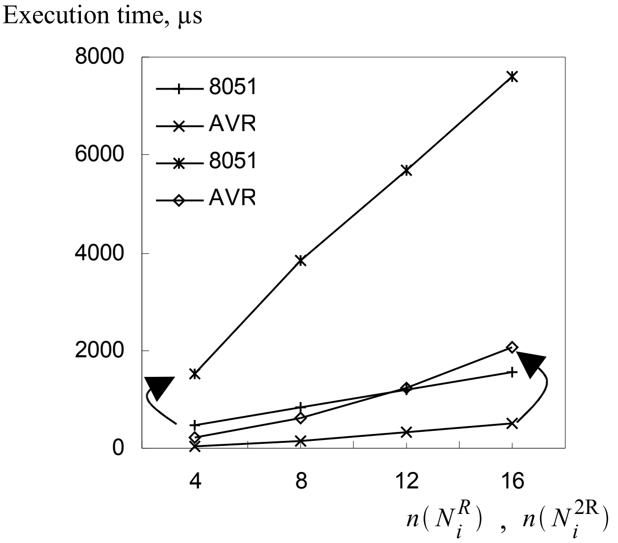

Fig. 5 Execution time to select the next relay

## VI. Security

The network functional partitioning into sensing, computation and communication can be used to deal with possible avenues of attacks. First, a misbehaving node may provide false sensor readings. In general, this kind of attack is not effective. Collected data is aggregated and a small number of malicious nodes can not change the profile of the physical event. However, a false alarm, an input has reached a threshold, will wake up several nodes and attack the batteries. Another attack related to the environment is a wrong location. Sensing is useful only in the context of where the data has been measured.

In contrast to sensing, a well placed enemy may successfully attack via wrong calculations. Aggregation is important for power efficiency and nodes that aggregate data packets are in a good position to attack.

Communication is what makes ad hoc networks most vulnerable and the multihop forwarding of packets unrolls ample possibilities for attackers. Once a malicious node has been included on the routing path, it will be in position to change the content of the packets. Along with data, packets may convey code. Mobile agent-based sensor networks distribute the computation into the participating leaf nodes [28], [29]. Since agents may visit a long path of nodes, a single modified packet can force several nodes to execute enemy code. Another axis along which packets can be affected relates to timing. A scheduling attack would change the number of past beacon periods a packet carries. Another form of a scheduling attack is delayed packets. An extreme type of this attack, termed black hole, is observed when a malicious node consumes packets. In a special case of black hole, an attacker could create a gray hole, in which it selectively drops some packets but not others. For example, the malicious node may forward control packets but not data packets.

## VII. REWARD Algorithm

REWARD (receive, watch, redirect) is a routing method that provides a scalable security service for geographic ad-hoc routing [33]-[35].

### *A.Black holes data base*

The algorithm creates a distributed data base for detected black hole and scheduling attacks. The data base keeps records for suspicious nodes and areas. The REWARD security service provides alternative paths for the geographic routing in an attempt to avoid misbehaving nodes and regions of detected attacks. The algorithm utilizes two types of broadcast messages, MISS and SAMBA, to recruit security servers. Security servers are nodes that keep records of the distributed data base and modify the geographic forwarding of packets to bypass insecure nodes and regions.

Assume that a demand-driven protocol performs a route discovery procedure. When the destination receives the query, it sends its location back and waits for a packet. If the packet does not arrive within a specified period of time, the destination node broadcasts a MISS (material for intersection of suspicious sets) message. The destination copies the list of all involved nodes from the query to the MISS message. Since the reason for not receiving the packet is most likely a black hole attack, all nodes listed in the MISS message are under suspicion. Nodes collect MISS messages and intersect them to detect misbehaving participants in the routes. The detected malicious nodes are excluded from the routing if other paths are available.

Radio is inherently a broadcast medium and nodes can detect black hole attacks if they listen to neighbor transmissions [32]. Fig. 6 shows an example. Each node tunes the transmit power to reach both immediate neighbors, $N_i^{+1}$ and $N_i^{-1}$ . We call this type of forwarding symmetrical. The nodes transmit packets and watch if the packets are forwarded properly. If a malicious node does not act as expected, the previous node in the path will broadcast a SAMBA (suspicious area, mark a black-hole attack) message.

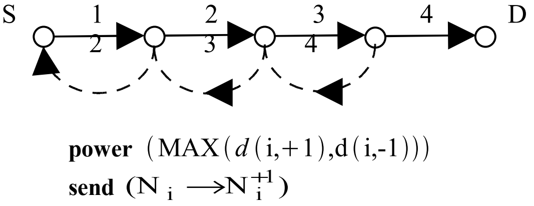

Fig. 6 Transmissions must be received by two nodes

Fig. 7 shows an example routing with the assumption that two malicious nodes would attempt a black hole attack. In this case the algorithm requires the nodes to listen for two retransmissions. Fig. 8 indicates the exact positions of two black holes in the path. The first malicious node forwards the packet using the required transmit power to deceive two nodes backward. The second malicious node drops the packet, however the attack is detected by the last node before the black holes. The missing transmission is shown by a dot line in Fig. 8. An extra black hole in the path would mask the attack.

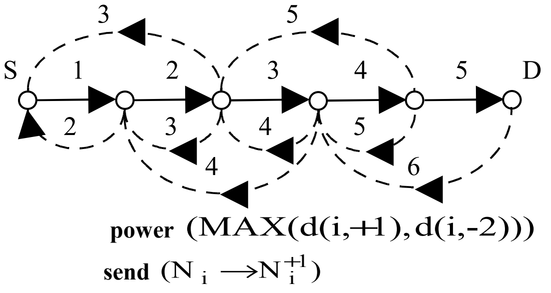

Fig. 7 REWARD against two black holes

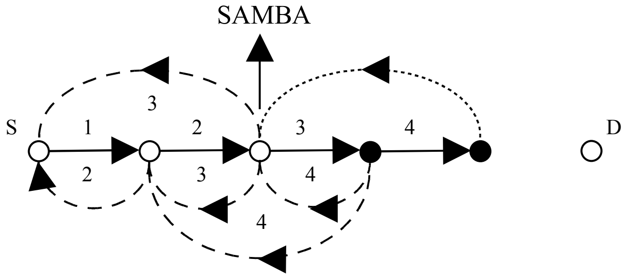

Fig. 8 REWARD detects the second black hole

In order to determine the effectiveness of REWARD we used ANTS (ad-hoc networks traffic simulator) [34],[35]. We assume that all nodes are stationary throughout the simulation. Fig. 9 shows simulation results of the throughput, 100 packets routing for eight example deployments. Each deployment has a density of 100 nodes randomly located in a square kilometer. The maximum communication range of the nodes is 100 meters. Also, the simulation results are obtained at 10% misbehaving nodes. MISS servers are recruited in a rectangular region. The source and destination locations define the diagonal of the rectangle.

Fig. 10 shows the fraction of malicious nodes detected against false detection. False detection is associated with nodes excluded from the network as malicious when in fact they are not. For the current simulation, nodes that are listed in two or more MISS messages are marked as malicious.

### *B. Energy overhead*

We distinguish between two types of security energy overhead. Static overhead is the additional energy required to watch for attacks. Dynamic overhead is the extra amount of energy spent to detect compromised nodes and mitigate routing misbehaviour. While the dynamic overhead will vary from application to application, the static overhead is a constant and an inevitable item in the energy budget.

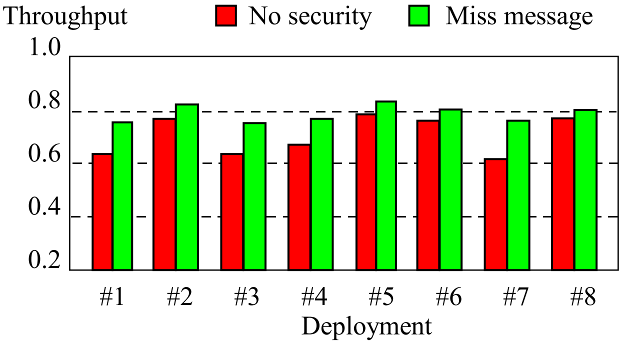

Fig. 9 The fraction of packets received for eight examples

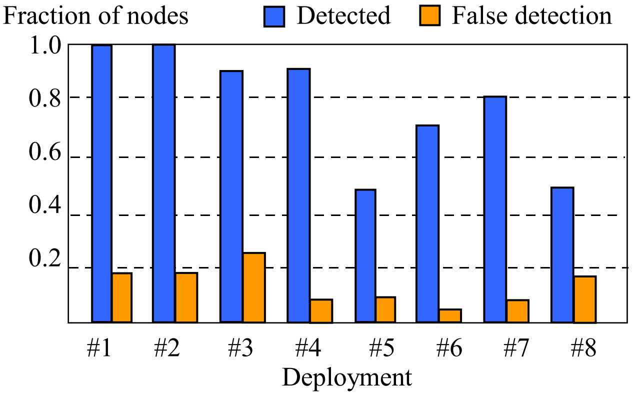

Fig. 10 Detected malicious nodes against false detection

Since secure routing protocols such as REWARD require symmetrical forwarding, the power efficiency is declined. Fig. 11 shows symmetrical routing for an example deployment. Three cases must be considered according to the distances:

$$d(i,-1)\le(d(i,+1))/2-r \qquad (11)$$

There is no security overhead in this case.

$$(d(i,+1))/2-r<d(i,-1)\le(d(i,+1))/2+r \qquad (12)$$

Again, there is no single-hop security overhead. Opportunities for partitioning of the link remain if neighbors are located within the shaded area, Fig. 11.

$$d(i,-1)>(d(i,+1))/2+r \qquad (13)$$

Symmetrical routing may not increase the energy , however partitioning of the link is not power efficient in this case.

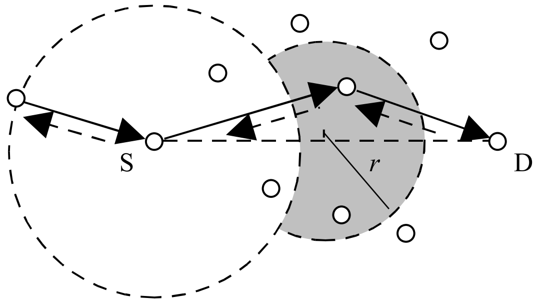

Fig. 11 Symmetrical routing

**Algorithm 5** MultiHopSym$(N_i, N_i^{+1})$

```
$s=(X^2+Y^2)^{1/2}$
if $d(i,-1)>(d(i,+1))/2+r$
  power $(MAX(d(i,+1), d(i,-1)))$
  send $(N_i \rightarrow N_i^{+1})$
  return
end if
if $d(i,-1)\le(d(i,+1))/2-r$
  for $1\le j\le n(N),\ j\ne i$ do
    if $d(j,m_{i,+1})\le MIN(r,s)$
      $s=d(j,m_{i,+1})$, $N_i^{+1}=N_j$
    end if
end for
  power $(d(i,+1))$
send $(N_i \rightarrow N_i^{+1})$
return
end if
for $1\le j\le n(N),\ j\ne i$ do
if $d(j,m_{i,+1})\le MIN(r,s)$ and
    $d(i,j)\ge d(i,-1)$
    $s=d(j,m_{i,+1})$, $N_i^{+1}=N_j$
end if
end for
power $(d(i,+1))$
send $(N_i \rightarrow N_i^{+1})$
```

Algorithm 5 provides multihop optimization for symmetrical routing.

## VIII. Conclusion

This paper manifests wireless ad hoc networks need multi-objective design. The multihop communication approach outlines tradeoffs between security, real-time and lifetime. We proposed a hierarchical communication model and employed it to compare how two MAC models are capable of link partitioning for non-regular topologies. The proofs can be used to organize look-up tables in the nodes memory and streamline the selection of the best next relay. We evaluated the static energy overhead associated with algorithms for secure routing, such as REWARD, which will help to reassess the lifetime of the network.

# A Method of Mobile Base Station Placement for High Altitude Platform based Network with Geographical Clustering of Mobile Ground Nodes

Ha Yoon Song
Department of Computer Engineering, Hongik University, Seoul, Korea
Email: hayoon@wow.hongik.ac.kr

***Abstract*—High Altitude Platforms (HAPs) such as Unmanned Aerial Vehicles (UAVs) which can be deployed as stratospheric infrastructures enable a sort of new configurations of wireless networks. Ground nodes must be clustered in multiple sets and one dedicated UAV is assigned to each set and act as an MBS. For the intra-set nodes, UAVs must communicate each other in order to establish network links among intra-set nodes. Here we find a geographical clustering problem of networking nodes and a placement problem of MBSs. The clustering technique of mobile ground nodes can identify the geographical location of MBSs as well as the coverage of MBSs. In this paper we proposed a clustering mechanism to build such a configuration and the effectiveness of this solution is demonstrated by simulation. For a selected region with a relatively big island, we modeled mobile ground nodes and showed the result of dynamic placement of MBSs by our clustering algorithm. The final results will be shown graphically with the mobility of ground nodes as well as the placement of MBSs.**

## I. Introduction

THE recent development of Unmanned Aerial Vehicles (UAV) leads to interests in High Altitude Platforms (HAPs) as Mobile Base Stations (MBSs) of wireless wide-area networks. UAVs usually carry wireless network equipments and require less management and thus have been regarded as one of the best method to deploy wireless network over wide area without typical ground network equipments. This new sort of network configuration requires a lot of unsolved research topics from the physical layer to transportation layer as well as the ideal configuration of network. Many researches have been concentrated on the communication between stratospheric UAVs and mobile ground nodes. These topics include establishments of communication links among UAVs as well.

The goal of HAP based network is to cover as wide area as possible with deployment of multiple UAVs, i.e. ultimate goal of HAP network is to deploy as many MBSs to cover dedicated area in order to construct a network structure. In this configuration, UAVs can act as mobile base stations for the network. This sort of network configuration raises a new configuration problem of UAVs and mobile ground nodes.

Here we suggest an idea. Mobile ground nodes consist a number of clusters in order to be served by MBSs and each MBS covers a dedicated cluster of mobile ground nodes. MBSs cooperate each other in order to support communication of mobile ground nodes in the whole area. The HAP based wireless network usually regarded as a viable solution for the networks with minimal ground infrastructures or countries under development and so on.

In this paper, we will show a method to deploy MBSs for a dedicated area with possible number of MBSs and to cover dedicated area efficiently. By adopting a clustering mechanism for mobile ground nodes, we can solve a placement problem of MBSs as well as the coverage of each MBS. For an island area we set mobility model and simulated the dynamic clustering of mobile ground nodes and find proper locations for MBSs and coverage.

This paper is structured as follows. In section II we will discuss research basis for this paper. In section III we will see the basic configuration concept of HAP based network assumed in this paper. In the following section IV we will explain our clustering algorithm for mobile ground nodes and MBS placement. Then we will show simulation experiment and results in section V. The final section will conclude this paper and will discuss the future research direction.

## II. Related Works

The basis of this research is usually categorized into two basic parts. The first one is HAP based networks. The second one is clustering algorithms. We will discuss about this two topics simply.

### A. HAP based Network

HAP based network is one of the most recent research topics while there have been a long idea about stratospheric platforms as a media of networking. With the development of network technologies as well as aerial industries, HAP can be actual one and the idea of HAP based network spawns into real world. Nowadays, most of countries research on this topic. Some of them regard this sort of network as national project while others act as an individual company bases. The Republic of Korea researches on this topic as a national project as shown in [1] with the fruitful research at ETRI (Electronics and Telecommunication Research Institute).

This work was supported by 2008 Hongik University Research Fund.

Japan has the similar situation. Japanese Aerospace Exploration Agency [2] has an ongoing effort with HAP based network, named as SkyNet project.

For EU nations or EU companies, there are projects such as HeliNet and CAPANINA. England was one of the early starter in this topic and most of EU nations are participated in those projects [3]. The Australian continent also has academic research on this topic [8].

Also in the US, projects such as Sky Station, High Altitude Long Operation, SkyTower, Staratellite, Weather Balloon HAPs are undergoing ones [4].

The characteristics of this project are that they are still assuming a single HAP platform and are mostly concentrated on communication links establishment.

For example, WRC started the first specification of frequency allocation for HAP network since the year 1997 and several bandwidth frequencies are allotted for specific nations [9]. By ITU, following radio frequencies and specifications for the Republic of Korea are allotted.

- Altitude 20.6 - 23.8 Km
- Frequency 47.9 - 48.2 GHz and 47.2 - 47.5 GHz
- Bandwidth 500Mhz

There have been several researches on the communication link establishment between mobile ground nodes and HAP base station [5], [6]. Also a protocol standard such as 802.16 can be a possible candidate for HAP networks [7]. For the inter-HAP links, there also have been researches such as [8].

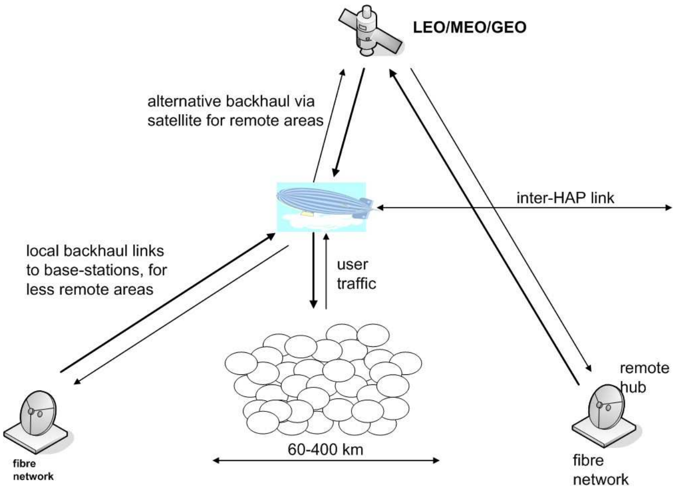
Apart from these researches, this paper assumes an environment of multiple heterogeneous HAPs. We regard each HAP as a MBS of mobile ground nodes and tried to cluster mobile ground nodes in order to solve the placement problem of MBS. As far as we know, no such topic has been dealt until the first submission of this paper. The most similar one is in [10] but it is on a positioning control for HAP station.

### B. Clustering Algorithms

In a field of data mining, there have been researches regarding clustering of data in a large Database [11]. And multiprocessor versions can be found in [12]. They are usually concentrated on the patterns of related data while we need a geographical clustering based on the ground node coordinates. Thus we screened out several candidates and tried combinations of those clustering algorithms.

The most prominent candidates are K-mean, BIRCH, EM, PROCLUS, and SUBCLUS. The K-mean is one of the most popular algorithm in the clustering world. Since we are dealing with mobile ground nodes, we cannot identify the exact coordinates but we only assume the probability of node coordination. In this aspect, we concentrated on Expectation Maximization with a probability of node coordinates.

Considering the limitations of number of nodes in a cluster, that is actually a bandwidth limitation of wireless routers equipped on HAP MBS, We need to split a cluster or merge clusters in order to balance the number of nodes in a cluster. The BIRCH and their successors can cope with such a requirement, thus we choose it as a possible candidate.



LEO/MEO/GEO
alternative backhaul via satellite for remote areas
inter-HAP link
local backhaul links to base-stations, for less remote areas
user traffic
remote hub
60-400 km
fibre network
fibre network

Fig. 1. Basic Configuration of HAP based Network

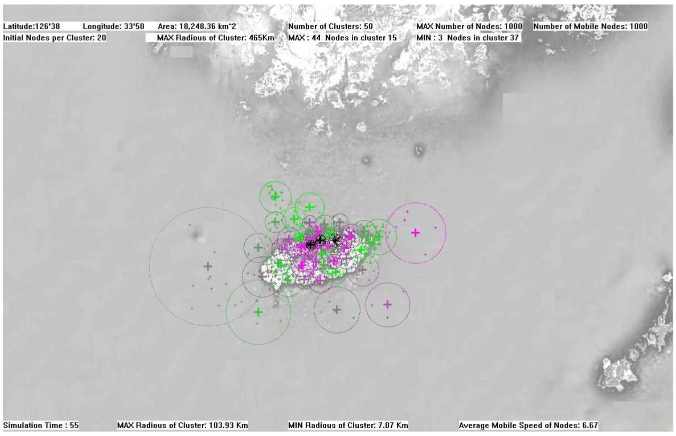
Even though EM and BIRCH are nice candidates for our application, these two cannot deal ideal initial clustering and the results are usually not a geographical one. Thus we need a multiphase clustering algorithm. Usually initial clusters can be drawn by K-mean algorithm and then the core cluster algorithm such as BIRCH or EM can work. For geographical consistency, a post processing of merging or splitting must be done. Two algorithms of SUBCLUS and PROCLUS are typical examples of multiphase clustering algorithms that attracts our interest.

However, apart from this existing algorithms, we will study the most appropriate clustering algorithms for HAP MBS placement. In this paper, we will show a basic result based on K-mean algorithm [13].

## III. Basic Concept of HAP based Network Configuration

The concept of HAP networking is similar to that of satellite communication. Characteristics such as Broadness, Simultaneousness, Flexible Configuration, and Broadbandwidthness of HAP based network are similar to that of satellite network, however, on-time supplements, ease of management, short communication distance, low power mini handset, low round trip time are typical characteristics of HAP network that cannot be found in satellite network. The key point here is low communication delay and flexible network configuration. In this paper, we spotted on flexible network configuration and will start the discussion from the basic configuration of HAP network. Figure 1 shows a basic configuration of HAP based network. HAP usually resides on stratospheric area, about 21km altitude with very low speed of winds as reported by NASA, USA.

Even though figure 1 shows only one HAP device, however there could be a lot of plans for multiple HAPs. This configuration with multiple HAPs will cause a interplatform link study and reapplication of traditional frequency reuse problem. It has been assumed that a Radio or a Optical communication



Latitude:126'38

MIN Radious of Cluster: 7.07 Km
Average Mobile Speed of Nodes: 6.67

Fig. 2. Geographical Simulation Results mapped on Cheju Island and Neighboring Seas

for interplatform link and it is another research area. Also a routing problem can be arisen while there are a lot of prepared routing protocol such as OLSR, TBRPF, DSDV, CGSR, WR, AODV, DSR, LMR, TORA, ABR, SSR, and ZRP.

Therefore we will concentrate on the multiple HAPs network. The first problem of this multiple HAPs network is a clustering of mobile ground nodes and finds an optimal location for multiple HAPs as a clusterhead or mobile MBS. We expect the final result looks like in figure 2 where we can see 50 MBSs work as clusterhead and the coverage of each MBS are defined by the population density.

For the environment of this multiple HAPs network, we have similar problems in wireless network listed below.

- Uncertainty of mobile ground node coordinates
- Link Error Rate, lower than satellite network
- Network Topology Variance, frequent
- Network Security

We can consider parameters below for network configuration.

- Total number of mobile ground node, network size N
- Network connectivity
- Topological rate of change
- Link capacity
- Fraction of unidirectional links
- Mobility of ground nodes
- Fraction and frequency of sleeping nodes

## IV. Clustering of Ground Nodes for MBS Placement

For multiple HAP network, mobile ground nodes are clustered into several clusters, and each HAP acts as MBS of a cluster or is regarded as clusterhead. Since the number of nodes in a cluster is a major parameter, another parameter of cluster coverage is a dependent variable. Each HAP has capability to adjust its coverage individually by adjusting its angle of elevation. These parameters can vary dynamically according to the mobility of ground nodes. We can assume the following scenarios of dynamic clustering.

- Initial clustering: The very first stage of network configuration. Almost a static clustering.
- Service oriented reclustering: New influx of mobile ground nodes to a specific cluster cause a overloaded router on a HAP and thus requires a reclustering. Maybe a new UAV can be added.
- Geographical reclustering: The mobility of ground nodes can cause more area to be covered by HAP based network. This situation causes reclustering.
- Airship backup reclustering: Failure of one or more UAV can cause a reclustering situation.
- Shrinking clustering: Decrement of the number of mobile ground nodes will cause a non-mandatory reclustering.

From the scenarios above, we assume a geographical reclustering situation in this paper. However all of the above scenarios require reclustering algorithm according to the geographical network coverage or mobile ground node distribution. In order to provide such an algorithm, we can assume the following requirements for network parameters.

1) An UAV as a HAP can equip MBS facilities.
2) An UAV can identify number of ground nodes served.
3) An UAV can identify the location of mobile ground nodes.
4) An UAV can identify the location of itself.
5) An UAV can vary the geographical network coverage by adjusting the angle of elevation.
6) An UAV can communicate with ground base stations.

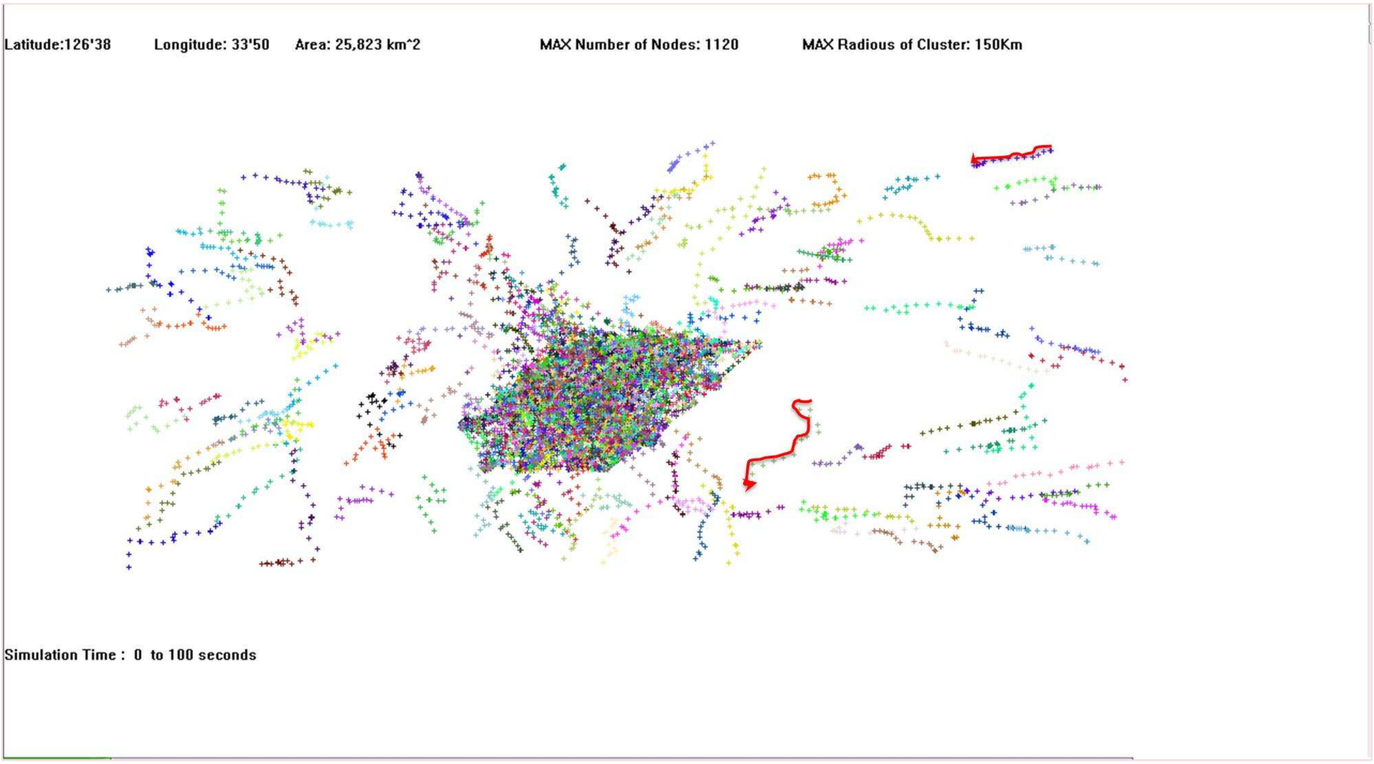
These assumptions can be realized with the help of aero engineering, electro engineering, antenna technology or other related modern technology. Under these assumptions, the following lists requirements for clustering algorithms of mobile ground nodes.

1) The sum of bandwidth requirement from mobile ground nodes in a cluster is equal to or smaller than the total bandwidth of an MBS for the cluster.
2) Each UAV can move in a limited speed. Thus the reclustering must consider the speed of UAVs.
3) Cluster algorithm requires realtimeness for continuous network service.

Here we can show a simple clustering algorithm based on K-mean clustering algorithm.

The exact location of each MBS for a cluster is a centroid of the each cluster. The centroid of a cluster is median value of geographical coordinates of mobile ground nodes in the cluster. Instead of mean value, we use median value in order to guarantee the efficiency of MBS coverage. Thus we can use this algorithm for MBS placement.

Even though we use K-mean algorithm, this algorithm can be replaced any of proper clustering algorithm. We experienced several clustering algorithms produce inclusive clusters. To resolve such problem, we need postprocessing of clusters that merges inclusive clusters to including cluster. We regard this problem as a future topic and will discuss basically in the conclusions and future research section.



Latitude:126'38
Longitude: 33'50
Area: 25,823 km^2
MAX Number of Nodes: 1120
MAX Radious of Cluster: 150Km
Simulation Time : 0 to 100 seconds

Fig. 3. Node Mobility Snapshot

**Algorithm 1** Clustering and MBS Placement

```
Require: B: Router Bandwidth Capacity on a HAP
    S: Total sum of required bandwidth by nodes in a cluster
    C: A set of coordinates of mobile ground nodes
    A: Total area size to be covered by network
    M: Maximum area can be covered by a HAP

Ensure: L: List of clusters
    P: List of cluster centroids

    SpB = S/B //Bandwidth requirement

    ApM = A/M //Geographical requirement

    Calculate the number of Cluster K = min(SpB,ApM)

    L = result of K-mean clustering algorithm with input C

    P = calculated centroid of each cluster.
```

The time complexity of algorithm 1 is $O(TN^2)$ where N is total number of mobile ground nodes and T is number of reclustering.

## V. Simulation of HAP MBS Placement

We do simulation experiment based on assumptions and algorithms for HAP based network. Our aim is to show simulation results geographically in order to identify clustering result and HAP placement result graphically. The simulation is done first by NS-2 with mobility models for nodes. With the NS-2 trail output, we parse them in order to identify node mobility in time and the parsed results are used by clustering algorithms. Finally a clustering results are visualized.

### *A. Simulation Environments and Parameters*

For the geographical environment for network simulation, we choose Cheju Island of the Republic of Korea and its neighboring seas. 1000 nodes are distributed according to population distribution on Cheju Island and several marine vehicles were also assumed. The reason why we choose this area is as follows.

- Two cities have denser population than other area.
- The other area has lower population.
- There is high mobility to or from two cities to other area.
- Almost all sort of mobility can be included. There are various type of mobility including human walk, ground vehicle, horse rider, and marine vehicle.
- There are frequent mobility between Cheju island and its two neighboring small islands which have lower population.
- Lots of travelers show very high mobility.

In addition we wanted to look at the phenomena that non-island areas are connected from island area by HAP MBS. The simulation parameters are as follows:

- 28,246 $Km^2$ coverage area
- Total number of mobile ground node is 1000
- Number of initial clusters is 50

- Number of average nodes in a cluster is 20
- Random Waypoint (RW) mobility model
- Speed of mobility is 4∼7 km/sec
- Node population is proportional to actual population density
- Simulation time up to 60 minutes
- Maximum 465Km for inter-hap links
- Maximum 150Km for cluster radius as specified by ITU [14]

Figure 3 shows a cumulated snapshot of mobile nodes trajectory for these simulation experiments.

### B. Simulation Results and Analysis

With this simulation parameters, simulation results are shown geographically in selected figures 4, 5, 6, 7, 8.

Each figures stands for the result of simulation from 15 minutes to 55 minutes after the start of simulation. In each figure, the radius of a cluster is magnified by the factor of 1.4 for visibility reason. The dots are mobile ground nodes while crosses are centroids of clusters and thus locations of HAP MBSs. Two cities with high population show a lot of clusters with small coverage. This is due to the restriction of network bandwidth provided by on HAP MBS. In order to guarantee minimum bandwidth for individual nodes, the maximum number of nodes per cluster is restricted since HAP MBS has limited bandwidth as a wireless router. The neighboring seas are covered by relatively larger clusters and smaller number of HAP MBS. The maximum number of nodes in a cluster is up to 47 while the minimum number is 2 for a cluster. The largest cluster has radius of 154Km in marine area while the smallest cluster has 6.5Km in city area. Note that 154Km of cluster radius slightly exceeds a maximum radius of HAP MBS coverage specified by ITU.

Even though some nodes look like multiple participant in a cluster, they are actually a member of specific single clusters. This sort of overlapping can be overcome by frequency allocation and reuse. Some clusters with dedicated MBSs look like an orphan. However, the presumably orphan MBSs are within 930Km of other connected HAP MBS, i.e. orphans are within the range of inter-hap links.

Some postprocessing algorithms required in order to merge or to split clusters with abnormal number of nodes. Clusters with larger number of nodes must be split and clusters with smaller number of nodes must be merged. The ultimate goal of post processing is to assign adequate number of nodes equally likely to clusters. We experienced the overloaded clusterhead (MBS) is usually a problem for network configuration. We will provide a simple postprocessing algorithm in section VI

We experienced less than 1 second for each clustering with usual Pentium based personal computers. We believe this guarantees realtimeness of our clustering algorithm.

