3. The last experiment was intended to evaluate the system with gender dependent data. First of all, data from male speakers were separated from data from female speakers. Each part of the data was divided into training data (9/10 of data, about 11.25 hours) and test data (1/10 of data, about 1.25 hours). Thus, four different experiments were held and the results are presented in Table I. The results in the table show several interesting tendencies. The results are much better for the gender dependent system then for gender independent. It might be caused by the significant differences in pitch between female and male voices. This proves the concept that pitch plays a major role in prominence detection.

Another conclusion is that SpInd yields better results then SpDep. This is probably due to the fact that training and test data within SpInd experiment included data from all speakers, while in SpInd experiment training data exluded the data of the test speaker. This shows that the data from seven speakers was not enough to train a speaker independent system and to predict the excluded speaker efficiently.

An overall efficiency of 84.2 % was achieved for speaker independent task. Table II shows the comparison of this result against the results achieved by other researchers in speaker independent systems.

The empty cells in the table mean that the authors did not present precision and recall results in their papers. As one can see, the efficiency of the current system is not the best one, but not the worst. However, it is worth highlighting that an amount of experimental data is by two orders of magnitude greater than the amount of data used to test other systems. Thus, the experimental results can be considered as positive and efficient enough to be a baseline for further research in the field of automatic detection of prominent words.

TABLE II
THE EFFICIENCY OF THE AUTOMATIC PROMINENT WORD DETECTION AS COMPARED TO SIMILAR RESULTS ACHIEVED BY OTHER RESEARCHERS

Research	Language	Amount of Data	Efficiency	Precision	Recall
Brenier et. al. [2]	English	2906 words	87,1		
Kroul [4]	Czech	2160 words	91.1		
Tamburini [9]	Italian	4780 syllables	82.5	75.6	77.9
Wang and Narayanan [10]	English	3247 words	76.2	82.1	73.4
Current System	Russian	211383 words	84.2	83.3	79.1

V. CONCLUSION

The paper presented results of the research dedicated to automatic detection of prominent words. Algorithms of prosodic features extraction were developed during this research. Three types of prosodic features were used: melodic, dynamic and temporal. CART with modified splitting criterion was used as a statistical classifier. The efficiency of the developed system was tested in a series of experiments. The efficiency of 84.2 % was achieved, that which is comparable to other research in this field. The undisputable advantage of this system is that it is the first such system of the kind that has been developed for the Russian language and it could undoubtedly be used within automated annotation of speech corpora modules and automatic speech recognition systems.

***Abstract*—Thanks to the participation of a large number of persons via web-based games, a large-sized evolutionary lexical network is available for French. With this resource, we approached the question of the determination of the word usages of a term, and then we introduced the notion of similarity between these various word usages. So, we were able to build for a term its word usage tree: the root groups together all possible usages of this term and a search in the tree corresponds to a refinement of these word usages. The labelling of the various nodes of the word usage tree of a term is made during a width-first search: the root is labelled by the term itself and each node of the tree is labelled by a term stemming from the clique or quasi-clique this node represents. We show on a precise example that it is possible that some nodes of the tree, often leaves, cannot be labelled without ambiguity. This paper ends with an evaluation about word usages detected in our lexical network.**

I. Introduction

In this paper, we describe an approach for acquiring lexical structures useful for word sense disambiguation (WSD). Having a word sense inventory is often mandatory prior to many text analysis application but those resources are quite rare especially for French. By text analysis, we mean here a task where word senses and relations amongst word senses are identified. Furthermore, being constructed either by experts (generally lexicographers) or from corpora, they barely reflect what people would think of. An adequate resource would then mostly refer to word usages than word senses (in the classical meaning of dictionaries) and would also try to evaluate the proper weight of an usage[1]. A very immediate usage of a term would have a higher weight than a rare one. We can then expect a quite large discrepancy between a proper inventory of usages and inventory of meanings (in dictionaries). Some usages would not be in dictionary either being elisions (like in French *sapin* for *sapin de Noël* – eng. *fir* for *Christmas tree*) or popular (like in French *caisse* as *car*). Some meaning would be absent of a *popular meaning inventory* when too technical, too rare or simply unknown by the vast majority of people. Can we try to define precisely what is the difference between a word sense and a word usage? Word usages are broader and would certainly include senses, but not the other way around. In French, for example, *sapin* (*fir*) beside being the tree, has a strong usage related to Christmas (*fir* as *Christmas tree*) and tends to become autonomous. A putative definition of a word usage could be a *specific meaning in a given context, popular enough to be spontaneously given by someone.*

The method and evaluation presented in this paper are based on a resource under construction but already freely available: the JeuxDeMots lexical network[2]. We first briefly remind the reader of the principles of two games which aim at building a base of relations between terms. The first of these two games (JeuxDeMots[3]) allows the construction of a lexical network, while the second game (PtiClic[2]) allows the user to strengthen associations acquired thanks to JeuxDeMots. With the network thus obtained, we tackle the problem of the word usage determination, by analysing the relations between every term and its immediate neighbours. The similarity between the various usages of the same term can be computed allowing us to build the classification tree of the usages of a term, the nodes of which being labelled.

[1] Definition for word usage is given several lines below, in this paragraph, and the weight of an usage is explained in section III.

[2] This resource is available at http://www.lirmm.fr/jeuxdemots/rezo.php for the lexical network and at http://www.lirmm.fr/jeuxdemots/diko.php for the obtained dictionary.

[3] JeuxDeMots and PtiClic are available at http://jeuxdemots.org and http://pticlic.org. An English version has recently been added, as well as a Thai, Japanese and Spanish versions (http://www.lirmm.fr/jeuxdemots/world-of-jeuxdemots.php)

Such a word usage tree structure as of primary interest for WSD should be evaluated against users before considering using it in applications. Furthermore, one of the objectives is to be able to connect the relations, not on the very terms (with ambiguities for polysemous terms), but on their usages (thus by clearing up lexical ambiguities).

II. Lexical network construction

The basic principles of JeuxDeMots (JDM) software, the game design, as well as the incremental construction of the lexical network, have already been described in [1]. A game takes place between two players, in an asynchronous way, based on the concordance of their propositions. When a first player begins a game, an instruction concerning a type of competence (synonyms, opposite, domains …) is displayed, as well as a term[4] T randomly picked in a base of terms. This player has then a limited time to answer by giving propositions which, to his mind, correspond to the instruction applied to the term T. The same term, along the same instruction, is afterwards proposed to another player; the process is then identical. For the same target term T and a same instruction (synonyms, domains, free associations…), we record the answers common to both players. Validations are thus made by concordance of the propositions between pairs of players. This validating process is similar to the one used by [2] to index images and, as far as we know, this has never been done in the field of the lexical networks. In Natural Language Processing, some other Web-based systems exist, such as *Open Mind Word Expert* [3] that aims to create large sense tagged corpora with the help of Web users, or *SemKey* [4] that exploits WordNet and Wikipedia in order to disambiguate lexical forms to refer to a concept, thus identifying a semantic keyword.

The structure of the lexical network we are building relies on the nodes and relations between nodes, as it was initially introduced by [5]. More precisely, JDM game leads to the construction of a lexical network connecting terms by typed and weighted relations[5]. These relations are labelled by the instruction given to the players and they are weighted according to the number of pairs of players who proposed them. The morphosyntactic category was not initially indicated in JDM. A recent evolution, published in [6], has allowed us to introduce the notion of refinement of a term. This refinement can depend on the meaning (case of polysemous terms) or on the morphosyntactic category of the term.

In a similar way to JDM, a PtiClic game takes place in an asynchronous way between two players. A target term T, origin of relations, as well as a cluster of words resulting from terms connected with T in the lexical network produced by JDM are proposed to a first player. Several instructions corresponding to types of relations (synonym, hypernym, hyponym, predicate relations like possible/typical agent, patient or instrument, part-of and substance, ...) are also displayed. The player associates words of the cluster with instructions he thinks correspond by a drag and drop. The same term T, as well as the same cluster of words and the same instructions, are also proposed to a second player. According to a principle similar to that set up for JDM, only the propositions common to both players are taken into account, thus strengthening the relations of the lexical network. Contrary to JDM, the players of PtiClic cannot suggest new terms, but are forced to choose among those proposed. This choice of conception has to allow to reduce the noise due to misspelt terms or to the confusions of meanings.

The collaborative building of resources by non-experts may induce some errors. In fact, as one may expect, we detected some of them, such as classical orthographic mistakes (eg: *théatre* for *théâtre*) or traditional confusions (eg: French singer *Dalida* with the biblical character *Dalila*) … These well-known mistakes are relatively rare and they can be manually detected.

According to the JeuxDeMots Web site, at the time of the writing of this paper, the lexical network contains around one million relations linking 221000 terms. Around 800000 games have been played corresponding to more than 13000 hours of cumulated play.

III. Similarity between usages of a term

A. Word Usage Determination

If a term T is polysemous, the terms which are directly connected with it (semantically connected in the lexical network) form several different groups, each of these groups constituting a word usage of T. The notion of word usage (often referred to as "usage") is much more accurate and relevant than the notion of meaning which, as shown by [7], is relatively poor when we refer to traditional dictionaries or to resources as WordNet. Our hypothesis is that the usages of a term correspond in the network to the various cliques this term belongs to. A clique is a set of terms constituting a fully connected subgraph in the lexical network. Two terms T_i and T_j belong to the same clique if there is at least one relation between T_i and T_j and at least one relation between T_j and T_i. Our approach is similar to the one developed by [8] from dictionaries of synonyms.

Why using the JeuxDeMots lexical network for our experiment instead of WordNet [9], EuroWordNet or WOLF [10] ? These resources are handcrafted contrary to the JeuxDeMots lexical network which is crowdsourced through some games, and by itself it is interesting to assess if common word usage can be identified. Similar approaches like [11] have been conducted on contexonyms but on

[4] A term can be a compound word (for example: *Christmas tree*) and each of its words may be a term (*Christmas* and *tree*).

[5] A relation can be thus considered as a quadruplet: origin term, destination term, type and weight of the relation. Between two same terms, several relations of different types can exist.

resources trained on very large corpora (and again not extracted from people).

For the clique identification, we take into account all relation types available in the lexical network. Of course we might certainly consider that they do not contribute equally to the induced word usage, but the principle of JeuxDeMots induce that the most important relations have the highest weights and that the most important relation types (for a given term) are the most populated. So, there is, *a priori*, no need to stress on specific relation type, as this information is already implicitly present in the network. Estimating the relevance of a usage consists in obtaining a measure of its importance both in terms of frequency and of lexical coverage. Considering the principle of the weighting of the relations, the weight of a usage is correlated with the weights of the relations between the terms of the clique which characterizes this usage. We have the following notations :

- C is a given clique for the term T (this is a set of terms and instances of relation).
- C_{all} is the union of all C (that can be seen as the full pseudo clique for T).
- W(C) is the sum of the weights of the relations between the terms of C.
- Card(C) is the number of terms in C.

So, for a clique C related to the term T, we define formally the *relevance* as :

$$Rel(C) = W(C) * \log(Card(C_{all})/Card(C))$$

The Rel measure for a clique may be seen as an adaptation of the tf/idf measure where, for the sake of simplicity, we have not divided by $W(C_{all})$. If there is only one clique, the relevance is equal to 0 and of course in that case we consider that there is only one usage. Figure 1 presents the obtained usages for the term *sapin* (*fir*), and the relevance of each of these usages.

0: 'sapin' 'fiacre' REL = 52
fir, hansom
1: 'sapin' 'cercueil' REL = 55
fir, coffin
2: 'sapin' 'montagne' REL = 38
fir, montain
3: 'sapin' 'épicéa' 'ginkgo' 'conifère' 'cèdre' 'mélèze' 'résineux' REL = 66
fir, spruce, ginko, conifer, cedar, larch,conifer
4: 'sapin' 'vert' 'arbre' REL = 126
fir, green, tree
5: 'sapin' 'épicéa' 'épinette' 'conifère' REL = 59
fir, spruce, spruce, conifer
6: 'sapin' 'aiguille' REL = 43
fir, needle
7: 'sapin' 'conifère' 'arbre' REL = 139
fir, conifer, tree
8: 'sapin' 'guirlande' 'Noël' REL = 111
fir, garland, Christmas
9: 'sapin' 'boule' 'boules' REL = 51
fir, ball, balls
10: 'sapin' 'boule' 'Noël' REL = 108
fir, ball, Christmas
11: 'sapin' 'Noël' 'sapin de Noël' 'sapin de noël' REL = 84
fir, Christmas, Christmas Tree, Christmas tree
12: 'sapin' 'Noël' 'fête' REL = 152
fir, Christmas, celebration
13: 'sapin' 'arbre' 'bois' 'forêt' REL = 219
fir, tree, wood, forest
14: 'sapin' 'arbre' 'bois' REL = 148
fir, tree, wood
15: 'sapin' 'conifères' REL = 71
fir, conifers

Fig 1 : 16 usages for the term *sapin* (*fir*) as found in the lexical network at the writing time.

The most relevant clique is {**sapin, arbre, bois, forêt**} *(fir, tree, wood, forest)* with a score of 219, followed by {**sapin, Noël, fête**} *(fir, Christmas, celebration)* with a score of 152.

B. Clique Similarity

The similarity between two objects can be defined according to [12] as being a function of their common characteristics with regard to all their characteristics. In NLP, we find several definitions of the similarity, for example [13] or [14]. More recently, [15] evaluated several different measures of lexical semantic relatedness, while [16] presents a general survey on this question. In our case, it corresponds to the ratio between the weight of the relations connecting two cliques and the total weight of the relations on all the terms of these two cliques. We note W(E) the weight sum of the relations between the terms of the set E (as in 3.1). The similarity between two cliques C1 and C2 will be equal to the *Jaccard* indice :

$$Sim(C1,C2) = W(C1 \cap C2) / W(C1 \cup C2)$$

We should note here, that the Jaccard indice is in our case applied on the set of relations and that the 'cardinality' of this set is the sum of the weights. Usually the Jaccard indice is applied on the true cardinality of the sets, considering equally all elements of the set. Figure 2 shows the similarities between the cliques of the term *sapin* (*fir*).

IV. Classification Tree of Word Usages

A. Construction

Our aim is to obtain a representation of the various usages of a term T in the form of a tree, with the root grouping together all the meanings of T and the branches corresponding to its various usages. Generally, most of terms possess several not separate cliques. In that case, the further away we go from the root of the tree, the more we meet fine distinctions of usages. In fact, we build the tree of the usages of a term T according to a "bottom - up" method: from all of its cliques, that is, from its leaves and going back up to its root which groups together all the meanings of T. For that purpose, we apply an agglomerative hierarchical clustering algorithm: we merge the cliques, two by two, beginning with those whose coefficient of similarity is the highest: thus, we build quasi-cliques representing groups of usages, close during the first fusions, less and less close during the successive fusions. The merging algorithm ends when all coefficients of similarity are equal to zero.

The usage tree of a term is a structure expressing the refinements of its various meanings as deduced from the state of the lexical network. It thus constitutes a decision tree, a data structure which can be exploited for disambiguation. Furthermore, nodes of this tree are weighted allowing to identify usages that are the most common, which is both useful for guessing default cases and ordering usages from the most activated for people to the least activated.

Fig 2 : Similarity matrix between the cliques of the term *sapin* (*fir*).
The clique numbers are those from figure 1.

B. Labelling

The labelling of the various nodes of the usage tree of a term is made during a width-first search, that is, according to a "top - down" method. The tree root is labelled by the term itself. Every node of the tree is labelled by a term stemming from the clique or the quasi-clique this node represents; the selected term is the one whose sum of the weights of its relation with the root term is the highest, after eliminating all the terms labelling the nodes of the tree situated in a depth lower than that of the concerned node. Thus, it is possible that a node cannot be labelled if all the terms which define it have already been used in the labelling of nodes previously done. In this case, this node, but also its brother and all its successors, are not labelled. Figure 3 shows the tree obtained for the term *sapin* (*fir*).

C. Tree pruning

The relevance of an inner node of the tree is computed as defined above considering the quasi clique obtained during the merging. We ignored the usages of the tree which relevance is below a given threshold (empirically set to 50 in our experiment). This threshold correspond to the configuration where both terms have been associated to each other to only two pairs of player (one pair for each direction) and maybe it could have been accidental. In figure 3, in the tree for the term *sapin*, we discard the *sapin (montagne)* node at level 1 which relevance is only equal to 38 (clique number 2 in Figure 1). The nodes for *sapin* as *fiacre*, *cercueil*, *arbre* and *Noël* have respectively a relevance of 52, 55 and more than 300 for the last two.

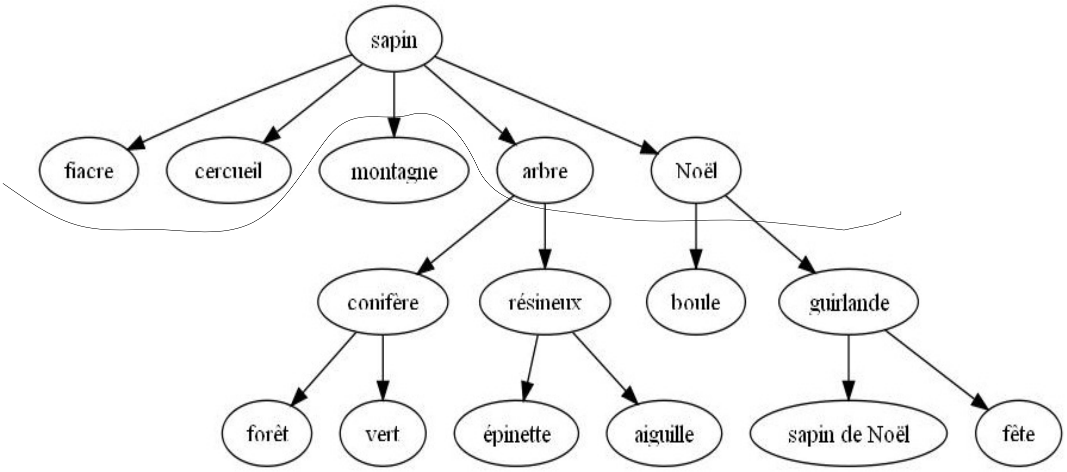

Fig 3 : Labelled word usage tree for the term *sapin* (*fir*). We pruned this tree by deleting nodes which cannot be labelled or which the relevance is too low (below 50 in our experiment)

V. Evaluation

A. Obtained Word Usages

Regularly, we examine the highly polysemous terms, and we ask an expert lexicographer to validate the meanings detected by JDM, after pruning the usage tree. The role of the expert does not extend beyond this validation: he doesn't add any meaning, even if he thinks some are missing, and he removes only those that obviously correspond to mistakes. As the time of writing this article, with the expert's help, we thus obtain 4412 validated word usages for 1263 terms, which correspond to a mean of around 3.5 usages per term. Out of these 1263 terms more than 80% are labeled as very common terms (at least one meaning should be known at the age of 12). The terms are mostly common nouns also some usages are tagged with other part-of-speech like verb or adjective. For example *dîner* in French can be at the same time a noun or a verb. The expert's role must go on to validate much more meanings detected in our lexical network.

B. User Evaluation

Evaluating the quality of such word usages is difficult, dramatically in the absence of adequate gold standard. As far as we aware of there is no such resources for French. If we had got any, a (semi-)automatic evaluation might have been feasible on a very much large scale. So, we decided to make a user based evaluation, trying to access qualitatively and quantitatively the word usages we obtained so far. We undertook the evaluation only at the first level of the usage tree computed for a given term.

We based our evaluation on naive users (i.e. not lexicographers) for two reasons. First, finding lexicographers for this task is not easy to say the least and certainly not more than few ones. Secondly, we wanted to have an evaluation confronting common people to our data. The idea is to identify word usages the same way (as a result at least) an average person would do. We remind here that the JeuxDeMots lexical network does not aim at being more than an average representation of associations between terms.

We asked 30 non-expert persons to undertake four slightly different tasks. Given a word and the set of associated named usages, they had to evaluate the number of missing usages and the number of supernumerary usages (either too specific or plain wrong). The task has to be done on two sets of different 50 words. On the first set, persons are not allowed to consult any dictionary (task Dict-), on the second they can check on dictionaries if they want to do so (task Dict+). The dictionary we proposed for reference is Wiktionary for French, but user where allowed to use any resources they want. Furthermore, the set of words is either taken from common words or non-common words (usually known or unknown at the age of 12).

An example of what is asked to the people is the following (translated for the purpose of this article):

> For the word *sapin*, we propose the following usages:
>
> - sapin(arbre) *(fir - tree)*
> - sapin(Noël) *(fir - Christmas)*
> - sapin(cercueil) *(fir - coffin)*
> - sapin (fiacre) *(fir - hansom)*
>
> Do you think some usages are missing, if yes how many ? Do you think some proposed usages are inappropriate, if yes how many ?

Word usages are ordered by decreasing relevance (as defined in section 3.1).

The four sets of words proposed to each evaluator are completely random (although verifying the constraints described before, that is to say either common or uncommon ones) and they are distinct (a given word may be present only in one set). Two different evaluators may have no distinct sets. The evaluators have all an age above 20 and had a similar proportion of 17 females and 13 males. The level of education was basically 2 years of university or more. The following tables present the collated result of this evaluation.

Common words	**Dict -**	**Dict +**
Missing usages	0.45	1.52
Added usages	0.66	0.37

Uncommon words	**Dict -**	**Dict +**
Missing usages	0.25	1.67
Added usages	0.76	0.28

Tables 1 & 2 : Average number of missing usages and added usages without and with the help of a dictionary for common (table 1) and uncommon (table 2) words used in our evaluation.

For users, added usages are those considered wrong (or at least far fetched). Missing usages are those which should have been present.

C. *Result Analysis*

How can we interpret those results? Without dictionary there is systematically less than one usage felt as missing or added. For the Dict- task, by debriefing the evaluators it appears that the added usage is quite often a proper usage that was unknown to the user (technical, old or rare). Conversely in the Dict+ task, the missing usages value rises as more usages, unknown to the user are found in the dictionary. It seems that globally we are missing much more usages than adding wrong ones. This is quite inline which the way the lexical network is constructed (by players indirect contribution). Missing usages are those quite specific, rare and basically unknown to users.

The task on uncommon words tends to strengthen this analysis. Indeed, without any dictionary people feel that they are more added usages than with common words and less missing usages. The result of the Dict+ is contravariant with the Dict-. Indeed, missing usage value rises and added usage value diminishes.

We can take several precise examples for illustrations. For the word *sapin* (a common word) we got :

sapin	**Dict -**	**Dict +**
Missing usages	0.5	0.9
Added usages	0.2	0.4

Table 3 : Average number of missing usages and added usages without and with the help of a dictionary for the term *sapin (fir)*.

The wiktionnary definitions are: **sapin** *masculin*

1. (Botanique) Arbre conifère résineux de la famille des abiétinées à aiguilles persistantes, au tronc droit, dont le fruit est un cône.
2. Bois de cet arbre utilisé en menuiserie.
3. (Par métonymie) Cercueil.
4. (Familier) (Vieilli) Fiacre.

Some people where doubting about the *sapin (fiacre)* usage although this is a correct one. The usage of *sapin* as wood (mater) is missing but roughly only one person out of two have been thinking of it without checking in a dictionary. The added usage compared to the dictionary is the *sapin (Noël)* although it is present as a locution.

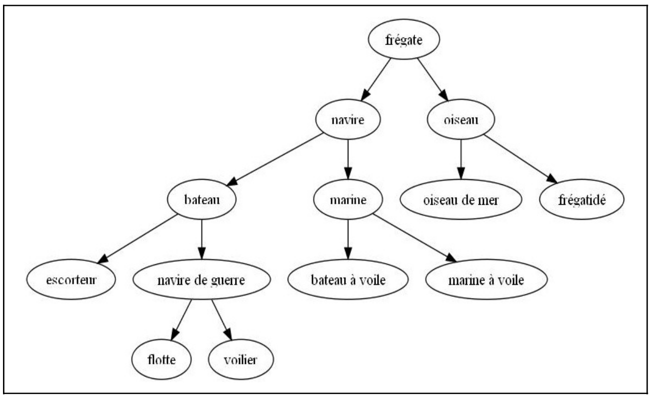

Fig 4 : Usage tree for the term *frégate (frigate)*.

For the word *frégate*, we found out the following usages:

- frégate (navire) *(frigate boat)*
- frégate (oiseau) *(frigate bird)*

frégate	**Dict -**	**Dict +**
Missing usages	0.15	0
Added usages	0.1	0

Table 4 : Average number of missing usages and added usages without and with the help of a dictionary for the term *frégate (frigate)*.

The wiktionnary definitions are: **frégate** *féminin*

1. (Histoire) (Marine) (Militaire) Bâtiment de guerre qui n'avait qu'une seule batterie couverte et qui portait de vingt à soixante bouches à feu.

2. (Zoologie) Oiseau de mer palmipède, d'une très grande envergure, et qui saisit à la surface de l'eau les poissons dont il se nourrit.

For *frégate,* some people made the distinction between the ancient boat and the modern boat. On a rare occasion the evaluator was doubtful on the bird meaning. Comparing with the dictionary we got an exact match.

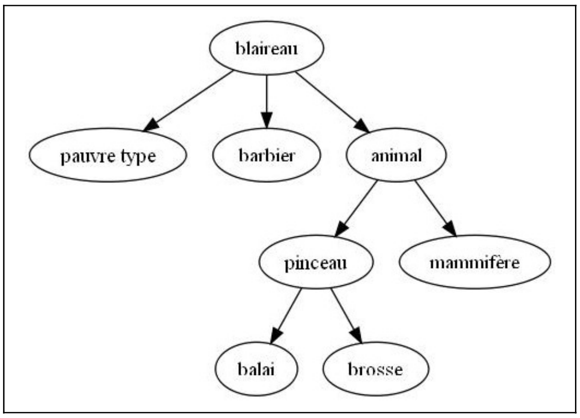

Fig 5 : Usage tree for the term *blaireau (badger, dork, shaving brush)*.

For the word *blaireau*, we found out and proposed the following usages:

- blaireau (animal) *(badger)*
- blaireau (pauvre type) *(dork)*
- blaireau (barbier) *(shaving brush)*

blaireau	**Dict -**	**Dict +**
Missing usages	0.3	1.1
Added usages	0	0

Table 5 : Average number of missing usages and added usages without and with the help of a dictionary for the term *blaireau (badger, dork, shaving brush)*.

The wiktionnary definitions are: **blaireau** *masculin*

1. Mammifère omnivore, bas sur pattes, au pelage noir, gris et blanchâtre, qui se creuse de profonds terriers.
2. (Arts) Brosse en poils de cet animal dont se servent les peintres et les doreurs.
3. Pinceau garni de ces poils dont on se sert, en se rasant, pour étaler et faire mousser le savon.
4. (Argot) (Vieilli) Nez.
5. (Argot) Individu grossier et antipathique ; imbécile, idiot.

For *blaireau* some people found that the *(painting) brush* (meaning 2 of wikipedia) is indeed missing. Most people missed the *nez* (nose – meaning 4) meaning, which is quite old.

All in all, although being preliminary, those results are very encouraging both on the soundness of the method for determining and naming word usage and the quality of the resource collected so far (although evaluating this resource was not the primary goal of this paper). They seem to correspond to what people know and not specifically to some resources made by lexicographers or experts.

What is the effect of the label on the evaluation? If for a given word usage a different label would have been chosen to which extend the results might be modified? In fact there is no much choice for a reasonable label, and generally choosing a substitute like an hyperonym (for example animal instead of bird, in case of frigate) does not alter the results. Of course, this is less and less true as we go deeper in the tree, but also there is less and less choices (if we stick to our labeling approach described in 4.2). Perhaps a deeper evaluation on this particular point should be conducted.

What can we do with the unlabeled usages? So far the answer is simple: nothing. But we should keep in mind that the network is in constant evolution and that some cliques existing now may be fusionned in the near future due to the players activity, or on the contrary being reinforced with new terms allowing them to be labeled.

VI. Conclusion

Viewing the results first obtained, these trees of named usages seem to correspond in their main structures to those a human non-expert would build. In particular, the main branches, directly stemming from the root, correspond in the majority of cases to the meanings of the root term as we could find them in a dictionary. These main branches are subdivided into sub-branches which are so many refinements in the usages.

In their detailed structures however, we notice elements that are different from what a human would have written as we showed on examples above. Are these differences (can we really speak about abnormalities?) due to our method of construction of the trees of the labelled usages with help of players who are not experts, or are they due to the fact that the lexical network is not "complete" enough yet? Moreover, do not the word usage trees sometimes distinguish too subtle refinements? Using the similarity between nodes, how would it be necessary to prune them?

A strong perspective of our work is to propose to the authors of the JeuxDeMots game to insert the identified word usages and proposed them to the players. Hence, the word usages are going to be associated to other terms of lexical database. It would be interesting to assess whether or not reapplying our algorithm leads to some convergence as expected. If it is not the case for a given term, either the usage identified or the label (or both) are not appropriate and should be revised.

Abstract—In this paper we present RefGen, a reference chain identification module for French. RefGen algorithm uses genre specific properties of reference chains and an accessibility measure to find the mentions of the referred entity. The module applies strong and weak constraints (lexical, morpho-syntactic, and semantic) to automatically identify coreference relations between referential expressions. We evaluate the results obtained by RefGen from a public reports corpus and we discuss the importance of the genre-dependent parameters to improve the reference chain identification.

I. Introduction

IN this paper, we present a new reference chain identification module RefGen, developed for French. Reference chains are linguistic markers indicating a topic shift or a topic continuation in the discourse [1]. RefGen is the main module of a topic detection system, integrated into a topic search engine. The search engine uses topic indexing to help users to retrieve relevant documents from the archives. The topic detection system takes into account the genres of the documents.

Reference chain identification is a key process for many NLP applications as topic detection or text summarization. To solve the reference, the systems identify the various referential expressions (e.g. pronouns, definite noun phrase, possessives) referring the same discourse entity. This is a criterion to form a reference chain in the document. A reference chain includes at least three referential expressions (e.g. *Barack Obama… il… lui 'Bara*ck Obama... he...his' / Le chat qui a mangé l'escalope...le chat...il' the cat that ate the escalope... the cat...it') which denote the same referent [2]. If this referent is common to several sentences of the same paragraph, it represents a potential topic candidate. Several paragraphs sharing the same referent indicates also a topic candidate.

Coreference resolution methods either apply heuristic rules manually defined (which select the most suitable antecedent for a given anaphora) or rules learned from annotated corpora. While supervised learning methods [3], [4] are effective in the processing of coreference relations, they require large, manually annotated training corpora. However, there is currently no large reference corpus annotated with reference chains in French [5] to apply machine learning techniques for reference chain detection. Coreference task of the SEMEVAL2010 conference provides annotated corpora for several languages, but no French data is yet available.

To identify referential expressions we propose a new knowledge poor method as adopted for pronoun [6] and coreference resolution [7], [8], [9]. We select the reference chain elements (mentions of the same entity) using criteria about accessibility and information content of various categories of referential expressions (Accessibility theory [10]), their syntactic function, but also some genre-dependent properties of the reference chains. The RefGen algorithm proceeds in two steps: it first selects the starting element of a reference chain and then it selects the next elements of the reference chain applying strong and weak constraints (lexical, morpho-syntactic, and semantic) [11] between antecedent-anaphora potential pairs.

The paper is organized as follows. In section 2 we describe the referential expressions, the coreference relations processed by our system, and the genre-specific parameters of the reference chains identified by a corpus analysis. In section 3, we present the RefGen module: the genre-dependent parameters used to identify chains, the annotation scheme adopted and the algorithm. We then discuss the first RefGen results obtained from a comparison with manually annotated corpora and we stress the importance of the genre-dependent parameters to improve the results of the algorithm (section 4). In section 5 we conclude and we present future developments.

II. The Reference Chains

A. Referential expressions

Following [2], we consider a reference chain as a relation between at least three mentions (three referential expressions). The reference chains include three types of constituents with a referential function: the proper nouns, the NPs (definite, indefinite, possessive or demonstrative) and the pronouns. The proper nouns have an important role in the discourse structure as they often open a reference chain, due to their capacity to point a unique, well-identified referent.

This work was supported by a French company, RBS (Ready Business System), Strasbourg (http://www.rbs.fr).

Indeed, a study of reference chains in the journalistic portraits [12] shows their importance in organizing the discourse. Apart from cases where there is a referential competition (the repetition of the proper noun eliminates ambiguity between two referents, e.g. “Paul and Pierre… Paul…”), the repetition of a proper noun signals a break in the reference chain. When a referring expression is used, it triggers a "particular recruitment process" of a referent. Thus, the demonstrative (e.g. “ce président”/‘this president’) points directly to the nearest referent while the anaphoric pronoun "il" recruits a referent that is already in mind and there is no concurrent referent [13]. The use of a particular mention (referential expression) is an indication for the reader to remember a specific referent. This referent becomes a local theme of the discourse. However, the use of a complete noun phrase instead of a pronoun is an indication of a reference change. These informations are useful to detect the end of the reference chain or the beginning of a new one.

We decide to first process single referential relations (excluding plural anaphora) between co-referent expressions within a paragraph. We treat direct coreference cases [14] for the coreferential NPs having the same head (eg “le changement climatique” 'climate change' / “ce changement” 'this change') and some indirect coreferences between a person name and a function (e.g. “Barack Obama … le president américain”). Other indirect coreference cases (hyponym/hyperonym) will be treated in the future extensions of the system.

B. Coreference relations

The elements of the same reference chain are related by coreference relations. This means that they are referring to the same entity. These coreference relations have various linguistic expressions: agreement in gender and number between antecedent and anaphor, similar syntactic functions or semantic relations (hyponym/hyperonym, or ontological relations). These properties might be simultaneously or only partially satisfied and they are usually exploited by automatic coreference resolution systems.

Several linguistic theories propose valid interpretations of these properties and rules to detect topic transitions and/or pronoun antecedents. [10] proposes a hierarchy of accessible entities in the discourse. The accessibility is defined in term of information content and rigidity. If the entity is accessible in mind, then it could be expressed by a low accessibility expression as pronoun or possessive. Its antecedent should be a previous nearest entity with high accessibility.

[15] treat the problem of the identification of the main discourse entity in term of focus, or center. The Centering theory uses an order of the possible centers of the discourse, following the syntactic function (the subject of the sentence is the most probable preferred center of the next sentence). This theory predicts topic changes, by defining four categories of focus change or maintenance, but treats only consecutive sentences.

Optimality theory reformulates the rules proposed by the Centering theory [15] in terms of constraints. [16] defines the specific notion of topic sentence as "the entity referred to in both the current and the previous sentence, such as the relevant referring expression in the previous sentence was minimally oblique".

To define the topic sentence as a sign of discourse coherence, [16] proposes a set of constraints:

- AGREE: Anaphoric expressions agree with their antecedents in gender and number
- DISJOINT: Co-arguments of the same predicates should be disjoint
- PRO-TOP: The topic is pronominalized
- FAM-DEF: Each definite NP is familiar, so refers to an entity already mentioned.
- COHERE: The topic of the current sentence is the topic of the previous one
- ALIGN: The topic is in the subject position.

These constraints, which might be reformulated in term of relations between an antecedent and an anaphor, are applied in a hierarchically manner. Moreover, the Optimality theory proposes criteria to select an antecedent from several candidates if it satisfies a maximum of these constraints. As [16] proposes, we also adopt an algorithm selecting antecedent-anaphor pairs by checking various categories of constraints.

C. Genre-dependent properties

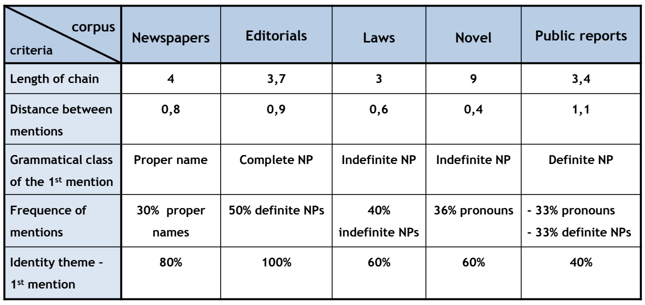
Other parameters used by our algorithm are genre dependent properties. Several studies in textual linguistics [17] aim to characterize genres, text types or registers, by a set of linguistic parameters (the frequency of lexical categories, the preference for some tenses, the frequency of the complex syntactic phrases). These linguistic parameters have a specific communicative purpose and they are used in a particular communicative situation. One category of these linguistic parameters is represented by the reference chain. Genres or types might influence the type of referential expressions used in the text and the choice of the various mentions of the same referent. Cohesion markers as reference chains are dependent on the genre as [12] identifies in newspapers portraits. We assume that reference chains have their specific properties, depending on the textual genre or on the type.

To identify the genre specific properties of the reference chains and to check this hypothesis on other genres, we study the reference chains in a French corpus (about 50,000 tokens) composed of five various genres [18]: newspapers from Le Monde (2004), editorials from Le Monde Diplomatique (1980-1988), a novel Les trois Mousquetaires (Dumas, 1884), some European legal standards from the Acquis Communautaire [19] and public reports from La Documentation Française (2001). We manually annotate the chains to determine which reference chain properties were relevant for a particular genre.

The reference chain study is based on [12]. For each genre, we examine the chains following five criteria:

- the average length of chains (the number of referential expressions referring the same discourse entity);
- the average distance between the elements of a chain (the number of sentences separating the elements);
- the frequency of the mentions depending on their grammatical class;
- the grammatical class of the starting element of a chain;
- the identity between the sentence theme and the first element of a chain.

The study reveals several differences across genres. For example, the average length of reference chains from text laws (Acquis Communautaire) is three mentions while the length is nine mentions for the novel. The difference between the average length of the two genres may be explained in that text laws involve many referents (referential competition between the referents, so many reference chains are opened) while the novel counts lots of descriptions about the main character (which maintains the current chain). Concerning the frequency of the referential categories, we notice that the newspapers contain mostly proper nouns (30.8%) while editorials contain 50% of definite noun phrases. Proper nouns are very frequent starting elements for newspapers reference chains, but indefinite noun phrases are preferred as first mention for text laws and for public reports. Indeed, the measures adopted by the European Commission have a generic scope extended to any state member of the community, hence the massive presence of indefinites (eg. “un Etat Membre”/ ‘Member State’, “une décision”/ ‘a decision’, “une mesure”/ ‘a measure’). In addition, the first element of the chain is identical to the sentence theme for 80% of the occurrences for the newspapers and only for 40% for the public reports. For this last criterion, we checked if it can be possible to gather the reference chains containing the same sentence topic (coreferent reference chains [2]) to identify the document topics.



corpus / criteria	Newspapers	Editorials	Laws	Novel	Public reports
Length of chain	4	3,7	3	9	3,4
Distance between mentions	0,8	0,9	0,6	0,4	1,1
Grammatical class of the 1st mention	Proper name	Complete NP	Indefinite NP	Indefinite NP	Definite NP
Frequence of mentions	30% proper names	50% definite NPs	40% indefinite NPs	36% pronouns	- 33% pronouns - 33% definite NPs
Identity theme - 1st mention	80%	100%	60%	60%	40%

Fig 1. The five genres and their properties

Thus, the corpus analysis of the reference chains highlights their genre-specific properties (Fig 1). We use these parameters to configure RefGen according to the genre.

III. The RefGen Module

In the section above, we present the study of reference chain properties on a corpus composed of several genres. Indeed, the study validates the hypothesis that reference chains have specific linguistic properties depending on the text genre and type (explanatory, narrative etc.). We exploit these properties for reference chain identification. Now, we present the RefGen module architecture and we present the linguistic annotations required (tagging, chunking and Named Entities Recognition). We explain the reference chains algorithm (CalcRef) before presenting the results of the evaluation.

A. The Architecture

RefGen is composed of several modules (Fig.2). The first processing module tags, lemmatizes and annotates the raw input text at chunk level. Then, we apply an annotation module, before proceeding to the reference chain identification step. Among the annotated phrases, we identify complex noun phrases and Named Entities, which represent potential candidates as the first mention of a reference chain. We identify the complex noun phrases among noun phrases modified by several prepositional phrases and/or modified by a relative clause. These phrases are very informative and they precisely identify the referred entity. In addition, in order to avoid wrong anaphora candidates, we annotate impersonal occurrences of the pronoun il. These occurrences are not taken into account by the reference computation module.

Then, after the annotation step, the reference computation module (CalcRef) associates a global accessibility score to each referential expression. Then, the module identifies the anaphora and their possible antecedents. To obtain only valid antecedent- anaphora pairs, the module checks several lexical, syntactic and semantic constraints.

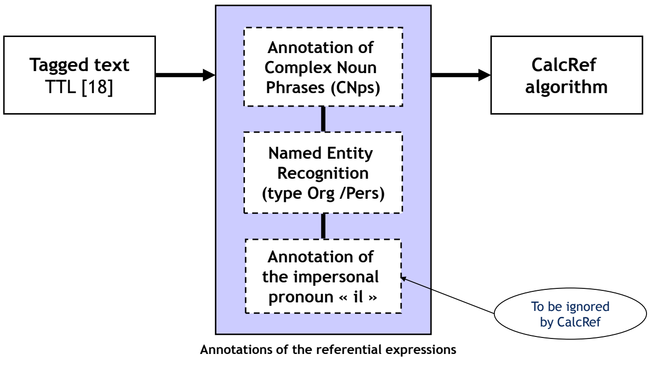


Fig 2. The architecture of the RefGen module

B. Annotations

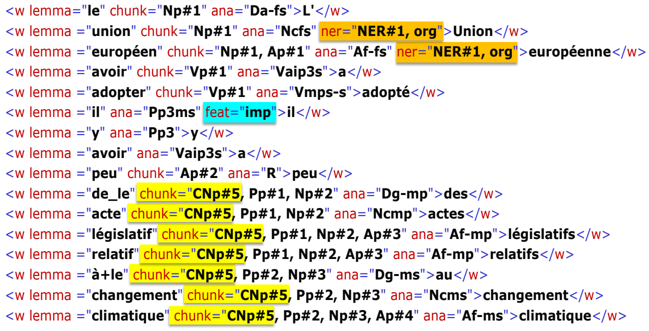
To identify the referential expressions, we tag, lemmatize and chunk the documents using TTL tagger [20].

This tagger identifies chunks (simple noun phrases (NP), prepositional phrases (PP)) and tags some morpho-syntactic properties (tense, mode, person, gender and number). TTL uses the MULTEXT tagset [21].

Then, we apply a set of rules to identify complex NPs (NP modified by at most two PP, NP modified by a relative clause), as “*l'élévation du niveau global de la mer*”/ 'the high of the global sea level' which are more informative than simple NPs. These complex NPs are self-explanatory and they often introduce a new discourse entity.

While we search topic entities, we apply some heuristic rules to identify person and organization names. Persons and organizations are the main actors of the text and they are often related to the main theme of the paragraph. As well, persons and organizations refer to a unique entity and they precisely identify this entity, so they represent good candidates to be a first mention of a reference chain.

In addition, we annotate the French impersonal pronoun il (e.g. *“il pleut”/'*it rains*'*) to eliminate non-anaphoric use of this pronoun. Fig.3 is an example of annotations including lemmas (`lemma`), chunks (simple `Np`, `Pp`; complex `CNp`), morpho-syntactic properties (`ana`), named entities (`ner`) and impersonal pronouns il (`feat="imp"`). We use these linguistic annotations to identify the reference chains and the anaphora pairs.



```

```

Fig 3. Annotations used to detect reference chains

C. The CalcRef Module

CalcRef is the main module of RefGen and it proceeds to reference chain identification by using genre-specific parameters and the linguistic annotations presented in the previous sections. Thus, we specify the genre of the indexed documents and we configure CalcRef according to the properties of the reference chains (average distance between the mentions, average chain length, and the preferred category of the first element of a chain). For example, for a corpus of public reports, the length of the chains is 4, the average distance is 2 sentences and the preferred type of the first element is a complete definite NP. To select the mentions of the reference chain, we define a set of weak and strong constraints, explained later in this section.

The algorithm follows the next steps:

```
 For each p paragraph:
 n=1st phrase of the paragraph;
 d= the average distance between candidates
(number of phrases)
 A.  Select the 1st mention candidates from
the complex noun phrases and the Named
Entities (their AG is greater than or equal
to 190).
 B.  Order the list of the first mentions
(according to global accessibility GA, the
function and the type), open several chains;
 C.  for each phrase, select the list of
anaphora candidates (GA less than 190). We
exclude the anaphoric use of the impersonal
pronouns.
   a. for each anaphoric candidate, select
 the candidate pairs checking the strong
 constraints (without reflexive pronouns)
 and apply weak constraints.
   b. order the pairs according to the
 number of checked constraints and select
 the pair checking the maximum number of
 constraints.
   c. recompose the reference chain from the
 identified pairs
 D. n=n+d and start again at A.
```

For each paragraph, CalcRef selects candidates for the first mention of the reference chains. Then, CalcRef identifies the next elements of the reference chains, by selecting a set of pairs of antecedent-anaphora candidates. Most of the candidates are filtered out by the application of several constraints. Then, we apply the transitivity of the coreference relation to compose the reference chains.

Ordering the referring expressions

For each paragraph, CalcRef selects candidates as first mention of the reference chains among expressions with a high degree of accessibility. [10] defines an accessibility hierarchy to classify the referential expressions according to their accessibility: less the referent is accessible, the referential expression should be longer, self-explanatory and rigid. Thus, indefinite NPs, proper nouns or complex NP, occupying the thematic position are used to mention a new entity (Table I), while short mentions as pronouns might be used to refer to entities already specified in the discourse. The global accessibility AG is computed by combining three elements: informativity (the amount of lexical information), rigidity (the possibility to pick up a specific referent) and attenuation (phonological size). With respect to the initial accessibility hierarchy, we also add indefinite noun phrases in the accessibility scale, even if this category of candidates generates several errors. We use weights on a scale of 10 to 110 for each of these elements (e.g. the global weight of the complete proper noun “Le président Barack Obama” is 220 while it is 150 for the pronoun “elle”).

TABLE I.
ACCESSIBILITY TABLE

Referential expressions	Informativity	Rigidity	Attenuation	Global Accessibility
Indefinite noun phrase	110	110	10	230
Complete proper noun	100	100	20	220
proper noun	90	90	30	210
Complex definite noun phrase	80	80	40	200
Simple definite noun phrase	70	70	50	190
Last name	60	60	60	180
First name	50	50	70	170
Demonstrative	40	40	80	160
Pronoun	30	30	90	150
Reflexive pronoun	20	20	100	140
Possessive	10	10	110	130

CalcRef computes the global weight of the candidates as a sum of the global accessibility weight and the syntactic role weight. We also define a scale for the syntactic role weights: 100 for the subject position, 50 for the direct object position, 30 for the indirect object and 20 for other syntactic functions. Then, genre dependent parameters (the preference for the first element type or the distance between the mentions) are used to increase the weight (+50) of some candidates (for example, if we treat law texts, indefinite NPs are preferred as starting elements of a chain). We order the first element candidates according to the global weight and we select the highest weight candidate as a first element of the current chain. We open a new chain for each element of the candidate list.

In addition, we use the accessibility scale to propose possible antecedent-anaphora pairs. The antecedent should have the global accessibility higher than the anaphor.

Searching valid antecedent-anaphora candidates

CalcRef selects the next elements of the reference chain from highly accessible expressions (pronouns, demonstratives etc.). We establish a set of possible antecedents from low accessible expressions. We combine elements from the two sets and we identify potential antecedent-anaphora pairs. The distance between the two elements of the pair should be less than the average distance defined by the genre parameters.

Then, we adapt the method proposed by [11]. This method checks several constraints between antecedent and anaphora to filter out impossible pairs. Indeed, [11] present a system implementing a constraint-based method for pronoun resolution inspired by the Optimality theory [16].

If the antecedent and the anaphor refer to the same discourse entity, they satisfy a set of constraints defined in section II (chapter B). These constraints are syntactic (similar syntactic function between the antecedent and the anaphor), morpho-syntactic (agreement in gender or in number) or semantic (hyponyms/hyperonyms). A pair antecedent-anaphor satisfying a maximum number of constraints is a valid candidate to be included in a reference chain. [11] adapts these constraints to several languages and proposes an implementation of the algorithm. In addition, the order of the constraints might be changed to obtain better results.

The Optimality theory limits the search space of the antecedent at the previous sentence. [11] propose the algorithm only for pronoun resolution. We extend the set of constraints to other anaphora categories (definite expressions, reflexive pronouns).

Following [11], we adapt the constraints for French. For each pair, we check some strong and weak constraints.

Weak constraints mean that they might be violated, even if there is a valid antecedent-anaphor pair:

- **MORPHO** – agreement in gender or number (between the personal pronoun and the candidate);
- **SYN** – the antecedent and the anaphora should have similar syntactic function;
- **SEM** – semantic relations between the antecedent and the anaphora (for example, person names might be valid antecedents of a NP expressing a function ({B. Obama – le président des Etats-Unis});
- **PROX** – the antecedent and the anaphor are near neighbours (for possessives and demonstratives).

Strong constraints must be satisfied:

- **IMB** – the imbrications mean that an element must not be nested in its antecedent, as [la soeur [de Marie]]), or co-arguments of a verb should not be coreferent;
- **TETELEX** – the identity between NP's head and the partial repetition of the same proper noun.

Moreover, for some specific anaphora, it is necessary to define the set of strong constraints to be satisfied. For example, for possessives or reflexives, the constraint **IMB** (checking the arguments of the verbs) is not useful.

If a pair fails to satisfy a strong constraint, then the pair is deleted from the candidate list. For each candidate pair satisfying all the strong constraints, we check the number of the weak constraints that are satisfied. If several pairs satisfy the same number of constraints, we keep the valid pairs into a large list.

For the semantic constraints, we apply the method proposed by [22]. We use a resource extracted from a 500,000 tokens corpus from computer science newspapers: we extract the occurrences of all the main verbs and their subjects. This resource is used to select a valid antecedent for the pronoun, when several possible antecedents satisfy the same number of constraints. For example, we search the antecedent of the pronoun "il*"* in:

*"*Le camion est passé en vitesse. Le chien a eu peur. Maintenant **il** mange son os". 'The truck was driven very fast. The dog was afraid. Now it eats *his bone.'*

The two candidates *"le camion"/'the truck'* and *"le chien"/'*the *dog'* satisfy the same number of constraints. To decide between the two candidates, we consult the resource. The verb *"*mange*"/'*to *eat'* has as subject *"*le chien*"/'*the *dog'* but no occurrences of a subject *"*camion*"/'truck'* are present in the resource. We deduce the preferred antecedent for "il" is *"*chien*"/'dog'*, because an animal is able to eat, but not an inanimate object.

Building reference chains

Then, we start from the first element of the chain and we search the pairs having this candidate as antecedent in the list. To build the reference chain, we apply the transitivity of the reference relation: if A is antecedent of B and B is antecedent of C, then they are part of the same chain. For example if we have three pairs "J. Chirac – il"; "il – il"; "le président - il" we can deduce that we have a reference chain with four mentions: {J. Chirac, il, le président, il}. We continue the process until the length of the current reference chain is greater than the average gender-specific length. We annotate the candidate pairs identified as part of the current reference chain.

We restart the whole process after selecting the next first candidate element from the ordered list of the current paragraph. The process is launched for every paragraph of the document.

IV. An Example

We present a full example processed by RefGen. We note the various entities mentioned in the discourse with small letters (i, ii, j, k, l, m, o, n, p, q, r, t, s, v, w, z). The example is extracted from a white paper of the European Commission about the climate change.

[**La lutte contre [le changement climatique]ii**]i doit se faire [à deux niveaux]j. Il s'agit d'abord et avant tout de réduire [les émissions de gaz à effet de serre]k ([au moyen [de mesures d'atténuation]l]m), puis de prendre [les mesures d'adaptation qui s'imposent]o pour faire [face aux conséquences inévitables de **[ce changement]p**]n. [L'Union européenne]q ([UE]r) a adopté il y a peu [des actes législatifs relatifs [au changement climatique]t]s, qui définissent [les mesures concrètes nécessaires à la réalisation de l'objectif fixé par [l'UE]v]w, à savoir réduire [les émissions de 20 % par rapport aux niveaux de 1990]z d'ici à 2020.

The algorithm first identifies the entities with a high global accessibility (Proper Nouns, indefinite descriptions or complex definite descriptions). In this genre (public reports), complex definite descriptions are very frequent. So RefGen identifies as potential first mentions the following candidates:

- **[La lutte contre le changement climatique]i,**
- les émissions de gaz à effet de serre]k,
- [au moyen [de mesures d'atténuation]l]m,
- les mesures d'adaptation qui s'imposent]o
- [face aux conséquences inévitables de [ce changement]p]n,
- [L'Union européenne]q,
- [des actes législatifs relatifs [au changement climatique]t]s,
- [les mesures concrètes nécessaires à la réalisation de l'objectif fixé par [l'UE]v]w
- [les émissions de 20 % par rapport aux niveaux de 1990]z.

The candidates are sorted by their global weight (the sum of the global accessibility, the syntactic function and the preference for the first mention category).The most probable first mention are i, q, s, w. We open 4 reference chains and we try to find the next pairs.

Then, for each first mention candidate, we establish a list of anaphor candidates (having the accessibility less or equal than 190): definite descriptions (ii, l, m, o, n, p, z), pronouns (il, il). Both occurrences of il are impersonal, so we check the validity of the constraints for definite descriptions. In this case **TETELEX** is the first constraint to be checked. For example, for the entity i, there is no other mention explicitly referring to "la lutte". But we found a reference chain starting from the entity ii.

We notice that several strong constraints **TETELEX** or **IMB** are violated for "[ce changement]p"(Table II). A constraint violated is marked as '*', a space means that the constraint is checked. We find many direct coreference cases, while pronouns are quite few and their use is impersonal.

TABLE II.
VALIDATION OF THE CONSTRAINTS FOR THE CANDIDATE P

	Id	MORPHO	IMB	SYN	SEM	PROX	TETELEX
p	i						
	ii			*			
	l	*					*
	m			*			*
	o						*
	k	*		*			*
	n	*	*				*

In contrast, we note an example extracted from the newspapers Le Monde diplomatique.

[M. Pons]i affirme en outre, dans [un entretien publié par le Figaro du 21 septembre]j, que " [l'immense majorité [des députés RPR]k]l souhaite [le calme et la sérénité]m et qu'[ils] se détermineront [le moment venu]n ". Minimisant [la fracture ouverte]p entre "balladuriens " et " chiraquiens ", **il** rappelle que [Jacques Chirac]r **lui** apparaît comme " [le candidat légitime]q " de **son** parti.

The algorithm first identifies the entities with a high global accessibility (Proper Nouns, indefinite descriptions, complex definite descriptions). So RefGen identifies as potential first mentions the following candidates:

- **[M. Pons]i,**
- [l'immense majorité [des députés RPR]k]l,
- [le calme et la sérénité]m,
- [le moment venu]n,
- [la fracture ouverte]p,
- [Jacques Chirac]r,
- [le candidat légitime]q.

The candidates are sorted by their global weight (global accessibility, and the syntactic function).The most probable first mention are i, l, r.

Then, we establish a list of anaphor candidates (having the global accessibility less than 190): definite descriptions (l, m, n, p, q), pronouns (ils, il, lui), possessives (son).

TABLE III.
VALIDATION OF THE CONSTRAINTS VALIDATION FOR THE PRONOUNS "IL" AND "LUI"

	id	MORPHO	IMB	SYN	SEM	PROX	TETELEX
il	i					*	-
	j			*		*	-
	l	*				*	-
	k	*		*		*	-
	n						
lui	i			*		*	-
	j			*		*	-
	l	*		*		*	-
	k	*		*		*	-
	n			*		*	-
	p	*		*		*	-
	r				*		

We notice that several strong constraints are violated between i and the definite descriptions. The pairs (i, il) and (i, lui) are the most probable (Table III**).**

V. EVALUATION

We present the first results of the evaluation of RefGen, we compare the reference chains extracted automatically against the manually annotated corpus. We present the results obtained for the CNp annotation module, for the NER module and for the chain identification module. The evaluation corpus is a small corpus (7,230 tokens) composed of public reports of the European Commission about the measures adopted by EU to limit the effects of the climate changes. We compute the recall, the precision and the f-measure of the intermediate modules, as well as the results for CalcRef. We check the results obtained for independent antecedent-anaphora pairs, as well as for reference chains (Table IV).

The NER annotation errors are due to the wrong identification of some acronyms or abbreviations (e.g. GES : gaz à effet de serre) which were annotated as organization names. Some NER annotation errors are due to tagging errors. The CNp identification module fails to identify several CNps (an NP modified by more than three PP), which were not described by the existing set of patterns. Indeed, the test corpus is characterized by very frequent, complex, informative NP.

The evaluation corpus contains 118 anaphoric pairs, but only 24 reference chains. Several antecedent-anaphora pairs are wrongly selected, due to tagging errors or due to the lack of external knowledge sources. For example, some of the antecedent-anaphora pairs were selected because they satisfy the same number of constraints (number, gender, syntactic function). An ontology might help to select the right antecedent.

We tested the system for three various configurations of the genre parameters. First, we use three genre-specific parameters:

(a) distance=2; length=4; preferred type=definite description.

We also tested the system after changing these parameters:

(b) we ignore these parameters and use only a default distance of 20 sentences

(c) we use the newspapers parameters (distance=1; length=3; preferred type = proper nouns).

If we ignore the parameters (case (b)), we obtain more antecedent-anaphora pairs than in the first case, due to the bigger distance between the mentions. Meanwhile, we obtain less reference chains because several smaller reference chains are grouped together. For all the cases, we obtain quite similar results for the pairs, but for the reference chain identification we obtain significant performance decreasing (b) f_measure: 0,51; (c) f-measure: 0,54 (Table IV).

TABLE IV.
FIRST EVALUATION RESULTS

	NER	**CNp**	**CalcRef (pairs)**	**CalcRef (reference chains)**
Recall	0,85	0,87	0,69	0,58
precision	0,91	0,91	0,78	0,70
f-measure (a)	0,88	0,89	0,73	0,63
f-measure (b)	0,88	0,89	0,71	0,51
f-measure (c)	0,88	0,89	0,70	0,54

VI. CONCLUSION

We presented RefGen, a reference chain identification method, developed for French. This new knowledge poor method uses a set of detailed linguistic annotations and the accessibility hierarchy of the referring expressions to select possible antecedent-anaphora pairs. Then, a set of lexical, syntactic and semantic constraints are used to filter some invalid pairs. RefGen also uses some genre-dependent properties of the reference chains (average length, preferred type of the first element, average distance separating several mentions of the same referent). These genre-dependent properties were identified from a corpus-based analysis. We describe a new algorithm designed to identify the reference chains and we present a first evaluation of the module. The evaluation is done with several genre-specific parameters. The evaluation results show an improvement of the results when we use the public reports parameters. The system is flexible; it is possible to add extra constraints to improve the quality of the output.

In the future, the module will be integrated into the topic detection system to be tested in real-life applications. The module will be extended to treat other cases of coreference: plural anaphora, hyponym/hyperonym equivalents, by adding knowledge sources as ontologies or synonym databases.

RefGen will be used to annotate large French corpora with coreference relations. It will then contribute to the development of a reference corpus for French, comparable with those provided by SEMEVAL for other languages.

In addition, future work concerns the adaptation of the system for other languages.

Is Shallow Semantic Analysis Really That Shallow? A Study on Improving Text Classification Performance

Przemysław Maciołek, Grzegorz Dobrowolski

Al. Mickiewicza 30, 30-059 Kraków, Poland
Email: {pmm,grzela}@agh.edu.pl

***Abstract*—The paper presents a graph-based, shallow semantic analysis-driven approach for modeling document contents. This allows to extract additional information about meaning of text and effects in improved document classification. Its performance is compared against the "legacy" bag-of-words and Schenker et al. approaches with $k-NN$ classification based on Polish and English news articles.**

I. Introduction

RESEARCH on computational linguistics has over 50 years of history. It is currently considered as an interdisciplinary field covering topics such as linguistics, psychology, cognitive science, artificial intelligence and others. While the research is done for more than a half of a century, there are still many basic open issues. One of such notable problems is relatively poor ability of machine text content understanding.

The state-of-the-art in modeling text meaning for document classification purposes is practically still basing on a statistical bag-of-words approach, developed in early 70's. In this method, single words are extracted and represented by a vector with their frequency.

Although many enhancements have been proposed to this approach, it has essential drawback: substantially limited amount of information that can be "captured" by such representation. Omission of information about words order is a striking example.

Numerous solutions leveraging graph-based representation of text were presented. One of such method was proposed by Schenker, Last, Bunke and Kandel [23], [22], [21]. The taken approach built document model as graph, where each sequentially found word was added as a next node. Also, links between nodes were tagged with information about section of the document where they were found (such as *title*, *body* or *link*). Thus instead of just calculating frequency of word occurrences, information about their order is also stored.

Other graph-based methods include graph node ranking method similiar to *PageRank* [15], analyzing structure of the document only (ignoring its contents) [8], extracting document features from previously built tree-like structures [10] and extracting features from Schenker *et al.* based graphs [14].

In this paper a new method is presented. Like in the Schenker *et al.* approach, document contents is represented using a graph model. However, the way the graph is built is different and takes into account part-of-speech information about each word. Also, semantic dictionary (such as *WordNet*) is used in the build process. The reasoning behind it is based on observations of language acquisition by children [24], [16] and statistical part-of-speech usage [12], [2].

The new method is compared to well-known Schenker *et al.* and bag-of-words approaches in document classification task. Test results are presented and commented in the final section of the paper.

II. Document Modeling Approaches

In this section, baseline text modeling methods are presented. As a prerequisite, they require processing raw document contents into a form that allows to extract relevant document features. The process might be summarized as an algorithm consisting of following steps:

1) Reading text from a source. Segmentation into sentences and words. Converting all letters to common case.
2) Removing stop-words. These are frequently found words, that do not provide substantial information about document contents (as they are commonly found in any kind of text). The stop-words list is arbitrary and might contain from zero to hundreds of such words. Typical elements are: *"the"*, *"in"*, *"he"*, *"one"*, *"of"*, *"is"*, etc.
3) Word stemming. In this process, the inflected or derived words are reduced to their stems (non-changeable parts). This allows properly treating words of the same base used in different forms (e.g. *"thankfully"* → *"thank*"*, *"thanks"* → *"thank*"*, etc.).

Vector Space

The most commonly used approach for document representation is to count each word occurrence, calculate its frequency and put it into a vector space. This allows to easily find distance between any two documents (vectors) using a selected metric, such as *Euclidean* or *Jaccard* distance [13].

It is worth noting that while the general idea of vector space text representation has not changed during the last 40 years, many methods improving selected vector features quality have emerged, such as *Latent Semantic Analysis*.

978-83-60810-27-9/09/$25.00 © 2010 IEEE

Schenker Text-to-Graph Approach

Schenker *et al.* [23] proposed a method (actually a variant of more general *text-to-graph* approach) for building a graph from hypertext. The process first marks three sections of the text: *title*, *links* and *text*. Next, the graph is being built using following rules:

1) If word (stem) A occurs for the first time, then new node A is created.
2) If word B occurs after word A in section 1, a connection $A \rightarrow B$ is created with label 1.

To reduce the graph size, only the n most relevant words are selected from the document for building the graph. Word occurrence counters are not incorporated (in the typical variant).

Definition 1: To calculate distance between any two graphs, following metrics are proposed:

$$dist_1(G_1, G_2) = 1 - \frac{|mcs(G_1, G_2)|}{max(|G_1|, |G_2|)} \quad (1)$$

$$dist_2(G_1, G_2) = 1 - \frac{|mcs(G_1, G_2)|}{|G_1| + |G_2| - |mcs(G_1, G_2)|} \quad (2)$$

$$dist_3(G_1, G_2) = 1 - \frac{|mcs(G_1, G_2)|}{|MCS(G_1, G_2)|} \quad (3)$$

where:
$mcs(G_1, G_2)$ - maximum common subgraph of graphs G_1 and G_2
$MCS(G_1, G_2)$ - minimum common supergraph of graphs G_1 and G_2
$|G|$ - size of graph G, defined as a sum of numbers of nodes (vertices) and edges: $|G| = |V| + |E|$

To calculate the distance, maximum common subgraph has to be found first. Finding such subgraph is, in general, a NP-complete problem. However, when taken into account that in the created graphs each node has a unique label, it is possible to construct an algorithm finding the solution with $O(|V|^2)$ computational complexity [6], [21].

The originally presented approach (*standard representation*) was further extended. One of the interesting variants was incorporating information about word counts into the graph model and discarding information about document section (such as *link*, *body* and *title*). Each node and edge was labeled with additional information about number of times each associated term appeared in the document (in case of nodes) and number of times two nodes were connected together (in case of edges). These numbers were stored as absolute values (*absolute frequency representation*) or as normalized values - divided by the maximum number of node occurrences in document (*relative frequency representation*).

Definition 2: Graph size used for models using frequency information is defined as:

$$|G|' = \sum_{i=1}^{|V|} v(i) + \sum_{j=1}^{|E|} e(i)$$

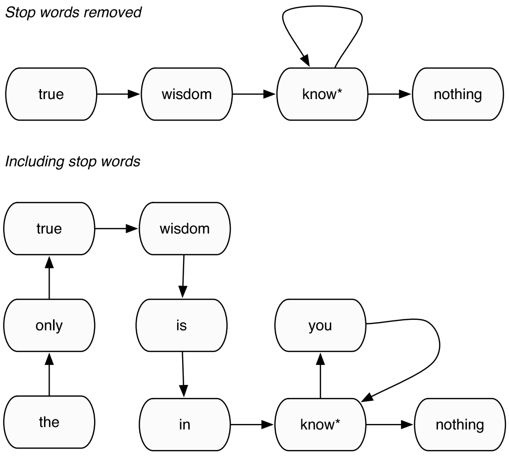

Fig. 1. Example of Schenker graph modeling for sentence *"The only true wisdom is in knowing you know nothing"*. Note: *know** is a stem of both *know* and *knowing*.

where:
$|V|$ - number of nodes in graph G,
$|E|$ - number of edges in graph G,
$v(i)$ - frequency associated to node i
$e(j)$ - frequency associated to edge j

According to the results obtained by Schenker, the *standard representation* provided generally better results for hypertext (HTML) documents in comparison to other *text-to-graph* algorithm variants. When information about links and title was not incorporated (such as when using *simple representation*) the performance slightly decreased. It might be expected that for documents with low number of hyperlinks (or without any of them) the frequency-type representation will provide the best results.

III. MOTIVATION

Almost any linguistics-related problem is still solved drastically better by humans than by machines. A human language is considered as one of the greatest achievements of evolution, practically unique for mankind. Even after so many years of research, we still possess relatively not too much knowledge about the way it really works. Basically, we do not even understand the mechanism in which the language is acquired (learned).

Our lack of knowledge in this area does not allow creating a general tool that would render a text understanding performance comparable to humans. However, while we do not (yet) see the "whole picture", a lot of observations about language development were collected during the years. This knowledge may help to improve computational linguistics mechanisms.

Verbs Absence During Language Acquisition

An important observation is that children learn primarily nouns, even if they can observe other parts of speech with similar frequency [24]. There is a huge disproportion: when child dictionary contains between 20-50 words, as much as

45% of them are nouns, and only 3% of them are verbs. While these numbers were observed for English language, in case of other languages the situation is very similar [3].

This finding might be linked as a consequence of the fact, that nouns are basically used for object labeling (such as "mom", "dad", "bed", "cat") and thanks to this they are relatively firm. The child usually knows elements (classes) which are named by nouns. On the other hand, the verbs might describe an action, state or occurrence and might have different meaning depending on the arguments and context used. Also, they might be often found in sentences describing abstract ideas. In effect, an advance of child development is required for possessing skills necessary for understanding and using verbs.

Polysemy and Parts of Speech Distribution

The WordNet 3.0 [7] database contains more than 155,000 unique strings, which are categorized either as nouns (117798 unique strings), verbs (11529), adjectives (21479) or adverbs (4481). Each string is assigned to one or more synsets (groups of words with similar meaning).

As it might be observed, there's notable difference in ratios of polysemous to monosemous words for different parts of speech (see table I). It is noticeably higher for verbs in comparison to other parts of speech.

It is reversed in case of nouns. Even if the absolute number of them is much higher than any other part of speech, the ratio is very low. Similar findings might be also found when analyzing large text corpora for other languages [12], [2].

TABLE I
WORDNET POLYSEMY STATISTICS [7]

POS	AVERAGE POLYSEMY (INCLUDING MONOSEMOUS WORDS)
NOUN	1.24
VERB	2.17
ADJECTIVE	1.40
ADVERB	1.25

Summary of Observations

An analogy can be observed: capabilities of machine text processing (classification, information retrieval, etc.) might be compared to skills of a young child, which does not yet posses general knowledge about the surrounding world.

Based on the presented observation, a following hypothesis might be suggested: the sub-optimal methodology for unstructured text processing is similar to the one observed for children language capabilities. That is, an emphasis should be put on information that are not troubled by ambiguity (such as nouns). Also, because there are many ways an action can be represented with different verbs, a method for generalizing their meaning (for example using synonyms from semantic dictionary) could improve machine text representation.

IV. SHALLOW SEMANTIC ANALYSIS FOR BUILDING A GRAPH MODEL

The method presented in this section is a special case of a more general solution, which is a member of family of methods based on the shallow semantic analysis approach for building a graph model. The algorithm presented in this paper is a variant, that was experimentally found to be sub-optimal for a document classification task. It is based on observations presented in the previous section and simplifications in predicate-argument sentence decomposition.

As a prerequisite, a number of steps must be performed on the input text. The complete process of transformation contains following phases:

1) Reading raw text from a source.
2) Text segmentation and removal of non-characters.
3) Tagging parts of speech; *Stanford POS Tagger*[1] [27], [26] is used for English and *TAKIPI*[2] [17] for Polish documents. The cited accuracy is approx. 97% for *Stanford POS Tagger* and 93.4% for *TAKIPI* (in the latter case, including gender and case resolution).
4) Finding synsets using semantic dictionary; *WordNet*[3] [7] and *plWordNet*[4] [18] are used for this purpose.
5) Word stemming. In case of English documents *Snowball Stemmer*[5] was used. For Polish, *Morfologik*[6] was chosen.

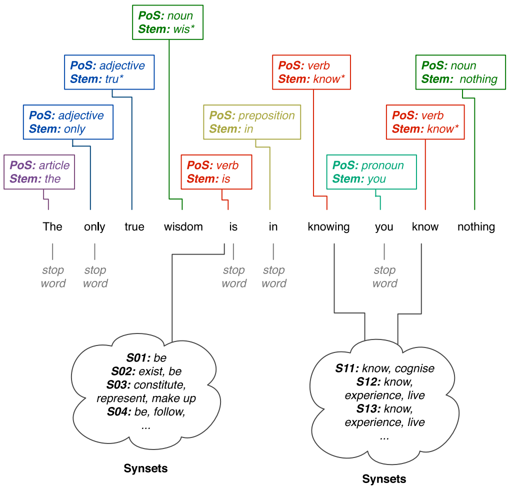

Fig. 2. Example of sentence decomposition

The processed document contents is sequentially analyzed, word after word. Graph representing the text is built using the following set of rules:

1) If a word A is a noun or adjective, and a node with label A does not yet exist, it is created. In case the word occurs rarely in the whole data set (e.g. less than

[1] http://nlp.stanford.edu/software/tagger.shtml

[6] http://morfologik.blogspot.com

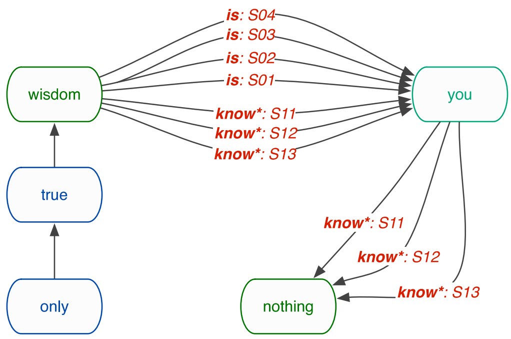

Fig. 3. Example of shallow semantic analysis based text-to-graph transformation result

predefined number of times), it is being replaced by its synsets.

2) If a noun or adjective B is found after another noun or adjective A, then a connection with empty label is created between nodes labeled with A and B.
3) If a verb C was found between nouns or adjectives A and B, then all synsets (sets of words with similar meaning and the same part-of-speech) of C are being added as connection between nodes A and B, labeled with synset identifier.
4) If adjective E is found between two nouns D and F, an additional direct connection between D and F is created.

New distance measures are proposed. They take into account not only the single maximum common subgraph, but all nodes and edges that were found to be common:

Definition 3: To calculate distance between any two shallow semantic analysis created graphs following measures will be used:

$$dist_4(G_1, G_2) = 1 - \frac{|G_1 \cap G_2|}{|G_1| + |G_2| - |G_1 \cap G_2|} \quad (4)$$

$$dist_5(G_1, G_2) = 1 - \frac{|V_1 \cap V_2|}{|V_1| + |V_2| - |V_1 \cap V_2|} \quad (5)$$

where:
$|V_a|$ - number of nodes in graph G_a.

The second of the new metrics ($dist_5$) takes into account number of nodes rather than the size of graph. It might be considered that such approach allows to find how many common subjects are raised in any two compared documents, especially giving the way the graph is being build, as the nodes are mostly constituted by nouns.

V. Tests

The analysed methods are tested using typical automated document classification scenario. It is based on assumption that having examples of documents from different classes it should be possible to automatically assign correct classes to previously unseen documents, as the distance between similar documents (that is from similar classes) should be generally minimal.

In presented scenario, $k - NN$ (k-Nearest Neighbors) classification algorithm is used. Each of the tested document collections is randomly split into two subsets: *training* and *test*. Next, for each document in *test* set, k nearest documents from *training* set are found. After that, a voting is performed among them. The most common occurring category is assigned to the *test* document.

To test usefulness of the new method for document classification problem, the following document collections (both English and Polish) have been chosen:

- *wiadomosci24.pl* - containing 1500 short articles from one of the leading internet news services in Poland. Each document is tagged with 1 to 5 out of 50 tags, such as: *Gdansk, Festival, Politics, Warsaw, Money, Culture, ...*.
- *Rzeczpospolita*[7] - a 800 documents subset of randomly chosen articles published in 2002 in one of major Polish newspapers. They are tagged with one of eight tags: *World, Culture, Law, Publicism-Commentary, Sport, Poland, Economy, Plus Minus*.
- *Reuters*[8] - a subset of 1800 articles randomly chosen from the *famous* Reuters-21578 "Lewis Split" data set. Each document is tagged with at least one out of 32 categories, such as: *wheat, trade, acq, ship, money-fx, etc.*
- *PDDP K-series*[9] [1] - a subset of 800 randomly chosen (out of 2340) *Yahoo!* articles originally extracted by Daniel Boley and used by various researchers for testing document classification performance (including Schenker). Each of them is tagged with 1 of 20 classes such as: *politics, tech, entertainment, business, etc.*

Benchmarks

Quality of results is typically measured using *precision* and *recall*. Instead of presenting both of these numbers, it is a common practice (used also in this paper) to present their harmonic mean also known as *F-measure*:

$$F_1 = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \quad (6)$$

As typically there are more than two classes in total being categorized, two approaches might be used for calculating the average results. The first one is calculating the precision and recall for each category and taking an average. It's called *macro-averaging*. The second one (*micro-averaging*) gives equal weight to every document (rather than category). In such case, precision and recall numbers are calculated for each document and averaged.

Results

For each document collection, considered here as a separate test case, documents are randomly split into training and test sets. Only documents from the ten most frequently occurring tags are selected.

[7] http://www.cs.put.poznan.pl/dweiss/rzeczpospolita
[8] http://kdd.ics.uci.edu/databases/reuters21578/reuters21578.html
[9] http://www-users.cs.umn.edu/~boley/ftp/PDDPdata/

The method parameters (such as maximum number of nodes in a graph, maximum number of features in bag-of-words approach, minimum word count to be selected as a feature, k-number, etc.) were optimized to achieve best results for each of the methods. In other words - multiple tests with varying parameters were run and the best case results are presented.

The tables and figures presented below show results for test/training set ratio of 0.5, so there is equal number of test and training documents. Tests were performed also for other ratios (in $0.1 - 0.9$ range) and relative results were similar (i.e. shallow semantic analysis based approach provided better results than other tested methods).

For *bag-of-words* method both *Jaccard* and *cosine* similarity (with *tf-idf*) were tested. Results for the better performing measure are presented. This is also the case for both graph methods - only the best performing metrics are presented in the results, even if all were tested.

The Schenker approach was implemented according to the description found in [23], [22], [21].

TABLE II
RESULTS - RZECZPOSPOLITA

		MICRO AVG. F1	MACRO AVG. F1
BAG-OF-WORDS	JACCARD	0.68	0.65
SCHENKER	$dist_3$	0.73	0.70
	$dist_4$	0.70	0.66
RANDOM		0.30	0.16
SHALLOW SEMANTIC ANALYSIS	$dist_4$	0.74	0.69
	$dist_5$	0.72	0.69

Polish Texts - Rzeczpospolita: Documents in this collection were tagged with the lowest number of tags in comparison to other sets. In effect, the categories assigned were more general. The only geographic tags were *world* and *Poland*.

TABLE III
RESULTS - WIADOMOSCI24.PL

		MICRO AVG. F1	MACRO AVG. F1
BAG-OF-WORDS	JACCARD	0.46	0.47
SCHENKER	$dist_3$	0.47	0.47
	$dist_4$	0.46	0.49
RANDOM		0.17	0.17
SHALLOW SEMANTIC ANALYSIS	$dist_4$	0.50	0.51
	$dist_5$	0.52	0.50

Polish Texts - wiadomosci24.pl: Lower (in comparison to other test cases) absolute results for *wiadomosci24.pl* articles might be related to the way the tags were assigned, as there were many disambiguations found. For example - document was tagged as *Sport* while in fact it was more related to other tags available for the set, such as: *Lodz, Football*.

English Texts - Reuters-21578: Reuters results provide highest absolute values. There are many reasons for this. One of them is the fact that the original collection was analyzed and "cleaned up" - so it might be expected that many incorrectly assigned tags were removed and some of the disambiguations fixed. Also, it was used as a training set for Stanford part-of-speech tagger, thus it should be most correctly tagged.

TABLE IV
RESULTS - REUTERS 21578

		MICRO AVG. F1	MACRO AVG. F1
BAG-OF-WORDS	JACCARD	0.87	0.73
SCHENKER	$dist_3$	0.87	0.71
	$dist_4$	0.87	0.72
RANDOM		0.46	0.13
SHALLOW SEMANTIC ANALYSIS	$dist_4$	0.89	0.78
	$dist_5$	0.88	0.75

TABLE V
RESULTS - PDDP K-SERIES

		MICRO AVG. F1	MACRO AVG. F1
BAG-OF-WORDS	JACCARD	0.81	0.78
SCHENKER	$dist_3$	0.83	0.79
	$dist_4$	0.84	0.80
RANDOM		0.22	0.15
SHALLOW SEMANTIC ANALYSIS	$dist_4$	0.85	0.81
	$dist_5$	0.84	0.81

English Texts - PDDP K-series: PDDP collection was a subject of tests by Schenker *et al.* Thus it was interesting to see how the shallow semantic analysis approach will compare to it. It is worth noting that size of the document collection used here is about twice as large as the collection size used by Schenker [22].

Analysis

For each of the test cases and benchmarks, except one (macro averaged F1 measure for *Rzeczpospolita* articles), shallow semantic analysis method presents results better than both the vector space and Schenker approaches. The improvement is most notable for *wiadomosci24.pl* and *Reuters* articles. The probable cause of this is the fact that *Rzeczpospolita* and *PDDP K-series* collections have too general tags assigned. For example - in case of *PDDP K-series* there is a single tag related to *business*, while for *Reuters* document collections there are: *acq*, *trade*, *money-fx* and others. It is similar for *Rzeczpospolita* vs. *wiadomosci24.pl* collections. The first one has only 8 possible tags, while the latter has 50 classes.

VI. CONCLUSIONS

A new method for building graph representation of text is presented. With a help of the part-of-speech tagger and semantic dictionary it is performing a shallow semantic analysis of input document producing a model reminiscent of semantic net. Preliminary experiments have been performed for both Polish and English documents to check its practical usability.

The obtained results show that the proposed approach has a slight edge over Schenker and bag-of-words approaches. This suggests that the new method is able to produce graphs better representing the latent meaning of document, even if it effectively uses only some of the terms from the original text representation.

It is important to note that the proposed algorithm, presented in section IV, is a current variant rather than a final version. Depending on the features of target documents and regimes, it might be accordingly modified and extended.

As for the metrics, it has been found that $dist_3$ produces the best results for Schenker method (with a close call for $dist_4$). For shallow semantic analysis approach, $dist_4$ gives the strongest performance. While the new proposed metrics work generally well for both graph methods, the $dist_1$, $dist_2$ and $dist_3$ produce poor results for the shallow semantic analysis.

The presented method is a subject of intensive research. The current focus is directed on two aspects. The first one is leveraging the *Anaphora Resolution* in the method, which should effect in even better classification results. The second is extracting weighted features from the graph (e.g. as presented by Markov *et al.* [14]) and using them with more sophisticated classifier (such as SVM).

***Abstract*—In this paper, we discuss an HPSG grammar of Persian (PerGram) that is implemented in the TRALE system. We describe some of the phenomena which are currently covered. While working on the grammar, we developed a test suite with positive and negative examples from the linguistic literature. To be able to test the coverage of the grammar with respect to naturally occurring sentences, we use a subcorpus of a big corpus of Persian.**

I. Introduction

IN THE past two decades, Head-driven Phrase Structure Grammar (HPSG, [1], [2]) was used successfully to formalize the phonology, morphology, syntax, semantics, and information structure of various languages. Apart from the role HPSG plays in theoretical linguistics, there is also an active community developing large scale implemented grammar fragments that can be used for parsing and generation. While there are large scale grammar fragments available for major languages like English [3] and German [4], [5], [6], [7], other languages such as Persian are understudied.

In this paper, we describe a fraction of the phenomena that are covered in an implemented fragment of Persian (PerGram). The focus is on the implementation of the grammar.

The structure of the paper is as follows: we will say a few words about Persian in general and also briefly describe some of its specific syntactic properties in Section II. Since the grammar is implemented in the TRALE system, we will introduce the general features of TRALE in Section III. In Section IV, some of the phenomena implemented in PerGram are discussed. Section V describes the test suites we are using. In Section VI, we summarize the paper.

II. Persian

Persian is a member of the Indo-European language family and it has many features in common with the other languages of this family in terms of phonology, morphology, syntax, and lexicon. Persian uses a modified version of the Arabic script and is written right to left. However, the two languages differ from one another in many respects. Persian belongs to the subject-drop languages with an SOV constituent order in unmarked structures. The constituent order is relatively free. Verbs are inflected for tense and aspect, and they agree with the subject in person and number. The particle /rā/ is used as an object marker. The language does not make use of gender [8]. Persian has simple and compound prepositions [9], [10]. There exists a closed list of simplex verbs and an open list of compound verbs.

III. TRALE

The TRALE system [11], [12], [13] is an extension of the Attribute Logic Engine (ALE) [14], [15]. TRALE has a parser and a generator and can be used to implement theoretical HPSG proposals rather directly. The only specification that is needed in addition to the constraints that are known from theoretical papers is a phrase structure backbone that has to be defined to guide the parsing process. The system is run with a graphical user interface called Grale that can be used to visualize lexical items, lexical rules, types, and macros as an Attribute Value Matrix (AVM) including relational constraints that might be attached to the respective objects. The GUI does unfilling, that is, features and types that are not more specific than the types in the type definition (the signature, see below) are not displayed. This is a very important feature for debugging large scale grammars. The most recent extension of TRALE features a Java-based graphical debugger, which makes it possible to debug the unification operations stepwise and to debug relational constraints during parsing [16].

To declare a grammar in TRALE, a *signature* file is required which defines the types and the features that are appropriate for them. In addition, a TRALE grammar has one or several files containing the definitions of lexical items, lexical rules, phrase structure rules, relational constraints, principles, etc.

To make the development of large scale grammars feasible, macros can be used in the definition of linguistic objects. Like types, macros can be organized in hierarchies. While the type hierarchy is stated explicitly in the signature file, the macro hierarchy is defined rather implicitly by calling macros in the definition of other macros. In contrast to types, macros can be parametrized. (1) shows an example of a parametrized macro in the lexical entry for /man/ ('I'):

(1) man ~~> @pers_pronoun(first, sg, human).

The macro for personal pronouns takes three parameters: one for person, one for number, and one for the semantic type of the pronoun. Macros are very useful for the development of the lexicon since they hide the complexity of the grammar and therefore make it possible for inexperienced users to write lexical entries.

While HPSG in general deals with linguistic phenomena belonging to all main dimensions of grammar (phonology, morphology, syntax, semantics, pragmatics), the implementation currently considers morphology, syntax, and semantics. The syntactic analysis uses the feature geometry and makes the basic assumptions that were worked out in [7] for German. See [17] for the details on Persian. The semantic analysis is based on Minimal Recursion Semantics (MRS) introduced by Copestake et al. [18]. MRSes can be displayed using 'utool' [19]. 'utool' also provides a scope resolver for MRS.

The TRALE system supports Unicode and it is therefore possible to parse Persian text that is written in the Arabic script. However, since in written Persian short vowels are omitted, a lot of information such as Ezafe, which we will describe in the following section, is left implicit. In order to be able to formalize and test constraints regarding the distribution of linguistically important short vowels, we transcribe Persian words with Latin characters. We already have a version of the lexicon in Arabic script and plan to extend the grammar in a way that makes it possible to use it with or without the transcription.

The implemented fragment of Persian shares a common core with fragments of German, Mandarin Chinese [20], Danish [21], and Maltese [22]. For more information on this core and for downloading the grammars see http://hpsg.fu-berlin.de/Projects/core.html.

IV. The Covered Linguistic Phenomena

A. Principles and Schemata

The grammar uses several immediate dominance schemata and principles that are similar to the ones that were originally suggested by P&S94 [2]. The Persian grammar uses a Head-Adjunct-Schema, a Head-Complement-Schema, a Head-Specifier-Schema, and a Head-Filler-Schema. In addition to these schemata, a Head-Cluster-Schema is used for the formation of complex predicates (see [23], [24], [17] for analyses of predicate complexes in German and Persian). In addition to these more general ID schemata, the grammar uses language specific schemata for the combination of nominal elements with their possessor and for noun compounding.

Principles that hold for all of the mentioned ID schemata are factored out of the schemata and are represented as constraints on an appropriate type, for instance *phrase* or *headed-phrase*. Examples of such principles are the 'head feature principle', the 'semantics principle', the 'specifier principle', and the 'nonlocal feature principle'.

B. Morphological Rules

The grammar contains morphological rules both for derivation and inflection. The morphological rules are modeled as lexical rules. For instance, for inflectional morphology, we use lexical rules that map roots or stems to fully inflected words.

The following lexical rule (LR) is responsible for noun inflection. It maps a nominal stem onto a word with exactly the same syntactic and semantic properties.

$$\begin{bmatrix} \textsc{phon}\ \boxed{1} \\ \textsc{ss}\ \boxed{2}\begin{bmatrix}\textsc{loc} \mid \textsc{cat} \mid \textsc{head}\ \textit{noun}\end{bmatrix} \\ \textsc{affix}\ \begin{bmatrix} \textsc{phon} & \boxed{3} \\ \textsc{num} & \boxed{4} \\ \textsc{sort} & \boxed{5} \\ \textit{noun-i-affix} & \end{bmatrix} \\ \textit{stem} \end{bmatrix} \mapsto \begin{bmatrix} \textsc{phon}\ \boxed{1} \oplus \boxed{3} \\ \textsc{ss}\ \boxed{2}\begin{bmatrix}\textsc{loc} \mid \textsc{cont} \mid \textsc{ind}\ \begin{bmatrix}\textsc{num}\ \boxed{4} \\ \textsc{sort}\ \boxed{5}\end{bmatrix}\end{bmatrix} \\ \textit{word} \end{bmatrix}$$

The input of the rule has a special feature the value of which contains the information about the affix. For nominal inflection, the affix has to have the type *noun-i-affix*. There is a constraint on this type that disjunctively specifies the inflectional paradigm.

$$\textit{noun-i-affix} \Rightarrow \begin{bmatrix} \textsc{phon} & \langle\rangle \\ \textsc{num} & \textit{sg} \end{bmatrix} \vee \begin{bmatrix} \textsc{phon} & \langle \textit{ān} \rangle \\ \textsc{num} & \textit{pl} \\ \textsc{sort} & \textit{human} \end{bmatrix} \vee \begin{bmatrix} \textsc{phon} & \langle \textit{hā} \rangle \\ \textsc{num} & \textit{pl} \end{bmatrix}$$

The respective PHON values provide information about the phonological contribution of the stem and the affix. These values are lists of phonemes and they are concatenated in the output of the lexical rule. $\oplus$ stands for the *append* relation. In addition to the concatenation of the PHON values, the values of NUM and SORT of the output of the rule are instantiated with the features provided by the affix. SORT is a feature that is used to enforce selectional restrictions. The values are based on a semantic ontology which will be described in the subsection IV-E.

In the lexical rule given above, the SYNSEM value of the input is identified with the SYNSEM value of the output. This is different in LRs for derivational morphology. For instance, in the LR that derives adjectives from verbs by appending the suffix *-i* ('-able'), the part-of-speech and the valence specification changes. In addition to these syntactic changes, the semantic contribution of the verb is embedded under a modal operator.

Apart from this derivational LR, we have lexical rules for participle to adjective conversion and for agentive nominalizations. All these morphological rules interact properly with the formation of complex predicates. See [17] for details.

C. Ezafe

The so-called Ezafe is a short vowel /e/ which functions to link the elements of a noun phrase (see for instance [25]). Ezafe appears on: a noun before another noun (attributive); a noun before an adjective; a noun before a possessor (noun or pronoun); an adjective before another adjective; a pronoun before an adjective; the first names before the last names; a combination of the above [26]. Ezafe is realized as /e/ after consonants and /i/ and as /ye/ after vowels other than /i/. Ezafe does not appear on a bare noun or adjective and its appearance indicates that the end of the syntactic phrase is not reached.

We defined an LR which adds the Ezafe at the end of a word. To distinguish Ezafe-marked words from unmarked ones, we employ a binary valued feature EZAFE. The lexical rule applies to words that have the value '−' and licenses words with the value '+'.

EZAFE is an edge feature, that is, a complex phrase is Ezafe-marked if an Ezafe is present at its right periphery. (This is similar to the possessive *'s* in English.) The Ezafe marking of phrases is taken care of by the following constraint on phrases:

$$\textit{phrase} \Rightarrow \begin{bmatrix} \textsc{ss} \mid \textsc{ezafe}\ \boxed{1} \\ \textsc{dtrs}\ \boxed{2} \end{bmatrix} \wedge \textit{last}(\boxed{2}, \left[\textsc{ss} \mid \textsc{ezafe}\ \boxed{1}\right])$$

The relational constraint *last* succeeds if the second argument ($[\textsc{ss} \mid \textsc{ezafe}\ \boxed{1}]$ in the example above) is the last element of the list that is provided as the first argument. The DTRS list is a list of daughters that is ordered according to the surface order of constituents, so *last* returns the rightmost daughter. The EZAFE value of this daughter is shared with the EZAFE value of the mother. Since there is no reference to the number of daughters in the constraint above, it applies to unary and binary branching phrases alike. Currently we only have unary and binary branching rules in the grammar, but of course the constraint would apply to structures with three or more daughters as well.

The distribution of the Ezafe is constrained by implicational statements like the following:

$$\begin{bmatrix} \textsc{head-dtr} \mid \textsc{ss} \mid \textsc{loc} \mid \textsc{cat} \mid \textsc{head}\ \ \textit{noun} \\ \textit{head-argument-phrase} \end{bmatrix} \Rightarrow \left[\textsc{head-dtr} \mid \textsc{ss} \mid \textsc{ezafe}\ -\right]$$

This constraint applies to combinations of nouns with their arguments. Since prepositional arguments have to be realized outside of the Ezafe domain, the head daughter is required to have the EZAFE value '−'. The schema that is used for the combination of a noun with a possessor requires the nominal constituent to have the EZAFE value '+'.

D. Negation

A verb or an auxiliary can be negated by attaching the prefix /na-/. This is implemented by a lexical rule that adds the phonological material and embeds the content of the verb under the negation relation. The syntactic properties of the verb are not affected by the negation and are carried over from the input of the rule to the output. Persian differs from languages like German in that it is impossible to negate a non-finite verb that is embedded under a modal. This is captured by a constraint that requires that the input to the lexical rule is a finite verb.

The LR applies to auxiliaries, simplex verbs, and the verbal element of complex predicates. In the latter case, the negation scopes over the whole complex predicate even though the negation attaches to the verb before the other part of complex predicate is combined with the negated verb. For details see [17].

E. Nouns

Several kinds of nouns are modeled. We implemented common nouns with and without arguments. The arguments are always optional and we have subclasses for nouns that take CPs and for nouns that take PPs as complement. In addition to common nouns, the grammar contains lexical items for proper nouns. Apart from common nouns and proper nouns, we have lexical entries for nouns that play a special role in complex predicate formation (process nouns and verbal nouns). See [17] for details on these nouns.

All non-expletive linguistic objects are classified with respect to an ontology. The ontology contains types like *human*, *agentive*, *substance*, and *geo-location*. This ontology is an extended version of the ontology that was developed in Verb*mobil* [27]. It can be used to specify sortal restrictions of governing verbs with respect to their arguments. Apart from this, it can be used to enforce certain syntactic constraints. For instance, one allomorph of the plural affix /-ān/ is only used with nouns that refer to humans.

F. Verbs

In Persian, there are two classes of verbs: a closed list of simplex verbs; and an open list of compound verbs. The latter group is composed of a preverbal and a verbal element. The verbal elements which belong to a subclass of the simplex verbs are called 'light verbs' and the whole predicate formation process is called 'light verb construction'. The implementation of this phenomenon in our grammar is based on [17] and is not discussed here.

Currently, the grammar has lexical entries for the following kinds of verbs: mono-valent verbs with one NP argument, bi-valent verbs with two NP arguments, bi-valent verbs with an NP and a PP argument, ditransitive verbs with two NPs and a PP, verbs with an NP and a clausal argument, copula verbs, modal verbs, mono-valent unaccusative verbs, and several types of light verbs.

As said, Persian is a language with a relatively free constituent order. This is captured by allowing the combination of an arbitrary element of the SUBCAT list with a head. For instance the head may be combined with the subject and then with the object or the other way round. Languages with strict constituent order like English do not allow this but require the combination of heads with the arguments in order of their obliqueness. See [28] for further discussion of this difference.

We follow [2] in assuming that there is a special representation of valence information, nowadays called Argument Structure (ARG-ST). For all heads there is a mapping from the ARG-ST list to other valence features like COMPS and SPR. For SVO languages like English and Danish the least oblique argument of a verb is mapped to SPR and all the other arguments are mapped to COMPS[1] [29]. The verb forms a VP together with the arguments that are selected via COMPS. This VP is combined with the subject to form a sentence. In contrast, in languages like German and Persian, all arguments of finite verbs are mapped to COMPS. This makes it possible to account for orders like OSV, in which the object and the verb are not adjacent.

While the arguments can be realized in any order with respect to each other, the order with respect to their head

[1] For historical reasons COMPS is still called SUBCAT in the implementation.

is rather fixed: Persian is an SOV language, that is, the verb follows its arguments.[2] On the other hand, Persian has prepositions, that is, the adposition precedes its complement. To capture this, we assume two phrase structure rules that are instances of the general Head-Argument-Schema: one head initial and another one head final. We use a head feature INITIAL, which has the value '+' for heads that are serialized initially and '−' for heads that follow their arguments.

All tense and aspect forms of the verbal paradigm are covered. The progressive and subjunctive marking is done by inflectional lexical rules. The auxiliaries that are used for periphrastic forms are described in [17] and the description will not be repeated here. Three types of complex predicate formation are also discussed in [17] and covered in the grammar.

G. Agreement

Subject verb agreement is handled by the lexical rule that licenses finite verbs. The rule requires that the least oblique NP in the ARG-ST list that bears structural case shares its person and number values with the person and number features of the inflectional affix. This treatment of subject verb agreement is also used for the grammars of German, Maltese, and Hindi. For a similar analysis of agreement in Spanish see [30]. In comparison to the other languages, Persian allows for an additional case: Plural NPs referring to non-agentive entities may also occur with verbs inflected for third person singular.

H. Prepositions

As mentioned above, prepositions differ from verbs in governing their complement to the right.[3] This is enforced by their INITIAL value, which is '+'. The fragment currently contains prepositions that form PPs that can be used as arguments, prepositions that can be used as modifiers, and a preposition similar to the English preposition *by* that can be used in passive constructions.

I. Clitics

Pronominal clitics can be used as possessives (2). As in noun phrases with a full NP as possessor phrase, the clitic is the rightmost element in the NP. Therefore there are two possible hosts for clitic attachment: a noun as in (2a) or an adjective as in (2b):

(2) a. ketāb=aš
book=3SG
'his/her book'

b. ketāb-e jadid=aš
book-EZ new=3SG
his/her new book

Clitics can also fill the slot of the direct object of a verb. In this case, the clitic attaches to the verb as in (3a) or to the preverbal element in a complex predicate construction (3b,c), or to the future auxiliary (3d):

(3) a. did-am=aš.
saw-1SG=3SG
'I saw him/her.'

b. bāz=aš kard-am.
open=3SG did-1SG
'I opened it.'

c. dust=aš dār-am.
friend=3SG have-1SG
'I love him/her.'

d. dust xāh-am=aš dāšt.
friend FUT-1SG=3SG have.SG
'I will love him/her.'

Currently these clitics are treated as postlexical clitics, that is, clitics are treated in the syntactic component. For clitics that fill the object slot of verbs, there is a special grammar rule in the phrase structure backbone used by TRALE. This rule is necessary since the order of clitic and verb is different from the usual order. Apart from these order differences, this grammar rule is an instance of the general Head-Argument-Schema. The noun possessor construction has the same structure for possessors that are realized as clitics and for possessors realized as full NPs. The only difference is the impossibility of the Ezafe when the possessor is realized as a clitic.

However, Samvelian argued for a treatment of clitics as phrasal affixes [25], and the grammar will be adapted in order to cover lexical and morphological idiosyncrasies.

J. Determiners

Persian makes use of prenominal and postnominal determiners: demonstratives like /in/ ('this') and /ān/ ('that') and the indefinite element /yek/ ('a/an') are realized prenominally and the indefinite marker /*-i*/ occurs postnominally.

The prenominal determiners are treated as dependents of the noun and are selected via the SPR feature as suggested by [2]. To establish the semantic relation between the quantifier and the noun, the determiner is able to access the variable of the nominal projection via the SPEC feature.

The indefinite marker /*-i*/ is currently not covered but the implementation of a lexical rule that has the desired phonological, syntactic, and semantic effects is straight forward.

K. Direct Object Marker

The particle /rā/ is used as a marker of a noun in object position. Since object marking is optional, we treat /rā/ as an adjunct. The following is the lexical entry of the particle /rā/:

$$
\left[\begin{array}{ll}
\text{PHON} & \langle \textit{rā} \rangle \\
\text{SS}\,|\,\text{L} & \left[\begin{array}{ll}
\text{CAT}\,|\,\text{HEAD}\,|\,\text{MOD}\,|\,\text{L} & \left[\begin{array}{ll}
\text{CAT} & \left[\begin{array}{ll}
\text{HEAD} & \left[\begin{array}{l} \text{CASE}\,|\,\text{MORPH-CASE}\ \textit{acc} \\ \textit{noun} \end{array}\right] \\
\text{SPR} & \langle\rangle
\end{array}\right] \\
\text{CONT} & \boxed{1} \left[\begin{array}{ll} \text{LTOP} & \boxed{2} \\ \text{IND} & \boxed{3} \end{array}\right]
\end{array}\right] \\
\text{CONT} & \boxed{1}
\end{array}\right] \\
\text{RELS} & \left\langle \left[\begin{array}{ll} \text{LTOP} & \boxed{2} \\ \text{ARG1} & \boxed{3} \\ \textit{specific} & \end{array}\right] \right\rangle
\end{array}\right]
$$

The modified linguistic object is required to have accusative case. This ensures that /*rā*/ attaches to an object. In addition, it is required to have an empty SPR list, i.e. it has to be an NP. We assume that the list of relations that is contributed by signs is not part of CONT, but rather represented at the top level of

[2] We are aware of the fact that arguments may be realized postverbally. Currently, only the postverbal realization of clausal arguments is implemented. We leave the other serialization options to further research.

[3] This shows that the assumption of a headedness parameter that has the same value for verbs and prepositions makes the wrong predictions for Persian. Therefore such a parameter should not be part of an innately specified UG, if there is such a thing at all. See [31] on a detailed discussion of language acquisition including a discussion of Principle & Parameter approaches.

the feature description. This yields a more restrictive theory as far as the locality of selection is concerned [32]. Since RELS is not part of CONT, the CONT values of the modifier and the modified element can be shared. */rā/* is treated as an intersective modifier, and hence the LTOP of the modified noun is identified with the LTOP of the specificity relation contributed by */rā/*. Of course, the argument of the specificity relation is identical to the referential index of the NP ($\boxed{3}$).

L. Complementizers for Subordinated Clauses and Relative Clauses

Embedded clauses are introduced by the complementizer */ke/* ('that'). We treat the complementizer as a head that selects a finite clause. In addition to this complementizer, we have another lexical entry for */ke/* which is used in relative clauses [33]. The grammar covers relative clauses with and without resumptive pronouns. Free relatives will be implemented in the near future. The analysis is described in detail in Taghvaipour's thesis about relative clauses.

M. Pro Drop

Initially pro drop was handled by a unary branching rule that discharges the subject from a valence representation after all other arguments of a finite verb have been saturated. While this rule works correctly, it is inefficient since it contributes edges to the bottom up chart parser even if an overt subject is present in a clause. We, therefore, implemented an underspecification analysis that originally was used for imperatives in BerliGram, an implementation of a grammar of German [7]. The grammars use a valence representation that comes with an additional feature REALIZED [34], [35]. Arguments that are not realized have the value '$-$' and once they are realized, the value is changed to '+' in the valence representation at the mother node. This representation can be used to represent optional arguments by underspecification (see [36] for a different solution using a binary feature): For the subject of finite verbs, the REALIZED value can remain unspecified. The unspecified value is compatible with '+' in the pro drop case and '$-$' in the case when a verbal projection is combined with an overt subject. During a parse of the 165 test sentences from the PerGram Test Suite (see Section V), the grammar version with unspecified REALIZED value licensed 12.7 % less passive edges in comparison to the one that uses the unary branching rule. This resulted in a reduction of parse times of 30.6 % in average.

N. Coordination

The grammar handles symmetric coordinations. The coordination of two or more NPs with */va/* ('and') results in a plural NP, so that the agreement facts are captured correctly. The analysis of coordination is basically the one suggested by [2], that is, the CAT and NONLOCAL values of the conjuncts are shared. However, there is a slight complication: since we use a non-cancellation approach to valence, examples like the one in (4) are problematic.

(4) Ali [[mard rā did] va [xandid]].
Ali man RA saw.3SG and laughed.3SG
'Ali saw the man and laughed.'

In (4), a VP with a transitive verb and one with an intransitive verb is coordinated. The valence representations of the respective VPs is shown in (5):

(5) a. mard rā did: SUBCAT ⟨ NP, ~~NP~~ ⟩
b. xandid: SUBCAT ⟨ NP ⟩

The valence representation of the VP with a transitive verb contains an NP that is marked as realized. Meurers [34] called realized arguments *spirit*. In comparison, the VP with the intransitive verb does not contain such an NP. The consequence is that the SUBCAT values of the conjuncts cannot be unified since the lengths of the lists are different. This problem is solved in the implemented grammar by using a relational constraint that returns all unrealized elements in a valence list. This constraint is applied to both conjuncts and the respective result lists are unified and represented at the mother node. As a result, the valence representation of [[mard rā did] va [xandid]] is ⟨ NP ⟩. The spirit NP (~~NP~~) is not represented at the mother node. The subject NPs of */didan/* ('see') and */xandan/* ('laugh') are unified and hence it is explained why *Ali* fills the respective slots of both verbs.

This analysis captures a lot of complicated coordination phenomena like Across the Board Extraction in unbounded dependencies (questions and relative clauses) and also interacts nicely with resumptive pronouns in relative clauses. However, there is one problem left: the analysis does not extend to German fronting data and case assignment for which it was introduced originally. Meurers [34] and Przepiórkowski [35] suggested representing the saturated complements at the VP level. Auxiliary verbs attract the arguments of the verb they embed. Case is assigned to arguments that are not raised by higher verbs. In the analysis of the sentences in (6), the auxiliary attracts the arguments of *gelesen* ('read') and assigns nominative to the subject and accusative to the object.

(6) a. [Einen Aufsatz gelesen] hat er nicht.
an essay.ACC read has he.NOM not
'He did not read an essay.'
b. [Ein Aufsatz gelesen] wurde nicht.
an essay.NOM read was not
'An essay was not read.'

The important point is that the case is not determined locally in the fronted VP, but assigned by the finite verb. In order to assign case, the finite verb has to raise the realized argument (the spirit) and hence it has to be accessible at the VP node.

With this background, the problem of the coordination analysis is obvious: We can coordinate two VPs and front them. According to the coordination analysis sketched above, realized arguments are not contained in the valence lists of the mother nodes of coordinated structures. Since these spirits are needed for case assignment, we have conflicting demands: coordination requires VPs with verbs of different arity to be syntactically parallel and case assignment (in German) requires all arguments to be present at the VP node.

(7) a. [[Einen Aufsatz gelesen] und [einen Report
an essay.ACC read and a report.ACC
geschrieben]] hat er nicht.
written has he.NOM not
'He neither read an essay nor did he write a report.'

b. [[Ein Aufsatz gelesen] und [ein Report
an essay.NOM read and a report.NOM
geschrieben]] wurde nicht.
written was not
'An essay was not read and a report was not written either.'

It remains to be seen if it is possible to develop a consistent analysis of coordination and non-cancellation approaches to valence.

O. Empty Elements

Currently, two types of analyses of unbounded dependency phenomena are entertained in the HPSG framework: one assumes an empty element for the introduction of a nonlocal dependency [2] and the other one introduces nonlocal dependencies lexically [37]. See [38] for an extended discussion. In our implementation we adopt a trace-based approach.

In addition to the empty element that is used in nonlocal dependencies, we also use an empty determiner for the analysis of NPs that do not have an overt determiner. The empty determiner introduces the quantifier relation that is needed for the interpretation of the NP. The alternative to this treatment would be a unary branching ID schema that discharges the valence requirement represented under SPR and introduces the appropriate semantics. By adopting this solution, one would miss the generalization about determiners. In our approach, the type definitions for overt determiners can be used for the covert determiner as well. No idiosyncratic ID rule is needed. There is just one place in the grammar where it is said that the phonology of a determiner may be empty.

We agree that empty elements should be avoided wherever possible and that they should not be stipulated on a cross-linguistic basis but rather be motivated by evidence from within the language under consideration. That is, a topic morpheme in Japanese should not be seen as evidence for an empty topic head in German, English, and Danish. If empty elements are assumed based on the evidence from the language under consideration, the language acquisition model does not have to assume a rich UG, but is compatible with data-driven approaches like the one that is entertained by Tomasello [39].

As is known from research on formal grammars [40], phrase structure grammars with empty elements can be converted into grammars without empty elements. This result does not transfer directly to grammars with typed feature structures, but most of the grammars that are currently suggested can be converted into grammars without empty elements by applying the techniques developed for PSGs (See [24], [31] for examples). TRALE does this kind of grammar conversion for the relevant cases automatically and transparently for the user and hence the grammars can be specified in a more compact way. For example, in the case of the empty determiner, a special variant of the Head-Specifier-Schema is created that has no daughter for the determiner. That is, TRALE compiles the grammar into one that has the unary branching rule that was mentioned above. See [41] for further discussion.

V. The Test Suites

During the development of the Persian grammar, we put together two test suites that are used for systematic testing and grammar profiling [42]. The first one contains examples from the linguistic literature that are relevant for the phenomena that are covered by the grammar. In addition, it contains ungrammatical examples that were constructed in the development process in order to rule out overgeneration of the grammar which was detected by systematic testing. This test suite consists of 165 sentences including both positive (132 sentences) and negative (33 sentences) examples.

To be able to test the coverage of the grammar, we randomly selected 130 sentences from a Persian corpus called 'Peykare'. Peykare [44] is a big Persian corpus provided by the University of Tehran and the Higher Council for Informatics of Iran. It contains texts from various data sources, both written and spoken.The part-of-speech of each word is annotated according to the EAGLES guidelines. The sentences were selected randomly in such a way that the balancedness of the original corpus is kept in the subcorpus; as a result, the 130 sentences have the variability of the existing registers in the Peykare corpus. Currently, most of the sentences do not parse because of missing lexical entries. We added lexical items for proper nouns, common nouns, and adjectives to the lexicon, but there are other missing lexical items (verbs, clitic forms of the copula, numerals, adverbs, adjectives derived from nouns) that affect 98 of the 130 sentences.

VI. Summary and Conclusion

In this paper, we briefly described some of the phenomena that are part of an implemented HPSG grammar of Persian. A full description of the phenomena and the analyses will be provided in [43]. The grammar covers the core aspects of Persian syntax and morphology and provides semantic representations in the form of MRS. The grammar is evaluated with respect to the example sentences that were collected from the linguistic literature and ungrammatical examples that were constructed during the development process. In addition, we started experiments with naturally occurring data that was selected from the Peykare corpus.

Acknowledgment

We thank Pollet Samvelian, Olivier Bonami, and three anonymous reviewers for comments on an earlier version of this paper. Of course all shortcomings of the paper and the implementation are entirely our fault.

The first author thanks Mina Esmaili, Pollet Samvelian, Yasser Shakeri, and Mehran A. Taghvaipour for help with the

Persian data. We thank Emily M. Bender, Felix Bildhauer, Olivier Bonami, Bob Borsley, Karine Megerdoomian, Ivan Sag, Pollet Samvelian, and several anonymous reviewers, for comments on and discussion of the complex predicate paper and/or Persian grammar in general.

This work was supported by a grant from Agence Nationale de la Recherche and Deutsche Forschungsgemeinschaft to the Franco-German project *PER-GRAM: Theory and Implementation of a Head-driven Phrase Structure Grammar for Persian* (DFG MU 2822/3-1).

WordnetLoom: a Graph-based Visual Wordnet Development Framework

Maciej Piasecki, Michał Marcińczuk, Adam Musiał, Radosław Ramocki, Marek Maziarz
Institute of Informatics, Wrocław University of Technology, Poland
Email: {maciej.piasecki,michal.marcinczuk}@pwr.wroc.pl

***Abstract*—The paper presents WordnetLoom – a new version of an application supporting the development of the Polish wordnet called plWordNet. The primary user interface of WordnetLoom is a graph-based, graphical, active presentation of wordnet structure. Linguist can directly work on the structure of synsets linked by relation links. The new version is compared with the previous one in order to show the lines of development and to illustrate the introduced difference. A new version of WordnetWeaver – a tool supporting semi-automated expansion of wordnet is also presented. The new version is based on the same user interface as WordnetLoom, utilises all types of wordnet relations and is tightly integrated with the rest of the wordnet editor. The role of the system in the wordnet development process, as well as experience from its application, are discussed. A set of WWW-based tools supporting coordination of team work and verification is also presented.**

I. An Editor for Wordnet

A LARGE wordnet[1] is a very complex graph of many thousands vertices and arcs, where vertices represent lexical units and sets of lexical units, and arcs represent lexico-semantic relations of several types. A wordnet can be expressed in a simple formal language, cf the language defined for the needs of Princeton WordNet [3] and used in "lexical source files". However, the size and the complexity of a large wordnet makes manual encoding of the wordnet structure error prone. Error probability can be reduced by the introduction of specialised wordnet editors that free linguists from learning a formal language of description and provide some forms of error checking. Several wordnet editors have been proposed.

Two applications were constructed for the EuroWordNet project [4]: Polaris — an editing tool, and Periscope — a graphical database viewer. However, Polaris is a commercial tool, its development has been closed, and it is not commonly available for research. Moreover, it is a modification of a previous ontology editor, is tightly associated with the EuroWordNet structure and was constructed for a limited number of platforms.

Because of the Polaris limitations, a new tool called VisDic was created for the Czech WordNet [5]. In VisDic the relation definitions are still written in text windows, but an XML based format is used and some immediate browsing is possible in the tool, e.g. bi-directional browsing of graphs of semantic relations. VisDic was used in the Slovene Wordnet [6] and was available for research. VisDic was a monolithic application directly working on XML files, contrary to its direct descendant DEBVisDic [7] – a client-server, lexical database editor. DEBVisDic reimplements and extends the functionality of VisDic and is based on the client-server architecture and an XML database server. DEBVisDic has become a popular tool used in several projects.

Both tools are oriented on editing a wordnet synchronized with wordnets for other languages by the Interlingua Index [4], that complicates their basic structure and user interface.

For the needs of the GermaNet[2] development a dedicated wordnet editor called GernEdiT was constructed [8]. GernEdiT stores data in a relational database and provides concurrent access for many users at the same time. GernEdiT offers graph-based, graphical presentation of the wordnet structure, but limited to the hypernymic links only. Other types of relations, including relations between synsets (called *conceptual relations* in GermaNet) are not shown. Moreover, direct editing of the relation graph is not possible. Data must be first changed or added via dialogue forms. This makes the association between an action and the effect more remote from the user point of view. Direct editing of the graph is more compatible with the idea of GUI (Graphical User Interface).

The majority of existing tools for visualising a wordnet focus only on the hypernymy structure, e.g. [9], [10], and only some of the graph-based tools offer possibilities of editing, e.g. [11].

When the project on the construction of plWordNet[3] started in 2005, DEBVisDic [7] was not available and VisDic [5] was not an alternative, as it is a single machine tool. We needed a tool supporting a group of linguists working in a distributed environment. A dedicated wordnet editor called plWordNetApp was built. It was not as universal and flexible as DEBVisDic, but it implemented the assumed procedure of linguistic work. Its interface was designed according to the estimated ways of performing linguistic tasks. plWordNetApp enabled cooperation of a linguist team on the basis of a central database accessed via Internet. A brief characteristic of the editor is given in Sec. II.

plWordNetApp has been used by the Polish wordnet development team since the year 2006. During this period we

[1] A wordnet is a large electronic thesaurus following the basic construction features of Princeton WordNet [1], [2]. In WordNet, one and multi-word lexical units are grouped into *synsets* – "sets of near synonyms", that are linked by semantic relations derived from lexico-semantic relations.

[2] GermaNet is a wordnet for German, the second largest wordnet in the world.

[3] The first publicly available wordnet for Polish – Polish name: *Słowosieć*

collected rich experience concerning usability drawbacks of the editor. Editing and browsing complex graphs of hypernymy appeared to be the biggest problem. The problem was gradually rising with the increasing complexity of the plWordNet hypernymy structure[4]. Linguists requested visualisation of the hypernymy graphs which would be improved in the comparison to simple tree-based, static visualisation offered by plWordNetApp. Thus an improved version of the editor was constructed with the graphical presentation of the wordnet structure as a basis for all kinds of interaction.

The goal of this paper is to present a new wordnet editor called WordnetLoom, which is built around the idea of visual, direct editing of the wordnet graph structure. The editor is integrated with a tool called Wordnet Weaver, which delivers automatic support for extending the wordnet.

In the rest of the paper we will first briefly describe plWordNetApp – the basis for the present version of the application. Next the core graph-based view will be introduced. Full integration of WordnetWeaver with the rest of the application is discussed. The paper is concluded with the presentation of a set of web pages enabling browsing of data important for the coordinators of a linguistic group and plans for further development.

II. plWordNet 1.0 Development Tools

From the very beginning of designing plWordNetApp we were trying to find a solution for the necessity of presenting and editing complex wordnet structures and, at the same time, fitting the resulting complex structures of user interface onto one screen. In order to avoid cluttering the main screen, we decided to divide the user interface of the application into two main screens, presenting two main perspectives:

- the *perspective of lexical units*[5]
- and the *perspective of synsets*.

plWordNetApp GUI lets the lexicographers avoid the use of an artificial language for the description of semantic relations, starting with introduction of a new lexical unit (LU) and its description; this improves on the practice in WordNet and GermaNet [1], [15]. Both browsing and making decisions (during editing) are done via GUI screen controls and transparently recorded in the server database.

The perspective of lexical units, cf [13, pp. 39], was intended to support grouping lexical units into synsets. The lexical unit list, present in the system, can be filtered according to several criteria, e.g. a selected domain. To facilitate searching, each synset is also automatically assigned to the domain of its first lexical unit. Domains are the main tool in organising the work of the linguist team: linguists are assigned complete domains to process by the coordinator. Once a lexical unit has been selected, its properties are presented and can be edited. A new lexical unit can be added in the lexical unit perspective (but in some other parts of plWNApp GUI, too).

All synsets including a given lexical unit are shown in the tabbed panel below the lexical unit property panel, cf [13, pp. 41]. Editing of the selected synset is possible in the tabbed panel to the right of it — the second, hidden tab pane contains the synset properties. We assumed that first a selected lexical unit is assigned to an existing synset or freshly created one, and then the synset is edited.

In the hidden tab pane of the synset list panel, one can browse and edit a list of lexical relations[6] of the selected lexical unit, i.e. between pairs of lexical units, e.g. antonymy or derivational relations. Derivational relations play an important role in the structure of plWordNet [16].

In order to support the consistency among the linguists' decisions a *substitution test* defined for the given relation is presented to the user, prior to adding any new instance of a semantic relation. The test templates are defined and can be edited by coordinators in a dedicated window. On the basis of a template, a test instance is generated from the template by filling it with the inflection forms of the tested lexical units — the morphological analyser *Morfeusz* [17] was applied. The inflection form properties are specified in templates by IPIC codes. The mechanism of the tests makes plWordNetApp different from other wordnet editing tools, e.g. DEBVisDIC.

From the property panel of the selected synset, the user can switch to the synset perspective set to this synset as the *source synset*.

The five panels of this synset perspective, cf [13, pp. 41], can be divided into the following groups:

- selection and editing of a *source synset* – the synset for which we are going to define a relation or whose relations we are going to browse and edit,
- selection and editing of a *target synset* of a relation to be defined.
- browsing of existing relations.

There are two possible views of synset relations: a tabular one, cf [13, pp. 41] and a tree one (the hidden tab pane). According to the linguists' demands, the initial browsing facility was extended with editing synset relations directly in this view. The browsing panel also enables the navigation along the graph of relations. The possibility of editing synsets directly in this perspective was introduced in order to facilitate

[4] The hypernymy is a lexico-semantic relation between a lexical unit of a more general meaning and a semantically subordinated lexical unit of a more specific meaning – a relation similar to the superclass-subclass relation – e.g. 'plane figure' is a hypernym of 'tree diagram'.

[5] Informally, lexical unit is a semantically disambiguated word in a broad sense. Technically, a *lexical unit* is a pair: *lemma* and one of the *meanings* represented across different occurrences of this lemma in language utterances, cf [12], [13], e.g. a pair: the lemma *kolejka*, [polysemous] 'narrow-gauge railway', 'train', 'round' or 'queue', and its meaning represented in *plWordNet* 1.0 [14] by the symbol `kolejka 3` – a kind of railway, means of transport.
A *lemma* is a morphological word form selected as an exponent of the whole set of word forms of the same Part of Speech, such that all word forms from the set are described by the same shared grammatical categories and the word forms differ only in the values of the subsequent categories, e.g. *program* 'program' as an exponent of a set: *programu*, *programie*, *programach*, ...or *maszyna parowa* 'steam engine' (multiword lemma) as an exponent of the set: *maszyny parowej*, *maszynie parowej*, *maszyn parowych* ...; we assume that the choice of a particular word form as a lemma is arbitrary and constrained only by some tradition.

[6] By lexical relation we mean a lexico-semantic relation described by pair of lexical units, in contrary to synset relations that link synsets and originate from the lexical relations defined for the lexical units belonging to them.

the correction of the initial synsets, e.g. it is possible to extract some lexical units from the source synset and to create a new hypernym synset.

Whenever a user wants to introduce an instance of a synset relation, the appropriate substitution test is presented. According to the definition of the synset relation introduced in plWN, it must be valid for any pair of lexical units from both synsets: the source and the target one. Thus, lexical semantic relations are extrapolated from relations on lexical units to relations on synsets. The substitution test window facilitates selecting all possible pairs of lexical units (from both synsets) and generating instances of the test.

Besides the main screen of the synset perspective, cf [13, pp. 41], an additional screen of synset editing was introduced during the plWordNetApp development. This screen is used for browsing synsets and have a layout similar to the lexical unit perspective: a large list of synsets on the left (rich filtering possibilities), and the tabular view of the selected synset relations, plus all synset editing panels on the right. The screen and the lexical unit perspective are synchronised, i.e. the filter setting and the selected synset and/or lexical unit are transferred to and from the lexical unit perspective during switching. It facilitates browsing the lexical unit relations of the lexical units belonging to the given synset.

III. Graph-based Wordnet Editor

The construction of plWordNetApp was focused on its use on slower computers as were used in 2005 and effectiveness of the primarily keyboard-based interaction. A new version of the application, called *WordnetLoom*[7], is built around the active, graphical presentation of the wordnet structure as a central element of the user interface. The presentation is described as 'active', as it enables not only browsing but also full editing of the structure. An example screenshot is presented in Fig. 1.

The organisation of the presentation is a mixture of the often used radial layout and a vertical tree-like scheme. The latter is often used for presenting large graphs and also wordnets, e.g. [9]–[11]. In the radial layout one synset (node of a graph) is selected as the central one (the present location of the user focus) and other synsets are presented around it in circular layers defined by the number of links from the centre.

According to our analysis, the radial layout expresses several drawbacks from the point of view of the active wordnet presentation. There is only one central element and simultaneous presentation of several sub-graphs sharing some nodes on one screen is difficult. A situation in which there are several

[7] The name refers to a static role played by the wordnet editor – it is a tool, which enables manual construction of a wordnet, while WordnetWeaver is a semi-automatic tool, which is a kind of 'active participant' of the wordnet development process.

paths from the central node to a node shared by the sub-graphs causes deformation of the layout. This is a problem for any layout, but the radial one is especially prone to this issue.

We modified this scheme in order to preserve presentation of the hypernymy in the form of a tree-like scheme. Thus, a synset which is selected by the user becomes the synset in focus. Along the vertical dimensions its hypernyms (direct and indirect) and hyponyms are presented, respectively above and below the central synset.

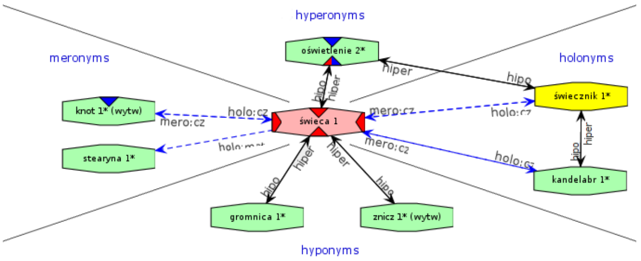

Fig. 2. Layout of the presentation of relation links (Glosses for synsets: *oświetlenie* 'lighting', *knot* 'wick', *świeca* 'candle', *kandelabr* 'candelabra', *stearyna* 'stearin', *znicz* 'candle', *świecznik* 'candlestick').

Meronymy and holonymy are shown along the horizontal dimensions: meronyms to the left and holonyms to the right, respectively. An example of the layout of relation presentation is shown in Fig. 2. Lines dividing the space and the relation names written in a blue bold face font are not a part of the screen, but they have been added for the presentation purpose only. Other types of synset relations, like near-synonymy[8], dweller (e.g. *mieszczanin* 'burgher' – *miasto* 'city'), markedness[9] are presented below the central synset, as they are close in their character to the hyponymy. Relations are visually differentiated by line style, line colour and labels. The definition of labels follows symbols used in the source files of Princeton WordNet. Optionally, shorten names of relations can be used instead, as it is shown in Fig.2.

Interaction starts with searching for lexical units in the left panel. Next, after a lexical unit has been selected the corresponding synset is shown as the central synset. Initially only synsets linked by the direct links to the central one are presented. However, the user can navigate by pressing triangular buttons on the sides of the octagonal synset symbols. The colour of the triangular buttons signals whether none, some or all links of the given type have been opened for the given synset.

A synset can contain several lexical units[10], each lexical unit can participate in several lexical relations, a synset can have several dozen relation links and there can be many synsets – it is impossible to show legibly all this information on one computer screen at the same time. Thus we had to remove a lot of data from the main panel and leave only the minimum of information required for the general understanding of the structure on it. We left only one lexical unit presented per synset, this is compatible with a linguistic practice of assigning the lexical unit which is the most representative for the given synset to first position. Moreover, in the case of a large wordnet the vast majority of synsets include only one lexical unit.

The whole set of lexical units of the central synset can be browsed and edited on the `Synset` panel – the pane in the middle of the right most column in Fig. 1.

Lexical relations have been moved to the separate pane in the bottom-right corner – `Lexical relations` in Fig. 1. Only relations for a lexical unit which is selected in the `Synset` panel are presented. Keeping the detailed information concerning synsets and lexical units in the separate panels defers access to this information and increases the load of the user's short-term memory, but it is a compromise with the possibility of having a more broad view on the wordnet structure.

Synsets are assigned a minimal representation in the graph, but still a wordnet structure of relations can be quite dense in some parts, and many synsets located in the upper parts of the hypernymy structure can have several dozens or even hundreds[11] of outgoing hyponymic links. Thus, by default, WordnetLoom presents only up to $k = 5$ (a parameter) links of the given synset relation (presently only hyponymy). If the number of links is greater, than only the first $k - 1$ are automatically presented and the rest is folded and hidden under the symbol of a circle with the number of hidden synsets shown on it. After clicking the circle a small list-window is shown, the user can browse across hidden links and unfold any sub-group of them – this situation is presented near the bottom of the main panel in Fig. 1. In any moment a link can be folded back into the group of the hidden links.

In large graphs the user can quickly get lost seeing only a small portion of a graph. As a support for navigating in the space of a large graph we introduced a mini-map overview panel in the top-right corner in Fig. 1. Synsets are presented only as point-size circles, but colours are used to distinguish the central synset and selected synsets. Moreover, synset descriptions are given in tooltips shown in response to holding the mouse pointer over some circle.

Visual, graph presentation gives an opportunity to perform editing directly on the relation structure. The context and potential consequences of an action to the presented part of the wordnet structure are clearly visible on the screen. However, only a subgraph can be presented and the biggest problem was to find a way for adding new relation links from synsets presented on the screen to those not. A gradual enlargement of the subgraph being unfolded by clicking triangular buttons is always possible, but only to some space limits. Unfolding of huge graphs is not an option if one has to look for the target

[8] Near-synonymy is different than synonymy expressed by synsets, and is used to link lexical units of the very close meaning but belonging to the different language registers, e.g. *chłopiec* 'boy' – *gówniarz* 'squirt'.

[9] Markedness is relation originating from the regular derivational associations and encompasses several sub-types like dimunitives, augmentative, expressive forms etc.

[10] There are a few synsets which include about 20 LUs each.

[11] E.g. *czynność* 'activity' has 376 hyponyms, mostly gerunds.

synset of a link in some different part of the wordnet. In order to facilitate simultaneous browsing of different parts of the wordnet the central panel was implemented as a multi-panel window enabling opening each sub-graph in a new sub-panel of the central panel. However, switching between sub-panels complicates the way in which selection of a target synset is performed. The user has to remember the state of the user interface as "in selecting a target". In order to make both the source and the target of the action accessible without switching between sub-panels, we introduced a *clipboard* – and additional panel – in which the user can keep references to the synsets that he is working on, are interesting to him, etc. `Clipboard` is located below the main panel, see Fig. 1. When adding a new relation link the user first selects the source synset by right clicking it, and then selects the target synset from the active sub-panel or from the clipboard. Only synset symbols are shown in the clipboard but one can activate a sub-panel, which is already open, or open a new sub-panel for a synset in the clipboard with mouse double clicking on its symbol.

The functionality of simultaneous opening several graphs in separate sub-panels supports comparing different parts of the wordnet structure – a challenging task but very important in the case of a large wordnet developed by a team of several linguists. Erroneously separated parts of the hypernymy structure can be immediately linked, and other corrections can be introduced, too.

It is worth to emphasise here that the graph-based editing and presentation is a significant advantage offered by *WordnetLoom* in comparison to *plWordnetApp*, at least according to the opinions of the linguist team members. The most important improvement is that a linguist can work on all relations (linking synsets and lexical units) using one set of panels without the necessity of switching to other screens. Moreover, he can still follow the general wordnet structure as it is defined by the synset relations and can be perceived only from the perspective of groups of inter-linked synsets not only singular synsets.

IV. Integrated Semi-automated Support

WordnetLoom includes a new version of WordnetWeaver as its integrated part [13]. WordnetWeaver is a tool supporting semi-automated expansion of plWordNet. It consists of the two parts:

- the algorithm of Activation-Area Attachment (henceforth, AAA) which for a new lemma from the outside of plWordNet generates a set of suggested new lexical units on the basis of several knowledge sources,
- and an user interface based on the active presentation of hypernymy subgraphs as descriptions of the suggested relations.

The latest version of the AAA algorithm was described in details in [18], here only a brief characteristics is given below. AAA utilises several knowledge sources describing semantic association of lemma pairs. The used set of five knowledge sources includes: Measure of Semantic Relatedness (1), which has been constructed automatically on the basis of a large corpus, lemma pairs – possibly hypernymic – extracted from the corpus by hand-written patterns (2) and also patterns learned automatically (3). Moreover, lemma pairs for which the measure returns high values are filtered by a classifier (4), which has been trained for the recognition of wordnet relations and finally lemma pairs in which both lemmas are mutually high on the their lists of the mutually close semantically related according to the measure (5), cf [13].

AAA works in three steps, described below in the perspective of adding one new lemma to plWordNet.

1) Semantic fit between a new lemma and each lemma in the wordnet is calculated on the basis of weighted voting applied to information concerning the new lemma from the knowledge sources.
2) Semantic fit between the new lemma and each synset is calculated:
    a) on the basis of cumulated fit between the new lemma and the synset lemmas,
    b) and also on the basis of the fit between the new lemma and synsets that are located in the close distance to the given synset.
3) Connected hypernymic sub-graphs of synsets expressing higher semantic fit to the new lemma are identified and presented as descriptions of potential new lexical units for the new lemma.

Connected sub-graphs identified by AAA are presented graphically to the user, e.g. in Fig. 3 for the new lemma *flinta* ('shotgun', 'flint-lock gun') one lexical unit is suggested and presented as a graph with the highest fit for the synset including *strzelba* 'shotgun'. On the screen, the purple oval represents the new lemma, synsets of the colours from yellow to red are elements of the identified sub-graph and green synsets do not belong to the suggestion but have been unfolded manually by the user. Synset colour expresses the strength of semantic fit between it and the new lemma: light yellow means weak strength of fit, darker yellow and red represents increasing strength. In the case of synsets presented as rectangles the fit was calculated on the basis of the Measure of Semantic Relatedness only ("weak fit" in [13], [18]), while octagons signal stronger fit supported by data from several knowledge sources ("strong fit" in [13], [18]).

The main change in the WordnetWeaver user interface is its full integration with WordnetLoom. Thus, suggestions are shown as hypernymic sub-graphs, but the user can browse relations of any type and add a new lexical unit for the new lemma with the help of any relation. In the previous version of WordnetWeaver [13] only hypernymic links could be browsed. A new lemma could be added to an existing synset member or as a new hypo/hypernym, but any other relation could not be directly used. WordnetWeaver was initially focused on expanding a wordnet along synonymy and hypernymy dimensions. That is why its effective use was limited to nouns, and the first attempts to apply it to verbs failed, as the verbal hypernymy structure is very limited. However knowledge sources assign high values of semantic association to lemma pairs that are linked not only by synonymy/hypernymy, but also by other lexico-semantic relations, e.g. meronymy/holonymy. Thus new LUs suggested for a lemma can be also motivated by relations other than synonymy/hypernymy.

In contrast to plWordnetApp, the user interface of new version of WordnetWeaver, presented here, has been changed to the new one developed for WordnetLoom. As a results, see e.g. Fig. 3, the user now has access to any relation defined in the wordnet and new lexical units can be attached by any relation. A new algorithm of the layout generation prevents overlapping presentation of synsets on the screen.

WordnetWeaver was intended to be a tool for a team of linguists working simultaneously, rather than for an individual linguist. Thus the work procedure is based on assigning disjoint sets of lemmas, called 'packages', to particular linguists. Packages are numbered and a package can be selected using the text edit called `Package number`. Instead of dividing lemmas into packages on the basis of their alphabetic order, lemmas are semantically grouped by the clustering algorithm implemented in CLUTO system [19] applied to the results of the Measure of Semantic Relatedness, cf [13]. We did not expect perfect clustering, e.g. in terms of cluster purity, we only wanted to achieve a practical effect of groups generally semantically coherent. Created lemma groups appeared to be quite coherent, on average 2–3 semantic domains (e.g. names of professions, food, plants, minerals, etc.) can be noticed. During two years of intensive practical use this method based on the off-the-shelf clustering tool proved its value. In the new version of the WordnetWeaver we added a mechanism of temporal blocking a package for the linguist editing it. The mechanism is transparent to the users and blocking starts with the first editing actions and is automatically removed after the linguist has closed the client application or switched to editing of another package.

Quality of suggestions generated by the AAA depends on the local quality of the wordnet structure, e.g. if for there are no appropriate hypernyms for the new lemmas in the wordnet structure, the generated suggestion can be accidental. Thus, WordnetWeaver is equipped with mechanism of re-computing suggestions, which is activated on the user request (the button `Re-compute`). This facility can be especially helpful in case of constructing a new hypernymy sub-graph for some domain which was scarcely populated at the beginning. In the older version of WordnetWeaver the re-computation was run for all packages, in the present version the process is limited to one package only and can serve simultaneously several requests putting them into an internal queue.

V. Management Tools

The linguistic team is organised into two subgroups: wordnet editors and coordinators. The task of coordinators is to take care of the consistency of decisions made by different editors and to check the quality of changes introduced. In order to support the work of coordinators and facilitate the team cooperation a set of tools was developed. The tools are accessible via web pages in order to make usable even in the case of low bandwidth network connections.

First, browsing all changes is possible, e.g. adding a new wordnet element (like lexical unit, synset, relation link, etc.), deleting and modifying. Each change is registered together with information concerning the exact time and person who made it. An example screenshot is presented in Fig. 4. The filtering functionality – the top-right part of the screen – enables limiting the data to particular period, linguist or domain. Moreover, each team member can search for the source of the observed wordnet element, e.g. in order to get explanations concerning the reason of the introduction of some specific lexical unit (word sense).

On the additional web page, coordinators can observe the pace of work in relation to particular linguists, and on the basis of the collected data they are able also to plan the distribution of work among linguists.

Some diagnostic reports have been introduced, as well. Coordinators can obtain data concerning synsets without hypernyms and/or any other relation link[12]. These reports are the basis for correcting the structure and joining separated hypernymic sub-graphs into larger structures in those cases where it is supported by the linguistic data. The whole hypernymy graph is being constructed in plWordNet in the bottom-up direction, i.e. starting with more specific lexical units and their relations.

The set of management tools is being continuously extended but even its present version is frequently used by the coordinators and the linguistic team.

VI. Further Research

The vast majority of WordnetLoom is now implemented. Its new version described in this paper has been used for the last three months and about 9000 LUs and almost 20000 relation links have been added into plWordNet with its help. The idea of the primarily graph-based user interface in a wordnet editing tool seems to work well in practice, especially in the case of group work on expanding larger wordnet in the process driven by data extracted from large corpora. In such a process different parts of the wordnet are being developed simultaneously, and the linguists must follow the changes in an appropriate way.

Concerning the application development, we concentrate now on fixing problems which appeared during the work of linguists, as well, as minor improvements introduced in response to requests of linguists.

We work now on a significant extension of the AAA algorithm which is the basis for WordnetWeaver. We aim for the use of all types of relation links as a basis for expansion (now, only the hypernymy structure is used) and generating suggestions targeted at particular relations as description of the

[12] The presence of a synset which is not linked to any hypernym does not necessarily mean an error in the wordnet. In plWordNet every relation link must be supported by the linguistic analysis. Thus it is only required that there must be at least one relation link for a synset, and each lexical unit (but not lemma) must belong to exactly one synset.

attachment place, i.e. a synset selected as a point of attachment will be described by the type of relation by which a new lexical unit should be linked to it.

WordnetLoom can be used for editing other wordnets than plWordNet. The application uses UTF encoding for characters, relation types are defined in the XML-based format of wordnet data and the list of domains can be easily extended (now we use the Princeton WordNet list of domains). Lists of synset relations that are presented in vertical and horizontal directions are defined in the set-up file. Import and export to the Princeton WordNet file format has been implemented (but the use of WordnetWeaver requires preparation of the appropriate data knowledge sources). The suggestion presentation mechanism can work on the basis of any list of triples: word, synset, fit value. However, the AAA algorithm needs tuning to knowledge sources other than those used by us. WordnetLoom can be used for editing any network of lexical semantic relations or even an ontology. However, in the latter case, the limited, fixed set of the LU properties can be a strong limitation: concepts in an ontology are mostly described by an expandable attribute-value structures while lexical units are attached a limited, fixed set of properties in a wordnet.

***Abstract*—There are numerous formats for writing spell-checkers for open-source systems and there are many descriptions for languages written in these formats. Similarly, for word hyphenation by computer there are TEX rules for many languages. In this paper we demonstrate a method for converting these spell-checking lexicons and hyphenation rule sets into finite-state automata, and present a new finite-state based system for writer's tools used in current open-source software such as Firefox, OpenOffice.org and enchant via the spell-checking library voikko.**

I. Introduction

CURRENTLY there is a wide range of different free open-source solutions for spell-checking and hyphenation by computer. For hyphenation the ubiquitous solution is the original TEX algorithm described in [1]. The most popular of the spelling dictionaries are the various instances of *spell software, i.e. ispell[1], aspell[2], myspell and hunspell[3] and other *spell derivatives. The TEX hyphenation patterns are readily available on the Internet to cover some 49 languages. The hunspell dictionaries provided with the OpenOffice.org suite cover 98 languages.

The program-based spell-checking methods have their limitations because they are based on specific program code that is extensible only by coding new features into the system and getting all users to upgrade. E.g. hunspell has limitations on what affix morphemes you can attach to word roots with the consequence that not all languages with rich inflectional morphologies can be conveniently implemented in hunspell. This has already resulted in multiple new pieces of software for a few languages with implementations to work around the limitations, e.g. emberek (Turkish), hspell (Hebrew), uspell (Yiddish) and voikko (Finnish). What we propose is to use a generic framework of finite-state automata for these tasks. With finite-state automata it is possible to implement the spell-checking functionality as a one-tape weighted automaton containing the language model and a two-tape weighted automaton containing the error model. This also allows simple use of unigram training for optimizing spelling suggestion results [2]. With this model, extensions to context-based n-gram models for real-word spelling error problems [3] are also possible.

We also provide a method for integrating the finite-state spell-checking and hyphenation into applications using an open-source spell-checking library voikko[4], which provides a connection to typical open-source software, such as Mozilla Firefox, OpenOffice.org and the Gnome desktop via enchant.

II. Definitions

In this article we use weighted two-tape finite-state automata—or weighted finite-state transducers—for all processing. We use the following symbol conventions to denote the parts of a weighted finite-state automaton: a transducer $T = (\Sigma, \Gamma, Q, q_0, Q_f, \delta, \rho)$ with a semi-ring $(S, \oplus, \otimes, \overline{0}, \overline{1})$ for weights. Here Σ is a set with the input tape alphabet, Γ is a set with the output tape alphabet, Q a finite set of states in the transducer, $q_0 \in Q$ is an initial state of the transducer, $Q_f \subset Q$ is a set of finite states, $\delta : Q \times \Sigma \times \Gamma \times S \to Q$ is a transition relation, $\rho : Q_f \to S$ is a final weight function. A successful path is a list of transitions from an initial state to a final state with a weight different from $\overline{0}$ collected from the transition function and the final state function in the semi-ring S by the operation $\otimes$. We typically denote a successful path as a concatenation of input symbols, a colon and a concatenation of output symbols. The weight of the successful path is indicated as a subscript in angle brackets, *input:output*$_{<w>}$. A path transducer is denoted by subscripting a transducer with the path. If the input and output symbols are the same, the colon and the output part can be omitted.

The finite-state formulation we use in this article is based on Xerox formalisms for finite-state methods in natural language processing [4], in practice lexc is a formalism for writing right linear grammars using morpheme sets called lexicons. Each morpheme in a lexc grammar can define their right follower lexicon, creating a finite-state network called a *lexical transducer*. In formulae, we denote a lexc style lexicon named X as Lex_X and use the shorthand notation $Lex_X \cup$ *input:output* Y to denote the addition of a lexc string or morpheme, `input:output Y ;` to the `LEXICON X`. In the same framework, the twolc formalism is used to describe context restrictions for symbols and their realizations in the form of parallel rules as defined in the appendix of [4]. We use $Twol_Z$ to denote the rule set Z and use the shorthand

[1] http://www.lasr.cs.ucla.edu/geoff/ispell.html
[2] http://aspell.net
[3] http://hunspell.sf.net
[4] http://voikko.sf.net

notation $Twol_Z \cap a{:}b \leftrightarrow l\ e\ f\ t\_r\ i\ g\ h\ t$ to denote the addition of a rule string `a:b <=> l e f t _ r i g h t ;` to the rule set Z, effectively saying that *a:b* only applies in the specified context.

A spell-checking dictionary is essentially a single-tape finite-state automaton or a language model T_L, where the alphabet $\Sigma_L = \Gamma_L$ are characters of a natural language. The successful paths define the correctly spelled word-forms of the language [2]. If the spell-checking automaton is weighted, the weights may provide additional information on a word's correctness, e.g. the likelihood of the word being correctly spelled or the probability of the word in some reference corpus. The spell-checking of a word s is performed by creating a path automaton T_s and composing it with the language model, $T_s \circ T_L$. A result with the successful path $s_{<W>}$, where W is greater than some threshold value, means that the word is correctly spelled. As the result is not needed for further processing as an automaton and as the language model automaton is free of epsilon cycles, the spell-checking can be optimized by performing a simple traversal (lookup) instead, which gives a significant speed-advantage over full composition [5].

A spelling correction model or an error model T_E is a two-tape automaton mapping the input text strings of the text to be spell-checked into strings that may be in the language model. The input alphabet Σ_E is the alphabet of the text to be spell-checked and the output alphabet is $\Gamma_E = \Sigma_L$. For practical applications, the input alphabet needs to be extended by a special any symbol with the semantics of a character not belonging to the alphabet of the language model in order to account for input text containing typos outside the target natural language alphabet. The error model can be composed with the language model, $T_L \circ T_E$, to obtain an error model that only produces strings of the target language. For space efficiency, the composition may be carried out during runtime using the input string to limit the search space. The weights of an error model may be used as an estimate for the likelihood of the combination of errors. The error model is applied as a filter between the path automaton T_s compiled from the erroneous string, $s \notin T_L$, and the language model, T_L, using two compositions, $T_s \circ T_E \circ T_L$. The resulting transducer consists of a potentially infinite set of paths relating an incorrect string with correct strings from L. The paths, $s : s^i_{<w_i>}$, are weighted by the error model and language model using the semi-ring multiplication operation, $\otimes$. If the error model and the language model generate an infinite number of suggestions, the best suggestions may be efficiently enumerated with some variant of the n-best-paths algorithm [6]. For automatic spelling corrections, the best path may be used. If either the error model or the language model is known to generate only a finite set of results, the suggestion generation algorithm may be further optimized.

A hyphenation model T_H is a two-tape automaton mapping input text strings of the text to be hyphenated to possibly hyphenated strings of the text, where the input alphabet, Σ_E, is the alphabet of the text to be hyphenated and the output alphabet, Γ_E, is $\Sigma_E \cup H$, where H is the set of symbols marking hyphenation points. For simple applications, this equals hyphens or discretionary (soft) hyphens $H = -$. For more fine-grained control over hyphenation, it is possible to use several different hyphens or weighted hyphens. Hyphenation of the word s is performed with the path automaton T_s by composing, $T_s \circ T_H$, which results in an acyclic path automaton containing a set of strings mapped to the hyphenated strings with weights $s : s^h_{<w_h>}$. Several alternative hyphenations may be correct according to the hyphenation rules. A conservative hyphenation algorithm should only suggest the hyphenation points agreed on by all the alternatives.

III. Material

In this article we present methods for converting the hunspell and TEX dictionaries and rule sets for use with open-source finite-state writer's tools. As concrete dictionaries we use the repositories of free implementations of these dictionaries and rule sets found on the internet, e.g. for the hunspell dictionary files found on the OpenOffice.org spell-checking site[5]. For hyphenation, we use the TEX hyphenation patterns found on the TEXhyphen page[6].

In this section we describe the parts of the file formats we are working with. All of the information of the hunspell format specifics is derived from the `hunspell(4)`[7] man page, as that is the only normative documentation of hunspell we have been able to locate. For TEX hyphenation patterns, the reference documentation is Frank Liang's doctoral thesis [1] and the TEXbook [7].

A. Hunspell File Format

A hunspell spell-checking dictionary consists of two files: a dictionary file and an affix file. The dictionary file contains only root forms of words with information about morphological affix classes to combine with the roots. The affix file contains lists of affixes along with their context restrictions and effects, but the affix file also serves as a settings file for the dictionary, containing all meta-data and settings as well.

The dictionary file starts with a number that is intended to be the number of lines of root forms in the dictionary file, but in practice many of the files have numbers different from the actual line count, so it is safer to just treat it as a rough estimate. Following the initial line is a list of strings containing the root forms of the words in the morphology. Each word may be associated with an arbitrary number of classes separated by a slash. The classes are encoded in one of the three formats shown in the examples of Figure 1: a list of binary octets specifying classes from 1–255 (minus octets for CR, LF etc.), as in the Swedish example on lines 2–4, a list of binary words, specifying classes from 1–65,535 (again ignoring octets with CR and LF) or a comma separated list of numbers written in digits specifying classes 1–65,535 as in the North Sámi examples on lines 6–8. We refer to all of

Fig. 1. Excerpts of Swedish, Northern Sl-á-lmi and Hungarian dictionaries

these as continuation classes encoded by their numeric decimal values, e.g. ’abakus’ on line 2 would have continuation classes 72, 68 and 89 (the decimal values of the ASCII code points for H, D and Y respectively). In the Hungarian example, you can see the affix compression scheme, which refers to the line numbers in the affix file containing the continuation class listings, i.e. the part following the slash character in the previous two examples. The lines of the Hungarian dictionary also contain some extra numeric values separated by a tab which refer to the morphology compression scheme that is also mentioned in the affix definition file; this is used in the hunmorph morphological analyzer functionality which is not implemented nor described in this paper.

The second file in the hunspell dictionaries is the affix file, containing all the settings for the dictionary, and all non-root morphemes. The Figure 2 shows parts of the Hungarian affix file that we use for describing different setting types. The settings are typically given on a single line composed of the setting name in capitals, a space and the setting values, like the NAME setting on line 6. The hunspell files have some values encoded in UTF-8, some in the ISO 8859 encoding, and some using both binary and ASCII data at the same time. Note that in the examples in this article, we have transcribed everything into UTF-8 format or the nearest relevant encoded character with a displayable code point.

The settings we have used for building the spell-checking automata can be roughly divided into the following four categories: meta-data, error correction models, special continuation classes, and the actual affixes. An excerpt of the parts that we use in the Hungarian affix file is given in Figure 2.

The meta-data section contains, e.g., the name of the dictionary on line 6, the character set encoding on line 8, and the type of parsing used for continuation classes, which is omitted from the Hungarian lexicon indicating 8-bit binary parsing.

The error model settings each contain a small part of the actual error model, such as the characters to be used for edit distance, their weights, confusion sets and phonetic confusion sets. The list of word characters in order of popularity, as seen on line 12 of Figure 2, is used for the edit distance model. The keyboard layout, i.e. neighboring key sets, is specified for the substitution error model on line 10. Each set of the characters, separated by vertical bars, is regarded as a possible slip-of-the-finger typing error. The ordered confusion set of possible spelling error pairs is given on lines 19–27, where each line is a pair of a ‘mistyped’ and a ‘corrected’ word separated by whitespace.

The compounding model is defined by special continuation classes, i.e. some of the continuation classes in the dictionary or affix file may not lead to affixes, but are defined in the compounding section of the settings in the affix file. In Figure 2, the compounding rules are specified on lines 14–16. The flags in these settings are the same as in the affix definitions, so the words in class 118 (corresponding to lower case v) would be eligible as compound initial words, the words with class 120 (lower case x) occur at the end of a compound, and words with 117 only occur within a compound. Similarly, special flags are given to word forms needing affixes that are used only for spell checking but not for the suggestion mechanism, etc.

The actual affixes are defined in three different parts of the file: the compression scheme part on the lines 1–4, the suffix definitions on the lines 30–33, and the prefix definitions on the lines 35–37.

The compression scheme is a grouping of frequently co-occurring continuation classes. This is done by having the first AF line list a set of continuation classes which are referred to as the continuation class 1 in the dictionary, the second line is referred to the continuation class 2, and so forth. This means that for example continuation class 1 in the Hungarian dictionary refers to the classes on line 2 starting from 86 (V) and ending with 108 (l).

The prefix and suffix definitions use the same structure. The prefixes define the left-hand side context and deletions of a dictionary entry whereas the suffixes deal with the right-hand side. The first line of an affix set contains the class name, a boolean value defining whether the affix participates in the prefix-suffix combinatorics and the count of the number of morphemes in the continuation class, e.g. the line 35 defines the prefix continuation class attaching to morphemes of class 114 (r) and it combines with other affixes as defined by the Y instead of N in the third field. The following lines describe the prefix morphemes as triplets of removal, addition and context descriptions, e.g., the line 31 defines removal of ’ö’, addition of ’ős’ with continuation classes from AF line 1108, in case the previous morpheme ends in ’ö’. The context description may also contain bracketed expressions for character classes or a fullstop indicating any character (i.e. a wild-card) as in the POSIX regular expressions, e.g. the context description on line 33 matches any Hungarian vowel except a, e or ö, and the 37 matches any context. The deletion and addition parts may also consist of a sole ‘0’ meaning a zero-length string. As can be seen in the Hungarian example, the lines may also contain an additional number at the end which is used for the morphological analyzer functionalities.