## VI. Conclusion and Future Research

In this paper, we present a HAP MBS placement solution over multiple HAP based wireless network. Considering the number of ground nodes and area coverage, mobile ground nodes are clustered in order to prepare placement location. As a result, each HAP based MBS can be placed at geographically suitable location in order to serve as a BS of a cluster. We experiment these scenarios by simulation and the results are visualized in a specific area of Cheju Island.

However, we can find several problems regarding the clustering results. First, we must suppress of mobility of MBSs for stable network service. Even if we assumed mobility of HAP MBSs, high mobility of existing MBSs would cause instable network service.

Second, other than K-mean algorithm, more sophisticated algorithm must be introduced. We are now focusing on Expectation Maximization (EM) and BIRCH [11], [12] as a core algorithm for HAP MBS placement. For uncertain coordinates of highly mobile nodes we can adjust probabilities for such nodes to be members of a specific cluster with the speed of mobile node or so. Then this probability set will be directly applied to EM based clustering.

Third, the number of nodes per cluster must be distributed evenly for stable network bandwidth allocation. Since there are no clustering algorithms that calibrate the number of elements per cluster, a new clustering algorithm must be introduced. And we sometimes observe inclusive clusters and semi-inclusive (highly overlapped) clusters in simulation results. BIRCH has the abilities of splitting or merging clusters by use of CF tree. These capabilities can be a useful method to assign evenly distributed number of nodes to clusters.

These combination of clustering algorithms ultimately leads to a multiphase clustering algorithm. We are now considering the following process.

1) Preprocessing with static clustering algorithms such as K-mean.
2) Main clustering with dynamic clustering algorithms such as EM.
3) Postprocessing for split and merge of clusters with algorithms such as BIRCH.

We believe the outmost clustering algorithm would be BIRCH since it requires another clustering algorithm for core clustering features.

For postprocessing as mentioned in section IV, we have the following idea. We can merge a cluster into outer cluster when the cluster is inclusive under the condition that $|C_1 - C_3| + R_3 < R_1$ and $N_1 + N_3 < N$, where $C_i$ is a coordinate for cluster $i$, $R_i$ is a radius for cluster $i$, and $N_i$ is number of nodes in a cluster $i$. The first term stands for Cluster $C_3$ is totally inclusive in Cluster $C_1$ and the second term restricts merge if the total number of nodes in two clusters exceeds a desired number of nodes $N$ in a cluster.

Similarly we can merge semi-inclusive clusters where most part of a cluster, e.g. 75%, is covered by another cluster.

*Abstract*—**Flooding algorithms are widely used in ad-hoc sensor networks, especially as building blocks of more sophisticated routing protocols. A distributed percolation-driven energy efficient probabilistic flood routing algorithm is proposed, which provides large message delivery ratio with small number of sent messages, using neighborhood information only. The performance of the algorithm is analyzed and the theoretical results are verified through simulation examples.**

## I. Introduction

Wireless sensor networks are made of large number of inexpensive nodes with limited processing and communication capabilities, and have limited energy reserves. Such networks have been used in a wide range of applications with various goals, using different platforms and technology [1][2][3][4]. Independently of the nature of the application, however, certain middleware services are always present, one of them being routing. Limited resources on the sensor nodes require that routing protocols be simple, energy-conserving and robust.

Depending on the actual deployment scenario and available hardware, several ad-hoc routing algorithms have been proposed. Location-aware routing schemes, e.g. greedy perimeter stateless routing [5], location aided routing [6], distance routing effect algorithm [7] use position information of the nodes obtained from GPS or other localization services. Other data centric schemes do not use location information, e.g. directed diffusion [8], ad-hoc on-demand distance vector routing (AODV) [9], dynamic source routing [10], temporarily ordered routing [11], or zone routing [12], just to name a few. To allow sensor networks better cope with scaling, hierarchical protocols were designed, e.g. Low-Energy Adaptive Clustering Hierarchy (LEACH) [13] and Threshold sensitive Energy Efficient sensor Network protocol (TEEN) [14].

The simplest routing protocol is flooding [15], which is a useful simple (but inefficient) protocol in itself, and also is a building block for several more sophisticated algorithms, e.g. directed flood-routing [16], controlled flood routing [17], tiny ad hoc routing [18], or AODV [9], which is used in Zigbee's routing protocol [18].

The basic flooding protocol is the following:

- When a source node intends to send a message to all other nodes in the network, it broadcasts the message to its neighbors.
- When a node first receives a message it rebroadcasts the same message to its neighbors. All other copies of the same message received later will be discarded by the recipient node.

Flooding naturally can be used in its basic form for network-wide dissemination of information. In this context the important performance criteria of the algorithm are delivery ratio, latency, and the energy efficiency. Flooding is also used for route discovery [9]. Route discovery protocols find a route from a source node to a destination node in two phases. First the network is flooded by a discovery request message originated from the source, and then a reply message is sent back from the destination to the source node. In this way the network learns the path from the source to the destination and this route will be used in the subsequent communication sessions. In this context the quality – primarily the length – of the discovered route is an important performance criterion as well.

Apart from its simplicity the main advantage of the flood routing protocol lies in its robustness: the implicit redundancy built in the algorithm provides resistance against high degree of message loss and node failures as well. The drawback of the algorithm is the large number of packets transmitted in the network, referred to as broadcast storm: whether it is necessary or not, each node will retransmit each message. In a dense network the unnecessarily high number of messages can cause frequent collisions (and thus performance degradation) and it wastes network energy as well [19].

To reduce the number of routing messages, probabilistic variations of the flood routing were proposed. The main idea behind these algorithms is that a node randomly decides whether to forward a message or not. Several variants of random flood algorithms were proposed. According to the simplest protocol, a node will rebroadcast a message after its first reception with probability $p$ and discards it with probability $1-p$ (clearly, $p=1$ results in basic flooding). Test results verify what intuition suggests: higher $p$ values provide higher network coverage than small $p$ values. Moreover,

978-83-60810-14-9/08/$25.00 © 2008 IEEE

in sufficiently large and sufficiently dense random networks there is an interesting bimodal behavior of the algorithm: if $p > p_c$ , where the critical probability $p_c$ depends on the network topology, the message reaches practically all nodes in the network, otherwise only a small portion of the network receives the message. Thus the optimal choice clearly would be $p = p_c$ . Modified algorithms try to further increase the performance by various modifications: e.g. premature message death can be avoided by varying *p* as a function of hop-distance from the source: nodes close to the source rebroadcast messages with higher probability, while distant nodes use smaller *p*. A comprehensive study on random flooding algorithms can be found in [15]. The common problem with these algorithms is that the design parameters (probabilities) depend on actual network layout, no automatic or adaptive solution is known. Especially in a network with varying node density the probabilistic algorithms tuned to work reliably will be suboptimal.

More sophisticated adaptive schemes can successfully handle networks with varying properties as well. Location based algorithms use node positions to optimize retransmissions [20], graph-based algorithms utilize connectivity information up to 2-hop neighbors to construct a dominating set in a distributed way [21]. Other heuristic rules, e.g. message counters and neighbor coverage schemes were also proposed [19]. These schemes can adapt automatically to changing topology at the price of higher complexity.

Sensor networks are often modeled by the Poisson Boolean model. In this model nodes are scattered on the plane by a Poisson point process with constant density $\lambda$, and each node has a fixed communication radius $r$ (disc model). Two nodes can communicate with each other if their distance is less than $r$ . The Poisson point process applies reasonably well to controlled, but still random deployments. The simplistic disc model, however, is far from reality, where communication range is not circularly symmetric, but rather has an anisotropic shape. Speaking of connectivity, however, the disc model has an important property: it can be considered the worst case model, since other transmission models provide easier percolation under similar circumstances [11].

Percolation theory [22] has important impact on wireless communication networks. Results in continuum percolation theory show that if the density of transmitting stations (or alternatively, their communication power) in a Poisson Boolean network is greater than a critical value $\lambda_c$ then an unbounded connected component is formed with probability one (the network percolates) [23], [24]. On the other hand, if $\lambda < \lambda_c$ then all connected components are finite with probability one. Thus percolation is an important property of a network if long distance multi hop communication is required.

In this paper a new percolation-inspired solution will be proposed based on probabilistic flood routing algorithms. The new algorithm adaptively sets the rebroadcast probability based on the network topology, using locally available neighborhood information only. The proposed algorithm provides high performance with a low number of messages and can adapt its behavior dynamically to the network properties. The proposed algorithm is only marginally more complex than the basic flood routing thus it can be successfully used in applications with limited resources as well.

The rest of the paper is organized as follows. In Section II related works will be summarized. In Section III the proposed algorithm will be introduced. An important property of the algorithm will be proven based on percolation theory: every message broadcast in the network will reach infinite number of nodes almost surely. In practice this property ensures that the message reaches almost all of the nodes in a finite-sized network. The performance evaluation of the algorithm through simulation can be found in Section IV. Conclusions are drawn in Section V.

## II. Related Work

Results of percolation theory have been applied to wireless networks, forming the theory of Continuum Percolation [25]. More realistic network models, i.e. unreliable communication links and anisotropic radiation patterns were studied in [23]. An important result of [23] shows that the debatable disc model actually provides a conservative estimate of the network connectivity: percolation in networks with disc communication shapes is more difficult than in networks with any other convex communication shape with the same surface (“discs are hardest” conjecture). This property justifies the usage of the disc model when connectivity issues are studied.

Results from percolation theory have been infiltrating various recent sensor networking algorithms. As a practical application of this phenomenon, the distributed minimum-link-degree rule was proposed to counterbalance local spatial inhomogeneities in ad-hoc networks [24]. To provide network-wide connectivity, the transmission powers of the nodes are tuned so that each node has at least a minimum number of neighbors.

In [26] a distributed energy saving mechanism is used by switching the nodes in the network on and off, while providing percolation in the network. The simple rule for the algorithm is to keep the active time ratio of the nodes larger than $\lambda / \lambda_c$ . This algorithm does not scale well since each node in the network has to know the global parameter $\lambda$ . The idea was further elaborated in [27], where a practically useable distributed algorithm was proposed for the control of the active time ratio. In this algorithm only the local density, namely the number of neighbors is used. For a node with degree $k$ the active ratio $\eta_k$ is defined as follows:

$$\eta_k = \begin{cases} \dfrac{\varphi}{k} & k > \varphi \\ 1 & k \leq \varphi \end{cases} ,$$

where $\varphi$ is a density-independent design parameter. A similar idea will be used in the proposed flooding algorithm.

## III. Percolation-driven flooding

The idea behind the percolation-driven flood routing is the following: Use probabilistic flooding and set the retransmission probability adaptively at every node so that with high probability the message reaches almost all of the nodes in the network. The algorithm is the following:

1. The source node broadcasts the message with probability one.

2. After the first reception of a message node $n$ rebroadcasts it with probability $p_n$, and discards it with probability $1-p_n$. Copies of the same message received multiple times are discarded with probability one. Probability $p_n$ is defined as

$$p_n=\begin{cases}\frac{K_{\min}}{K_n} & K_n>K_{\min}\\ 1 & otherwise\end{cases} \qquad (1)$$

where $K_n$ is the degree of node $n$ (i.e. the number of neighbors of node $n$ ), and the $K_{\min}$ design parameter is the required minimum number of neighbors. Two nodes are neighbors if they can hear each other (i.e. a symmetric link exists between them).

The algorithm requires neighbor discovery to determine the number of neighbors. Each node can gather this local information by transmitting and receiving HELLO messages. In practical situations parameter $K_{\min}$ is chosen around 7, as will be justified by the simulation examples.

*Theorem* 1: If in the infinite random network, generated by a Poisson Boolean process with density $\lambda$ and communication radius r, there exists design parameter $K_{\min}<\infty$ independent of $\lambda$, such that when node n with degree $K_n$ transmits a message with probability according to (1), then each message reaches infinite number of nodes with probability one.

Proof: Let us denote the graph representing the network by $G(\lambda,r,1)$, where $\lambda$ is the density, r is the communication radius, and the third parameter is a probabilistic value used in the generator process (used and discussed later) and is simply set to one at the moment. Using scaling, we define another process with density $\lambda'=\lambda r^2$ and communication radius 1. This process yields the same graph $G(\lambda',1,1)$. Now let us use the following Theorem 2 [27]:

*Theorem* 2: Given $G(\lambda',1,1)$ with $\lambda'>\lambda'_c$, there exists $2<\phi<\infty$, independent of $\lambda$, such that when each node with degree k is active with probability

$$p(k)=\begin{cases}\frac{\phi}{k} & k>\phi\\ 1 & k\leq\phi\end{cases},$$

then $G(\lambda',1,p(.))$ is percolated. The proof of Theorem 2 can be found in [27].

If in the network we decide *before* a particular message is broadcasted which nodes will retransmit the message (when they receive it) by activating/deactivating nodes with probability (1) we get $G(\lambda',1,p(.))$. In this way we construct a virtual network for each message and we can apply Theorem 2 to it. Thus there exist $K_{\min}=\phi<\infty$ so that $G$ percolates. From this it follows that the message will reach infinite number of nodes [22]. ■

In real-world finite-size networks Theorem 1 means that with an appropriate choice of $K_{\min}$ each message reaches practically all nodes in the network. Further properties of the algorithm will be analyzed through simulation examples.

## IV. Performance Evaluation

In this section the performance of the algorithm will be evaluated through simulation results. First the performance metrics and the network/communication models will be introduced, followed by the simulation environment and the simulation scenarios. Finally, the results of the simulations will be presented to illustrate the behavior of the proposed algorithm.

### A. Performance metrics

The main performance criteria of broadcast algorithms are the message delivery ratio and the number of sent messages. If the number of nodes in the network is N and the number of nodes receiving the message is $N_{rec}$ then the coverage ratio is defined as $C_r=\frac{N_{rec}}{N}$.

Clearly, $C_r$ close to 1 is required for a good quality of service.

Another quality metric is the total number of sent packets M while a message is propagated in the network. Trivially, for basic flood routing $M=N$, if $C_r$ = 1. We expect lower number of messages and still high delivery ratio for a good performance algorithm. For easier comparison, we will use the normalized number of messages defined as

$$M_{norm}=\frac{M}{N}.$$

If flooding is used for route discovery, an important performance metric is the length $L$ of the discovered route.

Other possible metrics are message delay/latency, length of flood period, and number of collisions. The actual low level details, e.g. implementation, hardware and MAC layer properties are not investigated in detail in this paper, but their effect is studied through high level parameters they effect, i.e. $C_r$, $M_{norm}$, and $L$ will be studied.

### B. Network model

To model random deployment of nodes or possibly mobile networks, in the simulations nodes are placed at random, according to a uniform distribution on a two-dimensional area. Finite communication distances are represented by the disc model, where a communication link is assumed between two nodes when they are less than the communication radius apart. According to the results published in [23], this – otherwise rather simple and idealistic – model can be considered a worst case model.

Our communication channel model does not deal with specific details of the physical layer or the MAC-layer; rather we use a probabilistic model: a message can reach a neighbor within the communication radius with probability $p_{rec}<1$. This high-level model represents message losses due to collision, fading, or other disturbances as well. The model does not distinguish between individual phenomena but rather incorporates the different sources in one parameter, thus some aspects of reality (e.g. inter-message dependencies) are neglected, but the model is faithful enough to provide useful and easy means for testing.

### *C. Simulation environment*

To perform high speed simulation, a simulator was written in C to validate the efficiency of the proposed algorithm. The program places nodes randomly according to the different test scenarios considered. The number of nodes *N*, the communication radius *r*, and $K_{\min}$ are input parameters.

In each simulation, a new placement is generated, and a source node starts transmission. The simulator returns the size of connected component containing the source node, the number of nodes receiving the packet, and the total number of messages. Optionally, the software can visualize the topology of the network, the active data paths, and the nodes' reception status.

### *D. Test scenarios*

In the test we used 2 different scenarios to model sensor network setups. The first scenario is a random uniform distribution (with constant density), while in the second scenario we used three regions; in each region nodes were placed with uniform random distribution, but with different densities. Typical examples for the test networks can be seen in Fig. 1 and Fig. 2.

### *E. Test results*

To test coverage ratio $C_r$ and the number of messages $M$ we placed 3000 nodes in a square-shaped area, as shown in Fig. 1. We varied the communication radius to provide different network densities: the average number of neighbors *K* was set to 10, 30, and 100. The $K_{\min}$ value varied from 1 to 20 in 0.25 steps. We run the simulation 100 times for each communication radius, $K_{\min}$, and $p_{rec}$ values, thus each point in the graph is the average of 100 experiments.

Fig. 3 shows coverage vs. $K_{\min}$, while $p_{rec}$ was set to constant 1. The graphs for different network densities are similar: When $K_{\min}$ is low ( $K_{\min}<3$ ), the message delivery ratio is very low. If $K_{\min}$ is increased, the coverage is increasing very quickly, the critical value being around $K_{\min}\approx 4.5$ . Coverage reaches 90% at $K_{\min}\approx 5$ . If $K_{\min}>7$ , practically all nodes in the network receive the message. Fig. 3 shows that percolation driven flood can indeed be used in networks with different densities: $K_{\min}$ is independent of the actual network density.

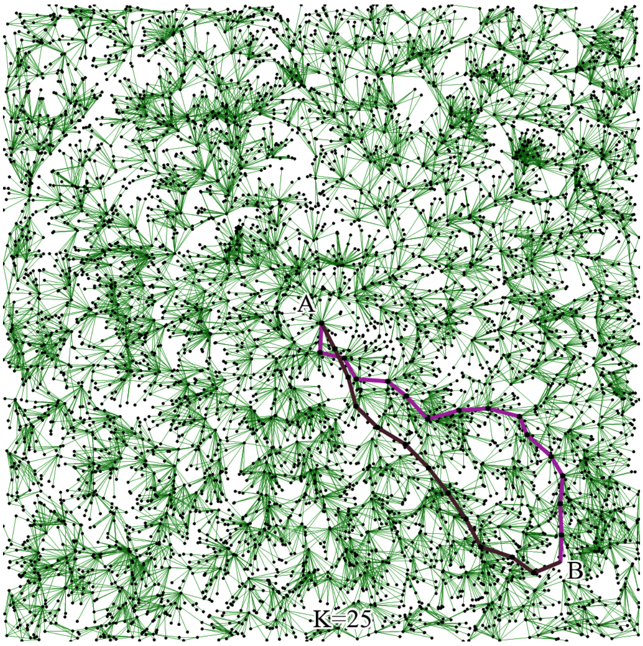

Figure 1: Uniform random distribution scenario with 3000 nodes. The average number of neighbors is 25. Black and purple lines show examples for the message paths between nodes A and B, discovered by flood and percolation driven flood, respectively.

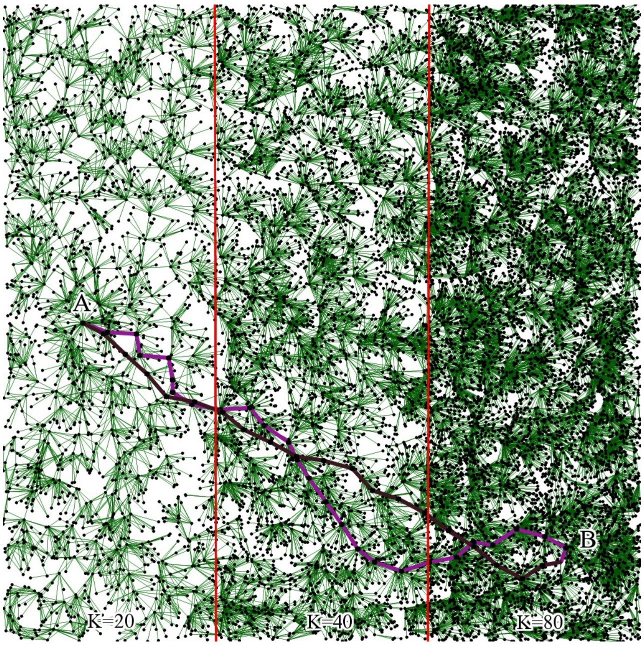

Figure 2: The 3-density scenario. The average numbers of neighbors in the regions from left to right are 20, 40, and 80. Black and purple lines show examples for the message paths between nodes A and B, discovered by flood and percolation driven flood, respectively.

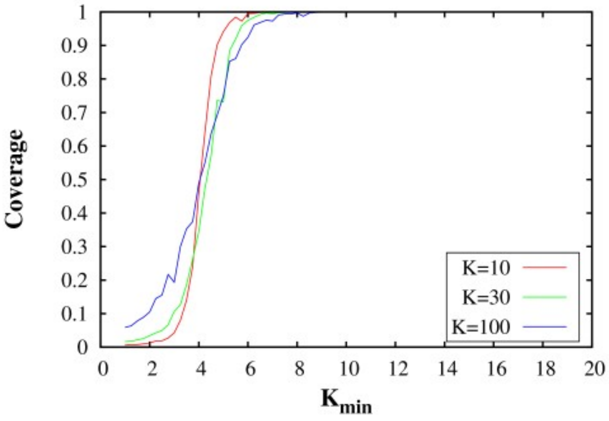

Figure 3: Coverage vs. $K_{min}$ for different network densities in the uniform distribution scenario (constant network density). $P_{rec}$ = 1.

In Fig. 4 the normalized number of sent messages $M_{norm}$ is shown vs. $K_{\min}$, for the previous experiments. In case of the conventional flood routing $M_{norm}=1$, because all nodes relay the received message. As Fig. 3 shows, $K_{\min}>7$ gives almost perfect delivery ratio. Around this value $K_{\min}\approx 7$ the total number of messages is greatly decreased, as shown in Fig. 4. Depending on the node density, in the tests the total number of messages were reduced by 30..95%, higher reduction rates belonging to higher densities.

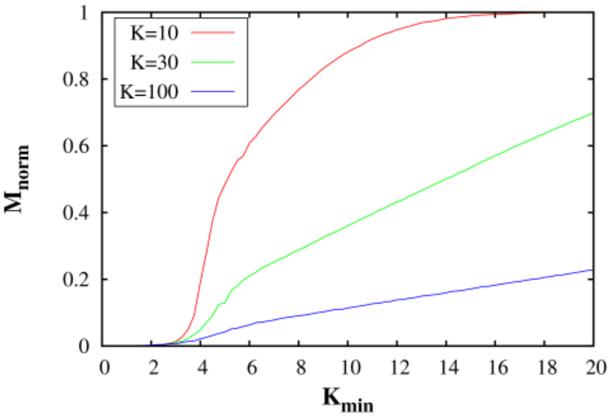

Figure 4: Total number of messages vs. Kmin for different network densities in the uniform distribution scenario (constant network density). Prec = 1.

Clearly, in networks, where the average node degree $K$ is only slightly higher than $K_{\min}$ the number of messages can be decreased only moderately, while in dense networks a much lower number of messages is enough to provide good delivery ratio, as shown in Fig. 4. According to Fig. 3 and Fig. 4, in dense networks the percolation driven flood algorithm can effectively reduce the number of message while maintaining good coverage.

Fig. 5 shows the effect of unreliable communication links. In the experiment a constant density (K=30) was used, while the $p_{rec}$ reception probability was varied between 0.3 and 1. The figure shows that the algorithm can provide high coverage even in the presence of bad quality communication links, but as intuitively expected, higher $K_{\min}$ is necessary as the communication channel degrades. Fig. 6 shows the associated number of messages for the unreliable communication experiment.

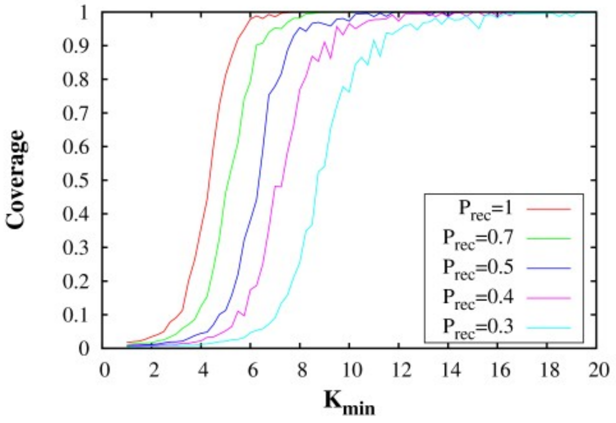

Figure 5: Coverage vs. Kmin for different prec in the uniform distribution scenario (constant network density). K = 30

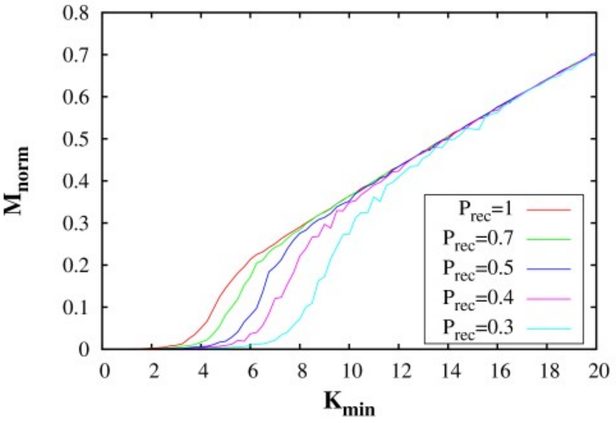

Figure 6: Number of total messages vs. for different prec in the uniform distribution scenario (constant network density). K = 30.

Percolation driven flood routing algorithm is capable of handling varying network densities. To test this property we used the scenario illustrated in Fig. 2, where three areas with different densities are present. Clearly, a constant retransmission probability would either be suboptimal (set to provide sufficient coverage in the less dense area as well) or would not provide good coverage in the sparse regions of the network. Fig. 7. illustrates the effectiveness of the percolation driven flood algorithm, showing the coverage vs. $K_{\min}$ when the densities of regions from left to right were set to [10, 20, 40], [30, 60, 120], and [100, 200, 400]; and $p_{rec}=1$. The behavior is quite similar to that of the first scenario (constant density): percolation happens around the same $K_{\min}\approx 5$, and practically full coverage can be provided if $K_{\min}>7$. The associated total numbers of messages are shown in Fig. 8, where the gain with respect to the basic flooding algorithm is apparent.

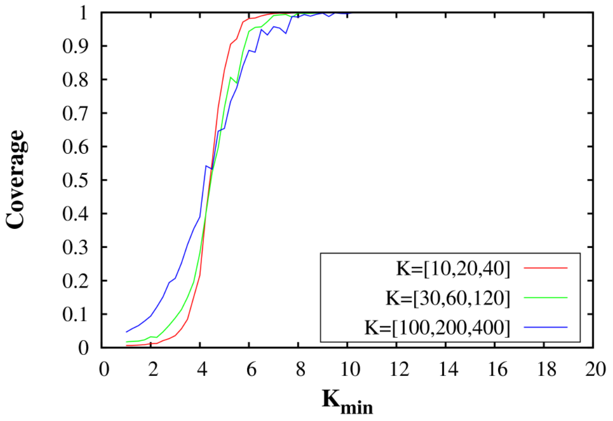

Figure 7: Coverage vs. Kmin for different network densities in the varying network density scenario. Prec = 1.

The length $L$ of the discovered route is important when flooding is used for route discovery. To test the properties of percolation driven flooding in this respect we measured hop-distances discovered by flooding and percolation driven flooding, for different $K_{\min}$ values. In the tests the uniform distribution (constant density) scenario was used with $K=35$ and $p_{rec}=1$ . The source node was placed to the center of the field and hop distances to all other nodes were measured. The histogram created from averaging 100 independent experiments is shown in Fig. 9.

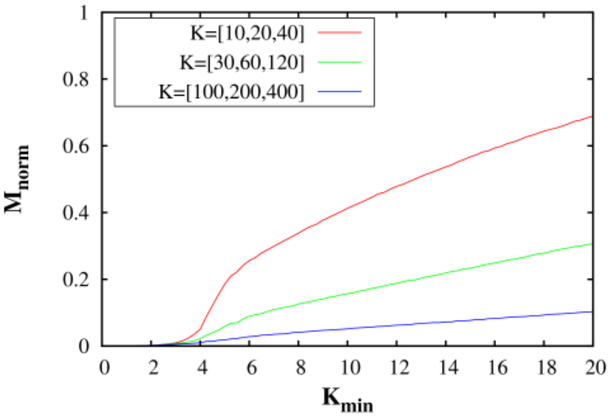

Figure 8: Number of total messages vs. Kmin for different network densities in the varying network density scenario. Prec = 1

The distribution is linear for small hop distances. The explanation is shown in Fig. 10 for the ideal case: messages are propagated in belt-shaped increments. The areas of the subsequent belts increase linearly, thus the number of nodes in each belt is linearly increasing. If the node density is smaller, the number of nodes in each belt is smaller, thus the slope of the histogram will be smaller. According to Fig. 9, smaller $K_{\min}$ also causes decrease in the slope: e.g. for $K_{\min}=9$ , the slope is 40% smaller than in the basic flooding case. This means that the detected route is 40% longer than that of the basic flooding.

The declining part at higher hop distances is due to the finite size of the network: the messages reach the network perimeter and eventually die. The tail of the distribution shows the maximum hop distance from the source, which is in the square setup ideally $\sqrt{2}$ times the hop distance connected to the maximum of the histogram.

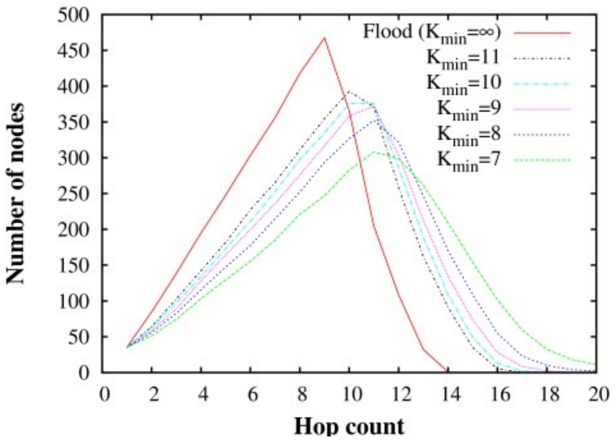

Figure 9: Distribution of the hop counts in the uniform distribution network for different Kmin values. Prec = 1.

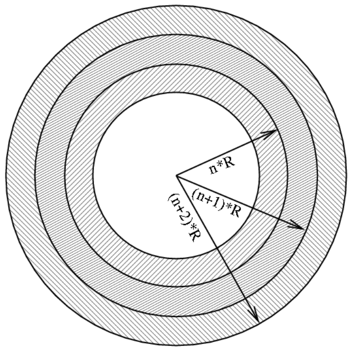

Figure 10: Ideal propagation of a message in a dense network.

The effect of unreliable links is shown in Fig. 11. The histogram shows the average of 100 experiments conducted in the uniform test scenario with K=35, and $p_{rec}=0.4..1$ . As intuitively expected, unreliable links cause smaller slope, i.e. higher hop distances. E.g., link quality $P_{rec}=0.7$ results in the increase of hop distance by 18%, while for the rather unreliable link quality $P_{rec}=0.4$ the increase was as high as 63%.

As simulation examples show, percolation-driven flooding results in considerably higher hop distances than basic flood routing when small $K_{\min}$ parameters are used. Naturally, low link quality also causes larger hop distances. This effect may be an undesired side effect in route discovery protocols, thus in these applications basic flooding may be more advantageous.

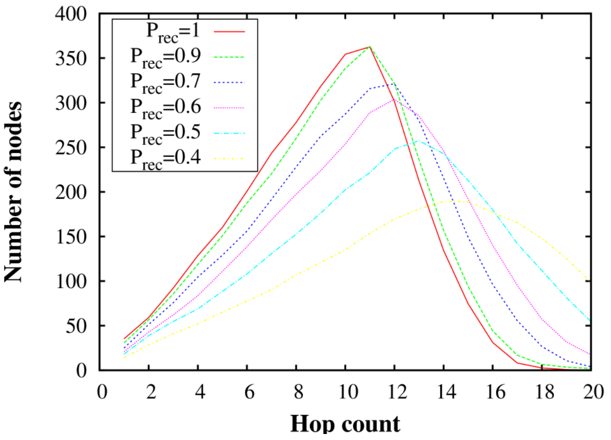

Figure 11: Distribution of the hop counts in the uniform distribution network for different $P_{rec}$ values. $K_{min}$ = 9

## V. Conclusion

A percolation driven flood routing algorithm was proposed, which uses only locally available neighborhood information to reduce broadcast storm. The algorithm is able to massively reduce the number of messages in the network and maintaining high delivery ratio at the same time. Theoretical results prove the usefulness of the algorithm: it is able to provide high coverage, if the network density is high enough.

Simulation tests were performed to validate the performance of the algorithm. The proposed algorithm reduced the total number of messages in the network by 30-95%, depending on the network density, while the coverage was almost 100%, with appropriate choice of $K_{\text{min}}$ $(K_{\text{min}}>7)$. The percolation driven flood algorithm is adaptive to changing node density thus provides high coverage with low number of messages in all scenarios. The algorithm is robust in the presence of unreliable links as well.

According to test result, the percolation-driven flood routing algorithm results considerably (even 50%) longer hop-distances when used for route discovery purposes.

The overhead of the algorithm is very low since only the number of neighbors must be known by each node. This information can be gained by simple neighborhood discovery protocols, e.g. sending and receiving HELLO messages.