Fig. 3. Excerpts from English TeX hyphenation patterns

B. TeX Hyphenation Files

The TeX hyphenation scheme is described in Frank Liang's dissertation [1], which provides a packed suffix tree structure for storing the hyphenation patterns, which is a special optimized finite-state automaton. This paper merely reformulates the finite-state form of the patterns, for the purpose of obtaining a general finite-state transducer version of the rules to be combined with other pieces of the finite-state writer's tools. In principle, the TeX hyphenation files are like any TeX source files, they may contain arbitrary TeX code, and the only requirement is that they have the 'patterns' command and/or the 'hyphenation' command. In practice, it is a convention that they do not contain anything else than these two commands, as well as a comment section describing the licensing and these conventions. The patterns section is a whitespace separated list of hyphenation pattern strings. The pattern strings are simple strings containing characters of the language as well as numbers marking hyphenation points, as shown in Figure 3. The odd numbers add a potential hyphenation point in the context specified by non-numeric characters, and the even numbers remove one, e.g. on line 8, the hyphen with left context 'f' and right context 'fis' would be removed, and a hyphen with left context 'ff' and right context 'is' is added. The numbers are applied in ascending order. The full-stop character is used to signify a word boundary so the rule on line 2 will apply to 'ache' but not to 'headache'. The hyphenation command on lines 13–16 is just a list of words with all hyphenation points marked by hyphens. It has higher precedence than the rules and it is used for fixing mistakes made by the rule set.

IV. METHODS

This article presents methods for converting the existing spell-checking dictionaries with error models, as well as hyphenators to finite-state automata. As our toolkit we use the free open-source HFST toolkit[8], which is a general purpose API for finite-state automata, and a set of tools for using legacy data, such as Xerox finite-state morphologies. For this reason this paper presents the algorithms as formulae such that they can be readily implemented using finite-state algebra and the basic HFST tools.

The lexc lexicon model is used by the tools for describing parts of the morphotactics. It is a simple right-linear grammar for specifying finite-state automata described in [4], [8]. The twolc rule formalism is used for defining context-based rules with two-level automata and they are described in [9], [8].

[8] http://HFST.sf.net

This section presents both a pseudo-code presentation for the conversion algorithms, as well as excerpts of the final converted files from the material given in Figures 1, 2 and 3 of Section III. The converter code is available in the HFST SVN repository[9] , for those who wish to see the specifics of the implementation in lex, yacc, c and python.

A. Hunspell Dictionaries

The hunspell dictionaries are transformed into a finite-state transducer language model by a finite-state formulation consisting of two parts: a lexicon and one or more rule sets. The root and affix dictionaries are turned into finite-state lexicons in the lexc formalism. The Lexc formalism models the part of the morphotax concerning the root dictionary and the adjacent suffixes. The rest is encoded by injecting special symbols, called flag diacritics, into the morphemes restricting the morpheme co-occurrences by implicit rules that have been outlined in [10]; the flag diacritics are denoted in lexc by at-sign delimited substrings. The affix definitions in hunspell also define deletions and context restrictions which are turned into explicit two-level rules.

The pseudo-code for the conversion of hunspell files is provided in Algorithm 1 and excerpts from the conversion of the examples in Figures 1 and 2 can be found in Figure 4. The dictionary file of hunspell is almost identical to the lexc root lexicon, and the conversion is straightforward. This is expressed on lines 1–1 as simply going through all entries and adding them to the root lexicon, as in lines 6—10 of the example result. The handling of affixes is similar, with the exception of adding flag diacritics for co-occurrence restrictions along with the morphemes. This is shown on lines 1—1 of the pseudo-code, and applying it will create the lines 17—21 of the Swedish example, which does not contain further restrictions on suffixes.

To finalize the morpheme and compounding restrictions, the final lexicon in the lexc description must be a lexicon checking that all prefixes with forward requirements have their requiring flags turned off.

B. Hunspell Error Models

The hunspell dictionary configuration file, i.e. the affix file, contains several parts that need to be combined to achieve a similar error correction model as in the hunspell lexicon.

The error model part defined in the KEY section allows for one slip of the finger in any of the keyboard neighboring classes. This is implemented by creating a simple homogeneously weighted crossproduct of each class, as given on lines 2–2 of Algorithm 2. For the first part of the example on line 10 of Figure 2, this results in the lexc lexicon on lines 11–18 in Figure 5.

The error model part defined in the REP section is an arbitrarily long ordered confusion set. This is implemented by simply encoding them as increasingly weighted paths, as shown in lines 2–2 of the pseudo-code in Algorithm 2.

Algorithm 1 Extracting morphemes from hunspell dictionaries

```
    $finalflags \leftarrow \epsilon$
 2: **for all** lines $morpheme/Conts$ in dic **do**
        $flags \leftarrow \epsilon$
 4:     **for all** $cont$ in $Conts$ **do**
            $flags \leftarrow flags + @C.cont@$
 6:         $Lex_{Conts} \leftarrow Lex_{Conts} \cup 0{:}[{<}cont]\ cont$
        **end for**
 8:     $Lex_{Root} \leftarrow Lex_{Root} \cup flags + morpheme\ Conts$
    **end for**
10: **for all** suffixes $lex, deletions, morpheme/Conts, context$ in aff **do**
        $flags \leftarrow \epsilon$
12:     **for all** $cont$ in $Conts$ **do**
            $flags \leftarrow flags + @C.cont@$
14:         $Lex_{Conts} \leftarrow Lex_{Conts} \cup 0\ cont$
        **end for**
16:     $Lex_{lex} \leftarrow Lex_{lex} \cup flags + [< lex] + morpheme\ Conts$
        **for all** $del$ in $deletions$ **do**
18:         $lc \leftarrow context + deletions$ before del
            $rc \leftarrow deletions$ after del $+ [< lex] + morpheme$
20:         $Twol_d \leftarrow Twol_d \cap del{:}0 \Leftrightarrow lc\ \_\ rc$
        **end for**
22:     $Twol_m \leftarrow Twol_m \cap [< lex] : 0 \Leftrightarrow context\ \_\ morpheme$
    **end for**
24: **for all** prefixes $lex, deletions, morpheme/conts, context$ in aff **do**
        $flags \leftarrow @P.lex@$
26:     $finalflags \leftarrow finalflags + @D.lex@$
        $lex \rightarrow prefixes$ {othewise as with suffixes, swapping left and right}
28: **end for**
    $Lex_{end} \leftarrow Lex_{end} \cup finalflags\ \#$
```

The TRY section such as the one on line 12 of Figure 2, defines characters to be tried as the edit distance grows in descending order. For a more detailed formulation of a weighted edit distance transducer, see e.g. [2]). We created an edit distance model with the sum of the positions of the characters in the TRY string as the weight, which is defined on lines 2–2 of the pseudo-code in Algorithm 2. The initial part of the converted example is displayed on lines 20–27 of Figure 5.

Finally to attribute different likelihood to different parts of the error models we use different weight magnitudes on different types of errors, and to allow only correctly written substrings, we restrict the result by the root lexicon and morfotax lexicon, as given on lines 1–9 of Figure 5. With the weights on lines 1–5, we ensure that KEY errors are always suggested before REP errors and REP errors before TRY errors. Even though the error model allows only one error of any type, simulating the original hunspell, the resulting transducer can be transformed into an error model accepting multiple errors by a simple FST algebraic concatenative n-closure, i.e. repetition.

Fig. 4. Converted dic and aff lexicons and rules governing the deletions

C. TEX Hyphenation

The formulation of hyphenation as finite-state transducers is simple. We use the hyphenation alphabet $\Sigma_H = -$. To model the context-based deletions and additions of hyphenation patterns, we use twol rules with centers of $\epsilon : -$ for addition and $- : \epsilon$ for deletion. The algorithm for creating the rule sets described in Algorithm 3 simply goes through the patterns, and for each hyphenation point of each pattern extracts left and right context strings and adds them to the contexts of a rule. The result is exemplified in Figure 6. There is one rule for each of the hyphenation point numbers. The rules may be composed into one single transducer at compile time or applied as cascade at runtime.

The TEX hyphenation pattern also contains explicit exceptions to the hyphenation patterns, which are simply specific word forms with hyphenations, and can be compiled as simple paths: e.g. for the pattern{as-so-ciate} we create a path $as\epsilon so\epsilon ciate : as-so-ciate$

Algorithm 2 Extracting patterns for hunspell error models

```
for all neighborsets $ns$ in KEY do
    for all character $c$ in $ns$ do
        for all character $d$ in $ns$ such that $c! = d$ do
            $Lex_{KEY} \leftarrow Lex_{KEY} \cup c : d_{<0>}\#$
        end for
    end for
end for
$w \leftarrow 0$
for all pairs $wrong, right$ in REP do
    $w \leftarrow w + 1$
    $LEX_{REP} \leftarrow LEX_{REP} \cup wrong : right_{<w>}\#$
end for
$w \leftarrow 0$
for all character $c$ in TRY do
    $w \leftarrow w + 1$
    $Lex_{TRY} \leftarrow Lex_{TRY} \cup c : 0_{<w>}\#$
    $Lex_{TRY} \leftarrow Lex_{TRY} \cup 0 : c_{<w>}\#$
    for all character $d$ in TRY such that $c! = d$ do
        $Lex_{TRY} \leftarrow Lex_{TRY} \cup c : d_{<w>}\#$ {for swap: replace
        $\#$ with $cd$ and add $Lex_{cd} \cup d : c_{<0>}\#$}
    end for
end for
```

Algorithm 3 Extracting hyphenation patterns from TEX

```
for all patterns $p$ do
    for all digits $d$ in $p$ do
        $l, r \leftarrow$ split $p$ on $d$
        if $d$ odd then
            $l, r \leftarrow l, r << 0 : \epsilon$
            $Twol_d \leftarrow Twol_d \cap 0 : \epsilon \leftrightarrow l\_r;$
        else
            $l, r \leftarrow l, r << \epsilon : 0$
            $Twol_d \leftarrow Twol_d \cap \epsilon : 0 \leftrightarrow l\_r;$
        end if
    end for
end for
for all hyphenations $h$ do
    $word \leftarrow h - hyphens$
    $Lex_{exceptions} \leftarrow Lex_{exceptions} \cup$ word:h #
end for
```

V. Implementation and Tests

We have implemented the spell-checkers and hyphenators as finite-state transducers using program code and scripts with a Makefile. To test the code, we have converted 49 hyphenation pattern files and more than 42 hunspell dictionaries from various language families. They consist of the dictionaries that were accessible from the aforementioned web sites at the time of writing. The Tables I and II gives an overview of the sizes

```

```

Fig. 6. Converted hyphenation models from TeXexamples

of the compiled automata. The size is given in binary multiples of bytes as reported by `ls -hl`.

In the hyphenation table, the second column gives the number of patterns in the rules. The total size is a result of composing all hyphenation rules into one transducer; it may be noted that both separate rules and a single composed transducer are equally usable at runtime. The separated version requires less memory whereas the single composed version is faster. For large results, such as the Norwegian[10] one, it may still be beneficial to keep the rules separated. In the Norwegian case, the four separately compiled rules are each of sizes between 1.2 MiB and 9.7 MiB.

For the hunspell automata in Table II, we also give the number of roots in the dictionary file and the affixes in affix file. These numbers should also help with identifying the version of the dictionary, since there are multiple different versions available in the downloads.

The resulting transducers were tested by hand using the results of the corresponding TeX `hyphenate` command and `hunspell -d` as well as the authors' language skills to judge errors. As testing material, a wikipedia article on the Finnish language[11] were used for most languages, and some arbitrary articles where this particular article was not found. In both tests, the majority of differences come from the lack of normalization or case folding. E.g. this resulted in our converted transducers failing to hyphenate words where uppercase letters would have been equal to their lowercase variants.

The hunspell model was built incrementally starting from the basic set of affixes and dictionary, and either adding or skipping all directive types of the file format as found in the wild. Some of the omissions show up e.g. in the English results, where omitting of the PHONE directive for the suggestion mechanism results in some of the differing suggestions in English tests, e.g. first suggestion for *calqued* in hunspell is *catafalqued*. Without implementing the phonetic folding, we get no results within 1 hunspell error, and get word forms like *chalked*, *caulked*, and so forth, within 2 hunspell errors. No other language has .aff files with PHONE rules, e.g. in French *comitatif* gets the suggestions *commutatif* and *limitatif* as the first ones in both systems.

VI. Conclusion

We have demonstrated a method and created the software to convert legacy spell-checker and hyphenation data to a more general framework of finite-state automata and used it in a real-life application. We have also referred to methods for extending the system to more advanced error models and the inclusion of other more complex models in the same system. We are currently developing a platform for finite-state based spell-checkers for open-source systems in order to improve the front-end internationalization.

The next obvious development for the finite-state spell checkers is to apply the unigram training [2] to the automata,

The Polish Cyc lexicon as a bridge between Polish language and the Semantic Web

Aleksander Pohl
Computational Linguistics Department,
Jagiellonian University, Cracow, Poland
Email: aleksander.pohl@uj.edu.pl

***Abstract*—In this paper we discuss the problem of building the Polish lexicon for the Cyc ontology. As the ontology is very large and complex we describe semi-automatic translation of part of it, which might be useful for tasks lying on the border between the fields of Semantic Web and Natural Language Processing.**

We concentrate on precise identification of lexemes, which is crucial for tasks such as natural language generation in massively inflected languages like Polish, and we also concentrate on multiword entries, since in Cyc for every 10 concepts, 9 of them is mapped to expressions containing more than one word.

I. Introduction

THE FACT that linguistic resources play a key role in any Natural Language Processing undertaking is well established. Abstract theoretical problems such as word sense disambiguation and parsing as well as practical, such as machine translation, information extraction and question answering, are insolvable without large set of fine grained rules, large semantic dictionaries or huge collections of hand-annotated texts.

When a researcher works on a language having much less available resources than English, she always has to decide, whether to create them from scratch employing the best available techniques or to adopt some of the already available lexicons, ontologies, etc. As the adoption of the WordNet lexical database in the GlobalWordNet project shows, there is no obvious answer for this question.

Considering Polish, which is a language with a constantly growing set of linguistic resources (there are at least several complete or semi-complete Polish inflectional dictionaries, two growing WordNets and one large national corpus containing hand annotated samples of syntactic structures) one has to decide, whether it makes sense to wait for other researchers to complete their undertakings or to start the construction or adaptation of other resources.

Considering semantics, which is our primary field of interest, we have to agree, that the most advanced Polish resource is the Polish WordNet [1][1]. Since it is available for the Polish research community without restrictions and is created according to the state-of-the-art techniques of building WordNets, it doesn't make sense to spend time and money, on the creation of another, similar resource.

The Polish lexicon for Cyc [2], is a mapping between Cyc concepts and their Polish lexical representations. Since the mapping does not have to be isomorphic and each concept might have many mappings, the set of mappings for a give concept might be considered as a synset. What is more, the taxonomy of concepts in Cyc, in its structure, is quite similar to the taxonomy of WordNet synsets. At the first glance it seems, that the Polish lexicon is much similar to the Polish WordNet and, as a result, it seems to be a fruitless effort. Thus the question arises: what are the special properties of Cyc and what are the design goals of the Polish lexicon, which make the decision of creating it valuable?

II. Motivation

Our primary concern is to build algorithms and tools which bridge the gap between Polish language and the Semantic Web, thus bringing the benefits of the technology to the Polish speaking community.

Even though the fields of the Semantic Web and Natural Language Processing have much in common, there are certain problems, which have to be solved, before the data available in the Semantic Web and the data made available by NLP techniques is fully translatable. This stems from the fact, that the reference resources for the Semantic Web are ontologies, while the Princeton WordNet and its incarnations for languages other than English, serve as the *de facto* standard for NLP. Yet, there exist mappings between concepts of ontologies and WordNets (e.g. there is a mapping between Cyc and Princeton WordNet 2.0), but these mappings have certain limitation, stemming from the fact, that the logical structures of ontologies and WordNets is different.

The most problematic difference, in our opinion, is the huge discrepancy between the number and semantics of the types[2] of relations employed in both types of resources. In ontologies, the number of relations is not restricted *a priori* – it is only limited by the complexity of the domain of the ontology and by the desired level of detail. For instance, the old version of Dublin Core[3] defined 15 relations[4], while the latest defines

[1] Available at `http://plwordnet.pwr.wroc.pl/browser/?lang=en`.

[2] From here, by relation we mean both type of a relation and instance of a relation. We hope this inadequacy will not introduce ambiguities, since in most cases the types of relations are discussed.

[3] http://dublincore.org/documents/dcmi-terms/

[4] In RDF/OWL oriented ontologies the relations are always binary and are called properties.

approx. 50; the Music Ontology[5] defines approx. 120 relations, DBpedia[6] approx. 1200 and Cyc approx. 17000 relations[7].

On the other hand, most of the WordNets is created in accordance with the original Princeton WordNet idea refraining from using cross-part-of-speech relations. What is more, the set of relations was primarily limited to these, which were well accepted by the linguistic researchers community. Even though there are exceptions to these rules (e.g. there are cross-part-of-speech relations in the Polish WordNet), and there are plans and proposals to extend the set of relations (see [3]), it is unimaginable that the set of relations will grow to the size observed in moderately complicated ontologies.

To explain why we have to bother with that difference, let us consider a prototypical scenario, in which a music information extraction application utilizes data available both in the Semantic Web and made available by WordNet-based NLP algorithms. Let us assume, that the NLP module is able to fully disambiguate the common concepts (common nouns, verbs, adjectives, etc.) which appear in a certain text and the Semantic Web module is connected with an ontology containing massive amount of information about music[8]. The system should be able to answer questions such as „Have Tool already released the Ten thousand days album?", by parsing the question and consulting the database or recent press releases. However, it is unlikely, that the NLP module would recognize Tool as a name of a music group, and it is even less likely, that the phrase „Ten thousand days" would be recognized as a title of a music product, since the NLP dictionaries should capture general linguistic knowledge. But the biggest problem lies in the fact that the information is intransferable from the NLP module to the Semantic Web module – the former doesn't capture the relations between the release event (in which a music entity makes some music product available to the audience), the music entity and the music product. It might capture a notion of an event's actor and object, but such an information is too vague for the ontology.

We argue, that in such an application the NLP module should be designed in such a way, that the ontology contents is directly available in it. This is why we think, that building the Polish lexicon for Cyc, is worth its effort. The other advantages of using Cyc as the primary resource for NLP-enabled Semantic Web applications are as follows: there exists a Semantic Web endpoint which is linked to other Linked Open Data resources[9], it has probably the largest number of relations employed to describe the stored and processed knowledge, CycL – the language of Cyc is very expressive (e.g. allows for expressing relations between relations) and the ontology is shipped with an efficient inference engine, allowing for not only accessing, but also processing the knowledge in a consistent manner. And the last, but not the least, the relations in Cyc (and other ontologies) have formal definitions, which means, among others, that their arguments are restricted to concepts defined in the ontology (e.g. the first argument of the relation `#$weaponTypeCanDestroyTargetType` is restricted to `#$Weapon` and the second to `#$SolidTangibleThing`).

As it was stated, our primary concern is to bridge the gap between Polish language and the Semantic Web. Our final goal is to create a system, which is able to recognize ontological relations with their arguments in Polish texts, as well as, being able to produce well-formed Polish sentences, on the basis of the contents of the ontology. So, besides the adoption of a large number of relations provided by Cyc, we have to embrace the second important phenomenon – multi-word expressions. The reason why they are so common in ontologies stems from the fact, that the ontologies contain two types of entities, which are mostly represented by multi-word expressions: proper names and „artificial" concepts.

Proper names are the primary means for describing particular things, and we think that they are quite valuable, since they might be used to automatically pick training examples for the relations, we have to embrace them. The „artificial" concepts, are concepts which are used to properly structure the contents of the ontology – e.g. in Cyc there are concepts such as `#$Agent-Generic`, `#$Agent-PartiallyTangible` and `#$Agent-Underspecified`, which are used to capture certain properties of various types of agents. They shall not be mapped to the same word – *agens* – since that would introduce false ambiguity. It is better to provide descriptive, distinct mappings for these concepts (e.g. *agens*, *agens materialny*, *uogólniony agens*), but multi-word expressions are indispensable here. This is why we pay special attention to the multi-word expressions.

III. Related work

In our work we use the transfer approach to translate the compound expressions. On the other hand there has been much research in the field of statistical machine translation of these expressions (see [4]) and there are commercial machine translation systems available, like Google Translate[10]. The problem we encountered, refraining us from using this approach, was the lack of resources – we didn't find any publicly available aligned English-Polish corpus, while using resources such as Wikipedia seemed to be too demanding for this task. What is more – direct application of Google Translate (which is discussed later) was too erroneous.

IV. Methodology

A. Goals

As it was stated in the Motivation section, our primary goal is to bridge the gap between Polish language, and the Semantic Web, using the Cyc ontology as the primary resource, by providing a tool which is capable of recognizing its relations in Polish texts, and by generating Polish paraphrases for them. The first step to achieve this goal is to build the Polish lexicon for the ontology. At the first glance, it seems that we should

[5] http://musicontology.com/

[6] http://wiki.dbpedia.org/Ontology?v=zj4

[7] ResearchCyc, system: 10.126767, KB: 7141, http://research.cyc.com

[8] e.g. http://dbtune.org/musicbrainz/

[9] http://sw.opencyc.org

[10] http://translate.google.com

build a full lexicon, that is a lexicon covering all symbols available in Cyc, but we think that this is not needed. The proposed algorithm would utilize the definitions of relations, the argument constraints in particular. It appears, that only approx. 4 thousands of concepts are used as the argument constraints and we propose to translate only *these* symbols (it might appear in the future, that translating more symbols, would bring better extraction results).

This assumption seems to be an oversimplification – even though we would be able to train the algorithm to recognize these relations with these concepts as their arguments on the basis of that mapping, we won't be able to recognize other concepts. E.g. we would be able to recognize the `#$releases-Underspecified` relation, in a sentence „Zespół wydał nową płytę" („A music group released a new album"), assuming that „music group" and „album" are the argument constrains of that relation, but we won't be able to recognize it in a sentence like „Tool wydał wczoraj CD Ten thousand days" („Tool released the Ten thousand days CD yesterday"), since „Tool", „Ten thousand days" and „CD" won't be recognized as the proper specializations of „music group", „album title", etc.

We agree, that this is a problem, but we won't resolve it by translating the full Cyc taxonomy. Instead, we are going to use the results of a project aiming at the extraction of the hyperonymy relation from the Polish Wikipedia, which was carried out in our research group [5]. In short, the results cover several hundreds of thousands of concepts, grouped within several thousands of semantic categories.

The particular goals we are going to achieve are as follows:

1) create translation for all the concepts which are used as the argument constraints in the Cyc relations (approx. 4 thousands)
2) map these concepts to the semantic categories extracted from the Polish Wikipedia

Achieving these two goals would allow us to:

1) automatically pick training examples for the Cyc relations
2) build linguistic models of these relations
3) build algorithms extracting these relations from Polish texts

The text generation feature of the designed system is not covered in this document, but the prototype applications utilize it.

B. The algorithm

The general algorithm for building the Polish lexicon is as follows – for each Cyc concept which is used as an argument constraint:

1) *translate* the English mapping of the concept into Polish (many results might be produced)
2) *map* the words of each translation to the entries of Polish inflectional dictionary
3) *transform* the translations to match syntax constraints
4) *rank* the translations
5) *present* the results to the human operator
6) *store* the selected result in the database
7) *search* for semantic categories extracted from the Polish Wikipedia, corresponding to the translation
8) *merge* or *link* the selected categories with the Cyc concept

C. Translation

The first necessary step in the creation of the Polish lexicon, is the translation or pairing of lexical units. This might be done by utilization of (in a transfer approach) a machine readable English-Polish dictionary or (in a statistical approach) a bilingual corpus. The latter approach is quite popular in the on-line translation systems, such as Google Translate and it has certain advantages – namely the translation algorithm is generic and the bilingual dictionary is not needed. Still, it seems that this approach is not well suited for the taxonomy translation task. It is due to the fact, that in most cases, the available training bilingual corpuses cover only texts containing regular sentences, having at least the SVO structure, while in most cases the Cyc concepts are described as a mere nominal expressions. What is more, the obtained translation should be canonical, that is, the head phrase should be in singular[11] and nominal case.

This prediction was verified on the Google Translate system. Out of 118 Cyc concepts, only 22 were translated exactly the same as by the human translator. 20 of them had certain syntax errors (e.g. „tangible agent" – „rzeczowe agent" where the adjective does not agree with the noun on case and gender), 40 of them had certain translation errors (e.g. „acquiring" – „przejmującej" where the concept denotes an event, while the translation is an adjective, thus a property), 64 of them were not in a canonical form (e.g. „animal" – „zwierząt" where the translation is in plural and in dative case, while it should be in singular and in nominal case), and 62 were translated differently, due to the general design principles of the lexicon (avoidance of ambiguities, among the others)[12].

This is why we choose the transfer approach, based on a large machine readable English-Polish dictionary „Wielki Słownik Multimedialny Polsko-Angielski/ Angielsko-Polski Oxford-PWN". Although the information which is available in such a dictionary is lexically rich – it signals the grammatical category of the entries, includes limited syntactical, semantical and pragmatical information – these features are not provided consequently and it is really hard to obtain precise mapping between Cyc concepts and the dictionary entries on the one hand, and translated entries and Polish inflectional dictionary entries on the other hand.

The translation strategy is as follows – when we translate some Cyc concept, which is represented by S_i^{en} character string, there might be the following general cases:

1) The character string is a single word, which *is not present* in the dictionary – we try to apply some trans-

[11] or plural for *plurale tantum* nouns

[12] The number of errors does not sum to 118, since one translation could be marked as invalid more than once.

formation to it, such as stemming, but if the result is not present as well, we have to ignore it. If it is present, this situation is reduced to the next one.

2) The character string is a single word, which *is present* in the dictionary – we pass the list of translations $(S^{pl}_{i,1}, S^{pl}_{i,2}, S^{pl}_{i,3}, \ldots)$ to the next step of the algorithm.
3) The character string is a multi-word expression, which *has direct* representation in the dictionary – since it seems to be a compound expression, we process it if it was a single word – pass the whole list $(S^{pl}_{i,1}, S^{pl}_{i,2}, S^{pl}_{i,3}, \ldots)$ to the next step.
4) The character string is a multi-word expression, which *doesn't have direct* representation in the dictionary – we divide the S^{en}_i string into single words: $W^{en}_{i,1}, W^{en}_{i,2}, W^{en}_{i,3}, \ldots$, which might be represented by the following character strings $S^{en}_k, S^{en}_l, S^{en}_m, \ldots$ in the dictionary. Then we remove stop words (such as determiners or prepositions) form the list. For each element of the resulting list we take the corresponding Polish strings and create a vector of lists, where each position is occupied by the corresponding translations, and order of the list reflects the order of the source words: $\left[(S^{pl}_{k,1}, S^{pl}_{k,2}, \ldots)_1, (S^{pl}_{l,1}, \ldots)_2, (S^{pl}_{m,1}, \ldots)_3, \ldots\right]$. The lower index attached to parentheses indicates the position of the source word in the source expression. This vector is passed to the next step of the algorithm.

To sum-up – the translation of a Cyc concept produces a vector of Polish words or lists of Polish words, and since a single word might be considered as a single-entry list, we might simplify the description, by assuming, that always a vector of lists containing Polish words is produced, where each element of the vector corresponds to one word in the English mapping of the concept, and each element of the list corresponds to one possible translation of the word.

For instance: if we translate `#$AddictiveSubstance`, which is mapped to the `addictive substance` expression in English, we might receive the following result: `[(uzależniający, wciągający)`$_1$`,(substancja, istota, ciężar, waga, podstawa, treść, realność, majątek)`$_2$`]`

D. Mapping to inflectional dictionary

Since the next step of the algorithm will transform the obtained translations to match the syntax constrains of the Polish language, the result of the previous step has to be mapped to Polish inflectional dictionary, such as one described in [6] or [7]. This dictionary should have at least two functionalities:

1) lemmatization – recognition of the lemma based on any of the inflected forms of a lexeme
2) inflection – production of an inflected form based on a provided set of tags

Since the first functionality might introduce ambiguity (e.g. the character string *goli* is an inflected form of lexemes having the following lemmas: *gol* (goal), *golić* (to shave), *golić się* (to shave oneself), *goły* (naked), *Gola* (a Polish surname) and *Goły* (a Polish surname)), for each character string $S^{pl}_{i,j}$ we might receive many lemmas:

$$S^{pl}_{i,j} \to \left[L^{pl}_a, L^{pl}_b, \ldots\right]_{i,j} \qquad (1)$$

where L^{pl}_a stands for the lexeme with an index a. The i, j indices indicate, that given vector corresponds to the $S^{pl}_{i,j}$ Polish character string.

The indexing of the lexemes in the dictionary needs some special attention – in general we would like to avoid the situation in which human interpretation of each lexeme requires looking it up in the index, so the lexeme should be at least represented by its lemma.

As it is discussed in detail in [8], there are no better means of differentiating the lexemes with the same lemma and different inflection, than by introducing some arbitrary marking of the homonymuous lemmas. [8] proposes numbering of the lemmas, while we think that the approach proposed in [7], namely to attach an inflectional label to each lemma, is better, since, provided that the person who looks at the mapping, knows the labeling system, doesn't have to check the ordering of these lemmas to determine, what is the inflectional paradigm of the lexeme, represented by the $< lemma, inflectional\ label >$ pair[13].

In the system described in [7] the inflectional label consist of capital letters and is constructed in such a way, that the most significant morphological distinctions are placed at the beginning of the label, thus the first letter determines the grammatical category of the lexeme (A – noun, B – verb, etc.) the second letter (in the case of nouns) determines their gender and so on. This idea has another advantage, that only the lemma, the inflectional label and the inflectional scheme is necessary to produce all the forms of a given lexeme, without the direct intervention of the dictionary, so it's easier to port across operating systems and versions of the dictionary.

In fact, the label could be replaced by a number, but the most important difference between theses systems is that, in the first case, the index indicates the position of the lexeme among other lexemes with the same lemma, while in the second case, it indicates position of its inflectional paradigm among other inflectional paradigms. This means that in the second case, the index is much less likely to change.

Since we assumed that the output produced by the previous step is always a vector, the result of this step is a vector of mappings obtained by merging the vectors produced for a given position in given single or multi-word entry:

$$\left[(S^{pl}_{k,1}, S^{pl}_{k,2}, \ldots)_1, (S^{pl}_{l,1}, \ldots)_2, (S^{pl}_{m,1}, \ldots)_3, \ldots\right] \to \qquad (2)$$

$$\left[\left([L^{pl}_a, L^{pl}_b, \ldots]_{k,1}, [L^{pl}_c, \ldots]_{k,2}, \ldots\right)_1, \left([L^{pl}_d, \ldots]_{l,1}, \ldots\right)_2, \left([L^{pl}_e, \ldots]_{m,1}, \ldots\right)_3, \ldots\right] \to \qquad (3)$$

[13] We have to mention, that in our formalization of lexemes $L^t_a, L^t_b, \ldots$ we keep abstract indices a, b, which should be interpreted as distinct $< lemma, inflectional\ label >$ pairs.

$$\Big[(L_a^{pl}, L_b^{pl}, L_c^{pl}, \ldots)_1, (L_d^{pl}, \ldots)_2, (L_e^{pl}, \ldots)_3, \ldots\Big] \quad (4)$$

where the vector $[L_a^{pl}, L_b^{pl}, \ldots]_{k,1}$ is merged with the vector $[L_c^{pl}, \ldots]_{k,2}$ producing the list present at the first position of the equation 4.

We have to mention that, some of the elements of the character string lists might be removed completely, when they are not recognized by the inflectional dictionary. Due to the productive character of languages, there are always some words, which are missing in such dictionaries. For example, the latest version of the dictionary described in [7] doesn't recognize forms such as *konfigurować* (configure) or *opcjonalny* (optional), which are recognized by modern general purpose Polish dictionaries such as the online version of the most popular Polish dictionary accessible on the website `http://sjp.pwn.pl`[14].

We also have to say that there are character strings, which are not recognized by the dictionary due to the fact, that they are multi-word expressions. It's because some English words might be translated as Polish multi-word expressions. In such a case we have two options: to ignore theme or to split them into single words. In our case we took the first approach in cases, when given Polish translation corresponded to one word in an English multi-word expression and the second approach in the opposite cases.

Considering the example from the previous step, the vector would be translated into the following result: `[(<uzależniać,BDA>, <uzależniać się,BDA>, <uzależniający,CAA>, <uzależniający się,CAA>, <wciągać,BDA>, <wciągać się,BDA> <wciągający,CAA>, <wciągający się,CAA>)`$_1$`, (<substancja,ADACBAA>, <istota,ADAAA>, <ciężar,ACAAAAA>, <Ciężar,AAAAD>, <waga,ADAB>, <Waga,AABACC>, <podstawa,ADAAA>, <treść,ADCCA>, <realność,ADCCA>, <majątek,ACABA>)`$_2$`]`

E. Transformation

The mapping step might produce tens or even hundreds of interpretations for a single Cyc concept, thus some transformations have to be applied, to reduce these numbers. There is also another problem, which stems from the fact, that for the translation to be consistent, certain features of the lexemes (such as gender of a noun and an adjective) have to be accommodated.

The general idea of the transformation step, is to look at the grammatical categories of the lexemes corresponding to the Polish character strings. It is observed, that for resources such as Cyc, many of the source entities were two-word expressions or three-word expressions containing a preposition or a determiner. Because determiners are not present in Polish, and preposition often disappear in the translation (e.g. „of" is replaced by the genitive case of the dependent nominal phrase), we had to deal with restricted number of grammatical category combinations and it was quite easy to order them in an effective, yet not much restricting manner:

1) noun + adjective
2) noun + noun
3) noun + verb
4) noun + other
5) other

Having such an ordering, the lexeme tuples taken from the Cartesian product of the vector from the equation 4, were partitioned into five sets and only the non-empty partition with the highest rank was selected. All the other lexeme pairs were dismissed. We haven't defined rules for triples of lexemes, since it turned out, that such complex expressions were rarely translated correctly, and they were processed rather slowly.

After this reduction, the inflectional forms of the lexemes were adjusted to fulfil Polish syntactic rules. For the first 3 cases the schema was as follows:

1) noun + adjective: the base form tagging for the noun was determined, which could be a nominal case of a singular or a plural form (the latter for *plurale tantum* nouns), then the form of the adjective was selected accordingly (its number, case and gender being taken directly from the noun form and its gender).
2) noun + noun: for each of the nouns the number was determined as in the previous rule. Then two pairs of forms where added: in the first, a nominal case for the first and genitive case for the second noun was selected, in the second – a genitive case for the first and nominal for the second lexeme[15].
3) noun + verb: the infinitive form of the verb and the accusative case[16] for the noun were selected.

In the other cases only the base forms were selected.

When these transformations had been completed the number of lexemes' pairs were significantly reduced. But what is even more important, for most of the cases, the obtained expressions were grammatically correct.

This step would transform example from the previous step as follows: `[uzależniająca substancja, uzależniająca się substancja, wciągająca substancja, wciągająca się substancja, uzależniająca istota, uzależniająca się istota, wciągająca istota, wciągająca się istota, uzależniający ciężar, uzależniający się ciężar, wciągający ciężar, wciągający się ciężar, ...]`

F. Ranking

When the transformation step is finished, the translations are ranked according to the number of their occurrences in a large corpus.

[14] Checked on the 7^{th} of March 2010.

[15] This idea was supported by the fact, that in nominal phrases consisting of two nouns, the subordinate noun, always has the genitive case, e.g. *wąsy kota* (whisker of a cat) – `plural:nominal singular:genitive`. In other words: noun governs genitive case.

[16] Since the syntactic features of Polish verbs are not yet fully described in a form of an electronic dictionary, we've taken this assumption, although it could produced many incorrect translations.

In general three different cases might appear as the result of the previous step:

1) there are only single words in the vector
2) there are pairs of lexemes produced by the transformation step
3) there is the original vector from the equation 4, if it contained more than two positions

In the first case, the results are ranked simply according to the number of their occurrences in the corpus. It is quite important, that there is one big lemmatized corpus of Polish available for free – the IPI PAN corpus described in [9].

In the second case, the results are ranked according to the number of occurrences of bigrams in the corpus. Even though the IPI PAN corpus is not well balanced, the mere fact that given pair of words occurs in it, is sufficient to properly order them and reject uncommon multi-word translations. In general case, if ngrams were employed in the transformation step, any kind of smoothing or backoff algorithm could be employed (see [10, pages 83–122] for details).

In the last case, when the complex transformation was not applied to the original vector, the translations should be ranked as in the first case, but separately for each position. It is not practical to check the number of occurrences of each combination of the character strings, as it might be really huge, and would significantly slow down the translation process (while the whole methodology is devised for its speed-up). Nevertheless, the ordering of translations for each position is still important, since it provides the human operator with translation hints and also signifies, which translation might be the most natural.

It might seem that the IPI PAN corpus is too small for such a task, and tools such as search engine should be consulted. In practice, this is not the best idea, since the number of queries which would have to be send to the server is quite large (at least tens for single concept), and as the tool is designed for interactive usage, this would slow down the process – simple looking through the list of results would be more efficient[17].

For the example provided above, only the „substancja uzależniająca" is recorded in the corpus and only this proper translation is presented to the user.

G. Selection

When the translations are ranked they might be presented to the human operator. If the number of translations is too large, they might be cut at some level (e.g. only 15 top ranked translations appear), since it doesn't make sense to go through all of theme (this might be more time consuming than figuring out the translation from scratch).

The selection should be as easy as clicking a button next to the correct translation. We think that the user should not be disrupted by the precise lexical information at the moment, so simple character strings should be displayed. This might introduce some ambiguity, but since the user always should have the option to enter the translation manually[18] the interpretation step is necessary anyway.

H. Interpretation

The last necessary step in creating the accurate translation is the correct interpretation of the character string selected by the user. Although if he selects one of the translations that was suggested by the system, the necessary information is available at hand. But when he enters the translation manually, the correct lexemes and taggings should be selected.

This is done with a support of a simple parsing algorithm. There is not enough space to discuss it in detail, that's why we give just its simple characteristic. In general the algorithm is based on the concept of unification, with features attached to the grammatical categories [10, pages 489–528]. Each grammatical category defines what values of features are required from the other grammatical categories if their instances are subordinate elements of the instances of the former category in the abstract syntax tree (e.g. genitive case for the noun which is a subordinate of some other noun). Some of the categories are supplemented with the information, that their instances require obligatory subordinate elements (like reflexive pronoun *się* for reflexive verbs). For given interpretation of the expression – if there exist tree of nodes constructed according to the optional requirements, and for each node all of its obligatory requirements are met, the interpretation is marked as valid.

Still, although for simple expressions, this algorithm produces many unambiguous results, there are cases[19], for which even the most clever algorithm would produce more than one interpretation. So in such cases, the human operator should be able to select the correct lexemes and taggings by hand.

As a final result, the Cyc concept is mapped to the list (in the simplest case – single entry list) of Polish lexemes with taggings[20] attached:

$$L_i^s \to \left[(L_a^t, T_{a,k})_1, (L_b^t, T_{b,l}), \ldots\right] \tag{5}$$

I. Searching for semantic categories

Since we have the proper mapping of the Cyc concept, we might search for the semantic categories extracted from the Polish Wikipedia, which are most similar to the translation. So far this algorithm is not much complicated – all the entires which contain the lexemes which appear in the translation are selected, and then they are ranked according to the following equation:

$$R_i = \frac{cm_{i,j}}{cl_i} * \frac{cm_{i,j}}{cl_j} * children_i \tag{6}$$

where

[17] On the other hand, if the results were cached, the search-engine approach would be much better and it is considered for the further development of the system.

[18] The rationale is that there are many cases, like compound metaphoric expressions not recorded in the bilingual dictionary, or entries containing many words (in our case, more than two) that will never appear as the result of the complex processing.

[19] E.g. the lexemes with lemma *zamek* differentiated by the `singular:genitive` *zamka:zamku* or the expression *akt własności*, where the second lexeme might be in singular or in plural.

[20] Indicating the selected forms.

1) R_i – is the rank of semantic category i
2) $cm_{i,j}$ – is the number of common lexemes in the semantic category i and the translation of the Cyc concept j
3) cl_i – is the number of lexemes in the name of the semantic category i
4) cl_j – is the number of lexemes in the translation of Cyc concept j
5) $children_i$ – is the number of instances in the semantic category i

This equation favors categories with many instances on the one hand, and also the categories, whose names are similar to the translation of the concept on the other.

J. Merging and linking the categories

As the last step of the algorithm the user might make the following decisions:

1) She might merge zero or more semantic categories with the Cyc concept. The result of the operation will be a direct attachment of all the instances of the category to the Cyc concept – the instances of the category will become the instances of the concept. E.g. the „miasto" (city) category might be merged with the `#$City` concept.
2) She might link zero or more semantic categories with the Cyc concept. In this case the category will become a specialization of the concepts, and its instances will be treated as indirect instances of the concept. E.g. the „miasto wojewódzkie" (provincial city) might be linked with the `#$City` concept.

The user is not restricted to merging one category, due to the fact, that the semantic category extraction algorithm produces many over specified categories (e.g. „miasto położone" (city situated), „miasto znajdujące" (city situated), which should be merged with the `#$City` concept).

Even though the previous step might produce many results, it is not needed to merge or link all of them – the less instances given semantic category contains, the less time should be spend for its analysis and some of them might be simply skipped.

V. Application

As a part of the research we constructed an application[21], along the lines of the described methodology. In our earlier research we found out, that although rough automatic translation of single-word entries produces promising results, the syntactic information, which is indispensable for the natural language production capability, has to be entered by the human operator. What is even more important, most of the entries which represent concepts of the ontology are multi-word expressions, which are mistakenly translated by the leading statistics based machine translation systems, like the above mentioned Google Translate.

Fig. 2. Translations suggested by the application.

The main window of the system is presented in Fig. 1 and it shows part of the list of concepts which are mapped to Polish expressions (the concept is on the left, while the translation is on the right). The user might get familiar with the meaning of the concept, by studying its hypernyms, hyponyms and directed instances (icons on the left) and by reading its comment (the left icon in the middle between the concept and its translation).

When he clicks the right icon in the middle of the table, he sees the translations suggested by the system (Fig. 2). The English mappings of the concept are present at the top of the translation box. The manual entry box and the suggested translations are below. The user might accept given suggestion by clicking the plus icon next to it or enter some other translation in the manual entry box. He might also consult statistics of given expression by clicking the `bigramy` link next to it.

In the rare case, that given expressions is morphosyntacticly ambiguous, the user is consulted once again (Fig. 3). The full tagging of each lexeme is presented, as well as the morphological information in a form of an inflectional label. If the user is not familiar with the inflectional scheme, he might click the lemma of the lexeme, and its full inflectional paradigm will be presented. The user accepts given interpretation by clicking the tick icon, which is below.

The user might validate his selection by clicking the icon which is on the left of the translation (Fig. 1). It will show Polish paraphrasing of sample of the taxonomical knowledge taken from Cyc (Fig. 4), which utilizes the morphosyntactic information attached to the translation.

Then the user might search among the semantic categories extracted from the Polish Wikipedia, to find these which could

be merged or linked with the concept (Fig. 5). This is done by clicking the icon on the right of the translation.

The user might merge the category with the concept, by dragging the splitted arrow and dropping it on the name of the concept. The user might also link the category with the concept, by dragging the straight arrow and dropping it on the name of the concept.

VI. Results

So far 560[22] of Cyc concepts out of 3600 selected for translations were mapped to the Polish expressions. The translations were carried out by two independent translators, reaching the inter-translator agreement of 56%. This means that the translation task is not easy. This is due to the fact, that the concepts selected for translations are quite general, and have to be translated carefully. The general precision[23] of the translations suggested by the system was 37% and recall[24] was 88%, while precision for two-word compounds was 27%.

On the other hand 193 of the translated concepts were linked and merged with Wikipedia semantic categories, covering more than 20000 Wikipedia instances (articles), which seems to be a good result for the very limited resources available for the project.

VII. Conclusions

Although the precision of the translation algorithm is quite low, the application speeds-up the creation of the Polish lexicon for Cyc. This is due to the fact, that it integrates several resources, namely the Cyc ontology, Polish inflectional dictionary, English-Polish dictionary as well as semantic categories and concepts extracted from Wikipedia, while presenting to the user only these pieces of information, which are relevant for the task. As a result, after few months (approx. 3) of work the created resource will cover thousands of Polish linguistic units incorporated into the formal framework of the Cyc ontology.

The usefulness of this resource is verified in experiments covering the extraction of semantic relations from Polish texts as well in demo application allowing for Polish paraphrasing of the knowledge available as Open Data and the preliminary results are promising.

[22] It took two weeks to translate these concepts. The translation of the rest of them will be started in September 2010, since the funds for the task are paid in tranches.

[23] Measured as the number of concepts for which the system suggested the translation selected by the translator.

[24] Measured as the number of concepts for which translations were suggested.

Tools for Syntactic Concordancing

Violeta Seretan and Eric Wehrli
LATL - Language Technology Laboratory
Department of Linguistics, University of Geneva
Email: {violeta.seretan, eric.wehrli}@unige.ch

***Abstract*—Concordancers are tools that display the immediate context for the occurrences of a given word in a corpus. Also called KWIC – Key Word in Context tools, they are essential in the work of lexicographers, corpus linguists, and translators alike. We present an enhanced type of concordancer, which relies on a syntactic parser and on statistical association measures in order to detect those words in the context that are syntactically related to the sought word and are the most relevant for it, because together they may participate in multi-word expressions (MWEs). Our syntax-based concordancer highlights the MWEs in a corpus, groups them into syntactically-homogeneous classes (e.g., verb-object, adjective-noun), ranks MWEs according to the strength of association with the given word, and for each MWE occurrence displays the whole source sentence as a context. In addition, parallel sentence alignment and MWE translation techniques are used to display the translation of the source sentence in another language, and to automatically find a translation for the identified MWEs. The tool also offers functionalities for building a MWE database, and is available both off-line and online for a number languages (among which English, French, Spanish, Italian, German, Greek and Romanian).**

I. Introduction

Knowledge of a word means knowledge of the relations that this word establishes with other words: “You shall know a word by the company it keeps!” [1, p. 179]. Hence, the study of words in context—in order to analyse how words are actually used and what their typical contexts are—is a major concern in any field dealing with language from diverse perspectives, no matter whether it is theoretically or practically motivated.

The advent of the computer era and the ever-increasing availability of texts in digital format allow for virtually unlimited exploration. Yet, this is at the same time one of the biggest issues that users presented with automatically detected contexts inevitably have to face. The information comes to them as huge amounts of unstructured data, characterised by a high degree of redundancy.

To help them overcome the problem of information overload, a new generation of concordancers have been developed that are able to pre-process textual data such that the most relevant contextual information comes first [2]. This is achieved using lexical association measures that quantify the degree of interdependence between words, by relying on statistical hypothesis tests, on concepts from information theory, on data mining techniques, or by making use of various other methods ([3], [4]).

A representative example of such a concordancer is the Sketch Engine [5]. It analyses a preexisting corpus of text in order to produce, for a given word, a one-page summary of its grammatical and collocational behaviour. In doing so, it first performs a shallow parsing of the corpus by relying on automatically assigned POS tags for words, then it applies an association measure derived from Pointwise Mutual Information [6]. For illustration, Figure 1 shows part of the “sketch” produced for the French word *atteindre* (“to reach, to attain”). By clicking on the links in the frequency column, users have the possibility to see the actual concordance line, with a left and right context for each instance found in the corpus.

Developed more or less simultaneously with the Sketch Engine, our concordancer *FipsCo* ([7], [8], [9]) shares several similarities with it, and was primarily designed with the specific goal of being integrated as a new type of tool in the workbench of translators from an international organisation. In this paper, we describe this tool, its underlying resources and methodology, its latest developments, and we present the manner in which it is currently integrated in the larger, evolving processing environment available in our laboratory.

The paper is organised as follows. Section II provides an overview of FipsCo. Section III presents the resources and methods on which it is founded. Section IV describes in greater detail its functionalities, then Section V introduces FipsCoWeb, its recently developed online version. Section VI discusses the manner in which FipsCo and FipsCoWeb are integrated into the larger language processing environment of LATL. The last section contains concluding remarks.

II. FipsCo: An Overview

In FipsCo, the system of syntax-based collocation extraction and concordancing developed in our laboratory, the input text is first syntactically analysed with a full parser, then it is processed with standard statistical methods which measure the strength of association between words.

Collocation, understood as “typical, specific and characteristic combination of two words” [10], is a generic term used here to encompass all syntactic word combinations found in a corpus that are relevant to the studied word, from a lexicographic point of view. As in [11], we consider that collocation refers, more generally, to “the way words combine in a language to produce natural-sounding speech and writing”.

This concept is allowed to overlap with other types of MWEs, like compounds (e.g., *wheel chair*), phrasal verbs (e.g, *to ask [somebody] out*) or certain types of less figurative idioms (*to open the door [for smth]* “to allow [smth] to happen”).

Fig. 1. The Sketch Engine [5]: Sample (partial) output, showing collocates for the French verb *atteindre*, "to reach, to attain".

The boundaries between the different kinds of MWEs are known to be particularly difficult to be drawn, as they are rather fuzzy [12]. From a practical point of view, all MWEs pose similar processing problems, regardless of any finer-grained classification. We will henceforth refer to the output of our system as to collocations (or collocation candidates), without making further, more elaborate distinctions.

As the Sketch Engine [5], our system outputs collocation candidates grouped by types (which conflate all the instances of a specific word combination detected in the corpus), partitioned into syntactically homogeneous classes, and ranked in the reverse order of the association strength. Thus, the user may easily consult a manageable amount of contextual data, consisting of the most relevant collocates. The data presented are organised and, to a certain extent, free of redundancy.[1]

Figure 2 shows some results obtained from a French corpus by using FipsCo. These results were filtered by the user so that they contain collocations for the sought word (in this case, the verb *atteindre*, "to reach, to attain") in a specific syntactic configuration; the configuration retained here was verb-object. According to the association measure applied, the noun the most collocationally related to this word is *objectif* ("objective"). It was detected 271 times in the source corpus, and it is indeed a good collocate candidate, as one might easily agree that *atteindre un objectif* ("to reach a goal") is a collocation in French.

The concordancer displays its 100th instance in the corpus, which, as can be seen, involves a rather complex syntactic context: the order of the items in the collocation is inverted, the items are inflected and not in the base word form, and there is additional material inserted in between. Due to a grammatical transformation (passivization), the original verb-object combination is realized, at the surface level, as a subject-verb combination. The identification of these type of complex cases, which are particularly difficult to handle by pattern-based shallow parsers, is possible in our system thanks to the deep analysis provided by the parser (cf. Section III).

Among the other combinations shown in Figure 2, one might find several other MWEs with the verb *atteindre*. The tool also presents the automatically retrieved translation of the context in another language, if parallel corpora are available. In a translation environment, such corpora are typically available from translation archives. Thus, when working on a new document, translators have the possibility to see how a given expression has previous been translated in various contexts.

Figure 2 also shows the buttons *Validate*, used for manually validating the automatically extracted results, and *Translate*, used for automatically detecting a translation for the selected collocations. The *Filter* button opens the interface in Figure 3, through which the user can control which corpus results to display.

FipsCo is freely available for research as an offline tool for Windows (cf. Section IV). One of the latest developments concerned the creation of a lighter-weight online version, which has already been made available to the public. A more detailed description of FipsCo and its Web version, FipsCoWeb, is provided in Section IV.

III. Underlying Resources and Methodology

This section provides details about the resources used by FipsCo and the method used to extract from text corpora the most relevant collocates for a given word.

A. Resources

FipsCo was built as an extension of Fips, a multilingual symbolic parser based on generative grammar concepts [13]. Fips can be characterised as a strong lexicalist, bottom-up, left-to-right parser. Given a sentence, it builds a rich structural representation combining *a*) the constituent structure; *b*) the interpretation of constituents in terms of arguments; *c*) the interpretation of elements like clitics, relative and interrogative pronouns in terms of intra-sentential antecedents; and *d*) co-indexation chains linking extraposed elements (e.g., fronted NPs and wh elements) to their canonical positions.

According to the theoretical stipulations on which Fips relies, some constituents of a sentence may move from their canonical "deep" position to surface positions, due to various grammatical transformations. For instance, in the case of

[1] All the corpus instances (tokens) of a same word combination are grouped under a single entry, the corresponding collocation type.

the French sentence shown in Figure 2, it is considered that the noun *objectif* moved from its original position of direct object into the surface position of subject due to a passivisation transformation. The parser keeps track of this movement by linking the (empty) object position of the verb *atteint* to the extraposed noun, *objectif*. In the normalised sentence representation it builds, the parser identifies this noun as the "deep" direct object. Consequently, the combination *atteindre–objectif* can successfully be identified from this sentence as a verb-object collocation, as the parser helps abstract away from the particular surface realization.

The parser is the most important resource on which syntactic concordancers like FipsCo rely in order to filter out "noise" and to return highly accurate extraction results.[2] However, parsers are only available for a handful of languages. Fips, in particular, relies on large resources (lexica and grammars) whose construction is time-consuming.

Currently available for English, French, Spanish, Italian, Greek and German, Fips is actually conceived as a generic parsing architecture, coupling a language-independent parsing engine with language-specific extensions. The language-independent part implements the parsing algorithm, based on three main types of operations: *Project* (assignment of constituent structures to lexical entries), *Merge* (combination of adjacent constituents into larger structures), and *Move* (creation of chains by linking surface positions of "moved" constituents to their corresponding canonical positions).

The language-specific part of the Fips parser consists of grammar rules of a given language and of a detailed lexicon for that language. In the formalism used by Fips, the role of most grammar rules is to specify the conditions under which two adjacent constituents may be merged into a larger constituent by a *Merge* operation. The construction of the lexicon is supported by a morphological generation tool that creates appropriate lexical entries corresponding to a specified inflection paradigm (when applicable). Unlike other parsers, Fips does not require POS-tagged data as input; the POS is assigned to words during the analysis, based on lexical information and on the parsing hypotheses.

Given the Fips architecture and the existing tools supporting the creation of lexical resources, we believe that the effort of extending Fips to a new language is comparable to the combined effort of building POS-taggers and developing

[2] An evaluation of FipsCo is presented in [14].

shallow parsers for the same language. Our recent work on Romanian [15] confirmed that a Fips parser version that can be satisfactorily be used for the purpose of collocation extraction can be built in a reasonable amount of time, of the order of several person-months.

B. Methodology

As mentioned in Section II, the extraction of collocations from text corpora is done by using a hybrid extraction method, which combines the syntactic information provided by the Fips parser with existing statistical methods for detecting typical lexical associations in corpora.[3]

Thus, in the first step, collocation candidates are identified as combinations of lexical items in predefined syntactic configurations (for instance, verb-object) from each sentence of the corpus, by traversing the parse structures returned by the parser. In the second step, the candidates obtained are ranked according to their probability to constitute collocations, as computed with the log-likelihood ratio association measure [16]. FipsCo actually implements a wide range of other measures that the user can choose for ranking collocation candidates; log-likelihood ratio is proposed by default as it is a well-established measure for collocation extraction.

The output of FipsCo is a so-called significance list, in which one finds at the top the candidates that are most likely to actually constitute collocations. A cut-off point can be applied by the user to the results, in order to retain only the candidates with higher scores. Typically, a frequency threshold is also employed to eliminate those combinations that only occur a few times in the corpus. This is because statistical measures are unreliable on low frequency data ($f < 5$). However, we opted for keeping all the candidate data (no frequency threshold), since relevant collocations may be found among combinations occurring only a few times in the corpus. Besides, a threshold can be applied by the user afterwards. The syntactic filter applied on the otherwise huge candidate data helps our system keep the statistical computation tractable. In the systems that do not use parsed data, high frequency cut-offs are often imposed only to reduce the amount of data to process.

IV. Detailed Description of FipsCo

FipsCo is implemented in Component Pascal under BlackBox Component Builder IDE,[4] just as the syntactic parser Fips, on which it relies. It makes an extensive use of the SQL database query language in order to store the extraction results, compute the collocation scores, filter the data that will be displayed, etc.

The system has, in principle, a pipeline architecture, as the typical execution flow follows the order in which the main components of the system are described below. However, there are no restrictions to the order in which the various components can be used, since the extracted and validated results can be stored and accessed later for visualisation.

A. File Selection

The source corpus used in an extraction session is specified by selecting the folder which contains the desired files and, optionally, by applying an automatic or manual filter on its content.

The automatic filter is based on:

- file location: inclusion or exclusion of the sub-folders; exclusion of sub-folders having a specific name;
- file name: this might be required to contain a given string of characters;
- file type: this must belong to a list of allowed types. The system supports all the file formats that can be currently imported by BlackBox, e.g., `odc` – Oberon document; `txt`, `htm`, and `html` – text; `rtf`, `doc` – rich text format; and `utf` – Unicode.
- file last modification date (from `date1` to `date2`; in the last `n` days).

In addition, the selection can be further narrowed manually, as the user may select or deselect items after the automatic filter applies. For instance, it is possible to choose items (files or folders) in the first level of the source folder with a mouse click, or by using standard selection commands (check all; uncheck all; invert selection).

B. Collocation Extraction

The collocation extractor is the main component of the system. It iteratively processes all the files in the selection. The number of files that can be processed is virtually unlimited. The collocation candidates identified from the parse trees are incrementally added to previous results until an extraction session ends. They are stored either in a database or in a single text file. As an option, they can also be stored file by file in a folder whose structure mirrors the structure of the source folder.

At the end of the extraction session, several processing statistics are computed for the source corpus that are derived from parsing information (e.g., the total number of tokens, sentences, sentences with a complete parse). Then, the candidates identified are ranked according to the chosen association measure (by default, log-likelihood ratio [16]).

C. Filtering

This component selects the results to be displayed in the concordancer, according to the parameters set by the user (see Figure 3). The extracted collocations can be filtered according to several criteria:

- syntactic type: the user can select one or more types from a list that is automatically built from the database containing the extracted collocations;
- collocation score: a range from `score1` to `score2`;[5]

[3] It is important to note that the method itself is not dependent on Fips or any of the specific theoretical assumptions made by Fips, but it can be used in conjunction with other parsers.

[4] BlackBox is developed by Oberon Microsystems (http://www.oberon.ch). A characteristic of this development environment is the ease of editing graphical user interfaces components, which turned into a big advantage for our system, in which visualisation plays a major role.

[5] The user is not required to know the actual maximal values; the corresponding fields can be left blank and these values will be retrieved by the system.

Fig. 3. FipsCo: Interface for filtering collocations.

- corpus frequency: a range from `freq1` to `freq2`;
- collocation keywords: the user can search for collocations containing a specific word.

In addition, the user can specify the range of results to display (from `rank1` to `rank2`), according to the order given by the collocation score or by the corpus frequency. The range restrictions can be applied both to collocation types and to collocation instances (tokens).

D. Concordancing

This component is responsible for the visualisation of extraction results according to the selection made by the user. The (filtered) list of collocations is displayed on the left hand-side on the concordance interface, and can be ordered by score, by frequency in the corpus, or alphabetically. On the right hand-side, a text panel displays the context of the currently selected collocation in the source document. The whole content of the document is accessible, and is automatically scrolled to the current collocation; this collocation and the sentence in which it occurs are highlighted with different colors (cf. Figure 2).

Each item in the list represents a collocation type; its corresponding instances are read from the database when the user clicks on it. The right panel automatically displays the first instance, then the user has the possibility of navigating through all the instances by using the standard browsing arrows (`<< - first`, `< - previous`, `> - next`, `>> - last`), or to skip to a given instance by entering its order number.

The visualisation interface also displays information about the rank of the currently selected collocation, its syntactic type, its score, and its status relative to the parser's lexicon (new collocation, or collocation in lexicon). The user can easily switch to a different source language in order to load the collocations already extracted for that language, if these were stored in the same database.

E. Complex Collocations

By treating already extracted collocations as single lexical items, FipsCo is able to identify complex collocations that can be seen as structures containing embedded collocations: for instance, *atteindre point culminant* ("to be at the highest level") is a complex collocation of verb-object type, which contains an embedded noun-adjective collocation, *point culminant*.

The detection of such complex collocation is particularly useful when the resulting expression constitutes a non-decomposable compound, or when it contains a nested compound. In these cases, it is important to highlight the whole expression rather than nonsensical sub-parts. For instance, *genetically modified organisms* is a compound, and it will be desirable to output it as a whole rather than only the sub-part *modified organisms*. The expression *second world war* is more compositional, as *world war* is a collocation on its own. However, it is desirable to eliminate *second war* from the extraction results, if it only occurs in the corpus in the longer expression *second world war* .

Our method of detecting complex collocations is described in [17] and [18]. FipsCo includes a concordancing interface for displaying complex collocations, which is similar to the standard interface shown in Figure 2.

F. Sentence Alignment

When parallel corpora are available, the target sentence containing the counterpart of the source sentence can be detected and displayed in the alignment interface below the source sentence. The user selects the target language from a list of languages and specifies the path of the target corpus and the filename transformation rule needed to determine the filename of the target document (i.e., of the translation) from the filename of the source document. These rules assume that the source folder and the target folder have the same structure, and that the target filename can be obtained from the source filename by replacing the prefix and/or the suffix of the filename (which are assumed to be variable across languages), while keeping the middle part constant. For instance, `35.1.001E.txt` can be obtained from `35.1.001F.txt` by replacing the suffix `F` with `E`.

Once the target file has been found, the sentence that is likely to be the translation of the source sentence is identified using an in-house sentence alignment method ([7], [9]). The alignment component is operational both for binary collocations and for complex collocations.

G. Validation

This component provides functionalities that allow the user to create and maintain a list of manually validated collocations from the collocations visualised with the concordance and the alignment interfaces. An entry contains basic information about a collocation (such as the collocation keywords, lexeme

indexes for the participating items, syntactic type, score and corpus frequency). A monolingual entry may also contain the source sentence of the currently visualised instance, which provides a naturally-occurring usage sample for the collocation. A bilingual entry stores, in addition, the target sentence found via alignment and the translation proposed for the collocation: the translation can be manually retrieved by the user from the target sentence.

Additional information related to the currently visualized collocation instance is stored (namely, the name of the source and target file, the file position of the collocation's items in the source and target files, and the file position of the source and target sentences). Most of this information is automatically filled in by the system. The entries in the list of collocations validated in a session can be updated, deleted, or saved—completely or in part—by the user in a monolingual and in a bilingual database.

H. Translation

This component attempts to detect a translation equivalent for the collocations visualised in the concordancer, by scanning the existing translations and using a strategy briefly described below.

First, a limited number of corpus sentences (50 in our current experiments) in the source language is retrieved for the source collocation, based on the corpus instances detected during extraction. The alignment component is then used for finding, for each source sentence, the corresponding target sentence in the desired target language, for which a parallel corpus is available.

The target mini-corpus thus obtained is parsed, and collocations are extracted from it using the same method that was applied to the source corpus. Finally, a process of collocation matching takes place, which tries to find, among the extracted collocations, the one that is likely to represent a translation for the source collocation. The matching is performed by applying a series of filters on the extracted pairs that gradually reduce their number until a single item is retained, which will be proposed as translation. An updated description of the translation method can be found in [19].

V. Online Version: FipsCoWeb

FipsCoWeb, which is introduced for the first time in this paper, is the online version of the FipsCo system. Its current interface is shown in Figure 4. FipsCoWeb allows the user to upload a file and to set the initial processing and visualization parameters (e.g., association measure, cut-off score, frequency threshold). After the processing is done on the server side, the user is presented with the results, as shown in Figure 5. The user has then the possibility to apply different parameters, to apply a syntactic filter, and to see the actual occurrences of a collocation by clicking on the corresponding link. The words in the collocation will be presented in the sentence context, and highlighted for readability (cf. Figure 6).

FipsCoWeb currently allows users to upload files containing up to 0.5 million words. While this is a reasonable size for online corpus exploration, the processing, which is performed at an average of 200 tokens/second, might take a while to complete. Depending on the file size, users might only be able to see the results after a few minutes or a longer lapse of time (typically, half an hour). For this reason, FipsCoWeb gives users the possibility to enter the e-mail address at which the link to results is sent when the server-side computation is completed. Results are stored on the server and can be

consulted later, until users explicitly decide to clear them, by clicking on the *Close Session* button. A feature that is currently unavailable in the system, but can be easily implemented, is the search for collocations with a given word.[6]

The Web version has been implemented in BlackBox (see Section II), and the Web server itself[7] runs as a BlackBox program. This made the integration between the involved software modules easier. However, since it runs as a unique Windows process, it cannot be efficiently used for the parallel processing of large files. A solution is currently being worked on to circumvent this problem. Future work will focus on implementing FipsCoWeb as a Web service.

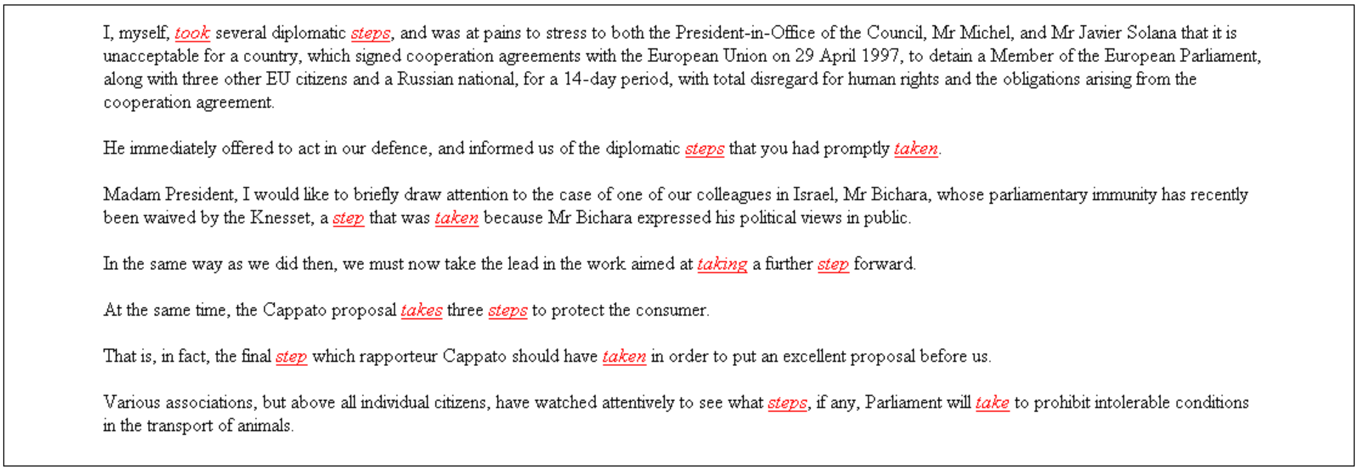
VI. Integration in the NLP Environment of LATL

LATL develops a range of NLP tools in several areas. FipsCo (and its online version, FipsCoWeb) are not isolated tools, but are part of a larger processing framework specifically dealing with MWEs, from different practical perspectives.

As a matter of fact, the corpus-based study of words and their collocates was not, in our case, a goal in itself. The collocations that lexicographers manually validate are entered into the lexical database of the parser Fips, and are used to guide future analyses performed by Fips [20]. Their translations (either manually or automatically obtained) are used to populate the bilingual lexicon of a rule-based machine translation based on Fips. The collocations added in the lexicon are further used in two applications of terminology assistance, Twic and TwicPen [21], which look up the lexicon and propose a translation for a given word that is compatible with the grammatical context. If the selected word is part of a MWE, these systems output the translation of the whole MWE, rather than a translation for the word in isolation. Work is under way to augment the MWE resources for all the languages supported by the Fips parser.

[6] Note that the online version does not aim to re-implement all the functionalities of FipsCo.

[7] O_3-WAF (Web-Application-Framework); http://o3-software.de/



I, myself, took several diplomatic steps, and was at pains to stress to both the President-in-Office of the Council, Mr Michel, and Mr Javier Solana that it is unacceptable for a country, which signed cooperation agreements with the European Union on 29 April 1997, to detain a Member of the European Parliament, along with three other EU citizens and a Russian national, for a 14-day period, with total disregard for human rights and the obligations arising from the cooperation agreement.

He immediately offered to act in our defence, and informed us of the diplomatic steps that you had promptly taken.

Madam President, I would like to briefly draw attention to the case of one of our colleagues in Israel, Mr Bichara, whose parliamentary immunity has recently been waived by the Knesset, a step that was taken because Mr Bichara expressed his political views in public.

In the same way as we did then, we must now take the lead in the work aimed at taking a further step forward.

At the same time, the Cappato proposal takes three steps to protect the consumer.

That is, in fact, the final step which rapporteur Cappato should have taken in order to put an excellent proposal before us.

Various associations, but above all individual citizens, have watched attentively to see what steps, if any, Parliament will take to prohibit intolerable conditions in the transport of animals.

Fig. 6: FipsCoWeb: Collocation instances in context (screen capture).

VII. Conclusion

In this article, we provided an updated description of FipsCo, a tool for extracting collocations (and multi-word expressions more generally) from corpora, which has been developed at LATL in the last several years. Since FipsCo is based on parsing and offers multiple visualisation functionalities, it can be seen as a tool for syntax-based corpus exploration, or syntactic concordancing.

Also, we introduced FipsCoWeb, the online version of this tool, recently developed and already functional. This version can be used to upload a user's own text corpus as a file and to consult the retrieved collocations. The two tools are part of a larger processing framework dedicated to MWEs, and are being used to provide resources for the two main long-term NLP projects pursued in our laboratory, namely, a multilingual symbolic parser and a machine translation system based on it.

***Abstract*—This paper presents an example of application of a PCFG parsing algorithm based on the A* search procedure in a machine translation system. We modified the existing CYK-based parser used in the machine translation system Translatica and applied the A* parsing algorithm in order to improve the performance of the parser.**

I. Introduction

PROBABILISTIC context-free grammars are a useful tool for modeling natural languages. One of the methods commonly used for parsing PCFGs is chart parsing. In general, the time complexity of chart parsing algorithms is worst-case cubic. In practice, for large grammars and long sentences, even cubic time can be insufficient.

The process of parsing PCFGs can be viewed as a process of finding a path in a certain weighted multigraph. This means that graph search algorithms can be used for parsing. The parse which has the highest probability from all the possible parses of the sentence is called the *Viterbi parse*. Finding a Viterbi parse of a given sentence can be realized by algorithms that find the shortest path in a graph. The graph algorithms are used to accelerate the chart parsing of PCFGs.

One of the methods of speeding up the parsing is the best-first strategy, described in [1] and [2]. The order of removing edges from agenda is determined by a figure of merit. If the figure of merit is properly chosen, the number of edges processed during the parsing can be significantly reduced.

Another method is a beam-search algorithm, described in [5] and [6]. In this method, only a limited number of best parses is tracked at any time. The fewer parses are tracked, the shorter time is required to complete the algorithm.

Both best-first parsing and beam-search parsing are greedy algorithms. Unfortunately, neither of them guarantees the finding of the actual Viterbi parse of a given sentence.

The A* algorithm is used to find the shortest path between two given vertices of a graph, assuming a heuristic function is specified. The heuristic function is defined on the vertices of the graph and estimates the distance between the given vertex and the target vertex. The algorithm tries to minimize the sum of the distance covered so far and the value of the heuristic.

Klein and Manning in [3] presented the algorithm that uses the A* procedure to parse the probabilistic context-free grammar. The authors showed that if a proper heuristic function is applied, the A* parsing algorithm can significantly reduce the time required to find the Viterbi parse of a given sentence.

II. The A* parsing algorithm

The A* parser is a kind of a chart parser. The basic data structure the parser operates on is called an edge. The edge is a triple $X[i,j]$, where X is a symbol of the grammar and (i,j) is the span of this symbol in the parse tree of the string $w = w_1 \dots w_n$, ie. X dominates the substring $w_{i+1} \dots w_j$. During the algorithm, a score is attached to each edge. The edges waiting to be processed are stored in the structure called agenda. The edges whose best parses have already been found are stored in a chart.

In the beginning, the edges representing the words of the parsed sentence are put into the agenda. Then, while the agenda is not empty, the following procedure (called a turn of the parser) is run: The edge with the highest priority is removed from the agenda. Then if the removed edge can be combined with some edges already in the chart then new edges are formed and inserted into the agenda. In other words, let $e = X[i,j]$ denote the removed edge. If there is an edge $Y[k,i]$ in the chart and a rule $Z \to YX$ in the set of productions, the new edge $Z[k,j]$ is inserted into the agenda. Similarly, if there is an edge $Y[j,k]$ in the chart and a rule $Z \to XY$ in the rule set, the new edge $Z[i,k]$ is formed etc. The rules of the grammar are used to combine the current edge with the symbols in the chart to create new edges and insert the newly formed edges into the agenda. The newly formed edges are put into the agenda and the process repeats until the agenda is empty.

Let $G = (V,T,R,S,P)$ be a probabilistic context-free grammar and $w = w_1 \dots w_n \in T^+$ a parsed sentence. Following [3], we will define the *Viterbi inside score* $\beta(e) = \beta_{G,w}(e)$ of an edge $e = X[i,j]$ as the logarithm of the probability of a best inside parse of e, ie. the maximum of the log-probabilities of the derivation $X \Rightarrow^* w_{i+1} \dots w_j$. We will denote by $b(e)$ the estimate of $\beta(e)$ which represent the log-probability of the best inside parse of e calculated so far. At the beginning of the algorithm $b(e) = -\infty$ and never decreases. When e is removed from agenda, $b(e) = \beta(e)$.

The *Viterbi outside score* $\alpha(e) = \alpha_{G,w}(e)$ of an edge $e = X[i,j]$ is defined as the maximum of the log-probabilities

978-83-60810-27-9/09/$25.00 © 2010 IEEE

of the derivation $S \Rightarrow^* w_1 \dots w_i X w_{j+1} \dots w_n$ (or the log-probability of the best outside parse of e). We will also estimate the value of $\alpha(e)$ by $a(e)$. We say that the estimation a is *admissible* if $a(e) \geq \alpha(e)$.

Provided that the value of $\beta + a$ never increases, we can use $\beta + a$ to prioritize edges in agenda. The β corresponds to the actual distance from the start vertex and a plays the role of the heuristic for the A* algorithm.

Klein and Manning in [3] present a series of different heuristic functions, based both on context summary estimates and grammar projection estimates.

The context summary estimates are based on the knowledge about the neighborhood of the current symbol. The value of the context summary estimate $a(X[i,j])$ is the maximum of all log-probabilities of the derivations $S \Rightarrow^* uXv$, where $uandv$ satisfies some given condition. There is a wide range of possible estimates, between the NULL estimate (when we have no information about the context), equal constantly 0, and the TRUE esimate (when we have the full information), equal the exact value of β.

The grammar projection estimates use the exact context but the reduced grammar. A probabilistic context-free grammar $G = (V, T, R, S, P)$ can be projected to some weighted context-free grammar $G' = (V', T', R', S', P')$ by a given function $\pi \colon V \cup T \to N$, where N is an arbitrary set of symbols, in the following way:

- $V' := \{\pi(A) \colon A \in V\} \subseteq N$,
- $T' := \{\pi(a) \colon A \in T\} \subseteq N$ and $T' \cap V' = \emptyset$,
- $R' := \{\hat{\pi}(r) \colon r \in R\}$, where

$$\hat{\pi} \colon R \to R',$$
$$\hat{\pi}(A \to X_1 \dots X_k) := \pi(A) \to \pi(X_1) \dots \pi(X_k),$$

- $S' := \pi(S)$,
- P' is determined as

$$P'(r') := \max_{r \colon \hat{\pi}(r) = r'} P(r).$$

The resulting grammar is not always probabilistic because the sum of the values $P'(A \to \zeta)$ for a fixed A can be greater then 1. For each rule $r \in R$ the following relation holds:

$$P'(r') \geq P(r)$$

which guarantees that the probabilities of the rules never decrease during the process of grammar projection. It implies that

$$\alpha_{G',w}(e') \geq \alpha_{G,w}(e)$$

for each edge e and its projection e', so we can use $a(e) = \alpha_{G',w}(e')$ as an estimate.