For route discovery purposes the application of the traditional flooding is more advantageous, if the side effect of the longer routes is undesirable. On the other hand, the proposed algorithm is a superior and robust alternative to traditional flooding algorithm in dense networks for message dissemination purposes.

# Workshop on Computational Optimization

MANY real world problems arising in engineering, economics, medicine and other domains can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints which ask for adequate computational methods.

The aim of this workshop is to stimulate the communication between researchers working on different fields of optimization and practitioners which need reliable and efficient computational optimization methods.

We invite original contributions related with both theoretical and practical aspects of optimization methods.

The list of topics includes, but is not limited to:

- unconstrained and constrained optimization
- combinatorial optimization
- global optimization
- multiobjective and multimodal optimization
- dynamic and noisy optimization
- large scale optimization
- parallel and distributed approaches in optimization
- random search algorithms, simulated annealing, tabu search and other derivative free optimization methods
- interval methods
- nature inspired optimization methods (evolutionary algorithms, ant colony optimization, particle swarm optimization, immune artificial systems etc)
- hybrid optimization algorithms involving natural computing techniques and other global and local optimization methods
- memetic algorithms
- optimization methods for learning processes and data mining
- computational optimization methods in statistics, econometrics, finance, physics, medicine, biology etc.

***Abstract*—The protein folding problem is a fundamental problem in computational molecular biology and biochemical physics. The high resolution 3D structure of a protein is the key to the understanding and manipulating of its biochemical and cellular functions. All information necessary to fold a protein to its native structure is contained in its amino-acid sequence. Even under simplified models, the problem is NP-hard and the standard computational approach are not powerful enough to search for the correct structure in the huge conformation space. Due to the complexity of the protein folding problem simplified models such as hydrophobic-polar (HP) model have become one of the major tools for studying protein structure. Various optimization methods have been applied on folding problem including Monte Carlo methods, evolutionary algorithm, ant colony optimization algorithm. In this work we develop an ant algorithm for 3D HP protein folding problem. It is based on very simple design choices in particular with respect to the solution components reinforced in the pheromone matrix. The achieved results are compared favorably with specialized state-of-the-art methods for this problem. Our empirical results indicate that our rather simple ant algorithm outperforms the existing results for standard benchmark instances from the literature. Furthermore, we compare our folding results with proteins with known folding.**

***Index Terms*—Ant Colony Optimization, metaheuristics, hydrophobic-polar model, protein folding**

## I. Introduction

THE number of amino acids and their sequence give a protein its individual characteristics. The number of amino acids in each protein ranges approximately between 20 and 40000, although most proteins are around hundred amino acids in length. Each protein's sequence of amino acids determines how it folds into a unique three dimensional structure that is its minimum energy state. Knowledge of 3D structure of proteins is crucial to pharmacology and medical sciences for the following important reasons. Most drugs work by attaching themselves to a protein so that they can either stabilize the normally folded structure or disrupt the folding pathway, which leads to a harmful protein. Thus, knowing exact 3D shapes will help to design drugs.

Determining the functionality of a protein molecule from amino acid sequence remains a central problem in computational biology, molecular biology, biochemistry, and physics. A system of differential equations is used to describe the forces, which affect the folding. It is very complicate and difficult to be solved. Even the experimental determination of these conformations is often difficult and time consuming. It is common practice to use models that simplify the search space of possible conformation. The aim is to find a conformation, which is close to the real one and than it to be specify using system of differential equations. So, as closer is the conformation, as less complex is the system of differential equations. Thus the computational time decreases. These models try to generally reflect different global characteristics of protein structures. In the hydrophobic-polar (HP) model [4] the primary amino acid sequence of a protein (which can be represented as a string over twenty-letter alphabet) is abstracted to a sequence of hydrophobic (H) and polar (P) residues that is represented as a string over the letter H and P. It describes the proteins based on the fact that hydrophobic amino acids tend to be less exposed to the aqueous solvent than the polar ones, thus resulting in the formation of a hydrophobic core in the spatial structure. In the model, the amino acid sequence is abstracted to a binary sequence of monomers that are either hydrophobic or polar. The structure is a chain whose monomers are on the vertices's of a three dimensional cubic lattice. The free energy of a conformation is defined as the negative number of non-consecutive hydrophobic-hydrophobic contacts. A contact is defined as two non-consecutive monomers in the chain occupying adjacent sites in the lattice. In spite of its apparent simplicity, finding optimal structures of the HP model on a cubic lattice is NP-complete problem [2].

Ant Colony Optimization (ACO) is a population-based stochastic search method for solving a wide range of combinatorial optimization problems. ACO is based on the concept of indirect communication between members of a population through interaction with the environment. Ants indirectly communicate with each other by depositing pheromone trails on the ground and thereby influencing the decision processes of other ants. From the computational point of view, ACO is an iterative construction search method in which a population of simple agents (ants) repeatedly constructs candidate solutions to a given problem. This construction process is probabilistically guided by heuristic information on the given problem instances as well as by a shared memory containing experience gathered by the ants in previous iterations.

This work is an investigation of the HP model in a three dimensional cubic lattice using an ACO as a tool to find the optimal conformation for a given sequence. The achieved results are evaluated and compared with other metaheuristic methods using 10 sequences of 48 monomers from the literature and with real proteins with known folding.

The paper is organized as follows: the problem is described in section 2. The ACO algorithm is explained

978-83-60810-14-9/08/$25.00 © 2008 IEEE

in section 3. The achieved results are discussed in section 4. The paper ends with a summary of the conclusions.

## II. The Protein Folding Problem

Efforts to solve the protein folding problem have traditionally been rooted in two schools of thought. One is based on the principles of physics: that is, the thermodynamic hypothesis, according to which the native structure of the protein corresponds to the global minimum of its free energy. The other school of thought is based on the principles of evolution. Thus methods have been developed to map the sequence of one protein (target) to the structure of another protein (template), to model the overall fold of the target based on that of the template and to infer how the target structure will be changed, related to the template, as a result of substitutions [1].

Accordingly methods for protein-structure prediction has been divided into two classes: de novo modeling and comparative modeling. The de novo approaches can be further subdivided, those based exclusively on the physics of the interactions within the polypeptide chain and between the polypeptide and solvent, using heuristic methods [9], [10], and knowledge-based methods that utilize statistical potential based on the analysis of recurrent patterns in known protein structures and sequences. The comparative modeling models structure by copying the coordinates of the templates in the aligned core regions. The variable regions are modeled by taking fragments with similar sequences from a database [1].

The processes involving in folding of proteins are very complex and only partially understood, thus the simplified models like Dill's HP model have become one of the major tools for studying proteins [4]. The HP model is based on the observation that hydrophobic interconnection is the driving force for protein folding and the hydrophobicity of amino acids is the main force for development of native conformation of small globular proteins. In the HP model, the primary amino acid sequence of a protein is abstracted to a sequence of hydrophobic (H) and polar (P) residues, amino acid components. The protein conformations of this sequence are restricted to self-avoiding paths on 3 dimensional sequence lattice. One of the most common approaches to protein structure prediction is based on the thermodynamic hypothesis which states that the native state of the protein is the one with lowest Gibbs free energy. In the HP model, the energy of a conformation is defined as a number of topological contacts between hydrophobic amino acid that are not neighbors in the given sequence. More specifically a conformation $c$ with exactly $n$ such H-H contacts has free energy $E(c) = n.(-1)$. The 3D HP protein folding problem can be formally defined as follows. Given an amino acid sequence $s = s_1 s_2 \dots s_n$, find an energy minimizing conformation of $s$, i.e. find $c^s \in C(s)$ such that $E^s = E(c^s) = \min_{c \in C(s)} E(c)$, where $C(s)$ is the set of all valid conformations for s. It was proved that this problem is NP-hard [2].

A number of well-known heuristic optimization methods have been applied to the 3D protein folding problem including Evolutionary Algorithm (EA) [9], Monte Carlo (MC) algorithm [10] and Ant Colony Optimization (ACO) algorithm [7]. An early application of EA to protein structure prediction was presented by Unger and Moult [11]. Their EA incorporates characteristics of Monte Carlo methods. Currently among the best known algorithms for the HP protein folding problem is Pruned-Enriched Rosenblum Method (PERM) [8]. Among these methods are the Hydrophobic Zipper (HZ) method [5] and the Constraint-based Hydrophobic Core Construction Method (CHCCM) [12]. The Core-direct chain Growth method (CG) [3] biases construction towards finding a good hydrophobic core by using a specifically designed heuristic function.

## III. ACO Algorithm for Protein Folding Problem

Real ants foraging for food lay down quantities of pheromone (chemical cues) marking the path that they follow. An isolated ant moves essentially at random but an ant encountering a previously laid pheromone will detect it and decide to follow it with high probability and therefore reinforce it with a future quantity of pheromone. The repetition of the above mechanism represents the auto-catalytic behavior of real ant colony where the more the ants follow a trail, the more attractive that trail becomes.

The ACO algorithm uses a colony of artificial ants that behave as co-operative agents in a mathematical space where they are allowed to search and reinforce path ways (solutions) in order to find the optimal ones. The problem is represented by graph and the ants walk on the graph to construct solutions. After initialization of the pheromone trails, ants construct feasible solutions and the pheromone trails are updated. At each step ants compute a set of feasible moves and select the best one (according to some probabilistic rules) to carry out the rest of the tour. The transition probability is based on the heuristic information and pheromone trail level of the move. The higher the value of the pheromone and the heuristic information, the more profitable is to select this move and resume the search. In the beginning, the initial pheromone level is set to a small positive constant value $\tau_0$ and then ants update this value after completing the construction stage. ACO algorithms adopt different criteria to update the pheromone level. In our implementation Ant Colony System (ACS) approach is used [6]. In ACS the pheromone updating consists of two stages: local update and global update. While ants build their solutions, at the same time they locally update the pheromone level of the visited paths by applying the local update rule as follows:

$$\tau_{ij} \leftarrow (1-\rho)\tau_{ij} + \rho\tau_0 \tag{1}$$

Where $\tau_{ij}$ is an amount of the pheromone on the arc $(i, j)$ of the 3D cube lattice, $\rho$ is a persistence of the trail and the term $(1-\rho)$ can be interpreted as trail evaporation. The aim of the local update rule is to make better use of the pheromone information by dynamically changing the desirability of edges. Using this rule, ants will search in a wide neighborhood of the best previous solution. As is shown in the formula, the

pheromone level on the paths is highly related to the value of evaporation parameter $\rho$. The pheromone level will be reduced and this will reduce the chance that the other ants will select the same solution and consequently the search will be more diversified. When all ants have completed their solutions, the pheromone level is updated by applying the global updating rule only on the paths that belong to the best solution since the beginning of the trials as follows:

$$\tau_{ij} \leftarrow (1-\rho)\tau_{ij} + \Delta\tau_{ij}, \tag{2}$$

$$\text{where } \Delta\tau_{ij} = \begin{cases} -E_{gb} & \text{if } (i,j) \in \text{best solution} \\ 0 & otherwise \end{cases}$$

The $E_{gb}$ is the free energy of the best folding. This global updating rule is intended to provide a greater amount of pheromone on the paths of the best solution, thus intensify the search around this solution.

There are six possible positions on the 3D lattice for every amino acid. They are the neighbor positions of the precedence amino acid. Since conformations are rotationally invariant, the position of the first two amino acids can be fixed without loss of generality. During the construction phase, ants fold a protein from the left end of the sequence adding one amino acid at a time based on the two sources of information: pheromone matrix value, which represents previous search experience, and heuristic information. The transition probability to select the position of the next amino acid is given as:

$$P_{ij} = \frac{\tau_{ij}^{\alpha}\eta_{ij}^{\beta}}{\sum_{k\in Unused} \tau_{ik}^{\alpha}\eta_{ik}^{\beta}} \tag{3}$$

Where $\tau_{ij}$ is the intensity of the pheromone deposited by each ant on the path $(i, j)$, $\alpha$ is the intensity control parameter, $\eta_{ij}$ is the heuristic information equal to the number of new H-H contacts if the position $j$ is chosen, $\beta$ is the heuristic parameter. Thus the higher the value of $\tau_{ij}$ and $\eta_{ij}$, the more profitable is to put the next amino acid on the position $j$. When the next amino acid is polar, the probability is $P_{ij} = 0$. In this case the position is chosen randomly between allowed positions. When the set of allowed positions is empty, the ant does some steps back and after that it continues construction of the solution. On a Fig. 1 is the ACO algorithm.

## IV. EXPERIMENTAL RESULTS

Ten standard benchmark instances of length 48 for 3D HP protein folding shown in Table I have been widely used in the literature [3], [7], [9]–[11]. Experiments on these standard benchmark instances were conducted by performing a number of independent runs for each problem instance, 20 runs. The following parameter settings are used for all experiment as: $\alpha = \beta = 1$, $\rho = 0.5$. Furthermore, all pheromone values were initialized to $\tau_0 = 0.5$ and a population of 5 ants were used. The algorithm was terminated after 200 iterations. All experiments were performed on IBM ThinkPad Centrino 1.8 GHz CPU, 512 MB RAM running SuSe Linux.

In Table II the achieved results by various heuristic algorithms are compared. For every of the benchmark instances the best found result by various methods is reported.

We compared the solution quality obtained by: hydrophobic zipper (HZ) algorithm [5], the constrain-based hydrophobic core construction (CHCC) method [13], the core-directed chain growth (CG) algorithm [3], the contact interactions (CI) algorithm [11], the pruned-enriched Rosenbluth method (PERM) [7], the ACO algorithm of Hoos (ACO) [10] and the ACS approach presented in this paper. For ACS the best found result and the average result over 20 runs are reported. In the majority of the cases our average results are better

| 9 | 31 | 34 | 33 | 32 | 34 | 34 | 46 | 34.44 |
| 10 | 33 | 33 | 33 | 32 | 33 | 33 | 46 | 36.45 |

than the best found results by other methods. And for all of the cases our best result is better than the best result of other methods. In ACO a local search procedure is used to improve the results. ACS approach is used without local search procedure. The main differences between ACO and ACS implementations are the location of the polar amino acids, the construction of the heuristic information and the pheromone updating. In ACO the authors put the polar amino acids on same direction as precedence amino acid. In our ACS we put the polar amino acids in random way, thus we give to the ants more possibilities in a search process. The main disadvantage of heuristic methods, as it is mentioned by other authors, is that they achieve good folding for short proteins only. For illustration, we compare two real proteins with known folding and the folding achieved by our ACS algorithm, which outperforms others on benchmark tests. Like test problems we choose Hepsidin and c-src Tyrosine Kinase Sh3 Domain (SrcSH3).

The Hepsidin consists of 21 amino acids: GCRFCCNCCP-NMSGCGVCCRP. His folding comprises two crossed sheets and unstructured part between them (see Fig. 2).

The HP representation of the Hepsidin is: HPPHPPPPPH-PHPHPHHPPPH. By our ACS algorithm we achieve the 3D folding represented on Fig. 3. The nodes represent amino acids and the lines represent their succession. We observe two tense, orthogonally situated parts. One of them consists of 3 amino acids and other consists of 4 amino acids. Between them we observe unstructured part. Thus we can conclude that there is high similarity between the real Hepsidin folding and this obtained by our algorithm.

The SrcSH3 protein consists of 62 amino acids. It folding comprise two long parallel situated sheets like a hairpin inside the protein and short sheets at the beginning and at the end of the protein, which are parallel each other and orthogonal to the hairpin, see Fig. 4.

By our ACS algorithm we achieve a folding represented on Fig. 5. The achieved H-H contacts are 19. We observe that there is not similarity between real folding and this achieved by our algorithm. Thus we prove the conclusion of other works [10], that heuristic methods are good for folding short proteins only. Therefore we decide to cut the HP chain of the SrcSH3 protein to short parts consisting of about 10-11 amino acids. We apply our ACS algorithm on every short part and at the end we assemble the folded parts to fold entire protein, see Fig. 6. The achieved H-H contacts are 20. We observe two tense long parallel parts like hairpin. One of them consists of 8 and other 7 amino acids. At one of the ends we observe short tense part orthogonal to the hairpin. Other protein parts are unstructured. Thus we can conclude that there is high similarity with real folding of this protein.

## V. Conclusion

Ant Colony System approach can be successfully applied to the 3D protein folding problem. Our algorithm outperforms the weel known from the literature methods. We have shown that the components of the algorithm contribute to its performance. In particular, the performance is affected by the heuristic function and selectivity of pheromone updating. The folding achieved by our algorithm is very similar to the real protein folding when it is applied on short proteins. When the protein is long, first we cut it on short parts, then we apply the algorithm on every one of the parts separately, finally we assemble the protein parts. Thus the achieved folding has high similarity to the real one. The obtained results are encouraging and the ability of the developed algorithm to generate rapidly high-quality solutions can be seen. In the future we will develope and improve the folding algorithm. The aim is to achieve more realistic folding.

***Abstract*—Recently it was produced a backtrack technique for the efficient approximation of a time series' future optima. Such an estimation is succeeded based on a selection of sequenced points produced from the repetitive process of the continuous optima finding. Additionally, it is shown that if any time series is treated as an objective function subject to the factors affecting its future values, the use of any optimization technique finally points local optimum and therefore enables accurate prediction making. In this paper the backtrack technique is compiled with a steepest descent methodology towards optimization.**

## I. Introduction

PREDICTING future was always a rather challenging task with levels of attractiveness in the case of financial issues. Stock prices prediction, regardless its attractiveness is a very difficult task [1]. The introduction and use of time series provided the task of prediction with data history, decreasing the level of arbitrariness when executing.

Many empirical studies throuhgout literature have discussed the predictability of financial time series in respect woth the data history. In finance the daily stock prices comprise a time series, but also in meteorology, daily maximum or minimum temperatures may report one, too. Agriculture, physics, or geology, as most scientific fields interested in reporting data based on time observations, tend to produce time series reports.

Apart from the data history itself, time series has promoted into a major forecasting tool, based on statistical methodologies that use historical data to predict not future points, but the future prices, of any time series regardless their data content.

However, in the case of financial time series it is of great importance to clarify that the average investor would rather be informed about the time that the lowest and highest values will occur than the next day's– -probably ordinary—value. In mathematical means this could be translated as the time series' local minimum and maximum, respectively. The lack of applications concentrating on when the maximum or minimum would appear regardless the next point's value, led us to the obvious: *Since all known forecasting methodologies are price-oriented, it is essential to focus on a point-oriented one in order to forecast not the value of the time series, but the time that its optima will occur*.

Time series is considered as a sequence of data points arranged according to time. Let $t$ be the time intervals of time $T$; thus, the time series $Y$ is given by

$$Y = Y_t : t \in T. \tag{1}$$

On the other hand, the phenomenon represented by a time series may be also treated as a mathematical function with $m$ variables. Thus, this phenomenon may be described by an unknown but existable function $F : \mathrm{I\!R}^m \rightarrow \mathrm{I\!R}$ given by:

$$Z = F(x_1, x_2, \ldots, x_m), \tag{2}$$

where $x_1, x_2, \ldots, x_m$ are the $m$ variables' values—each depending on time—that affect the phenomenon. Obviously, the values of the time series in equation (1) are equal to those in equation (2)

$$F(x_{1,t}, x_{2,t}, \ldots, x_{m,t}) = Y_t, \qquad \forall t \in T, \tag{3}$$

where $x_{i,t}$ denotes the values of the $x_i$ in time $t$.

The unknown function $F$ may be calculated for all possible values of any variable $x_i$. However, while the phenomenon evolutes the $m$ parameters are assigned by specific arithmetic values that are smoothly modified through time. Therefore, the time series $Y$ is also the graphical representation of discrete points that lead to a curve described by a function $g(x_{1,t}, x_{2,t}, \ldots, x_{m,t})$. So, every time series is the trace of the curve $g$ along the function $F$; on this basis the time series curve could be treated as a generic function of $m$ variables.

For example, assume that the graphical representation of a random function $F$ is as shown on fig. 1, while equation's $g$ trace on it is represented by the white line. Since this curve may be represented as a generic function, its graphical representation is shown in fig. 2.

So, the time series may be represented as the trace of the curve of $g$ along the function $F$. On this basis, any time series is equivalent to a curve on the $m$-dimensional space, thus for the optima's prediction any optimization technique may be applied.

In this paper we propose a backtrack technique that allows any optimization algorithm that obtains "memory" being applied in finding future local optima. Section II includes a brief literature review of most methodologies based on which time series prediction is made. The methodology proposed is decomposed on II-C. Finally in V further research interests and applications are proposed.

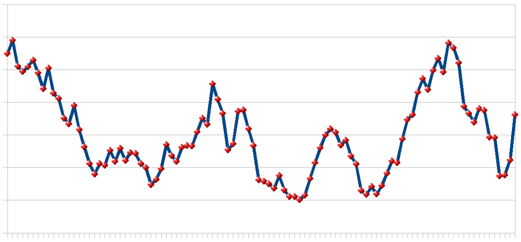

Fig. 2. The function plot of the $Y_t$ using points from the white line of 1.

## II. Time Series Forecasting

### A. Statistical Based Techniques

The widest used methodologies are based on the knowledge of *some* of the last known prices, i.e.

$$Y_t = \sum_{i=1}^{p} \Phi_i Y_(t-1) + \varepsilon_t \tag{4}$$

where $\Phi_i \in R$, and for the estimation of the new point $Y_t$ are used $p$ known points and a residual $\epsilon_t$ that satisfies

$$E[\varepsilon_t|\varepsilon_1, \ldots, \varepsilon_{t-1}] = 0 \tag{5}$$

It was H. Markowitz [2] who applied the mean-variance model on historical data and finally predicted future prices quite accurate in respect to the real ones. Based on his pioneer contribution that future points may be detected through the historical information provided by past data, and statistical assumption including means, variances and covariances, many applications in several subject areas introduced. Several bibliography on time series forecasting for finance incorporated with the probability theory. Sharpre, [3], in his pioneer work in 1970, set basis on the generalized portfolio theory of capital market, introducing the concepts of economics of risk and investment. In 1972, Merton, [4], incorporated with a set of assets by explicitly discussing the characteristics of mean-variance and efficient portfolio frontier. Further extensions added by Pang, [5], Perold ,[6], and extended the level of the parametric methods' usage in large scale selecting problems. In 1990, Best and Grauer, [7], included the general linear programming constraints and in 2000, Best and Hlouskova, [8], also included the concept of the fully and non-risky assets. The use of mean-variance efficient frontiers for the efficient assets' exchange in Jacobs et al, [9], also applied in long positions through the critical line algorithm (CLA); CLA traces out mean-variance efficient sets still including systems of linear equality or inequality constraints.

Furthermore, the distinctive introduction of the exponential smoothing model provided by Brown, [10], and Box and Jenkins, [11], arose new evidence towards predicting time series more efficiently. Such methodologies applied the so called auto-regressive integrated moving average (ARIMA) models to find the best fit of a time series on its own past values; the effectiveness of both methodologies though is a rather controversial issue according to Kuan and Lim, [12].

Most methodologies put aside the issue of the next point on which a research may focus and be interested in, and highlight on forecasting the next value. Thus, Taggart, [13], and Merton, [14], included the concept of the stock market timing in theoretical means, involving financial trends and macroeconomic policies.

### B. Artificial Intelligence Techniques

Alternative applications appeared at the late 90's, when, Lee and Jo, [15], and Edwards et al, [16], incorporated with the best time-to-market issue in terms of Artificial Intelligence to predict future stock price movements including weighted factors such as past data and market volatility.

Additionally, Pavlidis et al, [17], [18], incorporated the time series modelling and prediction through the spectrum of feed-forward neural networks as one-step local predictors applied on exchange rates. Grosan and Abraham, [1], and Chen et al, [19], incorporated results from genetic algorithms and neural network applications together, in a single multi-objective algorithm to conclude that the obtained results appear more accurate than the single use of one technique.

The common characteristic amongst these forecasting methodologies is that they neglect the aspect of *optima's* prediction in favor of that of *value*'s prediction.

### C. Optimization Techniques

*"Optimization is the act of obtaining the best result under given circumstances"* [20]. Mathematically this may be

$$\begin{aligned} \min \quad & f(X) \\ \text{s.t.} \quad & g_j(X) \leq 0, j = 1, 2, \ldots, m \\ & l_j(X) = 0, j = 1, 2, \ldots, n \end{aligned} \tag{6}$$

where $X = \{x_1, x_2, \ldots, x_n\}$ is an n-dimensional vector, $f(X)$ is called the objective function and $g_j(X)$ and $l_j(X)$ are, respectively, the inequality and equality constraints. This is the basic form of the constrained optimization problem. In the case of the lack of constraints, the problem is the unconstrained optimization one. It is common, by applying appropriate modifications, to transform any constrained problem into an unconstrained one.

A well known class of algorithms for unconstrained optimization is the Steepest Descent methods firstly introduced by Cauchy, [22],

$$x^{i+1} = x^i - \lambda_i^* \nabla F_i. \tag{7}$$

where $\lambda_i^*$ is the optimal step length along the search direction $-\nabla F_i$.

Vrahatis et al, [21], proposed a modification of the steepest descent algorithm model, called Steepest Descent with Adaptive Stepsize (SDAS-2) algorithm, based on the the Armijo's method [23].

The SDAS-2 is decomposed, using the parameters $x^0$ for the initial point, $\lambda^0$ as the randomly large initial stepsize, MIT the maximum number of iterations required and $\varepsilon$ as the predetermined desired accuracy.

**Algorithm 1** The SDAS-2 algorithm, [21]

```
Require: $\{F; x^0; \lambda^0; MIT; \varepsilon\}$
  Set $k = -1$
  while $k < MIT$ and $\|\nabla F(x^k)\| > \varepsilon$ do
    $k = k + 1$
    if $k \geq 1$ then
      Set $\Lambda^k = \frac{\|\nabla f(x^k) - \nabla F(x^{k-1})\|}{\|x^k - x^{k-1}\|}$
      if $\Lambda^k \neq 0$ then
        $\lambda = 0.5/\Lambda^k$
      else
        Set $\lambda = \lambda^0$
      end if
    else
      Set $\lambda = \lambda^0$
    end if
    Tune $\lambda$ by means of a stepsize tuning subprocedure.
    Set $x^{k+1} = x^k - \lambda \nabla F(x^k)$
  end while
  return $\{x^k; F(x^k); \nabla F(x^k)\}$
```

The following theorem—provided by Vrahatis et al, [21]—concerns the iterative scheme's convergence of the Algorithm 1:

*Theorem 1:* [21] Suppose that the objective function $F : \mathbb{R}^m \to \mathbb{R}$ is continuously differentiable and bounded below on $\mathbb{R}^m$ and assume that $\nabla F$ is Lipschitz continuous on $\mathbb{R}^m$. Then, given any $x^0 \in \mathbb{R}^m$, for any sequence $\{x^k\}_{k=0}^{\infty}$, generated by Algorithm 1, satisfying the Wolfe's conditions [24], [25], [26] implies that $\lim_{k\to\infty} \nabla F(x^k) = 0$.

## III. Decomposition of the Backtrack Procedure

As already mentioned in I the time series $Y$ is also the trace of a curve along function $F$ of $m$ variables. Thus, the problem of time series' optima search is equivalent to the constrained optimization problem (equation 6).

Using the notation of equation (6) lots of the unconstrained minimization methods are iterative in nature and hence they start from an initial random solution, $X^0 \in \mathbb{R}^m$ and proceed towards the minimum point in a sequential manner, $x^1, x^2, \ldots x^{\min}$. According to the time series notation in equation (1), point $t_i$ is denoted by $t_i = (x_1^i, x_2^i, \ldots, x_m^i)$.

Without lack of generality it is supposed that the prediction of future maximum is in question; the procedure is decomposed in two stages:

1) **Backward search for minimum** When applying any optimization technique, it is concluded that most of them in order to generate the new point use prior knowledge collected from the process data including points, function values, gradient values, matrix approximations etc. In our case, let $t_n$ be the last known point of time series, and by using the SDAS-2 algorithm the next estimation of local minimum is calculated when applying Algorithm 1. Obviously, in order to calculate an approximation of the $\nabla F$ we have used finite differences. Therefore, by applying the SDAS-2, the sequence of points that leads to a local minimum $[t_n, t_{k_1}, t_{k_2}, \ldots, t_{k_{m-2}}, t_{\min}]$, where $n > k_1 > k_2 > \cdots > k_{m-2} > \min$ is estimated.
2) **Forward search for minimum** When this "sequence" of points is viewed as a forward process, it appears as a sequence that starts from the minimum past point $t_{\min}$, crisscrosses the last known point $t_n$ and probably leads to a maximum future one $t_{\max}$. In this forward process the stepsize $\Lambda_i^*$ and the sequence of points are known from the previous stage 1. The constructed sequence of points provides us with all the information needed to proceed in estimating a future maximum. So, by applying one step of Algorithm 1 from the initial point $t_n$ an approximation of $t_{\max}$ is obtained.

Thus, the previously described process gives the following backtrack algorithm for the estimation of future local maximum; note that $\varepsilon$ is a very small positive number that reassures desired accuracy.

**Algorithm 2** The backtrack algorithm

```
Require: $\{t_n, \varepsilon\}$
  repeat
    Run stage 1 to compute a sequence of points $t_n$, $t_{k_1}$, $t_{k_2}$, $\ldots$, $t_{k_{m-2}}$, $t_{\min}$ that leads to "past" local minimum.
    Calculate "future" point $t_{n+k}$ by applying stage 2 using points $t_{k_{m-2}}$, $\ldots$, $t_{k_2}$, $t_{k_1}$, $t_n$.
    Set $t_n = t_{n+k}$
  until $Y'_{t_n} < \varepsilon$
  Set $t_{\max} = t_{n+k}$.
  return $t_{max}$
```

Note that the procedure described in Algorithm (2) is equivalent to the optimization problem given by equation (6). Therefore, since all assumptions of Theorem 1 are satisfied, the Algorithm 2 converges to an optimum future point.

## IV. Numerical Applications

To investigate the proposed method's reliability, the method was applied on two different time series samples; one fi-

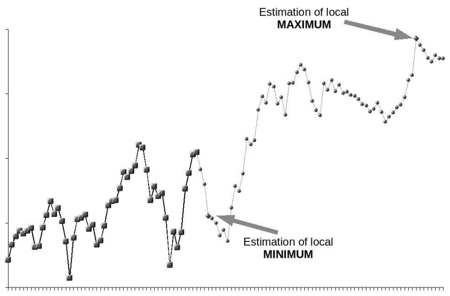

Fig. 3. An application of the backtrack algorithm on Athens Stock Market general index on April 14, 1999

nancial stock market data and another with meteorological ones.

## A. Athens' Stock Market

The proposed application is tested on the daily closing prices of the Athens' Stock Market. The data consists of the daily closing prices of 18 years—from 1985 until 2002. In Figure 3 is presented an application of the backtrack algorithm towards predicting Athens' Stock Market general index for the randomly chosen date of April 14, 1999. The last 50 known values of general index are used; i.e. in the case of April 14, 1999, the 50 last known indexes are from January 29, 1999 until April 14, 1999. These points are represented on Figure 3 with the square symbol. In Figure 3, again, the gray circles stand for the index's actual values index for the exchanging period from April 15, 1999 till July 14, 1999. Future values are connected together with the discontinuous line. The points depicted from the backtrack algorithm are symbolized with the rhomb symbol.

In Figure 4 is presented an application of the SDAS-2 backtrack algorithm towards predicting Athens' Stock Market general index for the randomly chosen date of July 13, 1998; then Algorithm 2 is applied to approximate future local minima and maxima. The last 50 known values of the general index are used; i.e. in the case of July 13, 1998, the 50 last known indexes are from May 4, 1998 until July 13, 1998. These points are represented on Figure 4 with the square symbol. In Figure 4, again, the gray circles stand for the index's actual values for the exchanging period from July 14, 1998 till September 16, 1998. Future values are connected together with the discontinuous line. The points depicted from the SDAS backtrack algorithm are symbolized with the rhomb symbol.

To investigate the SDAS backtrack algorithm's reliability, the algorithm was applied on 1000 randomly chosen prices to approximate the dates $t_{min}$ and $t_{max}$ that produce local minima and local maxima, respectively. Since we assume that the investor seeks for assets that are relatively cheap to buy and their price increase, the table only includes the cases that the local minima emerges before the local maxima.

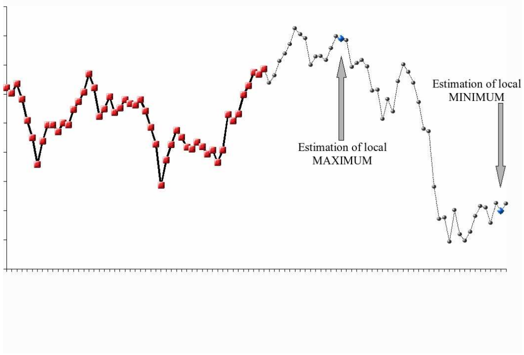

Fig. 4. An application of the SDAS backtrack algorithm on Athens Stock Market general index on July 13, 1998

TABLE I
STATISTICAL INDEXES APPLIED ON RANDOMLY CHOSEN ASSETS

| Quantity | Days | Return |
|---|---|---|
| **Min** | 1.00 | -0.2320 |
| $Q_1$ | 4.00 | 0.0020 |
| **Median** | 9.00 | 0.0520 |
| **Mean** | 15.54 | 0.0662 |
| $Q_3$ | 21.25 | 0.1162 |
| **Max** | 55.00 | 0.4020 |
| **s.d.** | 15.65 | 0.1343 |

The difference between the estimations for local minima and local maxima is extracted in terms of time, that is days of market activity. Furthermore, each asset's return was calculated based on the function

$$R = \frac{Y_{t_{\max}} - Y_{t_{\min}}}{Y_{t_{\min}}} \tag{8}$$

In Table I are briefly reported the statistical indexes that characterize the variables "days" and "return" obtained from equation 8. Specifically, the raw "days" includes indexes regarding the difference in market days between local minima and local optima, $t_{\max} - t_{\min}$; likewise, raw named "return" illustrates the indexes that result from variable $R$ estimated from equation (8). The abbreviations used as columns are referred to the local minimum, first quarter $Q_1$, mean value, median, third quarter $Q_3$ and standard deviation.

It is therefore, observed that the mean between the predicted local minima and local maxima is 15 days approximately. During this period the mean return is about $6.6\%$.

## B. Athens Temperature

As widely known, the time series derived from meteorological data appear to have several local optima due to weather's dependence from sensitive factors. We have constructed a time series based on the data collected from the National Technical University of Athens' meteorological station, that includes information about the temperature for every 10 minutes from February 14, 1999 until today.

If the time series' graph is closely observed, for instance for the Christmas Day of 2006 (Fig. 5), it is obvious that

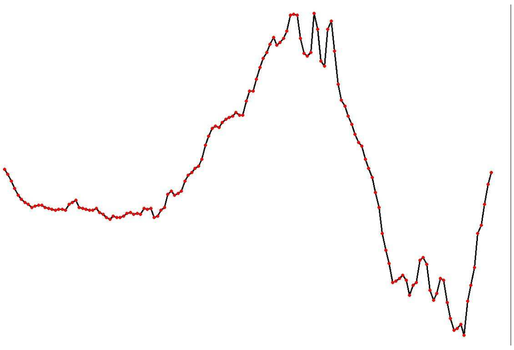

Fig. 5. Athens' temprature during Christmas Day of 2006.

TABLE II
STATISTICAL INDEXES APPLIED ON RANDOMLY CHOSEN ASCENDING TEMPERATURES

| Quantity | Forecasted Max | Forecasted Min |
|---|---|---|
| **Min** | -1.16 | -8.93 |
| $Q_1$ | -0.20 | -0.21 |
| **Median** | 0.03 | 0.01 |
| **Mean** | 0.20 | -0.08 |
| $Q_3$ | 0.24 | 0.28 |
| **Max** | 4.64 | 3.62 |
| **s.d.** | 0.99 | 1.39 |

there is a high number of optima. Furthermore, there are areas of continuous changes from minima or maxima, especially around the global maxima—occurred in 15.00—and the global minima—occurred in 22.30.

The proposed algorithm was tested on the time series data for the year 2006. In order to avoid the effects derived from the continuous changes we have randomly chosen points that appear to follow an ascent or a descent stream. It is supposed that a time series follows an ascent stream when its $m$ last known points are in an ascent order, too. Furthermore, when the time series appeared following an ascent stream, the backtrack algorithm was applied for the detection of the past known minima; the SDAS-2 algorithm was applied only for the prediction of the future local maxima. Samewise, if the time series appeared following a descent stream the backtrack algorithm was applied for the detection of the past maxima, and the SDAS-2 for the prediction of the local minima.

The results obtained from ascending temperature data are shown on Table II while those obtained from descending temperature are shown on Table III. In order to appraise the statement that for the ascending stream case the level of successfulness in predicting local maxima is greater than this for the local minima and vice-verca, table IV was constructed, it contains the successfulness level for each case.

The values shown on both "Forecasted Max" and "Forecasted Min" columns conclude from the difference between the value of the predicted local optimum point and the value of the initial known one.

TABLE III
STATISTICAL INDEXES APPLIED ON RANDOMLY CHOSEN DESCENDING TEMPERATURES

| Quantity | Forecasted Max | Forecasted Min |
|---|---|---|
| **Min** | -2.24 | -5.36 |
| $Q_1$ | -0.43 | -0.38 |
| **Median** | -0.11 | -0.07 |
| **Mean** | 0.16 | -0.37 |
| $Q_3$ | 0.34 | 0.10 |
| **Max** | 4.00 | 0.56 |
| **s.d.** | 1.24 | 1.12 |

TABLE IV
LEVELS OF SUCCESSFULNESS IN PREDICTING MAXIMUM AND MINIMUM IN CO-RELATION WITH THE TIME SERIES' STREAM

| Direction | Min | Max |
|---|---|---|
| Ascending | 47% | 52% |
| Descending | 55% | 38% |

The column "Direction" illustrates the timeseries' direction, in means of an "ascending" or a "descending" stream. In column "Min" is shown the level of successfulness in predicting local minima; same wise, the column "Max" demonstrated the successfulness level when predicting local maxima. It is observed that the local maxima's prediction while the timeseries follows an ascending stream is quite better than this of the local minima, and vice-versa. However, such behavior is rather expected due to the usage of the SDAS-2 algorithm that belongs to the category of the steepest descent algorithms. According to [27] this category of techniques tends to converge to the closest optima.

## V. Conclusions and Further Research Interests

This paper is structured based on the rationalization that the financial time series may be treated as a function subjected to those that represent all different factors affecting its values during time, thus we incorporated with optimization techniques instead of statistical ones. Obviously, such a rationalization provides strong enough evidence towards applying any optimization technique. Due to this, the proposed backtrack technique was applied using the SDAS-2 algorithm incorporated in [21]. The results obtained provide strong evidence regarding predictions' accuracy. Further, it is observed that the local maxima's prediction—while the timeseries follows an ascending stream—is quite better than this of the local minima, and vice-versa.

The SDAS-2 algorithm was applied since

(a) uses prior knowledge (calculates an approximation of Lipschitz constant using all sequence points), and
(b) as proposed by [27] the steepest descent methods are the most reliable as far as it concerns the convergence to the closest optimum; both characteristics could applied in portfolio optimization problems.

At this point, three directions could be proposed based on the backtrack technique: (a) applications of the backtrack technique in other minimization algorithms that use information collected from sequence points, such as quasi-Newton methods, conjugate gradient, etc, (b) using these techniques towards approximate a future minimum and a future maximum, as well, of an individual asset, so as to formulate an asset management technique for its behavior in an asset portfolio and (c) using backtrack technique with a multi-objective optimization method for managing a given portfolio.

Further research could be focused on these directions, due to the interesting results the technique provides; our research concentrates towards these directions, as well.

***Abstract*—We study in this paper a generalization of the basic strictly periodic scheduling problem where two positive integer constants, associated to each task, are introduced such that to replace the usual strict period. This problem is motivated by the combat of the dengue which is one of the major tropical disease. We discuss general properties and propose two integer mathematical models of the problem considered which are compared theoretically. We also suggest a lower bound which is derived from the structure of the problem. It appears to be quickly obtained and of good quality. Three greedy algorithms are proposed to provide feasible solutions which are compared with the optimum (when it can be obtained by the use of ILOG-Cplex10.0). It is shown that for special instances greedy algorithms are optimal.**

## I. Introduction

DENGUE is a flu-like viral disease spread by the bite of infected mosquitoes and occurs in most tropical areas of the world. One of a severe complication of this disease is dengue hemorrhagic fever which is often fatal. Unfortunately, there is no specific treatment for it. Consequently at the present time the only way of preventing or of fighting the dengue is to eliminate the vector mosquitoes which are located in breeding sites. More specifically equipped vehicles are sent in each infested and detected areas to pulverize insecticide. In practice those sites are divided in sub-areas which are computed so as to exactly obtain one working day for each vehicle (formally each task takes a duration of unite time). Unfortunately, the pulverized product only kills mosquitoes but leaves the larves in life. Indeed, it takes between 7 and 9 days for a larve to become an adult mosquito. Therefore, each sub-area has to be treated repetitively with a delay of at least 7 and at most 9 days between two pulverizations to achieve the best efficiency. We refer to [22] for more details on the logistic aspect of prevention and combat of the dengue. More formally, we consider the problem of minimizing the number of vehicles required to make periodic single destination equipped vehicle to a set of infested sub-areas. We therefore face to a periodic scheduling problem (which is in this basic form NP-hard [10]) where the periodicity is not strict but represented by both a minimum and a maximum delay (respectively, in this special case 7 and 9). We show in this paper that if all the maximum periods are equals for all tasks then the problem relative to our application of dengue prevention can be solved in polynomial time. We will then also study the more general case where all the maximum periods are different.

We therefore extend our work to a generalization of a strict periodic scheduling problem which is basically concerned with processing, on a set of identical machines (or identical unitary resources), periodic tasks or activities over an infinite horizon. Each activity $i$ is characterized by a duration $d_i$. We are actually concerned with the following generalization of the strict periodicity requirement: two positive integer numbers $\underline{F_i}$ and $\overline{F_i}$ are associated with task $i$ and correspond, respectively, to a minimum and a maximum delay for the repetition of activity $i$. Thus, if the $k^{th}$ execution of $i$ has been scheduled on time $t_{i,k}$ then $t_{i,k+1}$ must belong to $[t_{i,k}+d_i+\underline{F}_i, t_{i,k}+d_i+\overline{F}_i]$. We also consider a finite time horizon, all the task durations equals to 1 (i.e. $d_i = 1 \quad \forall i$) and unary resources. Our aim is to minimize the number of resources (or machines or vehicles) so as to execute all the activities.

In this paper, we examine the structure of this general problem (denoted by $GSPS$), giving some properties. We propose two integer linear formulations which we name "weak and strong" formulations for $GSPS$. We compare theoretically those formulations that asserts the named of each model. From the strong formulation we derived a lower bound denoted by $\lceil Z[\overline{GSPS}]\rceil$. We then suggest a second lower bound of $GSPS$ easier to be computed and of good quality which appears to be optimal for special cases, including when all the maximum delay are equals. Finally, we present three greedy algorithms which provide feasible solutions. Those upper bounds are evaluated and compared with both the optimal value of the integer linear model when it can be obtained in a competitive CPU time given by CPLEX10.0. and the lower bounds we proposed.

The paper is organized as follows. In Section II, we formally define the problem $GSPS$ and give necessary notations. Section III describes the relevant literature. We establish in Section IV some properties relative to the considered scheduling problem and provide a trivial lower bound. Section V is dedicated to the formulation of $GSPS$ by two integer linear programs.

In Section VI we propose three greedy algorithms so as to obtain good feasible solutions. The computational results are reported in Section VII. In Section VIII we summarize the main results of this paper and we point out some directions for future research.

## II. Problem definition

We consider in this paper a problem denoted by $GSPS$ which is a generalization of both the basic strictly periodic scheduling problem [10] and the problem derived from the combat of the dengue described in the introduction.

Formally, it can be stated as follows. We consider $J$ types of activities and associate at each type $j$ ($j = 1, .., J$) the following parameters:

- $n_j$, the number of activities of type $j$.
- $\underline{F}_j$ the minimum delay between two executions of an activity of type $j$.
- $\overline{F}_j$ the maximum delay between two executions of an activity of type $j$.

Each activity of each type requires an unary resource (at each time it is processed) and has a duration of a unit time. The resources are identical and renewable (i.e. right after having processed a task, the resource is available for another task).

The objective of the problem is to find a feasible schedule, with respect to the minimum and maximum delays between two executions of the same activity, over a time horizon $H$ while minimizing the number of used resources. The activities of type $j$ are required to be executed at least once in the first $\overline{F}_j$ units of time.

The following proposition establishes the complexity of the problem we study.

*Proposition 1:* The problem $GSPS$ considered here is NP-Hard.

*Proof:* If $\underline{F}_j = \overline{F}_j$, $\forall j = 1...J$ then $GSPS$ corresponds to the strictly periodic problem which has been shown as being NP-Hard (see [10] and [24]). Consequently, the strictly periodic scheduling problem is a special case of $GSPS$. Since it is NP-hard then $GSPS$ remains NP-hard. ■

To get a clearer reading, let us provide an example of a feasible solution (which actually happens to be optimal) represented by Figure 1. This solution uses 4 units of resource or machines (or vehicles if we refer the dengue application) over an horizon of 20 units of time, for the problem corresponding to the following data:

| type | n | $\underline{F}$ | $\overline{F}$ | activities |
|---|---|---|---|---|
| 1 | 3 | 0 | 2 | 1,2,3 |
| 2 | 2 | 2 | 3 | 4,5 |
| 3 | 1 | 2 | 4 | 6 |
| 4 | 2 | 3 | 4 | 7,8 |
| 5 | 1 | 6 | 6 | 9 |

where the first column corresponds to the type identifier, the second column reports the number of activities for the relative type, the third and fourth columns give respectively the minimum and maximum delay between 2 executions of an activity of this type and the last ones indicates which are the activities of this type.

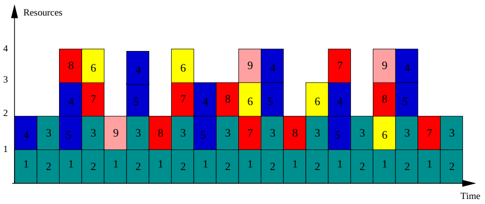

Fig. 1. A feasible solution

## III. Literature review

We review in this section the literature relative to periodic scheduling problems. More specifically, we begin by presented the state of art concerning the strictly periodic scheduling (and/or routing) problem. We note that the major attention with regard to this problem has been addressed to heuristics methods. We then pursue the literature concerning variant and generalization of the previous problem. We finally briefly describe other applications of periodic scheduling problems.

In a basic version of strictly periodic scheduling problem, all durations are equals to 1 and a period $T_i$ is also associated with each of the task so that if task $i$ ($\forall i = 1, ..., n$) is scheduled on time $t$ then it must also be strictly scheduled on times $t + d_i + T_i$, $t + 2d_i + 2T_i$ and so on. The problem consists then in minimizing the number of machines to process periodically the tasks. This basic problem has been shown as being NP-hard ([10], [24]) although it has also been shown that it is sufficient to compute a schedule over a time horizon equal to the lowest common multiplier of the $T_i$ (since the latest can be duplicated for larger time horizons [10]).

Generalizations of this basic periodic problem have then been introduced. Jan Korst's Ph.D. thesis [19] considers a periodic scheduling problem very similar but with general integral execution times. In Park and Yun [23] and Gaudioso et. al. [11], unitary duration times are considered with task $i$ requires $w_i$ units of resources, while being executed. Both problems are identical and do correspond with the basic problem when all $d_i$ and $w_i$ values equal one. A large integer program was then introduced by [23] and [12] to solve the resulting load minimization problem, however Park and Yun [23] also describe a method for decomposing the initial problem into smaller subproblems. They divide the set of activities into sets $N_1, N_2, \cdots, N_d$, where for any $i \in N_q$ and any $j \in N_r$, $p_i$ and $p_j$ (periods) are relatively prime. They then use integer programming to solve each resulting subproblem, minimizing the number of resources required for each subset of customer. If $K_q$ represents the minimum number of resources required for customer set $N_q$, Park and Yun [23] showed that the minimum number of vehicles required to service the customers is exactly $K_1 + K_2 + \cdots + K_d$ since the decomposition does not increase the number of vehicles required. Finally, Gaudioso et al. [12] also present a branching heuristic with several possible branching rules, where the greedy algorithm presented in [10] corresponds to one of the choice of these rules. Another generalization has been considered in [5], also in the strictly periodic case, by considering non unitary resources and non unary demands associated with every activities have a duration of 1 time unit. The concept of tree scheduling is then introduced, which is a methodology for developing perfectly periodic schedules based on hierarchical round-robin, where the hierarchy is represented by trees. Some optimal (exponential time) and efficient heuristic algorithms which generate schedule trees are presented.

Some authors relax the strict periodicity requirement ([14]): rather than exactly scheduling activity $i$ on times $t + d_i + T_i$, $t + 2d_i + 2T_i$, ..., it is allowed to be scheduled on time slots centered in $t + d_i + T_i$, $t + 2d_i + 2T_i$, ... Namely, the second execution of task $i$ must occur in $[t+d_i+T_i-a_i, t+d_i+T_i+b_i]$, the third in $[t + 2d_i + 2T_i - a_i, t + 2d_i + 2T_i + b_i]$, etc. where $a_i$ and $b_i$ are non negative real numbers associated with $i$. Baruah et al. [8] introduce the notion of Proportionate fairness (PFair) Scheduling. PFair scheduling differs from more conventional real-time scheduling approaches in that tasks are explicitly required to execute at steady rates and have been deeply studied [9], [7] and [3]. This (multiple-resource) periodic scheduling problem was first addressed by Liu[21]. Baruah et al. [8] showed that PFair scheduling can be solved in polynomial time.

Other closer works are found also in the periodic routing problems (PRP). In [10], the authors consider the problem of minimizing the number of vehicles required to make strictly periodic, single destination deliveries to a set of customers, under the initial assumption that each delivery requires the use of a vehicle for a full day. A greedy algorithm that is optimal in some special cases is proposed. A variant of this problem is also considered when the restriction of a full day for each delivery is relaxed. The same relaxation proposed in this article is also considered in [11], however, the authors address conjointly the routing problem for each day, which makes the problem much more difficult to solve due to the routing component and its interactions with the periodic scheduling problem.

Early work on periodic schedules was also motivated by Teletext Systems [2], [13] and [1], maintenance problem [4], [25] and [20] and broadcast disks [6], [18], [16] and [17]. This latter issue gained a lot of attention recently since they are used to model backbone communication in wireless systems, Teletext systems and efficient web caching in satellite systems. Finally in [15], the authors address how to sequence the movements of robots in order to minimize the number of robots required to complete a series of tasks over a fixed time horizon. In this case, the periodicity comes from the sequence of each robot's movement rather than from the jobs being processed.

## IV. Some properties and a trivial lower bound

We dedicated this section to the study of the structure of the problem $GSPS$. We thus first exhibit some observations and properties. We then provide a simple way to compute a lower bound of good quality for $GSPS$ derived from the structure of the problem which becomes to be optimal when all the maximum periods are equals.

*Observation 1:* As proved in [10] if the problem is a strictly periodic scheduling then to obtain a solution over an infinite time horizon, it is necessary only to find a solution over a time horizon equal to the lowest common multiplier of the periods. On the opposite, if we consider our problem $GSPS$, it is not feasible to duplicate over an infinite horizon a schedule computed over a horizon equal to the lowest common multiplier of the maximum period. Indeed, since the period is not strict any more then the previous property can not be established.

*Observation 2:* The decomposition procedure of the basic periodic scheduling problem, into sub-problems easier to be solved, suggested by Park and Yun [23] can not be extended in our context because the periodicity is not any more strict.

The two previous observations are straightforwardly validated by counter-examples, which are easy to be found.

In spite of the fact that the more general periodicity seems to be inconvenient for using the lowest common multiplier of the periods to establish properties, this notion still plays a key role in the computation of lower and upper bounds for our problem $GSPS$. Indeed, we present now a simple technique to compute a lower bound of $GSPS$ which becomes easier if the horizon time $H$ is greater than the common multiplier of the maximum delays $\overline{F_j}$, $\forall j = 1...J$. The upper bounds will be provided by greedy algorithms in Section VI.

A simple way to under-evaluate the number of needed resource units is to find how much time each activity has to be processed. For this purpose, let us consider a time $t$ ($\leq H$). Between times 1 and $t$, an activity of type $j$ will be processed at least $\lfloor \frac{t}{\overline{F_j}} \rfloor$ and therefore, between times 1 and $t$, we have to process at least $\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F_j}} \rfloor$ tasks, hence an average of:

$$\frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F_j}} \rfloor}{t} \qquad (1)$$

per time unit. Since the average of a set of values is smaller than the maximum, the smallest integer greater than quantity (1) (that is the ceil of (1)) is a lower bound to the number of resources needed to schedule all the activities between times 1 and $t$. In order to get the best (over the set of those lower bounds) lower bound for scheduling all the activities of all the types over the time horizon, we then have to compute;

$$TLB = \max \left\{ \left\lceil \frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F_j}} \rfloor}{t} \right\rceil / \quad t = 1, ..., H \right\} \qquad (2)$$

The above quantity will be referred as the "Trivial Lower Bound" (TLB).

The following proposition establishes the role of the lowest common multiplier of the $\overline{F}_j$ $(j = 1, ..., J)$ in the computation of the (TLB).

*Proposition 2:* If the time horizon $H$ is greater or equal than the lowest common multiplier of the $\overline{F}_j$ $(j = 1, ..., J)$, then the (TLB) is actually equal to:

$$TLB = \left\lceil \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \right\rceil \tag{3}$$

*Proof:* Note first that $TLB \leq \left\lceil \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \right\rceil$ : since $\lfloor \frac{t}{\overline{F}_j} \rfloor \leq \frac{t}{\overline{F}_j}$ , we obviously have:

$$\frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F}_j} \rfloor}{t} \leq \frac{\sum_{j=1}^{J} n_j \frac{t}{\overline{F}_j}}{t} = \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \tag{4}$$

It then follows that:

$$TLB = \max \left\{ \left\lceil \frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F}_j} \rfloor}{t} \right\rceil \Big/ \quad t = 1, ..., H \right\} \leq \left\lceil \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \right\rceil \tag{5}$$

Let now $F$ denote the lowest common multiplier of the $\overline{F}_j$ $(j = 1, ..., J)$. If $H \geq F$, we can consider inequality (4) for $t = F$. Since, $\frac{F}{\overline{F}_j}$ is integer, the inequality $\lfloor \frac{t}{\overline{F}_j} \rfloor \leq \frac{t}{\overline{F}_j}$ becomes an equality and, thus,

$$TLB = \max \left\{ \left\lceil \frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F}_j} \rfloor}{t} \right\rceil \Big/ \quad t = 1, ..., H \right\} \geq \left\lceil \frac{\sum_{j=1}^{J} n_j \frac{F}{\overline{F}_j}}{F} \right\rceil \tag{6}$$

Since,

$$\left\lceil \frac{\sum_{j=1}^{J} n_j \frac{F}{\overline{F}_j}}{F} \right\rceil = \left\lceil \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \right\rceil \tag{7}$$

we have,

$$TLB = \max \left\{ \left\lceil \frac{\sum_{j=1}^{J} n_j \lfloor \frac{t}{\overline{F}_j} \rfloor}{t} \right\rceil \Big/ \quad t = 1, ..., H \right\} = \left\lceil \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} \right\rceil \tag{8}$$

■

We show now, as mentioned in the introduction, that the application of the combat of the dengue, which represents a particular case of $GSPS$ can be solved in polynomial time.

*Proposition 3:* If all the types have the same maximum delay $\overline{F}$ (i.e. $\overline{F}_j = \overline{F}$ $\forall j = 1, ..., J$) then the problem $GSPS$ can be solved to optimality in $\lfloor \frac{H}{\overline{F}} \rfloor \sum_{j=1}^{J} n_j$ operations, that is in polynomial time with respect to the total number of tasks to be scheduled. In addition, the optimal value is exactly equal to the value provided by the Trivial Lower Bound.

*Proof:* With no loss of generality, we can assume that $H \geq \overline{F}$ (otherwise, it is not necessary to execute the activities). Let us consider a particular schedule that we are going to show as being feasible and which provides a objective function value equal to (TLB). As a consequence, this schedule will be shown as being optimal. This particular schedule is builded by the following greedy method:

- If $\sum_{j=1}^{J} n_j \leq \overline{F}$ then the problem is rather easy to solve : assign activity 1 on times 1, $1 + \overline{F}$, $1 + 2\overline{F}$ and so on; activity 2 on times 2, $2 + \overline{F}$, $2 + 2\overline{F}$,... etc ...
  It is then direct to observe that this procedure will use only one unit resource and that each activity will be executed with a strict period of $\overline{F}$ units of time. Thus, the produced schedule is feasible and optimal since no less than 1 resource unit can be used.
- Otherwise, i.e. if $\sum_{j=1}^{J} n_j > \overline{F}$, then we take the first $\overline{F}$ activities and assign activity 1 on times 1, $1 + \overline{F}$, $1 + 2\overline{F}$ and so on, activity 2 on instants 2, $2 + \overline{F}$, $2 + 2\overline{F}$,... etc ...
  Consequently, each of those activities are executed according to a strict period of $\overline{F}$ units of time and on one unit of resource.
  Repeat the same process for the next $\overline{F}$ activities and so on until that the number of remaining activities is no greater than $\overline{F}$. Then apply the same procedure as above. Once again, each of the activities are executed exactly $\overline{F}$ units of time (hence, the schedule is feasible) and after an easy calculation it can be straightforwardly established that this schedule requires $\left\lceil \frac{\sum_{j=1}^{J} n_j}{\overline{F}} \right\rceil$ units of resource. Since this quantity is exactly equal to the Trivial Lower Bound, the schedule is actually optimal.

■

## V. INTEGER LINEAR MODELS

In this Section, we first introduce two integer mathematical programs modelling $GSPS$ for the general periodic scheduling problem. Then, a theoretically comparison of the models is presented *via* corollary 1. Consequently, we will refer to a "weak formulation" and to a "strong formulation". We begin by establishing the so-called "weak formulation".

First are introduced some necessaries notations. Let $J(i) \in \{1, 2, ..., J\}$ be the type of activity $i$ and $n = \sum_{j=1}^{J} n_j$ the total number of activities to process.

Let us now define the following decision variables:

$$x_{it} \ = \begin{cases} 1 & \text{if task } i \text{ is processed on time } t \\ 0 & \text{otherwise} \end{cases}$$

where $i = 1, ..., n$ and $t = 1, ..., H$.

$R \ = $ the number of unit resources that we want to minimize

Let also $J(i) \in \{1, 2, ..., J\}$ be the type of activity $i$ and $n = \sum_{j=1}^{J} n_j$ the total number of activities to process. Then, the "weak formulation" can be stated as follows:

$$GSPS \begin{cases} \min \ R \\ s.t. \left| \begin{array}{l} (9), (10) \ or \ (12), (11) \\ x_{it} \in \{0, 1\}, \ \forall i = 1, ..., n, \ \forall t = 1, ..., H \\ R \geq 0 \end{array} \right. \end{cases}$$

where contraints (9), (10), (11) and (12) are respectively defined as follows.

At each time $t$, the number of used resources is greater or equal than the number of scheduled activities. Consequently we have constraint (9):

$$R \geq \sum_{i=1}^{n} x_{it} \quad \forall t = 1, ..., H \tag{9}$$

If activity $i$ is scheduled on instant $t$, then it must also be scheduled between instants $t + 1 + \underline{F}_{j(i)}$ and $\overline{F}_{j(i)}$. It follows constraint (10):

$$\sum_{l=t+1+\underline{F}_{j(i)}}^{t+\overline{F}_{j(i)}} x_{il} \geq x_{it} \qquad \forall i = 1, ..., n \ \ \forall t = 1, ..., H - \overline{F}_{j(i)} \tag{10}$$

Finally, each activity can be scheduled at most once on each period of $\underline{F}_{j(i)}$ consecutive days. We are then face to constraint (11):

$$\sum_{l=t}^{t+\underline{F}_{j(i)}} x_{il} \leq 1 \qquad \forall i = 1, ..., n \ \ \forall t = 1, ..., H - \underline{F}_{j(i)} \tag{11}$$

The "strong formulation" we proposed is obtained by substituting constraint (10) by:

$$\sum_{l=t+}^{t+\overline{F}_{j(i)}} x_{il} \geq 1 \qquad \forall i = 1, ..., n \ \ \forall t = 1, ..., H - \overline{F}_{j(i)} \tag{12}$$

Actually, this constraint states that, on each period of $\overline{F}_{j(i)}$ units of time, the activity must be executed at least once.

In the remainder of this paper, we will denoted by $\lceil Z[\overline{GSPS}] \rceil$ the smaller integer greater than or equal to the value optimal value of the LP-relaxation of $GSPS$ ("strong formulation").

The following proposition addresses the lower bound provided by the LP-relaxation of the "strong formulation".

*Proposition 4:* If the time horizon $H$ is greater or equal than the lowest common multiplier of the $\overline{F}_j$ $(j = 1, ..., J)$, then $\overline{x}$ defined by $\overline{x_{it}} = \dfrac{1}{\overline{F}_{j(i)}} \quad \forall i = 1, ..., n, \ t = 1, ..., H,$ is an optimal solution of the LP-relaxation of the "strong formulation" and, therefore, its optimal value is $\overline{R} = \sum_{j=1}^{J} \dfrac{n_j}{\overline{F}_j}$.

*Proof:* Let us show that $(\overline{R}, \overline{x})$ is feasible for the linear relaxation of the initial problem.

- $\sum_{i=1}^{n} \overline{x}_{it} = \sum_{j=1}^{J} \dfrac{n_j}{\overline{F}_j}$ and, hence, constraint (9) is satisfied by $(\overline{R}, \overline{x})$.
- $\sum_{l=t}^{t+\overline{F}_{j(i)}} \overline{x}_{il} = \dfrac{\overline{F}_{j(i)}}{\overline{F}_{j(i)}} = 1$ and constraint (12) is thus verified.
- $\sum_{l=t}^{t+\underline{F}_{j(i)}} \overline{x}_{il} = \dfrac{\underline{F}_{j(i)}}{\overline{F}_{j(i)}} \leq 1$ and constraint (11) is also verified.

Therefore, $(\overline{R}, \overline{x})$ is feasible for the linear relaxation. Let us now show that it is optimal. For this purpose, consider, for any (continuous) feasible solution $(R, x)$ of the linear relaxation the following quantity and any activity $i$ : $\sum_{t=1}^{F} x_{it}$ where $F$ is the lowest common multiplier of the $\overline{F}_j$. Then, from constraint 12, we have:

$$\sum_{t=1}^{F} x_{it} = x_{i1} + \ldots x_{i\overline{F}_{j(i)}} + x_{i\overline{F}_{j(i)}+1} \cdots + x_{iF} \geq \frac{F}{\overline{F}_{j(i)}} \tag{13}$$

since (12).

On the other hand, constraints (9) holds for any $t$ from 1 to $F$. Thus :

$$F \times R \geq \sum_{t=1}^{F} \sum_{i=1}^{n} x_{it} \tag{14}$$

and therefore (from(13):

$$F \times R \geq \sum_{j=1}^{J} F \frac{n_j}{\overline{F}_j} \tag{15}$$

that is

$$R \geq \sum_{j=1}^{J} \frac{n_j}{\overline{F}_j} = \overline{R} \tag{16}$$

It follows that the value provided by the objective function using any feasible solution is at least the value given by $\overline{x}$. As a consequence, $(\overline{R}, \overline{x})$ is optimal for the LP-relaxation of the "strong formulation" whenever the horizon is greater or equal to $F$. ■

*Corollary 1:* If the time horizon $H$ is greater or equal than the lowest common multiplier of the $\overline{F}_j$, then the two formulations are well named, that is the lower bound provided by the "weak formulation" is smaller or equal to the bound provided by the linear relaxation of the "strong formulation".

*Proof:* It is sufficient to establish that $(\overline{R}, \overline{x})$ is feasible for the "weak formulation", or in other words, that $\overline{x}$ satisfies constraint (10), using a simple calculation. ■

*Corollary 2:* If the time horizon $H$ is greater or equal than the lowest common multiplier of the $\overline{F}_j$ $(j = 1, ..., J)$, then the linear relaxation bound of the "strong formulation" is equal to the trivial lower bound.

*Proof:* Straightforward from propositions 2 and 4. ■

## VI. The proposed heuristics

We propose in this Section, three greedy algorithms so as to obtain good feasible solutions for $GSPS$. The main idea of the three heuristics is based on both the trivial lower bound and the possibility to schedule a task as late as it can be done. We successively give the main idea of the three greedy algorithms.

*Heuristics I and II.* First of all, Heuristics I and II only differ by a sorting criteria of the maximum periods. For both heuristics, the idea is to schedule first the most difficult types. The Heuristic I and II correspond to two different measures of what is a "difficult type". In Heuristic I, a type can be considered difficult if it is supposed to induce a large consumption of resources, which can be measured, from Proposition 2, by $\frac{n_j}{\overline{F_j}}$. Consequently, in Heuristic I, the types are sorted by decreasing order of the $\frac{n_j}{\overline{F_j}}$ whereas in Heuristic II, a type is "difficult" if we have only few possibilities to schedule a task after having chosen its first execution, that is if $\overline{F_j} - \underline{F_j}$ is "small". Thus, in Heuristic II, the types are sorted by increasing order of $\overline{F_j} - \underline{F_j}$. An outline of those two heuristics is given by Algorithm I and II.

**Algorithm 1** Heuristic I

```
Sort the types according to decreasing $\frac{n_j}{\overline{F_j}}$
for $j = 1$ to $J$ do
    Compute TLB for the first $j$ types
    if it is possible then
        Schedule successively the activities of type $j$ as late as possible within the open resources
    else
        open a new resource
    end if
end for
```

*Heuristic III.* We keep for this heuristic the sorting criteria relative to Heuristic II. Based on this we first schedule the tasks concerning the "easier" type and solve exactly the corresponding sub-problem on the whole horizon, using a branch-and-bound algorithm provided by Cplex10.0. We repeat this previous approach for all the types. The main steps of Heuristic III are reported in Algorithm 3.