As in the case of context summary estimates, there is a wide range of possible grammar projection estimates, between the NULL estimate (which corresponds to the constant projection) and the TRUE estimate (based on the identity projection).

III. The implementation of A* parsing algorithm in the Translatica translation system

A. Translatica machine translation system

Translatica is a rule-based machine translation system that translates between languages: Polish, English, German and Russian. The German language parser of the Translatica system (in this paper I will call it *the Translatica parser* for simplicity) uses a weighted context-free grammar and a CYK-based agenda parsing algorithm. The weights used in this parser are probabilities extracted automatically from the TüBa treebank[1] using statistical methods. We decided to try to use the A* parsing algorithm in the Translatica parser to improve its speed and performance.

The implementation of the A* algorithm in the Translatica parser consisted in the adaptation of the current parser to use the A* methods.

B. SX heuristic

One of the heuristics described in [3] is the SX context summary estimate. Let $G = (V, T, R, S, P)$ be a PCFG and $w = w_1 \dots w_n \in T^+$. SX estimate $a_{G,w}(X[i,j])$ specifies the number of terminal symbols to the left from the current edge (i), to the right ($n - j$) and the label of the considered symbol (X). We chose to use the SX heuristics because [3] predicted that the application of SX heuristics in A* parsing algorithm would result in significant edge savings and require relatively little precomputation.

In every turn of the parser the sum $\beta(e) + a(e)$ is found for each edge e. The value of $\beta(e) + a(e)$ is used to prioritize the edges in agenda. The edge e with the maximal sum $\beta(e) + a(e)$ is removed from the agenda and then processed in the way described before.

The value of the heuristic is calculated only if it is necessary. In the process of memoization, the value of the heuristic for a given context summary is calculated only for the first time and then stored in the memory. This process speeds up the calculations of heuristic.

C. Attribute grammar projection

The grammar used in the Translatica parser is not exactly a PCFG but rather a kind of an attribute grammar. Each rule is equipped with a set of attribute expressions. The rule can be used only if the actual values of the attributes associated with symbols occuring in the rule satisfy the epressions associated with the rule.

It is possible to construct the context-free grammar that is equivalent to a given attribute grammar. This can be obtained by considering all possible configurations of attribute values, fixing the values of attributes and taking the adequate rules into account.

We can project the probabilistic attribute grammar to a PCFG by fixing the values of selected attributes and omitting the others.

We have implemented the grammar projection by fixing the most common attributes.

time	absolute	relative	absolute	relative
without A*	5 min 52 s	1.00	2 m 56 s	1.00
with A*, SX heur.	11 min 50 s	2.02	4 m 32 s	1.55
with A*, NULL heur.	6 min 55 s	1.18	3 m 6 s	1.06

D. NULL heuristic

We have also implemented the NULL heuristics, in order to compare the results of implementing various heuristics. The NULL heuristic, as constatntly equal 0, is easy to implement.

IV. RESULTS

We have conducted various tests in order to compare the performance of the current Translatica parser and the new A*-based parser.

In the Translatica parser it is possible to limit the maximum number of turns of the parser by setting a so called *threshold*. The default value of the threshold in the Translatica parser is 50000.

We have done a series of machine translations (in different conditions) of a sample set of 100 German sentences on various topics. The tests differed in the following parameters:

- the parsing algorithm:
  - the previous Translatica parser,
  - the A* parsing algorithm with SX heuristic,
  - the A* parsing algorithm with NULL heuristic;
- the value of the threshold:
  - 50000,
  - 10000;
- the way the input is given:
  - single sentences,
  - a set of all 100 sentences,
  - a set of all 100 sentences repeated few times.

Differentiation of ways of providing input data is aimed to test the influence of memoization to the performance of the parser.

Table I presents the average times of translating the test set of the 100 German sentences for different threshold values and different heuristics.

Table II presents the average times of translating the test set consisting of 5 copies of the set of 100 German sentences used in the previous test.

The implementation of the A* algorithm applied in the experiment didn't speed up the process of translation in the comparison with the previous Translatica parser. The NULL heuristic was proved to be faster than the SX heuristic and was only slightly slower than the old parser. It is particularly clear for the threshold of 10000, when the translation time using A* with NULL heuristic was comparable to translationa time without A*.

The differences in the quality of the translation were rather insignificant. The majority of the translations were identical, if not, the differences were in general in the single words. There are senteces whose translations by A* algorithm for a threshold of 10000 are identical with translations done by the old algorithm for the threshold of 50000, and better than translations done by the old algorithm for the threshold of 10000. It can mean that the number of steps needed to find the best parse using the A* algorithm is lower then using the previous algorithm. The reason why the translation time with A* is still longer than without A* can be put down to the implementation difficulties. Moreover, it is worth mentioning that the quality of translation of some sentences was better than with the old parser.

V. CONCLUSIONS

The experiment was an innovative try to implement the A* algorithm in an existing CYK-based parser. The implementation was intended to be integrated with the existing parser and to require as little changes to the existing code as possible. The experiment brought a great experience and significant knowledge about the implementational issues of the A* algorithm and about the possibilities of parsing improvement.

There are reasonable grounds that future research will bring the desired results—the faster translation with the Translatica system using the A* algorithm—especially if the following issues will be resolved.

There are various possible reasons why the implementation of A* algorithm in the Translatica machine translation system haven't brought the expected performance improvement.

One of possible reasons can be the specific of the Translatica parser. The grammar used in the Translatica parser doesn't have a distinguished start symbol. A given sentence is parsed using the bottom-up method—the parse tree is built upward while it is possible to combine its edges with edges from the agenda. The advantage of such approach is that it is possible to parse the phrases that are not the full sentences but only the fragments. On the other hand, this solution is rather unfavorable for the implementation possibilities for the A* algorithm because distingushing the start symbol is necessary for proper heuristic calculation.

The other reason is that the fully functional implementation of the A* parsing algorithm in the Translatica parser would involve the significant changes in the structure of the very parser.

VI. FUTURE WORK

We will continue the research concerning the use of modern tools and algorithms to accelerate the process of machine translation. We plan to modify some mechanisms used in the Translatica parser in order to enable the implementation of a fully functional parser based on the A* algorithm and also some other minor improvements.

***Abstract*—Finding regularities in large data sets requires implementations of systems that are efficient in both time and space requirements. Here, we describe a newly developed system that exploits the internal structure of the enhanced suffixarray to find significant patterns in a large collection of sequences. The system searches exhaustively for all significantly compressing patterns where patterns may consist of symbols and skips or wildcards. We demonstrate a possible application of the system by detecting interesting patterns in a Dutch and an English corpus.**

I. Introduction

SYSTEMS that analyze large collections of sequential data, such as when searching for regularities in collections of texts, place strict requirements on the efficiency. Trivial implementations of such systems often yield correct results, but either take too long or use too much internal memory. These trivial implementations lead to limitations on the size of the data set that can be handled practically.

In this paper we propose a novel implementation of a system that can be used to search for regularities in sequential data. We show the practical applicability by searching for patterns in large text collections in two different languages. At the time of publication the source code of the implementation is publicly available on the web at http://ilk.uvt.nl/~stehouwer/.

To search the data sets efficiently, we initially used a data structure called a suffixtree. Suffixtrees are well-known data structures with many applications within the fields of bioinformatics, natural language processing, and many others. Ukkonen introduced an efficient online construction algorithm for suffixtrees in [9].

More recently, a similar data structure called suffixarray is often used instead of suffixtrees to search sequential data. A suffixarray is an ordered list of all suffixes in a sequence. This data structure was introduced in [6].

The reason for choosing suffixarrays instead of suffixtrees is the relatively large memory requirements of the suffixtrees. Gusfield discusses suffixtrees, their construction, and complexity requirements in great detail in his book [4]. The worst-case complexity of memory utilization of a suffixtree is $\Theta(m|\Sigma|)$ with m the length of the sequence and Σ the alphabet. This results in a suffixtree that can be searched in linear time (linear in the size of the search sequence). In contrast, suffixarrays are linear in their space utilization, regardless of the alphabet $|\Sigma|$.

In practical terms, a suffixtree build on the first 500.000 sentences from the British National Corpus took up 2.2GB. The suffixarray on the other hand only used 0.25 GB of main memory to be able to access the same data. From the last 10.000 sentences of the same corpus we generated a set of 70.000 queries. The suffixtree answered these queries in about 3 minutes, where the suffixarray system took around an hour.

Whereas usable suffixtree implementations can be found online[1], implementations of suffixarrays that we found available all have drawbacks. Often, the implementation limits the maximum size of the alphabet, which makes them unsuitable for our use.

In [1] several improvements to the original suffixarray data structure are combined to form what the authors call the enhanced suffixarray. One enhancement added to the enhanced suffixarray is the implementation of an encoding of an implicit tree structure. It is this implicit suffixtree structure that we will use in the application we describe here that allows us to find interesting patterns.

In this paper we will start by outlining the suffixarray data structure as well as its enhanced version. We concentrate on the implicit suffixtree structure that is made available through the enhancements. We will then show an application that finds patterns with skips (also called wildcards) in natural language data using suffixarrays by using the implicit suffixtree structure. Based on this application we show some experimental results on Dutch and English and in our conclusion we will suggest other possible applications of this kind of pattern finding.

II. Suffixarrays

In this section we will describe the techniques behind suffixarrays and their enhanced version.

A. *Regular Suffixarrays*

As introduced in [6] suffixarrays are relatively simple data structures that contain a lexicographically ordered list of all suffixes of the input sequence. The array does not contain explicit copies of the suffixes, but stores information on the suffixes implicitly in the form of an index on the original input. This means that much less memory is needed to store the suffixes compared to suffixtrees.

To build a suffixarray, we initialize an array of indexes describing all suffixes of the input sequence. This array is then

[1] See for instance http://ilk.uvt.nl/~menno/research/software/suffixtree.

sorted. When using a regular, efficient, sort algorithm, sorting takes $n \log n$ time. However, the ordering of the prefixes (of the suffixes stored in the array) can depend on multiple consecutive positions in the original input. This means that we have to perform sequence comparison which may need symbol comparisons of at most n positions. This results in a naive construction time of $n^2 \log n$ for a sequence of length n.

During the last several years, many sorting algorithms have been developed that can construct a suffixarray more efficiently in time requirements. The fastest algorithms run in $\Theta(n)$ time. These build a suffixtree first (which can be done in linear time) and then obtaining the sorted suffixes by a simple traversal of the suffixtree. Unfortunately, these algorithms need working space of at least $15 \times n$ [7].

In [7] a reasonably fast algorithm is proposed that needs working space of only $5 \times n$. This algorithm works by partially sorting the array into buckets which have the same x position prefix and afterwards sorting each of these buckets with a blind trie. This strategy is called *deep-shallow sort*.

An interesting aspect of suffixarrays is that suffixes that share a common prefix are grouped together in the array. This means that it can be used to locate the position and number of all infixes of an input sequence. This is done by finding all suffixes that start with the given infix. Since they are grouped together, they can be found efficiently.

B. Enhanced Suffixarrays

Several extensions to the regular suffixarrays have been proposed. The ones we will use (and have implemented) are described in [1]. The extensions combined with a regular suffixarray makes up an enhanced suffixarray. This data structure provides, among others, a different way of viewing the data, which is very similar to a suffixtree.

The enhancements store some information explicitly, which means that they require some additional storage in the shape of arrays. The first of those is the longest-common-prefix (or lcp) array. This array, parallel to the regular suffixarray, denotes the size of the prefix shared with the previous element. For instance, if the first element is *aard* and the second *aardvark* then the second element would have an lcp value of 4 as it shares a prefix of length four with the previous element in the suffixarray. This lcp array can be efficiently constructed in a single pass over the regular suffixarray.

The lcp values can be used to define the intervals, so called lcp intervals. An lcp interval can be seen as defining the interval corresponding to range of suffixes (in the suffixarray) with a specific prefix. An interval $[i \dots j], 0 \leq i < j \leq n$ with n the length of the sequence, is an lcp interval of the lcp value l if the following conditions hold (lcptab denotes the lcp array):

1) lcptab$[i] < l$,
2) lcptab$[k] \geq l$ for all k with $i + 1 \leq k \leq j$,
3) lcptab$[k] = k$ for at least one k with $i + 1 \leq k \leq j$,
4) lcptab$[j + 1] < l$.

TABLE I

AN ENHANCED SUFFIXARRAY ON THE SEQUENCE S = *acaaacatat* INCLUDING ITS LCPTAB AND CHILDTAB. THE FIELDS 1, 2 AND 3 OF THE CHILDTAB STAND FOR THE UP, DOWN AND NEXTINDEX FIELDS RESPECTIVELY. THIS EXAMPLE IS TAKEN FROM [1].

			childtab			
i	suftab$[i]$	lcptab$[i]$	1.	2.	3.	S[suffix]
0	2	0		2	6	*aaacatat$*
1	3	2				*aacatat$*
2	0	1	1	3	4	*acaaacatat$*
3	4	3				*acatat$*
4	6	1	3	5		*atat$*
5	8	2				*at$*
6	1	0	2	7	8	*caaacatat$*
7	5	2				*catat$*
8	7	0	7	9	10	*tat$*
9	9	1				*t$*
10	10	0	9			*$*

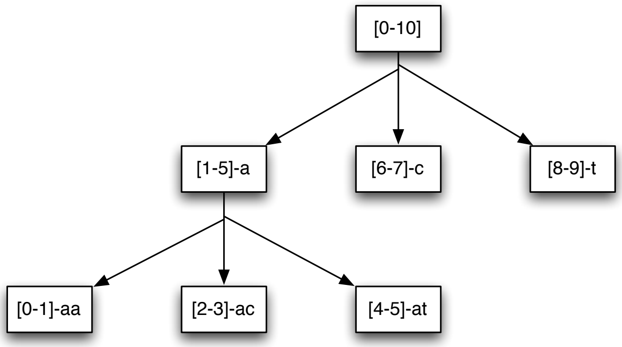

Fig. 1. An enhanced suffixarray on the sequence S = *acaaacatat* produces the lcp interval tree shown. This example is taken from [1].

The lcp intervals can have smaller lcp intervals embedded within them recursively. These recursive intervals can be seen as a tree structure and is called an lcp interval tree. This lcp interval tree is implicit. Furthermore, it has the same structure as the suffixtree if it were built based on the sequence in the suffixarray.

We would like to be able to access the implicit suffixtree structure in an efficient way. In order to do this we store the jumps through the suffixarray that we need for top-down traversal of the implicit suffixtree in an extra support array. This extra support array is called the child table in [1]. With this extra information we can determine the longest-common-prefix and its child intervals for each interval with a simple array lookup. For this to work we need to start with a valid interval. Luckily the interval $[0 \dots n]$ is always valid.

The construction of the child table can be done, just like the lcp value array, in a single pass over the suffixarray. However, building the child table depends on the presence of the lcp table, so after constructing and sorting the regular suffixarray we have to perform two more passes over the suffixarray to fill the support structures that allow access to the implicit suffixtree structure.

An example of a regular suffixarray enhanced with the lcp values and the childtab can be found in Table I. We also show the corresponding lcp interval tree in Figure 1.

III. Related Programs

In order to understand the context of the suffixarray-based patternfind program we will briefly describe related systems that are available.

The Ngram Statistics Package [2] can perform statistical tests on n-grams sampled from a window of size k. Effectively, this means that the package can look for sparse n-grams. It supports many statistical tests such as the Dice Coefficient, Fishers test, and Mutual Information. The Ngram Statistics Package is available on Pedersen's website at http://www.d.umn.edu/~tpederse/nsp.html.

Daciuk has developed several Finite-State based libraries and tools, including one for compressing FSA-based language models [3]. Such compression is related to the approach we take to find patterns with our patternfind software. This software is available at http://www.eti.pg.gda.pl/katedry/kiw/pracownicy/Jan.Daciuk/personal/fsa.html.

There are also software packages available for extracting significant n-grams and for performing statistical subsequence reduction as described in [8]. One implementation is that of Zhang, which is available at http://homepages.inf.ed.ac.uk/lzhang10/ngram.html.

PAFI is a piece of software for finding frequents patterns in large and diverse databases. In [5] some of the (graph-based) techniques that underly the system are described. The program is available from http://glaros.dtc.umn.edu/gkhome/pafi/overview together with related software.

IV. Implementation

Our implementation of the suffixarray is done in template-based C++. This leads to an extremely flexible implementation while making only limited demands on the container type. The template types used in the suffixarray must support only the following basic functionality:

1) The subtype has to support the following operators:
   a) The comparison operator $<$,
   b) The comparison operator $>$,
   c) The comparison operator $!=$,
   d) The comparison operator $==$,
   e) The assignment operator $=$,
   f) The increment operator: $++$,
   g) The output operator: $<<$.
2) The type contents must be accessible via several ways:
   a) Via the $[x]$ construct,
   b) Via the iterators x.begin() and x.end(),
   c) Via the const_iterators x.begin() and x.end().

Furthermore, when building a suffixarray, the input sequence must end with a unique element that is largest when compared to any other element in the sequence according to the comparison operators. This additional requirement allows us to eliminate several bounds checks in the heart of the sorting code.

In our implementation of the suffixarray algorithm, space utilization for a data collection of length n is

$$n \times \text{sizeof(index)} + 4 \times n * \text{sizeof(symbol)} + \text{exceptions}$$

This includes the additional arrays that are used to implement the enhancements as described in Section II-B.

In practice, building the suffixarray using our implementation is very time efficient (approximately 2–3 minutes for 1 million natural language sentences). However, for input sequences that have a high longest-common-prefix (lcp), our implementation will not be particularly efficient, due to the nature of the sorting stage. We use a deep-shallow sorting strategy with a blind trie, which was introduced by Manzini and Ferragina in [7]. Natural language data, however, which is our area of interest, is sorted very efficiently as it is by nature low in lcp.

We have implemented the enhancements that are needed for the implicit suffixtree structure as described in [1]. The hints and algorithms described in the article form the basis of the practical implementation.

V. Programs

The package contains three user programs. The usage of these programs will be described in more detail in the next three sections.

A. Patternfind

The pattern finding program looks for frequently occurring skip-grams as patterns. A skip-gram is similar to a regular n-gram with the possibility of containing non-consecutive skip positions. A skip represents a wildcard, which may match any number of arbitrary symbols. In article we will refer to such skip positions in patterns as **SKIP**. In Figure 2 a simple skip-gram is shown visually in a simple tree-structure.

1) Implementation: The pattern finding is done as an exhaustive, breadth-first search over the implicit suffixtree with pruning. During the search, the internal representation keeps track of the pattern represented so far, for instance *A *SKIP*A*, together with a set of [lcp-interval, depth] pairs.

An [lcp-interval, depth] pair represents a path through the implicit suffixtree. The lcp interval has an associated lcp value, which may be larger than the number of steps that have been taken to reach the lcp interval in the specific path. For instance, if the sequence S = *abcabc* is turned into a suffixarray, the lcp interval $[0, 1]$ has an lcp value of three as the first three characters of the two suffixes starting with *a* will be *abc*. Because we would like to be able to represent the step *a* we also associate a depth with the lcp interval to indicate the exact position in the implicit suffixtree. This example is illustrated in Table II.

The suffixarray is searched using the patterns, where for each pattern, all single steps are taken. A single step can be an explicit symbol as defined by the pattern or a skip position if the previously taken step was not a skip. Only continuations of the (sub-)pattern that are directly reachable from the set of [lcp-interval, depth] pairs are considered.

TABLE II
ILLUSTRATING THE SUFFIXARRAY, INCLUDING THE LCP TABLE, OF THE SIMPLE SEQUENCE *abcabc*.

i	suftab[i]	lcptab[i]	suffix
0	3	0	*abcabc$*
1	0	3	*abc$*
2	4	0	*bcabc$*
3	1	2	*bc$*
4	5	0	*c$*
5	2	1	*cabc$*
6	6	0	*$*

Obviously applying this approach directly results in an exponential explosion in the number of different patterns that are found in a dataset. To keep this amount manageable a threshold can be set. Based on this threshold, only interesting patterns are retained.

For each pattern discovered, a prune value is computed. This value depends on the compressibility score, which consists of the number of items in the pattern minus one, not counting the skip positions, multiplied by the number of times it occurs in the sequence. In this case, the compression rate of a uni-gram pattern is zero. To remove this limitation, we use the frequency in the sequence for patterns of length one as the compressibility score.

Based on the computed prune value, we decide whether the pattern should be pruned or not. If the score of the new pattern exceeds the prune value it is added to the pattern list for the next round.

After taking a few of such steps a pattern emerges. In Figure 2 we show a very simple implicit suffixtree and highlight the effect of the pattern *A *SKIP* A* on that example. All dark-grey nodes in the example represent [lcp-interval, depth] in the suffixarray that would occur in the cloud of the pattern in this example.

After having considered all valid steps during the pattern search phase, the remaining patterns (which have a score above the pruning threshold) are written to output. Only the patterns above a certain threshold are given to the user. The threshold can be set separately from the prune value.

The program itself is implemented in template-based C++ and in its distributed form can be applied to a sequence of text-based word tokens which are read from a file. Internally, these are mapped to a list of numbers. The suffixarray is built on the sequence of numbers. This list of numbers can be transformed back into a sequence of words using the one-to-one mapping, which is what happens during the output of the patterns. This transparent, internal mapping is done, because the comparison operators on integers are significantly faster than those on sequence objects. Additionally, a list of integers occupies less memory[2].

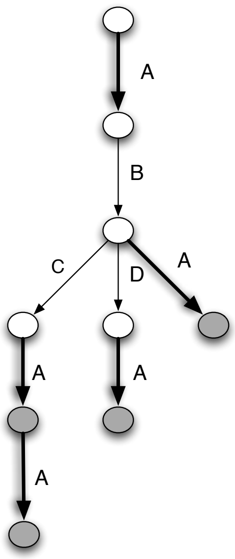

Fig. 2. An example of the pattern *A *SKIP* A* found in a simple tree. Notice how the **SKIP** can have different lengths. All dark-grey nodes represent members of the [lcp-interval, depth] set associated with the pattern *A *SKIP* A*.

TABLE III
THE OUTPUT OF THE PATTERNFIND PROGRAM WHEN RUN WITH THE −HELP OPTION.

```
patternfind -h
Usage: ./patternfind[OPTION]...
This program reads in a corpus and stores it in a suffixarray.
It then searches for all significant patterns in the corpus.
  -h, --help        Show this help and exit
  -f, --file FILE   Filename of the corpus to be read
  -p, --prune PRUNE-VALUE    The value at which to start pruning the found
          patterns.
        Determined by the number of occurrences and the size of the pattern.
  -o, --output PRINT-VALUE     The value at which to start printing the found
          patterns,  works the same as the prune value.
        If it is smaller or equal to the prune value it has no extra effect.
  -s --smallestskip SKIP    Minimum number of positions to skip for a SKIP
          part of a pattern.
  -l --largestskip SKIP    Maximum number of positions to skip for a SKIP
          part of a pattern.
```

2) Usage: The program that searches for compressing skip-grams contained in the suffixarray is called patternfind. As described above, this program identifies patterns that occur frequently and hence lead to a compression higher than a threshold. When patternfind is run with the `-help` option it gives the output as shown in Table III.

TABLE IV
THE OUTPUT OF THE PATTERNPOSITIONS PROGRAM WHEN RUN WITH THE −HELP OPTION.

```
patternpositions -h
Usage: ./patternpositions[OPTION]...
This program reads in a corpus and stores it in a suffixarray.
        It then reads in a file of patterns and for each of those patterns
        returns all occurring positions in the corpus.
  -h, --help        Show this help and exit
  -f, --file FILE   Filename of the corpus to be read
  -s --smallestskip SKIP    Minimum number of positions to skip for a SKIP
          part of a pattern. Should be the same value as used in patternfind.
  -l --largestskip SKIP    Maximum number of positions to skip for a SKIP
          part of a pattern. Should be the same value as used in patternfind.
  -p, --patterns FILE    The file containing the patterns to output the
          positions of.
         As output by patternfind. I.e. patternfind options > patternfile;
        patternpositions options -patterns patternfile
```

[2] Personally, we run a custom version of the code that takes as input a pre-mapped corpus that we have to manually map back and forth. By doing this we do not have to load the mapping in memory as well. For usability reasons we automated this process in the released tool.

The most important parameters specify an input sequence (in a file) and a prune value. The other values are optional and only modify the default behavior of the program. For example, we can look at the patterns found in the included README file by executing the following command. We will set the prune value to 10 and limit the skip to skips of the size 1–3.

```
./patternfind -f ../README -p 10 -s 1 -l 3
```

All status messages are written to standard error and all patterns are written to standard output. A pattern is presented together with a number representing its compressibility score on which pruning was done. **SKIP** denotes a skip position. At that point the pattern skips a flexible space of, in this case [1–3] positions.

B. Patternpositions

The patternpositions program searches a sequence for occurrences of patterns such as those output by the patternfind program. To specify the exact behavior of the skips, it takes the same options as the patternfind program. It takes one extra argument, namely the patterns file from which all the patterns will be read. The output of its help function can be seen in Table IV.

For each pattern in the pattern file, patternposition will print all the positions of occurrences of that pattern in the corpus. We can for instance run the program on the patterns we found in the README file with patternfind in the following way:

```
./patternpositions -f ../README -s 1 -l 3\
  -p ../README.patterns
```

Just like with the patternfind program we print all results to the standard output and all the status messages to the standard error.

C. Suffixarray

The final program included in the distribution is called suffixarray. This program has only one option, the file containing the sequence which should be used to build a suffixarray. This file should be a plain text file containing a white space separated sequence of tokens, such as words.

Running the program will result in a suffixarray being build from the specified sequence after which the program waits for input. At this point the program will answer simple n-gram queries by reporting the number of times the typed n-gram occurs in the sequence contained in the suffixarray. In these n-grams it is allowed to use simple single-positions wildcards, represented by the token *.

VI. Experimental Results

To show practical use, we performed preliminary pattern finding experiments on two natural language corpora: an English-language corpus, the British National Corpus (BNC) and a Dutch-language corpus, our own collection of texts of local newspapers known internally as the ILK-BDEDGE corpus.

The British National Corpus is a corpus of around 100 million words of both spoken and written English. We use

a 1 million sentence chunk for our pattern finding experiment. This chunk consist of around 21 million words.

The ILK-BDEDGE is a corpus consisting of material from the Brabants Dagblad, Eindhovens Dagblad and De Gelderlander. These are all regional, Dutch, newspapers. Again, we took a chunk of 1 million sentences from the corpus to perform experiments on. This chunk consists of around 16 million words. The average sentence length is somewhat smaller than that of the BNC.

On each of the 1 million sentences we ran the pattern finder program with a prune value of 1000. The 40 highest ranked patterns found on the BNC are shown in Table V. Likewise for the corpus of Dutch local newspapers, we show the 40 highest ranked patterns in Table VIII. For English we find 23,705 patterns and for Dutch 18,004 patterns in total that make the threshold.

The program took slightly less than 32 hours to run on the ILK-BDEDGE corpus part we used. During that time its memory usage peaked at approximately 700MB.

We see in these tables that function words such as determiners, that delimit the overall structure of the sentences, are found the most. Unsurprisingly, all these words together with punctuation marks are amongst the most frequent tokens in both languages. For instance in English we find as the most compressing pattern *the *SKIP* of* and in the Dutch list the corresponding pattern *de *SKIP* van* also scores very high.

When we look at the patterns found in the middle of the pack we see less generic and possibly more useful patterns, such as *with the *SKIP* a*. These patterns from the middle can be found in Table VI for English and Table IX for Dutch.

The lowest-scoring patterns are shown in Table VII for English and Table X for Dutch. These patterns start with punctuation and after that specialize in a specific way. Patterns with very low, compared to the size of the corpus, scores are not generally very informative. These patterns could be removed automatically by increasing the threshold.

VII. CONCLUSION

In this paper, we have described a package that contains an efficient, flexible and practical implementation of the suffixarray data-structure. Three programs are provided, allowing for efficient search in a large sequence of symbols and for finding interesting, compressing patterns.

The program that searches for compressing patterns has been applied to a collection of natural language texts. The patterns found describe the global structure of the sentences in which they occur. These patterns can be used by linguists to help them find naturally occurring constructions in language.

With respect to future work, this system could be applied in different areas. For instance, another application of the patternfind program can be found in the area of morphology. Instead of providing a collection of sentences, as shown here, a collection of words is provided to the system and patterns that occur regularly within words can be identified. This may lead to automatically found descriptions of the morphology of words.

Another possible application would be to apply the found patterns of several languages to a parallel corpus. The patterns can be used to identify often occurring patterns in the different languages, which can then be used to align translations of texts. Also, in the same line, the aligned patterns can be used to enrich a phrase-based machine-translation system.

Additionally, we would like to write several extensions to the programs, the simplest of them being a small program that identifies contexts for a given pattern in a specific position. This information is directly accessible in the suffixarray data structure, but cannot easily be identified with the current programs. Another, more complex addition we would like to write, is a program that given a pattern finds the most pertinent content that matches the skips in that pattern.

Finally, we would like to provide a version that is annotation-aware, allowing it to find patterns not only with skips that match any symbol, but taking specific annotation layer items into account. This could lead to patterns such as *the N of the N*, where the *N* specifies a noun as described by an annotation layer. This final improvement should also be extended to the program that tries to find the pertinent content that fills up skips in particular patterns.

***Abstract*—We formulate a novel problem of summarising entities with limited presentation budget on entity-relationship knowledge graphs and propose an efficient algorithm for solving this problem. The algorithm has been implemented together with a visualising tool. Experimental user evaluation of the algorithm was conducted on real large semantic knowledge graphs extracted from the web. The reported results of experimental user evaluation are promising and encourage to continue the work on improving the algorithm.**

I. Introduction and Motivation

KNOWLEDGE graphs are useful for representing semantic knowledge, often automatically extracted from open domains such as the web [1] in the form of entity-relationship triples. In this data model the nodes represent entities (e.g. a director or actor, in the movie domain), and directed arcs represent binary relations between the entities (e.g. “directed”,”acted in”, etc. in the movie domain). Multiple arcs between nodes are allowed (as a person can be a director and a producer of the same movie, for example) resulting in a directed multi-graph (fig. 1). There can be weights attached to nodes or arcs in the knowledge graph that reflect some additional information, for example “witness count” – reflecting the frequency of encountering the triple in the corpus, so that an arc with high witness count could be regarded as more “important”.

A standard example of this model is the RDF[1] data format with its SPARQL[2] query language, where a query can be viewed as a sub-graph pattern that is matched with the knowledge base to produce the results.[3]

Structured query languages for knowledge graphs such as SPARQL allow for semantic search and are very expressive, however they are quite complex for unexperienced users and they also assume some prior knowledge about the domain (e.g. names of relations, etc.) which limits their applications.

Simply speaking, there are currently two extremes in search paradigms: popular and simple keyword-based search interfaces that do not support semantic search, and prototype semantic search systems that enable very precise querying but demand a lot of knowledge and experience from the user.

Consequently, there is a gap between these two extremes: it would be ideal to have a tool that enables search over semantic knowledge bases and, at the same time, is very simple and does not assume any prior experience or knowledge.

In this paper we aim at filling this gap. Namely, we formulate a novel problem of answering “precis” queries on knowledge graphs, propose an efficient algorithm for solving it, and report on prototype implementation together with preliminary experimental results obtained on real data. Similar problem of “precis” queries was previously considered in the context of relational databases [4], from which we borrowed the name “precis” (meaning a short summary about a person, etc.) and in the context of query-dependent [3] and constrained [5] summarisation of XML documents.

A. Related Work

Summarization has been intensively studied for text documents, for example by Wan et al.[9], specificly for scientific papers by Hassan et al., [2], and for multiple documents by Wan [8]. Zhang et al. [10] (as a recent example for a large set of similar papers) consider the problem of creating concise summaries for very large graphs such as social networks or citation graphs; in contrast to this, our work aims at summarizing information around a single node in a graph. Ramanath et al. [6] propose methods for summarizing tree-structured XML documents within a constrained budget.

Similar problem to the one discussed here, but with a special focus on diversification was recently discussed in [7].

II. Problem Formulation

Assume a user would like to know “something about” an entity (e.g. “Woody Allen”) but does not know anything except its name to start searching.

It would be desirable that a semantic search system accepts the query ”Woody Allen” and returns some fragment of the knowledge graph that “reasonably summarises” this entity.

Unfortunately, such kind of query is not supported by the SPARQL standard.

The most equivalent SPARQL query seems to be *“Woody Allen” ?r ?x* that requires returning the whole subgraph of the knowledge base that is in the one-hop distance from the “Woody Allen” node. However, such a solution might be not the most desired one for at least two reasons:

[1] http://www.w3.org/RDF

[2] http://www.w3.org/TR/rdf-sparql-query

[3] Formally, data in RDF consists of triples: subject-predicate-object, but this is mathematically equivalent to the multi-graph model described above

Fig. 1: An excerpt from a semantic knowledge graph extracted from the IMDB database, concerning the movie domain.

1) the result may be too large to be comprehended by a user (e.g. in the knowledge graph extracted from the imdb database that we use, concerning movies, the "Woody Allen" node is adjacent to over 170 different arcs).
2) there may be "interesting" pieces of information concerning "Woody Allen" that are "closer" (in terms of arc weights) to the entity but are a few hops away from it in the knowledge graph (fig. 4,5)

To address these issues we introduce two elements to our model of "precis" query. First, we introduce a parameter $k \in N$ that models limited "budget" of user comprehension or display device capacity, etc. that specifies the upper bound on the number of the arcs in the presented result. Second, we introduce a novel but natural notion of distance between an arc a and node x in the knowledge graph. We assume it is the minimum sum of arc weights on a path connecting x and a, including the weight of a.

We propose the following specification of the "precis" query problem on knowledge graphs:

INPUT: B (knowledge base) – a multi-digraph with positive, real weights on arcs (considered as distance measure – currently, we use $1/\mathit{witnessCount}$ as the weight value); x (entity under interest) – a node of B; $k \in N$ (limit on arcs)

OUTPUT: subgraph D of B, containing at most k arcs of B, together with their end nodes, that are "closest" to x with respect to the arc-node distance

III. THE ALGORITHM

The problem is similar to some very well known ones such as the single source shortest paths or incremental search, however the specific conjunction of constraints such as multiple and weighted arcs, the notion of arc-node distance and limited presentation budget, taken together, make it a unique, novel graph problem, up to the author's knowledge. We propose the following algorithm to solve the problem (fig. 2).

It can be obiously viewed as a modification of the Dijkstra's single-source shortest paths algorithm adapted to the formulation of our problem. In each iteration an arc is added to RESULT thus the algorithm always stops after k iterations, at most. If we assume that there are n edges in the radius k from x in B and that comparison of *distance* value is the dominating operation, time complexity is $O(nlog(n))$ if we use a hashset implementation for RESULT and even if we use ordinary Heap for implementing PQ (the algorithm could be faster, though, if Fibonacci Heap is used instead).

```
visitTop-kClosestArcsInMultiGraph(B,x,k)

forEach a in radius k from x: a.dist := "infinity"
forEach a adjacent to x: {a.dist := a.weight; PQ.insert(a)}
while( (RESULT.size < k)
and ((currentArc = PQ.delMin()) != null) )
  forEach a in currentArc.adjacentArcs:
    if (not RESULT.contains(a)) then
      a.dist := min(a.dist, (a.weight + currentArc.dist))
       if (not PQ.contains(a)) then PQ.insert(a)
       else PQ.decreaseKey(a,a.dist)
  RESULT.add(currentArc)
return RESULT
```

Fig. 2: Algorithm for computing "precis" queries. We assume that each arc a has two real attributes: *weight* and *distance* as well as *adjacentArcs* attribute that keeps the set of arcs sharing a node with a (except a). *PQ* is a min-type priority queue for keeping the arcs being processed, with the value of weight serving as the priority and *RESULT* is a set. *PQ* and *RESULT* are initially empty. We also assume that "infinity" is a special numeric value being greater than any real number.

IV. Experimental Results

The algorithm has been implemented, integrated with a graph-visualising tool, and applied to the two real datasets concerning the domains of movies and books, respectively (figure 3). The selected results are visualised on fig. 4 and 5

A. User Evaluation Experiment

We also conducted a user evaluation experiment aiming at assessing the quality of results of the presented algorithm and collecting feedback in order to improve the algorithm.

We selected 20 active actors from the IMDB dataset, generated the summarisations for them, for two different levels of the egde budget k: low ($k = 7$) and high ($k = 12$) (20 results for each level). Next, we asked about 10 anonymous evaluators, who did not know details about the algorithm, for assessing the summaries. Technically, the summaries computed for 20 actors and for 2 different budget levels were presented to the evaluators by a web interface. The evaluators assessed them by answering the following questions:

- How useful do you find the result as a small entity summarisation with a very limited number of facts (edges) to be presented? ("good","acceptable","poor","useless").
- How many interesting/irrelevant/missing facts are in the presented summary? (three separate questions; possible answers: "almost all","some", "hardly any")

The evaluators could also give optional textual explanations of their answers. We collected about 70 assessments.

dataset	out-nodes	in-nodes	edges	relations	weights on arcs	source
IMDB-1	59013	106682	536455	73	1/witness count	www.imdb.com
LT-1	17254	45535	644055	12	1/witness count	librarything.com

Fig. 3: Datasets used for preliminary experiments. The IMDB dataset was further used for user evaluation experiment

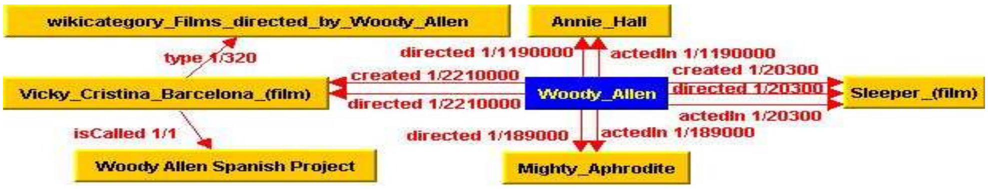

Fig. 4: An example of running the algorithm for precis query "Woody Allen" and $k = 11$ on IMDB-1 dataset. Weights represent $1/witnessCount$

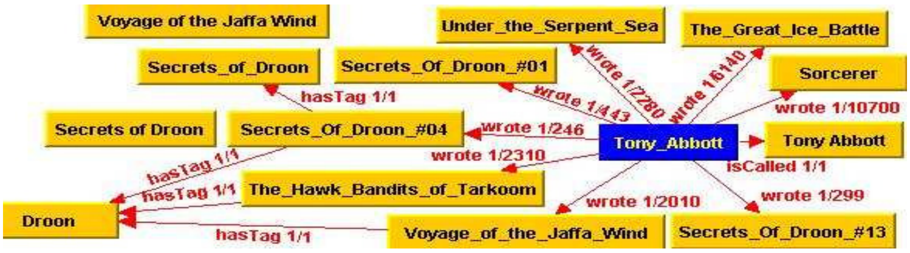

Fig. 5: An example of running the algorithm for precis query "Tony Albott" and $k = 13$ on LT-1 dataset. Weights represent $1/witnessCount$

In over 80% of the cases the summary was assessed as good or acceptable, for $k = 12$ (26% as good and only 19% as poor). In majority of cases the summary was assessed as good or acceptable (figure 6). It is noticeable that the results of the algorithm have better quality for higher value of k, while for the low value of $k = 7$, the majority of cases (67% of cases) was assessed as poor or useless (figure 6).

Concerning the assessment of the facts (edges) selected by the algorithm (figure 7), the algorithm selected "almost all" or "some" interesting facts in 83% of cases, according to evaluators. Missing facts were noticed only in 9% of cases. In 79% of cases, users did not complain about many "irrelevant" selected facts. Again, the assessments are better for the higher value of $k = 12$. See figures 8 and 9 for a detailed comparison.

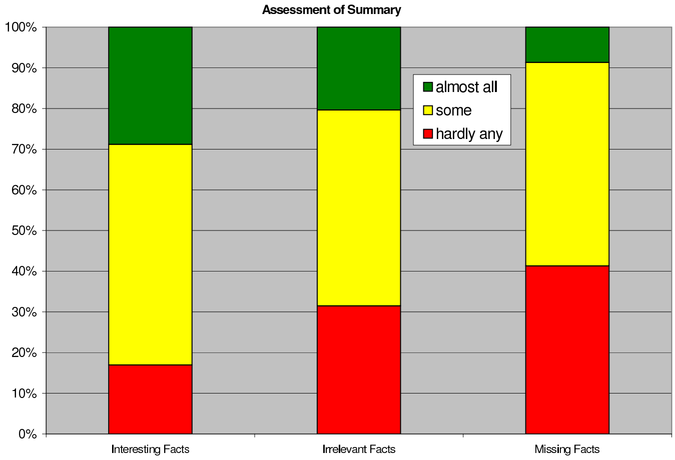

Fig. 7: Assessment of selected facts over all evaluated examples: interesting facts (left), irrelevant facts (middle), missing facts (right)

V. Conclusions and Further Work

To summarise, despite the relative simplicity of the algorithm, the results are quite positive, especially for the higher value of the limit on number of presented edges.

It seems that low assessments for the low value of k is caused by the redundancy of selected facts: "actedIn" in case of actors, or "wrote" in case of writers, for example. This is also confirmed by some textual explanations of the evaluators.

Due to this observation, to improve the summarisation algorithm in future continuation of this work we plan to pay special attention to the *diversification* of the results as preliminarily studied in [7].

Though experimentation on real datasets is still in progress, the preliminary experimental results are promising since the algorithm can reach interesting pieces of information that are a few arcs away from the entity under interest. We plan to continue experimentation, also with different settings, weights and distance computation methods and modifications of the algorithm, e.g. regarding the diversity of the returned summary.

***Abstract*—The paper analyzes multiple noun expressions, or compound nouns, as part of the implementation of Ontological Semantic Technology, which uses a lexicon, an ontology, and a semantic text analyzer to access and represent the meaning of text. Because the analysis and results depend on the lexical senses of words, general principles of lexical acquisition are discussed. The success in interpretation and classification of such expressions is demonstrated on 100 randomly selected sequences of noun compounds.**

***Keywords*—multiple noun expressions, meaning interpretation, ontological semantic technology**

I. Introduction

THIS paper describes the implementation of Ontological Semantic Technology (OST), an offshoot of Ontological Semantics [1], a theoretical and computational approach to meaning in natural language. OST is an advanced, improved, and revised application of Ontological Semantics for real-life commercial systems with its latest implementation currently being developed for RiverGlass, Inc. We will illustrate the process of OST implementation by presenting the elements of its ontology and lexicon, which are activated to analyze the difficult semantics of noun + noun expressions, a specific case that the OST multiple word expression (MWE) module is responsible for handling, and comparing the output of the OST semantic analyzer with an informal taxonomy of the meaning relations between the constituent nouns in these constructions. This approach [2] is not dependent on any training corpus but rather on the semi-automated acquisition of the OST static resources (the lexicons and ontology) which can be used for any text. Based on these resources, all OST processing is fully automated. In order to evaluate whether sentences or expressions are interpreted correctly by the OST software, familiarity with OST ontology is required. While the final evaluation of the approach can only occur on the full implementation of an application, we describe partial metrics both to assess progress and to improve the resources and the software, as necessary.

MWEs are well-known as a notorious problem in NLP [3] and workshops have been dedicated to their analysis since 2003 (http://multiword.sourceforge.net/). The central tasks that MWEs pose are their identification (extraction) as being multiword and not co-occurrences of several single words, and the interpretation and representation of their meaning. Our meaning-based linguistic method focuses on the latter task, which subsumes the former by necessity. Common approaches to the MWE subclass of noun compounds proceed without wanting to use costly-to-acquire world knowledge that would distinguish *fish knife* from *steel knife* with the help of knowing that *fish* are edible and not used as the material of artifacts while *steel* is not edible, but used as material in artifacts. The only knowledge used in such approaches is contextual clues [4], ideally specific paraphrases of the compounds, typically used in supervised learning approaches, e.g., [5]. While the relation between the concepts represented by the nouns in compounds is infinite, these approaches postulate subsets of relations, e.g., [6], [7], into which they aim to classify the compounds, with smaller sets naturally resulting in better performance numbers and the items in the sets almost never being motivated by an application. These consequently very coarsely grained subsets (commonly four to twenty items, cf. [8]) are often mapped onto prepositional paraphrases, in which *fish knife* would become *knife for fish* and *steel knife* would become *knife of steel.* Our approach, on the other hand, allows any property or relation available in our ontology to hold between the concepts and aims at the correct identification of each property with its functors.

II. OST Resources

A. OST Ontology

The OST ontology attempts to capture the users' knowledge of the world in a language-independent way. Text is interpreted in terms of the knowledge in the ontology; thus, it is important that as many relationships among concepts as necessary are accurately captured.

Formally, the ontology is a lattice of logically structured concepts (for a formal representation see [9]). It is divided into EVENTS, OBJECTS, and PROPERTYS, with the first two further divided into PHYSICAL, MENTAL, and SOCIAL subcategories. EVENTS and OBJECTS are connected through PROPERTYS, while strictly adhering to inheritance rules, creating the required richness of interrelationship among concepts. Figure 1 shows the top levels of the OST ontology; Figure 2 shows a sample concept with its (noninherited) properties.

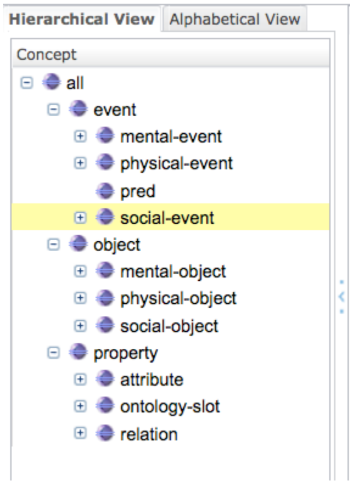

Figure 1. Top levels of OST ontology

B. *OST Lexicon*

The structure and format of lexical entries as well as lexicon acquisition strategies within ontological semantics have been discussed at length in [1: 230-245, 322-350]; acquisition techniques have been outlined in [10]; and the development of a toolkit for automated acquisition within OST has been proposed in [11]. This section will offer a concise outline of the structure and format and briefly discuss procedures of lexicon acquisition, only to the extent that they pertain to the paper.

1) *Definition, functions, and format*

In OST, all language-specific information is encoded in the lexicon. The lexicon is a machine-readable repository of words, non-compositional units (e.g., “hot dog”, “gut feeling”) and idiomatic expressions (e.g., “buy the farm”), whose meaning is defined through ontological concepts and whose morphology and syntax is defined through a set of part-of-speech tags, syntactic role tags and syntactic variables, properly ordered and co-indexed with their semantic counterparts.

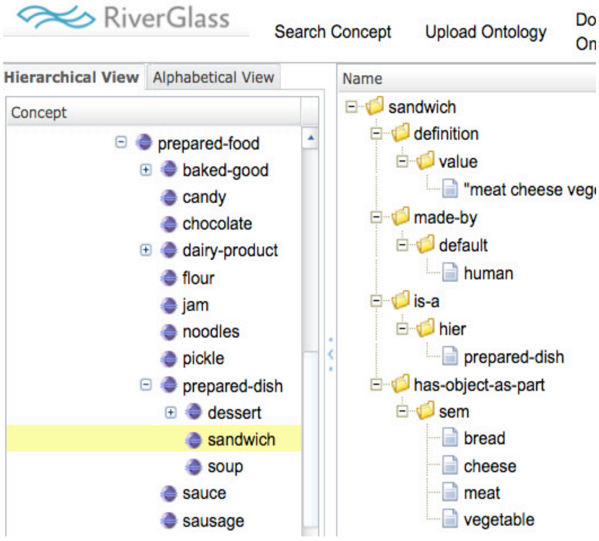

Figure 2. The concept SANDWICH

In relation to the ontology, the content and structure of which is language-independent and parsimonious, the lexicon captures all linguistic idiosyncrasies including language-specific senses, non-literal extensions, synonymy, homonymy, grammatical derivatives, optional phrasal particles, etc. As a resource immediately accessible by the Semantic Text Analyzer (STAn, see Section II C) during processing, the lexicon (1) directs the analyzer to the appropriate ontological concept, its properties, and their fillers, so that further computation can be performed based on that concept’s definition, and (2) follows restrictions stipulated in the ontology so that property fillers in lexicon senses can only narrow down (i.e., be children of) those outlined for respective ontological concepts or introduce new properties or fillers outside the branch of the parent’s filler’s ancestor.

A lexical entry template is shown below:

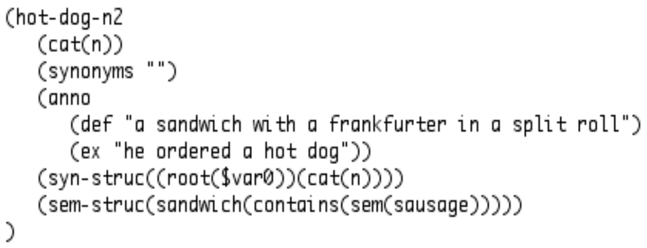
```
(head-entry
   (sense-1, 2, 3…
      (cat(n/v/adj/pro/prep))
      (synonyms "")
      (anno
         (def "")
         (comments "Acquired by <acquirer name> on <date>
            at <time>. ")
         (ex "")
      )
      (syn-struc(
         (root($var0))(cat(n/v/adj/pro/prep))
         (subject/object((root($var#))(cat(np/vp/s))))
         )
      (sem-struc
         (root-concept
            (property(value(^$var#
            (should-be-a(default/sem(concept))))))
      )
   )
)
```

The fields “synonyms”, “anno”, “comments”, and “ex” are of no value to the computer and serve the human acquirer. The fields “cat”, “syn-struc”, and “sem-struc”, meaning “category”, “syntactic structure”, and “semantic structure”, respectively, contain crucial information about the sense used by the analyzer in meaning computation.

The syntactic structure captures the position(s) a word can take in a clause: the root variable locates the word itself, and, for the case of events, syntactic roles of subject or object are indicated, along with their categorical features. For every syntactic role, a variable in the root stands for a specific word carrying this function. Every new syntactic role is assigned a new variable. If word order variation is possible, additional syntactic structures are listed.

The semantic structure anchors the meaning of the sense in ontological concepts, commonly a head concept most defining for the sense. In the case of EVENTs, every syntactic role indicated in the syntactic structure is given its case role interpretation drawn from the ontological definition of the respective EVENT. Variables for each case role are co-indexed with their counterparts in the syntactic structure. Fillers for case roles and other properties tighten more general ontological restrictions where necessary via the SHOULD-BE-A relation, the purpose of which is to further specify the ontological nature of the variable, and the DEFAULT or SEM facets, which prioritize and assign weights to the property values [9].

Figure 3 shows the entry "hot-dog-n2", meaning a sandwich with a sausage rather than the other common sense of "hot dog" which is just the sausage by itself:



```
(hot-dog-n2
   (cat(n))
   (synonyms "")
   (anno
      (def "a sandwich with a frankfurter in a split roll")
      (ex "he ordered a hot dog"))
   (syn-struc((root($var0))(cat(n))))
   (sem-struc(sandwich(contains(sem(sausage)))))
)
```

Figure 3. Lexicon sense of hot-dog

Since no direct concept for a hot dog is available in the ontology, the sense has been acquired by finding the nearest available concept SANDWICH and constraining it with the property CONTAINS filled with the concept SAUSAGE. All ontological restrictions have been observed and further specified: in the ontology, the domain and range of the property CONTAINS are filled with the concept PHYSICAL-OBJECT (of which SANDWICH and SAUSAGE are descendants).

2) *Lexicon acquisition*

A standard acquisition procedure implies creating machine-readable descriptions of lexical senses by listing appropriate concepts and their properties and restricting their fillers where needed. Given that defining the number of lexicon senses, choosing the appropriate head concept, and determining the "tightness" of restrictions for property fillers requires human competence, lexicon acquisition is largely human-driven. However, certain aspects of acquisition (entry format, inherited property fillers, domain/range compatibility check, template-based acquisition of specific word classes, etc.) lend themselves to automation, as demonstrated by various implementations of OST.

Depending on application objectives, the state of completion of the ontology, and the functionality of the Semantic Text Analyzer, three acquisition techniques have proven useful in various implementations [10]. Ontology-driven acquisition leads to a lexicon with the minimal lexicalization of concepts (i.e. one entry per concept), which is time-efficient but shallow and can only be used at early phases of ontology acquisition. Domain-driven acquisition focuses on topic-related vocabularies and onomasticons, repositories of named entities, as well as specific word classes, and is aided by the analysis of resulting text-meaning representations (TMRs) of domain-specific corpora and "gap detecting" toolkits identifying missing senses with further part-of-speech sorting. Analyzer-driven acquisition, the main method for quality-control and improvement, implies testing every newly acquired entry by the analyzer, followed by TMR analysis and subsequent modifications of the lexicon entry, ontological concepts, or functioning analyzer modules. The approaches are supplementary to each other, although, in practical applications, the domain-driven acquisition tends to dominate in order to ensure optimal lexical coverage and to minimize unattested input.

C. *Semantic Text Analyzer and InfoStore*

The Semantic Text Analyzer (STAn) is a software that interprets text according to knowledge from ontology and lexicon and assigns a TMR to each clause, with textually related clauses as linked TMRs. STAn does not have a graphical interface as its output is written directly into the InfoStore database, which collects all correctly processed TMRs. Thus, InfoStore is in unique possession of all machine-understandable interpretations of all texts processed, which it can then use to guide further interpretations by adding the counterpart of the linguistic and extralinguistic knowledge that humans use to disambiguate, complement meaning, and reasoning contextually.

For the work reported in this paper, we have not yet used InfoStore, but concentrated on STAn's interpretation results obtained only with the current limited ontology (about 2,000 concepts) and English lexicon (about 25,000 senses). The influence of the InfoStore on the overall interpretation process and the treatment of MWEs in particular as well as the resulting ontological adjustments deserve treatment in a separate paper.

Figure 4 shows STAn's interpretation of the sentence *management attempts to comply with local employment legislation* in debug mode. A more readable version of the final TMR is in Figure 5.

III. Multiple Word Expressions: N+N$^+$

In this section, we apply OST to the semantic analysis of English compound nouns. Such constructions are notoriously difficult to interpret, not only because of the English morphology which allows the adjectival usage of the first noun but mostly because any such construction can be analyzed syntactically as the transform of a clause, where the two nouns can be in any number of meaning relations. In other words, syncretism, prevalent in natural language in general, manifests itself here in the worst possible ways.

For example, the construction *IBM lecture* can mean a lecture about IBM, by IBM, at IBM, or sponsored by IBM ([1] see also [4, 12]), and the human hearers/readers have to use their knowledge of the world to understand the construction correctly—or to ask a clarification question about the intended meaning. Since no syntactic analysis can differentiate among the various possible semantic relations between the two words of a noun + noun compound, it is a good test case for the OST semantic capabilities.

It appears that [13: 589-591] contains a reasonably grain-sized listing of the possible meaning relations, which is reproduced below in an abbreviated form:

- Composition
  - N2 is made from N1
  - N2 consists of N1
- Purpose
  - N2 is for the purpose of N1
  - N2 is used for N1
- Identity
  - N2 has the same referent as N1 but classifies it in terms of different attributes
- Content
  - N2 is about N1
  - N2 deals with N1
- Source
  - N2 is from N1
- Objective type 1
  - N1 is the object of the process described in N2 or of the action performed by the agent described in N2
- Objective type 2
  - N2 is the object of the process described in N1
- Subjective type 1
  - N1 is the subject of the process described in N2
  - N2 is nominalized from an intransitive verb

- Subjective type 2
  - N2 is the subject of the process described in N1
- Time
  - N2 is found at the time given by N1
- Location Type 1
  - N2 is found or takes place at the location given by N1
- Location Type 2
  - N1 is found or takes place at the location given by N2
- Institution
  - N2 identifies an institution for N1
- Partitive
  - N2 identifies parts of N1
- Specialization
  - N1 identifies an area of specialization for the person or occupation given in N2; N2 is animate

It is immediately disclaimed in [13] that some cases may belong to two or more classes and that some cases may belong to none. What is clear is the mixed syntactic/semantic nature of the taxonomy, with the objective- and subjective-types clearly standing out as shallow and, therefore, semantically vague, thus guaranteeing the pretty crippling heterogeneity of the members of these classes.

We have selected the first 100 noun + noun expressions from the Enron corpus (http://www.cs.cmu.edu/~enron/), starting from a randomly selected text, and manually assigned each of them to the most appropriate of the class(es) above. We excluded from the selection the multi-word phrasals that OST treats as single lexicon entries as well as proper nouns. Several of the expressions were of the noun + noun + noun type, and we considered them as a single expression rather than two: the selected 100 expressions contain 6 triple-noun ones. Next, we ran STAn on the actual sentences containing these constructions and compared the OST treatment of them with the above taxonomy.

It is important to understand that OST deals with deep semantics, and therefore recognizes the fact that a shallow semantic—or even such a morphosyntactic category as part of speech—does not determine the ontological basis of a word. Thus, nouns in OST can be anchored in EVENTs (a walk), PROPERTYs (color), or OBJECTs, even though the last type is prevalent by far. The part of speech is used as a clue, often an unimportant one, along with other grammatical (morphological and syntactic) information because the emphasis in OST analysis is always on matches of semantic properties. These clues are nevertheless collected and used as needed in the analysis. As mentioned, noun + noun expressions are particularly interesting and difficult to analyze precisely because the grammatical clues fail to help in differentiating among the numerous types of connection between N1 and N2.

For any N1 + N2 construction, therefore, the Semantic Text Analyzer looks for a property of, typically, N2 such that N1 falls in the range of this property's value. The predominantly prepositive nature of the English adjectival constructions makes the reverse situation—when N2 is the value of the property of N1—rarer. The property, or semantic relation, is (automatically) selected by STAn so that:

$$\max_{p \in P}\{\max_{fct \in Facet}\{I_C(p(fct(I_D)))*\sum_i const*inhd(i)\}\},$$

where P is the property (*p*) set, Facet is the facet (*fct*) set, and I_C and I_D are interpretations of the meaning of N_1 and N_2 with C and D being concepts in $\mathcal{D}$; where $\mathcal{D}$ is the disjoint union of $\mathcal{D}$c (concepts) and $\mathcal{D}$d (literals), and given its interpretation function $\mathcal{I}$, for every atomic concept B, $\mathcal{I}$[B] $\subseteq\mathcal{D}$c; $\mathcal{I}$ [C(Rel(Facet(D)))] $\subseteq\mathcal{D}$c, $\mathcal{I}$ [C(Rel(Facet(D)))] = $\mathcal{I}$ [C] $\cap\mathcal{I}$ [Rel(D)]; and where i is C, D or p and inhd(i) is the inheritance distance measure.

In other words, after STAn selects all the properties of the concept(s) underlying either noun, such that the meaning of the other noun fits the range of those properties or the properties themselves, the main task becomes the selection of the most appropriate connecting property, and this is where the weighting metric described above becomes crucial.

A. *Analysis of 100 N+N(+N) with Biber's taxonomy*

We agree with [13] that some of the N+N expressions fall under several categories: we found 17 such cases. Most of these due to somewhat vague definitions of such rubrics as Content and Identity, but others resulting from the mixed syntactic/semantic nature of the taxonomy, so that *business community planning* could be described equally well as Content or Objective type 1. Also, an expression could be ambiguous, and the alternative meanings could belong to different rubrics and the sentence containing such an expression was not sufficient for disambiguation in isolation (and, as we mentioned above, we are not using InfoStore for this paper).

Table I shows the taxonomic distribution of the 100 expressions; those that belonged to two or more rubrics were counted as many times, thus driving the total above 100. The rubrics not represented in our sample are omitted.

TABLE I. TAXONOMIC DISTRIBUTION OF THE 100 EXPRESSIONS

Taxonomic rubric	**Number of expressions**
Composition	1
Purpose	11
Identity	20
Content	22
Objective type 1	19
Objective type 2	3
Subjective type 1	15
Subjective type 2	3
Time	2
Location type 2	3
Institution	7
Partitive	4
Specialization	6
No appropriate rubric	2

This open-ended and somewhat vague classification is hardly suitable for computation. In the next section we will demonstrate the results of the OST analysis of the same expressions, and compare these results with these in the most populous rubrics above.

B. Analysis of 100 N+N(+N) with OST

As mentioned above, English nouns can be anchored in OBJECTs, EVENTs, or PROPERTYs from the OST ontology. Thus, a more meaningful, although still crude classification is between these types, shown in Table II.

In English adjectives predominantly precede the nouns that they modify. Accordingly, the adjectival use of nouns before other nouns, possible in English because of its impoverished morphology, makes N1s in N1 N2 sequence the modifier of N2 much more frequently than the other way around. This premodification prevails in our sample, with just a sample of postmodification expressions.

TABLE II. TOP LEVEL ONTOLOGICAL DISTRIBUTION OF THE 100 EXPRESSIONS

N1 N2 (N3)	**Number of expressions**
Event Event	11
Event Object	13
Event Property	4
Object Event	19
Object Object	33
Object Property	6
Property Object	5
Property Event	1
Object Event Object	3
Property Event Object	1
Property Object Event	1
Object Object Object	2
Object Event Event	1

STAn relies on premodification-oriented rules and goes into the postmodification regime only after failing to find any possible premodified interpretation. As an example, consider *monitor performance* (taken from our data): while it is likely that a human will interpret it as monitor for performance (postmodification), the premodified interpretation is performance of the monitor, and it is the latter that was easier for STAn to access according to the rules it uses.

Honoring, as it were, the predominance of premodification in the sample and in the language, we will refer to N1+N2 constructions as EVENT-, OBJECT-, or PROPERTY- driven when N2 is an EVENT, OBJECT, or PROPERTY, respectively. The interpretation of the EVENT-driven expressions is clearly delimited by the properties of the events, such as AGENT, INSTRUMENT, THEME, LOCATION, etc, and just as many objects in a regular sentence fit comfortably enough as the fillers of these properties, they do so in the N+N expressions. Unfortunately, this group is minority in the sample (33 instances). The EVENT + EVENT combinations present several additional alternatives for the analysis, and the interpretation is typically more difficult, often requiring InfoStore input.

The PROPERTY-driven compounds are easy to compute as the portion most difficult to find, the property, is explicitly stated in N2. The only work that is required is then to check whether N1 should be in the domain or range of the given property.

The OBJECT-driven compounds, which constituted the majority of the sample (57 instances), are more difficult to interpret correctly than the previous two groups. Problematic among them are OBJECT + OBJECT expressions that require some connection, where this connection might go far beyond a single property, but rather require a “story” involving the two objects. Ellipses (see below) are rampant in this category: thus, *group plan* is actually an insurance plan for the group.

Using the taxonomy in [13], Table III indicates significant OST subclasses in the most populous taxonomic rubrics where the nature and difficulty of computational treatment differ a greatly from one subclass to another.

TABLE III. TOP LEVEL ONTOLOGICAL DISTRIBUTION OF THE 100 EXPRESSIONS

Biber \ OST	Object=N2	Event=N2	Property=N2
Identity	15	3	2
Content	15	6	1
Objective 1	8	11	0
Subjective 1	1	12	2

It is interesting to see how many different connecting properties OST establishes on the OBJECT-driven subclasses, the two most populous ones being the Identity and Content rubrics. The properties listed here were found by STAn and recognized by human expert judges as correct:

- Identity/OBJECT-driven:
  - HAS-SOCIAL-ROLE
  - SALIENCY
  - RANK
  - EMPLOYED-BY
- Content/OBJECT-driven:
  - HAS-TOPIC
  - REPRESENTED-BY

Thus, the OST properties provide a finer grain size. They also can move an expression from one rubric to another, overriding the weak intuition of a human taxonomist or confirming one of the possible choices and excluding the other.

Let us repeat the procedure for the next two most populous EVENT-driven subclasses:

- Objective type 1/EVENT-driven:
  - INSTRUMENT

- EXPERIENCER
- THEME
- THEME-OF
- HAS-TOPIC

- Subjective type 1/EVENT-driven:
  - AGENT
  - LOCATION
  - THEME
  - EXPERIENCER
  - BENEFICIARY
  - PART-OF-EVENT

The 6 subtypes of the last type are particularly noteworthy because they include almost all of the common event properties in OST, INSTRUMENT notoriously but understandably missing.

C. *Evaluation*

1) *Types of evaluation*

There are multiple factors contributing to the process of correct interpretation in OST. As far as noun compounds are concerned, these factors include:

- First and foremost, the correct disambiguation of each noun's meaning.
- The identification of the possible connection(s) between the nouns in the expressions, according to the ontological world model.
- The discovery of the best interpretation of the expressions.
- The assignment of the highest rank (weight) to the TMR with the best interpretation.

2) *The numbers*

For the final version of the paper, we used STAn 4.0 for the evaluation. In the 100 expressions that we used, there were 205 words, most of them with several senses in the OST lexicon. 196 senses of them (or 95.6%) were selected correctly. In the few cases when the words had only one sense each in the lexicon, OST still checked (and the human expert verified) whether the sense fit. So, technically, in 95.6% of the nouns the correct sense was reliably selected.

Next, we evaluated whether STAn selected a connection between the nouns which was possible according to its world model and plausible for human experts, according to their world knowledge. The triple-noun expressions count as one successful selection only when the entire interpretation is possible. We encountered 84 possible interpretations (or 84%) in our sample.

Obviously, only some of these possible interpretations could be considered the best of all possibilities in the given context. However, STAn also has a chance to rank its preference towards sentence interpretation. In other words, the degree of success in interpreting a noun + noun expression may be subordinated to the correct interpretation of the rest of the sentence. We are interested here in whether the best interpretation, according to the human experts, was found; and the number for that is 69 (69%); again, the triple-noun expressions counted as one unit.

Yet a lower number corresponds to the those correct interpretations that were ranked the highest by STAn:

- 46 of them had the highest rank
- 8 of them had the second-highest rank
- 6 of them had the third-highest rank
- 9 more were lower than the third-highest rank

Therefore, given a choice between TMRs, the selection by STAn and the human experts coincided 66.(6)%, or exactly 2/3 of all cases in the sample.

3) *Sources of failure*

There are three major reasons for failure, all of which will be removed at the later stages of OST implementation. First, we ran this sample on a limited lexicon, supported by a limited ontology. Both of these are steadily expanded—see [2] for the cost and time estimates for OST acquisition. The Unattested Input Module was not activated in this experiment, thus lowering STAn's robustness.

Second, we marked 9 conspicuous cases of ellipsis, accounting for 60% of all failures to identify the possible connection, and a closer analysis would probably reveal several more cases. As we mentioned before, STAn couldn't handle *group plan* correctly because it lacked the information that it was actually a group insurance plan. Semantic ellipsis remains an underrecognized and underexplored phenomenon, leading researchers to giving up occasionally on interpretations of such expressions—see, for instance, [14] on the meaning of *fast motorway*. OST can interpret the meanings of such expressions by looking at the domain of SPEED—"fast" is in the range of this property—and the conceptually contingent CAR, which is what is fast on the motorway.

For the reconstruction of ellipsis, OST has to use InfoStore, and the choice not to use information in it for this experiment is the third major reason for the failures, especially when the discovery of the best property and TMR ranking are concerned.

These and other possible problems are going to be corrected in the course of further OST implementation.

IV. Summary

We demonstrated, on a limited sample of 100 N+N$^+$ compounds, the principles of analysis and computational interpretation for compositional multi-word expressions in Ontological Semantic Technology. We compared this OST-based methodology with the traditional taxonomy for the meanings of noun compounds and achieved a finer grain size with the former. While the numbers characterize the experiment as reasonably successful, we also indicated the clear directions of improvement in the course of further OST implementation.

***Abstract*—In this paper, we describe the adaptation process of Apertium, a free/open-source rule-based machine translation platform which is operating in a number of different real-life contexts, to the linguistic needs of the Universitat Oberta de Catalunya (Open University of Catalonia, UOC), a private e-learning university based in Barcelona where linguistic and cultural diversity is a crucial factor. This paper describes the main features of the Apertium platform and the practical developments required to fully adapt it to UOC's linguistic needs. The settting up of a translation service at UOC based on Apertium shows the growing interest of large institutions with translation needs for open-source solutions in which their investment is oriented toward adding value to the available features to offer the best possible adapted service to their user community.**

I. Introduction

Machine Translation (MT) is one of the classic tasks of Natural Language Processing (NLP) and still an ongoing problem. Since the first attempts, dating from the 1950s [1], the presence of MT in a multitude of assimilation (understanding) and dissemination (publishing) scenarios has increased, as has interest in producing and accessing multilingual content. Companies, public and private institutions, and individual users have looked for solutions to cover their needs and this increasing demand has led, in the last years, to a growing interest of big companies (such as Google[1]) or big public-funded projects (such as EuroMatrix[2]) for the field of MT. The number of MT initiatives has risen greatly in recent years, mainly in statistical MT, as a result of the availability of vast multilingual parallel texts, but also in rule-based MT, example-based MT or hybrid systems. Many of these efforts have been released in the last decade as free/open-source systems (FOSS)[3] making MT available to the whole user community and not just to restricted groups.

This is the case of the Apertium[4] FOSS MT platform presented in this paper. Apertium is a framework in which rule-based machine translation systems can be created. It was first released in 2005 with only two available language pairs while today there are more than 20 stable language pairs available. Apertium has, since then, been chosen by a range of users to meet a number of MT needs. Examples can be seen in a wide variety of scenarios:

- individual users interested in using or developing the Apertium platform,
- less-resourced language communities, interested in increasing language visibility,
- research groups interested in carrying out R&D projects related to MT or NLP,
- companies interested in using MT or in improving the platform for internationalization or to offer commercial services,
- companies from the translation or localization industry interested in increasing productivity,
- public administrations interested in promoting languages and language technologies or,
- academic institutions working in multilingual environments.

From the scenarios above, we can see that Apertium is used in many different real-life contexts[5]. Apertium is, for example, used to publish online bilingual versions of *La Voz de Galicia* newspapers in Spanish and Galician, to generate, via translation, book reviews in many languages on the online Casadellibro.com bookshop or, recently, to produce bilingual versions of the University of Alicante (UA) website in Spanish and Catalan. Beyond Spain, Apertium is being used in companies such as Autodesk, where it is used to produce rough translations from Spanish into Brazilian Portuguese [2] as part of its localization workflow.

One of the most successful industrial applications of Apertium is the online MT web service at the Universitat Oberta de Catalunya (Open University of Catalonia, UOC). A long-term project developed within the UOC in collaboration with Prompsit Language Engineering, as the Apertium service provider, was set up in July 2008. The aim of this project was to improve and adapt Apertium to the UOC's needs for a translation service on its virtual campus. All the adaptations and improvements made by the UOC are free and open-source, and available on the Apertium platform. The UOC has become a regular developer on the Apertium platform, making

[4] http://www.apertium.org
[5] http://www.translationautomation.com/technology/open-mt-ready-for-business.html

contributions and benefiting from the improvements made by the whole Apertium community.

This paper describes Apertium and its application in the context of the UOC. Section II describes the Apertium platform and its main innovative features. Section III sets out the language needs at the UOC, and how Apertium has been integrated in response to these needs. Section IV presents the evaluation and user feedback obtained after integrating Apertium, and finally, section V details the main conclusions and work for the future.

II. Apertium

This section includes a description of the tool: the general architecture, a more specific technical description, and its historical evolution.

A. General Architecture

Apertium is a rule-based MT platform providing the engine, tools and data for a large number of languages under the GNU General Public License[6], and it is being developed by a community of users worldwide. The platform has been described in depth in papers such as [3]. Here is a brief overview of the platform, its history and the main innovative features.

B. Technical Description

The Apertium MT engine is a shallow-transfer system consisting of pipelined independent modules that intercommunicate using text streams (see the architectural diagram in Figure 1). Modules can be used in isolation and other modules can be added to the pipeline. Data and engine are fully decoupled to make the engine language-independent. During the translation, finite-state lexical processing, statistical disambiguation and shallow structural transfer based on finite-state pattern matching takes place. Linguistic data feeding the engine are coded in XML-based files which are compiled into binary format (finite-state letter-transducers [6]) to speed up the translation process (10,000 words can be processed per second on a basic desktop PC). An extensive documentation is also available[7].

The technology behind it is largely based on that of systems already developed by the Transducens group at the University of Alicante (UA), such as the Spanish–Catalan MT system interNOSTRUM[8] [4], and the Spanish–Portuguese translator Traductor Universia[9] [5].

Apertium-based systems consist of three different packages:

- `apertium`: MT engine modules for format management (deformatters and reformatters), part-of-speech tagging (tagger) and transfer tasks (structural transfer).
- `lttoolbox`: toolbox for processing and compiling letter transducers into which data are transformed (morphological analyzers and generators, lexical transfer and post-generators).
- `apertium-l1-l2`: language package containing XML-based data for translating between two languages, l1 and l2, (monolingual and bilingual dictionaries, post-generation dictionaries, data for part-of-speech tagging).

Moreover, the system has the following modules that are connected in a serial way to produce translations of texts in a diversity of formats:

- **Modules for format processing**: they are in charge of separating (without removing) the original format information from text to be translated and restoring the format at the end of the translation process. The **deformatter** and the **reformatter** are the modules that perform this processing.
- **Modules for lexical processing**: they use the information contained in the monolingual and bilingual dictionaries. These are:
  - the **morphological analyzer**, which provides all the possible lexical forms (consisting of lemmas and morphological information) for each word (surface form) in the original text;
  - the **lexical transfer** of the transfer module, which performs the word-by-word (or multiple-word-by-multiple-word) translation of each lexical form delivered by the morphological analyzer and, if needed, disambiguated by the lexical disambiguator;
  - the **morphological generator**, which generates the correct surface form for each lexical form of a word coming from the transfer module;
  - and the **post-generator** that performs some orthographical tasks such as contractions.
- **Lexical disambiguator**: it provides, based on probability estimates, one single lexical interpretation (and the most probable but not always the correct) of an ambiguous word for which the morphological analyzer delivers more than one lexical form.
- **Structural transfer module**: it performs one or three pass transfer operations (depending on the language pair) to apply structural changes between source and target language such as gender, number or case agreement, reorderings, changes in verb tenses (including clitics) or verbal structures, changes in prepositions, generation or deletion of partitives, articles, prepositions or subject pronouns for non-pro-drop languages, etc.

C. Historical Evolution

Since 2005, with the first release of the engine (which was aimed at dealing with closely related languages), tools and the Spanish↔Catalan and Spanish↔Galician pairs, the Apertium platform has been extended greatly:

[6] http://www.gnu.org/copyleft/gpl.html

[7] The Apertium Wiki provides documentation of a wide variety of development and usage scenarios (http://wiki.apertium.org/).

[8] http://www.internostrum.com

[9] http://traductor.universia.net

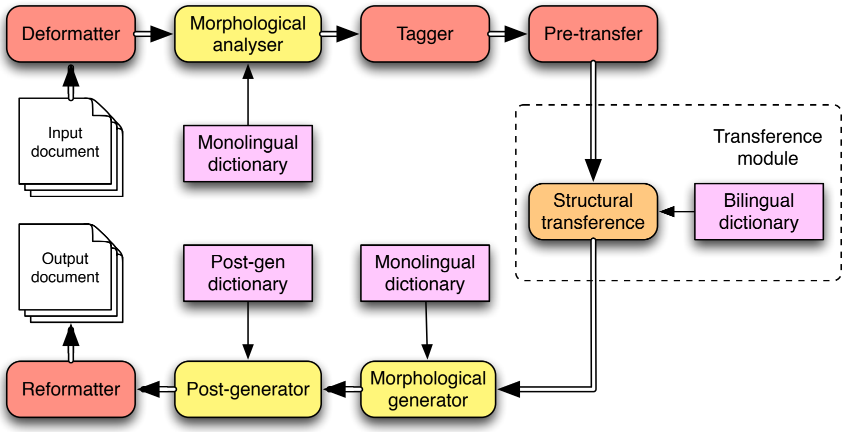

Fig. 1. Modules of the Apertium machine translation system

- more than 22 language pairs have been released[10] and many others have been started or are in development,
- the engine has been improved to deal with less related languages (thanks to the three pass transfer) and to be Unicode compliant
- file format support has been extended to all Office formats, Quark-Xpress, special XML-based formats, etc.,
- support for translation memories has been enabled (still experimental),
- language variants, polysemic or specific domain management has also been enabled,
- applications and tools have been developed for Apertium, such as Tinylex[11], a version of the bilingual dictionaries for mobile devices; `apertium-subtitles`, a tool for translating subtitles; user interfaces or add-ons for Firefox, and
- research on social MT development based on Apertium is currently being developed as part of a project entitled Tradubi [7].

All these efforts result in the continuous improvement of the Apertium platform and are carried out by a worldwide community of developers and committers acting individually or as groups in companies, organizations, research groups, etc.

We found that Apertium is especially suitable for its integration inside universities like UOC for various advantages:

- **Open source**: Apertium is licensed under the GPL (GNU General Public License). This implies that the source code is provided with the application, and this allows UOC to adapt both the MT engine and the linguistic data to its specific needs.
- **Free software**: GPL requires all derivative software to be also licensed under GPL; this promotes the availability of all new source code developed for Apertium by the user community. Therefore, anyone using the system automatically benefits from new developments made by third parties, both on the engine and the data.
- **Predictability**: Given that Apertium a rule-based MT system, the obtained results when translating documents are highly predictable. We believe that this is an advantage over other non-rule-based MT technologies for several reasons. Firstly, many of the systematic mistakes made by the MT system can be corrected in a systematical way. Secondly, human post-editors, once accustomed to the system behavior, are able to reduce the amount of work checking the original when post-editing a document. This reduction, which can even be automatized, makes their work simpler and more productive.

Some of the improvements described above, as well as linguistic improvements in existing language pairs, were made by Prompsit as part of the development project designed by the UOC as described in the following section.

III. Practical developments for adaptation to the UOC

The UOC is a private Catalan online university whose mission is to provide people with lifelong learning and education. The UOC community is made up of more than 54,000 students, over 2,000 teaching counsellors and faculty working alongside an administrative staff of around 500 people. More than 1,475,000 documents have been downloaded from its Virtual Campus[12], including articles, studies and teaching materials. Given these figures and the fact that the university mainly works with three languages: Catalan, Spanish and English, there is the vital need to make intensive use of language technologies. Thus, the Office of Learning Technologies[13] and the Language Service[14] at the UOC have been developing several language tools [8] in order to exploit and reuse the

[10] http://wiki.apertium.org
[11] http:www.tinylex.org
[12] Data from academic year 2007-2008
[13] http://learningtechnologies.uoc.edu/
[14] http://www.uoc.edu/serveilinguistic/

language data generated by the University. In this context, several machine translation tools were evaluated. Apertium, thanks to its modular architecture, fully customizable nature and coverage of the languages used at the UOC, was adopted and improved on to meet the University's needs. Once Apertium was selected, it was integrated with the aforementioned language tools in order to create a document flow [9] for semi-automation of language processes. Below is a description of the translation service functionalities available and the user interface developed as part of the integration process.

A. Features Installed and Improvements Developed

Apertium has been installed on the UOC's Virtual Campus and is available both for faculty and administrative staff. The translation service has been set up for Catalan, which is the language used most frequently at the University, and the supported language pairs are Catalan↔Spanish, Catalan↔English and Catalan↔French. The functionalities implemented include:

- text translation
- document translation
- translation as you browse
- advanced HTML treatment (with structure validation)
- compressed files
- TMX utilization creation

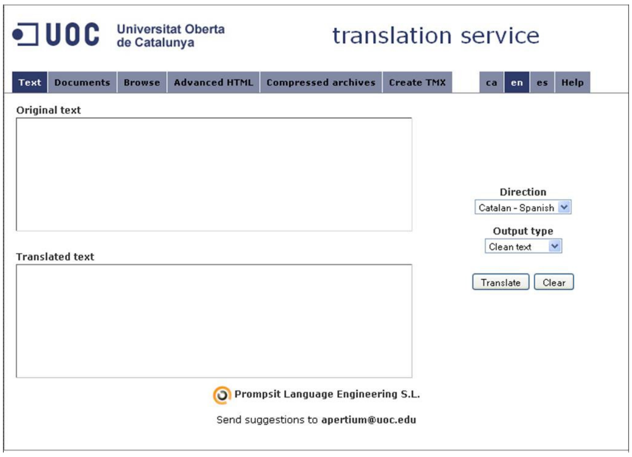
The integration in the Virtual Campus involved a series of specific actions in order to meet the UOC's needs. An upgrade was performed on the dictionaries using specific vocabulary extracted from the UOC's website. Regarding formats, specific support for Microsoft Excel and PowerPoint was developed. The marking of unknown and ambiguous words was adapted to ease post-editing.

Moreover, support for compressed files was developed so that users could send rar, zip, 7z, tar.bz or tar.gz files and receive an equivalent file with its contents translated.

In terms of the translation workflow, the use of translation memories prior to the machine translation phase was introduced in order to reuse the information generated within the university. This is especially useful in an institution where some departments generate similar documents, in which only small parts of them are modified, and many of the sentences translated could be reused in future translations. Moreover, since professors need to generate documentation in very specific domains, translation memories can help ensure more accurate and personalized translations.

B. User Interface

A special user interface was developed to integrate all the functionalities adopted or developed to create the translation service. This interface is available in Catalan, Spanish and English. Its different functionalities are structured by means of browser-like tabs as shown in Figure 2. Help is provided by means of HTML pages, and a downloadable PDF file, with detailed information on each functionality.



Direction: Catalan - Spanish

Output type: Clean text

Fig. 2. Apertium user interface

TABLE I
ERRORS OBSERVED WHEN TESTING THE FORMAT QUALITY OF ELEVEN DOCUMENTS.

Part of document	DOC	PPT	XLS
titles and subtitles	1	0	0
paragraph structure	0	1	0
bold and italics	0	1	1
figures	0	1	0
tables	0	1	1
headings and footnotes	3	0	0
lists	0	0	0
apostrophes	3	0	1
content (missing parts)	0	0	0
strange characters	2	0	0

IV. EVALUATIONS

Before releasing the first version of the translation system in December 2009, a series of tests were carried out in order to check its effectiveness in handling formats and the user interface's usability. To do so, we followed some of the ideas introduced in [10] and [11]. This section briefly outlines the design and the results obtained in both tests, performed by nine people from the university staff who volunteered to evaluate system quality for different formats and the usability of the interface.

After the release, the developers compiled user feedback from the suggestions and questions submitted to an address given for this purpose. The last part of this section summarizes the comments, frequently asked questions and suggestions made by users in order to improve interface usability and format handling.

A. Format quality test

The aim of the format quality test was to evaluate whether the use of different file formats led to problems in the translations or not, focusing on DOC, PPT and XLS formats. Table I shows the errors encountered by the nine evaluators in different parts of documents for each file format: titles and subtitles, figures, missing parts or strange characters in the translation, etc. A total of eleven documents were tested by the evaluators.

It can be seen from the table that most of the errors encountered were related to Microsoft Word documents and headings, footnotes and the appearance of strange characters.

Nonetheless, when enquiring about system performance when translating compressed files (zip), no problems were encountered: the format and folder structure were maintained in the output file, and all the files included in the compressed folder were completely translated.

This test allowed us to identify and solve minor problems when dealing with formats. This was true in particular when translating Microsoft Office documents, due to their closed internal structure.

B. *Usability test*

The goal of the usability test was to evaluate the general level of user satisfaction regarding a number of aspects. We mainly wanted to detect possible inconveniences in the information layout and the user's ability to perform the intended tasks. Table II shows the results obtained where *NA* stands for *not answered*, *0* means *disagree entirely*, *1* means *disagree*, *2* means *agree*, and *3* means *agree entirely*.

TABLE II
DEGREE OF SATISFACTION IN THE INTERFACE USABILITY TEST

Concept evaluated	**NA**	**0**	**1**	**2**	**3**
easy-to-use interface	2	0	0	3	4
information easy to find	2	0	1	2	4
information clearly organized	2	0	1	2	4
submitted tasks completed	3	0	0	2	4
understandable help	3	0	1	3	2
help easy to find	3	1	0	2	3
easy to access interface	2	0	0	3	4

As can be seen from the table, generally speaking, the interface's usability was rated highly.

C. *User feedback*

Once the translation system was opened to the UOC community, users had the opportunity to send their questions and suggestions. More than 400 users visited the web every month, and among the most frequent errors made were forgetting to select the format type via a drop-down menu. This menu left room for errors when selecting the appropriate format and this situation could have been avoided from the start by incorporating the automatic format detector that it is used when translating compressed files. Another of the most frequent errors was to try to translate a type of document that differed from the default extension, or cutting and pasting XML files into Word documents instead of translating them in XML format. This error stems from use of the previous machine translator used by the UOC community, where XML documents were translated in this way.

Among the suggestions received, the most frequent were to include the translation of PDF documents or automatic selection of the file format, whereby the user does not need to be aware of the type of file they wish to translate.

The feedback we obtained led to a series of actions. First of all, we compiled the most frequently asked questions in a document, providing answers to these questions. This document was made available through the user interface so it could be easily accessed by users.

D. *Linguistic quality*

An evaluation of the linguistic quality of the three available language pairs was carried out after the integration of the Apertium system at the UOC. These three pairs are at different levels of development:

- Spanish↔Catalan is the most actively developed pair inside the Apertium platform, having, for example, more than 41,000 bilingual correspondences in its dictionaries.
- English↔Catalan has also been part of various development projects. It has around 34,000 bilingual correspondences.
- French↔Catalan is the least improved pair, still considered a prototype, with around 12,000 bilingual correspondences.

The evaluation was done using the tool *apertium-eval-translation*, which compares the marked Apertium output of a text (unknown words are marked with a star before the word) and a post-edited version of the same text to calculate some evaluation variables based on edit-distance techniques. During our evaluation, two variables were assessed: *Coverage*, i.e. the percentage of words for which Apertium returned at least one translation, and *Word Error Rate* (WER), i.e. the percentage of words being post-edited to convert the MT output into the post-edited file, as shown in Table III. These results are the ones obtained after improving for Spanish↔Catalan as part of the development project carried out by the UOC. Catalan↔English is also being improved as part of two projects led by the Linguamon-UOC Chair in Multingualism. Catalan↔French is almost at the same level of development as it was before starting the project.

TABLE III
SAMPLE APERTIUM MT SYSTEM OUTPUT QUALITY.

Language pair	**Coverage**	**WER**
Spanish-Catalan	97.1%	4.3%
Catalan-English	94.1%	29.3%
Catalan-French	92.4%	21.9%

V. CONCLUSIONS AND FUTURE WORK

We have presented the details of the integration of a web-based translation service based on Apertium at the UOC. This integration was conducted together with a series of evaluations that lead us to make minor changes in the overall project in order to better meet UOC users' needs. The translation service has been running since December 2009 and the number of unique visitors in the first five months adds up to more than 600. Given that figure and the positive feedback obtained from the users via e-mail and the different evaluations made, we can say that the translation service has had a general good acceptance. Once we covered an internal testing period, and as a conseqence of the general good acceptance of the system, we decided to provide the translation service for the general public and it is now publicly available at http://apertium.uoc.edu.

In terms of future work, and in order to obtain more effective translations, we plan to include semantic domains that will allow for the disambiguation of polysemic and homonymous words. The semantic domains will be classified according to the subjects linked to studies at the UOC. For instance, the word *table* that can be translated as *tabla* (table of results) or *mesa* (dining table), depending on whether the word is related to mathematics or general vocabulary, would be clearly disambiguated through the use of semantic domains.

In addition to that, and inside the Google Summer of Code program, we are currently developing an online post-editing tool which will provide the user with a smooth integration of spell checker, grammar checker and dictionaries together with the Apertium platform.

Another direction for future work is improving the accessibility of the interface. In order to achieve this goal experts in accessibility are currently running a series of tests on the web service to be able to identify potential problems from this point of view.

In more general terms, user feedback will guide future work which will take into consideration improvements to the Apertium platform regarding new functionalities or increasing linguistic quality.

ACKNOWLEDGMENT

The authors would like to thank the Linguistic Service technician's fruitful suggestions which helped us to improve the overall system not only in terms of the linguistic information but also in terms of the user experience.

***Abstract*—The on-going project aiming at the creation of the National Corpus of Polish assumes several levels of linguistic annotation. We present the technical environment and methodological background developed for the three upper annotation levels: the level of syntactic words and groups, and the level of named entities. We show how knowledge-based platforms Spejd and Sprout are used for the automatic pre-annotation of the corpus, and we discuss some particular problems faced during the elaboration of the syntactic grammar, which contains over 800 rules and is one of the largest chunking grammars for Polish. We also show how the tree editor TrEd has been customized for manual post-editing of annotations, and for further revision of discrepancies. Our XML format converters and customized archiving repository ensure the automatic data flow and efficient corpus file management. We believe that this environment or substantial parts of it can be reused in or adapted for other corpus annotation tasks.**

I. Introduction

The National Corpus of Polish (Pol. *Narodowy Korpus Języka Polskiego*; NKJP; http://nkjp.pl/) is a 3-year project (2007-2010), involving a consortium of four partners coordinated by the Institute of Computer Science, Polish Academy of Sciences ([1], [2]). The aim of the project is to create a 1-billion (10^9) word corpus of Polish annotated at various levels, with a 300-million balanced subcorpus and a number of annotation tools. The following linguistic annotation layers are distinguished: segmentation (word-level and sentence-level), morphosyntax, word sense disambiguation (limited to around 100 lexemes), syntactic words, syntactic groups and named entities.

A 1-million word balanced subcorpus undergoes manual annotation at all these layers and it serves as a training corpus for various annotation tools (cf., e.g., [3]). The current paper gives an overview of methodologies and tools used for the semi-manual annotation of the 1-million corpus at the last three – broadly syntactic – layers.

The layer of syntactic words (SWs) builds on top of the morphosyntactic layer. Fine-grained word-level segments are grouped into more traditional words, including reflexive verbs (consisting of two segments: the verb and the reflexive marker), analytical tense and mood forms, etc. [4] Syntactic groups (SGs) are constructed on top of SWs, and include nominal groups, prepositional groups, clause-level groups, etc., but no attempt is made to solve attachment ambiguities. Finally, named entities (NEs), i.e. proper names of persons, geographical objects and organisation, as well as temporal expressions, refer again to the layer of morphosyntactically annotated segments.

II. Related Work

Some of the first treebanks were constructed fully manually, by drawing trees for particular sentences; this is the case, for example, for the Penn Treebank (PTB) of English [5], the German Negra/Tiger Treebank [6] and the Prague Dependency Treebank [7]. Some treebanks were created by converting existing treebanks to the new linguistic theory; for example, parts of roughly Chomskyan PTB were converted to Head-driven Phrase Structure Grammar, Lexical Functional Grammar and Constraint Categorial Grammar. However, the usual way of developing new treebanks consists in the automatic parsing of texts and the manual selection of the right parse. For example, [8] reports that the ERG grammar [9] covers around 80% of the Wall Street Journal part of PTB, with sentences not adequately covered by the grammar serving as the basis for further grammar development.

The outcome of the effort reported here will not constitute a typical treebank, as the annotation in NKJP stops at the partial (or shallow) syntactic markup (cf., e.g., [10], [11], as well as [4]), where structural ambiguity is not an issue.[1] Hence, the approach mentioned above, focussing on disambiguation, is not directly applicable to the task at hand, but the general semi-manual iterative methodology is similar: parse sentences using a manually constructed grammar, ask annotators to correct the results of parsing by hand, and use error and emission reports for the improvement of the grammar, before applying it to the next batch of sentences.

There are many multi-layer corpora developed by now, typically containig morphosyntactic, (deep) syntactic and some semantic and/or discourse representation. For example, the Prague Dependency Treebank mentioned above has these three layers (called morphological, analytical and tectogrammatical), currently further extended with coreference [13] and high-level

This research was funded in 2007-2010 by a research and development grant R17-003-03 from the Polish Ministry of Science and Higher Education.

[1] In fact, there is a separate project carried out at the same institute, aiming at the construction of a full constituency treebank on the basis of the same 1-million word subcorpus; cf. [12].

inter-clausal structure [14]. The current project adopts a more fine-grained and conservative approach, with three layers between morphosyntax and deep syntax proper: possibly multi-segment SWs, NEs and possibly partial SGs. We claim that this gradual procedure makes it possible to better control the quality of the linguistic annotation.

Also at the level of NEs, the annotation strategies adopted here are rather fine-grained, namely, not only the longest-match occurrences of NEs are annotated, but also all recursively embedded ones, and, moreover, overlappingly coordinated NEs are appropriately marked (cf. [15], [16]).

Let us finally note that, while only partial syntactic structures are annotated here, syntactic groups contain the kind of information not usually found in treebanks, namely, they mark both syntactic and semantic heads. For example, in case of prepositional groups, the preposition serves as the syntactic head[2], but the semantic head is the most meaningful word within the argument of this preposition. Arguments for the usefulness of this kind of annotation, and further details, may be found, e.g., in [17], [4].

III. Annotation Data Flow

The three syntactic annotation layers in the NKJP are organised into two parallel data flows: one for syntactic words and syntactic groups (henceforth, *syntactic annotation* in the narrower sense), and the other for named entities.

The main differences between the data flows show up during the pre-processing step – different tools, with different input specifications, are used for automatic pre-annotation. In case of the syntactic annotation (Fig. 1) a shallow parsing system called Spejd is used to extract SWs and SGs from the underlying morphosyntax level (cf. section IV-A). For the similar (from the data flow point of view) task of NE recognition another platform, Sprout, is used (see section IV-B).

Words & groups (PML-groups format)
Conversion
Words & groups (IPI format)
Conversion
Morphosyntax (IPI format)
Spejd

Fig. 1. Data flow in the syntactic annotation task of the NKJP corpus

Spejd takes structured text with segmentation and morphosyntax information as input. It requires a specific input format (called *IPI format* in Fig. 1) that can be automatically obtained from the NKJP morphosyntax level. Conversely, Sprout requires pure text as input, which complicates the whole process of data conversion (see Fig. 2). A raw text taken from the corpus repository is processed by lexical resources and grammar rules. The NEs identified in the process, together with their embedded structures, are marked in an XML Sprout-specific output. Since Sprout outputs the cardinal numbers of the beginning and ending characters of each recognized sequence, the converter consults the segmentation level of the text in order to translate text ranges into token identifiers. Moreover, for each token, its morphological tag and lemma are recopied from the morphosyntactic annotation of the text.

After the pre-processing step, files have to be prepared for manual annotation. In both data flows annotators use a tree editor TrEd (see section V) to examine and correct results of automatic annotation. Again, files have to be translated to TrEd-readable formats (PML-groups for syntactic annotation and PML-NE for NEs), which were defined using the Prague Markup Language (PML, http://ufal.mff.cuni.cz/jazz/PML/doc/). Due to the sampling methodology adopted in NKJP, files contained in the 1-million gold standard subcorpus are of a very variable length (from several to several thousand sentences). They do not correspond to complete texts taken from the 1-billion word corpus, but to randomly chosen paragraphs thereof. For the sake of ergonomy, it is important to present the annotator with text portions of a uniform length, thus easily manageable. Therefore, the converter divides each text which is too large into files of a limited number of sentences corresponding to roughly 1 hour of human annotation effort. Text splitting is designed so as to keep together all sentences appearing in one paragraph. Conversely, too small files (of one or several sentences), are organised into file lists and annotated as bigger units.

[2] because it governs the case inflection of its arguments

Finally, PML files are transferred to *corpus files management system* (see section V-C) which is responsible for distributing files between annotators and for storing results of consecutive annotation steps.

Two annotators work on each corpus fragment. An adjudicator reviews any cases of disagreement and chooses the correct annotation. Each annotator and adjudicator works offline with TrEd installed locally, connecting to the subversion repository only to send results of his work, or to download new files. Two TrEd extensions, NKJP_groups and NKJP_names, have been developed to support annotation of PML-groups and PML-NE files. An annotator can download (or upgrade) extensions from within the TrEd application, with no need to run separate installation process. Despite no particular computing background of the annotators, they successfully install and operate the whole annotating platform.

The last stage consists in converting the PML formats of the validated annotations into the final NKJP formats. Here, the subfiles have to be merged into files corresponding to the initial texts and embedded XML elements (NEs and SGs) get transformed into pointers (for stand-off annotation).

IV. Automatic Annotation

A. Shallow Parsing with Spejd

Syntactic annotation in the National Corpus of Polish consists in joining words together into constituents: first at the level of SWs, then at the level of, possibly embedded, SGs. At the former, fine-grained word-level tokens are replaced by coarse-grained SWs (e.g., analytical tense and mood forms, analytical degree forms, reflexive verbs, discontinuous conjunctions, etc.). The tagset at this level differs somewhat from the tagset of word-level segments in order to allow for broader grammatical classes and more traditional grammatical categories, such as tense, mood and reflexivity. The complete tagset for SWs is presented in [18].

At the SG level, each identified group is annotated with pointers to its syntactic head (SynHead) and semantic head (SemHead). Only those groups that can be recognized with very high accuracy are marked, so that the shallow grammar resulting from the manual correction process can be reliably applied to the whole 1-billion word corpus. For example, a nominal phrase that consists of a noun and a prepositional phrase, e.g., *dom z ogrodem* 'a house with a garden', is always treated as two SGs (*dom* and *z ogrodem*), without an attempt to solve PP-attachment ambiguities. We make an exception for compound prepositions that consist of two prepositions and an interposing noun (e.g., *w odniesieniu do* 'with reference to'), as well as for elective constructions (e.g., *jeden z najlepszych* 'one of the best').

The following SGs are distinguished in NKJP:

- nominal group (NG): *malarz kwiatów* 'a painter of flowers', *nic specjalnego* 'nothing special',
- numeral group (NumG): *stu z nas* 'a hundred of us',
- adjectival group (AdjG): *zbyt długi* 'too long',
- prepositional-nominal group (PrepNG): *za murami miasta* 'beyond city walls',
- prepositional-adjectival group (PrepAdjG): *[wyglądasz] na zmęczonego* '[you look] tired',
- prepositional-numeral group (PrepNumG): *[wakacje] dla dwojga* '[a holiday] for two',
- adverbial group (AdvG): *ładnie*[3] 'nicely',
- discourse group (DisG): *no cóż* 'oh well', *itd.* 'etc.',
- subordinate clause (CG) (with subordinate conjunction): *[powiedział], że nie przyjdzie* '[he said] he wouldn't come',
- interrogative clause (KG): *[nie rozumiem], dlaczego to zrobił* '[I don't understand] why he's done it'.

The manually constructed grammar, for both SWs and SGs, is encoded in the shallow parsing system Spejd (http://nlp.ipipan.waw.pl/Spejd/) [19], a novel open source tool for simultaneous morphological disambiguation (this functionality is not used in this project) and partial parsing with unification.

Spejd rules form a cascade, with the output of one rule constituting the input of the next rule. Therefore rule ordering is crucial. For example, since nominal groups are embedded in prepositional-nominal groups, the rules for the former precede those for the latter.

Spejd rules are created in a conservative fashion, so as to avoid excessive matching, and in order to detect errors on the underlying morphosyntactic level. Firstly, as a parser finds a match for a lemma it is usually checked for grammatical class. For example, in the rule for *nie tylko ..., lecz także* (see below), the word *nie* 'not' must be marked as `conj` and not `qub`. Secondly, rules are made maximally specific in that some SGs are divided into several subtypes, e.g., there are 11 types of nominal groups: `NGa` (`Noun`[4]+`Adj`), `NGs` (`Noun`+`Noun` with the same value of case), `NGg` (`Noun`+$\texttt{Noun}_{\text{gen}}$), `NGk` (`Noun`+and+`Noun`), `NGn` (`Noun`+`Num`), `NGb` (`Noun`+`Brev`[5]), `NGe` (`Noun` as a head of the elective construction), `NGx` (`PPron3`+`Adj`, e.g. *something special*), as well as special groups `NGadres, NGgodz, NGdata`, for describing addresses, hours and dates. So, instead of the plain `NG`, an alternative of subtypes is given in the rule, e.g., `NGa|NGs|NGk|NGg|NGn|NGb`.

A Spejd rule may consist of five elements: `Rule` (rule identifier), `Left` (left context), `Match` (specification), `Right` (right context), `Eval` (conditions and operations). Context specification is optional.

```
Rule    "frazeo: nie tylko [lecz także]"
Match:  [base~"nie" && pos~"conj"]
        [base~"tylko" && pos~"conj"];
Right:  []+ ns [base~","]
        [base~"lecz" && pos~"conj"]
        [base~"także"]?;
Eval:   word(Conj1:discr, "nie tylko");
```

The above rule[6] identifies the first part of a discontinuous

[3] Recall that a SG may contain one or several SWs.

[4] In fact it is a nominal group, not a single noun.

[5] `Brev` stands for an abbreviation.

[6] In this rule `ns` stands for "no space" between tokens, the operator ~ means equal, `&&` denotes logical conjunction, `Conj1` is a grammatical class tag for the first part of the discountinuous conjunction and `discr` is a value of the `continuity` attribute.

conjunction *nie tylko . . . , lecz także* 'not only . . . but also' (note that there must be second part of this conjunction in the right context).

Two types of syntactic operations are available: word, that joins tokens into SWs, and group, that joins SWs into SGs.

The word operation has two mandatory arguments: 1) information about a token in accordance with the tagset (i.e., grammatical class and grammatical category values; pieces of information are separated by colons), 2) the base form of the resulting SW. These two arguments may be preceded by an optional argument: reference to the token which provides some morphological information for the whole SW. In this case the second argument determines how this information should be modified. In Spejd, the token referred to in this way must be unique – it is impossible to inherit information from different components. For example, an analytical future tense (e.g., *będę szedł* 'I will walk') is a combination of future auxiliary (będzie) and past participle (praet). All the information is taken from the bedzie form, except for the gender, which should be taken from the praet form. A solution to this problem is a multiplication of rules. An example of a rule for future tense forms in the feminine (f) is presented below. Here, the gender, instead of being inherited from the third component, is explicitely fixed to be feminine. Similar rules have thus to be created for all other possible genders.

```
Rule    "analytical future tense:
        bedzie + się + praet (f)"
Match:  [pos~"bedzie"] [base~"się"]
        [pos~"praet" && aspect~"imperf"
        && gender~"f"];
Eval:   word(1,Verbfin:fut:ind:refl:f,3.base);
```

The group operation (as in example below corresponding to e.g. *po tych trzech zdaniach* 'after these 3 sentences'), has three arguments: 1) the type of the SG, 2) the reference to the SynHead of the phrase (*po*), 3) the reference to its SemHead (*trzech*).

```
Rule    "PrepNumG: Prep + Adj + Num + Noun"
Match:  [pos~"Prep"] [pos~"Adj|Pact|Ppas"]
        [pos~"Num|Numcol"]
        ([pos~"Noun"] | [type="NG"]);
Eval:   unify(case number gender,2,3,4);
        unify(case,1,3);
        group(PrepNumG,1,3);
```

The problems encountered in pointing at SynHeads and SemHeads were:

- absent heads
  The SemHead of an interrogative clause is a finite verb. In the sentence *Nie wiem, kiedy i ile.* 'I don't know when and how many.' there is no verb in the subordinate clause. In this case the SemHead is made equal to SynHead, here *kiedy*.
- coordination
  In a coordinated group (e.g., *rząd i parlament* 'government and parliament'), the first element is marked as both the semantic and the syntactic head. If the conjunction were the syntactic head of the group, any information about the part of speech, case, etc., of the conjuncts would be lost, which would render such a conjunction group practically invisible to further syntactic rules.

See Tab. I for breakdown of Spejd rules into various types.

TABLE I
TAXONOMY AND QUANTITIES OF SPEJD RULES

Syntactic words			Syntactic groups	TOTAL
multiword entities	abbreviations	others		
339	360	122	242	1063

Spejd rules are applied to a corpus when its underlying morphosyntactic level has already been disambiguated manually. We fully benefit from this fact in our rules. The information about context is used to a lesser degree. Rules are based mainly on morphological information of the matched items themselves. As a result, our grammar performs very well on a good quality disambiguated corpus. However if applied to a non- or poorly disambiguated corpus it would require more matching context data in rules.

B. Named Entity Recognition with Sprout

As discussed in [16], the automatic pre-annotation of named entities in NKJP is done by the general-purpose knowledge-based NLP platform Sprout [20]. This tool offers several convenient features such as: (i) a rather rich grammar formalism with finite-state operators, unification and cascading, (ii) a very fast gazetteer lookup, (iii) an XML-based output, called Sproutput, in the form of typed feature structures whose type hierarchy can be defined by the user. Existing Polish named entity grammar and resources for Sprout [21] have been extended and adapted for the annotation task in NKJP. They include a gazetteer of about 300,000 inflected forms (55,000 lemmas), and 120 grammar rules for 6 types and 8 subtypes: (i) personal names (persName) with subtypes forname, surname, and additional name (addName), (ii) names of organisations (orgName), (iii) names or geographical objects such as rivers, mountains, etc. (geogName), (iv) names of geo-political units (placeName) with subtypes district, settlement, region, country, and bloc, (v) date expressions, (vi) time expressions. Initial results show the overall precision of 88% and recall of 61%.

V. MANUAL POST-EDITING

Manual post-editing of annotations is the most labor-intensive subtask and requires efficient and user-friendly tools. We have evaluated several annotation platforms such as Synpathy[7], MMAX[8], and GATE [22], before selecting the tree editor TrEd[9] [23] for the following reasons: (i) admitting pre-annotated input and multi-level annotation, (ii) customizable open XML-based abstract data format (PML), (iii) easy manipulation of tree representations, (v) ergonomic customizable

graphical user’s interface, (vi) parallel edition of concurrent annotations, (vii) rich documentation, (viii) technical reliablility. TrEd is also widely used by the international community – it scored as the second most used annotation tool on the LREC 2010 map of language resources and tools.

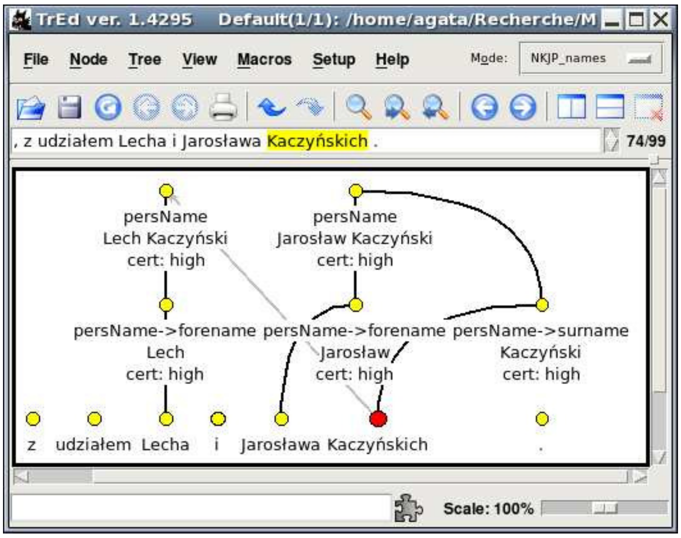
A. Annotator’s Workbench

1) Workbench for Syntactic Words and Groups: As shown in Fig. 3, in the central part of a TrEd’s window the annotation tree of the sentence is shown. Nodes are situated on three horizontal levels, which represent (from bottom to top) segments, SWs and SGs. The annotator can add or remove nodes, and draw edges between them. Each node has a set of type-specific attributes editable in a separate window on double-clicking the node. Toolbar icons are useful for navigation between sentences (or files), as well as undo and redo actions.

For each annotation level special *TrEd extention* has been prepared. NKJP_groups extention for syntactic annotation supplies a set of macros and keyboard shortcuts for: adding a SW or a SG, adding a regular or a secondary edge[10], pointing at the SynHead or SemHead, grouping multiple nodes at a time, etc. It also provides a PML schema defining PML-groups format and a stylesheet with encoded rules of syntactic tree visualisation. In Fig. 3 the SynHead of each constituent is marked in green and the SemHead is marked with a triangle. Thus, *Władze* is both a SynHead and a SemHead while *do* is a SynHead and *wtorku* a SemHead head only.

When closing a file, a final checkup is done via TrEd in that missing SynHeads and SemHeads of each group are reported.

2) Workbench for Named Entities: The annotator’s workbench for named entities is presented in detail in [15]. We recall here its main facilities with respect to the relatively rare but linguistically difficult phenomenon of overlapping in coordination. Fig. 4 shows a sentence in which two coordinated names have been annotated according to the guidelines. Both of them are personal names with an embedded forename and a common embedded surname *Kaczyńskich*, which appears only once. Since TrEd does not allow one tree node to have two father nodes, the highlighted node representing the surname is assigned to one father by a regular edge, and to another one by a secondary edge (in grey). As in all trees, most attributes of a node are visible below it, and their rapid modification is possible by mouse clicks. These attributes include: the type and subtype (*persName→forename*), the lemma (*Lech Kaczyński*), the derivation type and base, if



, z udziałem Lecha i Jarosława Kaczyńskich .

Fig. 4. Annotating coordinated names in the phrase ‘with the participation of Lech and Jarosław Kaczyński’

[10] A secondary edge is used in case of overlapping segments.

any (irrelevant here), and the certainty degree of the annotation (*cert:high*).

B. Workbench for Revision of Annotations

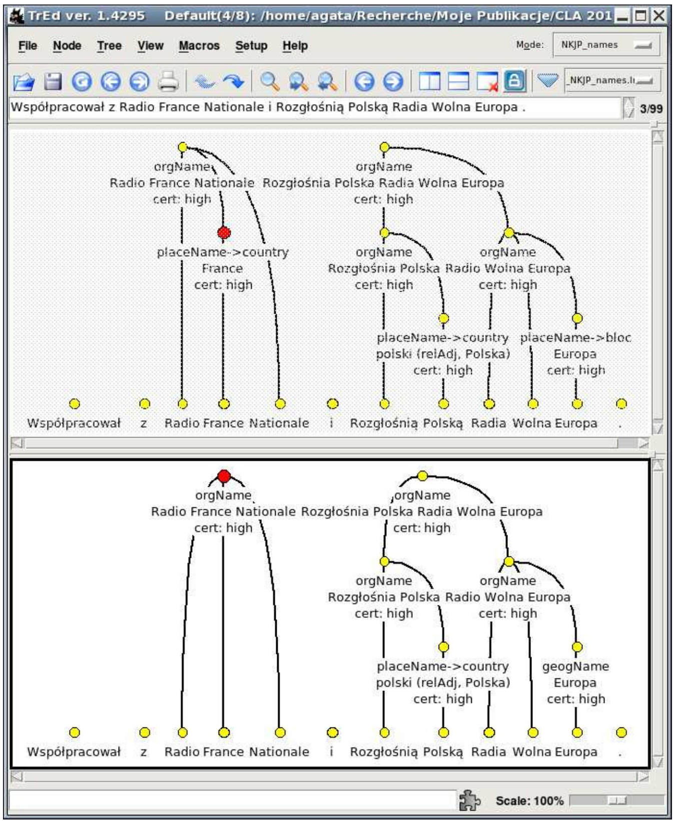
As mentioned above, each text of the gold standard subcorpus is to be annotated at each level by two annotators. Disagreement cases are further reviewed and resolved by an adjudicator (called *super-annotator*), who usually is a person with rich previous experience in annotation at the same level. In order to maximize the objectivity of judgement, the general principle is that: (i) the two annotators of the same text know nothing about each other's results, except what they may learn via the discussion list, (ii) a super-annotator cannot review any portion of the corpus that he or she has previously annotated.

In order for the annotator's work to be most effective, a set of macros and keyboard shortcuts were developed to automatically find discrepancies in two annotations of the same text. Thus, the super-annotator does not review annotations on which the two annotators agree. Another macro exists for an automatic transfer of an annotation between two files. Fig. 5 shows a TrEd screenshot with two NE annotations of the same sentence, containing recursively embedded organisation and location names. The lower window, corresponding to the annotator *a2*, was chosen as the final version of the annotation. However, the upper window, corresponding to the annotator *a1*, contains a node for the country name *France* that hasn't been annotated as a NE by *a2*. The nodes corresponding to this discrepancy are highlighted in red in both windows. By a single keyboard shortcut we can transfer the missing node to the lower window, over node *France* and under node *Radio France Nationale*, so that the remaining nodes remain intact. The automatic detection and transfer of discrepancies act not only on missing or dislocated nodes, but also on a node's attributes. In Fig. 5 the next difference to be highlighted will be the node over *Europa* that has been assigned different types (here *a2* chose the correct type, thus the annotation by *a1* will not be transferred). The same types of macros exist for the revision of disrepancies in annotated SWs and SGs.

C. Managment of Corpus Files

Corpus files management system consists of two main components. The first one is the svn[11] repository, where all files earmarked for annotation are stored. The second element is a textual database (versioned XML file), which contains all information regarding the current state of annotation.

Every annotator has access to his own, private directory in the repository. There he keeps currently annotated files, which he can modify and send back to the `/zakonczone` directory in the subversion repository – target directory for completed files. As a rule, every file will be examined by two different annotators. The annotator does not have the necessary permissions to run all svn operations – he can edit files in the private directory, but cannot add, move or delete files in the repository. The additional functionality – downloading files for annotation and sending off the completed files – is realised by a special `message.txt` file, placed in the private directory. This file works as an interface between the annotator and the subversion server. For example, in order to download five files to his private directory, the annotator has to add the `checkout = 5` line to the `message.txt` file, and run *svn commit* [12] and *svn update* [13] on the directory. The rest of the work – finding appropriate files and moving them throughout repository – is performed on the server side by means of a post-commit subversion hook[14]. Another command, *checkin* (with `checkin = FILE_NAME` syntax), can be used to send annotated files to the `/zakonczone` directory.



TrEd ver. 1.4295 Default(4/8): /home/agata/Recherche/Moje Publikacje/CLA 201

Współpracował z Radio France Nationale i Rozgłośnią Polską Radia Wolna Europa .

Fig. 5. Comparing two NE annotations in TrEd for the same sentence 'He collaborated with Radio France Nationale and the Polish Station of the Free Europe Radio.'

For super-annotation, similar commands, *s_checkout* and *s_checkin*, exist. The *s_checkout* command will download a chosen number of files to compare – every file in two copies, validated by two different annotators. It is guaranteed that the super-annotator will not get files which he has previously seen. The super-annotator corrects one of the downloaded files, using the NKJP_diff TrEd extension to compare it with its second copy (see section V-B), and finally calls *s_checkin* to send corrected version to the `s_zakonczone` directory.

While the `message.txt` file can be modified by the anno-

[11] Version control system, keeps track of changes made in maintained files.

[12] Sends locally modified files to central subversion repository.

[13] Brings changes from repository into local directory.

[14] Process run on server after every `commit` operation.

tator directly, a client-side GUI application – with *[s_]checkout* and *[s_]checkin* functionality – has been developed for annotators' convenience. It fills out the `message.txt` file automatically, thus saving the annotator's effort of editing additional commands manually.

The database – a versioned `db.xml` file – keeps track of every important repository operation. The information about every new file placed in `/nowe` directory is stored automatically in the database. When files are downloaded or sent by an annotator (*[s_]checkout* and *[s_]checkin* operations), his name and the operation date are also saved in the `db.xml` file. There are two main reasons for saving this kind of information in a separate database file. First, it allows to quickly find the information about the current state of the annotation, which is important, e.g., for the implementation of the server-side part of the *[s_]checkout*/*[s_]checkin* operations. Second, it simplifies searching the repository – most of the important information can be obtained from the database, without looking into the repository itself. Extending repository with database brings about the need for additional integrity-preservation mechanism. Atomicity of generic svn operations is guaranteed, but in case of *[s_]checkout*/*[s_]checkin* operations the whole process (commit and post-commit) has to be carried out in one transaction. As a solution to this problem, a FIFO[15] with one element has been set up on the server. Every special operation has to borrow an element from the FIFO in advance (and return it when operation is completed), so two post-commit processes will never modify the repository simultaneously.

To simplify querying the database another tool has been developed. It takes, as command-line arguments, a number of various searching parameters – annotator's name and file name (as regular expressions), file status (checked in or checked out), checkin date range, etc. Another option can be used to extract number of sentences and words from particular files (in this case the tool has to consult the repository, because files statistics are not stored in the database). Additionaly, the tool can be used to find files left for annotation (that is, files which haven't been downloaded by two annotators yet).

D. Project Managment

Multi-level corpus annotation such as in NKJP is a complex and labor-intensive task. To ensure the coherence of annotations, detailed annotation guides have been edited for both tasks, as well as a Frequently Asked Questions list for the NE task. Additionally, NKJP-proper user's guides have been prepared for TrEd and for the svn client tool SVNTortoise[16] used by the annotators. All these documents are regularly updated and diffused via the repository.

Currently, the team working on the two annotation levels consists of three project managers, one programmer, 15 annotators for the syntactic level, and 6 for the named entities. The project managers and the programmer meet on a monthly basis, while communication with the annotators is mainly maintained via discussion lists. The annotation of SWs and SGs seems particularly challenging, as witnessed by the rather rich activity on the corresponding discussion list. During a sample week about 70 messages have been sent to the list containing: (i) mentions of new multi-word entities to be accounted for, (ii) proposals of new grammar rules, (iii) errors on the underlying morphosyntactic level, (iv) various problems with the scope, type and heads of SWs and SGs such as time expressions, fractions, internet and postal addresses, and unexpected syntactic constructions (e.g., *od kiedy* 'since when' is a group of the *preposition-adverb* type, which is not allowed by traditional grammars). The discussion list for NEs mainly receives questions whether a given sequence should or should not be annotated (e.g., names of animals), and doubts about the type and subtype of a NE (e.g., *Palestyna, Kosowo, Arab*).

VI. Links between Two Annotation Levels

Clearly, SGs are tightly connected to NEs. However, as discussed by [24] and [25], a NE does not necessarily precisely coincide with a nominal group. The following types of mutual relations between NEs and SGs were identified in our corpus:

- a NE coincides with a nominal group, e.g., *Stany Zjednoczone* 'United States',
- a NE is a subsequence of a nominal group, e.g., *[ksiądz biskup [Leszek Głódź]$_{persName}$]$_{NG}$* 'priest bishop Leszek Głódź',
- a NE embraces a sequence of SWs and SGs, e.g., *[[Komisja Badań]$_{NG}$ [na Rzecz Rozwoju Gospodarki]$_{PrepNG}$]$_{orgName}$* 'Research Commission for Economical Development'.

A partial overlapping of a NE and a SG seems infeasible, and we plan to detect such problems during the final corpus consistency check.

With the above typology it is clear, on one hand, that a pipelined processing of the annotations on both levels would not be a satisfactory solution. On the other hand, a completely joint processing of both levels seems rather complex, and inconsistent with pre-existing multi-format resources for Polish. Thus, we think that a parallel processing of both annotation levels is a good solution, even if some knowledge must be encoded twice (e.g., some Spejd rules have to cover most frequent types of NEs, described also in more details by the Sprout grammar). We believe that a common project managment of both tasks, enhanced with shared communication means, as described above, helps in assuring the consistence of the annotations.

VII. Present Outcome and Future Work

The annotation on the SW, SG and NE levels is currently at its zenith. Until mid-August, out of about 85,000 sentences of the gold standard subcorpus over 41,000 have been double-annotated for SWs and SGs, and 73,000 for NEs. Thus, 15% through 52% of the corpus remains to be annotated, including particularly demanding extracts of spoken dialogue data. The revision of annotations is done for 14% of the corpus for SWs and SGs, and is just starting for NEs. Moreover,

[15] Named pipe, inter-process communication method.

[16] `http://tortoisesvn.tigris.org`

the whole corpus needs to be revised by super-annotators. Further, the 1 billion-word main corpus will be annotated first with a morphosyntactic tagger trained on the gold standard subcorpus, then with enhanced Spejd and Sprout grammars, finally additional machine learning tools will complete the automatic NE annotation. We are also currently developing the final conversion tool that will allow to obtain the TEI P5-conformant format (cf. [26], [27]) for both annotation levels out of the TrEd PML format.

In future, we expect the NKJP corpus to be used in advanced linguistic corpus studies of Polish, and as a training or evaluation corpus for various linguistic processors such as taggers, parsers, and information retrieval engines.

VIII. Conclusions

We have presented the methodology and the technical environment developed for the annotation tasks in the National Corpus of Polish on three levels: syntactic words and syntactic groups (annotated jointly), as well as named entities. Two rule-based annotation platforms, Spejd and Sprout, are used to automatically pre-annotate the corpus. The Spejd grammar developed within this study and containing currently circa 1063 rules is among the largest chunking grammars for Polish.

An interoperable tree editor TrEd allows for manual correction of annotations by human experts, as well as for the revision of dual annotations by a super-annotator. NKJP-proper extensions, macros, keyboard shortcuts and stylesheets for TrEd enhance the annotator's and super-annotator's workbench. Several XML-to-XML converting tools enable the necessary processing chains between Spejd, Sprout, TrEd and the NKJP TEI P5 conformant encoding standard.

A central versioning repository with custom facilities is responsible for the corpus file managment. We think that its architecture is an interesting alternative to web graphical interfaces used in other annotation projects: (i) it limits the server's charge, (ii) the annotators do not have to rely on constant high-capacity Internet connections – they only connect to the server for down- and uploading the files to be annotated. Here, again, automatic procedures have been developed, such as repository access statistics, automatic creation of file lists, coherence verification, etc. They reduce the annotators' efforts with respect to the manipulated files, facilitate the project management and ensure the security of the corpus.

While the project is still on-going, we think that its solid technical and organisational environment gives it a good chance of success. We also believe that this environment, or substantial parts of it, can be reused or adapted for other annotation tasks.

TREF – TRanslation Enhancement Framework for Japanese-English

Bartholomäus Wloka, Werner Winiwarter

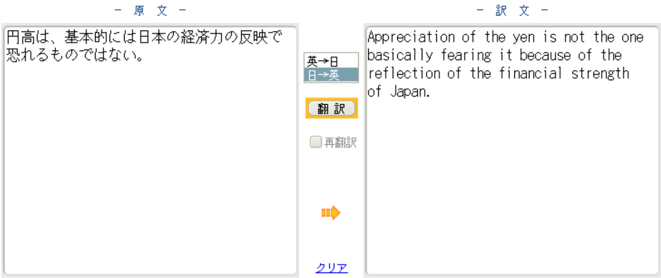
Abstract—**We present a method for improving existing statistical machine translation methods using an knowledge-base compiled from a bilingual corpus as well as sequence alignment and pattern matching techniques from the area of machine learning and bioinformatics. An alignment algorithm identifies similar sentences, which are then used to construct a better word order for the translation. Our preliminary test results indicate a significant improvement of the translation quality.**

Index Terms—**Machine Translation, Syntactical Analysis, Sequence Alignment.**

I. Introduction

MACHINE translation has been an active research area throughout the last 40 years. During this period, many promising concepts were proposed; however, there is still much room for improvement [1]. Especially when translating languages with radically different surface characteristics, as it is the case for Japanese-English, current machine translation techniques tend to produce unsatisfying results. The problems of automated translation between these languages become readily apparent when looking at current Web-based translations, e.g. from `www.excite.co.jp/world/english`, which is shown in Fig. 1. While the translations of short phrases are of reasonable quality, translation systems struggle with long sentences. This is due to the growing complexity of sentences with increasing length and the vast differences in word and subclause order between these langauges. Additionally, the characteristics of the Japanese language pose a great challenge for translation into other languages in general [2], [3]. Those characteristics are:

- two syllabaries and a system of several thousand kanji, i.e. originally Chinese characters with several pronunciations and readings,
- lack of spaces to delimit word boundaries,
- a very high ambiguity in the grammar, as there exist no articles to indicate gender or definiteness,
- the tendency to omit information which can be inferred implicitly,
- sociolinguistic factors, e.g. avoiding direct and decisive expressions for reasons of politeness,
- an extensive system of formality with several levels of politeness forms, honorific expressions, and humble verb forms depending on the social status, relationship and other factors of the people involved.



円高は、基本的には日本の経済力の反映で恐れるものではない。

Appreciation of the yen is not the one basically fearing it because of the reflection of the financial strength of Japan.

Fig. 1. Example of current Web-based machine translation

To overcome those intricacies, we have directed our attention to a new and interdisciplinary approach. We have designed and implemented a method for finding structurally similar sentences with the help of an algorithm usually employed in the field of bioinformatics [4], [5]. The underlying assumption of our approach is that there is a significant overlap between the **structure** of a sentence and its **meaning**. In this paper, we show that it is possible to enhance statistical machine translation results using this assumption. The *TRanslation Enhancement Framework* (TREF) [6] utilizes aligned and clustered sentence pair data to enhance the output of the statistical machine translation system *Moses* [7].

Though trained for the Japanese-English language pair, the system is modular and flexible. An adjustment or extension to other languages is a matter of changing mere implementation details and adding the language-specific resources, such as lexica, parser, corpora, etc. It is important to mention, however, that our translation framework is specifically designed and well-suited for languages with radically different surface characteristics, e.g. European-Asian language pairs.

The rest of this paper is organized as follows: In Sect. II the research relevant to our work is narrated, before we discuss TREF in Sect. III. Section IV presents our evaluation method and the results, followed by a conclusion and future work in Sect. V.

II. Related Work

The ultimate goal of machine translation, i.e. abolishing language barriers, is presented by [8] in an entertaining narration. This ambitious pursuit of a system which will relieve the lingua franca and enable boundless communication between cultures is not quite yet in the realm of the possible. Nonetheless, research efforts towards this goal have been undertaken. In this section, we outline the research relevant to our work.

A. Corpora

A vital resource for machine translation are bilingual corpora. Unfortunately, these are very rare, especially for the

978-83-60810-27-9/09/$25.00 © 2010 IEEE

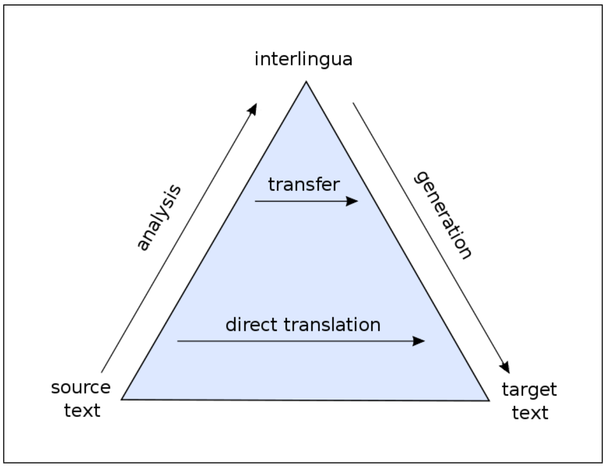


Fig. 2. Translation pyramid

Japanese-English language pair. The currently predominant ones are the *Tanaka corpus* [9], the *Jenaad corpus* [10], and the *Verbmobil treebank* [11]. The Verbmobil treebank contains dialogs from telephone conversations in English, German, Japanese, and other languages, collected during the speech recognition research project of Verbmobil. The Japanese part contains around 160,000 words of text and is written in *Romaji*, i.e. the transcription of Japanese script into Roman literals. The Tanaka corpus consists of roughly 180,000 sentences and has a very broad domain. It has been collected over several years from various sources and compiled by Yasushito Tanaka in 2001. The Jenaad corpus is a collection of close to 150,000 sentence pairs. Extracted from news articles, it offers a certain consistency in terms of sentence types, while still offering a wide range of vocabulary and a variety of grammatical constructs. Because of these qualities, we have chosen the Jenaad corpus for our work. In addition, it is written in Japanese script, thereby avoiding potential ambiguities of the Romaji transcription.

B. Machine Translation

The research in machine translation has ever since included many different approaches. An overview of different techniques can be obtained from [1]. Their visual classification is exemplified by the Vauquois' triangle in Fig. 2 [12]. The historically first method, located at the very top of the triangle, is the *interlingua* approach. It aims towards a language-independent representation, which mediates between two or more languages. In contrast, *statistical machine translation* is at the bottom of the triangle, where no intermediate information is considered in the process, and there is a direct mapping from source to target text, depending on previously trained statistical data. A good overview of this technique can be obtained from [13].

Other approaches, which are also described in more detail in [14], are found somewhere between those two extremes, and the advantage of each depends on the demands of the given language pair. The challenges of translating Japanese to English gave birth to the new idea of *corpus-based* machine translation [15]. Apart from its success in translating between these languages, it further provides the opportunity for enhancing language learning environments by presenting the intermediate steps, i.e. the linguistic analysis of the translation process, to the learner. This was successfully accomplished by [16], [17]. The corpus-based method was quickly adopted by the machine translation community and merged with other techniques, as for example in [18]. Together with the idea of [19], that a mapping of grammatical functions and semantic roles is crucial for the Japanese-English pair, we have decided to mold these ideas into a new approach.

We have chosen a statistical machine translation method for a baseline translation in TREF, since it performs well in terms of translation of individual words and short phrases. It does not adhere to finding transition rules for syntax ordering and therefore leaves a good first candidate for the post-editing done by TREF.

Amongst different tools, we have chosen *Moses*, since it is particularly effective when trained with a sufficiently large bilingual corpus. Moses scores well for structurally similar languages; however, for language pairs like Japanese-English, the word order is disarranged, which significantly lowers the quality of the translation, up to the point where the meaning of the sentence is irrecognizable. Moses does not consider any grammatical rules, so the output is syntactically wrong most of the time. The post-editing and rearranging of the Moses output aims at addressing this problem. Our method finds the correct word order for the translation result and produces a grammatically correct sentence, which conveys the meaning of its English counterpart.

C. Natural Language Processing

To analyze the tokens of our bilingual corpus, we have used the *MontyTagger* from the *MontyLingua* project [20] for English, and *ChaSen* [21] for Japanese. Besides a part-of-speech tagging capability, MontyLingua offers an end-to-end natural language processing toolkit. ChaSen is a high-quality part-of-speech tagger tool for Japanese. Recently, *CaboCha* [22], a Japanese dependency parser, which offers an even wider spectrum of NLP capabilities, has been developed, and we plan to integrate it into TREF in the near future.

D. Sequence Alignment

The Needleman-Wunsch algorithm for computing similarities in protein building blocks, i.e. amino-acid chains, was published in 1970 [23]. Quickly, many derivatives and extensions of this method followed. The basic idea behind this concept was to depict amino-acid chains as strings of alphabetic characters, align them to offer the best match between two strings, and compute a similarity measure [24]. This method was further improved by [25], using a distance measure in conjunction with dynamic programming. Many other research efforts found different distance measures to identify the similarity of sequences. The approach of [26] is generic enough to be extended to the area of machine

translation, therefore we use it in our research effort by treating sentences from a bilingual corpus analogous to the sequence alignment of amino acid chains.

III. TREF

The overview of the architecture of TREF is shown in Fig. 3. The *PoS-Tagger/Formatting* module tokenizes the input sentence and assigns PoS tags in a format which is described below. The sentences in their tokenized format are then aligned with the clustered corpus to find the target structure, which is sent to the *Comparison and Merging* module. This module takes this input as well as the translation from *Moses* and enhances its translational quality applying a template approach. The resulting translation can then be evaluated and added to the corpus. Each step is described in detail in the following subsections.

A. Part-of-Speech Tagging

The input sentence is sent to either one of the *part-of-speech* (PoS) tagger modules MontyTagger [27] or ChaSen [21]. The result of this process can be seen in Fig. 4 and Fig. 5 for Japanese and English respectively. The Japanese sentence is written in Roman transcription for the reader's convenience. The tags produced by ChaSen consist of a sentence token, its *katakana* representation (one of the Japanese syllabaries, which indicates the pronunciation of a kanji), and a numerical representation of the morphological data. The English tags contain the word itself and the PoS tag as an acronym. After each sentence token is assigned a PoS tag, the sentence and its tags are compared with the sentences already stored in a clustered corpus, which is a customized and enriched version of the *Jenaad* Corpus [10]. We have modified it by removing as much noise as possible, assigned PoS tags to each sentence token, and stored them in an SQL database. We have kept the data with all available PoS tags and additionally created a reduced and optimized tag set, which provides a quick access for efficient processing. Other representations and tag sets can be added easily to satisfy different needs in future work.

B. Aligning and Clustering

In order to identify similar sentences, we have used a slightly modified alignment algorithm from bioinformatics. Instead of aligning protein chains, we align chains of words, i.e. sentences. We have applied relational sequence alignment [4], [5] to obtain clusters of structurally similar sentences. The alignment is done according to the Nienhuys-Cheng distance function.

An example of a distance between the tokens of each sentence is shown in Fig. 6. If the token and its PoS tag differ, the distance is 1. In the case of a structural match, the distance is 0.5, and 0 for a perfect match. The subsequent distance calculation of an entire sentence is depicted in Fig. 7. Gaps, which are identified and symbolized with *(g)* in the example, are assigned variable *gap penalties*. In order to achieve better

d(nn(house),nn(house))	= 0
d(nn(house),nn(office))	= 0.5
d(nn(house),dt(the))	= 1

Fig. 6. Distance calculation example

S1	He	went	to	the	store	to	buy	(g)	milk

T2	PRP	VBD	TO	DT	NN	TO	VB	DT	NN
D	0.5	0.5	0	0	0.5	0	0.5	1	0.5

$SentenceDistance$	$\frac{1}{2 \times 9} \times (0.5+0.5+0+0+0.5+0+0.5+1+0.5) = 0.19444$

Fig. 7. Sequence alignment distance calculation example

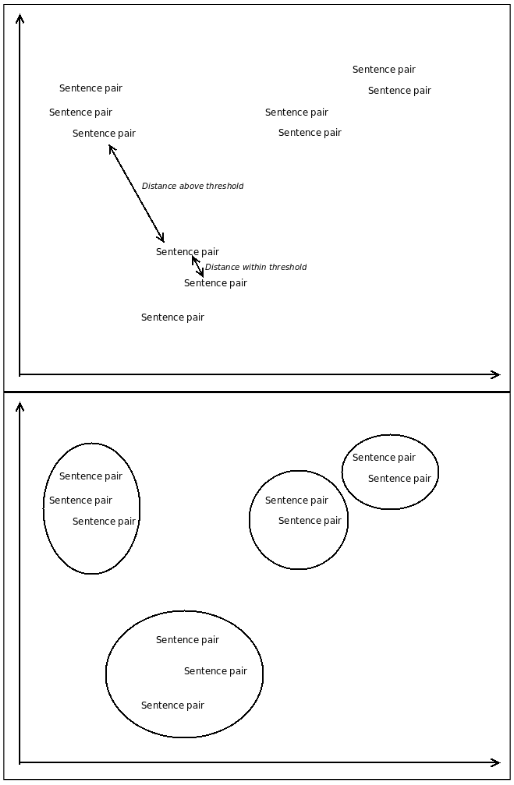

Fig. 8. Clusters in Euclidean space

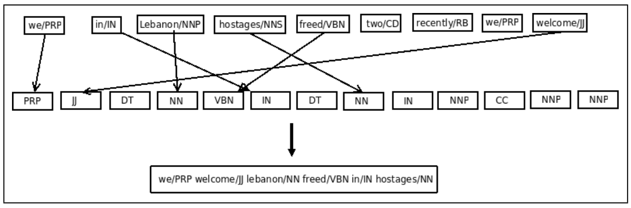

Fig. 9. Matching

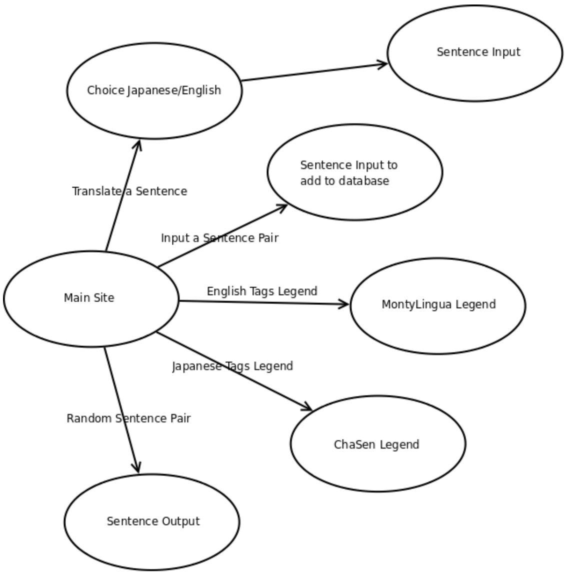

Fig. 10. Structure of the Web framework

matching results, we differentiate between *gap opening* and *gap extension*, which allows us to separate subordinate clauses from otherwise non-matching word sequences.

The similarity measure parameters can be adjusted to fine-tune the result, depending on the text type and text domain. By allowing lower similarity values, a higher number of candidates can be produced, whereas a higher similarity value reduces the number of candidates. This flexibility can be utilized for a language learning application to present an arbitrary amount of similar translations to the student. The output is then evaluated by the user and added to the corpus. Once the distances are computed, clusters can be defined setting a threshold value. This concept is shown in Fig. 8 in a Cartesian coordinate system. Each sentence which has a distance lower than a certain threshold value is assigned to a cluster and is therefore considered *structurally similar* to sentences in this cluster.

C. Comparison and Merging

The comparison of the query sentence with the clusters yields several similar structures. At the same time, the query sentence is processed with Moses to obtain a preliminary translation. This translation is then used to fill the template of the structures which have been found in the previous step. Thereby, a certain number of translation candidates is produced. The filling of the structure templates from the aligning step is shown in Fig. 9. In this example, we use the sentence: “We welcome the progress achieved in the dialog between North and South Korea.” The translation by Moses is: “we in Lebanon hostages freed two recently we welcome”. TREF transforms this by filling the structure template into “we welcome Lebanon freed in hostages”. As can be seen, some tokens are lost in the process of filling the template, which leaves room for future work and potential for further improvement of the translational quality.

D. Web Interface

The clustered corpus of PoS tagged sentence tokens in several representations, as well as morphological information, is stored in a MySQL database and is accessible through a Django Web framework (`http://www.djangoproject.com`). In Django, all interactive content as well as settings, modules, and database setup are written in Python, which made it a good candidate for our system due to its powerful string and text manipulation capabilities. Further, Django provides stable Web development and administrative utilities. In particular, the communication to the database and efficient Web design tools including HTML code inheritance made it an ideal developing environment. The structure of the framework is depicted in Fig. 10. From the main site, the user can navigate to the translation module, the sentence pair input, the random sentence output, as well as legends for the PoS tags for English and Japanese. The translation module offers an interface, which upon input of a sentence sends it to the server and – after the above described translation process – displays the result. The sentence input module takes a sentence pair input, which is flagged as a new addition and is checked manually before being added to the database. The random sentence output is a first step towards the language learning functionality and outputs a sentence from the database including its translation, its tags, and morphological information. We have created a page for the explanation of PoS tags. The translation of the original Japanese ChaSen tags into English is, to the best of our knowledge, the only English ChaSen PoS-tag legend available.

The framework is available on the Web server maintained by the authors under the URL: (`https://wloka.dac.univie.ac.at/project/`).

E. Showcase

Figure 11 shows an example of the workflow from the input of a sentence to an output of several translation candidates. The input ”My name is Yamada.” is tagged and compared with the clustered data. The PoS tags for the sentence in this case are: `My/POP` (personal pronoun), `name/NN` (noun), `is/VBZ` (verb), `Yamada/NNP` (proper noun). The alignment detects sentences in the database, which are similar in terms of words and PoS-tags (see Fig. 6). The translations of the identified structures are also checked for similarities within other clusters. This step, which we call *structure-to-meaning-mapping* identifies other structures of potential translation candidates. These structures are sent to the *matching and translation step*, where the structures and the output from Moses are merged to yield the final output, i.e. the translation candidates.

IV. Evaluation

To create a testing scenario, we have extracted 1000 out of the total 150,000 sentences from the Jenaad corpus. The remaining 149,000 sentences were used as training data for Moses and for clustering. Due to the long processing time for each sentence, we have decided to analyze fewer sentences in detail instead of using standard scoring tools, such as [28] or [29], which would be more significant for larger amounts of output. Morover the validity of automated scoring tools of this kind has been criticized by [14], [30]. Hence our evaluation was done by an expert who judged each translation on four categories: word order, word translations, semantics, and fluency. The categories were equally weighted with a top score of 25 each (see Fig. 12). A total of 40 sample sentences were evaluated, and a statistical significance of the result was verified with a Wilcoxon signed-rank test [31]. The result was a better score for the sentences processed with TREF with a score of W=139 over a sample size of N=34 and a P(1-tail) value of 0.119.

V. Conclusion

In this paper, we have described a design for enhancing state-of-the-art machine translation using sequence alignment from the area of bioinformatics, combined with PoS tagging and clustering of a bilingual corpus. Our results have proven that similarities in sentence structure can be used to create templates for translation candidates, in particular for the Japanese-English language pair. We have described our implementation of the system and its Web framework. We have trained the system with the Jenaad Corpus and tested the system for Japanese-English. The evaluation of the system yielded promising results. At the time of writing, TREF is already integrated in another research project focusing on ubiquitous translation and language learning with the help of mobile devices.

For future work, we plan to optimize the parameters in the aligning process to fine-tune the word reordering as well as adding grammatical parsing steps after the template filling to improve the syntactical correctness of the sentence. An additional dictionary lookup will be integrated to amend word translations, which could not be processed by the statistical translation step.

We want to extend the language learning aspect of the system to offer a Web-based learning platform and improve the efficiency of the entire system with pre-computing and indexing methods. We plan to incorporate a Japanese dependency parser. The currently active research efforts on the Japanese WordNet [32] and CaboCha [22] are promising candidates for an additional extension for TREF as a language learning platform offering extensive semantic and syntactic information as well as visual representations of vocabulary.

***Abstract*—A Web-based system for human evaluation of machine translation is presented in this paper. The system is based on comprehension tests similar to the ones used in Polish *matura* (secondary school-leaving) examinations. The results of preliminary experiments for Polish-English and English-Polish machine translation evaluation are presented and discussed.**

I. Introduction

THE SUCCESS of Statistical Machine Translation, well illustrated by the popularity of Google translation tools, has a positive impact on the development of the whole Machine Translation discipline. This phenomenon brings about the need for comparing the quality of MT tools and systems that keep appearing, both in the academic field and on the commercial market.

In [1] Papineni et al. introduced the BLEU metrics that counts well-translated n-grams (sequences of n words). Improvements of the metrics have been proposed by Doddington [2] (NIST) and Lavie and Agarwal [3] — METEOR. The common feature of those approaches is that evaluation is executed fully automatically, by comparing the text translated by an MT system to the reference translation, prepared by a human.

One of the advantages of automatic evaluation is that it can be used for training. For example, Tenerowicz [4] uses the METEOR metrics in a genetic algorithm that trains the probabilistic grammar used in a parser of the Translatica MT system.

The drawback is its weak correlation with human evaluation. Turian et al. [5] claim that the most popular MT evaluation metrics, BLEU and NIST, fail to correlate well with human judgements of translation quality. In the experiment of Tenerowicz [4], a significant number of translations, improved by the METEOR measure, were estimated as worse translations by linguists.

One of the reasons behind it is the following common feature of automatic evaluation tools: they assign points for parts of sentences, even if the whole sentences are not comprehensible. Points are not assigned for translation adequacy if it is not mirrored by appropriate word strings (although METEOR tries to overcome this drawback by scoring synonyms).

On the other hand, in human simple evaluation (ranking quality of translations or choosing the best one from a given set, when a source sentence is known) evaluators' knowledge of sentence meanings affects the measurement results.

We propose an idea of human evaluation with evaluators being not aware of the source sentence. Evaluators are supposed to give answers to a prepared set of questions, knowing only the target text translated automatically. The evaluation resembles the comprehension test for the Polish *matura* (i.e. secondary school-leaving examination) foreign language exam.

The *Matura* Evaluation obviously measures the comprehensibility of the translated text as well as its adequacy. The latter is achieved by preparing the test questions based solely on the source test.

Please note that our approach does not require evaluators to be native speakers or experts on the target language.

The idea to use comprehension tests for machine translation evaluation is not new [6] [7]. What is new is the use of Web-based application for such purposes.

II. Experiment summary

Matura Evaluation is an experiment for human-based evaluation of machine translation. Its main idea was to compare intelligibility and adequacy of different translations of the same source text, with the correctness of answers being the measurement criteria.

The experiment was performed using two directions of translation between Polish and English. Several source texts were translated by each translation system under test. Source texts came with about 10 questions. Each experiment participant was presented with a random translation of a random text along with a relevant set of questions. The participants were expected to answer these questions using the information provided in the translated text.

It is assumed that if the source text is translated correctly by an MT system, i.e. all the information from the source text can be found also in the translation in an intelligible form, then the participant should easily find the correct answer. On the other hand, if the sentence meaning is changed in

978-83-60810-27-9/09/$25.00 © 2010 IEEE

the translation, the experiment participant obtains the wrong information and, hence, chooses the wrong answer. It is also likely that the relevant information was translated correctly, yet it cannot be inferred from the whole sentence/paragraph where the answer is to be found; or that the translation is difficult to understand. In such a situation the participant is supposed to mark "Translation impossible to understand" as an answer.

III. Texts and Translations Used in the Experiment

Translations were done in two directions between English and Polish. Nine source texts were used in the experiment: five in Polish and four in English. Each of them was translated by each of the three MT systems tested: Google Translate (*http://translate.google.com/*), Kompas (http://www.kompas.info.pl/) and Translatica (http://www.translatica.pl/).

Texts used in the experiment differed in topic and level of difficulty: some of them were supposed to be more specialised (e.g. summary of the *System of Education Act*), other more general (e.g. an article from Wikipedia on *Alice's Adventures in Wonderland*), yet another were parts of literary works (*Little Prince* by A. de Saint-Exupery and *The Deluge* by H. Sienkiewicz). The aim of this diversity was to compare the results for translations of different types of texts. It is well known that it is much more difficult for an MT system (and for human translator as well) to translate literary works than other types of texts, because they contain a large number of metaphors, which cannot be translated literally.

We decided to use real texts, not artificially crafted for the purposes of machine translation evaluation. The following texts were used in the experiment:

1) Polish source texts:
   - article from Wikipedia about the book *Alice's Adventures in Wonderland* (1581 words)
   - part of the first chapter of *The Deluge* by H. Sienkiewicz (2128 words)
   - an article *Aesthetics of the Pythagoreans* (1575 words)
   - summary of the *System of Education Act* (1659 words)
   - an article *Vanishing Venice* (2748 words)
2) English source texts:
   - English translation of the first chapter of *Little Prince* by A. de Saint-Exupery (1753 words)
   - an article about *Greater Poland Uprising* (826 words)
   - an article about the history of St. Patrick's Day celebrations (767 words)
   - an article by Paul Graham *What You Wish, You'd Known* (5083 words)

IV. Questions

Questions were based on the source texts, but written in the target language of the translations. About ten questions based on the source text were prepared in the target language. There were three/four variant answers prepared for each question but only one of them was correct.

Questions were supposed to check if some precise information from the source text had been preserved during translation. Therefore a very specific information was usually expected as an answer to each question.

Various types of questions were prepared for the experiment. Some of them were supposed to check if a word with multiple meanings was translated correctly.

For example, in the text about *St. Patrick's Day* there was a question:
Why did the experiment fail in Savannah?
which the answer to could be found in the following paragraph:
"[...] in 1961, Savannah mayor Tom Woolley had plans for a green river. Due to rough waters on March 17, the experiment failed[...]".
The relevant answer was the correct translation of the word *rough*. There were three answer variants:

- *surowy*
- *szorstki*
- *wzburzony*

All of the answers are different (and, in general, correct) translations of the word *rough* into Polish. However, only the third translation fits the context. It turned out that only one MT system tested (Translatica) translated this word using the correct meaning.

Other questions checked if the meaning of the sentence, possibly with more than one negation word, was not changed (some MT systems have problems with complex negative sentences). It sometimes happens that two negation words, related to two different words in the source text, appear one after another in the translation, thus changing the meaning of the sentence or making it impossible to understand. A sentence from the *System of Education Act* is an example of negation-related problems in translation. The sentence started with the clause *If the child didn't go to nursery school*, which was translated correctly by Kompas and Translatica. However, Google Translate did not manage to translate this sentence correctly. In its translation, the output sentence started with *If the child went to kindergarten*, which totally changed the meaning of the sentence.

Another type of questions was supposed to check the adequacy of translation of compound sentences, especially relative clauses – if the logical relation between parts of the sentences remains the same after translating the source text. However, these relations were usually preserved in translations.

Preparing the questions for such an experiment is quite a challenge, because they should check various aspects of translations. Moreover, it is impossible to check if every sentence is translated correctly. Due to the time limit imposed on the participants, there had to be a limited number of questions to each text. In this experiment we decided that ten questions for each text would be enough to check the general understanding and some chosen specific information.

V. Participants

The *Matura* Evaluation experiment was carried out through the Internet. It was prepared in the form of web application created in Silverlight, so persons taking part in the experiment could access it through the website. Participants were provided with random translations of randomly selected source texts and the corresponding questions. They were supposed to select answers based on the information from the given translation.

The majority of participants taking part in the experiment were students (mainly from the Faculty of Mathematics and Computer Science, but not only). All of them were educated enough to be able to find the correct answer in the text if it was translated clearly and correctly enough. Of course every person has different reading comprehension skills and different deduction abilities, so this experiment should be conducted on a large number of participants for credible and meaningful results. Sometimes it also could happen that the participant knew the answer to the question even without reading the text. It was due to the fact that texts used here were not written for the purpose of this experiment. On the contrary, they consisted of well known fragments of literature works (*The Deluge*, *Little Prince*), articles describing problems which could be known to the participants (Greater Poland Uprising, aesthetic of Pythagoreans etc.). The aim of this experiment was to check the quality of translations, not the knowledge of people taking part in it. Therefore participants were asked to choose answers according to the given text, not their previous knowledge or guesses.

All the participants were Polish native speakers. As the experiment tested the translations between Polish and English in both directions, every participant was supposed to define their English skills prior to its beginning. Texts in English were given only to participants who described their English skills as *good* or *medium*. All the other participants were provided with texts in Polish. Of course the ideal situation would be to give English translations to English native speakers to be sure that if they choose the wrong answer, it is because the text is translated wrongly, and not that the participant's reading comprehension skills in English are too poor. However, we wanted to test how an automatically translated text is perceived by source language native speakers (commercial Polish-English MT systems are usually reviewed in the press or on the Internet by Polish native speakers rather than English native speakers). Therefore, the following solution was used: an additional answer variant was added to each question - *My English skills are not good enough to provide the correct answer to this question*. It was done in order to prevent a participant from guessing the correct answer or choosing the option *translation impossible to understand*, while the translation could be actually quite good but in English too advanced for the participant to understand.