**Algorithm 2** Heuristic II

```
Sort the types according to increasing $\overline{F_j} - \underline{F_j}$
for $j = 1$ to $J$ do
    Compute TLB for the first $j$ types
    if it is possible then
        Schedule successively the activities of type $j$ as late as possible within the open resources
    else
        open a new resource
    end if
end for
```

**Algorithm 3** Heuristic III

```
Sort the types according to increasing $\overline{F_j} - \underline{F_j}$
for $j = 1$ to $J$ do
    Successively schedule on the whole horizon each of the activities of the current type by minimizing R taking into account the activities already scheduled.
end for
```

## VII. Computational results

The objective of the computational study we conducted in this paper is to determine and/or assert:

- if the "strong formulation" allows a solver like ILOG-Cplex10.0 to solve to optimality large scale instances;
- if the lower bound ($\lceil Z[\overline{GSPS}]\rceil$) provided by the use of the "strong formulation" is of good quality and obtained quickly;
- if our (TLB) provides a good lower bound for $GSPS$ for both if $H$ is greater than the lower common multiplier of the maximum delays or not;
- the quality of the three upper bounds obtained utilizing the three algorithms we suggest, comparing those performance between each other and between the lower bounds;
- the approaches (I), (II) and (III) we proposed behave well and in a very fast CPU time.

Since no benchmark for $GSPS$ is available nowadays, we consider different two major types of randomly generated instances endowing each a particular structure:

1) ($H < lcm$): $H$ is lower than the lower common multiplier (lcm) of the maximum delays;
2) ($H \geq lcm$): $H$ is greater than or equal to the lower common multiplier (lcm) of the maximum delays. Actually, we set $H = lcm + 1$ (otherwise (lcm) takes very large values).

The rationale for utilizing instances (1) and (2) stems from the theoretical study of $GSPS$ which shows that the lower common multiplier (lcm) of the maximum period plays a key role in the evaluation of lower bound and in the resolution of $GSPS$.

In addition with regard to (1) and (2) problems, parameters $\overline{F_j}$, $\underline{F_j}$ and $n_j$ were respectively uniformly drawn at random in the range $\{1, ..., 20\}$, $\{1, ...\overline{F_j}\}$ and $\{1, ..., 20\}$ (cf. (1)) and such that $\{1, ..., 10\}$, $\{1, ...\overline{F_j}\}$ $\{1, ..., 10\}$ (cf. (2)). We reduce to $10$ the integer value possibility concerning instances (2) because of the largest value of the corresponding (lcm) which implies a very large value for $H$. Indeed, $H$ is a parameter which depends on the value of (lcm) which is computed after generation of the maximum delays. We also generated two sub-types of instances as follows:

(1.a) $(H < lcm)$ and all the parameters $\overline{F_j}$ and $\underline{F_j}$ are randomly generated in the range defined previously;
(1.b) $(H < lcm)$ and a half of the parameters $\overline{F_j}$ and $\underline{F_j}$ are equals and otherwise generated basically;
(2.a) $(H \geq lcm)$ and all the parameters $\overline{F_j}$ and $\underline{F_j}$ are randomly generated in the range defined previously;
(2.b) $(H \geq lcm)$ and a half of the parameters $\overline{F_j}$ and $\underline{F_j}$ are equals and otherwise generated basically.

The coefficient $J$ (i.e the number of types), is given. We chose to get $J = 5$ and $J = 10$. Consequently, the total number of the tasks equal to $\sum_{j=1}^{J} n_j$ is obtained by a simple calculation. On average concerning instances (1), (2) the number of total tasks is respectively equal to $55$, $30$ (cf. $J = 5$) and $106$, $120$ (cf. $J = 10$). We also play on the gap between the values of $\overline{F_j}$ and $\underline{F_j}$ so as to create more difficult instances. Indeed, smaller the gap is so more difficult is $GSPS$ to be solved to optimality in a fast CPU time (see instances (1.b et 2.b)). For example, the relative gap between the maximum and minimum delays is on average equal to $4$ for (1.a) and (2.a) where as it is on average equal to $2$ with regard to instances (1.b) and (2.b) when $\overline{F_j} \neq \underline{F_j}$ otherwise the gap is equal to $0$. In addition, $H$ is approximatively equal to $220$ for the simulations (1) where as its value is on average $400$ for problems (2). Finally, the size of problem $GSPS$ depends on the quantity of the tasks by type and on the size of the horizon time. Consequently the number of variables and contraints of $GSPS$ can be easy computed to give an idea of the difficulty of problems treated. For example, concerning instances (1.a) and (1.b) the problem size is of $12100$ and $23320$ variables whereas with regard to instances (2.a) and (2.b) the number of variables of $GSPS$ is equal to $12000$ and up to $48000$ variables. Thereby, we consider here very large scale problems which suggest that they would be difficult to be solved exactly using ILOG-Cplex10.0, especially for instances (2).

To assess the quality of the two lower bounds (LB) (namely, (TLB) and $\lceil Z[\overline{GSPS}]\rceil$) and the three upper bounds (UB) (cf. instances (1)) we used the optimum (when it can be found) to compute the relative gap (Gap = (UB - optimum)/(UB) or (optimum - LB)/(optimum)). Nevertheless, as the size of the problem $GSPS$ dramatically increases when $H \geq lcm$, the optimum is almost never reached by the use of the branch-and-bound provided by ILOG-Cplex10.0. Consequently, in the context of instances (2) we compared the lower bounds with the value of the upper bound we proposed i.e. Gap = (UB - LB)/(UB).

Our lower (TLB) and upper bounds were coded in C++ langage. The lower bound $\lceil Z[\overline{GSPS}]\rceil$ relative to the LP-relaxation of $GSPS$ as well as the optimum value of $GSPS$ were obtained using the commercial solver ILOG-Cplex10.0. Simulations were run on a bi-weon 3.4 GHz with 4 GB of main memory.

Table I displays the average deviation of each bound to the optimum over ten replications of each types of instances (1). It appears that our (TLB) as well as $\lceil Z[\overline{GSPS}]\rceil$ on average always reach the optimal value. It could be surprising because $H < lcm$ for these instances. Nevertheless, those two lower bounds behave very well even if when the gap between the maximum and minimum delays is small or equal to $0$ (cf. (1.b)). Concerning the feasible solutions, the lowest gap is obtained by Heuristic III which suggests that both sorting the type according to the lowest gap between the maximum and minimum periods and solving exactly each sub-problem corresponding to this selected type provide a feasible solution of good quality. However, Heuristic II (which utilizes the same previous sorting criteria) behaves less well than Heuristic I. Consequently, the only use of criteria relative to Heuristic II would not be sufficient to imply an upper bound closed to the optimum. Finally, for this type of problems (1), the “strong formulation” allows the branch-and-bound of ILOG-Cplex10.0 to solve to optimality most of the instances. Indeed, over $40$ replications, only two were not solved in a time limit equal to $10800$ seconds.

TABLE I
COMPARISON OF THE QUALITY OF THE UPPER AND LOWER BOUNDS WHEN OPTIMUM IS OBTAINED: INSTANCES (1)

| Inst. | # types | (TLB) | H.I | H.II | H.III | $\lceil Z[\overline{GSPS}]\rceil$ |
|---|---|---|---|---|---|---|
| | | Gap (%) | | | | |
| (1.a) | 5 | 0.0 | 9.49 | 22.86 | 5.05 | 0.0 |
| (1.b) | 5 | 0.0 | 10.2 | 25.1 | 7.3 | 0.0 |
| (1.a) | 10 | 0.0 | 12.68 | 28.69 | 5.85 | 0.0 |
| (1.b) | 10 | 0.0 | 13.2 | 29.62 | 6.02 | 0.0 |

Table II is concerned with the average deviation of each lower bound to the upper bounds over ten replications of each types of instances (2). Since, $H$ is greater than the lower common multiplier of the $\overline{F_j}$, its value is very large which implies that the problem size of $GSPS$ model also corresponds to very large instances. Indeed, $GSPS$ is an integer linear program which is well known to be difficult to solve in practice. Moreover, even if Heuristic III still provides the lowest gap, we note that Heuristic I behaves also well. In addition, concering the lower bounds, (TLB) and $\lceil Z[\overline{GSPS}]\rceil$ provide the same lower bound of quite good quality which asserts the theoretically result presented in Corollary 2.

Table III displays the CPU time in seconds required to compute the two lower bounds, the three upper boundsand the optimum (using ILOG-Cplex10.0) concerning instances (1) and (2). The advantage of using greedy heuristics strikingly appears: the branch-and-bound algorithm requires on average at most $291$ seconds to reach the optimum value. In any case, (TLB) and the two feasible solutions given by Heuristic I and II require less than one second to provide a value. The most time consuming bound is the LP-relaxation with a maximum

TABLE II
COMPARISON OF THE QUALITY OF THE UPPER AND LOWER BOUNDS WHEN OPTIMUM IS NOT REACHED: INSTANCES (2)

| Inst. | # types | (TLB) | | | $\lceil Z[\overline{GSPS}]\rceil$ | | |
|---|---|---|---|---|---|---|---|
| | | H.I | H.II | H.III | H.I | H.II | H.III |
| (2.a) | 5 | 8.93 | 10.17 | 6.16 | 8.93 | 10.17 | 6.16 |
| (2.b) | 5 | 9.07 | 11.18 | 7.02 | 9.07 | 11.18 | 7.02 |
| (2.a) | 10 | 21.65 | 40.75 | 3.53 | 21.65 | 40.75 | 3.53 |
| (2.b) | 10 | 22.01 | 41.03 | 4.08 | 22.01 | 41.03 | 4.08 |

of about 987 seconds to solve one of the harder instances (2.b). The time to compute the feasible solution provided by Heuristic III deviates at most of $36.67$ seconds for the largest problems (2.b). As a result, even if the quality of the upper bound obtained by Heuristic III is better than the two others, it takes a running time almost important which will not be advised to be used in a branch-and-bound algorithm. Finally, $\lceil Z[\overline{GSPS}]\rceil$ is very time consuming (up to $987$ seconds). Since in this particular instances, (TLB) and $\lceil Z[\overline{GSPS}]\rceil$ provides the same lower bound, it would be an advantage to utilize (TLB) instead of $\lceil Z[\overline{GSPS}]\rceil$ because of its faster running time.

## VIII. CONCLUSION

In this paper we have studied $GSPS$ which is a generalization of the strictly periodic scheduling problem. After giving some properties, we have designed a simple technique to compute a lower bound (TLB) of good quality and obtained immediately. We also have proposed two mathematical formulations for $GSPS$. We have shown that "strong formulation" is more appropriated to solve $GSPS$. The lower bound derived from the resolution of the LP-relaxation of $GSPS$ "strong formulation" gives a value equal to (TLB) if $H \geq lcm$ and of good quality in any case. Finally, three greedy algorithms are suggested to get feasible solutions. Heuristic I and II provide upper bound of less quality than Heuristic III. Nevertheless, Heuristic III is very time consuming. A possible way to get further improvement of the computation time of the best feasible solution, would be to generate valid cuts so as to accelerate the resolution of each sub-problem.

***Abstract*—In multiobjective optimization, there are several targets that are in conflict, and thus they all cannot reach their optimum simultaneously. Hence, the solutions of the problem form a set of compromised trade-off solutions (a Pareto-optimal front or Pareto-optimal solutions) from which the best solution for the particular problem can be chosen. However, finding that best compromise solution is not an easy task for the human mind. Pareto-optimal fronts are often visualized for this purpose because in this way a comparison between solutions according to their location on the Pareto-optimal front becomes somewhat easier. Visualizing a Pareto-optimal front is straightforward when there are only two targets (or objective functions), but visualizing a front for more than two objective functions becomes a difficult task. In this paper, we introduce a new and innovative method of using three-dimensional virtual reality (VR) facilities to present multi-dimensional Pareto-optimal fronts. Rotation, zooming and other navigation possibilities of VR facilities make easy to compare different trade-off solutions, and fewer solutions need to be explored in order to understand the interrelationships among conflicting objective functions. In addition, it can be used to highlight and characterize interesting features of specific Pareto-optimal solutions, such as whether a particular solution is close to a constraint boundary or whether a solution lies on a relatively steep trade-off region. Based on these additional visual aids for analyzing trade-off solutions, a preferred compromise solution may be easier to choose than by other means.**

## I. Introduction

IN MANY real-world problems, decision making with multiple conflicting objectives in every day operation can be demanding. Moreover, an unfavorable decision can be financially expensive or even hazardous in some situations. There exist different ways to support a decision making process [1], and some of them are based on multiobjective optimization. Multiobjective optimization methods are capable of handling multiple conflicting objectives at the same time. Solutions of the multiobjective optimization problem form a Pareto-optimal front, i.e. a set of compromised trade-off solutions. However, even when different Pareto-optimal solutions are found, choosing a particular optimal compromise solution is not a trivial task. Furthermore, the objectives in a multiobjective optimization task do not need to be commensurable. In such a case, the multiobjective decision making task gets more difficult, especially when the number of objectives is larger than two. This is why there is a need for developing new methodologies for supporting the decision making process.

A Pareto-optimal front, from where an individual final solution can be chosen (e.g. by a decision maker [2]) is often studied with different visualization tools. In this way, the decision maker can extract useful information from the results and thus, a comparison between solutions gets easier. A Pareto-optimal front is quite simple to visualize when there are only two objective functions. However, visualizing with more than two objectives has so far been problematic, and few attempts have been made to visualize a higher dimensional Pareto-optimal front [3], [4], [5]. Virtual reality (VR) is a visualization environment that offers facilities to present high-dimensional spaces and it has also been applied for Pareto-optimal fronts, see [6], [7], [8]. In this paper, we suggest the use of the VR environment not only to visualize a higher dimensional Pareto-optimal front, but also to analyze and understand the nature and relative location of solutions in order to help choosing the best solution for the particular problem.

Basically, the VR is a computer created environment which can be used for visualizing three-dimensional (3D) objects (see, e.g. [9], [10]). Hence it makes possible to visualize and compare solutions which are on a 3D Pareto-optimal front. Thus, a visualized 3D Pareto-optimal front can be examined in many ways: it can be zoomed and rotated, and it also allows the decision maker to dive into the front to get a feel of the nature of the solutions. Moreover, VR enables the user to interact with the visualized Pareto-optimal solutions. This makes easier to compare neighboring solutions and allows the decision maker to learn about the problem and

978-83-60810-14-9/08/$25.00 © 2008 IEEE

the interrelationships among objectives. Based on these VR facilities the decision maker can identify a particular solution which is an adequate compromise.

In this paper, there are two case studies utilizing 3D VR facilities presented. First, we use an evolutionary computation -based multiobjective optimization scheme for generating a large number of Pareto-optimal solutions. In addition, an interactive visualization scheme in the VR is used to decipher some interesting features of the solutions obtained by using existing methodologies such as the concept of *innovization* [11]. Second, there is an industrial example having four conflicting objectives presented. Although we show a few capabilities of a VR system here for decision making purpose, certainly many other innovative methodologies are possible, and this paper should encourage execution of further studies in the coming years.

## II. Multiobjective Optimization and Virtual Reality

A multiobjective optimization problem is often defined as follows:

$$\begin{aligned}&\text{minimize}\,\{f_1(\boldsymbol{x}),\ldots,f_k(\boldsymbol{x})\}\\&\text{subject to }\boldsymbol{x}\in S,\end{aligned}\tag{1}$$

where $\boldsymbol{x}$ is a vector of decision variables from the feasible set $S \subset \mathbb{R}^n$ defined by linear, nonlinear and box constraints. An objective vector can be denoted by $\boldsymbol{f}(\boldsymbol{x}) = (f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), \ldots, f_k(\boldsymbol{x}))^T$. Here we minimize, but if an objective function $f_i$ is to be maximized, it is equivalent to consider minimization of $-f_i$.

Optimality in multiobjective optimization is understood in the sense of Pareto-optimality or non-dominated solutions [12]. The Pareto-optimality is defined as follows: *a decision vector $\boldsymbol{x}' \in S$ is Pareto-optimal if there does not exist another decision vector $\boldsymbol{x} \in S$ such that $f_i(\boldsymbol{x}) \leq f_i(\boldsymbol{x}')$ for all $i = 1, \ldots, k$ and $f_j(\boldsymbol{x}) < f_j(\boldsymbol{x}')$ for at least one index $j$.* These Pareto-optimal solutions form a Pareto-optimal set or a Pareto-optimal front. There are two concepts often used in multiobjective optimization: an ideal objective vector $z^* \in \mathbb{R}^k$ and a nadir objective vector $z^{nad} \in \mathbb{R}^k$ that give lower and upper bounds, respectively, for the objective functions in the Pareto-optimal front (see [2] for details). All the Pareto-optimal solutions are equally good compromises from a mathematical point of view, and there exists no trivial mathematical tool to find the best solution in the Pareto-optimal front. Typically a decision maker, who is an expert in the field from where the problem has arisen, is needed in order to find the best or the most satisfying solution. The decision maker can participate in the process of finding the solution in the different ways and also the different phases of solving process by determining which of the Pareto-optimal solutions is the most satisfying to be the final solution. However, decision making is sometimes tricky, because comparing the numerical values of the solutions is difficult. Thus, some additional information and aids are needed to support decision making process.

### A. Virtual Reality Environment

Virtual reality is a medium which makes it possible to visualize and experience objects from an animated world having visual, sound and haptic experiences realized through immersion, interaction, and collaboration of the VR elements. According to [10] four key elements create the VR environment: a virtual world, immersion, sensory feedback, and interactivity. *The virtual world* is a content of given medium including a collection of objects, and their relationships and rules in the space. *Immersion* into an alternative reality means possibility to perceive something besides the world in which one is living currently. Immersion is sometimes divided into physical and mental immersions, but often they both exist in a VR system. *The sensory feedback* is the third key element. It is based on user's physical position, and the aim is that the objects and the whole space alter depending on the user's position. The last element is *interactivity* which means real-time response to the user's actions. There are many applications that can utilize virtual reality technology: visualizing scientific results, interior design in architecture, and prototype testing in industry [13], [14], for example.

In the VR laboratory objectives can be examined in their real size or small objectives can be enlarged, which makes VR usable in several applications. VR can be also build in PC environment with feasible equipment, software, active stereo glasses etc. Then navigation is not comprehensive as in laboratory, but the user is still able to interact with VR similarly to laboratory environment.

### B. 3D Virtual Reality Utilized in Multiobjective Optimization

The VR system can be used in visualizing Pareto-optimal solutions, and thereby supporting the decision making in a multiobjective optimization process. The flexibility associated with a 3D VR system makes it an alternative way of visualizing the Pareto-optimal front and suing visual information in the decision making process. In addition, analyzing the solutions in order to understand the interactions of objective functions and decision variables comes easier. In Fig. 1 the users utilize a VR environment in order to examine an approximated Pareto-optimal front. The front is controlled (zoomed, rotated and scaled) by the user using a wand (also called a 3D-mouse). In the VR, the users can study the relationships between objective functions and then get ideas what kind of compromises between the multiple objectives can be made. This process will then aid in selecting the final compromised solution. When complexity of the data increases, valuable information of the Pareto-fronts and problem's behaviour can be extracted from graphical presentation efficiently. One should note that the real immersion and 3D objects can be experienced only in a virtual reality laboratory, not in the figures presented in this paper.

Integration of multiobjective optimization and VR requires a computerized algorithm for calculating Pareto-optimal solutions and a hardware system for a VR environment coupled with a software for visualization in stereo [10]. The VR environment used in this research has been built at the University of Kuopio in Finland, and it is based on OpenDX visualization

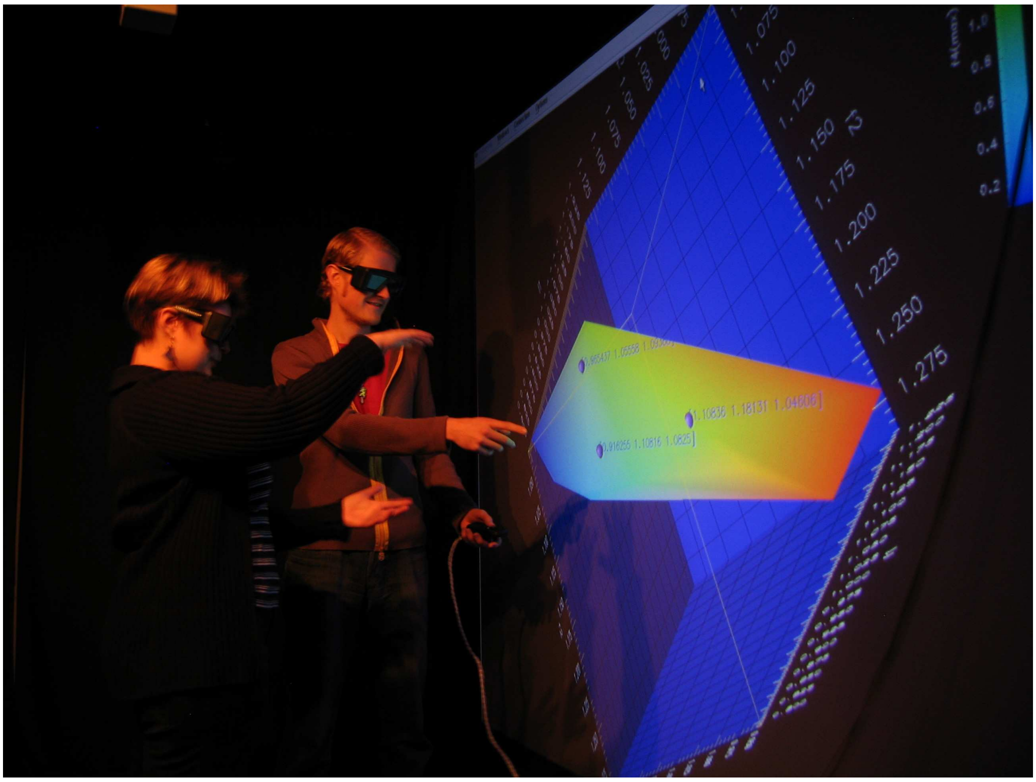

Fig. 1. Analyzing a Pareto-optimal front with the 3D VR system. A 3D Pareto-optimal front visualized in the VR system is presented in a two-dimensional figure here, because the real immersion on a front can be experienced only in a laboratory.

software. Graphics Computer SGI Prism with 8 CPUs (a 64-bit, 1.5 GHz, Intel Itanium 2, 24 GB memory, 48 Gflops) is used with SuSe Linux Enterprise Server 9.3 as an operating system. 3D-effects are generated through wireless set of liquid crystal shutter eye wear (active stereo glasses). Stereo glasses shut alternately left and right eye view with frequency about 45 pictures per eye per second. Visualized 3D-objects (in this paper Pareto-optimal fronts) are controlled through the wand. Polhemus equipment is used to follow the wand's movements to control the objects in the VR environment.

## III. Visualization Examples

In this section, we present two examples illustrating the new visualizing aspects which a VR facility can offer. In the first example, a standard three-objective test problem having a disconnected set of non-linear Pareto-optimal fronts was solved by evolutionary multiobjective optimization (EMO). EMO procedures are generic population-based meta-heuristic optimization algorithms [12]. They use natural evolutionary principles, such as reproduction, mutation and recombination, iteratively to attempt to find a set of Pareto-optimal solutions. EMO methodologies are capable of finding a large set of trade-off solutions as presented in the first example.

In the second example, we consider a real-world paper-making optimization problem with four objective functions in which the advantages of decision making aspects with the VR system are presented. This example was solved by a classical multiple criteria decision making method. The solution process contained two steps, and in the first step a genetic algorithm with a scalarizing function [2] was used. Then neighboring solutions were connected with a hyper-plane in visualization, and any point in the hyper-plane could be chosen as a reference point. Thus, in the second step the corresponding Pareto-optimal solution could be obtained by solving an achievement scalarizing function [2], [5], [15].

### *A. A Test Problem with Highlighted Solutions*

First, we considered a multiobjective optimization test problem (DTLZ6) [16]. In the general form of this problem, there are $k$ objective functions with a complete decision variable vector partitioned in $k$ non-overlapping groups $\boldsymbol{x} \equiv (\boldsymbol{x}_1, \ldots, \boldsymbol{x}_k)^T$. We solved a three-objective version of the problem that is written as follows [16]:

$$\begin{array}{ll} \text{minimize} & \{f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), f_3(\boldsymbol{x})\} \\ \text{subject to} & 0 \leq x_i \leq 1 \text{ for } i = 1, \ldots, 22, \end{array} \tag{2}$$

where the objective functions were defined as $f_1(\boldsymbol{x}_1) = x_1$, $f_2(\boldsymbol{x}_2) = x_2$ and $f_3(\boldsymbol{x}) = (1 + g(\boldsymbol{x}_3))h(f_1, f_2, g)$. The functionals were $g(\boldsymbol{x}_3) = 1 + \frac{9}{|\boldsymbol{x}_3|}\sum_{x_i \in \boldsymbol{x}_3} x_i$ and $h(f_1, f_2, g) = 3 - \sum_{i=1}^{2}\left[\frac{f_i}{1+g}(1+\sin(3\pi f_i))\right]$. The functional $g(\boldsymbol{x}_3)$ required $|\boldsymbol{x}_3| = 20$ variables and $n$ was the total number of variables, here $n = 22$. In this test problem, there were $2^2 = 4$ disconnected Pareto-optimal regions.

The NSGA-II procedure [12] was used as an EMO algorithm in this study and it was run with 1,000 population

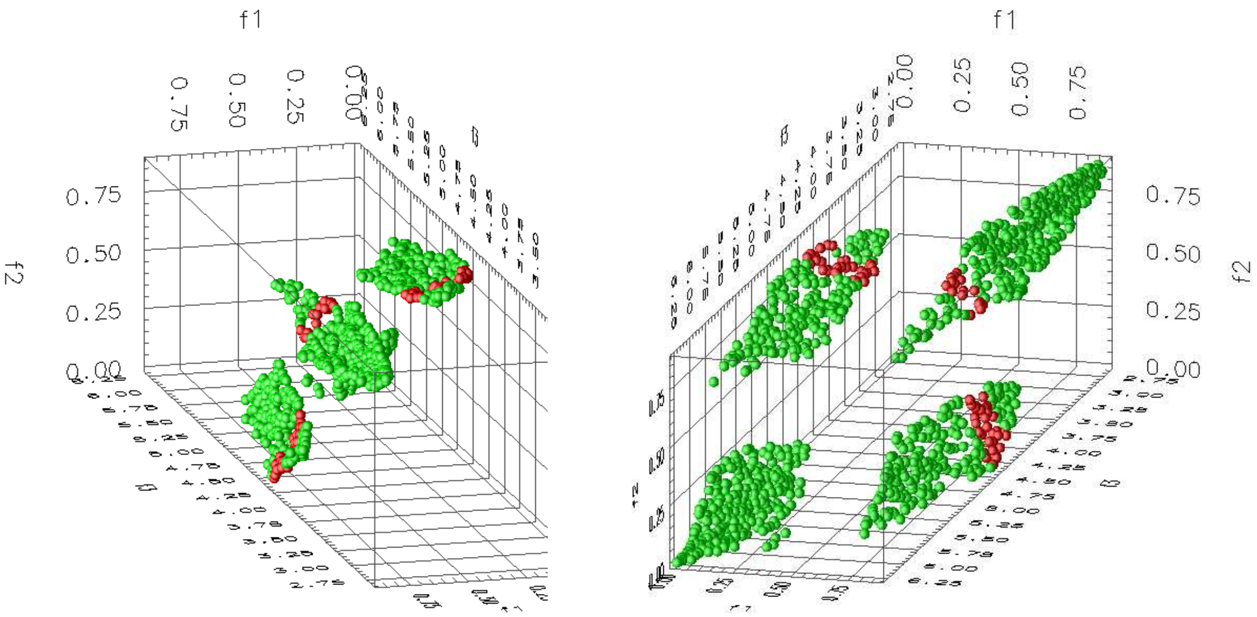

Fig. 2. Disconnected set of nonlinear Pareto-optimal regions (forming the Pareto-optimal front) in evolutionary computation example (DTLZ6) in a VR environment. Solutions having $4.2 \leq f_3 \leq 4.4$ are colored red.

members. The final solutions were visualized with the proposed VR system and they are shown also in Fig. 2. With the 3D visualization capabilities, the nonlinear feature of the disconnected Pareto-optimal regions was much easier to see compared to the earlier studies [16]. In this example, the decision maker was first interested in seeing all the solutions in which $4.2 \leq f_3 \leq 4.4$ as presented in Fig. 2. As one can see in the figure, this constraint made possible quite different compromises between the other two objectives: highlighted solution were located into three separate Pareto-optimal regions. Thus, understanding the trade-offs between different targets was more clear. Moreover, because of zooming, rotating, and immersion possibilities, the Pareto-optimal front was easy to comprehend. Also, the trade-offs between targets were easy to understand, and hopping from one Pareto-optimal region to another got simplified.

In the concept of *innovization* [11], the task of evolutionary multiobjective optimization is followed by a search of hidden interactions among decision variables and objective functions within obtained solutions. This concept has revealed interesting and important insights about design and optimization problems. Here, we argue that the proposed VR based visualization tool can be used as an aid to assist in the *innovization* task. Combining these two concepts allows the decision maker to test the validity of different interrelationships among the decision variables and objective functions. For example, the existence of a given relationship, such as $\Phi(\boldsymbol{f}, \boldsymbol{x}) = 0$, can be tested by marking all solutions (among the obtained EMO solutions) which restrict the absolute value of $\Phi$ within a threshold, say $\epsilon = 10^{-6}$, in red. The location and trace of these solutions on the Pareto-optimal front will provide a plethora of information to the decision maker about the importance of the above relationship before choosing a particular solution. To illustrate, we return to the DTLZ6 test problem and investigate the existence of Pareto-optimal solutions satisfying the following relationships:

$$\begin{aligned}
\Phi_1(\boldsymbol{f}, \boldsymbol{x}) &: x_1 = 0 \quad \text{(Red)},\\
\Phi_2(\boldsymbol{f}, \boldsymbol{x}) &: x_2 = 0 \quad \text{(Blue)},\\
\Phi_3(\boldsymbol{f}, \boldsymbol{x}) &: x_1 = 1 \quad \text{(Brown)},\\
\Phi_4(\boldsymbol{f}, \boldsymbol{x}) &: x_2 = 1 \quad \text{(Purple)}.
\end{aligned}$$

The above conditions check if any Pareto-optimal solution made box constraints on variables $x_1$ and $x_2$ active. In Fig. 3, there are marked all such solutions with $\epsilon = 10^{-6}$. It is interesting to note that there were no solutions on the Pareto-optimal front close to the upper bound of these two variables and there were a number of solutions which were close to their lower bounds. Only a few solutions made $x_1$ close to zero, but there exist a number of solutions which made $x_2$ close to zero. Furthermore, all these solutions seemed to lie on only one of the four Pareto-optimal regions. It could be useful to identify solutions close to constraint boundaries and a further investigation and relaxation of active constraints could lead to better solutions. Such information was not only interesting but could be useful if problem-specific relationships were tested.

As seen from this example, the VR environment can be used as a 3D visualization tool for Pareto-optimal solutions obtained with an EMO procedure. These solutions can be studied with a VR tool not only to make a better visualization of the front, but also to gather more useful information and properties of Pareto-optimal solutions. Next, we present a more complex real-world industrial decision making problem.

### B. Industrial Example: Papermaking Optimization

In papermaking, the aim is to produce paper as much as possible with as low costs as possible [17], [18], [19]. In addition, there are several quality properties which should

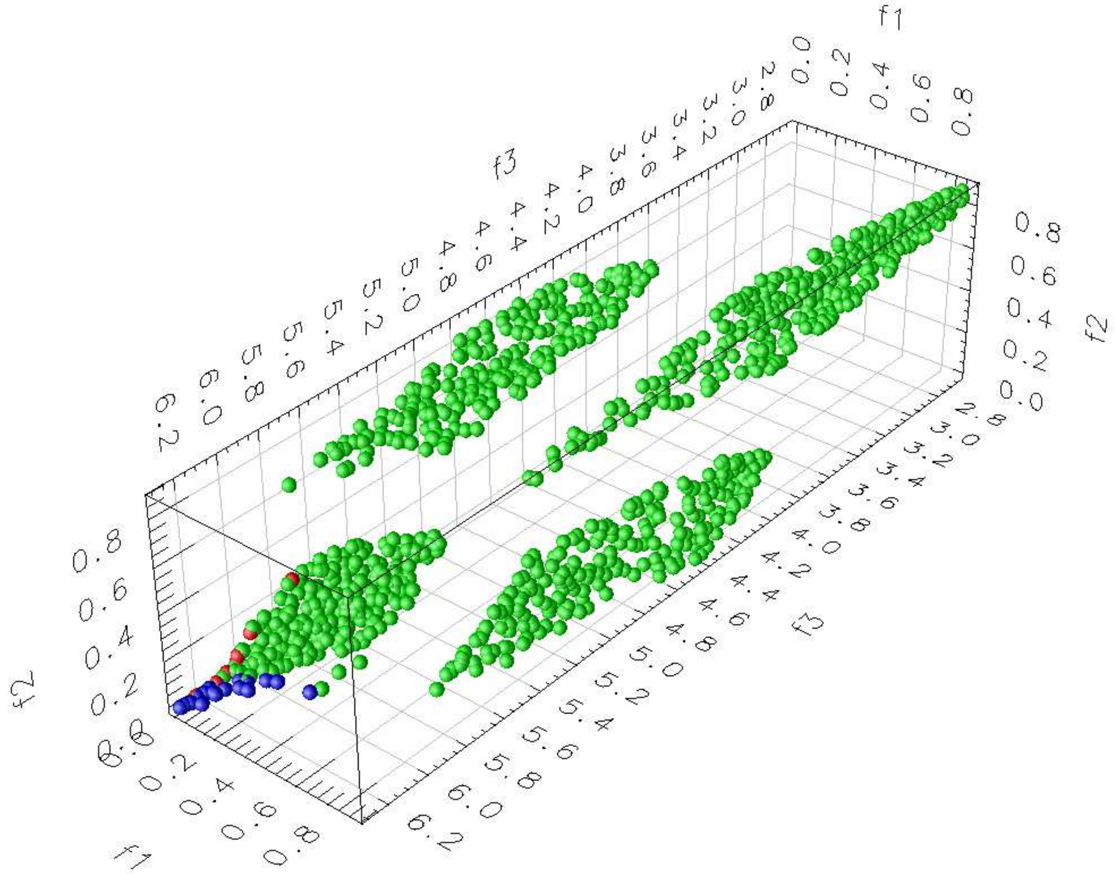

Fig. 3. Pareto-optimal solutions close to the constraint boundaries are highlighted with red and blue colors using the VR environment for the DTLZ6 test problem.

obtain acceptable values at the same time. These targets are often conflicting, and thus the optimization problems become naturally multiobjective. In this example a papermaking optimization problem is studied. Because of the long computational time, the decision maker wanted to compute as few solutions as possible. The Pareto-optimal solutions computed were visualized as 3D points in the VR, and an approximation of a Pareto-optimal front was formed with these few solutions.