VI. Results of the Experiment

The experiment results are presented in Table I. In the top row of the table the average results (i.e. the percentage of correct answers) obtained by each of the tested MT systems are displayed. As we can observe, all the systems received quite high rates: from 65.45% up to 74.81%. From these figures we can deduce that the translations produced were generally quite understandable, because in average every participant was able to answer correctly about six – seven questions out of ten. This result is quite optimistic, because it implies that an average translation was in about 70% understandable and adequate in reference to its source text.

All the average results presented in Table I are counted using weighted arithmetic mean. Weights depend on a number of times a specific translation was used in the experiment (as mentioned before, translations and texts were chosen randomly for each experiment). Table II indicates how many times each translation of each text was used in the experiment.

When we compare the results obtained by each of the MT systems in both directions of the translations tested in this experiment, we can notice quite a difference. Generally translations from Polish into English received higher marks than translations in the opposite direction. This is even more interesting if we keep in mind that all the experiment participants were Polish native speakers and, hence, able to better understand texts written in their mother tongue, Polish, even after translation. However, the assumption turned out to be false. Polish translations were not only more difficult to understand then the English translations, but texts translated into Polish more often contained wrong information. This could be because English is more difficult to parse than Polish and Polish is more difficult to synthesise than English (because of complex morphosyntactic agreements) and therefore it is more difficult for an MT system to generate a correct and understandable sentence in Polish than in English.

VII. Result Analysis

The interesting fact is that for some texts translation results differ significantly between MT systems. The most essential difference can be observed between the translations into Polish, e.g. Polish translation of *Greater Poland Uprising* translated by Google Translate obtained 73.33% (the best score for translation of this text), while the same text translated by Translatica received an average mark of 33.33%. Quite the opposite results were obtained by these MT systems as far as translation of the article about *St. Patrick's Day* is concerned: Google Translate received the lowest mark for this translation: 37.50%, while Translatica 84.00%. These both results are quite objective, because the translations mentioned above were used in almost the same number of experiments: translation of *Greater Poland Uprising* by Google Translate: 5 times, by Translatica: 6; translation of *St. Patrick's Day* by Google Translate: 4 times, the same amount by Translatica. Translation from Polish into English did not differ so significantly. The largest differences in marks occurred in translation of the most specialised text – *System of Education Act*. Again Translatica translated it in the best way, obtaining 89.47% score, while Google Translate only 66.67%. However, these results cannot be compared in a very credible way, because translation by

Translatica was used 6 times in the experiment, while the translation by Google Translate only 3.

If we want to go deeper in our analysis, we can compare the number of wrong answers which were given to each question after reading translations generated by each MT system. There were two types of answers considered as "wrong": an answer which was not the correct one and an answer saying that *translation is impossible to understand*. The number of such answers was counted for each text and for each translation separately. The most interesting were situations in which one question was answered almost always correctly when using one translation, and the wrong answer was provided based on another translation. Usually it implied that the translation of the paragraph/sentence with information needed to answer the question was much worse in the second case.

An example question with sentences from different translations to illustrate such a situation comes from the article about *Alice's Adventures in Wonderland*. Question no. 8 was not answered correctly by anyone using translation by Google Translate, and it was answered correctly by 3 out of 4 participants using the translation created by Kompas:

Question 8: Who was the author of the first [Polish] translation closest in meaning to the original text?

- *Chuck Connors (1965) – The first translation in line with the original (Google Translate)*
- *Maciej Słomczyński (1965) – the first translation corresponding to the original (Kompas)*

Correct answer to this question is "Maciej Słomczyński". Of course no one reading translation by Google Translate would be able to answer this question correctly because of changed name (*Maciej Słomczyński* was translated into *Chuck Connors*).

Another interesting example comes from the second chapter of *Little Prince* and a question *Over how many parts of the world did the author fly?* All the participants reading this text translated by Google Translate (5 persons) gave the wrong answer, and all the participants using translation made by Translatica (6 persons) answered correctly. The assumption that something was wrong with the translation of Google turned out to be correct. The original sentence *I have flown a little over all parts of the world* was translated by Google into *Mam lotu mało w stosunku do wszystkich części świata*, what gives the wrong understanding that the author has flown *not much*.

VIII. Conclusions

The experiment called *Matura Evaluation* turns out to be a good method of human-based evaluation of machine translation. Results obtained in this experiment show the correspondence with the quality of translations. However, such an experiment has to fulfil some requirements for its results to be credible. First of all, a large number of participants must take part in the experiment. Moreover, all tested translations should be used by similar number of participants. There are also some requirements regarding the experiment preparation: the texts should be correctly selected, different in style and difficulty to enable the comparison of translations of different types of texts.The questions should be clear, prepared based only on source texts for the results of experiment to be objective. All answers should be easy to find in the source text (and, in consequence, in the correct translations), because this experiment does not check the participants' reading comprehension skills, but the quality of translation.

German subordinate clause word order in dialogue-based CALL

Magdalena Wolska, Sabrina Wilske
Computational Linguistics,
Saarland University,
Saarbrücken, Germany
{magda,sw}@coli.uni-saarland.de

***Abstract*—We present a dialogue system for exercising the German subordinate clause word order. The pedagogical methodology we adopt is based on focused tasks: the targeted linguistic structure is embedded in a naturalistic scenario, "Making appointments", in which the structure can be plausibly elicited. We report on the system we built and an experimental methodology which we use in order to investigate whether the computer-based conversational focused task we designed promotes acquisition of the form. Our goal is two-fold: First, learners should improve their overall communicative skills in the task scenario and, second, they should improve their mastery of the structure. In this paper, we present a methodology for evaluating learners' progress on the latter.**

I. Motivation

VERBAL communication in a foreign language, actual interaction, is for the language learner the ultimate site of language acquisition. Dialogue is a source of naturally occurring comprehensible input as well as useful negative feedback, reformulations or clarification questions, which may arise from communication problems and which draws attention to correct forms. What is crucial is that dialogue is an opportunity for learners to *produce language* as well as to *modify* their language in response to feedback. All these aspects of conversational interaction have been shown to promote learning [1], [2], [3], [4].

The communicative approch to language teaching advocates the use of goal-oriented realistic communicative activities, *tasks*, in the foreign language classroom, in order to encourage learners to use their developing language [5]. Important definitional characteristics of tasks are: focus on meaning, well defined communicative outcome, and free use of linguistic forms. If a specific grammatical structure is the target of instruction, the latter property of tasks turns out problematic: because learners are free to use any forms they want, it cannot be guaranteed that they will use the forms of interest. To remedy this, *focused tasks*, encouraging the use and processing of specific linguistic features, have been proposed [5]. Focused tasks combine focus on forms with the communicative approach to instruction by, among others, exploiting scenarios which are likely to elicit the structures of interest in an unobtrusive way, promoting thereby their incidental acquisition.

In this paper we report on a system we built and an experimental method designed to find out whether *computer-based* conversational focused tasks also promote acquisition of forms. The structure we targeted was the German word order in subordinate clauses. The goal of the computer-based communicative task was two-fold: On the one hand, learners should improve their overall communicative skills in the task scenario and, on the other hand, they should expand their mastery of the target structure. We have conducted a preliminary small-scale experiment with the system we built in order to assess the feasibility of an in-classroom evaluation. The learning gains results we have observed so far have, however, *not* been statistically significant. In this paper we concentrate on the system itself and the evaluation methodology in general.

The idea of computer-based dialogue activites for foreign langauge learning is not new: computer assisted language learning (CALL) has been an active research field for many years. With the progress in language technology, the number of intelligent CALL systems which allow learners to use natural dialogue has been growing. The study we present is at the intersection of two fields that are intuitively close: second language acquisition (SLA) and Natural Language Processing-enhanced CALL.

A CALL system can be evaluated in terms of learning gains it generates [6], [7], in terms of its usability (How did learners enjoy playing with the system? [8], [9], [10]) or its performance from an engineering perspective (Did it fail? [11]). We built a CALL system which implements two established SLA methodologies (focused tasks and conversational interaction) and attempt to evaluate whether iteracting with the system produces learning gain.

Outline The paper is organized as follows: In Section II we introduce the linguistic form of interest and the task scenario. In Section III we present two language learning activities we designed. The architecture of the system is outlined in Section IV. In Section V we summarise the setup of an experiment and the results. Section VI concludes the paper.

II. The target form and the task

For the focused communicative activity we selected a grammatical form and a task with the following considerations in mind: Firstly, we wanted a "non-trivial", demanding structure, i.e. a structure of certain complexity, one which is not aquired at the first stages of learning German. Secondly, a structure for

which we could find a scenario in which it is natural to use, so that we can create incidental opportunites for the learner to produce it. Thirdly, it has enough distinguishing features to be easily tested in a controlled experiment. Finally, in line with task-based teaching, we wanted a meaningful, realistic scenario and communicative task, useful for the learner.

Given the above criteria we opted to focus on the German word order in causal subordinate clauses and framed the usage of these structures in the context of a "Making appointments" scenario. We introduce the two parameters below.

A. *Form: Subordinate clauses*

Subordinate clauses are clauses that are dependent on another clause (main or subordinate). In German, subordinate clauses are characterized by a specific word order: the position of the finite verb in a subordinate clause is at the end of the clause. This position is obligatory. The canonical placement of the finite verb in the main clause is at the second position.

One of the subordinate clause types is an adverbial clause in which the subordinate clause, taking the function of an adverbial, qualifies the action expressed in the main clause by supplying additional information. An example of an adverbial clause is the causal clause which provides the reason for what is said in the main clause.

Examples (1) and (2) below show a causal clause introduced by the subordinating conjunction *weil* (Eng.: because) in the verb-final position and of a single main clause in which the finite verb **muss** is in second position:

(1) . . . weil ich arbeiten **muss**.
because I work-inf must-fin.
'because I have to work'

(2) Ich **muss** arbeiten.
I must-fin work-inf
'I have to work'

The specific word order of subordinate clauses is problematic for learners and it has been shown that it is the last to be acquired by children and adult learners of German [12].

While subordinate clauses are a useful means to structure content and express relations between different propositions, they are used much less in oral communication than in written text. The proportion of subordinate clauses of all clauses ranges from 0.25 to 0.12 in corpora of spoken language, while it is 0.5 in written language [13],[14],[15], as cited by [16]. A possible reason for this dispreference is that subordinate clauses are more complex and thus require more effort to process, which is harder in spontaneous interaction.

B. *Task: Making an appointment*

In order to elicit causal clauses, we created a task in which the learner had to refuse a proposal and, for pragmatic, politeness considerations (a dispreferred second [17]) would likely provide a reason for the refusal.

The scenario in which we embed the focus on subordinate clauses is about arranging a meeting. The task for the learner is to make an appointment given a set of constraints on the available times: the learner is provided with a schedule with a set of occupied and free slots, as illustrated on the left side of Figure 1, and activites planned in the occupied slots (i.e. the reasons for refusals).[1]

[1] The agenda also includes conditionally busy slots, marked with *wenn* (Eng.: if) which can optionally serve to elicit conditional subordinate clauses characterised by the same verb-final word order.

```

else
  output 'Sorry, I didn't understand.'
```

Fig. 2. Dialogue strategy in the free production activity

The system would propose appointment times known to be occupied on the learner's schedule, thus expecting the learner to refuse the proposal and give a reason. However, keeping in mind that it is not obligatory to provide the reason at all and that a subordinate causal clause is an optional construction, in one of the activites we designed (described below) the system-side of the dialogue was modelled in such a way that it provided examples of the clauses of interest by embedding them in reformulation/paraphrasing utterances and giving them an appearance of implicit confirmation moves.

III. Task-based Activities

We designed and implemented two variants of a role-play type activity framed within the scenario described above: In both variants it involved a *type-written* dialogue with the system we built, with a goal of making an appointment. The system controls the interaction by means of a state-based dialogue model and explicitly implements form-focusing mechanisms: in one variant, this is done as part of the dialogue model, while in the other, by restricting the input mode.

The dialogue model encodes subdialogues which serve to *elicit the target forms* and it *provides feedback on forms* in case of learner form errors. The two variants of the activity differ in the extent of freedom of language production they offer and the realisation of form-focused feedback: one variant allows learners to freely formulate their dialogue contributions (free production) and provides implicit corrective feedback, while in the other learners are asked to produce only the target forms (constrained production) and the feedback merely informs whether the supplied form was correct. We elaborate on the properties of the respective system variants below.

A. Free language production

In the free-production system, the learner is able to type their utterances freely without any restrictions on the language used. The system implements two input interpretation strategies: one based on a grammar with mal-rules, and a fall-back strategy based on keyword matching; details follow in Section IV. It classifies the learner's input into one of the three categories ("TF" stands for "target form"): TF-realized-correct, TF-realized-incorrect, TF-not-realized. The high-level dialogue and feedback strategy is summarised as pseudo-code in Figure 2.[2]

The system provides implicit feedback in case of learner errors in the TF by reformulating (*recasting*) the learner's utterance (or parts thereof). Recasts are realised in a way so as to give them an appearance of implicit confirmation type of grounding moves, as in **S1**, below, which corrects the error made in **L1**:

(3) **L1:** *Nein, ich kann nicht, weil ich muss arbeiten.
'No, I can't because I have to work.'
S1: Ah, du kannst nicht, weil du arbeiten musst.
'Ah, you can't because you have to work.'

The dialogue model encodes three strategies of eliciting causal clauses if the learner does not use them spontaneously: (**A**) If the learner gives a reason for refusal, but does not produce a subordinate clause the system will recast the refusal into a subordinate clause and put emphasis on the conjunction **weil** by setting it in bold face as illustrated below:

(4) **L2:** Nein, ich kann nicht, ich muss arbeiten.
'No, I can't, I have to work.'
S2: Ah, du kannst nicht, **weil** du arbeiten musst.
'Ah, you can't **because** you have to work.'

(**B**) If the learner fails to give a reason in their refusal the system will ask for one explicitly:

(5) **L3:** Nein, am Montag um 15 Uhr kann ich nicht.
'No, I can't make it on Monday at 3.'
S3: Warum kannst du denn nicht?
'Why can't you make it?'

(**C**) In order to present an example of a causal clause not as part of a recast, but as an original refusal-reason pair the system will refuse any learner-initiated proposal with a reason formulated as a causal clause. If the learner does not initiate a proposal the system will try to elicit one by asking the learner what day and time would suit them.

B. Constrained production

In the constrained system the learner's production is restricted to supplying the target form by putting a set of words in the correct order creating a dialogue turn in this way. The words are given in a random order, as in the example below:

(6) **S4:** Kannst du am Montag um 10 Uhr?
'Are you available on Monday at 10am?'
L4: Nein, ich kann nicht, weil ($\boxed{\text{arbeiten}}$ $\boxed{\text{muss}}$ $\boxed{\text{ich}}$)
'No, I can't because I have to work.'

The learner is allowed three attempts to produce the correct form. In case an invalid form is supplied, the system signals it with a message 'That was wrong!' and subtracts one point

[2] We omit some system turns signalling non-undertanding due to unknown words to simplify the presentation.

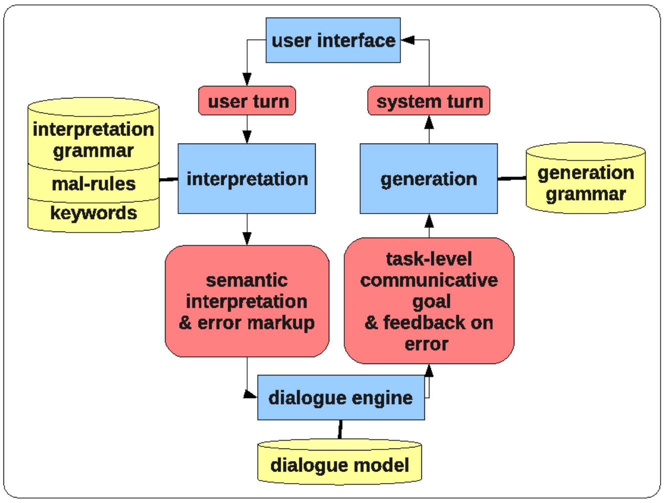

Fig. 3. The system architecture

from a learner's "score" on the activity; correct forms increase the score by one. The feedback and the score are displayed in a designated feedback area. After the third unsuccessful attempt the correct utterance is appended to the dialogue. The system then generates its next turn based on the dialogue model.

The following section summarizes the architecture and the implementation of the system.

IV. The system

Both dialogue activities are implemented on the same system architecture; we concentrate on the components required for the free production activity because the constrained production activity is its simplified variant.

The system maintains a dialogue with the learner by following a dialogue strategy outlined in Section III (see Figure 2). This involves interpreting the learner's input, responding to the learner by selecting a communicative goal according to the dialogue model and the paedagogical strategy, and realizing the goal as a surface string. Specifically for the learning context, the system has to recognize errors in the learner input and generate feedback on them.

Figure 3 shows the system's architecture: the modules and the flow of information between them. We describe each of the functions below.

A. *The task and dialogue model and the dialogue engine*

The dialogue model represents the sets of possible turn transitions: alternating turns produced by the user and the the system. Task-related parameters, the information about the slots in the time-table, are encoded in an external data structure which is imported into the dialogue model.

The dialogue model is implemented as a state machine using State Chart XML (SCXML) as an underlying representation. We use the Java implementation of Apache SCXML.[3] The framework also provides a dialogue execution engine which receives input interpretations and triggers the system responses according to the given model.

B. *Interpretion of learner's input*

In general, interpreting the user input involves mapping a surface string of an utterance to a meaning representation. As typical in small-scale dialogue systems, we implement the system's language model (the set of linguistic expressions) as a context free grammar with semantic tags. For parsing, we use the Java Speech API implementation of the CMU parser which is part of the Sphinx system.[4] The semantic tags encode two types of information: first, the symbolic meaning of utterances, and second, information on violations of grammatical constraints; more on error handling below.

1) Fuzzy matching for unknown words: In order to ensure robustness with respect to typos and spelling errors the system first identifies unknown words in the input and tries to map them to known words by calculating the Levenshtein distance between the unknown word and known words. Candidates for replacement of out-of-vocabulary words are those known words which have a Levenshtein distance within a certain range normalized by word length.

2) Grammatical error handling: Since the system interacts with learners, i.e. non-native speakers of German, their input is likely to contain other errors apart from misspellings, in particular errors in the target structure. An essential requirement of the system is to recognize those errors and give feedback on them. One strategy to deal with errors is to explicitly integrate anticipated errors into the grammar in the form of so called mal-rules, i.e. grammar productions which are outside of the standard rules of the given language. Erroneous utterances are parsed using mal-rules and the parse result contains information about the error.

The drawback of this approach is that it is hard to anticipate all possible errors that might occur. Therefore, our system also implements a fall-back strategy based on keyword spotting: If no parse is found for an utterance, we create a semantic interpretation based on content words, using a keyword lexicon. We encoded a set of mal-rules based on informal prior pre-testing of the system with beginner learners.

C. *Generation of system responses*

The system output realization is performed using a template-based approach. The output is produced by generating a dialogue move selected according to the dialogue model using a context free generation grammar. The grammar associates atomic keys representing communicative goals with sets of possible realizations. Slots in the generation templates are filled using feature-value pairs passed as arguments to the templates along with the communicative goals to be realized.

D. *User interface*

The user interface is implemented as a Java applet embedded in a website. The applet displays the task material,

[3] http://commons.apache.org/scxml

[4] Available at http://cmusphinx.sourceforge.net

an input field for learner, the dialogue history and additional buttons for editing the input utterances and selecting specific tasks. Figure 1 shows the graphical interface including the task-material (the agenda; left) and a part of a dialogue history (upper right) with an example of a system recast (as in (3)) and of an elicitation strategy (as in (5)).

V. Evaluation

In this section we present an evaluation methodology which we use to evaluate learning gains produced by the system variants discussed above. The evaluation is based on in-classroom activities with the system we built.

We have conducted a preliminary small-scale experiment using the experimental design introduced below, however, the results we have obtained so far have not been statistically significant. Therefore, we present the current results only very briefly in Section V-B.

A. Methodology

Design The experimental design we use is a nonrandomized pretest multiple-posttest design involving students from German language classes at the university, taught by different teachers. The classes are split randomly into two sub-groups: one assigned to the free production condition, and the other to the constrained production condition. We are interested in two questions: 1) whether the interactive activities produce learning gains, and 2) whether the free production condition, which requires more computational effort (e.g. in interpreting the learners' turns), produces more gains than the activity in which the learners' production is restricted.

Procedure At the first session, time 1., both groups complete a pretest, then interact with one of the system variants (repeating the exercise twice), and subsequently complete an immediate post-test (posttest1). At the next session a week later, time 2., the groups again perform an in-classroom exercise with the system in a different configuration of the schedule and complete another post-test at the end of the session (posttest2). Finally, time 3., after a couple of week's break (five weeks in the pilot study) the groups complete another post-test (delayed posttest).

After the second session the participants fill out a demographic/learning history survey (anonymous) and a feedback questionnaire on the interaction with the system; we ask about the usability, usefulness, interest in future use, etc.

We provide two different variants of the task for each participant. The basic scenario frame, a weekly time schedule, is kept, but the character of the system is changed: In the first variant, the system takes the persona of a fellow student, whereas in the second it is introduced as a learner's supervisor. The motivation for the latter is that an interaction with a superior might produce behaviour which more closely conforms to the politeness norms, in this case, providing reasons for declining a proposal and hence also the target forms. Also the set of days and times which the system proposes is different for each exercise. In the first repetition of the activity, the system makes 5 different proposals, for the second it makes 4 proposals, thus we expect 9 uses of causal subordinate clauses according to our dialogue script.

Tests We use two types of assessment tests: a timed grammaticality judgment test, targeting implicit knowledge, and an untimed sentence construction test, targeting explicit knowledge. Implicit knowledge refers to knowledge accessible through automatic processing and which learners are intuitively aware of, while explicit knowledge is knowledge accessible through controlled processing [18].[5]

a) Timed grammaticality judgment: Following Ellis [19] we designed a timed grammaticality judgment test to measure implicit knowledge. The test items include causal subordinate clauses of different complexity. The complexity varies as to the amount of additional material present in the clause, e.g. objects, modal verbs, negations or additional modifiers.

The test consists of 6 grammatical, 6 ungrammatical test items and 9 grammatical and 9 ungrammatical distractor items, including a subset of other subordinate clauses. We set the time-limit for the test to 10 seconds per item. This is roughly twice the maximum time a native speaker used. Ellis timed his test at 20% above the average time native speakers needed [19]. Han and Ellis used 3.5 seconds as the time constraint in [20] based on pretesting the items, while Bialystok used an even shorter time limit [21]. Based on our own pretest with native speakers, we performed, already the threshold of 3.5 seconds would have excluded a couple of slow native speakers. Since we are not aware of research which explicitly addresses the issue of the time limit on the timed judgement tasks, we opt for a more generous time-limit.

Each correctly judged item is scored at 1 point, each incorrectly judged item is scored at 0.

b) Sentence construction: For the explicit knowledge test, participants are asked to complete sentences given the beginning of a sentence and a set of unordered uninflected phrases or words as in the example below:

Item: Ich kann nicht (weil, arbeiten, müssen, ich)
Solution: Ich kann nicht, weil ich arbeiten muss.
'I can't because I have to work.'

The test consists of 6 test items for causal conditional clauses. There is no time-limit. The items are scored at 1 point if the word order is correct, 0 otherwise. All form errors other than those in the target structure are neglected.

We created four versions of the tests described above to be administered at the four times of assessment (pretest, posttest1, postest2, delayed postest). The versions differ in the combinations of lexemes, but are otherwise comparable with regard to complexity of the lexical items used. The assignment of a test version to a time varies between participants in order to compensate for unintended differences between versions. Within each test, items are presented in random order.

[5] The tests are prepared and administered using Webexp Experimental Software (`http://www.hcrc.ed.ac.uk/web_exp/`).

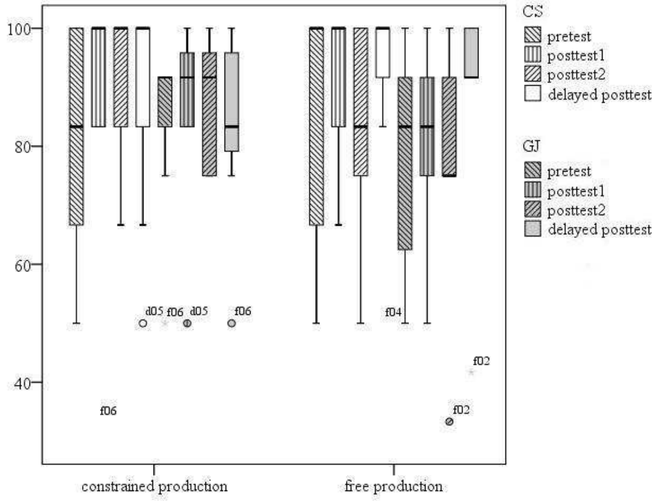

Fig. 4. Overall results for sentence construction (SC; white) and grammaticality judgement (GJ; gray) for both conditions

NUMERICAL RESULTS OF THE TIMED GRAMMATICALITY JUDGMENT TEST: MEANS AND STANDARD DEVIATIONS FOR PERCENTAGE SCORES

		Pretest		Posttest 1		Posttest 2		Delayed Posttest	
	N	M	SD	M	SD	M	SD	M	SD
Percentage scores Constrained	7	83.33	15.96	85.71	17.16	86.90	11.64	83.33	17.35
Free	7	77.38	19.07	80.95	17.16	77.38	22.42	88.10	20.89

B. Pilot experiment

We conducted a small-scale experiment, using the setup described above, in order to assess the feasibility of an in-classroom evaluation and in order to get an impression of whether the learners benefit from the system(s). As we had mentioned earlier the results we have obtained so far have *not* been statistically significant in neither of the groups, however, the usability questionnaires and the feedback we got from the participants of the study encourage us to pursue the free-form exercises further. We are therefore planning to conduct another analogous experiment in the coming fall semester, however, we will invite learners from German courses at a lower proficiency level than the groups we had access to for the pilot study. Below, we briefly outline the current results.

Participants For the pilot experiment we had access to 26 learners from two German language courses. The participants came from different language backgrounds, were both male and female, with an average age of 25 years, and had been learning German for an average of about two years prior to experiment.[6] The courses met twice a week for 90 minute sessions. The experiment started 6 weeks (ca. 15 instruction hours) into the course.

The subjects participated in two sessions of in-classroom exercises with one of the system variants with one week's break between the sessions. Each session consisted of at least two repetitions of the activity in different configurations of the task material (the time schedule) as described in Section II. To complete the activity the participants took between 5 and 25 minutes in the free condition and between ca. 2 and 10 minutes in the constrained condition.

With the experiment spanning over a few weeks, subject drop-out was inevitable. Due to a high course drop-out rate (42%), at this point we have data for only 15 subjects for all the four assessment points for both tests: 7 subjects in the free production condition and 8 in the constrained production. We removed a set of data for one subject in the constrained condition who obtained full scores at all the assessment points obtaining a data set with two groups of 7 subjects.

Analysis Because of the small sample size and because of the violation of parametric assumptions[7] we perform non-parametric analyses: in order to compare within subject differences we use the Friedman test.[8] For between groups comparisons we use the Mann-Whitney U test. We set the significance level at 0.05.

Results and discussion The overall results are shown in Figure 4. Because of the small sample size, the skewed distribution of scores (as seen in the figure) we cannot draw any ultimate conclusions: In both groups the repeated measures statistic turned out to be not significant. The reason for this is likely to be the fact that both of our groups started off with relatively high scores. There was no significant between-group difference on the pretest, according to Mann-Whitney U test, i.e. the groups started off at the same level. However, this pretest level was at an average of 81% and 83% of the total scores on the sentence construction test in the constrained and free production condition respectively, and 83% and 77% in the free production. That is, the subjects were perhaps too familiar with the target structure.

Table I and Table II show the percentage scores' means and standard deviations for the pretest, posttest1, posttest2, and delayed posttest for the *sentence construction test* and the *grammaticality judgement test*. The general pattern in the scores on both tests is the same: Both groups increased accuracy in the use of subordinate clause word order from pretest to posttest1, however, while the constrained production group further increased between posttest1 and posttest2, the

[6] Their German proficiency level was classified as ranging from A2 to B1+ CEF level, based on scores on an initial course placement test.

[7] According to Shapiro-Wilk and Levene tests both the normality assumption and the assumption of homogeneity of variance were violated on at least some of the within-subject and/or between-subject variables on either tests in the pilot study.

[8] Since we did not obtain a statistically significant result, we did not perform post doc tests at this time.

free production group declined. The accuracy then declined between posttest2 and delayed posttest in the constrained condition, but improved in the free production condition. As mentioned above, these differences were, however, not statistically significant at the level we had set. Neither were the differences in between-group comparisons of the scores. Some of the differences were, however, marginally significant at a more liberal level of 0.1.

As mentioned at the beginning of this section, we do not draw ultimate conclusions as to the learning gains based on the pilot study results. We believe that the experiment is definitely worth re-running in a course at a lower proficiency level than the one we were working with at this time. We are planning such an experiment for the coming fall. The free production system was rated significantly higher on the questionnaire than the constrained production system and some of the lower scoring learners did declare that they would like to use such a system for at-home exercises, were it available.

VI. Conclusion

We presented an architecture of a dialogue system for interactive computer-based exercises for the German subordinate clause word order. The exercises are designed based on an established communicative-teaching methodology of focused tasks. The system implemets elicitation mechanisms which cue the learner on using the target structure of interest. In one exercise variant the target structures are ellicited in an unobtrusive way, while the other exercise has more of a drill-like character. We also presented an evaluation methodology for assessing learning gains upon interaction with the system.

While our small-scale pilot study was not conclusive, we believe our appoach is worth pursuing further based on encouraging feedback from the participants of the pilot study. One conclusion we might perhaps draw is that the exercise mode we propose is more suitable at an earlier stage of acquisition of the form we target, i.e. around the time when the learners are first introduced to the subordinate clause word order, rather than being familiar with it already. However, we would certainly need another experiment to confirm this and we do intend to conduct a larger scale study using the methodology we described.

Based on the same architecture and a modified implementation, we also built another dialogue activity for exercising the German locative use of the Dative case, framed in a "Directions giving" scenario. In an analogous pilot study, using the same evaluation methodology as described in Section V, we found significant improvement in the use of Dative upon exercising with our system [22].

Acknowledgements

We would like to thank Dr. Kristin Stezano Cotelo and Meike van Hoorn, language instructors at the German courses of the International Office at the Saarland University, as well as their students who participated in the experiments, for the help in conducting this study.

***Abstract*—The phonemic statistics were collected from several large Polish corpora. The paper presents methodology of the acquisition process, summarisation of the data and some phenomena in the statistics. Triphone statistics apply context-dependent speech units which have an important role in speech technologies. The phonemic alphabet for Polish, SAMPA, and methods of providing phonemic transcriptions are described with detailed comments.**

***Index Terms*—Natural language processing, triphone statistics, speech processing, automatic speech recognition, Polish**

I. Introduction

The paper describes processing of linguistic data and constructing the statistics of Polish phone system by analysing large amount of text corpora using Cyfronet high performance computer cluster. There is a trade-off of quality of such statistics and time spent on calculations. The high performance computers enable obtaining the linguistic rules from the vast number of texts in reasonable time.

Statistical linguistics at the phone, word and sentence level are under considerations for several languages [2], [4], [9], [1]. The frequency of phonetic units appearance can be used in several speech processing applications, for example modelling in automatic speech recognition (ASR). Models of triphones which are not present in a training corpus of a speech recogniser can be prepared using phonetic decision trees [11]. The list of possible triphones has to be provided for a particular language along with phones' categorisation. The triphone statistics can also be used to generate hypotheses used in recognition of out-of-dictionary words including proper names or to provide additional probabilities in speech modelling (Fig. 1).

Some similar statistics collected from a few large corpora: Rzeczpospolita corpus (containing articles from a newspaper) [13], literature corpus [12] and Wikipedia corpus [14] (over 250 000 000 words) have been already presented. However, a space was included in the list of phones in the previous publications. This was not necessarily a good decision because coarticulation happens between words as well. The process of speaking combines toegether several words and the borders between words are often indistinguishable on phonetic level.

Context-dependent modelling can significantly improve speech recognition quality. Each phone varies slightly depending on neighbouring phones due to a natural phenomena of coarticulation. There are no strict boundaries between phones because they overlap each other. It results in interference of acoustic properties. Speech recognisers based on triphone models rather than phone ones are much more complex but give better results [10]. Let us introduce examples of different ways of transcribing word *zero*. The phone model would be *z e r o* while the triphone one is **-z+e z-e+r e-r+o e-r+**. In case a specific triphone is not present, it can be replaced by a phonetically similar triphone (phones of the same phonetic group interfere in a similar way with their neighbours) using phonetic decision trees [11] or biphones (applying only left or right context) [8].

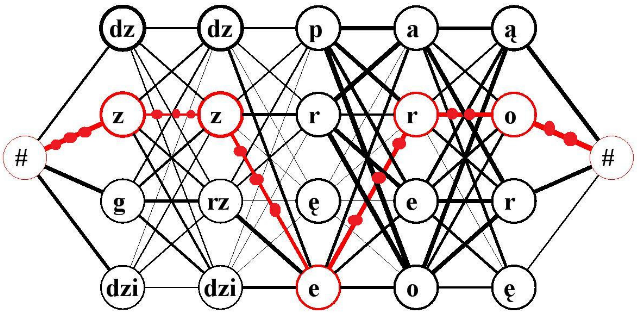

Fig. 1. An example of applying biphone statistics to speech recognition. The graph presents four phone hypotheses for each time slot with different probabilities (the highest row has the highest probabilities). The recognition based on audio information only would be *dz dz p a aę*, which is not close to any Polish word. The best path after including biphone probabilities on edges is *z z e r o*, marked with extra dots. The word *zero* was actually spoken.

II. Algorithm

Sophisticated rules and methods are necessary to obtain the phonetic information from an orthographic text data. Transcription of text into phonetic data was applied by PolPhone [3] using extended SAMPA phonetic alphabet with 39 symbols (plus space) and pronunciation rules for cities Poznań and Kraków. Then the spaces were removed and our own digit symbols corresponding to SAMPA symbols were used, instead of typical ones in the aim of distinguishing phones easier while analysing received phonetic transcriptions. Stream editor (sed) was applied for this tasks.

Afterwards, statistics can be simply collected by counting the number of occurrences of each symbol, pair, and triple in an analysed phonetic transcription, where each character represents a phone. It was conducted using Matlab.

The necessity of investigating large text corpus pointed to the use of the Polish phonetic transcription system PolPhone [5], [3]. The transcription process is performed by a table-based system, which implements the rules of transcription. Matrix $T \in S^{m \times n}$ is a *transcription table*, where S is a set of strings and the cells meet the requirements listed precisely in [3]. The first element $t_{1,1}$ of each table contains currently processed character of the input string. For every character (or character substring) a table is defined. The first column of each table $\{t_{i,1}\}_{i=1}^{m}$ contains all possible character strings that could precede currently transcribed character. The first row $\{t_{1,j}\}_{j=1}^{n}$ contains all possible character strings that can proceed. All possible phonetic transcription results are stored in the remaining cells $\{t_{i,j}\}_{i=2,j=2}^{m,n}$. A particular element $t_{i,j}$ is applied as a transcription result, if $t_{i,1}$ matches the substring preceding $t_{1,1}$ and $t_{1,j}$ matches the substring proceeding $t_{1,1}$. The longer context is always prefered for transcription, to increase accuracy. Additional tables handle exceptions.

The phonetic alphabet used in PolPhone does not differentiate h and χ. However, it does differentiate w∼ and j∼. It can be seen as an unusual phonetical decision, but we are forced to use the existing tool as it is.

Several Rzeczpospolita (Polish daily journal) and Wikipedia articles were used as input data in our experiment. Due to their character, they contain quite many names and places, including foreign ones, what may influence the results slightly. The corpus consists also of several literature books in Polish. Some of them are translations from other languages, so they also contain foreign words. The whole corpus consists of around 267 000 000 words of over 3 000 000 word tokens.

III. RESULTS

The frequency of phones is quite similar to the presented in [6] (Table I). The comparison to the other statistics [7] is not simple, because they include a space. It should be mentioned here, that it is an acoustic space, which we could rather call short pause. It means, that it does not appear between all words, but only where a speaker took a breath. A general correlation can be seen, however, the exact order of the statistics differs quite a lot (Tables II and IV).

The total number of around 1 119 000 000 phones were analysed with 39 tokens being specified. Exactly 1 397 biphonetokens (Fig. 2 and Table II) for 1 521 possible combinations were found, which constitutes 91.8%.

38 708 triphone tokens (see Table IV) were detected. The list of the most common triphones is presented in Table IV. With 39 phone tokens there are 59 319 possible triples. It leads to a conclusion that around 65% of possible triples were detected as triphones. It corresponds very well to Young [10], who estimates that in English, 60-70% of possible triples exist as triphones. It allows to make an assumption that all or nearly all triphone tokens were detected in our experiment.

Some values are similar to statistics given by Jassem a few decades ago and reprinted in [1]. We applied computer clusters, so our statistics were calculated for much more data. On the other hand, Jassem’s work was based on manual transcription, while ours uses an automatic method to provide phone transcription, which might be less acurate.

Our results were compared with [7]. The phone statistics are quite similar, because they can be extracted from a small corpus and be representative. Because of this similarity we believe that the grapheme-to-phone automatic method we used has quality close to hand transcriptions done by [7]. The biphone statistics from [7] are less correlated to ours, with triphone ones quite different. We concluded that with correlation on uniphone level, the differences for biphones and triphones are due to much larger corpus which was analysed in our work. Biphone and triphone statistics from [7] are probably quite dependant on transcriptions which were used in their experiment. Our experiment was conducted on much larger corpus so it is much more data independent.

Besides the frequency of triphone occurrence, we are also interested in distributions of their frequencies. These are presented in logarithmic scale in Fig. 3. We have found around 2 200 triphones which occurred once, around 1 200 which occurred twice, and 900 three times. There are quite a lot of triples which occured few times but also there are generally much more triples than for a similar experiment with a space as a phone because there are new triples on words connections. Some threshold can be set and the rarliest triphones can be removed as errors caused by unusual Polish word combinations, acronyms, slang and other variations of dictionary words, onomatopoeic words, foreign words, errors in the process of introducing phone transcriptions and typographical errors in the text corpora.

Zipf’s law states that given some corpus of natural language utterances, the frequency of any word is inversely proportional to its rank in the frequency table. In the case of triphones it seems to be not the case. The changes in frequency between the common triphones are smaller then would be expected from Zipf’s law, while the changes between rare triphones are larger. This type of distribution is very good from practical point of view. It can be estimated that triphones which are in the right part of the Fig. 3, where differences are very sharp are errors.

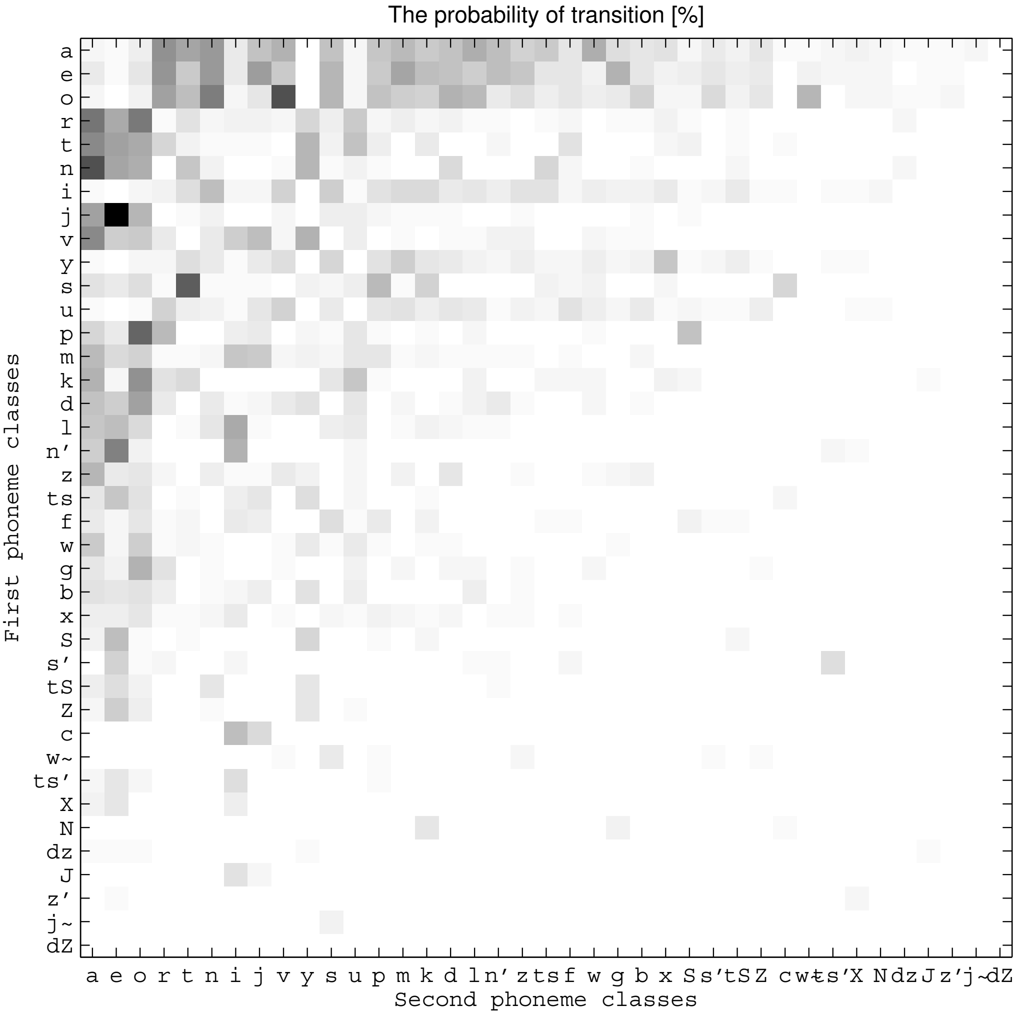

Fig. 2. Frequency of biphones in Polish

Spaces appear between written words but they rarely apear in spoken language. However, pauses can indeed occur between, e.g., longer phrases. Our statistics were collected using phonemic transciption based on written texts. One would say that a better way would be to use transcriptions made directly from audio records. However, in that case the amount of investigated material would be significantly smaller what would have impact on quality of the statistics, especially the triphones.

Entropy

$$H = -\sum_{i=1}^{40} p(i) \log_2 p(i), \qquad (1)$$

where $p(i)$ is a probability of a particular phone, is used as a measure of the disorder of a linguistic system. It describes how many bits in average are needed to describe phones. According to Jassem in [1], the entropy for Polish is 4.7506 bits/phone but including a space. From our calculations, the entropy for phones is 4.7322, for biphones 8.6832 and 12.1987 for triphones. The fact that they do not follow a 1:2:3 proportion is an indication of some level of correlation.

IV. Conclusions

250 000 000 words from different corpora: newspaper articles, Internet and literature were analysed. Statistics of Polish phones, biphones and triphones were created. They are not fully complete, but the corpora were large enough, that they can be successfully applied in speech processing applications. The collected statistics are the largest for Polish, one of the most common Slavic languages, of this type of linguistic computational knowledge. It has several phones different than English and the statistics of phones are also different.

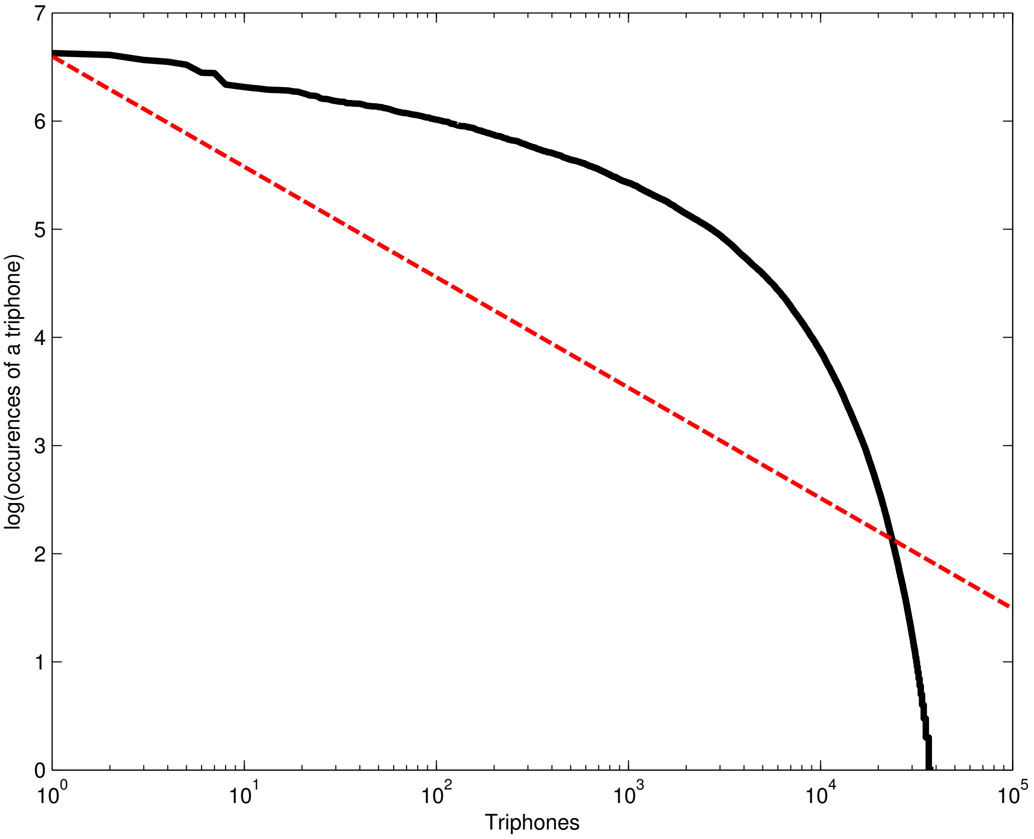

Fig. 3. The solid black line represents phone occurrences distribution while the red, dashed one is an ideal Zipf's law distribution (1/x). It can be estimated that the triphones which fall under the (1/x) Zipf's line are errors rather then real triphones and can be removed from the statistics

V. Acknowledgements

Abstract—**Automatic subtitling of television content has become an approachable challenge due to the advancement of the technology involved. In addition, it has also become a priority need for many Spanish TV broadcasters, who will have to broadcast up to 90% of subtitled content by 2013 to comply with recently approved national audiovisual policies. APyCA, the prototype system described in this paper, has been developed in an attempt to automate the process of subtitling television content in Spanish through the application of state-of-the-art speech and language technologies. Voice activity detection, automatic speech recognition and alignment, discourse segment detection and speaker diarization have proved to be useful to generate time-coded colour-assigned draft transcriptions for post-editing. The productive benefit of the followed approach heavily depends on the performance of the speech recognition module, which achieves reasonable results on clean read speech but degrades as this becomes more noisy and/or spontaneous.**

I. Introduction

SUBTITLING plays an important role in the increasingly multimedia and globalised world we live in. Its usefulness extends from the enrichment of TV content – in order to make it more accessible for people with hearing difficulties or to facilitate audiovisual information retrieval – to its application in noisy environments such as airports and transit stations, where it is not possible to hear TV broadcasts. In addition, subtitling has also become a priority need for many Spanish TV broadcasters, who will have to broadcast up to 90% of subtitled content by 2013 to comply with recently approved national audiovisual policies[1].

However, subtitling is a labor-intensive and economically costly process. As a general rule, manual production of high-quality subtitles can be assumed to take between 8 and 10 times the length of the video material [1]. Nevertheless, mainly due to the higher demands, the time allotted to production of the subtitled material has decreased in recent years [1], [2].

Experienced professionals currently employ dedicated subtitling software tools to help them generate subtitles faster. However, these tools simply display the subtitles on the computer screen as they will appear on the television or movie screen and facilitate purely mechanical functions, such as cueing the subtitles, spell-checking and other basic text processing functions [3]. Only recently speaker-dependent automatic speech recognition has become popular for live subtitling through re-speaking, a technique in which a professional subtitler is trained to dictate live subtitles as the programme happens. Products such as Protitle Live® (NINSIGHT)[2] and WinCAPS® (Sysmedia)[3] allow trained speakers to dictate live subtitles into trained ASR engines. Nevertheless, there is still no ASR-based system in use for fully automated subtitling.

The application of the following state-of-the-art technologies can also contribute to making the subtitling process more automatic and productive:

A. Voice Activity Detection (VAD)

TV content presents a wide range of acoustic conditions: e.g. music, clean speech, outdoor speech, speech with background music, sound effects, noise, etc. However, only those segments that contain speech are to be subtitled. In addition, the different acoustic conditions might require different kinds of processing.

VAD technology can be used to automatically detect the audio segments containing speech. VAD segmentations can also be used to automatically classify and group audio segments with similar acoustic characteristics for further processing.

B. Automatic Speech Recognition (ASR) and alignment

ASR can be employed to obtain automatic transcriptions of the spoken information. Even though ASR can potentially save a lot of time, it is a difficult task mainly due to the high variability of the spoken environments, speakers and speech types present in TV content. Spoken environments vary from clean (studio recordings) to noisy (outdoor recordings, speech mixed with background music or sound effects). The type of speech may differ from dictation (newsreader) to spontaneous (debate or interview). The combination of these

[1] S. Government, “Spanish Audiovisual Law on Subtitles. http://www.cesya.es/es/normativa/legislacion/Financiacion_Radio_TV,” 2008.

[2] http://www.ninsight.fr/FR/

[3] http://www.sysmedia.com/

978-83-60810-27-9/09/$25.00 © 2010 IEEE

possibilities seriously challenges ASR technology, which also needs to deal with speaker independence and the uncontrolled vocabulary of TV programs.

The time-stamps output by the ASR system can also be employed to align the recognised transcripts to the audio signals. In cases where the transcripts already exist, forced alignment can be used instead of recognition to obtain more accurate synchronizations between audio and text.

C. *Discourse segment detection (DSD)*

The detection of entities, relationships or individual events of speech and its segmentation into sentences and phrases is a crucial step for the transition from speech recognition to its full understanding. Unless explicitly dictated, speech recognisers output strings of words without a right segmentation of the output into discursive segments. As a result, ASR transcriptions consist of raw text that is quite difficult to understand for the reader.

DSD techniques can be used to automatically segment ASR transcriptions into segments which contain whole meaning, in order to make them more readable.

D. *Speaker diarization (SD)*

SD is the task of segmenting a multi-speaker audio signal into homogeneous parts and clustering them into different groups, each containing the voice of a single speaker.

In the context of subtitling, SD can be employed to automatically assign a specific color to the subtitles spoken by each speaker.

APyCA, the prototype system described in this paper, integrates the four technologies described above in a unique application, whose aim is to facilitate the manual production of subtitles by experienced professionals, reducing as a result the high cost of subtitle production.

The paper is structured as follows. Section 2 describes the state-of-the-art of the technologies involved and Section 3 presents the resources and tools developed and integrated within the project. Section 4 then describes the implemented prototype. Evaluation of the different modules is presented in Section 5 and finally, Section 6 discusses the main conclusions and further work.

II. State of the art

Much work has been made on the four main technologies involved in APyCA: Voice Activity Detection (VAD), Automatic Speech Recognition (ASR), Discourse Segments Detection (DSD) and Speaker Diarization (SD).

A. *Voice Activity Detection (VAD)*

With increasing demand for voice interfaces, the ability to distinguish human speech from other sounds is becoming crucial. Many works have attempted to discover characteristic features of human voices that are present only in speech. Since such characteristic features have not yet been discovered, short-time energy, zero crossing rate (ZCR), low-variance spectrum (LVS), spectral entropy (SE), periodicity, and so on have been used instead [4], [5]. While it is true that speech has such characteristics, the problem is that they can also be present in some non-speech sounds. This leads to a high false acceptance rate for specific kinds of noise. For example, loud white noise can also have high energy and ZCR.

For these reasons, statistical pattern classification approaches such as Gaussian Mixture Models (GMMs) have gained wider acceptance [6], [7]. In statistical VAD methods, both speech and noise models are trained via corresponding training data. Then, log likelihood ratio tests are applied to input data for speech and noise discrimination. These VAD methods have been shown to exhibit superior performance than the previous approach.

B. *Automatic Speech Recognition (ASR)*

There have been several projects focused on the development of ASR technology for the automatic transcription of Broadcast News (BN). However, most of them were developed for languages other than Spanish, such as English [8], French [9], Portuguese [10] or German [11]. As a result, there is not much data available in Spanish to train a robust speech recogniser for the automatic transcription of broadcast content. Several studies [9], [12] state that at least 100 hours of annotated and transcribed data is required for the adequate training of BN ASR engines and practical development works tend to use as much data as possible. For example, [13] uses up to 1000 hours of training speech data for Persian while [14] employs 81 hours for English, 52 for Portuguese and, in comparison, only 15 for Spanish. This lack of data is the main reason why we decided to use a commercial ASR engine within the APyCA prototype, and to explore adaptation of its default models to improve performance.

Despite the improvement of automatic speech recognisers, developing a system for the automatic transcription of content broadcasted in radio or television is still a challenge for many research groups. A system aimed at the automatic transcription of Portuguese BN, working in a real application scenario currently is [10]. It is based on a hybrid acoustic modelling approach that combines the temporal modeling capabilities of Hidden Markov Models (HMMs) with the pattern discriminative classification capabilities of Multilayer Perceptrons (MLPs). Such acoustic modelling combines phoneme probabilities generated by several MLPs trained on distinct feature sets resulting from different feature extraction processes. The feature extraction methods are PLP, Log-RASTA and MSG. The training of the language model is done using both, Portuguese newspaper texts combined with the transcriptions used for acoustic model training.

With regard to the performance of the ASR systems developed for the different languages on the broadcast domain, the resulting error rates reflect in general the varying level of the acoustic and linguistic complexity of the recordings [11]. WERs range from 16.1% to 64.5%. For Spanish, [14] achieved a mean WER of 18.9%, while [12] managed to decrease it up to 10% by restricting the recognition domain.

The vast majority of the previous studies consider classifying, labeling and structuring the acoustic signal into homogeneous segments essential to optimise the training of the acoustic models of the recogniser, for its subsequent proper operation [15].

C. Discourse Segments Detection (DSD)

The most widely investigated two sources of information to resolve the problem of detecting discursive segment boundaries are word transcriptions (what the speakers say) and prosody (how they say it). It is common to use two statistical models: language and prosodic models. In general, the language model gives the probability of a segmental boundary occurring in a context, while the prosodic model expresses the relationship between prosodic features and segmental boundaries.

Most previous works on discourse segment detection, e.g. [16], are based on the combination of these two information sources. [17] presents a system for punctuation generation which combines both prosodic and linguistic information, in addition to acoustic models. [18] and [19] use a general HMM framework that allows the combination of lexical and prosodic information to recover punctuation marks. A similar approach was used to detect sentence boundaries in [20] and [21].

D. Speaker Diarization (SD)

The varied and wide applicability of speaker diarization technology has led different research groups to develop several systems. The SD process often consists of three main phases: front-end acoustic processing, initial segmentation and final speaker clustering and refinement. The pre-processing step has two main goals. The first one is to normalise the signal in order to remove corrupting noise. In [22], for example, Wiener filtering is applied on each audio channel with that purpose. The second one is to parameterise the signal. Mel Frequency Cepstum Coefficients (MFCC) and Linear Frequency Cepstrum Coefficients (LFCC) are commonly used parameter features, in vectors of several dimensions which often include deltas and/or deltas-deltas.

The initial segmentation phase aims to provide an approximate speaker turn labeling to initialise and speed-up the subsequent segmentation and clustering stages. Several distance criterions can be used in this step. While [23] applies a classical GLR speaker turn detection criteria, [24] uses a segmentation similar to the KL2 metric, measuring the maxima of a local Gaussian divergence between two adjacent sliding windows of five seconds.

The most common clustering method employed in the speaker clustering and refinement phase is the Bayesian Information Criteria (BIC) or a variation called ΔBIC [22, 24]. Initial clusters are generally modelled by single Gaussians with full covariance matrices estimated on the acoustic frames of each segment output by the initial segmentation step. The BIC or ΔBIC metrics are commonly used both, to measure inter-cluster distances and as stop criterions.

III. Resources, tools and applications developed

The main tools integrated in APyCA are: (1) a VAD module; (2) a large vocabulary continuous speech recognition module for recognition and alignment and modules for (3) the detection of discursive segment boundaries and (4) speaker diarization.

A. Voice Activity Detection (VAD)

In order to feed the speech recogniser with audio segments containing speech, a previous segmentation and classification of the audio signal is required. This classification should be as comprehensive as possible, to ensure that no misclassified speech segments are lost.

APyCA segments and classifies the input audio into four different acoustic types: speech, speech plus noise, noise and silence, based on the speech detection functionality of the open source LIUM_SpkDiarization tool [25]. Such segmentation is obtained through Viterbi decoding of one-state Hidden Markov Models (HMMs) trained for the different acoustic conditions on the ESTER broadcast news corpus.

B. Automatic Speech Recognition (ASR) and alignment

APyCA employs the Windows Speech Recogniser (WSR) 8.0 as its ASR engine, integrated through the SAPI 5.3 functionality on the .NET Framework 3.5 environment.

In order to improve its performance, default models have been adapted with acoustically similar (i.e. clean speech vs. noisy speech) and/or TV genre-specific data by feeding the system with the corresponding audio recordings and text transcripts.

As well as for generating textual transcriptions of the spoken information, the ASR module is also used to obtain word-level time-stamps to align the audio and the text. In those cases where transcriptions already exist and the recognition step is not required, audio and text synchronization is computed by an alignment module developed using the HTK Toolkit [26]. The alignment module is a monophone recogniser trained on the Albayzin corpus [27], which extracts 39-dimensional feature vectors containing MFCC, delta and delta-delta coefficients on 25ms windows every 10ms and uses the Spanish version of SAMPA as its phoneme set, plus silence and short pause models. Each monophone (except from the short pause model) consists of non-emitting start and end states plus three emitting states, connected left-to-right with no skips and modelled by a single Gaussian. Viterbi is used for decoding.

C. Discourse Segment Detection (DSD)

Any subtitling platform integrating a speech recognition engine requires the development of algorithms for the automatic segmentation of the recognised output into dircursive segments.

APyCA has four different ways to automatically predict discourse segment boundaries: two of them are related to the acoustic and prosodic processing of the speech signal, another one is based on the linguistic analysis of the transcribed text and the last one combines the previous three approaches. The different techniques employed are presented in more detail in the following sections.

1) DSD based on Acoustic Information

Acoustic pauses are detected by analysing word start and end time-stamps produced by the recogniser or the alignment module during the recognition and alignment processes respectively. Whatever the difference, any non-coincidence in time between the end of a word and the start of the next has been taken as a potential acoustic pause.

It is important to emphasise at this point that even if acoustic pauses do not always correspond to discursive breaks, their relationship is evident in many cases.

2) DSD based on Prosodic Information

Acoustic pauses are not always grammatically correct as they may coincide with breathings, stops or speech difluencies that are not always related to true discursive boundaries. Discourse segment detection based on prosodic information can help resolve this problem.

The implemented algorithm detects discursive segment boundaries based on CART classifiers trained with the Waikato Environment for Knowledge Analysis (WEKA) tool [28]. Three different classes have been used: “silence”, “question” and “nothing” - corresponding to the cases where a word is followed by silence, question mark or nothing, respectively. Each class is trained on prosodic features extracted for each word of the Multext Prosody corpus [29] using the Purdue Prosodic Feature Extraction Tool (PPFE) [30]. 232 prosodic features are extracted around each word. These features are mainly related to:

•***Duration:*** the duration and normalised duration of each word and word boundary are extracted. In addition, the duration and normalised duration of the last vowel and rhyme before a word boundary are also measured.

•***Pitch:*** several different types of F0 features are computed, based on the stylized pitch contour.

○ *Range features:* these include the minimum, maximum, mean, and last F0 values of each word and reflect its pitch range.

○ *Movement features:* measure the movement of the F0 contour within the voiced regions of the words preceding and following a boundary. The minimum, maximum, mean, first and last stylized F0 values of each word are computed and compared to those of the following word, using log differences and ratios.

○ *Slope features:* the last slope value of a word preceding a boundary and the first slope value of a word following a boundary are also calculated.

•***Energy:*** similar to the F0 features, a variety of energy related range features, movement features, and slope features are computed, using various normalization methods.

Each word in the training corpus was manually labeled to belong to one of the three classes defined above.

3) DSD based on Linguistic Information

The linguistic algorithm has the same purpose as the prosodic and acoustic algorithms, i.e. estimating discourse segmentations of the transcribed text. The philosophy used to develop this module has been based on two types of heuristics: grammatical and structural.

On the one hand, a probabilistic part-of-speech (PoS) tagger based on Hidden Markov Models (HMM) has been developed in order to grammatically categorise each word. It has been trained on a proprietary lexical database that includes thousands of grammatical categories of words. In addition, heuristic rules have been developed to detect combinations of grammatical categories, before or after which it is more likely to have segment discourse boundaries.

On the other hand, the most frequent and meaningful structural elements present in the Multext Prosody corpus before or after which it is highly likely to have a discourse segment boundary have been identified. Based on this information, heuristic rules to detect discursive boundaries have been designed.

The latter approach has been found to be more robust than the former one in the automatic subtitling scenario, since recognition errors can lead to grammatical miscategorisations which weaken the designed grammatical heuristic rules.

4) DSD based on Combined Information

The global APyCA DSD system is modular in nature. This means that the input text can be independently segmented into discourse segments using any of the modules designed: acoustic, prosodic and/or linguistic.

A combined model has also been developed, which takes the predictions and confidence measures provided by the three modules described above and gives a final result based on their weighted combination. In general, if two modules detect a pause in a word boundary with enough confidence, we take it as a real pause. This approach exploits the complementarity of the three very different sources of information used for the detection of discourse segments.

D. Speaker Diarization (SD)

This module aims at segmenting the acoustic signal according to the speaker identities, so that each speaker can be assigned a different subtitle colour.

APyCA uses the LIUM_SpkDiarization open source tool [25] to solve the task of speaker diarization. Signals are parameterised using 13 Mel Frequency Cepstral Coefficients (MFCC) including coefficient C0 as energy, computed with the Sphinx 4 tools [31]. 20 ms windows are employed with an overlap of 10 ms. Cepstral Mean Normalisation (CMN) is not applied, due to its tendency to increase the error rate of the diarization task.

The diarization process consists of three main phases. Instantatenous signal change points corresponding to segment boundaries are detected first, using distance-based segmentation metrics which combine the Generalised Likelihood Ratio (GLR) and Bayesian Information Criterion (BIC). GLR is computed using full covariance Gaussians estimated on sliding windows of five seconds and followed by a second ΔBIC pass, which also uses full covariance Gaussians, to fuse consecutive segments of the same speaker.

Then, nonadjacent segments of the same nature and speaker are brought together in clusters using a hierarchical agglomerative clustering algorithm with a stopping criterion based on the ΔBIC metric.

Finally, Viterbi decoding is performed to generate improved segmentations. Each cluster is modeled by a one-state HMM, represented by a GMM with 8 components and a diagonal covariance matrix learned by Expectation-Maximization Maximum-Likelihood (EM-ML) over the segments of the cluster. The log-penalty between two HMMs is fixed experimentally.

IV. Integration of Components into a Demo Application. Description of the Prototype

APyCA is a prototype oriented towards the automatic transcription of TV content in Spanish which integrates the technologies described in the previous sections of the paper and aims to serve the professional subtitlers as a tool to facilitate the creation and editing of subtitles. The following sections describe the main features and architecture of the developed demo application.

A. Features

Its input is TV content in the form of video or audio. It supports many different formats, including the main standards used by television producers, such as *mpeg2, h.264, aac or wav.*

Its output is a well-formed STL (binary) or SRT subtitle file, which respects the maximum number of characters allowed per line and includes colours to differentiate speakers. Time-spotting is based on the estimated word time-stamps and discourse segment boundaries. If needed, these subtitle files can be easily edited further using commercial software for subtitle generation, e.g. WinCAPS, FAB Teletext and Subtitling, Subtitle Workshop, etc.

The technologies involved have been grouped into three automatic functionalities: transcription, time-spotting and

Fig 1: System screen capture

speaker diarization – which can be applied and edited independently through dedicated graphical user interfaces.

•The **Automatic Transcription** screen shows the raw text returned by the ASR engine for those segments that contain speech. It also allows playback and editing of the transcriptions, so that subtitlers can manually correct the errors of the recogniser. The fewer the transcription mistakes, the better the time-spotting will be.

•The **Automatic Time-Spotting** functionality chunks the transcribed text into discoursive segments and aligns them with the audio. The start times, end times and text of each subtitle can be edited manually.

•The **Speaker Diarization** screen automatically assigns different colours to the subtitles spoken by different speakers, also allowing their manual edition.

These three functionalities can be combined to suit the needs of the professional subtitlers. It is possible, for example, to skip the automatic transcription step and upload already transcribed audiovisual content. Or to generate the subtitle files without speaker diarization information.

The prototype has been developed entirely using the Microsoft .NET platform, the C# programming language and several Perl scripts for text processing.

A screen capture of the system is shown in Fig. 1.

B. Architecture

Fig. 2 illustrates how the different modules interact within the system and with the user.

The system supports the input of TV content in video or audio formats, as well as with or without its corresponding textual transcription. The FFmpeg [32] tool is used to extract the audio from the video in different formats and configurations. If the transcription does not exist, the audio will be recognised. If the transcription exists, forced alignment will be applied instead to obtain word time-stamps. In any case, time-stamps are required for the discourse segment detection and speaker diarization modules. Output subtitle files can be generated after recognition/alignment, after discourse segment detection or after speaker diarization.

The modular architecture of the system will allow simple integration of additional modules providing new functionalities in the future.

V. Evaluation

A. Data

The main modules of the APyCA prototype have been evaluated individually on two different genres of TV content: weather forecasts and political interviews.

Weather forecasts do not present difficulties related to the the spoken environment, the type of speech used, the number of speakers involved or the quantity and quality of their interventions. In fact, they contain just one anchor presenter following a previously written and rehearsed script in a noise-free recording studio. However, the employed vocabulary is very specific of the meteorological domain. Political interviews involve many different types of spoken environments (studio, parliament, street), types of speakers and speech (presenters following pre-prepared scripts and/or spontaneous interviewees) and a very domain specific vocabulary, with many mentions to names of politicians.

Ten programs of each type were recorded and used for training (8) and testing (2) the different modules of the system. Their reference transcripts were obtained by manually correcting the transcriptions output by the WSR 8.0 with default models.

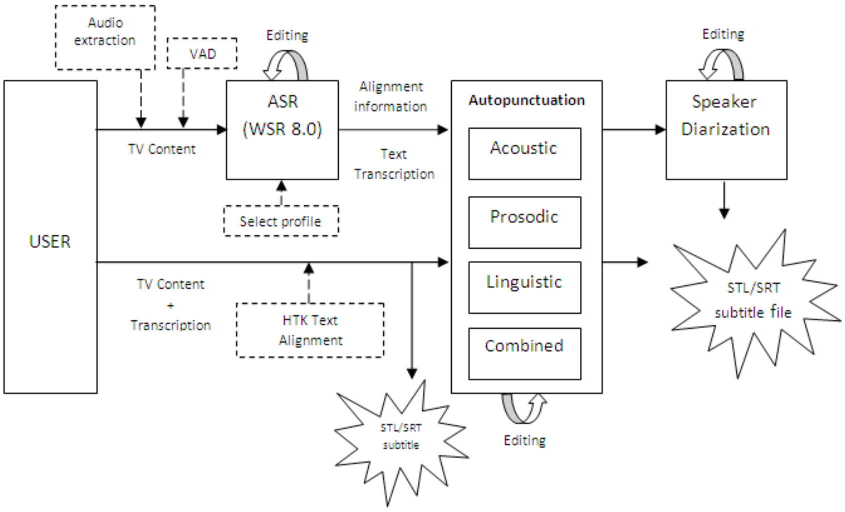

Fig 2: System architecture

B. Automatic Speech Recognition (ASR)

The performance of the WSR 8.0 recogniser was tested in three different conditions: (i) using the default recogniser models, (ii) using clean and noisy speech profiles adapted to the clean and noisy acoustic conditions found in each corpus, and (iii) using TV genre-specific profiles trained for the weather forecast and political interview domains.

Results for *the weather forecast* corpus are shown in Table 1. The average percentage of words correctly recognised overall is especially promising. The column labeled *Baseline* shows the performance of the default profile of the commercial WSR 8.0 engine. The column labeled *TV-genre profile* corresponds to the recognition rate achieved using a profile trained with all the training content of the weather forecast corpus. The *Acoustic profiles* column shows the results obtained after applying the recognition profiles trained with clean and noisy speech. Contrary to expectations, acoustic profiling does not achieve the best results probably due to the loss of context caused by the more detailed audio segmentation involved.

Table I.
Average recognition rate in the weather forecast corpus

Baseline	*TV-genre profile*	*Acoustic profiles*
81.3 %	96.65 %	92.34 %

Results for the *political interview* corpus are shown in Table 2. Less satisfactory recognition rates were obtained with this corpus overall, due to the inherent difficulty of the content type. It is remarkable that the application of acoustic profiling did not improve the results obtained by the default recognition profiles. On the other hand, TV-genre profiling only improves baseline results slightly.

Table II.
Average recognition rate in the political interview corpus

Baseline	*TV-genre profile*	*Acoustic profiles*
79.54 %	79.80 %	78.60 %

C. Discourse segment detection (DSD)

Results concerning the evaluation of the different DSD modules are shown in Tables III, IV and V.

Each module was evaluated individually, against manually labeled reference test files. Acoustic labels take into account acoustic silences and short pauses. Prosodic labels are based on the intonation of the related sound files. Linguistic labels consider syntactic information of the associated text.

According to the followed evaluation methodology, "*Matching breaks*" refers to the percentage of breaks that match the reference file, while "*Unassigned breaks*" relates to the percentage of breaks present in the reference labels which have not been assigned by the different modules. The percentage of extra breaks assigned by the DSD modules that do not appear in the reference files is counted as "*Extra breaks*".

Table III.
Results of the acoustic module

Matching breaks	*Unassigned breaks*	*Extra breaks*
92.67 %	7.33 %	16.60 %

Table IV.
Results of the prosodic module

Matching breaks	*Unassigned breaks*	*Extra breaks*
64.49 %	35.51 %	63.64 %

Table V.
Results of the linguistic module

Matching breaks	*Unassigned breaks*	*Extra breaks*
51.92 %	48.08%	1.44 %

Results show that in 92.67% of the cases, acoustic segmental boundaries were assigned correctly, 7.33% of the acoustic pauses were not detected and 16.80% were wrongly assigned, particularly those matching breathing stops and speech disfluencies. Spontaneous speech was the main enemy of the prosodic module, mainly trained under a database of read speech. Nevertheless, it achieved a non negligible 64.49% accuracy rate. As for the linguistic module, its performance was penalised by the recognition errors which affect the designed heuristic rules. Overall, the acoustic module has proved to be the most efficient to detect discourse segment boundaries, due to its high speed and hit rate.

D. Speaker Diarization (SD)

The speaker diarization module achieved very good performance. Even in the rich acoustic environment of the political interview corpus, results achieved 87% success rate. Errors were mainly due to background acoustic changes, which caused the same speaker to be classified as two in some cases where the background acoustic environment was different, since the BIC criterion employed in APyCA for speaker diarization was actually designed to classify those segments as different.

VI. Conclusions and further work

Voice activity detection, automatic speech recognition and alignment, discourse segments detection and speaker diarization technologies have been developed, customized and integrated in a prototype to support the subtitle generation process of Spanish TV content.

Objective evalutation of the different modules has shown that the proposed approach is feasible and applicable to generate automatically time-coded and colour-assigned draft transcriptions for post-editing. The commercial WSR 8.0 engine has shown adequate performance for the task. Adaptation of the default profiles to each TV-genre has shown to improve recognition accuracy. However, transcription performance degrades overall as the input speech becomes more noisy and/or spontaneous. Acoustic discourse segment detection has been found to be very efficient in terms of high speed and hit rate for time-spotting. The LIUM_SpkDiarization tool has also shown good results in the colour assignment task.

However, there is still quite a lot of room for improvement. Techniques to enhance ASR accuracy in noisy and/or spontaneous environments could be integrated. The prosodic DSD module could be trained on spontaneous and/or emotional speech corpora to better match intonation patterns of certain TV content. Finally, feature normalization techniques could be added to the speaker diarization module to obtain one-to-one relationships between clusters and speakers. Although some positive informal usability tests have been done with professional subtitlers, a more comprehensive assesment should be carried out in order to verify the feasibility and quantify the time and money savings which could be provided by a software tool similar to the developed prototype.

Acknowledgment

This work has been partially funded by the Basque Government. The authors would like to thank Mixer, Irusoin and ETB for providing the corpora and giving usability feedback.

10th International Multidisciplinary Conference on e-Commerce and e-Government

We would like to invite original papers concerning all aspects of electronic commerce, electronic government and related issues. The conference is meant to be of interest to the academic community as well as representatives of business, industry, government, NGOs and the information technology sector. Thus – apart from research papers – practical presentations of existing solutions are also invited.

The areas of e-Commerce, e-Governance, e-Government etc. are interdisciplinary by nature: they involve people whose background is in economy, management, artificial intelligence, computer science, sociology, psychology, law etc. We feel that a meeting of specialists in those areas may help to cross the boundaries between the traditional disciplines, but also between the communities of theorists and practitioners. This can also create a better understanding of mechanisms underlying electronic markets, electronic administrations and networked organizations.

The general list of topics includes:

- electronic markets and electronic marketing
- business models and processes in e-Commerce and e-Government
- languages and models for e-Commerce and e-Government
- Artificial Intelligence in e-Commerce and e-Government
- electronic contracting and public procurement
- legal aspects of e-Commerce and e-Government
- electronic interaction and negotiation
- Virtual Enterprises and Knowledge Management
- technology for e-Commerce and e-Government
- Internet computing, networked enterprises and networked governments
- social aspects of e-Commerce and e-Government
- futurology of e-Commerce and e-Government
- e-Inclusion and its influence on e-Commerce and e-Government
- national and cross-boarder e-Government services
- productivity and efficiency in e-Commerce and e-Government

***Abstract*—A good data model designed for e-Commerce or e-Government has little value if it lacks accurate, up-to-date data [22]. In this paper data quality measures, its processing and maintenance in *IBM InfoSphere MDM Server* and *IBM InfoSphere Information Server* is described. We also introduce a notion of *trust*, which extends the concept of data quality and allows businesses to consider additional factors, that can influence the decision making process. In the solutions presented here, we would like to utilize existing tools provided by IBM in an innovative way and provide new data structures and algorithms for calculating scores for persistent and transient quality and trust factors.**

I. Introduction

MANY organizations have come to the realization that they do not have an accurate view of their business-critical information such as customers, vendors, accounts, or products. As new enterprise systems are added, silos are created resulting in overlap and inconsistency of information. This varied collection of systems can be the result of systems introduced through mergers and acquisitions, purchase of packaged applications for enterprise resource planning (ERP) or customer relationship management (CRM), different variant and versions of the same application used for different lines of business or home grown applications. Data in these systems typically differs both in structure and in content. Some data might be incorrect, some of it might just be old, and some other parts of it might show different aspects of the same entity (for example, a home vs. a work address for a customer).