In this example, there were four papermaking objectives and eight decision variables. The problem was formed as a model-based optimization problem [18], where the objective function values could be evaluated based on the solution of equations describing the system, i.e. a simulation model of a paper machine. Thus, the optimization problem was written as follows:

$$\begin{aligned} &\text{optimize } \{f_1(\boldsymbol{x},\boldsymbol{q}_1,\ldots,\boldsymbol{q}_{27}),\ldots,f_4(\boldsymbol{x},\boldsymbol{q}_1,\ldots,\boldsymbol{q}_{27})\} \\ &\text{subject to } \begin{cases} A_1(\boldsymbol{x},\boldsymbol{q}_1)=0 \\ A_2(\boldsymbol{x},\boldsymbol{q}_1,\boldsymbol{q}_2)=0 \\ \vdots \\ A_{27}(\boldsymbol{x},\boldsymbol{q}_1,\ldots,\boldsymbol{q}_{27})=0 \end{cases} \\ &\qquad\qquad \boldsymbol{x}\in S, \end{aligned} \tag{3}$$

where $f_1$ presented paper tensile strength ratio and it was given the desired value 3.4. The objective functions $f_2$ and $f_3$ were paper formation and basis weight, which were given the desired values 0.36 $g/m^2$ and 50.5 $g/m^2$, respectively. The fourth objective function $f_4$ was evaporated water which was to be maximized. A vector $\boldsymbol{x} \in S$ contained all the decision variables that were typical controls of paper machine and the feasible set $S$ was formed of their box constraints. Mappings $A_i$ for all $i = 1, \ldots, 27$ denoted unit-process models constituting a simulation model for the entire papermaking process, and $\boldsymbol{q}_i,\ i = 1, \ldots, 27$ were the simulation model outputs [18].

The optimization process contained two separate steps. *In the first step*, a set of the trade-off solutions were calculated with a genetic algorithm with scalarization by achievement scalarizing function. Then, an approximation of the Pareto-optimal front was generated in the VR environment using these solutions. The left plot in Fig. 4 shows the solutions and the approximated front obtained after the first step. The values of the objective functions $f_1, f_2$ and $f_3$ are presented on the axes and $f_4$ is presented by colour in the figure. Here, the proposed VR environment was found to be quite effective tool to explore the multidimensional Pareto-optimal solutions and the approximated front between them. The decision maker observed that there was a conflict between the first two objective functions, i.e. a good tensile strength ratio caused a large formation value which was not desired and vice versa. Thus, there exists a trade-off. Another observation was that a

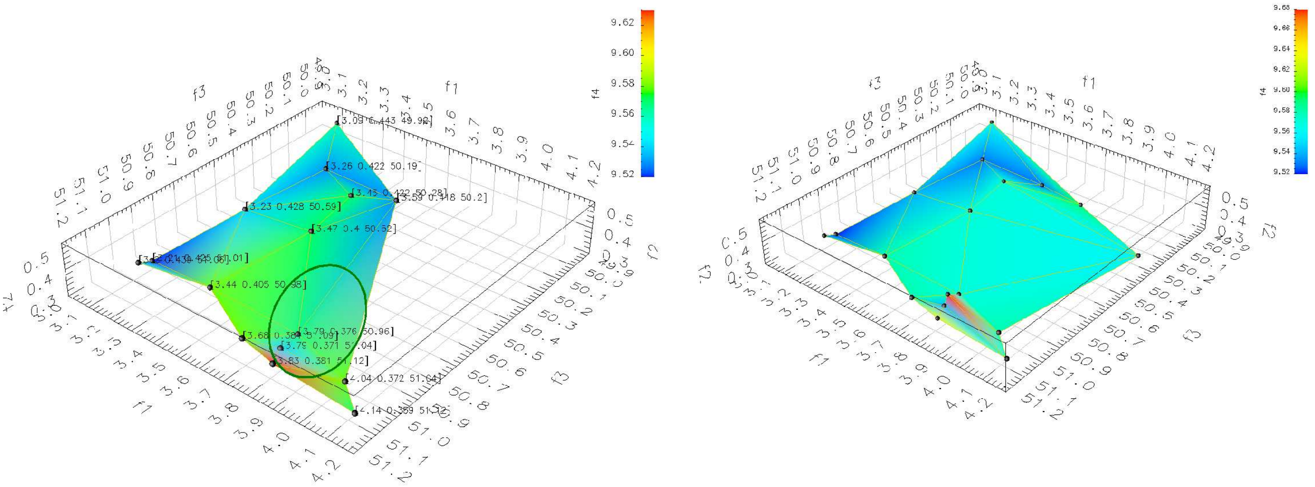

Fig. 4. On the left, solutions after the first step, and on the right, all solutions after the first and the second steps. The objective functions from $f_1$ to $f_3$ are presented as a 3D surface and $f_4$ is presented as a variation in color.

large value of the fourth objective function came with a large value of the third objective function, thereby producing also a conflict between these two objective functions: the desired value of $f_3$ could not be achieved at the same time with a good value of $f_4$. However, there were good compromise solutions between the objective functions on middle and front part of the approximated set. Based on these observations, the region highlighted by an ellipse (shown in the figure) was chosen and the optimization process was re-directed towards this region in the second step. This preference information was obtained with the help of visualization through the VR tool, where the decision maker could examine the existing solutions in many ways by rotating and zooming the Pareto-optimal set.

*In the second step*, three new solutions were calculated with help of the reference point method and the gradient-based optimizer. The decision maker's preferences, the circled region in Fig. 4, was utilized in defining the reference points. Unfortunately, only one of the three new solutions generated was located into the preferred region and other two were located in such a part of the solution space, where there were no solutions after the first step. The plot on the right side in Fig. 4 shows all the solutions, that is the solutions produced in the first step complemented by three solutions produced in the second step. Two of the new solutions were interesting from the papermaking point of view: one located inside the preferred region (circled in Fig. 4) and another one located on the right side having values ($\boldsymbol{f} = (3.78, 0.39, 50.19, 9.59)^T$), which presented also a good compromise between the objective functions. However, the first-mentioned solution (inside the circled part) had objective function values: $\boldsymbol{f} = (3.79, 0.41, 51.02, 9.68)^T$ and it was the most satisfying compromise solution to be the final one according to the decision maker's knowledge.

The ability to visualize trade-off information among objective functions through the 3D VR system makes it possible to focus on interesting part of the solution space. This will certainly enhance the decision making ability in computationally demanding real-world optimization problems and reduce the number of uninteresting solutions needed be calculated. In addition, better visualization technique allows one to get more information about the relationships between the solutions and objective functions than a simple plot of the numerical data. We believe that the VR tool will help the decision maker to understand and analyze the Pareto-optimal front, and thus make it easier to choose a single preferred solution.

## IV. Discussions and Conclusions

In multiobjective decision making, Pareto-optimal fronts are often visualized because in this way a comparison between solutions becomes easier. A Pareto-optimal front is easy to visualize when there are only two objective functions, but visualizing more than two objective functions is problematic. In this paper, we have integrated multiobjective optimization with the 3D VR tool to study the Pareto-optimal solutions and approximated Pareto-optimal fronts to help to make a better decision when choosing the final solution. The 3D VR tool makes easier to compare solutions, navigate from one solution to the other by zooming and rotating the front. Thus, it allows a better comprehension of solutions with desired properties through highlighting. In addition, using sophisticated visualization tools means that fewer solutions need to be computed in order to learn and understand the interrelationships of the conflicting objectives. This is important especially if a problem is computationally expensive (e.g. in real-world industrial cases).

In this paper, different kinds of 3D visualizations with the VR environment have been discussed and demonstrated. First, a large number of solutions forming a dense set of Pareto-optimal solutions obtained by EMO was visualized. In this set, some interesting features of the solutions were highlighted and studied. In the second problem, a few Pareto-optimal solutions were calculated with different optimization techniques and they were visualized using the proposed VR environment. The information gathered from this exercise helped to find an interesting Pareto-optimal region for the decision maker to concentrate. Such a technique will be valuable for handling large number of objective functions.

This paper, so far, has shown a number of advantages of using a VR environment in making a better realization of the Pareto-optimal front in a multiobjective optimization task. In addition, we have emphasized capabilities of VR that helps decision making in real-world applications, which we see as one of the potential application of the VR systems. These initial results are promising and open up a number of challenging research issues, such as handling a large number of objective functions, simultaneous visualization of objective and solution spaces, faster an optimization software and a VR hardware interactions, etc. The purpose of this paper is to discuss the power and usefulness of the VR environment in multiobjective optimization, and to bring out the technique as a new and promising mean of visualizing and understanding complex interactions among objectives and solutions.

*Abstract*—**Particle Swarm Optimization is applied on an instance of single and multi criteria network design problem. The primary goal of this study is to present the efficiency of a simple hybrid particle swarm optimization algorithm on the design of a network infrastructure including decisions concerning the locations and sizes of links. A complementary goal is to also address Quality of Service issues in the design process. Optimization objectives in this case are the network layout cost and the average packet delay in the network. Therefore a multi-objective instance of the hybrid PSO algorithm is applied. The particular hybrid PSO includes mutation to avoid premature convergence. For the same reason repulsion/attraction mechanisms are also applied on the single objective case. Mutation is passed on to the multi-objective instance of the algorithm. Obtained results are compared with corresponding evolutionary approaches.**

## I. Introduction

The increasing complexity of the network design problems calls for advanced optimization techniques. Network design problems where even a single cost function is optimized are often NP-hard [1]. In addition communication network design problems are not time critical. Therefore approaches have been designed to address these problems based in meta-heuristics such as simulated annealing, taboo search, evolutionary computing, nature inspired algorithms or both [2][3]. Concerning evolutionary computing in telecommunication network design, a comprehensive study is presented in [4] up to 2005 containing relevant research study references, where network design problems are classified in node location problems, topology design, tree design, routing, restoration, network dimensioning, admission control and frequency assignment/wavelength allocation. The optimization techniques employed are mainly variations of Genetic Algorithms. Additional work on telecommunication network optimization has followed in the last three years.

Real world network design problems normally involve the simultaneous optimization of multiple and usually partially contradicting objectives. Therefore more often than not, there is not a single optimal solution, given the diversity of the set of objectives, but a set of congruent solutions, known as Pareto-optimal. The topological design of communication networks is usually a multi-objective problem involving simultaneous optimization of the cost concerning network deployment as well as various performance criteria (e.g. average delay, throughput) subject to additional constraints (e.g. reliability, bandwidth). These problem specific objectives are often opposing; for example a way to reduce average delay in the network is over provisioning; that is to increase available link capacities which will consequently result in the increase of the total network deployment cost.

In this paper we will use Particle Swarm Optimization algorithm for the Topological Network Design problem, including capacity allocation, considering shortest path routing. Therefore the target is to design a near optimal network infrastructure, including decisions concerning the locations and sizes of links. For that purpose, a hybrid version of the PSO algorithm will be applied to the real network problem introduced by Rothlauf [5] and its efficiency will be evaluated against GAs. In addition a bi –criteria communication network topology problem is considered to address Quality of Service issues in the design process. For the corresponding delay function, a Poisson traffic model is utilized [1][3][7]. This real world application is addressed using multi-objective PSO. The Pareto front obtained by the MOPSO application is compared to the results obtained by a multi-objective GA (NSGA-II [6]). Relevant work on the subject has been presented in [1][7] among others using EAs. An alternative approach is also proposed in [8] where the relevant Delay Constrained Least Cost Path problem is addressed, utilizing the principle of Lagrangian relaxation based aggregated cost, where a PSO and noising metaheuristic are used for minimizing the modified cost function.

Of crucial importance to the success of the optimization procedure is the choice of candidate solutions representation. Especially for evolutionary algorithms a variety of encodings have been proposed as characteristic vectors, predecessors, Prufer numbers, link and node biasing, edge sets etc. In [8] [9] a tree based encoding/decoding scheme, based on heuristics has been devised for representing the paths as particles. In the presented work a tree is encoded with the network random keys (NetKeys) scheme introduced in [10].

978-83-60810-14-9/08/$25.00 © 2008 IEEE

In [11] Random keys were adapted to represent spanning trees. In this coding, a tree is represented by a string of real-valued weights, one for each edge of the complete graph. Therefore the size of the encoded string for a graph representing *N* nodes is *N∗(N-1)/2*. In order to decode the string, the edges are sorted by their weights and Kruskal's minimum spanning tree algorithm considers the edges in sorted order. The mapping is one to one since any string of weights is a valid tree. Using NetKeys, that represents a tree with normalized real values, allows the optimization algorithms to avoid making binary and hard decisions on whether to establish a link or not.

In Section II a short overview of the PSO and multi-objective PSO algorithm is provided, alterations to the basic PSO algorithm for the single and multi objective cases are introduced and general notes on GA-PSO comparison are made. In Section III the network design problems are formulated (as single and multi-objective problems) and the corresponding fitness functions are defined. In Section IV, the obtained results of the proposed methodology are critically evaluated against the evolutionary algorithms' performance in terms of design goals satisfaction and convergence behavior, while in Section V the most important conclusions and future work are briefly discussed.

## I. Particle Swarm Optimization

### A. Hybrid Simple PSO

Particle Swarm Optimization (PSO) is a population based algorithm that exploits a set of potential solutions to the optimization problem. Each potential solution is called a particle and their aggregation, in each iteration step, forms the swarm. Swarm particles fly through the multi-dimensional problem space subject to both deterministic and stochastic update rules to new positions, which are subsequently scored by a fitness function. Each particle knows the best position $\vec{p}_l$ that it has ever found, called the local best and is also aware of the best position $\vec{p}_g$ found by any neighbor, called the global best.

$$\begin{aligned} \upsilon_{k+1} &= \upsilon_k + c_1\rho_1\left(p_l - x_k\right) + c_2\rho_2\left(p_g - x_k\right) \\ \upsilon_{k+1} &= 7 sign\left(\upsilon_{k+1}\right)\ \min\left\{\left|\upsilon_{k+1}\right|, \upsilon_{\max}\right\} \qquad (1) \\ x_{k+1} &= x_k + \upsilon_{k+1} \end{aligned}$$

Consequently the individual particles are drawn stochastically toward the positions of their own previous best performance and the best previous performance of their neighbors, in accordance to velocity update equations (1) that should be applied to each dimensional component of the velocity vectors, where *k* denotes the generation number, $\vec{x}_k$ and $\vec{\upsilon}_k$ represent the particle's position and velocity, and $\rho_1$, $\rho_2$ are uniformly distributed random numbers between 0 and 1. The parameter $c_1$, associates the particle's own experience with its current position and is called individuality. The parameter $c_2$ is associated with social interaction between the particles of the neighborhood and is called sociality. The velocity clamping parameter $\upsilon_{max}$ controls the algorithm's step size and is applied to all dimensional components of the particle's velocity, thereby limiting the chances that particles will leave the boundaries of the search space. A more refined way of constraining particles is by using "hard boundary conditions" [12], such as the reflective or absorbing boundary conditions. These do not enforce velocity clipping but rather inverse (RBC) or nullify (ABC) the velocity vector.

When the whole swarm is considered as a neighborhood, the global variant of the PSO is employed. Local neighborhoods may also be used to avoid entrapment of the algorithm on local minima but at the cost of slower convergence. For the network design problem specified in the following section, the Inertia Weight variance of PSO was used [13]. A global as well as a grid neighborhood was defined for improved convergence results and the RBC was enforced along with small $\upsilon_{max}$ values.

A major problem with PSO is premature convergence, which results in great performance loss and sub-optimal solutions. In order to avoid premature convergence, diversity guided PSO was utilized (Attractive and Repulsive PSO [14]) whereas mutation was also applied to the particles—hence the term hybrid simple PSO. ARPSO evaluates the global diversity of the swarm, triggering modes of global attraction or repulsion when predefined thresholds are crossed. Mutation has been demonstrated to successfully complement PSO and improve its performance [15][16][17]. In this study uniform mutation is applied to each particle prior to fitness evaluation with a probability of $p_m$, alternating a predefined percentage of the particle. The application of the mutation operator on the swarm improved significantly the convergence behavior of the algorithm.

### B. Comparison to Genetic Algorithms

The PSO shares many similarities with evolutionary computation techniques such as Genetic Algorithms. Both techniques begin with a group of a randomly generated population; utilize a fitness value to evaluate the population and search for the optimum in a partially stochastic manner by updating generations. There are however important differences. Although PSO algorithm retains the conceptual simplicity of the GAs, its' evolutionary process does not create new population members from parent ones; all swarm individuals survive. The original PSO does not employ genetic operators such as crossover and mutation and particles only evolve through their social behavior. Particles' velocities are adjusted, while evolutionary individuals' positions are acted upon. In GAs chromosomes share information with each other, thus the whole population moves like one group towards an optimal area whereas in PSO the information exchange information is a one-way process since only the (local) global best provides information to members of the (sub) swarm. PSO in comparison with GAs, has less complicated operations and it is much easier to implement and apply to design problems with continuous parameters. Moreover in [18] it is shown that binary PSO outperforms GAs in terms of convergence, results and scalability of the problems at hand. In the same study it is suggested that a hybrid model combining characteristics of GA and PSO is preferable. In [19] PSO is shown to exhibit faster convergence compared to GAs. In this paper, the performance of the two algorithms will be compared, for network design problems, since GAs is the EC technique that has been mostly applied to such problems [14].

### *C.Multi Objective PSO*

The main approaches to multi objective optimization consist of weighted aggregation multi objective schemes and population Pareto-based techniques. Pareto-based techniques maintain the set of Pareto-optimal solutions. Pareto-optimal solutions are non dominated solutions in the sense that there are no other superior solutions given the particular search space and set of objectives. Using mathematical notation, a multi-objective optimization problem given a set of *n* objectives and *m* decision parameters is denoted as:

$$\text{Optimize } F(\vec{x})=(f(x), f(x), \ldots, f(x)) \quad (2)$$

Where $\vec{x} \in S$ is a vector satisfying a set of inequality constraints $g_i(\vec{x}) \leq 0,\ i=0,\ldots,k$ . A vector $\vec{u}=(u_{1,}u_{2,}\ldots u_m)$ is said to dominate $\vec{v}=(v_{1,}v_{2,}\ldots v_m)$ if the solution $\vec{u}$ is no worse than $\vec{v}$ in all objectives $(\forall i \in \{1,\ldots,m\},\ F(u_i) \leq F(v_i))$ and the solution vector $\vec{u}$ is better than $\vec{v}$ in at least one objective $(\exists i \in \{1,\ldots,m\},\ F(u_i) < F(v_i))$ . A solution $\vec{x} \in \Omega$ is said to be Pareto-optimal with respect to $\Omega$ , if there is no $\vec{z} \in \Omega$ for which $F(\vec{z})$ dominates $F(\vec{x})$ .

During the past decade, several Multi-Objective Particle Swarm Optimization (MOPSO) methods have been proposed. However there are inherent drawbacks of the PSO algorithm concerning its application on multi-objective optimization. The tendency of the particles to converge to the (single) best solution in the global variant of the PSO is inappropriate for multi-objective optimization, whereas the local variant provides just a refinement near the local optima [20]. Weighted aggregation multi objective schemes were described in [21][22] and Pareto-ranking techniques [23][24][25]. In this study the MOPSO proposed in [25] is used. The particular technique is inspired from MOEA; therefore an external fixed repository is used in which every particle deposits its flight experiences after each flight cycle. The updates to the repository are performed considering a geographically-based system defined in terms of the objective function values of each particle. The search space is divided in hyper-cubes that are appointed a fitness value based on the containing number of particles (fitness sharing). Roulette-wheel is applied to select the hypercube from which a leader for a particle of the swarm will be selected randomly. Mutation as in (II-A) is also applied to the particles with possibility $p_m$.

## II. Real World Telecommunication Tree Network Design Problem

Optimum Communication Spanning Tree Problem (OCSTP) is a special case of the Network Design Problem. Given a connected graph $G=(V,E)$ , *V* represents the node set and *E* the arc set (links). There are communication demands among the nodes V. The traffic demands are specified by a demand matrix *R= (r* $_{ij}$*)* where $r_{ij}$ is the volume of traffic demand among nodes *i, j* for all $(i,j) \in E$ . A distance matrix *D=(d*$_{ij}$*)* represents the distance among sites for all $(i,j) \in E$ . The problem can be stated as: given a set of node locations $G=(V,E)$ specific traffic demand and distance among every set of nodes *i* and *j* , the goal is to construct a spanning tree such that the total cost of communication is minimum among all the spanning trees of *G*. In the classical OCST problem as proposed by Hu [29] the cost of the tree is calculated as the product of the distance of the edge times the overall traffic over the edge. However in real world network design problems, capacity of links is assigned in discrete increments and this is the case that will be addressed in the particular study.

Simple generational genetic algorithms have been proved to provide adequate solutions for the particular problem [10] . However PSO is a simple and robust to control parameters algorithm, whereas the computational efficiency of the technique in comparison the GAs, renders it attractive for application in large scale network design optimization problems. In [26] the authors prove that PSO outperforms GAs in terms of computational efficiency, although the quality of the solutions found is similar in unconstrained nonlinear problems with continuous design variables. Therefore we utilize NetKeys encoding the importance of the links in a continuous manner (see section I ).

In order to evaluate the performance of the PSO on this special case of the network design problem, benchmarking of the algorithm against an instance of the OCST has been performed. Several instances of the OCSTP problem have been presented in literature. In most of them [26][7] the communication cost was given by (3) for a variety of node sets, traffic and distance matrices.

$$min \sum_{i,j \in V} r_{ij} \times d_{p_{(i,j)}} \quad (3)$$

Rothlauf [5] introduced a set of real world telecommunication tree network design problems from a company with nodes located around Germany with modular link capacities. The available capacities for the links are discrete, determined by a fixed cost – for link installation - and a variable cost. The cost of the link per capacity is piecewise linear and monotonically increasing with the length of the link, with decreasing slope (Figure 1).

One instance proposed will be utilised in the particular study. It involves the creation of a communication network including one headquarter and 15 branch offices [10]. It deals with the cost optimization of a rooted spanning tree, where the root of the initial connected graph *G* is the “headquarter” realizing demands towards branch offices. This instance is being studied since it resembles tree/star hierarchical access networks [3]. The demand matrix and the location of the nodes as well as the modular cost function are provided in [28].

The formulation of the single objective problem is given by (4) where F denotes the set of used links, $d_{ij}$ the distance weights of the links between nodes *i* and *j*, $Cap_{i,j}$ the capacity of the links and $b_{ij}$ the traffic flowing directly and indirectly over the link between nodes *i* and *j.* The second equation in (4) denotes that the capacity of the link connecting nodes *i* and *j* must exceed the overall traffic flowing over that link. The form of one available capacity type function is presented in Figure 1.

$$\begin{gathered} min \sum_{i,j \in F} f\left(d_{i,j}, Cap_{i,j}\right) \\ b_{i,j} < Cap_{i,j} \end{gathered} \tag{4}$$

Very often topological design of WANs involves determining the links between nodes given the mean or peak inter node traffic so as to optimize certain QoS parameters [3]. In the multi-objective optimization case presented, the total network cost and average link delay is minimized simultaneously to obtain a Pareto front including optimal non-dominated solutions. A typical *M/M/1* queuing delay model is assumed [1][7] for one type of network service. Therefore two objective functions are used; the cost function delineated by the previous paragraph and the following delay fitness function.

$$min\ AvgDelay$$

$$AvgDelay = \frac{\sum_{i}\sum_{j} \frac{LinkFlow_{i,j}}{Cap_{i,j}} - LinkFlow_{i,j}}{\sum_{i}\sum_{j} LinkFlow_{i,j}} \tag{5}$$

## III. Results

A global and a local version of the hybrid PSO were applied to the Single Objective (SO) problem regarding optimization of network topology deployment. The presented results were obtained after repeating the optimization process for 100 times in order to obtain more statistically important indicators on the algorithm's convergence behavior over several runs.

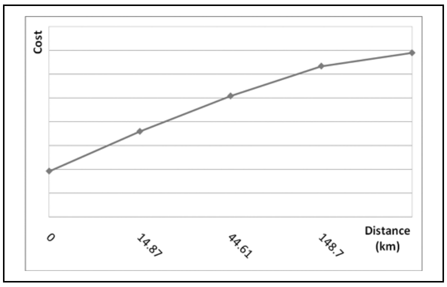

Fig. 1 Link Cost per Capacity

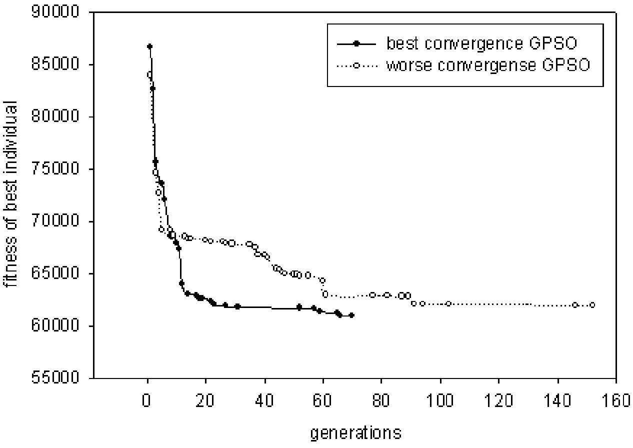

Fig. 2 Convergence Behaviour of Global PSO

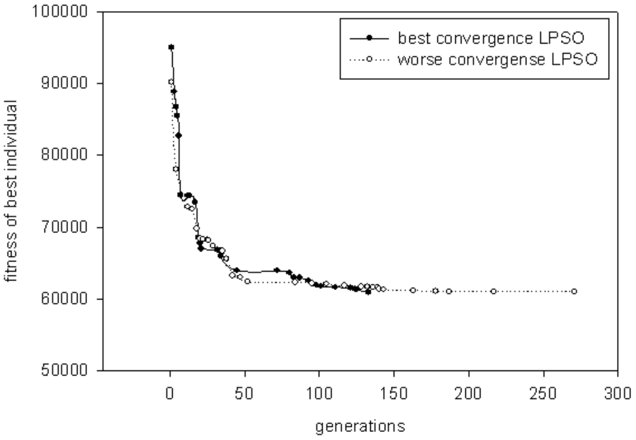

Fig. 3 Convergence Behaviour of Local PSO

The inertia weight PSO was set to sociality $c_1$=0.9, individuality $c_2$=0.9 and a velocity clamping of $\upsilon_{max}$= 0.11. The inertia weight parameter was gradually reduced from $w_1$=0.7 to $w_2$=0.2 during the optimization run. Repulsion threshold was set to 0.1 whereas attraction threshold to 0.2. Mutation was enforced with a probability of 0.005 alternating 10% of the particle (12 edges of the complete graph represented by a particle of 120 edges for 16 nodes). The PSO parameters were found to produce optimal results for the given problem formulation after several trial runs.

In Figure 2 the convergence behavior of the PSO with a global neighborhood is presented while solving the SO network design problem. Indicators included in Table I represent obtained mean fitness value, standard deviation of fitness values and normalized deviation of the mean value from the best solution which is depicted in Figure 4. The best run was able to locate the global best configuration of the network within 70 generations, requiring a total of 17920 fitness function evaluations (for a swarm population of 256 particles). In terms of convergence the worse run was able to obtain a fitness value of 61934.27 on the 152th generation and afterwards stagnated on this local minimum position. Overly, when the algorithm was allowed to evolve for a maximum of 390 generations, it failed to obtain the global minimum 46 times thus yielding an effective success rate of 54%. Although the mean fitness value obtained for the 100 runs (61051.91) is numerically close to the absolute minimum value of 60884.2 for the presented problem, the above results indicate that the use of a global neighborhood can often lead to premature convergence on non-globally optimal solutions.

Respectively, the convergence behavior of the PSO when a rectangular grid neighborhood topology (lateral size = 16) is employed while solving the same network design problem, is presented in Figure 3. The convergence indicators are presented in table Table I (100 runs). The best run was able to locate the global optimum of the problem within 133 generations, requiring a total of 35245 fitness function evaluations (for a swarm population of 265 particles). The worse run was able to obtain a fitness value of 61005.19 on the 271th generation and afterwards stagnated on this local minimum position. When the algorithm was allowed to evolve for a maximum of 390 generations, it failed to obtain the global minimum 11 times thus yielding a success rate of 89%. The obtained mean fitness value (60891.59) improves on the mean value obtained from the PSO with a global neighborhood, indicating that the use of a grid neighborhood improves the convergence behavior of the optimization algorithm for the selected problem. Another key aspect highlighting the above conclusion is that the mean fitness value of the non-successful runs is lower compared to the respective values obtained with a global PSO. Nevertheless, the improved convergence behavior comes at the expense of slower convergence (mean number of generations required to obtain best solution).

The proposed methodology shows an improvement in most cases over the results obtained and presented in [7]. Both PSO variations are able to outperform the performance of the GA with a tournament selection scheme with the exception of the obtained fitness deviation indicator value when the global-neighborhood PSO is used (Table I). The latter can be attributed to the already highlighted worst convergence behavior of the global PSO variant. The indicator values obtained when a grid neighborhood is used shows a ten-fold improvement over the respective GA result for the normalized deviation indicator (0.121% vs. 0.77%).

On the other hand, when a GA is employed using (μ+λ) selection, the obtained mean value is better than the respective value of the grid neighborhood PSO (60886.62 vs. 60891.59), although the PSO optimums have a smaller deviation (40 vs. 23.35). The deterministic nature of the (μ+λ) selection helps to preserve the encoding of the so far best solution found in the population but no analogous mechanism exists in the PSO algorithm. The slightly better performance of the GA over the local PSO in terms of $p_w$ (0.0039 vs. 0.0121%) can be attributed to this effect.

Concerning the multi-criteria instance of the network design problem, the only change applied in PSO parameters was velocity clamping of $\upsilon_{max}$= 0.7. Regarding the multi-objective GA, the algorithm was specified with $p_c$=0.8 and $p_m$=0.005 as crossover and mutation probabilities respectively whereas binary tournament selection, uniform crossover and random mutation on each component of the particle with $p_{m.}$ The results were carried with the same instance of the 16 node network design problem for a population of 265 particles and 400 generations.

The target is to compare the Pareto fronts that are obtained with the same number of fitness evaluations, with a relatively small number of iterations and population size. The fronts from the two multi-objective algorithms are depicted in Figure 5. We notice that the MOPSO algorithm

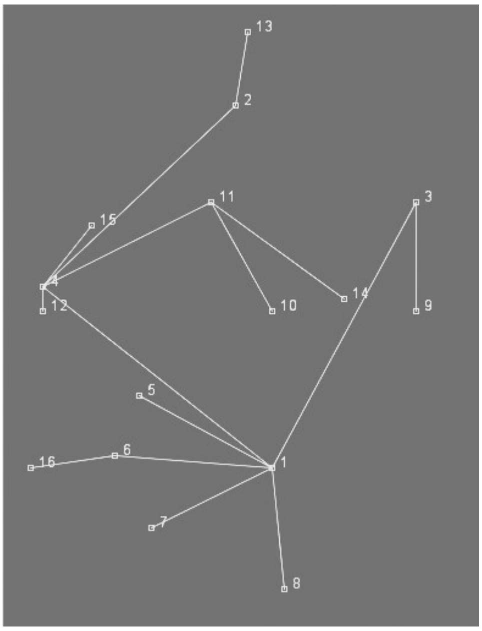

Fig. 4 Optimum Network Topology

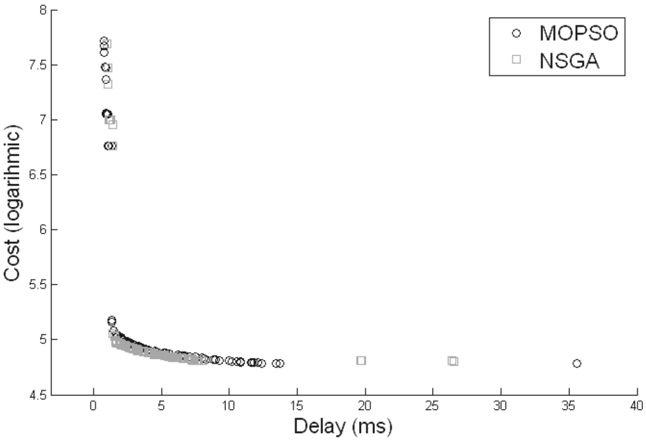

Fig. 5 Pareto Front Comparison among NSGA-II and MOPSO

with mutation, although it acquires a smaller number of non dominated solutions these are more evenly distributed in comparison to NSGA-II. Moreover a wider range of non dominated solutions were obtained in order to approximate the front with more accuracy. With the NSGA-II algorithm a

region of the front is acquired. In this region it slightly outperforms the MOPSO in terms of the quality of non dominated solutions.