Master Data Management (MDM) is an approach that decouples master information from the applications that created it and pulls it together to provide a single, unified view across business processes, transactional and analytical systems. Master data is not about all of the data of an organization. It is the data that deals with the core facts about the key entities of a business: customers, accounts, locations and products. Master data is high value data that is commonly shared across an enterprise – within or across the lines of business. MDM applications, such as IBM's InfoSphere Master Data Management Server, contain functionality to maintain master data by addressing key data issues such as governance, quality and consistency. They maintain and leverage relationships between master data entities and manage the complete lifecycle of the data and support multiple implementation approaches. MDM system itself is designed to support enterprise in the master data processing, integration and analysis.

As very important, quality of master data requires special attention. Different aspects or dimensions of quality need to be considered and maintained in all processes of the enterprise. *Trust scores*, introduced by this paper, can provide important information to the decision makers. Our approach to the quality of data is slightly different than described so far in the literature [4], [6], [9]. Our goal is to provide the user with the estimates of data quality and trust. Trust in this case is the aggregated value of multiple factors, and is intended to cover quality and non-quality aspects of master data. We are not making the attempts to build fixes nor enforce any quality policy. The information provided by us is intend to identify weaknesses of data quality or trustworthiness. The data quality enforcement should be then improved based on this information.

This paper focuses on the creation of measures, or trust factors, that serve to determine the trustworthiness of data being managed by MDM applications, specifically those being introduced in IBM's InfoSphere MDM Server. We would like to define here the model for data quality and methods of their processing in MDM. This new notion involves creating *trust scores* for trust factors that enhance the notion of data quality and the more broad quality-unrelated features such as lineage, security, and stewardship. All these have one goal – to support businesses in the decision making process, or data stewardship by providing information about different aspects of data. We would like to be more focus in this work on the quality aspects of data, especially the accuracy, which is one of the most commonly used quality dimension in the literature [2], [4], [12], [16], [20], [21], [26], [29], [31].

This paper is organized as follows. Section II presents the underpinning principles of Master Data Management (MDM), related concepts as well as the tools we used to prepare the trust scoring prototype. Section III provides a short overview of data quality and introduces the notion of trust. Section IV presents structures and methods used to acquire and store information about one of the most commonly used qualoity factor – accuracy. Section V describes our approach to accuracy estimation in SQL query processing.

II. MDM AND INFORMATION SERVER

Master data management is a relatively fast growing software market. Many customer acknowledge they have data quality and data governance problems and look for solutions to these problems. Crucial parts of such MDM solutions are data quality and data trust mechanisms [8], [10], [23]. In this section we present the MDM environment and the comprehensive approach to data trust and data quality that utilizes tools provided by IBM.

A. Definitions

Master Data Management (MDM) provides the technology and processes to manage Master Data in an organization. Master Data is the data an organization stores about key elements or business entities that define its operation. An MDM solution enables an enterprise to govern, create, maintain, use, and analyze consistent, complete, contextual, and accurate master data information for all stakeholders. Master data is typically high value information that an organization uses repeatedly across many business processes. For these to operate efficiently, this master data must be accurate and consistent to ensure correct business decisions. Unfortunately in many organizations, master data is fragmented across many applications, with many inconsistent copies and no plan to improve the situation.

Master Data Management (MDM) products differs from traditional approaches to the masted data, that include the use of existing enterprise applications, data warehouses and even middleware. It *is not* domain-centric approach such as CRM application for the customer domain or ERP application for the product domain. Some MDM products decouple data linked to source systems so they can dynamically create a virtual view of the domain, while others include the additional ability to physically store master data and persist and propagate this information. Some products are not designed for a specific usage style, while others provide a single usage of this master data. Even more advanced products provide all of the usage types required in today's complex business-collaborative, operational and analytic-as out-of-the-box functionality. These products also provide intelligent data management by recognizing changes in the information and triggering additional processes as necessary. Finally, MDM products vary in their domain coverage, ranging from specializing in a single domain such as customer or product to spanning multiple and integrated domains. Those that span multiple domains help to harness not only the value of the domain, but also the value between domains, also known as relationships. Relationships may include customers to their locations, to their accounts or to products they have purchased. This combination of multiple domains, multiple usage styles and the full set of capabilities between creating a virtual view and performance in a transactional environment is known as multiform master data management.

Achieving a high level of data quality is key prerequisite for many of the MDM objectives. Without high quality data the best analytics and business intelligence applications are still going to deliver unreliable input to important business decisions. Another key aspect of the management of the master data is achieving a high level of trustworthiness in the data. It is a key factor for customers to have reliable information about the data. Information about the quality, the origin, the timeliness and many other factors influence the business decisions based on the provided data.

The introduction of *data governance* in the organization is a vital prerequisite to come to more trusted information. Moving to master data management can be the cornerstone of a data governance program. It is important however to note that at the same time, moving to MDM cannot be successful without data governance.

Data governance is defined as "the orchestration of people, process and technology to enable an organization to leverage information as an enterprise asset" [15]. It manages, safeguards, improves and protects organizational information. The effectiveness of data governance can influence the quality, availability and integrity of data by enabling cross-organizational collaboration and structured policy-making.

B. MDM Tools

We will present here some tools provided by IBM that are very useful in terms of quality assessment and management. All of them are parts of the IBM InfoSphere platform.

IBM InfoSphere MDM Server is an application that was built on open standards and the Java Enterprise Edition(JEE) platform. It is a real-time transactional application with a service-oriented architecture that has been built to be scalable from both volume and performance perspectives. Shipping with a persistent relational store, it provides a set of predefined entities supporting the storage of master data applicable to each of the product's predefined domains. It also includes the MDM Workbench – an integrated set of Eclipse plug-ins to IBM Rational Software Architect/Developer that support the creation of new MDM entities and accompanying services, and a variety of extensions to MDM entities. *IBM InfoSphere Information Analyzer* that profiles and analyzes data so that the system can deliver trusted information to users. The Information Analyzer (IA) is used to scan or sample data stored in diverse sources to assess its quality. MDM also uses some complementary tools: *IBM InfoSphere QualityStage*, which allows us to define rules to standardize and match free-form data elements which is essential for effective probabilistic matching of potentially duplicate records, and *IBM WebSphere AuditStage*, which enables us to apply professional quality control methods to manage the accuracy, consistency, completeness, and integrity of information stored in databases. We also use statistics provided by *IBM InfoSphere DataStage* to compute chosen quality and trust factors.

This set of tools provides a comprehensive approach to data quality and data trust management. This approach not only resolves some problems during the data acquisition but also allows us to control the level of data trust and to give up-to-date information about the trustworthiness to a user. This comprehensive approach is novel. Moreover our solution does not require any specialized hardware or operating system and is able to cooperate with any commercial data base systems.

1) IBM InfoSphere MDM Server: The InfoSphere Master Data Management Server has a new feature allowing users to define and add quality and trust factors to the data of their enterprise. This new data structure enables the user to store metadata required to compute scorings for trust and quality of data. Provided wizards allows user to modify the data model in a simple way.

2) IBM Information Server: IBM Information Server addresses the requirements of cooperative effort of experts and data analysts with an integrated software platform that provides the full spectrum of tools and technologies required to address data quality issues [1]. It supplies users and experts with the tooling that allows the detailed analysis of data through profiling (*IBM InfoSphere Information Analyzer* and *IBM InfoSphere AuditStage*), cleansing (*QualityStage*) and data movement and transformation (*DataStage*). In this paper we concentrate on data profiling and analysis handled mostly by Information Analyzer (IA), AuditStage (AS), and partially on QualityStage (QS).

IA, as an important tool of *data quality assessment* (DQA) process, aids the exposing technical and business issues. The technical issues detection is a simpler part of the process based on technical standards and covers important problems including different or inconsistent standards in structure, format, or values, missing data and default values, spelling errors, data in wrong fields, and buried information in free-form fields. Business quality issues are more subjective and are associated with business processes such as generating accurate reports. They require the involvement of experts.IA helps the expert in systematic analysis and reporting of results, thereby allowing him to focus on the real problem of data quality issues. This is done through tasks like column analysis, key analysis(Primary and Foreign Key) and cross-table analysis.

a) QualityStage: IBM InfoSphere QualityStage (QS) complements IA by investigating free-form text fields such as names, addresses, and descriptions. QS allows users to define rules for standardizing free-form text domains which is essential for effective probabilistic matching of potentially duplicate master data records. It provides user with functions such as free-form text investigation, standardization, address verification and record linkage and matching as well as survivorship that allows best data across different sources to be merged.

b) AuditStage: IBM WebSphere AuditStage (AS) enables user to apply professional quality control methods to manage different subjective quality factors of information stored in databases such as accuracy, consistency or completeness. By employing technology that integrates Total Quality Management (TQM) principles with data modeling and relational database concepts, AS diagnoses data quality problems and facilitates data quality improvement effort. It allows performing assessment of the completeness, validity of critical data elements and business rule compliance. AuditStage is very useful tool for assessment of the *consistency* factor allowing cross-table rules validation.

III. The Notion of Trust

Trust is an extension of data quality. We are looking for additional factors because data quality is not the only factor influencing the trustworthiness of data and these two concepts are not necessarily correlated. Low-quality data may be trusted in some situations and high-quality data may have low trustworthiness in other. The value of trust strongly depends on the user requirements and usage context. In this section we discus a data quality and we describe the notion of trust.

A. Data Quality

The data quality concept has been widely discussed in literature [2]–[4], [6], [9], [11], [19]–[21], [25], [27], [28], [32], [33] usually in the context of a single data source. Some work tough has been also done in the context of integrated data [5], [7], [12], [13], [18], [24] emphasizing the importance of data quality assurance in this area. Batini and Scannapieco [4] have given three examples of organizational processes where DQ aspects are particularly important.

- Customer matching – it is a common issue in organizations where more than one system with overlapping databases exists. A typical result is an inconsistent and duplicate information.
- Corporate house-holding – is a problem of identifying members of household (or related group). This context-dependent issue is widely described in [30].
- Organization fusion – is the issue of integration legacy software in case of organizations or units merge.

The definition of the quality that we are using in this work originates from the one provided by Naumann [18] as an attempt to provide an operational definition of DQ as an aggregated value of multiple IQ-criteria (Information Quality Criteria). IQ-criteria are there classified into four sets:

- Content-related – intrinsic criteria, concerned with the retrieved data,
- Technical – criteria measuring aspects determined by software and hardware of the source, the network and the user,
- Intellectual – subjective aspects of data that shall be projected to the data in the source,
- Instantiation-related – criteria related to the presentation of the data.

We follow the Naumann's approach by defining data quality as a aggregated value of multiple DQ-factors. Later we will extend this definition introducing the trust notion.

B. Trust Definition

Following Naumann's definition of data quality, we define trust (data trust, DT) through factors that influences the trustworthiness of data.

Definition 3.1 (Data Trust): Trust is the aggregated value of multiple Data Trust factors.

This definition provides flexibility when defining trust for a specific industry and user requirements. The trust factor (DT-factor) may be a DQ-factor, or non-quality (NQ) factor.

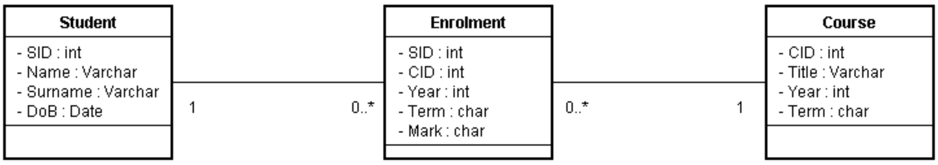

Fig. 1. Sample database schema representing enrollment of students into courses

Here we concentrate on data quality factors, and especially on accuracy dimension. However other factors like data lineage, security or trust of data source can be considered.

C. Accuracy dimension

Accuracy is included by most data quality studies as a key factor [2], [4], [12], [16], [20], [21], [26], [29], [31]. Although the term has an intuitive appeal, there is no commonly accepted definition of what it means exactly [29]. Ballou and Pazer [2] describe accuracy as ”the recorded value being in conformity with the actual value.” Kriebel [16] characterizes accuracy as ”the correctness of the output information.” Thus, it appears the term is viewed as equivalent to correctness.

In [4] accuracy is defined as ”the closeness between a value v and a value v', considered as the correct representation of the real-life phenomenon that v aims to represent.” The simple example can be the name of the city $Toronto$, the value $v = Tronto$ is incorrect (inaccurate) and $v' = Toronto$ is correct (accurate).

Parssian et al. [20], [21] formalize the notion of accuracy and propose quality metrics to assess the quality of basic queries. However definition proposed by Parssian et al. describes accuracy on the higher level of granularity. They consider the tuple as a whole, we in a contrast considering each attribute separately.

The accuracy may be calculated in three possible ways:

1) Inspection by expert – the expert reviews records and marks inaccurate ones;
2) Automatic or Semi-Automatic inspection – the system refine set of candidate records based on some predefined set of rules. Expert may or may not review and correct the result;
3) As a distance function utilizing dictionary sets – we may calculate the minimal number of operation required to transform the value v into the closest dictionary entry v'. Based on that calculation experts may identify low quality entries and apply changes to improve quality.

In all cases we consider only measurement. Experts and system is not allowed to perform any changes in data content. Moreover the (semi-)automatic inspection may be done only if some patterns apply to the field or dictionary may be defined. Examples of fields for which we can define some accuracy rules are SIN, postal code or phone numbers where some common rules apply. The dictionary, sometimes called code table, may be defined for fields like city, country etc. However, there are fields where we are unable to define neither rules nor dictionary. I.e. notes defined as a text field may contain any string. Moreover it is not possible to confront in the automatic way the stored data with real world to confirm the accuracy.

The accuracy and inaccuracy of data may be perceived in many different ways depending on the domain. At this point we will consider two approaches *error bar* and *boolean*. The first one, borrowed from engineering, gives some flexibility but is applicable only to ratio- or interval-scaled types [14]. The second one considers the value strictly in ”black and white” – it may be accurate or inaccurate, one or zero, and there is nothing in between.

1) Error bar: In many areas of science, especially in physics and engineering, the metrology defines a way of calculation of measurements' error and its propagation in calculations. We can see data stored in database as such measurements' results taken with some error and can define *inaccuracy* of data as the relative error. Value of this error is normalized. Such definition applies to numerical fields, ratio- and interval-scaled, where the distance between two values is meaningful, and expresses the relative distance between stored value and real world value. For text fields we can define distance using number of atomic changes required to transform our value into real world value divided by length of real world value.

Accuracy defined in this way however is applicable only to limited types of attributes (preferably numerical) and in specific domains. In general this kind of interpretation is inapplicable in database environment, where we are not provided with any information about inaccuracy of stored data.

2) Boolean accuracy: Boolean approach originates from the idea or rather assumption that each stored record has some source in the real world, and that this source can be ”linked” in an unambiguous way to the stored tuple. In such case we consider the value accurate if the value of stored instance is equal to the value of its real world source. This approach bounds the instance and source, however does not provide any flexibility. The stored instance is either accurate or inaccurate, and there is nothing in between of those extremes, even though this approach can be applied widely.

3) Hybrids: The third approach merges two ideas. We allow our stored instance to vary slightly from the real world source but the result remains boolean. The stored value v is considered accurate in this case if $|v - v'| \leq \epsilon$, where v' is a real world value and ϵ is some predefined, acceptable variation. This variation may also be expressed as a relative value (i.e. percentage). Then value is accurate if $\frac{|v-v'|}{v'} \leq \epsilon$.

In the following consideration we restrict the calculation methods to boolean interpretation of the accuracy; however

TABLE I
SAMPLE DATA IN TABLES STUDENT, COURSE AND ENROLLMENT FROM THE DATABASE FROM FIGURE 1. GRAY FIELDS CONTAIN INACCURATE VALUES

Student

CID	Name	Surname	DoB
111111111	AAAAAAAA	AAAAAAAAAA	1971-01-01
222222222	BBBBBBBB	BBBBBBBBBB	1981-01-01
333333333	CCCCCCCC	CCCCCCCCCC	1973-05-02
444444444	DDDDDDDD	DDDDDDDDDD	1971-09-10

Course

CID	Title	Year	Term
CSE2222	Software Tools	2009-10	F
CSE2222	Software Tools	2009-10	W
CSE2222	Software Tools	2009-10	S
CSE1111	Data Bases	2009-10	F

Enrollment

SID	CID	Year	Term	Mark
111111111	CSE2222	2009-10	F	A
222222222	CSE1111	2009-10	F	B
333333333	CSE2222	2009-10	F	A
222222222	CSE2222	2009-10	W	C

hybrid interpretation may be used as well. The only requirement is that method should be defined before, so we can use it to determine the accuracy of data.

D. Accuracy – Definitions

The base concept of the accuracy here is the confrontation of stored values with their real world sources. We assume that each tuple can be unambiguously linked with the real world element through the accurate key. If we can identify this real world element, then we can compare stored values and real world values to determine the accuracy of stored values. This real world element is called *source*. The linkage with real world entity is a key property in accuracy semantic and is necessary to provide the interpretation of derived accuracy values. We are using the distinction between keys and measures used commonly in warehouses. We would like to provide the definitions for both those types. The key attribute can be seen as a link connecting stored data with source entities. The ability of unambiguous identification of the source by the key is the base for accuracy calculation.

Example 1 (Accuracy interpretation): Let's consider the sample schema presented on Figure 1. This schema consists of three relations:

- $Student(\underline{SID}, Name, Surname, DoB)$
- $Course(\underline{CID}, \underline{Year}, \underline{Term}, Title)$
- $Enrolment(\underline{SID}, \underline{CID}, \underline{Year}, \underline{Term}, Grade)$

There are defined also two foreign key constraints on the table Enrollment:

- FK(SID) – where SID is a key in Student relation
- FK(CID, Year, Term) – where CID, Year and Term are compound key in Course relation

The accuracy of any field in Student relation can be determined only if we can determine the real world source. This determined value can be also interpret only in presence of the key. For example, let's consider student with SID=111111111. The accuracy of the Surname can be determined only by comparison of stored value and source value. If the source value is different than the stored one we say that stored value is inaccurate.

Now considering student record with SID=333333333, which is marked as inaccurate, we are not able to link this entry with source. In such situation we cannot compare stored values with source, because source is unknown.

Base on the above example we see that we have to distinguish two types of accuracy:

- accuracy of key – determines the accuracy of the entire row,
- accuracy of measure – is determined by two factors: the accuracy of the key and the source (by comparison of the stored and source values)

In this example we also see that inaccurate key breaks the linkage between stored entity and source entity making impossible the assessment of the accuracy of measures.

Definition 3.2 (Accuracy of key): The key attribute is accurate if and only if it unambiguously identifies the source object. If the key is a composite the accuracy is calculated for the entire key, and is inherited by each key element.

Example 2 (Accuracy of key): Let's consider relations `Student` and `Curse` presented by Table I. Relation `Student` has a key attribute `SID`. It can be the same number that appears on the students id and it allows us to identify a student in unambiguous way. If we cannot identify the student (i.e. there does not exist student with chosen SID) all data related to this key will be inaccurate. Relation `Course` has a compound key that consists `CID`, `Year` and `Term`. This triple allows us to identify courses. If one of those elements is inaccurate (i.e. term is equal `'T'` which is incorrect value), entire key is inaccurate and all data related to this key is considered as inaccurate. Moreover, if `SID` or one or more key elements from `Course` are inaccurate, then all related entries in `Enrollment` will be inaccurate.

The accuracy of measure is dependent on the accuracy of the key. The accuracy of the measure is based on the idea that the data to be accurate should match source data.

Definition 3.3 (Accuracy of measure): We consider the measure accurate if and only if the key of the tuple ($x.X_0$) is accurate and measure's value ($x.X_i$) is equal to the real world value ($x'.X_i$) identified by the key of the tuple that both key and measure belong to.

$$Acc(x.X_i) = \begin{cases} 1 & \text{if} \quad x.X_i = x'.X_i \wedge Acc(x.X_0) = 1 \\ 0 & \text{if} \quad x.X_i \neq x'.X_i \vee Acc(x.X_0) = 0 \end{cases} \tag{1}$$

IV. Acquisition and Processing of Accuracy

Trust and quality processing described below is one of the most novel aspects of our work. An important advantage of our approach is the use of existing set of tools, slightly modified or extended to serve in the new context. We extended these tools by creating data structures to store and process meta-data describing data quality and trust. We have designed mechanisms for assessing accuracy of data. Our approach is view-based estimation of accuracy of a SQL answer.

In this section we will explain how the information about the accuracy of data is gathered and processed. We will use the view-based model to estimate the accuracy of data in each view's attribute, then the estimated accuracy will be inherited by view's attribute elements.

A. Quality Data Structures

MDM provides a mechanism that enables an extension of the existing data with trust/data quality factors. These extensions may be defined as *persistent object* and stored in the database or be as *transient objects* calculated at run time. We would like to use this mechanism and employ it to tag stored data with the accuracy score.

B. Views

Thinking about the accuracy of data we can easily notice that checking each value and confronting it with the source is not applicable approach, especially in the context of huge governmental or commercial databases. From the other hand big picture defined by some general statistical analysis is often not enough. Our idea inspired by Motro and Rakov's work [17] is employing views over base tables to represent external knowledge about the quality of data.

Definition 4.1: View is a intentional or extensional set of tuples chosen from base table.
In other words the view can be defined by specifying a query or by specifying an extension – set of tuples – by pointing directly members of this set.

Views can overlap. It means that one tuple from the base table can be a member of one or more view. We assume also that each tuple is a member of at least one view. This assumption can always hold, because the entire base table can be seen as one, very general view.

We preserve the relational semantic of view, which can be seen as a set of attributes (in exactly the same way as a table). For each attribute then, the accuracy metric can be calculated. This metric expresses the statistical likelihood of choosing accurate value. The value of this metric is inherited by all elements of the attribute.

Value of the accuracy metric is calculated base on accuracy measure. When operating on sufficiently small set, we can test each value to calculate metric, otherwise sampling and statistical methods can be used to determine the likelihood of choosing accurate value.

The view overlapping rises some problems. Without detailed knowledge of error distribution we are not able to assess the accuracy of the intersection of two views. As an intersection we understand a set that is a subset of both views. In such case we assume that smaller view provide us with more detailed information hence we will use its metrics to tag tuples from the intersection.

Example 3 (View-based accuracy): Let's consider the relation Course (Figures 1 and I). Let's also assume that we have information that the accuracy of entries inputed for the summer term 2009-10 have lower accuracy than average. Base on that knowledge we define view V containing all courses having Term='S' and Year='2009-10'. For each attribute we calculate two metrics: one general, which covers entire attribute, the second one over view V. Each value of the attribute is tagged with appropriate value – if it is covered by view V, it is tagged with metric calculated for the view's attribute, if not, the general metric is used.

C. View elements tagging

In previous subsection we have defined accuracy metrics, which are calculated for each attribute of the view. Here we will explain how view's elements are tagged with the accuracy scores (value of accuracy metric).

Let's remind the assumptions we have made: (1) Views may overlap; (2) Inaccurate elements are distributed over attributes in uniform way. Value of the accuracy calculated for the attribute of the view is inherited by each element of the attribute. Those tags can be aggregated at the end of the processing. The average calculated over all tags will be an equivalent to the weighted average over views. We will use values assigned to elements rather than view in the estimation of the accuracy of query answer.

V. Query processing with accuracy

The trust alone is just yet another piece of data given to the user. The really important question is *What can be done with this information?* Lets consider now some use cases showing usage of the trust in the system.

We have shown that the trust score can be incorporated in our meta-data and linked with each field in the database if desired. This information can be then returned to the user. Even though this information is very detailed, it is not practically useful in all cases. Without algorithms to propagate trust in the query processing, we can only annotate a tuple and return it to the user. However we can build some statistics over this information that can be used later.

One of the problems that are currently unsolved is propagation of trust scores in the query processing. We are currently working on methods allowing us to estimate the trust of the result of the SQL operator based on the estimated trust of entry set. We are using estimates in this context because it is significantly less expensive than reaching out each time for the data.

Analyzing the quality of the query response, the key operation to be considered is selection. All other operations, except projection, rely somehow upon selection. For example *join* operation can be expressed as Cartesian product followed by

TABLE II
DIFFERENT CASES OF THE ACCURACY DEPENDING ON THE AGGREGATION AND TYPE OF SELECTION

	With aggregation		**Without aggregation**
	Count	Other	
Non-trivial	$Acc(X_i) \cdot 1$	$Acc(\sigma) \cdot Avg(Acc(X_i))$	$Acc(\sigma) \cdot Acc(X_i)$
Trivial	$1 \cdot 1$	$1 \cdot Avg(Acc(X_i))$	$1 \cdot Acc(X_i)$

selection and *group-by* operation can be seen as a bunch of selections followed by aggregations.

The accuracy of measure can be determined and interpreted only in the presence of the accurate key. Because of this strong relation between key and accuracy of measures, the latter can be seen as functionally dependent on the key.

Definition 5.1: The accuracy context is a set of key attributes allowing for an unambiguous assignment of accuracy for a field of specific entity or aggregate over a set of entities.

Example 4 (Context preservation): Let's consider the relation Student (Figure I.) and two queries:

- `SELECT * FROM Student`
- `SELECT Name, Surname, DoB FROM Student`

Both queries return all records from the relation Student. The first query however returns entire relation (all attributes) when the second query eliminates the key of the relation (SID). As a result of the elimination of SID from the answer we are unable to connect the arbitrary element from the output with its source entity, hence we cannot calculate the accuracy.

A. Considered query types

In this work, the following types of queries will be considered:

- equi-selects – we consider the equi-select with the key of selection being an attribute which has nominal or ordinal type, preferably a relation key;
- range selects – can be done over attributes which have ratio- or interval-scaled type (the distance between values has a meaning) or over ordinal attributes (the order has a meaning), but not over nominal attributes;
- select with aggregation – both equi- and range select can consist the aggregation. We have found two subsets of this type of queries:
  - count – the value of the attribute (if not NULL) does not influence the result;
  - other aggregates – values have an influence on the result, the scale of the impact depends on the aggregate function.

When considering range selects following problem arises: some ranges may be defined in a way that the answer is entire relation. We consider this class of queries because even though is seems that some comparison is required to determine if tuple should be returned, in fact, no comparison is necessary.

Example 5 (Trivial range selection): Let's consider the relation Student and following range query:

```
SELECT * FROM Student
WHERE
DoB BETWEEN 1900-01-01 AND 2100-12-31
```

The range of DoB is from 1971-01-01 to 1981-01-01. We clearly see that the WHERE clause of the query covers entire relation and because of that the query is semantically equivalent to the query `SELECT * FROM Student`. In such case, comparisons are not necessary to derive the answer.

B. Accuracy components

We have identified two main components of the accuracy of the selection's result. The first one is the accuracy of the attribute factor, denoted as $Acc(X)$ where X is an attribute. Including this component seems to be natural and obvious. The second component is the accuracy of selection, denoted as $Acc(\sigma)$, which expresses the likelihood that an arbitrary tuple has been accurately selected. It is the likelihood that the arbitrary element from the selection key is accurate. This component has to be covered and propagated over all derived attributes.

We have to explore how those components interfere in different types of queries. It can be easily noticed that selection component will not appear in trivial selections since we cannot make any mistake. On the contrary in the query employing counting operation the accuracy of attribute being counted does not meter because we are interested only in the number of elements, not the exact values. Table II gathers all cases that we have identified. It also presents our preliminary proposition of calculation of the accuracy of the selection's result. It is based on the assumption that attributes are independent in terms of errors' distribution. In such case we can see the accuracy of derived element as a result of two independent events: accurate selection and accurate value of the considered attribute.

VI. CONCLUSIONS

Measuring data quality and data trust is one of the key aspects of supporting businesses in decision making process or data stewardship. Master Data Management in other hand supports sharing data within and across lines of business. In such case trustworthiness of the shared data is extremely important. Our investigation has resulted in consistent method of gathering and processing quality and trust factors.

In this work we have presented the *IBM InfoSphere MDM Server* and elements of *IBM Information Server* such as DataStage, QualityStage, AuditStage and Information Analyzer, and their ability to handle data quality and data trust. We have also presented the new notion of data trust. The process of gathering and computing data quality and trust factors has been described and explained using example.

This work covered only the introduction to the accuracy processing. We consider select as a most basic operation, which is necessary to proceed with other operations and though should be explored soon. We have proposed the data model for the accuracy storing and processing. In the future we are going to cover in our consideration all SQL operators including accuracy neutral operators (Cartesian product, projection) and other accuracy sensitive operators (join, group-by and set operations). We suspect that projection and Cartesian product are accuracy-neutral because those operations does not relay upon accuracy of input. They do not "touch" data values.

Abstract— **In this paper we report the findings of the EU 6th Framework Programme Project "Rural Wings" concerning the selection, performance and evaluation of the satellite internet pilot sites, based on the case studies of ten such sites in Poland. First, we present the methodology of ex-ante assessment of specific needs concerning the intensity and the scope of use of the DVB-RCS bidirectional satellite internet technology in the mountain and rural areas that led to the selection of rural sites, where the bidirectional satellite terminals were installed . Then we review the operation of the pilot sites and their final performance evaluation. We compare the rankings resulting from the initial needs assessment with that one derived from the final evaluation and analyse the divergences. Finally, we propose a learning scheme resulting from ex-post evaluation of the initial ranking procedure, which allows to assess the adequacy of the multicriteria decision-making approach applied to derive the initial pilot sites' ranking.**

I. Introduction

OVER 25 million citizens of Europe live in the remote mountain, island or rural areas, where ground-based broadband internet is hardly available - or not available at all. An improvement of the internet infrastructure is therefore necessary to bridge the digital divide by ensuring the access to information, e-government, e-commerce and e-learning applications to the members of rural communities. In some European regions, such as low-populated Bieszczady mountains in Poland, Greek islands, or northernmost parts of Sweden or Finland, the satellite internet can provide a competitive, or the only solution to cope with this problem. Consequently, the European Commission has approved a series of research projects devoted to analyze the needs and find the best technical and organizational solutions for the deployment of satellite technologies for citizens, institutions and businesses in rural areas. One of them, the 8,8 MEUR project "Rural Wings" (www.ruralwings-project.net, www.pbf.pl/ruralwings), financed by the European Union within its 6th Framework Programme, started in January 2006, with the main aim to select, launch, and maintain pilot stations of satellite internet in the bi-directional DVB-RCS (Digital Video Broadcasting - Return Channel via Satellite) technology [1], [2] in 16 countries of the world. The stations should be situated in the remote rural or mountain areas, with no – or only poor quality – broadband internet access, and serve local communities in accessing the web, supporting thus a move from the traditional agriculture to the development of innovative and sustainable agriculture and other branches of rural economy such as agrotourism. The achievement of specific goals of each pilot station, related mostly to e-government, e-learning, and e-commerce, but also to the dissemination of research carried out at some of the stations, should had been assisted, monitored, improved, advised and reported by the partners of the above project assigned the role of National Coordinator in each country. The infrastructure of pilot stations consisted of the satellite terminal (D-Star) with dedicated software and hardware. Last, but not least, most sites have been connected to Local Area Networks and WiFi networks. The technical supervision comprised measurements of the technical performance of the satellite internet terminals (D-Star) and satellite transponders (in Poland's case Eutelsat Atlantic Bird 1B), including the transmission rates for down- and uplinks, investigation of transmission failures, and tracing the sources of disturbances.

The present paper reports the methodology of evaluation of the project's results in Poland, where the Progress and Business Foundation from Cracow, an academic NGO (www.pbf.pl) has been selected to play the role of the National Coordinator. As the assessment of a network of satellite internet local hubs had not been described before in the literature, the methodology elaborated for the network of ten sites in Poland has been also presented and made available to all other Project's partners..

The paper is organized as follows: first, we will present the methodology of assessment of specific needs concerning the intensity and the scope of use of satellite internet in the DVB-RCS technology in the remote mountain areas in Southern Poland. We will review the operation of the pilot sites where the bidirectional satellite terminals were installed, then we will analyse their final performance evaluation. In the final section we will compare the rankings resulting from the initial needs assessment with that one derived from the final evaluation. While the technical criteria of needs

The project Rural Wings was supported in part by the European Commission, grant No. FP6-IP-516161. The assessment of the applicability of its outcomes in Poland was co-funded by the ERDF within the Innovative Economy Operational Programme, 2007-2013, project No. WND-POIG.01.01.01-00-021/09: „Scenarios and development trends of selected information society technologies until 2025" carried out by the Progress & Business Foundation, Cracow, Poland, www.pbf.pl

assessment and evaluation were different, the target goals, i.e. intensity of use, measured as the transmission volume, the number of users and their regularity, measured by the standard deviation of the above, as well as the second goal: filling-in the gaps in the broadband coverage, and the third-one: the number of users willing to use the applications made available within the project, could be compared as *ex-ante* expectations at the stage of selecting the pilot sites, and as *ex-post* evaluation results. To make such a comparison possible, the criteria actually measured need to be transformed to the measures of the above goals, taking into account the stochastic character of the initial expectations. The method here proposed allows to derive a set of relevant needs assessment criteria from a larger set of criteria considered at the selection phase of the project. It is also possible to assess the adequacy of the multicriteria decision-making approach applied to derive the initial pilot sites' ranking. The above approach is universal in the sense that it can be applied to any similar problem, involving an initial *ex-ante* and *ex-post* rankings based on the actual performance.

II. The Needs and Analysis and Selection of Pilot Sites in the Beskidy Mountains

One of the first tasks of the project was the selection of pilot sites. Taking into account that the only geographical regions in Poland where the problems with low broadband access was related to the topography and geographical isolation were the Beskidy mountains in southern Poland, we made the decision to restrict the selection to the Małopolskie and Podkarpackie Voivodships, specifically to their counties situated in the mountains and fulfilling initial low-broadband-access assumptions.

Following the initial indications concerning the site selection criteria provided by the responsible project's partners, a site selection methodology tailored to the specific country needs was elaborated. The main three groups of selection criteria are listed below:

- **Geographical situation of sites** – according to the Project's goals, the more remote and isolated the site, the more eligible for the Project, but the diversification of geographical locations and an even distribution of sites over target areas were taken into consideration as well.
- **Existing internet infrastructure –** the pilot stations should be installed in areas without broadband facilities or – at least - the internet access provided by third parties should have lower transmission rates or be less reliable than the Rural Wings system. On the contrary, other existing IT infrastructure, such as school computer labs, LAN etc. would be of advantage for the project.
- **Availability of potential end-users** willing and capable to engage in the activities of the pilot station.

The assessment of each of the above criteria was based on the evaluation of a set measurable subcriteria, which were calculated from the data gathered in two questionnaires assessing the community and individual needs at potential pilot sites. The forms and criteria were enhanced by country-specific additional issues, in Poland relating a.o. to the ability to supply research results via satellite internet. The method to aggregate the data gathered in the questionnaires to the measures of the above criteria, as well as the choice of the multicriteria outranking method to establish the final sites' ranking was the task of the National Coordinators.

The pilot site selection was performed in four-steps:

(i) First, the country needs as a whole and the needs of regions, sectors and types of institutions were assessed in order to choose most appropriate target groups and areas.

(ii) Then the questionnaires were mailed to the selected target groups: local authorities, schools, national parks, research establishments, and business support organisations providing adult training. The data gathered were then verified during field visits and otherwise.

(iii) Taking into account the volume and the quality of data gathered, we elaborated a method to transform the questionnaire data into the measures of subcriteria. Then we used the multicriteria outranking method based on the reference sets approach [3] to establish a preliminary ranking of sites.

(iv) The selected sites, were visited in the order yielded by the outranking procedure, to present the Rural Wings project to the appropriate local authorities. Based on the technical feasibility of installing the DVB-RCS equipment at the selected sites, the results of negotiations, and the final assessment of the viability and usability of site derived from the field visits, the Selection Committee could either decide to eliminate a site from the list, e.g. in case of the lack of support from the school authorities for this site, or to change its rank. The latter might happen usually when the final decision to sign the agreement was postponed by local authorities. Then it followed the installation of DVB-RCS D-Star terminals according to the finally derived order.

Consequently, the above selection process started in Poland in early 2006 from a detailed country needs analysis in the areas of DVB-RCS technology, e-government, e-learning and other e-services and applications, which were to be provided by the project to the end-users. The above mentioned applications have been the top priorities of the „ePoland" [6] programme, first phase of which was realised prior to launching the Rural Wings project. It created thus a background for the implementation of the Project providing IT training of teachers, creating multimedia information centres, educational content and portals, electronic libraries, and content servers.

Based on the statistical data concerning the broadband access in different regions of Poland we refined the study to identify geographical areas and institutions relevant to the project, such as research institutes, national parks, local cultural centres, schools, public libraries etc. with no or only a poor-quality broadband access (nb. the dial-up connections were already commonly available via the National Telecom since the 90's). The systematically updated maps of broadband penetration were used to veryfy the needs. Future plans to establish commercial wireless broadband access by local providers were considered as well.

Thus, it was decided that the Polish sites should be situated in Southern Poland, except two potential locations in Polish off-shore research stations in Svalbard and Antarctic St.

George Island. The other potential implementation region in Northern Poland is more likely to be covered by wireless internet as it is situated in the lowlands. Furthermore, the study allowed to determine the main categories of potential satellite internet pilot stations in Poland, namely:

- public access points in local government offices, cultural centres and telecentres,
- rural schools and public libraries,
- remote research stations and national parks, and
- touristic establishments in mountain areas.

Other categories considered were policlinics and fire brigade centers in remote rural areas that perform also educational activities, for which, as it turned out, there already existed governmental or regional plans to endow them with modern IT infrastructure, including broadband access.

As only two sites had to be installed in phase I of the project, the country needs analysis was extended and updated prior to the phase II in 2007. The needs analysis in the areas of DVB-RCS technology, e-government, e-learning and other Information Society services, technologies and applications, has been performed using the IST foresight results for Poland elaborated during the 5th Framework Programme FISTERA project [5],[6], while the analysis of future applications has been performed within the ERDF-financed foresight project quoted in the footnote above.

In the second step, the questionnaires were distributed to over 400 institutions in Małopolskie and Podkarpackie regions (Voivodships) identified as potential pilot sites. From over 120 replies, about 70 seemed to be eligible pilot stations. Individual site visits and interviews reduced this number to about 40, eliminating non-public institutions or multiple institutions in one village.

Further, in Step (iii), the sites' selection criteria and selection methodology have been refined using the multicriteria analysis. We have elaborated a dedicated multicriteria site selection methodology which uses the reference sets approach [3] and takes into account the specific Poland's needs.

A preliminary ranking using a set of target reference points was established, so that for each of the above listed four categories of pilot stations a model pilot site was defined, characterized by desirable values of each of the above three metacriteria. The models played the role of non-attainable (ideal) target reference points in the above outranking method, namely for each of the complete questionnaires received form an eligible pilot site we calculated the distance to the model target point representing an appropriate category. At the same time minimal requirements, specified within the Project, had to be fulfilled by all sites considered; they played the role of status quo reference points, as defined in [9] and had been used as constraints. Ten sites with the highest distance scores were thus found to be the candidates for the 1st phase installations of the Rural Wings project in Poland. Only two of them had to be actually installed, while the others could remain candidates for the subsequent phases two and three.

TABLE I.
THE INITIAL RANKING OF RURAL WINGS PILOT SITE CANDIDATES IN POLAND

Rank	Name of the Pilot Site	Place, Region	Type	Users	Employees with IT background	Internet available
1.	Arctowski Research Station	St. George Island, Antarctica	Research	a) researchers b) visitors	All researchers at the Station	NONE
2.	Babiogórski National Park	Zawoja, Małopolska (Beskidy Mts.)	Wildlife reservation/ Research / Tourism	a) scientists b) visitors c) local community members	Two IT-specialists	Dial-up connection 64Kb/sec (DSL)
3.	Polish Polar Station – Hornsund	Hornsund Fjord, Svalbard	Arctic Research	a) scientists c) visitors	All researchers working at the Station	(Satellite, high disturbances)
4.	Polana Primary School	Polana, Podkarpackie (Bieszczady Mts.)	Primary School	a) schoolchildren b) farmers c) tourists	One IT teacher responsible for the hardware and LAN	NONE
5.	Magurski National Park	Krempna, Małopolska, Beskid Niski Mts.,	Wildlife reservation/ Tourism/ Research	a) scientists b) visitors c) local community members	One IT-engineer	Radio ADSL connection (disturbances)
6.	Gładyszów Primary School	Gładyszów South-Eastern Małopolska	Primary School	a) schoolchildren b) farmers c) tourists	One IT teacher responsible for the hardware and LAN	Ground-based ADSL connection

Source: Progress & Business Foundation (2009)

In the final, fourth, phase of the selection procedure we investigated the synergy with other projects of similar nature and goals as Rural Wings, that - if carried out in the same area - would constitute a challenge to the Project. Each such situation had been investigated in detail and the results actually influenced the final ranking. For instance, sites endowed already with broadband access from earlier programmes, such as “Ikonka” or “Interkl@sa”, were not taken into account for the Rural Wings pilot phase, that allowed to reduce the number of initial highest-ranked candidates to six.

During the selection process we took into account new opportunities that arose from the contacts with the leaders of local action groups, institutions hosting pilot sites, and local administration. A possibility to establish bi-directional scientific and educational data interchange between several Polish research stations: the polar station in Hornsund, the Antarctic research station on St. George Island, the Magurski, and Babiogórski National Parks, has been investigated as an additional chance and added value of the Project requiring the use of specialised software tools. The local administration representatives have been interested mostly in e-government applications and in teaching the members of local communities how to use them.

The results of the above presented selection procedure – six locations in the Antarctica, Svalbard and in the Beskidy mountains - are presented in Tab.1 above.

By the end of June 2006 the phase I of the pilot sites selection was completed and working contacts established with the representatives of all selected candidate sites. However, the Antarctic Arctowski Research Station, ranked 1, could not get the satellite connection because of the technical infeasibility of the Atlantic Bird 1 B satellite to reach the St. George Island. Furthermore, heavy snowfalls, that came as early as in September, made the installlation of the D-Star terminal in Hornsund, Svalbard, impossible. Finally, sites ranked 2 and 4: the Babiogórski National Park and Polana Primary School turned out to be successful winners of the phase I of the selection process. A similar procedure has been performed for the 2nd phase pilot sites, yielding a list of next-best eight pilot stations. All they are presented in the next Sec.3.

III. The operation of the DVB-RCS pilot sites in Poland

First two pilot sites, selected within the above described procedure, were installed in March 2007: the Babiogórski National Park with the site in the Park's headquarters in Zawoja, Beskidy Mountains, Małopolskie Region, and the Polana Primary School, situated in the Bieszczady Mountains, Podkarpackie Region. The selection of sites performed for the second project period yielded eight subsequent sites. All selected sites are shown in the Fig.1 and Tab.2.

The phase II installations started in two municipalities in in the Beskidy Mountains in Małopolska in 2008: Wiśniowa with the sites at the Lubomir mountain – the didactic astronomical observatory of the Jagiellonian University and in the Wiśniowa Secondary School, and the municipality of Raba Wyżna with sites at the Rokiciny Podhalanskie Telecenter and at the Public Library in Skawa. Following a needs' analysis, the sites have been endowed with the software and hardware suitable for the selected scenarios of use, and the terminals were connected to WiFi networks.

The remaining four pilot sites were established at the Primary School in Nowy Łupków, the Secondary School No. 9 in Kęty, finally, the Primary Schools in Myczkowce and Harkabuz in 2009. The latter sites are situated in the mountains as well: Kęty in the Beskid Żywiecki Mountains, Nowy Łupków and Myczkowce in the Bieszczady Range in South-Eastern Poland, and Harkabuz in the Central Beskidy Mountains. Basic characteristics of all above-mentioned pilot sites is presented in Tab.2 on the next page.

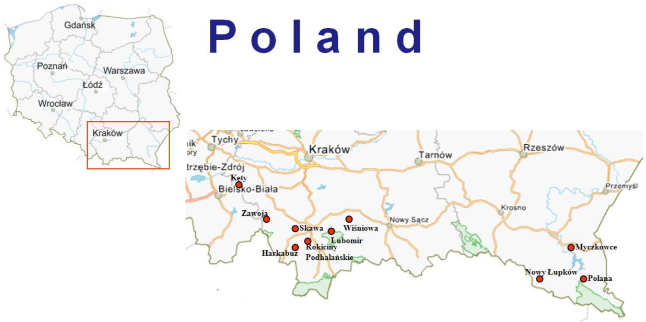

Fig 1. The situation of Polish satellite internet pilot sites selected for the Rural Wings project

The technical and training support activities provided by the National Coordinator were supplemented by monitoring the operation of the pilot sites and collecting the data for final evaluation. They included a.o. on-site consultancy, measurement of transfer rates, consulting concerning hardware of satellite terminals and WiFi installations, monitoring the use of applications supplied by other project's partners.

Further needs analysis concerning the hardware and software, based on the actual users' needs elicited during the pilot phase, had been carried out.

The National Coordinator's team reviewed the users' scenarios available in the Rural Wings project in order to plan a most effective project implementation and to assist the users. A new package "Improving internet access to public services and the electronic office (e-government) features learning" was defined and included in the scenario portfolio as this has been expected to be the most relevant issue in Poland at time when the project was carried out. Then the recommended scenarios for each pilot sites were chosen by the local community leaders assisted by the national Coordinator. The initial assignment of scenarios is presented in Tab. 3 in the next Section.

The *ex-ante* expectation concerning the use of satellite internet shown in Tab.3 served as a base for the *ex-post* assessment of the operation of sites and project's goals achieved that are discussed in the next Section.

IV. Final evaluation of the project's results in Poland

The evaluation of the project's results in Poland presented in this paper was based on the data gathered by the National Coordinator during the period of 2006-2010 when the project was carried out. Having selected and implemented the pilot sites, the evaluation process had a twofold character: on one hand it was performed as a project's internal workpackage, according to the same rules and criteria for all countries and regions.

The core of the corresponding evaluation methodology was provided by the Coordinator of the project and by the Consortium Partner responsible for the evaluation, while this methodology was continuously improved during the exchange of views at all Consortium meetings and the e-mail discussions afterwards. This part of the evaluation process was user-centered, based on the evaluation forms that had been sent to the end-users, filled-in at the training seminars and during other project's events, and were available on the web to be filled-in on-line.

Other streams of the monitoring and evaluation activities were linked to the technical aspects of the current operation of pilot sites, especially the users' feedbacks, have been analyzed by the National Coordinator's experts. The data on the transmission rates (down- and uplink) were continuously monitored and gathered for a later overall evaluation. Similarly, the information about the use of the terminals, such as the applications used, number and social structure of end-users, time at use, technical problems encountered, were gathered as well. The functionality of applications used and their responsiveness to the needs of different groups of end-users have been also evaluated.

While multicriteria outranking approaches based on weighting the individual criteria are commonly prevalent in deriving the rankings from individual scores, we have found out that a similarity measure to the ideal and satisfactory objects

Table II.
The pilot stations of the 6th FP Rural Wings project in Poland

ID	Place, host institution	Start of operation	Geographical situation	Description and type of the pilot site	No. of inhabitants / users	Goals to be achieved by this site and main target groups
POL 01	ZAWOJA, Babiogórski National Park	2007.03.28	longitude: 19°54, latitude: 49°65, altitude: 650 m asl	The pilot site is situated in the headquarters of the Babia Góra National Park (BGPN). close to Babia Góra (1725 m asl) Site type: Research Station & Wildlife Reservation	6200 / 2000	1. Supporting local administration in environmental issues 2. Better environmental education, enriching science learning and scientific activity in remote rural areas: high school and university students, teachers, ‘green schools’ participants 3. Using internet access for carrying out scientific research. Specific applications: producing and disseminating videos with observations of the Park's wildlife
POL 02	POLANA, Polana Private Salesian School	2007.03.29	longitude: 22°35, latitude: 49°18, altitude: 639 m asl	Polana is a small village in the south-eastern edge of Poland. It is situated in the central area of the Bieszczady Mountains. Site type: rural school	400 / 80	1. Using internet access for learning at school. 2. Using internet access for learning at home. Specific applications: local e-office access, WebTV - schoolchildren use cameras to record school events, then upload them to the web, e-learning applications supplementing the biology and English lessons
POL 03	WIŚNIOWA, The Private Adult Secondary School	2008.02.26	longitude: 20°12, latitude: 49°79, altitude: 380 m asl	The Wiśniowa Municipality is located in the mountains. 50 km to the south from Krakow It is surrounded by Site type: rural school	1900 /40	1. Using internet access for learning at school 2. Using internet access for learning at home Specific applications: UNITE platform -used during English lessons, and supplementing the biology and geography lessons
POL 04	MT. LUBOMIR, The Astronomical Observatory of the Jagiellonian University	2008.02.27	longitude: 20°08, latitude: 49°75, altitude: 904 m asl	Mt. Lubomir is situated in the north-eastern part of Beskid Makowski Mountains. The site is endowed with indoor WiFi for employees, and outdoor one for visitors. Site type: remote research station	1200 /100	1. Using internet access for carrying out scientific research. 2. Using internet access for learning. Specific applications: Discovery Space (D-Space) and similar applications allowing to transmit astronomical data from Lubomir via internet and to join the network of similar observatories. With D-Space the visitors of the Observatory are able to compare the views of astronomical objects from different telescopes
POL 05	ROKICINY PODHALAŃSKIE, Raba Wyżna Telecenter	2008.02.28	longitude: 19°91, latitude: 49°57, altitude: 550 m asl	Rokiciny Podhalańskie is a village in the Raba Wyżna municipality, about 70 km south from Krakow, in the Beskidy Mts. The pilot site serves the local telecenter. The outdoor WiFi, reaches the nearby recreational area. Site type: rural telecenter	Raba Wyżna Municipality: 13632, Rokiciny Podhalańskie: 1450 / 250	1. Intensive e-government-oriented training programs 2. The use of municipal web service of Raba Wyżna 3. Using internet access for learning at school 4. Using internet for learning at home and during leisure time 5. Using internet access for learning at work Specific applications: Electronic consultations on local community matters proposed by municipal authorities, WebTV - users record relevant events from the life of Raba Wyżna municipality, then upload it to the web.
POL 06	SKAWA, The Municipal Public Library	2008.02.29	longitude: 19°90, latitude: 49°62, altitude: 514 m asl	Skawa is a village in the Beskid Zachodni Mountains about 70 km south from Kraków. Site type: rural library	4000 / 300	1. Using internet access for learning at school 2. Using internet access for learning at home 3. Using internet access for learning at work Specific applications supplement the lectures on ecology and biology at the Library, and municipal web service of Raba Wyżna (e-govt)
POL 07	NOWY LUPKOW, Primary School	2008.11.06	longitude: 22°05, latitude: 49,15, altitude: 592 m asl	Nowy Łupków is situated in the Podkarpackie Voivodship, in the Bieszczady Mountains. Site type: rural school	390 /60	1. Better education: Enriching science learning and scientific activity in remote rural areas 2. Rural school teachers’training Specific applications: WebTV, schoolchildren record school events, then upload the movies to the web
POL 08	KĘTY, Secondary School No.9 in Kęty	2008.11.07	longitude: 19°90, latitude: 49°62, altitude: 514 m asl	The Community of Kęty is located in the Soła river valley, at the foot of the Beskidy mountains. Site type: county-level school	19500 / 300	1. Better education: Enriching science learning and scientific activity in remote rural areas 2. Rural school teachers’ training Specific applications: Teachers` IT training seminars. Xplora, UNITE platform, Experinet have been used to enhance natural science lessons
POL 09	MYCZKOWCE Primary School	2009.02.06	longitude: 22°24, latitude: 49°26, altitude: 364 m asl	Myczkowce is a village in the Podkarpackie Voivodeship in south-eastern Poland. Site type: rural school.	510 /120	1. Better education: Enriching science learning and scientific activity in remote rural areas, 2. Rural school teacher training Specific applications: e-govt-oriented training, Cret@quarium, WebTV
POL 10	HARKABUZ, Primary School	2009.03.18	longitude: 19°50, latitude: 49°32, altitude: 809 m asl	Harkabuz is a village in the Raba Wyżna municipality, in the Beskid Zachodni Mountains. Site type: rural school	530 / 75	1. Better education: Enriching science learning and scientific activity in remote rural areas, 2. Rural school teacher training Specific applications: municipal web service of Raba Wyżna (e-govt), Cret@quarium, WebTV

defined at the selection phase would better correspond to the ideas underlying the functioning of pilot sites.

First, data characterizing the individual pilot stations' performance, containing 12 indicators, were gathered and indicators grouped into three groups: technical, intensity-of-use-related, and qualitative, Then the groups of criteria were aggregated to three synthetic objectives: those technical, based on transmission quality, those related to the intensity of use, and those describing the quality of fulfilling the Project's goals, based on interviews and qualitative assessments. The final ranking was derived by comparing the values of synthetic objectives with the corresponding values for reference sets containing the model and satisfactory objects.

The results of the *ex-post* evaluation, as of December 31, 2009, reported until March, 2010, are presented in Tab.4. For reference, in Cols. 9 and 10 we include a comparison with the results of *ex-ante* assessment and scenario expectations presented in Tabs. 1 and 3.

It is to be noted that, despite the deficiencies of the weighting methods, all technical criteria in Tab. 4 were aggregated based on an equal weighting. Thus the overall technical assessment criterion (col. 7 in Tab.4) was a result of rounding and normalising to the scale [0,…10] of the linear combination of the absolute transfer rates (positive weights) with the unreliability of the link expressed by the standard deviation of the down- and uplink rates (with negative weights).

Observe that the highest mean values received for downlink in the site POL05 were accompanied by highest connection risk that reduced the technical score. The main,

or for most sites even the only reasons of a lower-than-expected use of dedicated applications were lower-than-expected transmission rates, that made the use of some applications more difficult, and the initial lack of the most wanted e-government-oriented learning applications, tailored to Polish circumstances, that was supplied by the National Coordinator in the third year of the project.

Neither the National Coordinator nor the sites themselves had an influence on the technical criteria contained in cols. 3-6 in Tab. 4. The transmission rate values assumed in the project were 4 Mbaud for downlink and 2 Mbaud for uplink, so the values reached actually differ substantially from those initially assumed. Intensity of using Project's dedicated applications by all sites were measured by access time to the specific web pages and supplied by the project's partner responsible for these measurements. These data were normalised for all sites, taking into account the transmission rates at this site and the assumed number of potential users. It is to be noted that the ranking in Tab.4, should be regarded as touching upon only the aspects specified in this paper and it might not reflect the overall assessment of the sites' operation. Therefore the differences between the *ex-ante* (selection-stage) and *ex-post* evaluation ranks contained in col. 10 of Tab. 4 may serve exclusively as an illustration of the evaluation method and not as the final assessment. On the other hand, the values obtained show a good compliance between the expectations, that served as reference values, and actual results.

An additional aspect of the above evaluation resulting from the interdependence between the (*ex-ante*) needs analysis and *ex-post* evaluation of pilot sites, is to justify the rationale for the initial selection of sites. While the technical criteria of needs assessment and evaluation were different, the target goals, i.e. intensity of use, measured as the transmission volume, the average number of users per week and its stability, measured by the standard deviation of the above, as well as the second goal: filling-in the gaps in the broadband coverage, and the third-one: the number of users willing to use the dedicated applications made available within the project, could be compared as *ex-ante* expectations at the stage of selecting the pilot sites, and as *ex-post* evaluation results. To assess each individual site, its final outcomes were adjustted to the potential capacity of this site, rather than measured in absolute numbers. The difference between *ex-ante* expectations at the stage of selecting the pilot sites, and *ex-post* evaluation results, was taken into account, to measure the progress achieved. To assess the entire sites' selection process, the assessment of the overall benefits, resulting from the operation of all sites, can be taken into account as a separate criterion as well.

V. CONCLUSIONS

Based on the data gathered at the satellite internet pilot sites by the National Coordinator for Poland, and the studies carried out afterwards, we can conclude that the *'most probable'* Polish Information Society (IS) development scenario until 2025 and beyond contains a considerable use of satellite internet access in selected remote rural areas, where the duty of the dominating telecom operator to provide a broadband access to all citizens, that is imposed by law, can be

fulfilled by the DVB-RCS or a similar bi-directional satellite technology in a most efficient and economical way.

The recommendations and conclusions resulting from the implementation and evaluation of the Rural Wings project in Poland, can be summarised as follows:

- The installation and operation of the satellite internet access points in the DVB-RCS technology overlaps with the middle-term Information Society (IS) policy goals, as specified in the related Polish IS policy documents, and with the statutory duties of dominating telecoms,
- With the forthcoming new generation of satellites, the DVB-RCS internet can provide safe and affordable e-infrastructure with geographically unlimited access,
- The successful operation of the D-Star terminal installations depends on the availability of comprehensible e-government, e-learning platforms, content and services,
- A growing role of e-health-related applications, that have to be made available to everyone, without geographical limits, is to be taken into account when designing the future deployment plans of the DVB-RCS technology,
- The satellite internet access can foster the extension of common intellectual sphere in the e-space and eliminate digital divide in rural areas;
- The development of local information societies in rural areas based on the satellite DVB-RCS technologies will support a move from the traditional agriculture to the development of future innovative, sustainable, environment-friendly agriculture that supplies high-quality end products and uses sophisticated IT, such as robotics, monitoring and control. Similarly, other branches of rural economy, such as tourism, specifically agrotourism, will benefit from the satellite broadband access.

Furthermore, the conclusions resulting from the *ex-post* evaluation of the initial ranking procedure give an insight on the overall evaluation methodology for the satellite internet access points. The *ex-post* evaluation of the initial ranking, based on the comparison of initial ranking and the *ex-post* assessment criteria studied in Sec.IV, may allow to derive a learning scheme, which – in turn – can be useful to assess the adequacy of the selection criteria, the adequacy of choice and correctness of using of the multicriteria outranking procedure applied in the selection process and the credibility of data supplied by the applicants. To make such a comparison possible, the actually observed criteria need to be transformed to the measures of the above goals, taking into account the uncertain character of the initial expectations. The evaluation process of the functioning of ten DVB-RCS pilot sites in Poland allows to derive a subset of relevant needs assessment criteria from a larger set of criteria considered at the site selection phase.

A similar approach to the presented above can also be applied to assess the adequacy of the multicriteria decision-making method applied to derive the final (*ex-post*) pilot sites' ranking. The core of the procedure consists in calculating the distance between the initial and final rankings, which reflects the efforts that would be needed to get the results anticipated, as seen *ex-post*. An aggregated value function, describing the quality of assessment and quality of performance of selected sites can be defined as well. In case of repeated decision problems, its outcomes can be used as inputs for a learning scheme. This approach is universal in the sense that it can be applied to any similar problems, involving an initial ranking, and the performance of *N* selected objects based on this ranking. Specifically, a general methodological framework to select satellite internet access points could be based on the scheme here proposed.

Finally, let us mention that based on the economic forecasts and scenarios for Poland [6], the infrastructural IT satiation in Poland will come between 2014 and 2017 [7], together with the development of commonly accessible e-economy, e-government, e-health, and e-learning applications [8]. This breakthrough will set the high-quality broadband access and common IT literacy among citizens to one of the top policy priorities.

To sum up, there is a considerable potential for satellite-based e-government, e-learning and e-health in Poland, the latter especially for preventive medicine and m-health applications [4]. One can expect that m-health in remote and sparsely populated areas shall be based on the satellite internet, which is regarded as more reliable that the wireless-ground-based connections. It is also worth to mention that e-learning, e-government and e-health-related actions, activities and public funding have been included in the strategic local policy documents in Polish regions concerned, i.e. in Małopolska and Podkarpackie Voivodships, which makes future implementations plans, resulting from the Rural Wings project feasible.

Abstract*—The article features the results of two initial stages of the Infomat-E project. The project is to provide access to information to people with sight and hearing dysfunctions through a hardware-software solution. So far, a number of analyses have been conducted within the project with respect to the method in which the contents of information is presented as well as interaction with the devices that present this information. These included the analysis of suitable colours, font sizes, ergonomic layout of screen menu bars, and ergonomic keyboards – to make them most convenient for people with sight and hearing dysfunctions. There were also analyses conducted how written texts are understood, especially in the case of the deaf. The project assumes integration of elements which were results of separate research projects. Within the project, the following will be used: speech synthesis, speech analysis, presentation of ideas with the use of the sign language. The project will result in the Infomat-E system which will present information in kiosks specially designed to suit the needs of people with sight and hearing dysfunctions. The article features the results of the conducted analytical works which lay at the basis of the technical concept of the system. This concept is presented in the article too.

I. Introduction

MODERN public administration requires that the customers should have more and more knowledge, especially in the field of administration issues. It is necessary to know regulations, administrative procedures, to be familiar with one's own rights and duties resulting from the national and local laws. To meet the clients' expectations in this field, administration offices provide information in different ways. There are guidebooks, web sites, public information newsletters, information kiosks, and other methods to provide assistance in everyday contacts between citizens and public administration.

Among people who use public administration services there are handicapped people whose dysfunctions cause not only health problems but also communication problems. Among the handicapped, 30% are people with sight dysfunctions, while about 14% – with hearing dysfunctions [1]. As there are about 5.5 million handicapped people in Poland[1], the group of people with sight or hearing dysfunctions is considerably large, and this group is particularly affected by communication problems as far as the access to information or information exchange are concerned. Many institutions lack solutions that would allow the blind and the deaf to deal with administration issues easily and, what is even more important, by themselves. In the case of blind people, there is no information that would contain, for example, a set of guidelines how to move inside a building in order to get to the place where a given issue is dealt with.

While the problems of blind people seem to be regarded as evident, it is often understood that written information is an alternative for the deaf. However, deafness significantly affects the way a deaf person functions in a society, causing difficulties in understanding both written and spoken information and in expressing oneself. This affects particularly those who have been deaf from birth as the Polish language is a foreign one to them – their mother tongue is the sign language which has totally different syntax and grammar regulations and whose terms have different semantic ranges than those characteristic of Polish [2]. Vocabularies are significantly different too as far as the number of words is concerned. Generally speaking, sign languages used in Poland have only several thousand signs each. Information provided by different institutions, not only administration offices, is often too complicated (due to such reasons as: too sophisticated words, too long sentences, the use of compound-complex sentences). Such statements are too difficult to understand not only by a deaf person but also by an average citizen.

As a result of all these factors, people with hearing and sight dysfunctions have become socially excluded as far as the contacts with public administration are concerned.

Currently available devices that support the deaf and the blind in their everyday living are separate for each of these two groups. There are no integrated and, at the same time, publicly available solutions that would support people with each type of dysfunction, not only individual users.

II. Infomat-E project

The researchers of EMAG had recognized the numerous, varied and yet unsolved issues and launched a project aimed

The presented results are the results of the project No N R02 0059 06/2009

[1] National Census 2002.

at solving at least a part of problems of the handicapped. Within the project No N R02 0059 06/2009 EMAG began the development of an integrated set of hardware and software components which will allow efficient information transfer to people with sight and hearing dysfunctions. The objective of the project is to develop a prototype which will make it easier to deal with widely understood public issues. The solution will be based on providing information with the use of specially designed information kiosks. This article aims at presenting the results of analytical works related to the project along with the concept of the Infomat-E system development.

III. Analyses results

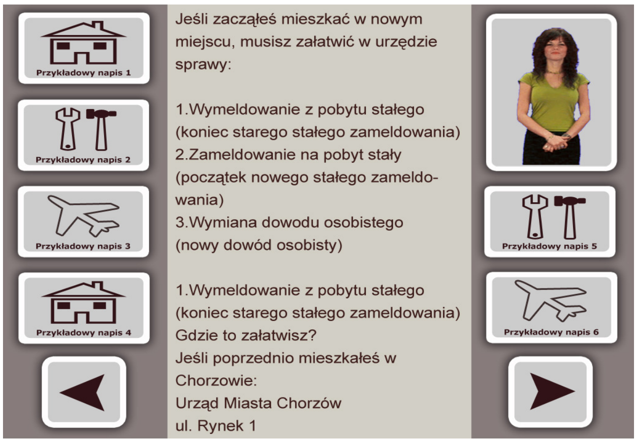
The Infomat-E project is developed in co-operation with two groups of handicapped people, according to the project assumptions. All analyses presented here, along with proposed technical solutions, were consulted with potential future users of the system, i.e. blind, poorly sighted, deaf, and hard-of-hearing people.

A. Requirements about appearance of the device

The Infomat-E project is based, to a large extent, on presenting information to the user. The information is presented in kiosks and the objective of the project is, among others, to make the presentation method and navigation through the system as easy as possible for people with sight and hearing dysfunctions. For this clearly defined objective there were requirements identified and analyzed within the project. The article features a part of these requirements with comments. For blind people it is important that the information should be property voiced and that an ergonomic control method should be applied (voice, well adapted keyboard). For poorly sighted people it is important that the information should be well visible. These issues are contained in WCAG (Web Content Accessibility Guidelines) [3]. This specification refers, largely, to the issues of web site content presentation. An information kiosk is a kind of a specific web site, thus the guidelines included in WCAG were a starting point for writing down the guidelines on how to present information in the kiosk. The layout of information sites was prepared. Then the sites were evaluated by poorly sighted people from the Polish Association of the Blind (PZN). It turned out that some WCAG guidelines were too lenient with respect to the colours or contrast applied in the presentation. A large part of screen layouts of the future Infomat-E presented to the poorly sighted were questioned due to poor readability, though all proposals complied with the WCAG requirements.

As a result of discussions between the project developers and PZN, some additional requirements, supplementary to those of WCAG, were prepared. The requirements about colours and general appearance of the site must help poorly sighted people pay attention to the most important information.

The sites should have high contrast applied to such elements as the text and diagrams. The background of the site should be uniform so as not to distract the poorly sighted person's attention. The site should be visible for the poorly sighted but, at the same time, should have an esthetic appearance for able-bodied people who will use it as well. Due to contrastive colours the site lacks esthetic qualities and, therefore, does not look professional. As a result of analytical works and consultations with the poorly sighted, it was decided that the best colours would be different shades of grey. Such a set of colours (Fig. 1) meets the requirements both about high contrast and esthetic requirements.



Jeśli zacząłeś mieszkać w nowym miejscu, musisz załatwić w urzędzie sprawy:

1.Wymeldowanie z pobytu stałego (koniec starego stałego zameldowania)
2.Zameldowanie na pobyt stały (początek nowego stałego zameldowania)
3.Wymiana dowodu osobistego (nowy dowód osobisty)

1.Wymeldowanie z pobytu stałego (koniec starego stałego zameldowania)
Gdzie to załatwisz?
Jeśli poprzednio mieszkałeś w Chorzowie:
Urząd Miasta Chorzów
ul. Rynek 1

Fig 1. Standard layout of a touch screen [source: own]

The site of the information kiosk should present the content with a contrast ratio of 7:1, according to the pattern described in WCAG, while the font size should be at least 20px[2] , which means that on 96dpi monitors the text will have a minimum height of 6 mm. After the analyses, the minimum recommended height was increased to 10 mm. As far as navigation buttons are concerned, they should be well visible against the background. This can be achieved by contrasting frames. The buttons should be placed in regular distances from one another, in flat rows. It is possible to use shadows around buttons, however each shadow should be symmetrically placed around the button.

In order that the function of the button could be better understood, it is possible to place an icon on it. The icon is also helpful for the deaf as it helps to understand the use of the given option – it creates certain associations. The icon on a button has to be in proper distance from the caption. The icon has to be outlined. Filling of the outlines should be avoided as this way the whole picture would be blurred and the pictogram would be seen as a shapeless blotch. Thus the used icons were quite big while the captions on buttons relatively small. There are certain arguments for such a choice. If big-size fonts were used – readable for poorly sighted people – the place in which to place the pictogram would be much smaller. It is possible to increase the size of buttons but this would cause problems with distributing larger num-

[2] px stands for screen pixel. All calculations of quantities referring to font sizes or other displayed elements have to take into account the real resolution of the monitor. It is necessary to remember that these could be different values for the X and Y axes. In this article the resolution of 96dpi was applied in calculations.

ber of buttons which give access to information contained in the Infomat-E system. Another argument to diminish the size of captions is the fact that one's associations are better developed on the basis of pictures rather than texts. Additionally, smaller captions on buttons will be readable for users who do not belong to two basic groups selected for the project. No matter whether the graphic layout is readable to the poorly sighted or not, those users will have additional support from those functions of Infomat-E which were designed for the blind. The whole of the system will be voice-enabled, including buttons.

B. *Guidelines about text presentation*

The method of text display in the kiosk should be compliant with a number of requirements. The text should be written in a sans-serif font, aligned to the left and should not contain words in italics. The recommendation to use a sans-serif font is the result of discussions with PZN and is different from the recommendations stipulated by WCAG. Sans-serif fonts are particularly clearly seen on raster scan displays, such as a computer monitor. Serif fonts and italics, well readable on printouts, are not displayed well on screens. The displayed text should contain enough blank space (line spacing, inter-paragraph spacing) to distinguish between particular information units. It is necessary to have two spaces after each sentence and a single line of the text should have no more than 80 characters. Interlinear spaces should have at least 2 px, while inter-paragraph spaces should be 1.5 times bigger. All texts displayed in the kiosk should have a uniform appearance, without unnecessary text formatting. The only exception are words that have to be specially distinguished, for example links to other sites. The letters in the words should not be placed too narrowly since they might merge into one another.

C. *Understanding the texts*

Understanding the texts is another important element which affects the kiosk accessibility by the handicapped. In this case the key factor is how information is understood by people who are deaf from birth because they particularly face difficulties while reading standard texts.

The deaf use the sign language every day. This language has a different structure and logic than the Polish language because the latter is based on linear language structures. Each sentence in Polish is a series of successive elements coming in a certain order which cannot appear all at the same time. In the sign language it is possible to use non-linear mechanisms, thus one can say a few things at the same time [2]. It happens so due to communication transferred along three channels at the same time (body language, voice-sound, words). As the deaf lack one of these channels, they reinforce other, i.e. the body language channel. Using body language is a natural thing here because this channel is responsible for the majority of communicated messages. Still, looking at the words transferring channel, in the case of the sign language, in long sentences the SVO[3] order dominates (the subject is before the verb and the object comes as the last one) while in short sentences – the SOV[4] order (the subject is before the object and the verb is the last element).

Another problem is the vocabulary range of the sign language. Currently in Poland the sign language contains, officially, about 2,500 words [4]. This concerns the documented and analyzed version of the sign language used in Poland, i.e. the Sign and Language System (SJM). A larger vocabulary range is the one of the Polish Sign Language (mother tongue of the deaf). However, this range is not contained in any dictionary and there are differences between regions where it is used. Independently on the version of the sign language, its vocabulary is much smaller than that of the Polish language. Therefore, if a text is to be understood by the deaf, it has to be simplified, to make a kind of translation, which is a very difficult task if one takes into account numerous differences in the vocabulary ranges between Polish and the sign language. It is important to note that many hearing people who use the Polish language every day have problems in understanding complicated texts, e.g. official texts, legal texts [5] [6]. Additionally, when official texts are simplified, it is forbidden, due to formal reasons, to translate certain precise expressions and the representatives of public administration are reluctant to allow such translations as some elements, such as the names of documents or departments, should not be modified.

Having in mind these two groups of people and other formal requirement, some recommendations were worked out on which the descriptions displayed in information kiosks should be based:

- The text should not contain long and complex sentences.
- Each sentence should have only one verb in second person singular and the SVO order which is the basic syntactical order of the Polish language and understood by the deaf.
- Passive voice must not be used.
- The texts should contain words only from the set of vocabulary of the sign language. If it is necessary to have in the description an expression incomprehensible to the deaf, the expression should be described by means of basic words.
- It is recommended to use expressions which show how a given activity should be performed with the use of concrete everyday things, e.g. the sentence "Submit an e-form" can be replaced by: "Save your data in the computer on the web site of our office".

D. *Navigation*

For blind people it is particularly important to have proper navigation guidelines which enable them to get to the desired place. After consultations with the blind it was decided that navigation guidelines should contain orientation points, such as: stairs, door, lift. One should not forget about putting a starting point into the guidelines either. It is not necessary to say how long the distance is, it is enough to describe the way and give the destination point or places where direc-

[3] SVO - Subject Verb Object

[4] SOV - Subject Object Verb

tions change. Navigation guidelines should not contain too many details as this can make it difficult for a blind person to remember or comprehend the description. Other users can make use of basic information about the place where a given issue is dealt with, i.e. room number and floor. Additionally, it is planned to have an interactive map that will picture the location of selected places in the building and how to get there.

IV. Concept of the solution

As a device, a multi-media kiosk is a specially prepared computer equipped with a touch screen, keyboard, camera and microphone.

As far as its application is concerned, the kiosk can be defined as a place where it is possible to get context information about things related to the institution in which the kiosk has been installed (office, shop, exhibition, museum, etc.).

People with different dysfunctions will have different problems when contacted with a typical information kiosk. The poorly sighted (or the blind) have problems with using touch screens. Sometimes there are keyboards on touch screens which make the latter useless for the blind. In the case of mechanical keyboards, there are often untypical keyboards used. The keyboard buttons have small key travel (weak tactile feel).

The kiosks also lack screen voicing in the form of the screen content being read aloud. It is possible to use the so called screen reader but, as the interaction with the kiosk is different than with the computer (no mouse), it is necessary to employ extra mechanisms. Using a speaker in the kiosks makes the users feel they have no privacy. People with hearing dysfunctions and deaf usually have difficulties in understanding written texts (the written language is, in fact, a foreign language to them). The best solution would be to present the content with the use of the sign language. Obviously, hard-of-hearing people find it difficult to hear sounds too, particularly when standard speakers are used.

To sum up, the requirements for the Infomat-E system, from the point of view of an information kiosk, are the following: proper voicing (both speech synthesis and analysis), presenting the content in the sign language, providing ergonomic operation of the device (proper receiver, keyboard). Other requirements regarding the information display are the following: suitable layout and content (avoiding too much information), simple texts (comprehensible texts), proper colours and sizes (contrast, brightness, colours).

While the technical concept of the solution was worked out, it was assumed that the solution should enable easy adaption of the existing kiosks. The kiosk structure should not divide the users into groups. There should be a common interface provided that would meet the requirements of all users. These objectives will be achieved through the use of proper software and a dedicated device – a manipulator.

The software will include several components which will facilitate access to particular pieces of information linked with one another so that their co-operation could bring a desirable effect.

The voicing will be achieved by providing speech synthesis in such a way to enable ergonomic listening (possibility of repeating already heard messages, reading sentences, reading words, explaining difficult words). Additionally, voice control will be available as a supplementary function to keyboard and touch screen based control.

To facilitate the system operation by the deaf, there will be an avatar presenting the information content in the sign language. This solution is developed in co-operation with the Silesian Technical University and the Progress company [7] [8]. It is composed of two elements: a module which is responsible for controlling the avatar's movements and a mechanism which translates sentences into the sign language (necessary simplifications, change of word order, etc.). This way it will be possible to present the content in the sign language automatically.

Apart from the software that will support handicapped users, there will be software to support the administration of the whole system. It will comprise; a tool supporting the verification of the content complexity (checking the words used in descriptions so that they should fall within a certain range, e.g. the range of the sign language), a tool verifying the used colours (measuring contrast according to the standards given by WCAG so that the colours should be suitable for the poorly sighted), an administration panel to manage the content and interactions with the kiosk.

Apart from the software, it is expected to have a special device added to the system – a manipulator (Fig. 2).