From the network designer's point of view the solution fronts can be divided into three different areas IV, a Low Cost High Delay (LCHD) region, a Medium Cost Medium Delay (MCMD) region and High Cost Low Delay (HCLD) region. In this case in the LCHD area the cost of infrastructure deployment was chosen arbitrarily to be lower than 65.000 whereas in the HCLD area over 150.000 For the LCHD region the MOPSO algorithm with mutation as well as the NSGA-II obtain similar number of solutions though again the range of the MOPSO solutions is greater. Non dominated solutions in this area are easier to obtain than the HCLD region. However it must be noted that concerning the HLDC region the multi-objective PSO outperforms the NSGA-II both in terms of quality and range. Finally the NSGA-II acquires a slightly better approximation of the Pareto front in the MCMD region.

## IV. Conclusions—Future Work

In the particular study, a hybrid version of a single and multi objective PSO algorithm was applied successfully on a communications network topology design problem. The multi-criteria instance of the problem addresses also QoS issues. Optimization objectives in this case are the network layout cost and the average packet delivery delay. NetKeys representation of candidate solutions is utilized. This hybrid version of the particle swarm algorithm applies mutation to the swarm with a probability of $p_m$ whereas additional mechanisms (inertia weight, attraction/repulsion) are utilized to improve convergence behaviour. The proposed methodology shows an improvement in the optimization process in comparison to GAs, concerning both the single and multi objective instance. Future work will include the application of PSO metaheuristic on the topological design of multiservice networks for realistic self similar traffic models.

***Abstract*—In this paper, we present a new multi-criteria assignment problem that groups characteristics from the well known Bin Packing Problem (BPP) and Generalized Assignment Problem (GAP). Similarities and differences between these problems are discussed, and a new variant of BPP is presented. The new variant will be called generalized assignment problem with identified first-use bins (GAPIFB). The GAPIFB will be used to supply decision makers with quantitative and qualitative indicators in order to optimize a business process. An algorithm based on the GAP problem model and on GAPIFB is proposed.**

## I. Introduction

Within the context of the French competitive cluster[1] "Industrie du commerce", with the collaboration of COFIDIS[2] and ALFEA consulting[3], the project GOCD[4] aims to set up a new dematerialized workflow system, to treat the received contracts at COFIDIS. Our participation was to install a new optimization and decision-making tool for the new system with the necessary key performance indicators. Every day, COFIDIS receives from the post office thousands of contracts and credit demands of different types (for facility we will use the terms contracts for contracts and credit demands). The quantities and the types of contracts are known in the morning and can change from one day to another. Some contracts must be treated at the same day others can wait for some days. The treatment time for a contract by a collaborator is defined by a matrix of competence, as each collaborator has different skills and experiences with respect to contract type. The contracts are distributed currently to company collaborators according to past acquired experience in heuristic method. This distribution is not optimal, but hoped to be approximated to the optimal one. The daily work hours for the collaborators are not equal, in reason of human resources management considerations. If the capacity of the collaborators is overloaded, the decision makers can either come to the aid of temporary workers to treat the overloaded contracts or they can holdup the treatment of unimportant type of contracts. The objective is to find the best distribution of contracts that will best exploit collaborators capacities, and to determine if the daily load of contract exceeds current collaborators capacities. In this case decision makers need to know the exact number of temporary workers required to treat all the contracts. This problem can be seen as a multi-criteria optimization problem with discrete variables.

In examining the actual used heuristic, we can identify three problems. The first one concerns the assignment method used to distribute contracts. In this method, contracts are distributed depending on previous experience, and not on approved optimal method. Bad distribution of contracts could lead to unnecessary call of temporary workers. Different distributions of contracts could result in different total time of treatment, this can be seen clearly when the current load of contracts is close to company optimal capacity. The second problem is to detect in advance overloaded situations and to decide which contracts to treat if decision makers don't prefer to hire temporary workers. The third problem is to determine the exact number of temporary workers when needed. To the best of our knowledge, there is no model capable to represent completely these problems; rather we find models with partial solution for partial problem.

The paper is organized as follow. In the next section, a formulation of the problem is presented. In section three, we study two famous assignment problems, the BPP problem and GAP problem. The different variants of each problem are discussed and their weaknesses regarding our problem are clarified. We will demonstrate that neither of these problems can solitary gives a complete answer to the mentioned problem. In section four, we present our approach to solve the problem, followed by mathematical formulation and evaluation results. We terminate by our conclusions and future work.

## II. Problem formulation

A generic formulation and notation for the problem is as the following

- $NC$ : Number of all tasks (contracts),
- $N$ : Number of primary agents (company workers),

[1] A competitive cluster is an initiative that brings together companies, research centers and educational institutions in order to develop synergies and cooperative efforts. http://www.industrie.gouv.fr/poles-competitivite

[2] French consumer credit company. http://www.cofidis.com

[3] French information system consulting company. http://www.alfea-consulting.com

[4] GOCD : French acronym for Management and optimization of document life cycle

978-83-60810-14-9/08/$25.00 © 2008 IEEE

- $M$ : Number of available secondary agents (temporary workers),
- *CAP*: Primary or secondary agents capacities (in hours), $CAP = \{CAP_1, CAP_2, .., CAP_N, .., CAP_{N+M}\}$,
- $T_{ij}$: Needed time for primary or secondary agent *i* to treat task *j*,
- $U_i$: Boolean. 1 if primary or secondary agent *i* is used, otherwise 0, $U = \{U_1, U_2, .., U_N, .., U_{N+M}\}$,
- $X_{ij}$: Boolean. 1 if task *j* is assigned to primary or secondary agent *i*, otherwise 0.

The objective functions are

$$Min \sum_{i=1}^{N+M} U_i \tag{1}$$

$$Min \sum_{j=1}^{NC} X_{ij} \times T_{ij} \tag{2}$$

Subject to,

$$\sum_{i=1}^{N+M} X_{ij} = 1, \qquad \forall j \in \{1, 2, .., NC\} \tag{3}$$

$$\sum_{j=1}^{NC} X_{ij} \times T_{ij} \leq CAP_i \times U_i, \qquad \forall i \in \{1, 2, .., N+M\} \tag{4}$$

$$U_i = 1, \qquad \forall i \in \{1, 2, .., N\} \tag{5}$$

Notice that for all *i* ∈{1, 2,.., N}, $U_i$ represents a primary agent and for all *i* ∈{N+1, N+2,.., N+M}, $U_i$ represents a secondary agent. The objective function (1) searches to minimize the number of secondary agents used to treat all tasks. We have chosen in objectives function (2) to minimize the total treatment time as example, other objectives can be designed by the decision makers. Constraint (3) indicates that all tasks must be distributed, and each task is given only to one agent. Constraint (4) explains that the capacity of each used agent must not be violated. Finally constraint (5) is used to be sure that all primary agents are used. As we can see, our problem is a specific case of this generic case, where the contract treatment time is defined by its type and the agent treating it. For simplification, in our proposed solution, we will reformulate the generic problem and new notations will be used where the contracts of the same type assigned to one agent are presented by one integer variable in stead of a set of binary variables for each contract. In fact, we pass from linear multi-criteria problem with binary integer to linear multi-criteria problem with integer variables and this will reduce the number of variable to use. For example, an instance of the problem with 100 primary agents, 10 available secondary agents, 5 contract type and 3500 contracts, will need 385110 binary variables if we use binary representation (100+10 variable to present agents and 100+10*3500 to present the contracts). Whereas by grouping the contract of the same type assigned to an agent will require 660 variables (100+10 variable to present agents and 100+10*5 to present the assigned contracts)

## III. Bin packing and Generalized assignment problems

In literature, we find some assignment problems which are similar to our problem. These problems were widely studied and analyzed. The closest ones to our problem are Bin Packing Problem and Generalized Assignment problem.

Bin packing problem(BPP) is well known for being one of the combinatorial NP-hard problems [1]. Many researches were realized to find the optimal or an approximated solution for this problem [2] [3] [4]. In its simplest form, we have a set of bins of equal capacity and a list of objects, each object has an equivalent weight (costs of treatment) for all bins. The objective is to find the minimum number of bins in order to pack all the objects in the list. A bin packing problem can be either on-line or off-line. In on-line packing problem, we have information only about the current object in the list to be packed, and no objects can be repacked later. In off-line packing problem complete information about all objects are known in advance. Variants of BPP include, two dimensional bin packing [5] [6] [7] [8] and three dimensional bin packing problem [9] [10], in which each object have either two dimensions (area) or even three dimensions (volume). Another variant and well studied BPP is the extendable bin packing problem [11] [12] , where the sizes of the bins are extendable when necessary to answer work needs.

Another famous problem is the generalized assignment problem (GAP), a generalization of Multi-knapsack problem [13]. In GAP problem, a set of objects with cost and profit, are assigned to a set of agents. Each object can be allocated to any but only one agent, and the treatment of an object needs resources which change, depending on the object and the agent treating it, each agent can have different capacity. The objective is to maximize the profit without exceeding agent's capacities. A survey on the algorithms used to solve this problem can be found in [14].

It is clear that the two models have different objectives and different formulation. In the BPP problem, we search to minimize the number of used bins to pack all the objects without any consideration to profit. Whereas in the GAP problem, profit is considered but the allocation of all objects is not important, which means the possibility to have an optimal solution without distributing all objects. More over, in BPP the objects have an equal value whatever was the bin used to pack them, which is not the case in the GAP problem, where the profit of an object depends on the object and on the agent. From the previous description for BBP and GAP problem, we see that our assignment problem corresponds to GAP problem in that it search to optimize certain predefined objectives by decision makers. But unfortunately, it is unable to determine the minimum number of temporary workers needed to achieve these objectives in overloaded cases, as the number of bins (workers in our problem) in GAP problem must be defined in advance.

On the other hand, BPP model can find the minimum number of workers to treat all the contracts. Still neither classical form nor its variants are capable to distinct between company collaborators and temporary workers in there solution. This can lead to solutions which exclude some company workers if the utilization of temporary workers gives better solutions than using company workers. This is an important matter, as we must first verify company workers capability to treat all the contracts and to wait decision maker to decide whether to hire temporary workers or not. Before integrating temporary workers with company workers to find optimal solution.

## IV. Proposed Approach

To solve this multi-criteria problem, we propose to decompose it into two mono-criteria problems. Each mono-criteria problem is presented by a model, and an exact method is used to find the optimal solution for each of these models as the size of our problem is not large. We can imagine this solution in two stages. In the first stage, we use GAPIFB model to search the minimum number of secondary agents needed to treat all contracts. This is a major concern to enterprise managers as it is considered the most enterprise financial resources consumers. In GAPIFB, a set of tasks (objects) must be assigned to a set of agents (bins). The size of each task can vary from one agent to another, agent's capacities are not equal, and the set of agents includes two types of agents, primary agents and secondary agents. The use of secondary agents is allowed only when the primary agents are not capable to treat all the tasks. The objective function is to find the minimal number of secondary agents to be used with the primary agent to treat all the received contracts. At the end of this stage, decision maker not only knows company situation if it is overloaded or under loaded but also he knows the exact number *EN* of secondary agents needed to treat all contracts in overload situation. Decision maker must also decide whether the company will hire secondary workers or not, and if the decision was to hire secondary workers, is it to hire the exact number of secondary workers needed to treat all the contracts or to hire certain number *L* of needed secondary workers?

In the second stage, a group of objectives function is available to decision maker which supply him with comprehensive vision of all possible decision scenarios that can be taken, and their effect on company contracts distribution process. The choice of this objective is left to decision makers. One objective can be to give high treatment priority to contracts that can not be delayed or to contracts considered as profitable to the company. Another objective could be to treat important contracts types uniquely by company collaborators as they have the best experience and skills. The fairness of collaborators loads can be significance objective from the social vision of point. To maximize the rate of profitability by collaborators can be an interesting objective from economic vision. For facility in this paper, an objective function which is to minimize the total treatment time of contracts was been chosen. Figure 1 demonstrates decision making process for our approach. Mathematical formulation for GAPIFB and GAP models are discussed in details in the next sections.

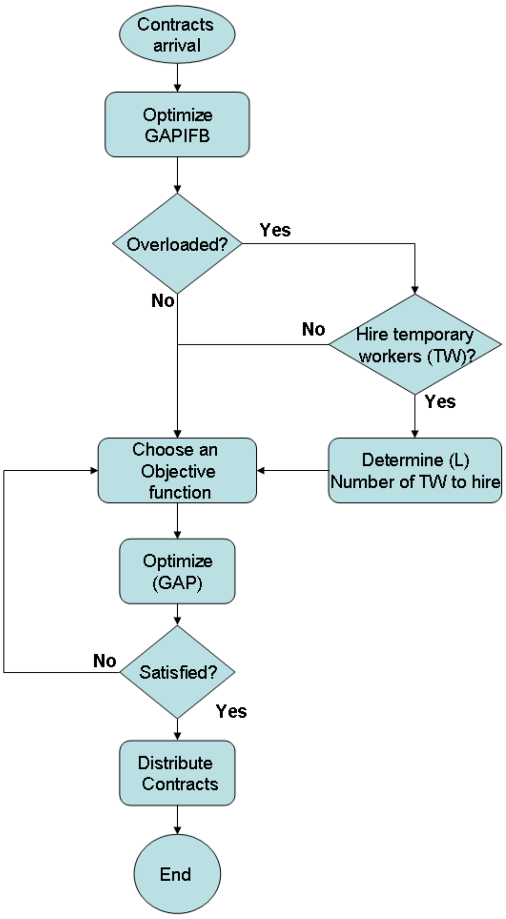

Fig. 1. Proposed decision making process

### A. Mathematical formulation

For the first stage, a linear formulation with integer variables is used to present GAPIFB. In GAPIFB, a set of tasks(contracts) must be assigned to a set of agents(bins). The size of each task can vary from one agent to another, agent's capacities are not equal, and the set of agents includes two types of agents, primary agents and secondary agents. The use of secondary agents is allowed only when the primary agents are not capable to treat all the tasks. The objective function is to minimize the number of secondary agents used with primary agents to treat the whole quantity of received tasks. In this formulation we used binary variable $U_i$ to represent both primary agents and secondary agents, where for *i* ∈{1, 2,.., N}, $U_i$ represents a primary agent and for *i* ∈{N+1, N+2,.., N+M}, $U_i$ represents a secondary agent. $X_{ij}$ is used to indicate the number of tasks of type *j* attributed to primary or secondary agent *i*. Notice that in this stage, $X_{ij}$ is an integer variable and not binary variable, and $T_{ij}$ presents the treatment time for contract of type *j* by agent *i*. The new modified notations and a formulation to the first stage objective function with constraints are given as follows:

- *Z*: Number of tasks types,
- $QT_j$: Quantity of tasks of type *j*,

- $T_{ij}$: Needed time for primary or secondary agent *i* to treat a task of type *j*,
- $X_{ij}$: The number of tasks of type *j* assigned to primary or secondary agent *i*.

$$Min \sum_{i=1}^{N+M} U_i \tag{6}$$

Subject to

$$\sum_{j=1}^{Z} X_{ij} \times T_{i,j} \leq CAP_i \times U_i, \qquad \forall i \in \{1,2,..,N+M\} \tag{7}$$

$$\sum_{i=1}^{N+M} X_{ij} = QT_j, \qquad \forall j \in \{1,2,..,Z\} \tag{8}$$

$$\sum_{i=1}^{N} U_i = N, \tag{9}$$

Constraint (7) ensures that the capacity of agents is not violated. Constraint (8) ensures that all tasks are allocated and each task is assigned to only one agent. To ensure that the solver will search the optimal solution within the solutions that used all primary agents we added constraint (9), where $U_i$ presents a primary worker ∀ i ∈{1,2,...,N}. Without constraint (9), it is possible that the solver gives us a solution that excludes some primary agent if the use of secondary agents gives better results.

The second stage is formulated as classical GAP problem. Consider the following.

- *L* : Number of secondary agents to be hired (decision maker decision),
- $i \in \{1, 2, ..., L\}$ and $j \in \{1, 2, ..., Z\}$.

As we mention before we consider here only one objective function which is to minimise the total treatment time for all contracts. In using the new notation, the objective function (2) is replaced by the objective function (10) as the following:

$$Min \sum_{i=1}^{N+L} \sum_{j=1}^{Z} X_{ij} * T_{ij} \tag{10}$$

Subject to

$$\sum_{j=1}^{Z} X_{ij} \times T_{ij} \leq CAP_i, \qquad \forall i \in \{1,2,..,L\} \tag{11}$$

$$\sum_{i=1}^{L} X_{ij} = QT_j, \qquad \forall j \in \{1,2,..,Z\} \tag{12}$$

Constraint (11) ensures agent capacity not to be violated. Constraint (12) ensure that the distributed quantity of tasks type *k* is less than the received quantity of that type.

### B. *Evaluation and test results*

In order to evaluate our approach, a formulation of the problem as mixed integer program was realized[5]. The optimal solution in the two stages were computed using Cplex9[6] solver, which uses an advanced mathematical programming and constraint-based optimization techniques. Many samples were generated randomly with different numbers of primary agents and secondary agents and with different competence matrix and different capacities for each sample. The quantities and types of each tasks was generated to be near to the average of company capacity. It was found that the proposed approach is capable to detect under loaded situation and to find the optimal solution to distribute all tasks. In overloaded situation, the proposed GAPIFB model was able to find the minimum number of secondary agents needed to treat all the tasks, all company agents were included in every produced solution. Within the size of our problem, the execution time was ordered in milliseconds for bothe the first stage and in the second stage. This execution time was very satisfactory for company decision makers. When the number of contracts increases respectively with the number of agents (primary and secondary), execution time is increased to be in seconds. In fixing the number of primary agent and increasing the number of available secondary agent the execution time increase considerably. Table 1 shows the execution time for some realized samples.

## V. Conclusion

In this paper, we presented a new multi-criteria assignment problem for decision making and proposed a new exact approach to solve it. The problem consists of allocating a set of different type of tasks to a set of primary agents; in case of overload secondary agents can be used to treat all tasks. Each agent has different capacity and different experience per task type according to matrix of competence. The treatment time of a task, as a result, will depend on the type of the task and the agent treating it. The first objective is to determine company situation (underloaded or overloaded) and to give the exact number of secondary agent in the overloaded cases. The second objective is to give a comprehensive vision of all possible scenarios for allocating tasks to decision maker. To solve this problem we divided it into two parts (stages) with mono-objective function for each. Exact methods were used to solve each stage. In the first part, we used the proposed GAPIFB. This model is able to distinguish between primary agent and secondary. Primary agents imperatively appear in the optimal solution, which is not the case in using simple form of BPP where the solver search the optimal solution whatever was the agent to use. This makes it possible to exclude some primary agents if the use of secondary agent gives best solution. In addition, simple BPP defines fixed treatment cost by task type, which is not the case in GAPIFB.

[5] Tests were held on Intel Dual Core T7200 2.00GHz machine, 2Go of RAM

[6] CPLEX : an optimization software package produced by ILOG. http://www.ilog.com/

TABLE I
SIMULATION RESULT FOR THE FIRST STAGE—GAPIFB OPTIMISATION

| Primary agents | Secondary agents | Number of contracts | Execution time second |
|---|---|---|---|
| 100 | 15 | 3500 | 0.047 |
| 100 | 15 | 3500 | 0.031 |
| 100 | 15 | 3500 | 0.031 |
| 500 | 75 | 17500 | 0.078 |
| 500 | 75 | 17500 | 0.078 |
| 500 | 75 | 17500 | 0.073 |
| 1000 | 150 | 35000 | 0.141 |
| 1000 | 150 | 35000 | 0.125 |
| 1000 | 150 | 35000 | 0.14 |
| 5000 | 750 | 175000 | 1.00 |
| 5000 | 750 | 175000 | 1.031 |
| 5000 | 750 | 175000 | 1.016 |
| 10000 | 1500 | 350000 | 3.172 |
| 10000 | 1500 | 350000 | 3.14 |
| 10000 | 1500 | 350000 | 3.187 |
| 15000 | 2250 | 525000 | 6.375 |
| 15000 | 2250 | 525000 | 6.312 |
| 15000 | 2250 | 525000 | 6.297 |

In the second stage, a GAP model is used with different objective functions to give decision makers ideas about the suitable method to distribute the tasks. Others objectives can be used, this choice is left to company decision makers.

A formulation with integer variables was used instead of binary variable to implement GABIFB, which reduce the total number of variables. In this formulation, both primary and secondary agents are represented as binary variables. Many samples were generated and tested, and our approach proved to be capable to define the minimum number of needed secondary agent. The time of execution was ordered in milliseconds. Future work can be conceived to extend our work in order to deal with and take in consideration contracts flow for long period e.g. one week flow. Other objective functions to distribute the contracts can be imagined in order to construct and supply new efficient Key Performance Indicators (KPI) for the decision makers.

# Adaptive Differential Evolution and Exponential Crossover

Josef Tvrdík
University of Ostrava, Department of Computer Science
Email: josef.tvrdik@osu.cz

***Abstract*—Several adaptive variants of differential evolution are described and compared in two sets of benchmark problems. The influence of exponential crossover on efficiency of the search is studied. The use of both types of crossover together makes the algorithms more robust. Such algorithms are convenient for the real-world problems, where we need an adaptive algorithm applicable without time-wasting parameter tuning.**

## I. Introduction

THE GLOBAL optimization problem is considered in this paper in the following form:

$$\text{minimize } f(\boldsymbol{x}) \quad \text{subject to} \quad \boldsymbol{x} \in D,$$

where $\boldsymbol{x}$ is a continuous variable with the domain $D \subset \mathbb{R}^d$, and $f(\boldsymbol{x}) : D \rightarrow \mathbb{R}$ is a continuous function. The domain $D$ is defined by specifying boundary constrains, that are lower $(a_j)$ and upper $(b_j)$ limits of each component $j$, $D = \prod_{j=1}^{d}[a_j, b_j],\ a_j < b_j,\ j = 1, 2, \dots, d$. The global minimum point $\boldsymbol{x}^* = \arg\min_{\boldsymbol{x}\in D} f(\boldsymbol{x})$ is the solution of the problem. The global optimization problems that use boundary constrains only are usually referred as unconstrained ones [1], due to the fact, that boundary constrains are easy to handle and in computer numerical solution there are ”natural” boundary constrains, given by the representation of numbers in floating-point format.

The global optimization problem is not easy to solve and standard deterministic algorithms tend to stop the search in local minimum nearest to the input starting point. Therefore, heuristic search is widely used in the global optimization. Such heuristics are often inspired by natural processes, mainly by the evolution in populations. Evolutionary algorithms are able to find the acceptable solution with reasonable time demand, but efficiency of the search is sensitive to the setting of control parameters. Application of evolutionary algorithms usually requires time-consuming tuning of control parameters to the problem to be solved. Thus, great effort has been focused to the development of self-adaptive variants of evolutionary algorithms, applicable without preliminary tuning of control parameter.

## II. Differential Evolution

The differential evolution (DE) was introduced by Storn and Price [2]. Nowadays the DE has become one of the most frequently used evolutionary algorithms solving the global optimization problems [3]. The algorithm of DE in pseudo-code is shown in Fig. 1. New trial point $\boldsymbol{y}$ (line 4 in DE algorithm) is generated by using mutation and crossover.

There are various strategies, how to create the mutant point $\boldsymbol{v}$. The most popular strategy denoted by abbreviation DE/rand/1/ generates the point $\boldsymbol{v}$ by adding the weighted difference of two points

$$\boldsymbol{v} = \boldsymbol{r}_1 + F\left(\boldsymbol{r}_2 - \boldsymbol{r}_3\right), \tag{1}$$

where $\boldsymbol{r}_1, \boldsymbol{r}_2$ and $\boldsymbol{r}_3$ are three mutually distinct points taken randomly from population $P$, not coinciding with the current $\boldsymbol{x}_i$, and $F > 0$ is input parameter.

```
1 initialize population $P = (\boldsymbol{x}_1, \boldsymbol{x}_2, \dots, \boldsymbol{x}_N)$, $\boldsymbol{x}_i \in D$
2 repeat
3     for $i := 1$ to $N$ do
4         generate a new trial vector $\boldsymbol{y}$
5         if $f(\boldsymbol{y}) < f(\boldsymbol{x}_i)$ then insert $\boldsymbol{y}$ into new generation $Q$
6                             else insert $\boldsymbol{x}_i$ into new generation $Q$
7         endif
8     endfor
9     $P := Q$
10 until stopping condition
```

Fig. 1. Differential evolution—Algorithm in pseudo code

Kaelo and Ali [4] proposed a slightly different attempt to generating a mutant point $\boldsymbol{v}$ by (1). They called it random localization. The point $\boldsymbol{r}_1$ is not chosen randomly, but it is tournament best among $\boldsymbol{r}_1$, $\boldsymbol{r}_2$, and $\boldsymbol{r}_3$, that is $\boldsymbol{r}_1 = \arg\min_{i\in\{1,2,3\}} f(\boldsymbol{r}_i)$.

The crossover operator constructs the offspring $\boldsymbol{y}$ by mixing components of the current individual $\boldsymbol{x}_i$ and the point $\boldsymbol{v}$ generated by mutation. There are two types of crossover used in DE, binomial and exponential ones.

Binomial crossover replaces the elements of vector $\boldsymbol{x}_i$ using the following rule

$$y_j = \begin{cases} v_j & \text{if} \quad U_j \le CR \quad \text{or} \quad j = l \\ x_{ij} & \text{if} \quad U_j > CR \quad \text{and} \quad j \ne l\,, \end{cases} \tag{2}$$

where $l$ is a randomly chosen integer from $\{1, 2, \dots, d\}$, and $U_1, U_2, \dots, U_d$ are independent random variables uniformly distributed in $[0,\ 1)$. $CR \in [0, 1]$ is an input parameter influencing the number of elements to be exchanged by crossover. Eq. (2) ensures that at least one element of $\boldsymbol{x}_i$ is changed, even if $CR = 0$. This kind of crossover according to (2) is commonly expressed by abbreviation DE/·/·/bin.

For exponential crossover (DE/·/·/exp), the starting position of crossover is chosen randomly from $1, \ldots, d$, and $L$ consecutive elements (counted in circular manner) are taken from the mutant vector $\boldsymbol{v}$. Probability of replacing the $k$-th element in the sequence $1, 2, \ldots, L, \quad L \leq d$, decreases exponentially with increasing $k$. There are two main differences between binomial and exponential crossovers:

- $L$ adjacent elements are changed in exponential variant, in binomial one the changed coordinates are dispersed randomly over the dimensions $1, 2, \ldots, d$.
- While the relation between the probability of crossover and the *CR* is linear in binomial crossover; in the exponential one, this relation is nonlinear, and the deviation from linearity enlarges with increasing dimension of problem.

Probability of crossover, $p_m$, determines the number of exchanged elements ($p_m$ being the mean value of relative frequency). Zaharie [5] derived the relation between $p_m$ and *CR* for exponential crossover. Her result can be rewritten in the form of polynom

$$CR^d - \ d\, p_m\, CR + \ d\, p_m - 1 = 0. \tag{3}$$

It is apparent that the polynom (3) has the only one real root in the open interval of $(0, 1)$ for $p_m \in (1/d, 1)$. The crossover parameter $CR = 0$ for $p_m = 1/d$, and for $p_m = 1$ the value of $CR = 1$. Thus, for given $p_m$ we can find unique corresponding value of *CR*, to be set as crossover parameter.

Differential evolution has a few control parameters only, namely the size of population $N$, selection of mutation strategy, choice of crossover type, and pair of parameters $F$ and *CR*. However, the efficiency of differential evolution is very sensitive especially regarding the setting of $F$ and *CR* values. The most suitable control parameters values for specific problem may be found by trial-and-error tuning, but it requires a lot of time. There are some recommendations for the setting of these parameters. Zaharie [6] suggested the intervals for the control parameters based on the variability of population, for other proposals see [2], [3], [7], [8].

Self-adaptive setting of control parameters was studied in several papers. Ali and Törn [9] proposed a simple rule for adapting the $F$ scaling factor value during the search process. Some other attempts to the adaptation of DE control parameters are summarized in Liu and Lampinen [10]. Recently, Quin and Suganthan [11] proposed self-adaptive choice of mutation strategy combined with controlled random adjusting the values of $F$ and *CR*.

Evolutionary self-adaptation of control parameters $F$ and *CR* suggested by Brest et al. [12] and competitive self-adaptive setting of the control parameters introduced by Tvrdík [13] (both variants with binomial crossover) have proved good convergence in the applications to various problems of the global optimization [14]. Experimental comparison of these self-adaptive patterns and influence of exponential crossover is the goal of this paper. These self-adaptive algorithms are described in detail in next section.

## III. Variants of DE in Comparison

DE with evolutionary self-adaptation of $F$ and *CR* was proposed by Brest et al. [12]. The values of $F$ and *CR* are initialized randomly for each point in population and survive with the individuals in population, but they can be mutated randomly in each generation with given probabilities $\tau_1,\ \tau_2$. Authors used binomial crossover with the values of $CR \in [0,\ 1]$ distributed uniformly, and DE/rand/1 mutation with values of $F$ also distributed uniformly in $[\,F_l,\ F_u]$. They set input parameters $F_l = 0.1$, and $F_u = 0.9$.

The competitive setting of the control parameters was described in [13]. In this self-adaptation approach, we choose among $H$ different settings of $F$ and *CR* randomly with probabilities $q_h,\ h = 1, 2, \ldots, H$. These probabilities are modified according to the success rate of the settings in preceding steps of search process. The $h$-th setting is considered successful, if it generates such a trial point $\boldsymbol{y}$ that $f(\boldsymbol{y}) < f(\boldsymbol{x}_i)$. Probability $q_h$ is evaluated as the relative frequency

$$q_h = \frac{n_h + n_0}{\sum_{j=1}^{H}(n_j + n_0)}\ , \tag{4}$$

where $n_h$ is the current count of the $h$-th setting successes, and $n_0 > 0$ is a constant. The setting of $n_0 > 1$ prevents a dramatic change in $q_h$ by one random successful use of the $h$-th parameter setting. To avoid degeneration of the search process, the current values of $q_h$ are reset to their starting values $q_h = 1/H$, if any probability $q_h$ decreases bellow some given limit $\delta > 0$. Several variants of such competitive differential evolution with binomial crossover were numerically compared in [15], and two best performing variants were included into open Matlab library [16].

The mutation according to (1) could cause that a new trial point $\boldsymbol{y}$ moves out of the domain $D$. In such case, the point $\boldsymbol{y}$ can be skipped and a new one generated. More effective attempt is to replace value of $y_j < a_j$ or $y_j > b_j$, either by random value in $[a_j,\, b_j]$, see [7], or by reversed value of this coordinate $y_j$ into $D$ over the $a_j$ or $b_j$ by mirroring, see [17]. The latter method is used in algorithms implemented for numerical tests.

The goal of experiments was to compare the impact of crossover type to the performance of in the both self-adaptive kinds of DE algorithm.

The four most efficient competitive variants from twelve variants of DE tested in [18] are selected for experimental comparison. These variants have proved significantly better efficiency than the standard DE. Two variants in experiments are based on the Brest approach to self-adaptation [12] and two other variants in experimental tests combine both approaches. The tested variants are denoted by mnemonic labels.

The labels of competitive variants begin with capital letter ”C” in bellow text. In variant label, the type of crossover is followed by number of competing settings. The presence of random localization is marked by suffix ”rl”. Where the variant uses both types of crossover, ”rl” is related to both of them. Nine settings of $F$ and *CR* for binomial crossover are created from all combinations of $F \in \{0.5, 0.8, 1\}$ and *CR* $\in \{0, 0.5, 1\}$). If there are 6 settings in competition only, the value $F = 1$ is not used. The same values of $F$ are used for exponential crossover. However, *CR* values are derived from the crossover probability, given by (3). Actual values of crossover probability can vary in interval $[1/d,\ 1]$, because at least one coordinate of current point $\boldsymbol{x}_i$ in changed in both types of crossover. Notice, that for extreme values of probability, $p_m = 1/d$ and $p_m = 1$, exponential crossover does not differ from binomial one. In order to ensure the different behaviour of exponential crossover from binomial one, the following three levels of crossover probability $p_1$, $p_2$, $p_3$ were chosen. Value of $p_2$ is in the middle of the interval $[1/d,\ 1]$, $p_1$ in the middle of the interval $[1/d,\ p_2]$, and $p_3$ in the middle of the interval $[p_2,\ 1]$, i.e.

$$p_2 = \frac{1 + 1/d}{2}, \quad p_1 = \frac{1/d + p_2}{2}, \quad p_3 = \frac{p_2 + 1}{2}. \tag{5}$$

The values of crossover probability and the corresponding values of parameter *CR* for $d = 10$ and $d = 30$ are given in Table I.

TABLE I
VALUES OF CROSSOVER PROBABILITY AND THE CORRESPONDING VALUES OF *CR* PARAMETER FOR EXPONENTIAL CROSSOVER

| | $d = 10$ | | | | $d = 30$ | | |
|---|---|---|---|---|---|---|---|
| $i$ | 1 | 2 | 3 | | 1 | 2 | 3 |
| $p_i$ | 0.3250 | 0.5500 | 0.7750 | $p_i$ | 0.2750 | 0.5167 | 0.7583 |
| $CR_i$ | 0.7011 | 0.8571 | 0.9418 | $CR_i$ | 0.8815 | 0.9488 | 0.9801 |

Two variants based on Brest approach are labeled *Brestbin* and *Brestexp*. *Brestbin* uses binomial crossover with control parameters values recommended in [12], i.e. $\tau_1 = \tau_2 = 0.1$ and $F_l = 0.1$, $F_u = 0.9$. In the *Brestexp* variant, values of *CR* are distributed uniformly in $[CR_1,\ CR_3]$, see Table I. The random localization was not applied in these variants.

The last two variants of DE in tests combine both the competitive and Brest self-adaptive mechanisms. Two types of crossover compete according the rules described above, the parameters of crossover are the same as in *Brestbin* and *Brestexp*. Two pairs of *CR* and $F$ values are kept with each individual in population, the first pair is used for exponential crossover and the second pair for binomial one. Variant labeled *Brestcmp* is without random localization. In variant labeled *Brestcmprl* random localization is applied to the mutation.

Thus, four competitive DE variants, labeled *Cbin9rl*, *Cexp9rl*, *Cbin9exp9rl*, and *Cbin6exp6rl* are included into experimental comparison with four other variants labeled *Brestbin*, *Brestexp*, *Brestcmp*, and *Brestcmprl*.

## IV. Experiments and Results

### A. Standard Benchmark

*1) Test Functions:* Five commonly used functions [9], [3], [2] were applied as standard benchmark:

- Ackley function—multimodal, separable,

$$f(\boldsymbol{x}) = -20\exp\left(-0.02\ \sqrt{\tfrac{1}{d}\textstyle\sum_{j=1}^{d} x_j^2}\right) - \\ -\exp\left(\tfrac{1}{d}\textstyle\sum_{j=1}^{d}\cos 2\pi x_j\right) + 20 + \exp(1)$$

$x_j \in [-30, 30]$, $\boldsymbol{x}^* = (0, 0, \dots, 0)$, $f(\boldsymbol{x}^*) = 0$.

- Griewank function—multimodal, nonseparable,

$$f(\boldsymbol{x}) = \sum_{j=1}^{d} \frac{{x_j}^2}{4000} - \prod_{j=1}^{d} \cos\left(\frac{x_j}{\sqrt{j}}\right) + 1$$

$x_j \in [-400, 400]$, $\boldsymbol{x}^* = (0, 0, \dots, 0)$, $f(\boldsymbol{x}^*) = 0$.

- Rastrigin function—multimodal, separable,

$$f(\boldsymbol{x}) = 10\,d + \sum_{j=1}^{d} [{x_j}^2 - 10\cos(2\pi x_j)]$$

$x_j \in [-5.12, 5.12]$, $\boldsymbol{x}^* = (0, 0, \dots, 0)$, $f(\boldsymbol{x}^*) = 0$

- Rosenbrock function (banana valley)—unimodal, nonseparable,

$$f(\boldsymbol{x}) = \sum_{j=1}^{d-1} \left[100(x_j^2 - x_{j+1})^2 + (1 - x_j)^2\right]$$

$x_j \in [-2.048, 2.048]$, $\boldsymbol{x}^* = (1, 1, \dots, 1)$, $f(\boldsymbol{x}^*) = 0$.

- Schwefel function—multimodal, separable, the global minimum is distant from the next best local minima,

$$f(\boldsymbol{x}) = -\sum_{j=1}^{d} x_j \sin(\sqrt{\mid x_j \mid})$$

$x_j \in [-500, 500]$, $\boldsymbol{x}^* = (s, s, \dots, s)$, $s = 420.968746$, $f(\boldsymbol{x}^*) = -418.982887\,d$

Two levels of problem dimension were chosen, $d = 10$ and $d = 30$. The names of test functions (or their self-explaining abbreviations) are used as labels when reporting the results.

*2) Experiments and Results:* One hundred of independent runs were carried out for each function and level of $d$. The search was stopped if the difference between maximum and minimum function values was less than $1e{-}6$ or number of function evaluations (hereinafter *ne*) exceeded the limit $20000\,d$. Population size was set to 40 for problems with $d = 10$ and 60 for for problems with $d = 30$. Parameters controlling the competition of settings were set to $n_0 = 2$, and $\delta = 1/(5\,H)$.

Number of function evaluations *ne* and the success of search were recorded in each run. The search was considered successful, if $f_{min} - f(\boldsymbol{x}^*) < 1e - 4$, where $f_{min}$ is the minimum value of objective function in final population. The reliability (estimator of convergence probability), hereinafter $R$, was evaluated as the percentage of successful runs.

The performance of variants were compared using Q-measure. The Q-measure was proposed by Feoktistov [7] to integrate time demand and reliability into a single criterion of convergence. The formula of Q-measure is

$$Q_m = \overline{ne}/R, \tag{6}$$

where $\overline{ne}$ is the average of number of function evaluations in successful runs and $R$ is the reliability in %.

TABLE II
COMPARISON OF VARIANTS USING THE VALUES OF Q-MEASURE.

| $d$ | Variant | Ackley | Griewank | Rastrig | Rosen | Schwefel | Average |
|---|---|---|---|---|---|---|---|
| 10 | Cbin9rl | 176 | 179 | **152** | **250** | 135 | 178 |

| 10 | Brestexp | 100 | 89 | 100 | 100 | 100 | 97.8 |
| 10 | Brestcmp | 100 | 96 | 100 | 100 | 99 | 99.0 |
| 10 | Brestcmprl | 99 | 64 | 95 | 96 | 93 | 89.4 |
| 30 | Cbin9rl | 100 | 100 | 100 | 100 | 100 | 100.0 |
| 30 | Cexp9rl | 100 | 100 | 100 | 100 | 100 | 100.0 |
| 30 | Cbin9exp9rl | 100 | 100 | 100 | 100 | 100 | 100.0 |
| 30 | Cbin6exp6rl | 100 | 100 | 100 | 100 | 100 | 100.0 |
| 30 | Brestbin | 100 | 97 | 100 | 100 | 98 | 99.0 |
| 30 | Brestexp | 100 | 82 | 100 | 98 | 98 | 95.6 |
| 30 | Brestcmp | 100 | 95 | 100 | 100 | 100 | 99.0 |
| 30 | Brestcmprl | 85 | 66 | 100 | 93 | 82 | 85.2 |

The values of Q-measure for all variants and test functions are shown in Table II. The best and second best values of $Q_m$ are printed bold, the best values are underlined. Comparing the performance of self-adaptive variants of DE, *Brestcmprl* was the best in 7 of 10 test problems and its averages of $Q_m$ are the smallest for both dimension levels, but it does not appeared within best two variants in some problems (Rosenbrock, problem dimension $d = 10$, Rastrigin, both levels of dimension).

Reliability of the search is shown in Table III. Comparing the values of $Q_m$ in Table II and reliability in Table III, it is apparent, that higher efficiency of *Brestcmprl* is paid by less reliability of the search by this algorithm. Overall view shows that competitive variants are more reliable, but sometimes less efficient than the variants based on the evolutionary self-adaptive mechanism proposed by Brest et al.

### *B. Composition Functions*

The novel hybrid benchmark functions were proposed by Liang et al. [19], in order to make testing more similar to real-world problems. Commonly used standard benchmark problems are criticized due to the fact that their global minimum points have the same coordinate values in each dimension (the case of all functions in our standard benchmark), or the global minimum point is in the domain center of gravity (the case of Ackley, Griewank, and Rastrigin). The novel hybrid benchmark functions are not featured with any kind of such symmetry. Each of them is composed from several various functions by non-trivial transformations including matrix rotation. Thus, they are non-separable functions with many local minima, and the global minimum point cannot be found easily.

Six evolutionary algorithms were tested in this composite functions benchmark in [19]. Among these algorithms, comprehensive learning particle swarm optimization (CLPSO) was the most efficient in CF1, CF2, CF3, and CF5 problems, standard PSO algorithm in CF4 problem, and a variant of DE with exponential crossover in CF6 problem. Details and references are given in Liang et al.

*1) Experiments and Results:* The same eight variants of self-adaptive DE tested with standard benchmark were applied to hybrid benchmark functions. To enable the comparison of our results with the experimental results of the algorithms in [19], the arrangement of experiments was the same, i.e. for each test function, each algorithm was run 20 times and maximum function evaluations are set to 50,000 for all the algorithms. The domains are $D = \prod_{j=1}^{10}[-5, 5]$ for all test functions. Population size was set up to $N = 50$ for all the algorithms in tests. Other control parameters had values used for standard benchmark.

The averages and standard deviations of computed minimum function values of 20 runs are reported in Table IV respectively. Results of the best algorithm from [19] are reported, as well. The values less than the best ones found in [19] are printed bold, the least value for each function is underlined. The value 0 in CF1 column stands for the positive values less than 4.94e-324, which is the accuracy of double-precision arithmetic used in the implementation environment.

From eight new self-adaptive variants of DE, at least four variants outperformed the most successful algorithm in [19] for each function except CF6. In the case of CF4 even all seven variants were more efficient than the best algorithm reported in [19]. For CF1 problem, five self-adaptive variants achieved better results than those reported former, but the solution found by CLPSO in [19] is acceptable, so the improvement attained by self-adaptive variants is not important. Surprisingly, the bold values of standard deviation in Table IV are scarce, what implies that only small part of self-adaptive DE variants is more robust than the best algorithms from [19].

There is no unique winner among the DE variants tested on composition benchmark problems. However, we can con-

clude that the novel self-adaptive DE variants were able to outperform advanced evolutionary algorithms in the majority of these hard test problems.

## V. CONCLUSIONS

Both self-adaptive patterns used in tested variants have proved the efficiency. All eight novel self-adaptive DE variants outperformed standard evolutionary algorithms in some test problems.

These results were achieved with implicit setting of control parameters without tuning their values. For given subset of benchmark problems the population size was set the same for all the DE variant. The influence of population size on algorithm efficiency was not examined in this study. This question should be solved in future including an attempt to solve some self-adaptive mechanism of population size.

The use of stand-alone exponential crossover increases efficiency in comparison with binomial crossover only for small part of problems. Applying competitive parameter setting together with both crossover types brings better convergence in standard benchmark problems. The combination of both self-adapting approaches results in the most efficient algorithm for standard benchmark problems. In the case of composition benchmark, the combination of both crossover types was beneficial for less part of problems.

Summarizing the results from both benchmarks, there is no generally winning variant. This is an implication resulting from the No Free Lunch Theorems [20], stating that any stochastic search algorithm cannot outperform others, when all possible objective functions are taken into account. Nevertheless, it does not exclude the possibility to propose novel variants of self-adaptive algorithms with better efficiency for wider range of objective functions and the self-adaptive variants of DE seem to be good examples of such algorithms advisable to the application in real-world problems of global optimization.

# Solving IK problems for open chains using optimization methods

Krzysztof Zmorzynski
Warsaw University of Technology
Faculty of Mathematics and Information Science
Email: zmorzynskik@student.mini.pw.edu.pl

***Abstract*—Algorithms solving inverse problems for simple (open) kinematic chains are presented in this paper. Due to very high kinematics chains construction complexity, those algorithms should be as universal as possible. That is why optimization methods are used. They allow fast and accurate calculations for arbitrary kinematics chains constructions, permitting them to be used with success in robotics and similar domains.**

## I. Introduction

THE problem of finding kinematic chain configuration for given position of its effector is called inverse kinematics (IK) problem. One of the major application of solving IK problem is robotics: having destination translation and orientation of the end effector, robot joints configuration should be found to achieve this translation and orientation. Robot mechanical constraints (for arms and joints) should be taken into consideration.

For some special cases, analytical and geometric methods for solving IK problems effectively exists [7], [9]. General explicit solution does not always have to exist, however. Also, as presented in [4], obtaining analytical solution might be very laborious and complex. These are the main drawbacks of analytical methods.

Methods based on Jacobian matrix and its inverse are widely described in literature [6], [8], [10]. When Jacobian matrix is not invertible, transposition or pseudoinverse Jacobian matrix is used instead [6], [8]. Computational cost of Jacobian matrix operations might be very high, though, not to mention stability problems in the neighborhoods of singularities.

In this paper optimization methods to solve IK problem are used. In contrast to methods mentioned above, they allow full automatization and perform all computations on a machine. They are also very universal, so can be used to solve arbitrary IK problem for open chains. Badler [1] used these methods to solve IK problem for more complicated chains containing many effectors, such as human skeleton. However, computation cost turned out to be to high to be used in real time, or even close to real time. Kim, Jang, Nam [2] used optimization methods to solve IK problem for binary manipulators (that is, each joint can take one of two possible positions).

More general manipulators are considered in this paper, with joints able to take any value from specified bounds. Supplied application allows user to modify chain construction, set effector's target translation and orientation and a real time visualisation of chain state during computations. It is a robust method to validate chain construction and check if desired target position can be achieved.

## II. Chain representation

### A. Chain configuration space

Open chains with each joint having single degree of freedom are considered in this paper. Whole chain configuration can be written as:

$$c = (q_1, q_2, \ldots, q_n) \in C \tag{1}$$

where $C$ is chain configuration space, $q_i$ is $i-th$ joint parameter and $n$ is number of joints.

### B. Joints

Two types of joints are specified: prismatic joints and revolute joints. Parameter value of each joint has to be between minimum and maximum values $q_i^{min}$ and $q_i^{max}$. Joints are connected to each other along their local $Z$ axes. It is also possible to set constant offset value along this axis (as presented in fig. 1). This is slightly simpler representation than in [5].

In the case of **prismatic** joint, parameter is additional (beside fixed offset mentioned above) length along local joint $Z$ axis.

In the case of **revolute** joint, parameter is the rotation angle (in degrees) along specified local rotation axis. It is clear, that in order to model revolute joint with greater DOF, it is sufficient to create many revolute joints, with their fixed offsets set to $0$, each allowing rotation about proper axis.

Beside parameter, each joint is represented also by its position, vector $g = (v, r)$, where $g$ is element from space $L = \Re^3 \times S^3$. $v$ is translation in world coordinates, $r$ is rotation quaternion also in world coordinates. Joints translations and orientations are calculated in forward kinematics manner, starting from first (or root) joint. Formally, position of the effector is the map:

$$\begin{aligned} E : C &\rightarrow L \\ c \in C &\rightarrow E(c) \in L \end{aligned} \tag{2}$$

The use of quaternions instead of rotation matrices allows faster computations.

Effector's target translation and orientation is also represented by element $e$ form space $L$.

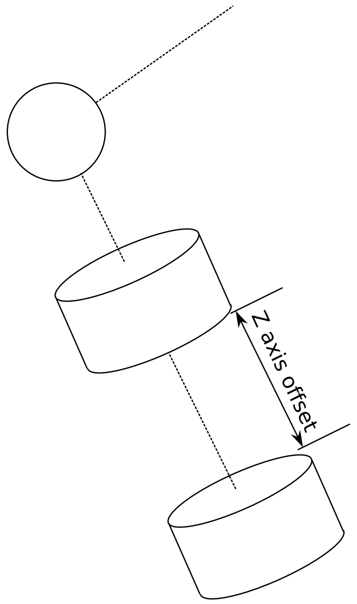

Fig. 1. Sample configuration. Dotted lines represent offsets along local Z axes.

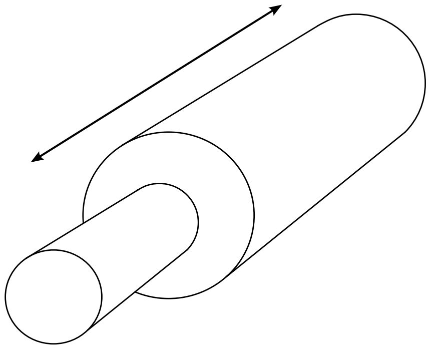

Fig. 2. Prismatic joint

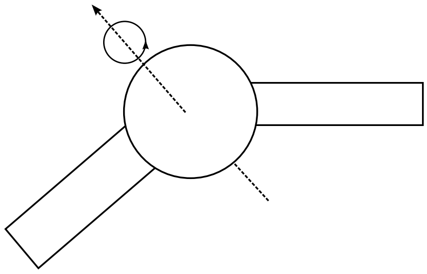

Fig. 3. Revolute joint. Dotted line is a rotation axis.

## III. Optimization methods

### A. Objective functions

In the case of solving IK problem, objective functions are generally distance (potential) functions from effector's current translation and orientation to effector's target translation and orientation. Written in a formal way, it is a function:

$$\begin{aligned} d : L \times L &\rightarrow \Re^+ \\ (x, y) \in L \times L &\rightarrow d(x, y) \in \Re^+ \end{aligned} \tag{3}$$

where $x$ and $y$ are two elements from space $L$.

Following objective functions can be distinguished:

- translation only difference - Euclidean metric can be used:

  $$d_{pos}(x, y) = \sqrt{(x_v - y_v) \cdot (x_v - y_v)} \tag{4}$$

  where $\cdot$ is dot product in $\Re^3$. Square root can be omitted in calculations.
- orientation only difference:

  $$d_{rot}(x, y) = \sqrt{(x_r - y_r) \cdot (x_r - y_r)} \tag{5}$$

  where $\cdot$ is dot product of unit quaternions in $S^3$.
- translation and orientation difference at the same time:

  $$d(x, y) = w_p d_{pos} + w_r d_{rot} \tag{6}$$

  where $w_p$ and $w_r$ are weights for translation and orientation functions, respectively.

### B. Optimization methods and calculations

To minimise objective function, one can use gradient based methods, such as **conjugate gradient method**. It converges faster than steepest descent method since it takes conjugate (with respect to gradient) vector when choosing minimisation direction. Fletcher-Reeves formula for computing ”direction factor” $\beta$ can be used (see [3]). When $\beta$ equals $1$ it means that conjugate direction is no longer valid and should be set to $0$ to make it steepest descent method.

Quasi-Newtonian methods, like **BFGS**, are even better than conjugate gradient. Although they require Hessian matrix computation, which may be expensive, it is also possible to use an approximation based on a function gradient value (described in [13]). The BFGS algorithm is presented in [12]. Its implementation available at [11] was used in the application.

One of the above functions, name it $d$ (4-6), is chosen to be minimised. It takes current and target position of the effector. Recall that from eq. 2, its position is based on current chain configuration:

$$\begin{aligned} c &\in C \\ e = E(c) &\in L \end{aligned} \tag{7}$$

where $c$ is chain configuration.

It could also be written, that the following function $f$ is being minimised:

$$\begin{aligned} f : C &\rightarrow \Re^+ \\ c \in C, y \in L &\rightarrow f(c) = d(E(c), y) \in \Re^+ \end{aligned} \tag{8}$$

where $c$ is current chain configuration, $y$ is the effector's target position. The function $f$ is minimised with respect to chain configuration and that means joints parameters. Joints parameters constraints should be taken into consideration while performing calculations (see next section).

### C. Gradient computation

Gradient of the function $f$ for conjugate gradient method is calculated using difference quotient (**two point**) method:

$$\bigtriangledown f(c) = (\frac{\partial f}{\partial q_1}(c), \ldots, \frac{\partial f}{\partial q_n}(c)) \tag{9}$$

where $c = (q_1, \ldots, q_n) \in C$ and $\frac{\partial f}{\partial q_i}$:

$$\frac{\partial f}{\partial q_i}(c) = \frac{f(q_1, \ldots, q_i + h, \ldots, q_n) - f(q_1, \ldots, q_i, \ldots, q_n)}{h}$$

where $h$ is appropriate small value (see IV on how this value could be chosen). While calculating partial derivatives $\frac{\partial f}{\partial q_i}$, joints constrains $q_i^{min}$ and $q_i^{max}$ are taken into account. It is ensured that:

$$q_i^{min} \leq q_i + h \leq q_i^{max} \tag{10}$$

When value $q_i + h$ is out of the bounds, it is truncated to $q_i^{min}$ or $q_i^{max}$.

The use of BFGS method requires more precision in gradient computation. **Four point** method is used:

$$\begin{aligned} \frac{\partial f}{\partial q_i}(c) &= \frac{1}{12h}(f(q_1, \ldots, q_i - 2h, \ldots, q_n) \\ &- 8f(q_1, \ldots, q_i - h, \ldots, q_n) \\ &+ 8f(q_1, \ldots, q_i + h, \ldots, q_n) \\ &- f(q_1, \ldots, q_i + 2h, \ldots, q_n)) \end{aligned} \tag{11}$$

Thanks to definition of $f$ like in eq. 8 it is possible to move from the original IK problem to the problem of multivariable objective function minimisation.

## IV. Application

Created application allows user to interactively create and modify chain construction, save it to a file and load it later. Modification of joints parameters result in real time changes in chain visualisation. This applies to not only when user manipulates the parameters, but also while solving IK problem so it could be seen how the solution is being found. For given chain construction and end effector's target position, user chose which data types should be used in computations (see below), which objective function to minimise (see III-A) and which optimization method to use (see III-B). When calculations are finished, it is possible to view objective function value dependence on computation time and on iteration number.

| ParameterL | -180 |

Color

Parameter: -18,79572

Fig. 4. Application screenshot.

The application is written in `C# 2.0` language. Calculations are based on `generics` objects, so every floating point number type in this language: 32 bit `float`, 64 bit `double` and 128 bit `decimal` can be used in computations. This allows to easily tell how much each data type has impact on the efficiency and precision of calculations.

When calculating function gradient as stated in III-C, it is crucial to chose right value for $h$. As it turns out, it is not always when the smallest value performs best. ”Batch” mode is available which allows user to compute with different values for $h$, so it could be estimated best for given chain construction and chosen data type.

By using the `.net 2.0` platform, it is possible to add new objective functions and optimisation methods solvers without need to recompile whole application. They are dynamically read at application startup from external `.net` dynamic link libraries (DLL) and added to internal database.

User can chose between `DirectX` or `OpenGL` graphics libraries used to render the scene. It is also possible to resign from rendering at all, increasing the same application performance.

## V. Examples

Following examples were computed on a AMD Turion 64 X2 (two cores, each 1.6GHz) notebook, on Windows XP 32 bit with 1GB RAM and .net 2.0. Optimization algorithm was running on a separate thread, which also means on the other core than main application thread. Null renderer was selected to avoid unnecessary rendering overhead.

All calculations starts with all joints parameters set to $0$ (fig. 5). Objective function 6 was used, with $w_p$ set to $0.5$ and $w_r$ to $1$.

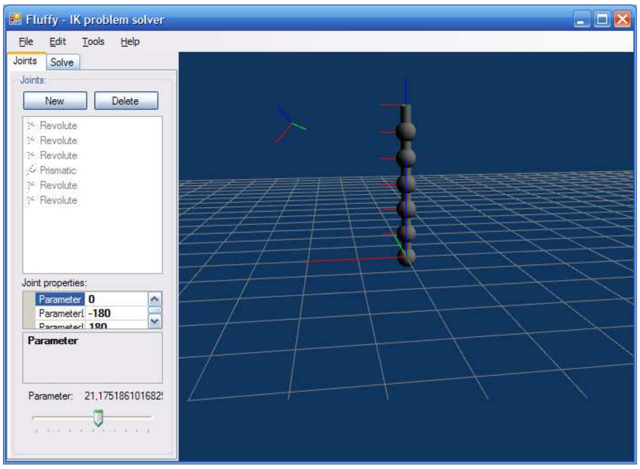
Today's widely used robots have mechanical arms precision set at about $10^{-4}$ and $10^{-5}$ [m]. IK problems solvers should be able to find chain configuration to achieve one of those precision. In this paper both values were researched.

### A. Example 1—relatively close to initial configuration

Chain with 6 joints was used, listed in order from the first (root) joint: first three revolute joints with rotation axes around $X$, $Y$, $Z$, respectively, then prismatic joint and then two additional revolute joints with rotation axes $X$ and $Z$. All revolute joints has parameters constraints set to $(-90, 90)$ degrees, where prismatic joint has $(0, 2)$.

Effector's target position was set relatively close to chain's initial configuration. Figure 6 presents final calculated configuration.

All three data types were investigated, with $h$ value (see III-C) set in batch mode. Tables I, II presents best times and values for each data type for $10^{-4}$ objective function precision,



| | |
|---|---|
| Parameter | 0 |
| Parameterl | -180 |
| Parameterl | 180 |

Parameter

Parameter: 21,175186101682

Fig. 5. Starting configuration.

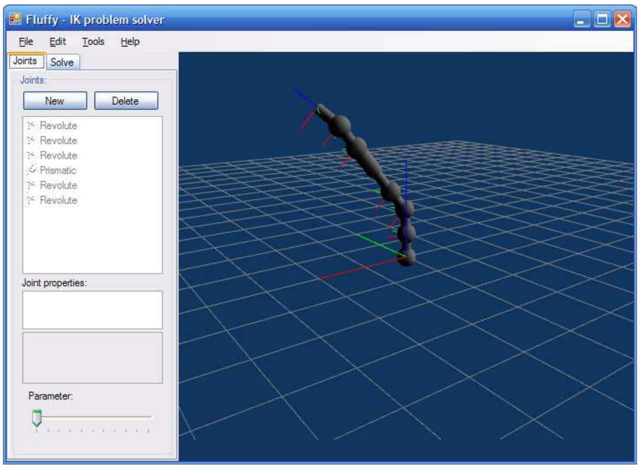


Fig. 6. Example 1 solution.

for conjugate gradient method and BFGS, respectively. Results for $10^{-5}$ are presented in tables III and IV.

TABLE I
EXAMPLE 1 RESULTS FOR $10^{-4}$ AND CONJUGATE GRADIENT METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-5}$ | 80 | 35 |
| `double` | $10^{-10}$ | 75 | 65 |
| `decimal` | $10^{-12}$ | 80 | 300 |

TABLE II
EXAMPLE 1 RESULTS FOR $10^{-4}$ AND BFGS METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-2}$ | 45 | 25 |
| `double` | $10^{-6}$ | 45 | 45 |
| `decimal` | $10^{-2}$ | 40 | 230 |

It can be seen from the tables I, II, III and IV, that `float` and `double` types performs best, due to their hardware support. `float` is fastest, probably because of smaller loading times from memory that `double`. Number of iterations for all types are similar. `decimal` type has significant calculation impact—nearly 10 times slower than `float`, mainly because of its software `.net` emulation.

TABLE III
EXAMPLE 1 RESULTS FOR $10^{-5}$ AND CONJUGATE GRADIENT METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-4}$ | 105 | 48 |
| `double` | $10^{-10}$ | 105 | 80 |
| `decimal` | $10^{-12}$ | 90 | 320 |

TABLE IV
EXAMPLE 1 RESULTS FOR $10^{-5}$ AND BFGS METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-2}$ | 50 | 30 |
| `double` | $10^{-10}$ | 40 | 45 |
| `decimal` | $10^{-2}$ | 45 | 250 |

Clearly, BFGS method is faster by about 50% than conjugate gradient method. It also needs half of the iterations to find the solution.

Figure 7 presents rough overview of how convergence was achieved in the matter of iterations (left plot) and time (right plot).

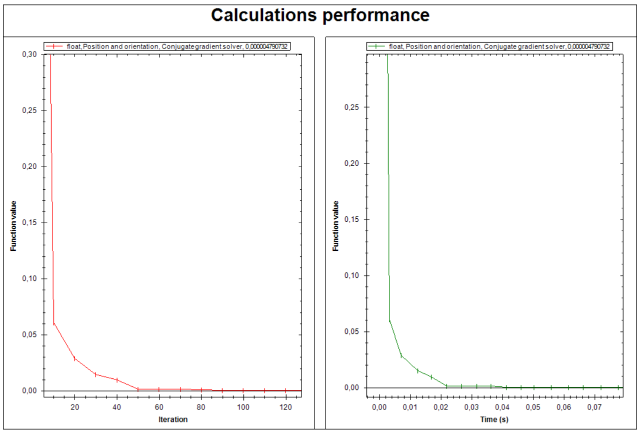

Fig. 7. Example 1 convergence overview.

## B. Example 2

This time effector's target position was farther than in previous example (as in fig. 8), so computation time was expected to be longer. Also, to ensure that effector reaches target position, additional revolute joint was added at the end of the chain, and each revolute joint has constraints set to $(-180, 180)$ degrees. All revolute joints, except the first and the last one, have fixed offset set to $0$.

Results are presented in tables V and VII.

TABLE V
EXAMPLE 2 RESULTS FOR $10^{-4}$ AND CONJUGATE GRADIENT METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-3}$ | 105 | 50 |
| `double` | $10^{-6}$ | 90 | 65 |
| `decimal` | $10^{-5}$ to $10^{-12}$ | ˜110 | ˜400 |

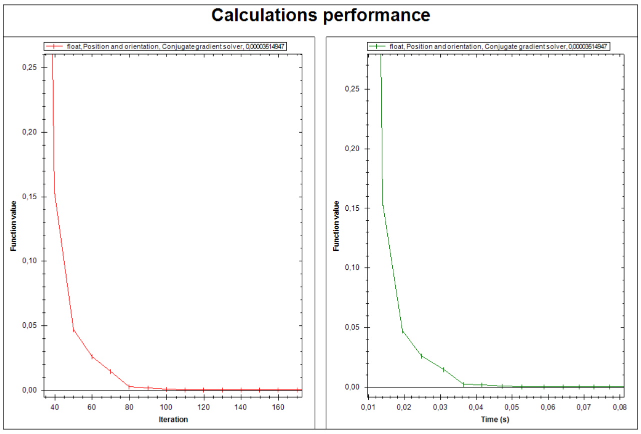

Fig. 9. Example 2 convergence overview.

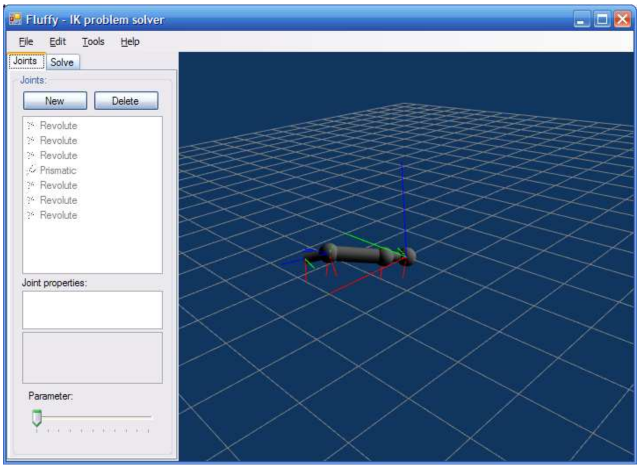

Fig. 8. Example 2 solution.

TABLE VI
EXAMPLE 2 RESULTS FOR $10^{-4}$ AND BFGS METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-2}$ | 40 | 25 |
| `double` | $10^{-1}$ | 35 | 45 |
| `decimal` | $10^{-1}$ to $10^{-12}$ | ˜35 – 40 | ˜250 |

TABLE VII
EXAMPLE 2 RESULTS FOR $10^{-5}$ AND CONJUGATE GRADIENT METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-3}$ | 120 | 58 |
| `double` | $10^{-6}$ | 100 | 76 |
| `decimal` | $10^{-5}$ to $10^{-12}$ | ˜120 | ˜500 |

TABLE VIII
EXAMPLE 2 RESULTS FOR $10^{-5}$ AND BFGS METHOD

| data type | $h$ | iterations | time (ms) |
|---|---|---|---|
| `float` | $10^{-3}$ | 45 | 30 |
| `double` | $10^{-1}$ | 40 | 50 |
| `decimal` | $10^{-1}$ to $10^{-12}$ | ˜35 – 40 | ˜300 |

This time, calculation times excludes `decimal` type from any practical usage. For conjugate gradient method, two other types performs slightly worst than in the previous example, but still in the almost real-time. For BFGS method, there are almost no differences between both examples. For all data types, iteration count is quite similar to each other.

Figure 9 shows how convergence was achieved.

## VI. CONCLUSIONS AND FUTURE WORK

It is clear from above examples, that optimization methods can be widely used to solve IK problems in the real time, even on commonly available customers computers. This leaves no need of use dedicated and expensive workstations, as it has been before.

Applying commonly used and available methods (such as conjugate gradient and BFGS) seems to work well in most cases. Their adaptation to multithreaded or multiprocessor environments may perform even better.