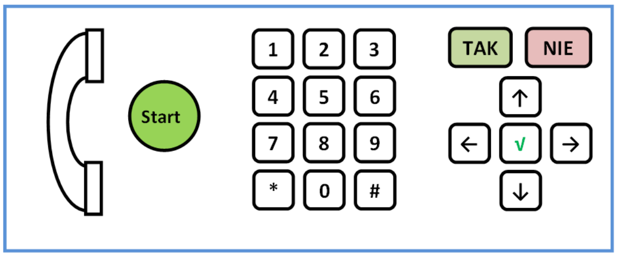


Fig 2. Sample layout of the manipulator panel [source: own]

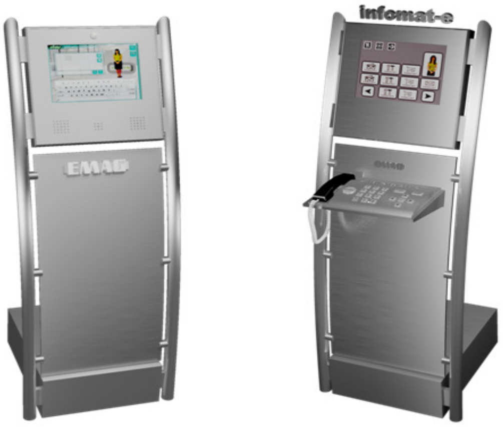

Fig 3. A typical information kiosk and a kiosk of the Infomat-E system [source: own]

The basic element of the manipulator will be a keyboard consisting of two parts: a numerical keyboard and a navigation keyboard (arrows). Both keyboard systems are very popular and commonly used (the numerical keyboard is used as a standard in phones, while the navigation keyboard – mobile phones). The START button will be specially distinguished. Its role will be to return to the initial state of the dialogue or to check whether the kiosk is operable. The keyboard will have clearly marked button travel while the buttons will have convex-print captions. There will be convex prints of symbols and Braille alphabet signs. The manipulator will also have a telephone receiver in order that the user could have some privacy. Additionally, the receiver will enable voice contact (listening and control) and will help people with hearing devices to use the system thanks to a built-in induction loop. There are plans to add a movement sensor to the manipulator so that a person approaching the kiosk could be detected. This will allow to implement certain reactions of the kiosk to such a situation. A Bluetooth module will allow to use the Infomat-E system through a mobile phone. It will be possible to send a note to a mobile phone, information about how to get to a certain place (map of the building), etc. What is more, it will be possible to connect the manipulator to already existing and functioning kiosks (Fig. 3). Thus there are two solutions worth mentioning here. The panel of the manipulator will be connected to the kiosk by means of special handles – this way if the manipulator needs to be adapted to a new type of kiosk, it will not be necessary to re-design it. The second quality which makes the system more universal is the use of a USB connection to connect the manipulator to any computer.

The concept of the Infomat-E system focuses on the part which is responsible for information display – the information kiosk. However, the kiosk is not the only element of the system. The system structure will make it possible to start the system on a single kiosk or on many kiosks operating within a network (Fig. 4).

It is planned that one database with texts will be used for many types of interfaces – the same content and different way of presentation on different devices. Thanks to one coherent management of such content, the quality of information service is increased because the presented data are coherent and updated (a change in one place is followed by changes in all types of interfaces).

V. Conclusion

The project enables to integrate the elements which have been scattered so far and which are results of separate research projects. The developed system will facilitate contacts with administration and other public institutions for a wide group of users, particularly those who have sight or hearing dysfunctions. The adopted concept of the system development allows easy information management within the system. The project contributes to all efforts against social exclusion and is an answer to social needs for such types of systems.

Additionally, the objective of the project is to develop a solution that would allow integration with any information kiosks offered by commercial companies on the market, provided that the kiosks comply with the technical requirements stipulated by the project. The presented technical concept enables to fulfill this objective.

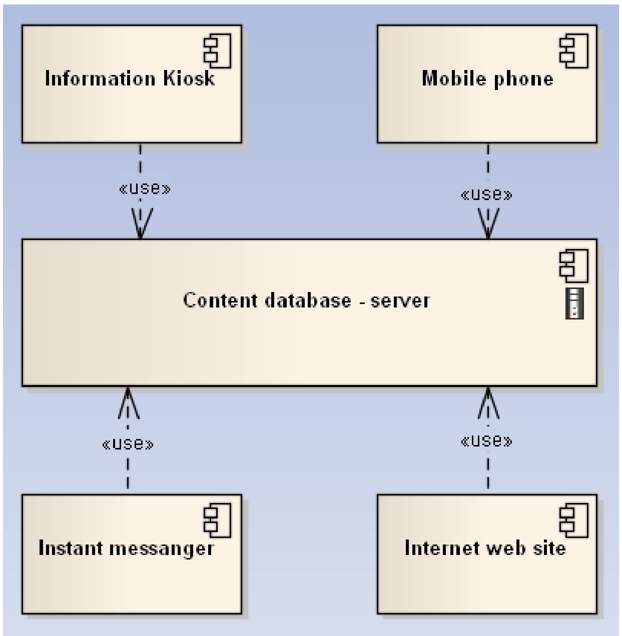

Fig 4. Infomat-E system architecture [source: own]

The results of conducted research and analyses will allow better identification of difficulties encountered by the blind, poorly sighted, deaf and hard-of-hearing. Higher awareness with respect to the existing barriers is sure to initiate another projects aimed at assisting the handicapped in their everyday living, similar to the Infomat-E project. Particularly the results of analytical works related to the presentation methods and content can be helpful in other projects which aim at providing access to information to people with sight or hearing dysfunctions.

***Abstract*—Democracies need elections for choosing their authorities and governments. This process has many factors that shape today's procedures. However, the Internet is a medium that may change the possibilities and elections. The main issue is concern on how changes may influence the whole democratic process. This paper shows two possible ideas – that of bidirectional voting and continuous voting, and considers possible reasons for introducing changes as well as the consequences. An introductory research in into this matter gives additional hints.**

I. Introduction

THE INTERNET changes almost everything. It introduced powerful digital goods markets, it empowered the role of information as a strategic good. In this paper the author shows the considerations on how it may affect an election process in order to make it more efficient. For discovering that, it is necessary to bring some thoughts on the politicians' motivations on elections - which seems to be somehow parallel to the process of raising children by its parents. Of course this should be said in context of the aims of the whole election process. Therefore this paper consists of a discussion on the voting process (including Internet voting), brought in chapter 2, followed by an analysis of the politicians' motivations. Then two solutions are proposed that may increase an election effectiveness – namely the bidirectional voting and continuous voting concepts. Those theoretical considerations should be followed by a research on voters' opinions, which is presented in chapter 6. Last chapter presents the author's conclusions.

II. Voting process and Internet voting

To propose any changes in electoral systems we need to think about their meaning, function and purpose. In Book II, Chapter 2 of his book 'The Spirit of Laws', Montesquieu states that in the case of elections in either a republic or a democracy, voters alternate between being the rulers of the country and being the subjects of the government. By the act of voting, the people operate in a sovereign (or ruling) capacity, acting as "masters" to select their government's "come." [6]

In more practical way we may read in Encyclopedia Britannica that regular elections serve to hold leaders accountable for their performance and permit an exchange of influence between the governors and the governed. The availability of alternatives is a necessary condition. [7]

We need to remember, that due to fact that people may vote against ruling government, for having effective elections their organization must safeguard the privacy of voting – understood as the impossibility to trace who voted how and as much as possible, the impossibility to influence on given votes. It is important, while providing election officials with an audit trail that can be used to conduct recounts of election results. [2] Moreover, we need to remember that the whole process needs to gain public acceptance and trust. So, one basic precondition for e-elections must be the feasibility of implementing the voting under such conditions that the principles underpinning the electoral system are not disregarded. Accordingly, the system must be at least as secure as corresponding traditional voting procedures. Another precondition is that the e-voting procedure must be simple and function smoothly for the voters. Its overall purpose is to enhance accessibility to voters. [10]

Therefore an electronic voting system via the Internet must fulfill the following basic requirements according to its trustworthiness and legitimacy [10]:

- Only people eligible to vote should be able to vote (identification).
- It should be possible to use one's vote only once .
- Ballots should be absolutely secret.
- It should not be possible for a vote cast to be changed by anyone else.
- The system should ensure correct tallying of votes at all levels (voting district, constituency and area).

We can count some opportunities to electronic voting [8]:

- Most countries believe that Internet voting will occur within the next decade.
- Internet voting options satisfy voter's desire for convenience.
- Internet voting can meet the voting needs of the physically disabled.
- Several countries are ready to try Internet voting for a small application immediately.

978-83-60810-27-9/09/$25.00 © 2010 IEEE

- Several countries are contemplating voting system replacement and are frustrated with the limited number of options available.

But such system would face many barriers as well – like the difficulty of guaranteeing ballot secrecy with an absolutely certain guarantee. Another is a the question of the reliability of the system, i.e. that the system will in all situations function in the manner in which it is meant to function. Another disadvantage is the expense of development and operation. All in all, then, the primary considerations are security and reliability. [10]

Some others may be [8]:

- Lack of common voting system standards across nations.
- Time and difficulty of changing national election laws.
- Time and cost of certifying a voting system.
- Security and reliability of electronic voting.
- Equal access to Internet voting for all socioeconomic groups.
- Difficulty of training election judges on a new system.
- Political risk associated with trying a new voting system.
- Need for security and election experts.

III. Are Politicians Like Kids?

Now we can think about the motivations that drive politicians taking part in elections. We may understand their goals idealistically, ie. that they are trying to serve country and/or community. But serving people requires getting into power – in words; winning elections. Unfortunately, common observations make most of people to doubt such motivation, making many people believe that their most important aim is to get into power using the program as a tool rather than the goal itself. Of course, it shouldn't be generalized – especially that winning elections almost always requires many alliances with factions fractions that may sometimes have very distant views on selected topics.

However, one may try to find similarities between the election process and raising kids, when they grow. They both are observing responses from the surrounding world (politicians through pools and children through observation of their parents' and other persons' reactions). So by giving them a feedback information, giving hints to what is good and what is bad. They both (politicians and kids) try to behave in a way that maximizes their goals. In the case of politicians of course the aim is to get as many votes as possible.

Children interact with parents constantly – and parents may react in different ways. So let us now consider models of the process of raising kids. Usually we may distinguish two contradictory models and some located in between. We shall discuss only the extreme ones. The First one is a very strict model of raising kids (where children have a lot of restrictions and are punished when they do wrong, but ideally a lot of sensitivity and appreciation when they do good as well). Second one is so called 'stress-less' raising (where children are positively motivated and allowed many things that would be banned by strict parents – which means that they are rarely or never punished, ideally with as much positive motivation as possible and as little punishment as possible). It is Commonly is known, that in first case children will probably care more about others' people needs, but normally will be more backward behaving, they normally shall think about consequences before they do something. In the stress-less case children will be probably more open, active and sometimes even pushing the limits in search what they can. Having less fear they will experiment more willingly even without deeper considerations.

More deep considerations may be found in articles by Diana Baumrind [3], [4] who found what she considered to be the four basic elements that could help shape successful parenting.

Table 1:
Parenting styles [5]

		Strictness/supervision	
		High	**Low**
Acceptance/ Involvement	**High**	Authoritative	Indulgent
	Low	Authoritarian	Neglectful

Such descriptions would be reasonable as well for politicians' deeds. But we need to find two basic distinctions between kids and politicians.

First one is that raising kids is a continuous process – and elections happen (normally nowadays) once every 3-5 years (depending on country and subject of election). During the period in between elections politicians are not effectively rated - in terms of bouncing out-of the position.

The second difference is that in raising kids we may see two models (discussed earlier – strict with negative and positive incentives and stressless – with mostly positive incentives), whilst on elections basically we have only positive votes (which is positive incentive) and after elections politicians are normally safe (until next elections), which may be perceived just as lack of any incentives.

This may lead to conclusion, that lack of negative incentives pushes politicians to strategies of freely pushing limits in search what they can (regardless of true intentions) for getting into power (almost), which is reminiscent of the stressless way of raising kids. Of course in the case of politicians, we'd willingly see responsible, forward-looking persons serving country and regional needs. However achieving this may require (just like in a the process of raising children) adding some negative incentives as well as continuous feedback.

IV. Bidirectional voting

Negative voting (as of intentions) is said to occur when circumstances are unfavorable to the interests or preferences of constituents and evoke a stronger electoral response than comparable favorable circumstances evoke. [11]

The idea of bidirectional voting means giving voters possibility of having two votes – one positive (as usual) and one negative (new). Each voter would have ability to decide which votes to give to whom (and if any – voter would have a chance to give only one – either positive or negative vote). That idea is sometimes called 'negative voting' (in terms of votes), which seems to be miss-named to the author – while negative voting should be exactly opposite to the traditional way, which may be called 'positive voting', as voters have only positive votes. Thus negative voting should mean eliminating candidates (instead of choosing as it is now), which may lead to choosing people and parties without any ideas.

The idea of giving both positive and negative votes would bring a new possibility of expressing disagreement with politicians. One of possible ways of dealing with such votes, could be that negative votes would have to be subtracted from positive ones. This might enforce more responsibility on politicians, as their false or freaky ideas would decrease their election chances, especially in case if it would be required a quite straightforward requirement to gain more positive votes than negative ones (either or both in case of whole parties and in case of each candidate).

It has to be pointed that such a system would bring the possible risk of almost randomly chosen parties – for instance in the theoretical situations when

- a party 'A' would gain
  49% of positive votes and 48% negative votes,
- a party 'B' would gain
  47% of positive votes and 48% negative votes,
- a party 'C' would gain
  3% of positive votes and 1% of negative votes,
- a party 'D' would gain
  1% of positive votes and 3% of negative votes,

a party 'D' would gain 1% of positive votes and 3% of negative votes - the winners would be parties 'C' and 'A' with 2% and 1% of votes net, which recalculates to 67% and 33% and gives a majority to extremely small party, which gained only little votes. However, this problem might be reduced by keeping the normally existing thresholds of for instance 5% of all positive-only votes (which in example above would eliminate tiny parties 'C' and 'D') .

Furthermore it is worth mentioning, that in case of possible (not mandatory) giving positive and/or negative votes, a much more probable situation then mentioned above would be gaining by all parties more negative votes than positive ones. This would drive into the situation, when no-one could be elected, which would enforce the need for another election. However, this would give a possibility to show, that current politicians have lost connection with real-life (which is quite often regarded not to be very rare in politics). Such situation would require then organization of next elections in a short period of time, but would show, that radical changes in the politicians' programs are deeply expected and required.

V. Continuous voting

It is possible to figure out probable reasons why elections are hold every 3-5 years. Quite straightforward one of them seems to be of economical nature – elections preparation and conducting does cost quite a lot. So it wouldn't be sensible to organize it too often. Similarly, chosen politicians do have to have a reasonable time for bringing their programs into life (which normally is a huge task concerning a scale of a whole state). Moreover, politicians on the election year tend to promise and do almost only things that might be perceives as popular. On the other hand, organizing elections too rarely would limit possibilities of changing politicians in case of poor or ineffective leading state (or local) affairs.

Things seem to be different in case of an Internet voting. In this case it is possible to organize it far cheaper, which may give a chance for organizing votings much more often. But we need to think about possible reasons for more often votings – just as at the beginning of this chapter were given reasons for not doing it too often. That implies, that it shouldn't play role of simply more frequent elections as we know them nowadays. But, in chapter 4 (are politicians like kids?) we reached a conclusion, that a form of an feedback seems to be very important in controlling politicians. And this is the field, where continuous voting may seem to be very valuable. Furthermore, in the same chapter 4 we pointed, that a form of negative motivation usually helps in balancing behaviours, which may be very valuable for making politicians' work more for the society than nowadays it seems to be on average. For instance, voting for the worst politician (in terms of chosen in elections – like deputy, parliament member etc.) for having such deputy somehow punished may have a chance to be very positive in terms of quality of their work for the society. Such punishment should be serious one – probably most perceptible and most fair punishment for a deputy that had been chosen the worst one would be taking back such person's seat (mandate). Such continuous, serious threat would force taking into consideration voter's perception of their actions. This might constantly remind the reason why they were chosen.

To achieve same effect at parties level – such seat might stay empty until next elections, which would weaken party of the worst deputy.

On the other hand very important seems to be the positive motivation. So just like choosing the worst deputy as well the best one might be chosen. What might be a serious reward for the best deputy? Probably mandate (seat) in next elections (meaning without taking part in elections). Would it be unfair? Rather no, as this comes from people's voting, just like during elections.

Next we should consider how often such votings should be organized. Probably quite often, as it is known from the pedagogy and psychology, that the punishment (or reward) needs to be immediate. On the other hand, a threat of facing only very little votes given (which would make it meaningless) and on the other hand facing too many deputies left in negative voting (or safeguarded in positive voting) their seats shows that such votings shouldn't be organized too often as well. In author's opinion the right scale for this process would be potential elimination of 3 to 5% (maximum of about 10%) of deputies as well as rewarding the same quota. In such case, a feasible frequency for Poland would seem to be for instance once every 3 months, which would cause potential threat (and opportunity) for maximum 15 deputies during 4 years period. It is worth mentioning that bidirectional voting in such case would additionally give chance to people to say 'no one deserves punishment (reward)' by not giving negative (positive) votes, which is good, because in fact it shouldn't be obligatory to punish (or reward) someone every time.

Thinking about a punishment (reward) we need to point another problem – in case that there is only minimal number of people taking part in such voting – let's say only 10 persons gave their votes. Of course in such case it would not be fair to regard such a voting to be binding one. But this problem is easy to eliminate – it may be added a requirement that for instance at least 5% of voters has to vote for regarding such voting to be a valid one. Additionally for safeguarding controversial, but fair and effective deputies, who may receive a lot of both positive and negative votes – it may be required that for punishing (rewarding) of such controversial deputy would be necessary to reach difference of not less than 3% of all given votes between positive and negative votes.

VI. Research

The research was conducted on 68 students of Gdańsk University of Technology, in April 2010. It was devoted to search main reasons of voting and possible ways of making it more effective.

To understand the outcomes, we should realize that participation in elections in Poland is not compulsory, which results in frequencies below 50%. Moreover, voters are presented ballots with names of parties and candidates of these parties blocked together. Voters are choosing only one person, giving their vote to this person and its party at the same time. To enter the parliament or a local authority, a party needs to gain at least 5% of valid votes. Then, a number of mandates for each party is calculated and seats are allocated to candidates that won relatively most votes.

The first question of research was „which statement presents best your motivation for giving a vote to the candidate you voted for during last elections (and for going to elections at all)". The most important motivations were "I didn't support any of parties, so I voted choosing least evil option" (19,1%), "I didn't took part in elections because I saw no sense in voting (or as a private protest)" (17,6%), "I support both the party and the person I voted for" (17,6%), "I know and support the party and I chose a more or less random person from the party" (16,2%), "I didn't go for elections because there was no one worth voting for" (11,8%).

It seems to be worrisome, that three out of five most important motivations, chosen by a total of 48,5% of respondents, were negative (1st, 2nd and 5th), whilst voting is meant to be primarily positive choice process.

In next question respondents were asked "how long before elections have you decided on whom to vote". The most frequent answers were "a couple of days" (32,4%), "just before elections" (22,1%), "a couple of months" (17,6%), a couple of weeks" (13,2%).

These answers do not really seem to be constructive as well, as they show that voters don't have stable views – as a couple of days before elections about 54,1% of them didn't know whom to vote for. Situation is even worse a couple of weeks before elections, ranging about 67,3% of undecided voters.

Another question asked was an attitude for the bidirectional voting concept. It was formulated as a general question "If it would be possible to give a vote 'against' apart from vote 'for', would you:" followed by five statements:

- "use such possibility":
  'definitely yes' 54,4%, rather yes '32,4%',
  'rather no' 10,3%, 'definitely no' 1,5%
- "give both votes":
  'definitely yes' 38,2%, rather yes '45,6%',
  'rather no' 11,8%, 'definitely no' 2,9%
- "feel that it would be easier to make a decision":
  'definitely yes' 27,9%, rather yes '36,8%',
  'rather no' 29,4%, 'definitely no' 4,4%
- "feel that you can more completely show your views":
  'definitely yes' 50,0%, rather yes '41,2%',
  'rather no' 4,4%, 'definitely no' 2,9%
- "consider it to be fair":
  'definitely yes' 41,2%, rather yes '45,6%',
  'rather no' 7,4%, 'definitely no' 4,4%

This shows, that young, educated voters would welcome a new option of bidirectional voting - voting 'against' as a complimentary to voting 'for'. What is additionally important, among respondents who in the first question („which statement presents best your motivation for giving a vote to a candidate you voted for during last elections") pointed most frequent answer "I didn't support any of parties, so I voted choosing least evil option" 100% chosen that they would like to use possibility of giving negative vote. Moreover, of these who pointed answer "I didn't do for elections because I saw no sense in voting" 75% chosen that they would like to use possibility of giving negative vote. And among those, who pointed answer "I didn't go for elections because there was no one worth voting for" 62,5% chosen that they would like to use possibility of giving negative vote. This shows, that introducing bidirectional voting may help people to show their preferences in a better way, which should drive to potentially higher level of participation in elections.

Last question was asking about attitude towards voting through Internet in terms:

- "I think that voting through Internet should be available"
  'definitely yes' 61,8%, rather yes '23,5%',
  'rather no' 10,3%, 'definitely no' 4,4%
- "I would willingly give vote through Internet"
  'definitely yes' 58,8%, 'rather yes' 23,5%,
  'rather no' 14,7%, 'definitely no' 1,5%

This shows that young, educated people would welcome possibility of voting through Internet, which technologically would allow bidirectional voting, as it was described earlier.

VII. Conclusions

As we may see, Internet use in elections may help introduce new ideas on how to vote for having politicians to be more motivated for better taking care of common issues. The idea of bidirectional voting may help people to show their preferences in a better way, which may drive to a potentially higher level of participation in elections. On the other hand introduction of the continuous voting (which due to costs wouldn't be possible without Internet use) may introduce better control over politicians' deeds by continuous grading, which because of immediate reaction normally is most effective way of controlling of all recent deputy initiatives. This reflects that bringing these ideas into life may help election process to achieve a new, better quality and give a chance to improve democratic processes.

***Abstract*—The aim of this paper is to attract attention to the double jeopardy phenomenon. Double jeopardy seems to very often go unnoticed by companies while they look for an explanation as to why their efforts to enhance the intensity of brand usage are unsuccessful. The clue is that the companies do not pay enough attention to raising the market share. Our discussion in this paper refers to informational websites. Our aim is not to form a final conclusion as to whether there is a double jeopardy phenomenon or not on this particular market. Instead, the conclusion is reached that although the double jeopardy pattern can be observed on the virtual market, the nature of virtual markets can oppose this phenomenon.**

I. Introduction

In the early 60s when Whilliam PcPhee examined the double jeopardy phenomenon (DJ), he might not have expected how universal his idea would be. Nowadays, double jeopardy is observed not only on the traditional market, but on the virtual market as well. Although on the virtual market the double jeopardy phenomenon is competing with the famous 'long tail' theory (the internet enhances the sale of small brands), the Internet distribution does not seem to protect 'small brands from losing twice' [1]. This means that brands on both the Internet and as traditional markets follow the double jeopardy phenomenon – small brands not only attract fewer customers, but these brands are less preferable.

Based on the previous research cited in literature we suspected that our analyses of the usage of the different websites would bring more evidence to suggest the breaking of marketers' 'double jeopardy myopia'. Marketers often do not like the idea of double jeopardy, as they tend to believe that marketing tactics can easily enhance the brand usage. We thought that our conclusion would be that "[...] long-term growth is seen to be a function of penetration not of increased repeat-purchase. This fits the Double Jeopardy pattern but not perhaps the common conception of brand loyalty among practitioners" [2]. But our analyses do not show clear picture of the double jeopardy phenomenon among different categories of websites. Our findings confirm that although the websites are visited by internet users according to the double jeopardy rule, there are many exceptions.

Although the double jeopardy phenomenon has been well-known for over half of century, few studies can be found in marketing literature. On the traditional market the consumers' behaviour during the process of purchasing their coffee, newspapers, soap or breakfast flakes is consistent with the double jeopardy phenomenon [5]. Furthermore, one of the latest publications is the work of C D A Graham [3] who presented a survey based on data gathered from 4,000 of UK households. The results confirmed the double jeopardy phenomenon and the fact that market equilibrium extends into the long term - "[...] exceptional, permanent, structural change in share (i.e. more than 6 points in as many years) does appear to have a common causality. It is strategic, achieved not through everyday manipulation of the promotional mix, but by a major change to brand architecture, or some discontinuous innovations" [4]. A. Elberse [6] pointed out the double jeopardy phenomenon on the virtual market. Her findings show that although as a medium the Internet enlarges the assortment of informational products (this means that according to long tail theory the tail is going to lengthen), the obscure products which form the end of the 'tail' still find few customers. The tail is going to be longer and flatter, not necessary bulked up. This fits with the double jeopardy phenomenon – less popular brands lose 'twice'. On the virtual market the double jeopardy phenomenon was also observed on Polish informational portals [7].

II. The analysis of Business and Informational Polish Portals

In order to examine how double jeopardy affects brands on the virtual market we conducted analyses of three different categories of websites: business and informational portals of Poland and additionally, in the next chapter - social networking sites in the United States.

First, we examined the two categories of Polish portals: business portals (category business, finance and law) and informational portals. The data were taken from the Megapanel PBI/Gemius survey from February 2010. For business portals the frequency of purchase refers to the frequency of visiting the website by the user. Therefore the variable 'views per user' reflects the process of 'buying' information from a particular portal. Trying to explain the double jeopardy phenomenon we use so called model 'w(1-b)'. This model takes into account three variables [8]:

- b_x represents the proportion of customers who buy at least once brand X during the analysed period
- w_x is the frequency of purchasing brand X during the analysed period

- the frequency of purchasing the brand X can be estimated according to the equation that $w_x = w_o/(1-b_x)$, in which w_o is the constant. W_o – is calculated as an average of the $w_x(1- b_x)$ for the all analysed brands.

If the double jeopardy phenomenon can be observed within the data about the reach, users and views for business and informational portals it would mean that the biggest portals (with furthest reach) should also have the highest numbers views. The empirical statistics seem to confirm this pattern. As we can see in Table I and Table II, the higher the reach of the portal (column 4), the higher the number of visits per 'average' internet users (column 5). The correlation between variable 'reach' and 'views per user' is strong:
- for business portals the correlation is 0,73 (R Spearman, p<,05)
- for informational portals the correlation is 0,75 (R Spearman, p<,05).

We can also apply the model of 'w(1-b)' to both analyses allowing us to calculate the expected numbers of visits on the basis of the reach of a particular portal. In this case, the model helps to answer the question: "Taking into account the reach of the portal, does the number of views fit to the reach?" Referring to the example, if the observed usage of a portal is similar to the number calculated using the 'w(1-b)' model, it means that the brand follows the pattern of double jeopardy. The problem for marketers starts when the usage of the brand is lower than calculated. This means, that the brand could be more intensely used, but some factors (unsuccessful campaign, negative PR) contributed to lowering the intensity of usage.

Analyses of Polish business and informational portals seem to confirm that 'small brands lose twice' – not only do fewer users see them, they are also used less intensively (the constant wo is 8.8 for business category and for informational portals wo constant is 16.7). However, we may observe that within both categories there are some brands which go 'against the double jeopardy phenomenon': 1) within the business category e.g. Group Wirtualna Polska– business, Group Bankier.pl or Group Interia.pl – business and 2) within the category informational portals e.g. Wirualna Polska – information, TVN – information or Group Polskie Radio.

III. The analysis of US social networks sites

Let us also analyze the correlation between market share of social networks sites and the activity of their users [Table III]. It should be noted that 'social software' has emerged as a driving force of Web 2.0. The term Web 2.0 was coined by Tim O'Reilly in 2005, to describe a sea of changes in web services and technologies. Overall, there is an increasing presence of social software applications that allow users to communicate, collaborate, and share their personal interests [9]. We examined the data from the five major social networks sites based in the United States: Facebook, MySpace, Tagged, Twitter, myYearbook [10]. If the double jeopardy phenomenon exists on this market, it would mean that users of the largest social network sites are more active than those on the smaller ones. The data only partly confirms this prediction. The changes in the market partly reflect the double jeopardy phenomenon – it means that when MySpace's [11] share of the market decreased,

18	eioba.pl	505 441	-	0,03	-	17,2
19	pogodynka.pl	409 554	7 063 355	0,02	17,2	17,1
20	teleman.pl	401 147	4 665 509	0,02	11,6	17,1

the average time which users spent on this social networks site was also reduces. A similar correlation can be seen in an analysis of Facebook [12] – Facebook grew significantly which lengthened the time per user. Data regarding Twitter, however, runs contrary to the double jeopardy phenomenon: the average time spent on Twitter shortens as its market share rises.

TABLE III.
AVERAGE TIME SPEND ON THE TOP FIVE SOCIAL NETWORKING SITES (RANKED BY MARKET SHARE) AND THEIR MARKET SHARE AMONG US INTERNET USERS, SEPTEMBER 2008&2009 [16]

	September 2009		September 2008	
	market share	minutes:seconds	market share	minutes:seconds
Facebook	58,59	23:00	19,94	18:38
MySpace	30,26	25:56	66,84	29:37
Tagged	2,38	25:17	1,62	23:31
Twitter	1,84	15:52	0,15	36:27
myYearbook	1,05	18:07	1,76	26:12

IV. Looking for Explanation

The presented data partly confirms the double jeopardy phenomenon. The larger virtual portals (ranked by reach) are more intensively used (more views per user or longer time spend on the portal). However there are also smaller portals which do not lose 'twice' – they have similar level of usage as bigger ones. Why? We would like to point out a few possible explanations.

Firstly we wonder how far we can compare 'buying' by spending time on informational portals to buying other goods such as coffee, soaps. In a traditional or internet shop the customer can see different competitive brands and decide what to buy. Under image theory customers' behaviour in this situation is based on the pattern that "[...] most choices are actually choices *not* to do something, in other words, *rejections*." [13]. It means that it is very likely that 'big' brands (which are familiar for customer) simply 'win' the process of selection and this way the pattern of the double jeopardy is enhanced. In the process of choosing informational or business portals the situation is different. Although selected portal can be easily changed to another, because it does not directly require spending money, we should notice that the usage of websites is connected with time, convenience and psychological costs. So we may take into consideration that currency is in this case not money, but time (the 'budget' of time which a user poses and is willing to spend on websites is somehow limited) or convenience (the internet user can be attached to the portal, because they think: 'I'm familiar with navigating this web site', 'I have a mail box on this portal, which makes it easier to use business section on this site'). At the same time, it must be remembered that the internet user can easily read two or more different portals more or less simultaneously. The ease of using many different brands by a user at the same time (in this case portals) means that the double jeopardy pattern is somehow 'diluted'.

The case of social network sites seems somehow different. The value of a social network site increases when more users are within the social network. The effect of 'closeness' appears – the more users have their profiles on a social networks site, the more valuable the site seems to be. Therefore the effect of the double jeopardy phenomenon should (theoretically) be even more visible. Partly, we observed the effect – as Facebook enlarges its share of the market, the time spent visiting it grows. But we analyzed the data from very short period of time. This means that every change, even a temporary one, is reflected in the analyses presented and we are far from saying that the double jeopardy phenomenon has been proved.

To conclude, we observe the pattern of the double jeopardy phenomenon among users of websites. Smaller portals can lose 'twice' – meaning that if the portal attracts less customers, the customers are less willing to spend more time on it and visit less often. Therefore 'the more the better'- the more users the website pulls in, the more time they will spend on it and the more actively they will use it. However, according to our analyses, the reach of the portal is not everything. Smaller portals can enhance the level of activity of their users and break the double 'losing' (e.g. delivering unique utility and features, targeted to niche).

International Symposium on E-Learning – Applications

E-Learning – Applications (EL-A) symposium is organized within a framework of the International Multiconference on Computer Science and Information Technology (IMCSIT), and focuses on development of e-learning technologies and their different application areas.

The EL-A will provide an international forum for experts from the academia, the R&D sector, and the industry to discuss and exchange current results and new ideas based on the ongoing research and experience.

We are seeking the submission of high-quality and original research papers that have not been previously published and are not under review for any another conference or journal. Submissions will be reviewed by at least two referees on the basis of the originality of the work, the validity of the results, chosen methodology, writing quality and the overall contribution to the field of e-learning.

Topics include but are not limited to:

- Reusable Learning Objects – good practices and issues
- Learning Management Systems and Learning Content Management System
- Authoring Tools for Online-based Education
- Design and Development of Online Courseware
- Digital rights management and access management
- Best Practices and experiences of Online-based Education
- Global Trends in e-Learning
- Open Source and Open Content
- Semantic web in e-Learning
- E-Learning 2.0
- E-Learning as a Social Activity
- Collaborative e-Learning – tools
- Communication Technology Applications in Online-based Education
- Use of Multimedia in e-Learning
- M-Learning
- Virtual Reality Applications in Online-based Education
- Use of Gaming in e-Learning
- Scientific Virtual Laboratories.

Simple Blog Searching Framework Based on Social Network Analysis

Iwona Dolińska
University of Economics and
Computer Science in Warsaw
Stokłosy 3, 02-787 Warsaw, Poland
Email: iwona.dolinska@wsei.pl

Abstract—**Blogs are very popular Internet communication tools. The process of knowledge sharing is a very important activity in the contemporary information era. Blogs are used for knowledge sharing on any subject all over the world. Knowledge gathered on blogs can be used in personal e-learning, which is a more informal and personal way of learning than the one offered by traditional e-learning courses. However, it is not easy to find valuable knowledge in the huge amount of invalid information. In this study the Simple Blog Searching framework is proposed to improve the blog searching process. The social network analysis methods of centrality measuring help to choose more easily the best results form the long list of hits, received from a blog search tool. To incorporate social network analysis methods, the blog searching have to be expanded with the blog links searching.**

I. Introduction

BLOGS are one of the most popular of the contemporary Internet communication tools. Blogs make an easy Internet publishing available to everybody. They are used for knowledge sharing. Some blogs are authored by very active and knowledgeable bloggers focused on specific knowledge domains [1]. Any kind of information on every subject can be found in the blogosphere.

Knowledge sharing is an activity through which knowledge (i.e. information, skills, or expertise) is exchanged among people, e.g. friends, or members of a family, a community or an organization. For knowledge sharing to happen, opportunities for interaction must be present. Blogs are very good tool for such kind of interaction.

Knowledge gathered on blogs can be used in personal e-learning, which is a very important aspect of present day life [2]. In the era of the knowledge economy many workers have to improve and extent their personal knowledge almost every day.

Everyone, who wants to learn anything can use knowledge collected on blogs [1], [2]. Blogs offer high searchability, because each post can be tagged with a category and can be retrieved easily by a simple search within that specific chosen category. But there is one fundamental problem with searching the blog content – the huge amount of hits, even using a specialized blog search tool. It can be very time consuming and frustrating for the learner to browse a long list of sources to find the relevant one.

To overcome this problem a simple search blog framework idea has been elaborated and will be presented in this article. The social network analysis (SNA) methods are used in this framework to improve search efficiency. SNA methods of centrality measuring allow to choose easily the best results form the long list of hits, received from a blog search tool.

II. The role of blogs in knowledge sharing

A. Knowledge sharing evolution

We can observe the rapid expansion of the process of information exchange and information sharing during the last few years. The industrial economy is replaced by the knowledge economy. Information technology continues to infiltrate all aspects of activities in a human society, such as business, schooling etc. Nowadays, more and more information builds the human knowledge. On the other hand, the human knowledge is build not only from information. Human knowledge is build also by sharing experiences and skills. People often learn from others. The knowledge has to be properly managed to remain being accessible and to be shared among people. For knowledge economy to function well, good knowledge workers are the foundation [1]. The good knowledge worker is a person possessing a decent understanding of knowledge searching and having the skills to convey knowledge sharing effectively.

Knowledge sharing is in some aspects similar to e-learning. Both are incorporating an Internet and multimedia technologies, both can use shared knowledge repositories, accessible by web tools and finally both of them are types of technology supported learning [3].

For knowledge sharing to happen, opportunities for interaction must be present. Traditionally, people communicate to share their learned lessons, experiences, insights and best practices through face-to-face meetings. Knowledge is usually shared by telling stories. However, these methods are practical only, when community is small and immobile. These methods are not effective for connecting the minds of people dispersed around the globe [1].

Nowadays only the Internet technologies are relevant for globally sharing of knowledge and experiences among people. Chat tools enable people to meet and discuss topics of their interest in a synchronized manner, i.e. simultaneously, when all engaged parties are on-line. Internet fora allow to discuss different subjects by writing text posts to the post list. All discussion members can read and answer the posts. Blogs provide much more possibilities and are the most con-

978-83-60810-27-9/09/$25.00 © 2010 IEEE

venient and the most advanced tool for knowledge sharing and distance learning.

B. Blogs supported knowledge sharing

Blogs allow to publish posts with rich content, tagged with categories [2]. In their posts authors can place links to another posts or another information gathered on the Web. Many blog providers support a blogroll – a list of links to other blogs or sites, used or recommended by the blog author. On the other hand, blog readers can place comments and reviews, often with links to their own blogs or another Web content. All these kinds of links are presented in Fig 1. In the other words, blogs offer bidirectional communication between authors and users on the scale, which is impossible to be achieved with earlier communication tools, i.e. e-mail, discussion lists, static personal websites or even Internet forums [3].

With all these kinds of links, blogs has formed a giant network, which is called blogosphere. Blogosphere is a collective term encompassing all existing blogs and their interconnections. It is often perceived that blogs exist together as a connected community (or as a collection of connected communities) or as a social network [5].

There are several purposes for writing blogs and corresponding types of blogs in blogosphere [7]. Blogs, which serve as diaries are called personal blogs. Blogs providing commentary and opinions are called issues blogs. And blogs, which articulate ideas through writing or serve as community forums are called topical blogs [7]. From the point of view of knowledge sharing the last type is more important than the others. The blogs with significant amount of knowledge collected on them are also called as knowledge blogs (or k-blogs) [8].

Blogs create a context for dialogues between bloggers and readers. Through conversations initiated by bloggers and engaged with by readers, blog platforms build a solid base of shared experiences and mutual relationships [2]. The interaction between bloggers and other users is also reflected by the role conversion of bloggers. Initially, bloggers receive information. During this process, bloggers are data consumers. Then, bloggers absorb the knowledge they have gained and publish new knowledge on their blogs. In this case, bloggers act as knowledge publishers [6].

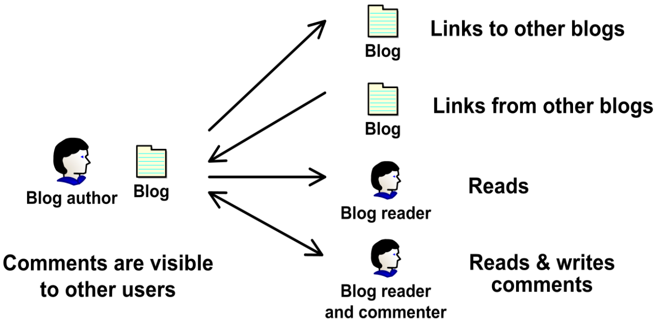

Fig 1. Bidirectional communication offered by blog, based on [4]

Computer-mediated discourse is shaped both by specific technology features and afforded by social practices of users. To better characterize blogging discourse, it is helpful to compare blogging briefly with other CMC (computer-mediated communication) fora. Blogging shares some features and practices with social networking applications within the technologies under the Web 2.0 umbrella, but it also has some distinct characteristics [8]. RSS (real simple syndication) and mashup applications, for example, allow users to summarize information items and access only updated information from multiple sources and to combine multiple sources of information into a single outlet. Bloggers, in contrast, usually develop their own content, even when referencing MSM news sources or other blogs or searching for content to create lists of links to interesting websites. Blog readers can use RSS and syndicate their favorite blogs in order to access only the latest posts [8].

III. Blogs as a knowledge source in personal e-learning

The traditional e-learning environment is asymmetric, with clear distinction between the roles of a teacher and a student [9]. Traditional learning theory emphasize mainly the teacher's point of view. The teacher is the person who prepares the curriculum, learning aids and points out learning path. The students' role is more passive in such situation – they learn from materials prepared earlier and accomplish exercises and quizzes. This traditional approach has been used for a long time in formal university e-learning courses. E-learning systems, which can be briefly categorized as learning management systems (LMS) or learning content management systems (LCMS), still concentrate on the knowledge delivery by lecturers only [9].

In the last years the need of more informal learning has been arisen. Many university programs require numerous informal learning activities, which are difficult to be achieved with LMS or LCMS systems. On the other hand, the Web 2.0 expansion brought new tools, like wikis, blogs, news readers, communication tools etc. They allow for new possibilities, like learning with people, controlling the learning resources, managing the student activities, and integrating the formal learning with informal learning [10].

The traditional asymmetric learning environment, with its clear distinction between the roles of instructors and students, is becoming more symmetric and based on communities of practice. Students will no longer passively consume learning materials but actively create and disseminate knowledge. Personal learning environments (PLEs) emphasize symmetric connections with a range of services in both formal (instructor-led) and informal (student-led) learning, work, and leisure. Rather than integrating tools within a single context, PLEs coordinate connections between users and a wide range of services offered by organizations and other individuals [11].

Personal learning environment can be defined from different points of view. For some, the PLE concept facilitates choice and control by students, allowing the selection and combination of informal and formal learning opportunities from a variety of sources. Others see the PLE as an extension of the portfolio, providing a learner-centered environment in which students can record achievements and plan and work towards new goals [10].

But in spite of these differences, personal e-learning environments are well adapted to the life-long learning, which is very important activity in the nowadays information world. Personal learning includes a progress of knowledge identification, knowledge acquisition, knowledge development and knowledge utilization [12]. The stages of identification and acquisition of knowledge can be supported by using knowledge gathered on blogs. But the most valuable and innovative knowledge is hard to be found, and it lies within distributed communities and networks.

IV. Searching in blogosphere

A. Blogosphere searching problems

Everyone, who wants to learn about any subject can use knowledge gathered on blogs [1], [2]. Blogs offer high searchability, because each post can be tagged with a category and can be retrieved easily by simply searching within that specific chosen category. But, like it was mentioned above, there is one fundamental problem with searching in blogs – the huge amount of hits (low query selectivity), due to tremendous dimension of the blogosphere. There are specialized blog search tools like Google Blog Search, Yahoo API Search, Blog Pulse (http://www.blogpulse.com/), BlogCatalog (http://www.blogcatalog.com/), and others in blogosphere. These tools allow users to search for data in blogs by tipping some keywords. But even using such specialized blog search tool does not make the search result list shorter. They all give extremely long lists of results. It can be very time consuming and frustrating for the student to break through such list of sources to find the most relevant ones. The most valuable knowledge is usually hard to be found.

The researchers have already worked out some solutions to solve the problem of searching in blogs. Blog searching has usually a specialized research purpose. The blog searching methods incorporate different techniques, depending on the domain of use. One part of these methods are based on blog ontology, another is based on clustering methods and finally some of them incorporate social network analysis methods.

B. The solutions developed in blog searching domain

The example of using blog ontology is described in [13]. Campos and Divino give a strict definition of the formal specification of structured Social Web data to express the information contained blog data sources [13]. The semantic structure provided in the blog ontology can be used by users and applications to state semantic tagging to blog resources. It can help then to retrieve relevant resources, to categorize and to organize content, and to navigate it meaningfully. The authors of this study propose also a framework for Blog Visualization System, which is based on the blog ontology. This tool can help users to track and analyze the spreading of memes through blogs. The term "meme" refers to a unit of cultural information (including deities, concepts, ideas, theories, opinions, beliefs, practices, habits, dances and moods) that is transmitted verbally or by demonstration from one mind to another mind [13]. So this is a specialized tool for visualization of meme spread path in the blogosphere.

Agarwal, Galan, Liu, and Subramanya present the blog clustering method in [14]. Blog site clustering helps better organize the information. This method also allows for optimizing the search engine by reducing the search space. So the search results are obtained faster [14]. Presented method of clustering incorporates a collective wisdom, gathered by bloggers on Blog Catalog directory, which allows bloggers to label the blogs under a given hierarchy. The collective wisdom is the wisdom generated by bloggers, when they tag and catalog their posts. Clustering method is applied to the labels rather than to blogs [14]. It means that the authors cluster blog categories. Such approach is time sensitive and adaptive to the current interests. But this method is difficult to use by an individual user.

A blog mining framework described in [7] is another very interesting example of blogosphere analysis. This framework consists of blog spider, blog parser, blog analyzer and visualizer [7]. Blog spider monitors and downloads content from multiple bloghosting sites. Blog parser extracts information from blogs, it is a specialized tool for blog content analysis. Blog analyzer extracts particular key phrases by using text mining technics. The blog analyzer is also capable of analyzing the network relationships among bloggers. And finally the blog visualizer presents content and network analysis [7]. Described framework allows to make complex analysis of the blogosphere on specified domain, like politics, business, cultural studies, and others [7].

C. Social network analysis in blogosphere searching

Many researches use social network analysis for the blogosphere exploration. But this method is used to find particular blogger groups rather than for blog searching.

Pikas studied the communities within the science blogs network [15]. She applied social network analysis to yield an understanding of the topology of the science blogosphere, basing on the blogs gathered on ScienceBlogs.com. The research started with an initial list of blogs, from which the blogroll links were gathered. Another list of links was selected from links in comments. Obtained lists of blogs were used to create a blog network and then social network analysis methods were applied to detect and describe network communities of scientists owning blogs [15].

Social network analysis is also used for finding friend groups in blogosphere, like it is described in [16]. S.-T. Kuan, B.-Y. Wu, and W.-J. Lee present a pre-processing algorithm based on n-clique extension for social network. After the pre-processing of social network the cliques can be directly found. These cliques can be formed into some representative friend groups [16].

V. Simple blog searching framework

A. The simple blog searching framework overview

Social network analysis, as it is mentioned, is often used to analyze blogosphere content, to describe relationship between bloggers or to find influential bloggers in the network. The fact that influential bloggers usually possess good knowledge blogs is the basis of the presented research. A blog of influential blogger, from the SNA point of view, has a high centrality value. As a simple centrality measure the in degree value can be used. In the blogosphere the in degree value denotes the number of links pointed at this blog. In the other words, the in degree value corresponds to the number of the links from other blogs to this blog. These links can be placed on blogroll or in posts. The fact that a blog has the high in degree value means, that many other bloggers regard this blog as a valuable one. Such blog can be useful in e-learning [17].

To find links pointed at the blog, the other blogs have to be searched and links from their blogrolls have to be collected. All these links form a social network, which can be visualized in the form of a graph and than can be analyzed with SNA methods. If knowledge blogs with the high in degree centrality are found in the blogosphere, these blogs could be used in e-learning.

The entire blogosphere can be represented as a directed graph, so any graph node (i.e. blog) can have not only the in degree measure, but also the out degree measure and the out degree centrality. The out degree value denotes the number of links from this blog to the other blogs. If a blog has a high out degree value, it means, that many links pointed out to another blogs are gathered on this blog. This fact is also incorporated in the described framework. High out degree value usually means, that the blogger, possessing his blog, has surfed a lot through the blogosphere and that he has gathered many interesting links and a lot of information on the blog. So such blog can be useful in e-learning as well [17].

For directed graph the all degree value for node can be calculated as a sum of in degree and out degree values. All degree centrality can be also used in blog searching process. It could be used as a additional criterion, confirming the value of a blog for e-learning.

In this article the simple blog searching (SBS) framework is proposed to enable users to make the process of searching in the blogosphere easier than with search tools described in the previous chapter. The scheme of this framework is presented in Fig 2. In this framework all the centrality measures, described above, are used to find the most valuable knowledge blogs.

B. *The simple blog searching framework modules*

The simple blog searching framework consists of four modules: BL Search Tool, SNA Analyzer, Network Visualizer and K-Blogs List. All of them are working in a pipe manner, i.e. the output of one module is the input for the next one.

The first module of SBS framework is BL Search Tool. BL means that this module is searching for the blogs and for links connecting these blogs. The links between blogs are needed for the next step, i.e. SNA analysis.

In the presented framework the blog searching process starts from finding the blog list with a blog searching tool. User has to define the selected category for this search. This category is specified by one or more blog tags or post tags. Additional criteria can include a time range or a blog language. After that, from the obtained blogs, all blogroll links are gathered and then passed to the next step of the analysis. To obtain a better result, i.e. better connected network, the blogroll link gathering can be repeated several times. The initial list of blogs for each repetition is a result list from the previous repetition. This means that newly found blogs (pointed by links originating from the initial blog list) are added to the intermediate result. The number of link search steps can be one of the parameters of the module. The BL Search Tool can be implemented as a specialized script.

The next SBS part, SNA Analyzer is the module, in which SNA methods are used to form the network graph and then to find important network nodes. First, SNA Analyzer analyzes the list of blogs and links connecting them, obtained from the first module. All the data is formed into the directed graph, representing obtained social network of blogs. Then SNA Analyzer finds the nodes with the high values of in degree centrality and the out degree centrality measure. The nodes with the high all degree centrality measure can be found next, as a sum of two previous centrality values. The nodes with the high centrality value can be selected in two manners. User can choose the nodes with a degree greater than the configured threshold value or he can choose *n* nodes with the highest degree value, where *n* is a configured number of nodes.

In the current version of the SBS framework, Pajek [18] works as SNA Analyzer and Network Visualizer. Implementation of these two steps is of course not restricted to this tool only. One can use another social network analysis tools, like Graphviz [19], R [20] or Ucinet [21].

The last SBS framework step is K-Blogs List, module presenting the final results of blog search to the user.

VI. Application of the SBS framework

A. *Data Gathering*

For the purpose of this research it is assumed that potential framework user wants to learn about e-learning methods and practice, so blogs about "e-learning" (Pol. e-learning) and "distance learning" (Pol. nauczanie na odległość) were searched for. Data gathering was performed in April and May of 2010. Data gathering started with an initial list of blogs acquired from a specialized blog search tool, described in section IV.A. The search was limited to blogs written in Polish only. Blog searching included two cate-

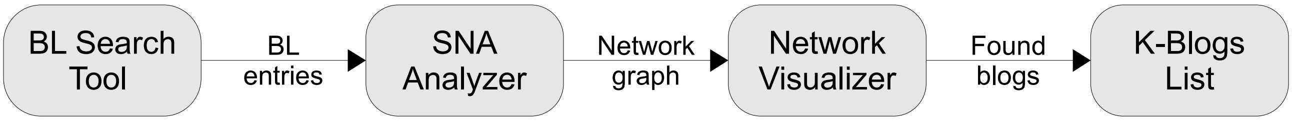

Fig 2. Simple Blog Searching framework scheme

gories, defined by tags “e-learning” and “nauczanie na odległość”.

The obtained list of blogs was then manually visited with the web browser (Firefox was used) to verify the value of the knowledge featured. Commercial blogs were left out. For the purpose of this research the small sample of Polish blogs about e-learning was finally chosen. After finishing the initial list creation, all blogs from this list were visited again to gather the blogroll links. And this step was repeated once again, as it was explained in section V.B. The first module of the SBS framework, the BL Search Tool, finished its work with the network file, containing the list of blogs and links connecting these blogs.

B. Data Analysis

The obtained blogs and links, i.e. BL entries, were then forwarded to the SNA Analyzer, and that to Network Visualizer. As it is mentioned above, Pajek was used in this example to analyze and visualize the network. The resulting network is presented in Fig 3. It turned out that there is a very small number of blogs about e-learning written in Polish in the blogosphere. The resulting network graph of the e-learning blogs network is weakly connected, so the density of the network is very small (0.05). But even such a simple sample is still sufficient for showing different aspects of using the SBS tool.

The first step of network analysis is finding the nodes with the highest in degree value. Fig 3 presents the result of this step (green point represents the blog with the highest in degree value, blue points represent the second places, red points represent the remaining blogs). Table 1 contains the five nodes with the highest in degree values. The first and second column of this table contains the data obtained from SNA analysis: node number (*NN*) and its in degree value, i. e. in degree centrality measure (*InD*). Following two columns contain blog name and blog address. The fifth column shows the effect of manual checking of the blog content to judge its quality for usage in classroom scenario. This inspection was done to verify the SNA analysis result. In the Table 1 the most valuable (with the highest in degree centrality value) is the node number 5. Manual checking shows it is a very well written blog and a good source of knowledge. In this paper author's opinion the first and the second blog could be quite easily used in classroom scenario. The three following blogs also contains useful information and their parts could be used as a supplementary lecture.

The second step of network analysis is finding the nodes with highest out degree value. Fig 4 shows the result of this step (green point represents the blog with the highest out degree value, blue points represent the second places, red points represent the remaining blogs). Table 2 contains the three nodes with the highest out degree values. The meaning of the table columns is the same as for Table 1, with exception for the second column, containing out degree values for nodes (*OutD*). The first blog in this category, blog number 7, has the highest out degree in the presented example, because its author prepared a rich blogroll. In this paper author's opinion all three blogs could be used in classroom scenario, but the second (number 1) in some topics only (a very good blog about cognitive science).

Both described steps of searching (for the highest in degree value and for the highest out degree value) give good results for established task of knowledge blogs finding. It means that a user can also take into account the result of the all degree value, which can be the next step of analysis. The result is presented in Fig 5 (point colors like in Fig 4). The best blogs in this classification are presented in Table 3. The result of this classification is the combination of the best results in first and second stages of analysis. It points out, that it is good criterion.

This research shows additionally that, from the point of view of presented method of blog searching, the connection making between blogs is a very important activity of the blog authors. The more connections from and to the blog, the more easily the potential student will find and use this blog.

The single nodes visible in Fig 3, are blogs with a very few information about e-learning or rarely updated blogs, but found by the search tool, because they have posts labeled with "e-learning" tag. The method of searching implemented in the SBS framework efficiently eliminates such nodes. They have zero in degree and out degree value. So they can be filtered out by such searching method.

Generally all blogs gathered in this research are valuable source of knowledge in the area of "e-learning".

VII. Conclusions

The process of knowledge sharing is a very important activity in the contemporary information era. This process can be effectively supported by good and useful technologies like blogs. The huge amount of knowledge is gathered on blogs, but the most valuable and innovative knowledge is hard to be found, and it lies within distributed communities and networks. This study presents a framework for simple blog searching, to make the process of knowledge gathering easier.

Simple Blog Search framework consists of four modules. SNA measures of in degree centrality and out degree centrality are used to help user in searching the blogosphere. The all degree centrality could be an additional searching criterion, confirming the blog usefulness. To use such a method the connections between blogs, constructing the network (i.e. hyper-links), must be used. To incorporate social network analysis methods, the common blog searching (i.e. searching with one or many tags) have to be extended with the blog links searching. In presented example links between blogs were gathered from blogrolls only. It is an easier way, but it can lead to weakly connected network, like shown in Fig 3. To create better connected network, links from comments and posts should be also collected. This is the subject for future work, because it demands more advanced scripts for links searching and collecting.

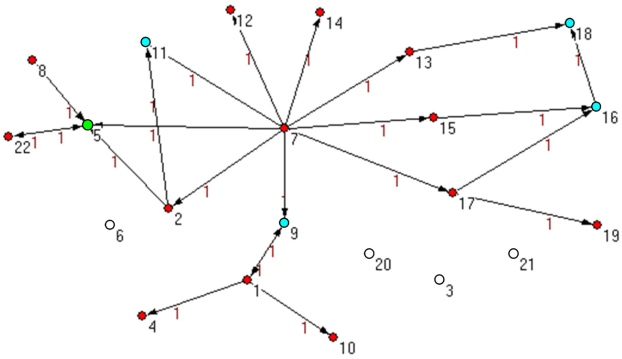

Fig 3. The acquired social graph of the e-learning blog network with in degree partition marked [17]

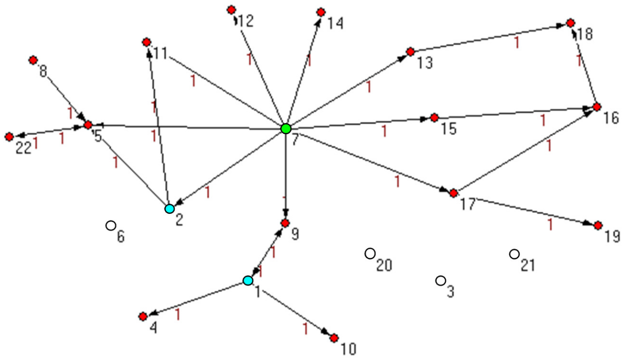

Fig 4. The out degree partitions of the e-learning blog network [17]

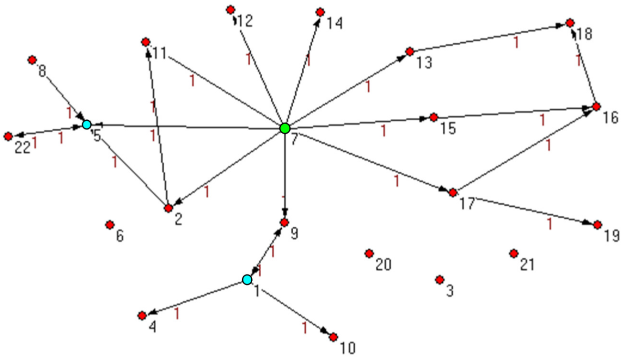

Fig 5. The all degree partitions of the e-learning blog network

Also the core of this method, i.e. centrality measuring manner (in degree and out degree centrality) will be replaced in the future research by more advanced measures of centrality and prestige measure calculation. To better confirm presented method of blog searching the English sites will be used in the future. It allows to extend the example sample and probably get more interesting result.

Table 1. The nodes with the highest in degree value

NN	InD	Blog name	Blog address	Blog usefulness

6th Workshop on Large Scale Computations on Grids and 1st Workshop on Scalable Computing in Distributed Systems

The Large Scale Computing in Grids (LaSCoG) workshop originated in 2005, and when it was created we have stated in its preamble that:

"The emerging paradigm for execution of large-scale computations, whether they originate as scientific or engineering applications, or for supporting large data-intensive calculations, is to utilize multiple computers at sites distributed across the Internet. In particular, computational Grids are collections of distributed, possibly heterogeneous resources which can be used as ensembles to execute large-scale applications. While the vision of the global computational Grid is extremely appealing, there remains a lot of work on all levels to achieve it."

While, it can hardly be stated that the issues we have observed in 2005 have been satisfactorily addressed, a number of changes has happened that expanded the world of large-scale computing. Today we can observe emergence of a much more general paradigm for execution of large-scale applications, whether they originate from scientific or engineering areas, or they support large data-intensive calculations. These tasks utilize computational Grids, cloud-based systems and resource virtualization. Here, collections of distributed, possibly heterogeneous resources, are used as ensembles to execute large-scale applications.

This being the case, we have decided to keep the LaSCoG workshop tradition alive, but to co-locate it with a conference which will have an appropriately broader scope. This is how the Workshop on Scalable Computing in Distributed Systems (SCoDiS'10) emerged.

The LaSCoG-SCoDiS'10 pair of events shares a joint Program Committee and is envisioned as a forum to promote an exchange of ideas and results aimed at addressing sophisticated issues that arise in developing large-scale applications running on heterogeneous distributed systems.

Covered topics include (but are not limited to):

- Large-scale algorithms and applications
- Cloud computing
- Symbolic and numeric computations
- High performance computations for large scale simulations
- Large-scale distributed computations
- Agent-based computing
- Data models for large-scale applications
- Security issues for large-scale computations
- Science portals
- Data visualization
- Performance analysis, evaluation and prediction
- Programming models
- Peer-to-peer models and services for scalable Grids
- Collaborative science applications
- Business applications
- Data-intensive applications
- Operations on large-scale distributed databases
- On-demand computing
- Computation as a service
- Federation of compute capacity
- Virtualization supporting computations
- Self-adaptive computational / storage systems
- Volunteer computing

***Abstract*—GridSpace 2 is a novel virtual laboratory framework enabling researchers to conduct virtual experiments on Grid-based resources and other HPC infrastructures. GridSpace 2 facilitates exploratory development of experiments by means of scripts which can be written in a number of popular languages, including Ruby, Python and Perl. The framework supplies a repository of gems enabling scripts to interface low-level resources such as PBS queues, EGEE computing elements, scientific applications and other types of Grid resources. Moreover, GridSpace 2 provides a Web 2.0-based Experiment Workbench supporting development and execution of virtual experiments by groups of collaborating scientists. We present an overview of the most important features of the Experiment Workbench, which is the main user interface of the Virtual laboratory, and discuss a sample experiment from the computational chemistry domain.**

I. Introduction

MODERN life sciences, particularly simulations in biochemistry, genetics and virology, impose significant requirements on underlying IT infrastructures. Such requirements can be loosely grouped into two general domains: demand for computational resources and demand for new software tools facilitating effective, productive and collaborative exploitation of such resources by a vast range of beneficiaries. While the key goal of supporting scientific experimentation with computerized infrastructures remains the provision of large-scale computational and data storage facilities [1], it is equally important to supply scientists with tools enabling them to collaboratively develop, share, execute, publish and reuse virtual experiments.

The presented Virtual Laboratory, first conceived as part of the ViroLab project [2] and currently being extended within the scope of the PL-Grid project, aims to respond to these requirements by supplying software which permits the execution of virtual experiments. Experiments can be written in popular scripting languages and executed on the distributed resources provided by HPC institutions participating in the project. The goal of the Virtual Laboratory is to a propose a model and facilities for exploratory, incremental scripting – already omnipresent in e-scientific research – and make it reusable and actionable for entire communities. Our framework bridges the gap between the oft-inaccessible high performance computing infrastructures and the end users (i.e. domain scientists), accustomed to running calculations and collating experimental data on their desktop computers. Rather than persuade the scientists to change their daily habits, we want to provide an environment which meshes seamlessly with their style of work, yet extends their experimentation and collaboration potential with the capabilities of high-performance computing clusters.

Our experience gathered in the course of developing the ViroLab Virtual Laboratory for virologists [2], [3], [4], the APPEA runtime environment for banking and media applications in the GREDIA project [5] as well as the GridSpace environment for running in-silico experiments, has been augmented with user requirement analysis conducted during the initial phase of the PL-Grid project, involving groups of scientists from various domains such as physics, chemistry and biology. The Virtual Laboratory presented in this paper should be considered as an evolution of the approach undertaken in the ViroLab project. The new virtual laboratory is focused on interactive and exploratory programming [6], together with a Web 2.0 interaction model.

This paper is organized as follows. In section II we compare our concept with other approaches. After describing our motivation in section III we introduce the main concepts of Virtual Laboratory in section IV while its architecture is discussed in section V. In section VI we introduce GridSpace platform, which is the base technology which implements the virtual laboratory. Section VII contains an overview of the most important features of the Experiment Workbench, which is the main interface of the Virtual laboratory. Further on, we provide a description of the steps which the user undertakes while working with the Virtual Laboratory (section VIII), together with use cases. The conclusions and future work can be found in section IX.

II. Related Work

Scientific workflow systems are important tools for development and execution of e-science applications [7]. Thanks to the well-defined workflow and dataflow models in systems such as Taverna [8] or Kepler [9] it is possible to graphically design applications which can then be executed on remote infrastructures. Scientific workflows can be subject of exploratory programming, as in the case of Wings project [6], as well as of collaborative sharing, such as in the case

978-83-60810-27-9/09/$25.00 © 2010 IEEE

of myExperiment social networking website [10]. The main drawbacks of workflow systems are related to the fact that contrary to programming languages, abstract workflow models are often insufficient for describing the required application flow.

Scripting environments are becoming increasingly important in scientific applications and modern petascale systems. An example of this evolution is Swift Script [11] – a dedicated language designed to describe large-scale computations, involving massive data processing. An important feature of Swift is its mapping between data files and programming language variables, which facilitates input/output processing. Scripting can also be used for debugging and instrumenting parallel applications [12]. Our approach is similar in the sense that we intend to use scripting to describe the high-level workflow of the application while retaining interactivity and enabling multiple interpreters to be combined together.

The need to integrate diverse applications, data sources and technologies emerges not only in scientific applications, but also in enterprise systems [13]. Enterprise Service Bus solutions such as ServiceMix or GlassFish, aim to facilitate such integration in the Web service context [14]. The BPEL workflow language can also be applied to scientific applications [15]. However, we believe that such enterprise workflow systems are too heavyweight for simple exploratory programming, where a scripting approach seems to be more appropriate.

The GridSpace environment, which is the foundation of the ViroLab Virtual Laboratory [4], has beed developed by our team to support complex applications running on e-infrastructures such as clusters, Grids and Internet-accessible Web services. One of the goals was to support heterogeneous middleware systems using the Grid Object abstraction layer [16] and facilitate access to distributed data sources. Additional important features include support for collaborative work including tools for application development, sharing, reuse and Web-based accces. Moreover, provenance and result management components provide semantic descriptions of data and enable users to view experiment execution histories. The limitations of GridSpace include its relatively high architectural complexity and the fact that only the Ruby scripting language is supported.

III. Motivation and Goals of the Virtual Laboratory

The main features of Virtual Laboratory result from the experience gained during the ViroLab project, the requirements of external users, as well as from discussions with potential users of the PL-Grid project. The main high-level objectives are as follows:

- To provide an environment which facilitates dealing with scientific application throughout its entire lifecycle (development, deployment, operation, maintenance);
- To reflect and support the day-to-day work of scientists who need to deal with software tools – workflows, procedures (including informal ones), scripts, etc. – enhanced by modern Web 2.0 tools;
- To addresses exploratory programming and a specific type of applications called experiments.
- To support collaborative work of teams of scientists in a Web 2.0 model.

The specific goals of Virtual Laboratory are based on the analysis of e-science applications and discussions held with their authors. The main contributions come from the fields of bioinformatics and computational chemistry. Requirements include:

- Support for different scripting languages – particularly Ruby, Python, Perl and awk;
- Provisioning of tools for publishing and reusing applications/experiments;
- Support for dynamic workflows – as each step of an experiment may depend on the results of previous steps, some workflows cannot be entirely predefined. Moreover, some experiment steps may involve batch jobs;
- Support for parameter-study research, conducted either on the level of a single tool or an entire workflow;
- Support for logging experiments and ensuring their reproducibility;
- Providing easy access to scientific software packages; (the suites most commonly used in PL-Grid include Gaussian, GAMESS, TurboMole and ADF1);
- Direct access to local PBS systems without an additional grid middleware layer;
- Support for creating and using format converters for different tools, as well as adapters for different data sources (not necessarily databases);
- Secure management of user credentials and other sensitive data.

In addition to these requirements, the virtual laboratory needs to satisfy several non-functional and more technical requirements, which are described in more detail in section VI.

IV. Virtual Laboratory Concepts

The key concept associated with the Virtual Laboratory is the experiment. As defined in [3], an experiment is a process that combines data with a set of activities (programs, services) which act on that data in order to produce experiment results. it is important to distinguish the experiment plan – a specific piece of software, written using scripting languages – from the experiment run (execution of the experiment). The key feature here is that the experiment may represent a complex workflow, going beyond simple, repeatable manual execution of installed programs.

The *experiment plan* combines steps realized by a range of software environments, platforms, tools, languages etc. It is developed, shared and reused collaboratively by ad-hoc research teams. The experiment is composed of collaboratively owned libraries and services used (called *gems*) and experiment parts (called *snippets*). Gems are used to represent either program libraries, such as BioPython [17], or applications such as

Figure 1. The GridSpace 2 experiment concept

Gaussian [18] or external services, such as the ones from EBI [19]. Snippets refer to separate pieces of code, either in scripting languages, such as Python or Bash, or in other domain specific languages or input file formats, such as used by Gnuplot or Gaussian.

The key paradigm of the enhanced version of virtual laboratory, namely exploratory programming, involves experimentation – step-by-step programming where steps are not known in advance but rather defined on an ad-hoc basis, depending on the results of previous steps. The experiment may need to be re-enacted numerous times, with some ad-hoc customization introduced dynamically, once workflow execution has already commenced. Experiment execution cannot be fully automated and requires continuous supervision, validation or even intervention. This implies a dynamic nature of experiment plan – certain decisions need to be taken at runtime (e.g. code provided from input data). Nevertheless, experiment execution has to remain traceable, verifiable and repeatable.

Due to its focus on exploratory programming, the virtual laboratory is best suited for a try-evaluate-decide process, without losing the context of the experimentation, as opposed to applications with well-known implementations. The virtual laboratory aims at composing and automating higher-level, time-consuming workflows that combine existing software. This property contrasts with applications which perform "atomic" processing. Another interesting feature involves support for novel combinations of existing software modules, data sources and computational capabilities which may result in valuable utilities, as opposed to well-defined workflows which are already addressed by existing software.

V. Architecture of Virtual Laboratory

Fig. 2 presents the architectural overview of the Virtual Laboratory. It is divided into four layers: the Experiment Wokbench layer, available to the user as a set of Web applications, the Experiment Execution Layer which forms the runtime environment of the platform, the Gem Layer which includes all generic and application-specific libraries accessible to the experiments, and the Grid Fabric layer, with all the resources and middleware needed to access them.

The topmost layer is formed by a Web portal which constitutes an entry point for the whole Virtual Laboratory. This gives users access to the Virtual Laboratory from any workstation equipped with a web browser. This layer exposes a portal which is intended as a common, tool-rich workbench for all Virtual Laboratory researchers where they can perform their daily experimentation, collaborate, communicate and share resources (including reusable code). This layer is accessible to end-user browsers via the HTTPS protocol. File Manager is responsible for easy access to data files, Experiment Console allows editing and running experiment snippets, Credential Manager helps handle passwords, certificates and other secrets required by some parts of experiments, and Graphical Experiment Builder is intended to construct more complex experiments graphically.

Further down lies the Experiment Execution Layer where consecutive parts of experiments, provided by the users through the Portal, are evaluated in the context of a particular user account on an experiment host machine. A single experiment can invoke multiple interpreters, such as Python or Ruby. The key concept here is that an experiment can be developed in a piecewise fashion. Individual experiment parts are executed by an experiment interpreter which preserves state (namespace, runtime values) between evaluations. Consequently, experiment development and execution may overlap, and the activities of writing and executing code are intertwined. Such an approach admits introspective, interactive, explorative and dynamic experimentation recorded as experiment code. Moreover, interpreters are executed in separate processes, which provides better isolation and fault tolerance (i.e. a crash o a single interpreter does not influence the others). The Experiment Workbench Layer and the Experiment Execution Layer are in constant communication via the SSH protocol family. We also intend to allow direct user access to the Experiment Execution Layer though bare SSH and SCP.

The next layer consists of Gems which are libraries/modules/utilities invoked by experiments at runtime. The Gem Layer provides APIs for experiment developers, enabling programmatic access to underlying resources (Grid, clusters) and functionality exposed in the form of libraries or services. There are gems which are generic, such as the one which provides access to PBS batch system, or application specific ones, such as Gaussian.

The Grid Fabric Layer forms the lowest level of the infrastructure. It consists of grid resources available to Virtual Laboratory users, including clusters accessible through PBS, grids available through their dedicated middleware packages (e.g. gLite), external services (e.g. Web Services) and data sources (e.g. RDBMSs) which the users may explit of in the course of their research activities.

The entire Virtual Laboratory operates in a Single Sign On (SSO) mode, according to the accounts defined in the external authentication system and incorporating security policies involved in accessing Grid middleware. In the case of PL-Grid installation, it uses PL-Grid LDAP directory so that the virtual laboratory is automatically accessible to all registered PL-Grid users.

The four layers of the Virtual Laboratory are distributed and spread over physical computational nodes. The Experiment Workbench Layer operates on the so-called Portal Host. The

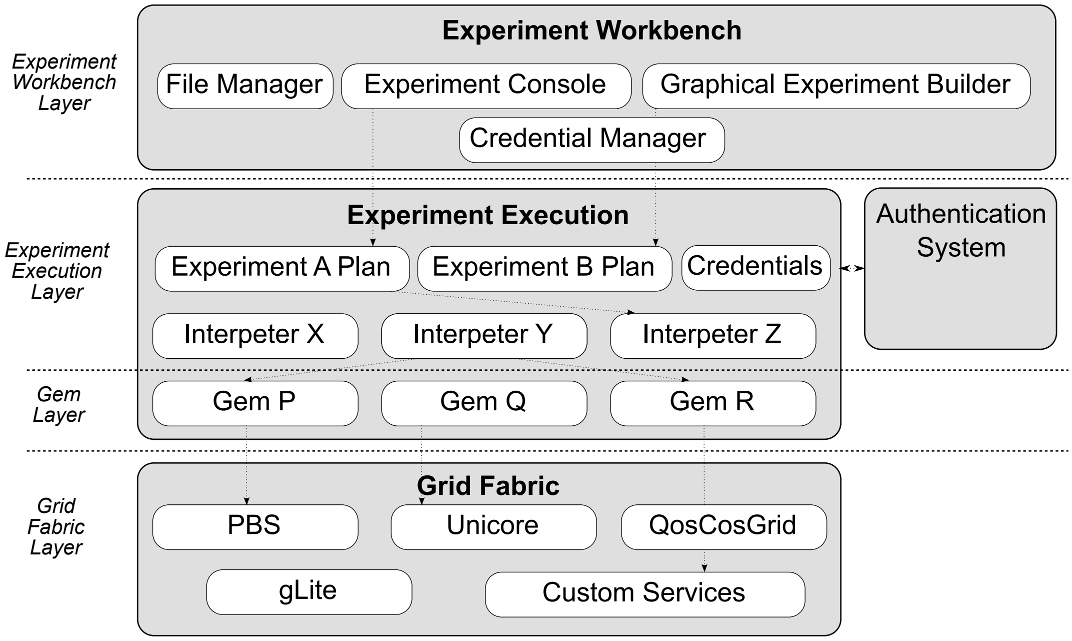

Figure 2. Architecture of the Virtual Laboratory including logical layers (captions on the left-hand side), main modules and their dependencies.

Experiment Execution Layer and the Gem Layer reside in one or more Experiment Hosts, which can be one of the front-end machines (user interfaces) of the clusters. The Grid Fabric Layer spans many distributed computational resources. The Portal Host and the Experiment Host may reside on distinct machines (in order to improve scalability); however they may also operate on a single host when system compactness is more important.

VI. GridSpace – Implementation

The presented Virtual Laboratory, is based on the core technology, called GridSpace, first conceived as part of the ViroLab project [2] and currently being extended within the scope of the PL-Grid. While still supporting the earlier version of the GridSpace framework, in GridSpace 2 we implement the new functionalities which focus on interactive and exploratory programming [6], together with a fully Web-based user interaction model.

In addition to the requirements specified in section III, there are some technical goals, which were not satisfied by earlier versions of the Virtual Laboratory. They include support for multiple scripting languages and more interactive and ad-hoc scripting capabilities. Non-functional requirements such as performance, maintability and ease of use have also been taken into account, motivated by the need to deliver production-quality software to be deployed on the PL-Grid national infrastructure.

It is important to note that GridSpace is a generic environment rather than a specific application. This means that it can be used to set up a specific instance of the Virtual Laboratory in support of a specific application domain. It can be applied whenever existing software modules, interpreters etc. need to be combined with other components. The learning curve involved in porting an application to the platform should be minimized.

Another feature of GridSpace is that it exploits Web 2.0 mechanisms by facilitating application development, operation and provisioning. This means that the entire experiment development and execution cycle is accessible from within a web browser, and moreover, experiments and their results can be shared among community members.

VII. Current Features of the Experiment Workbench

The main features of the current version of the Experiment Workbench include:

- File management
- Dedicated visualization openers
- Interactive interpretation of experiment script snippets
- Storing and sharing experiments using XML format
- Secure management of user credentials (passwords, certificates etc.)

The main exeriment workbench window is shown in Fig. 3. The file management tab is seen on the left, while the right-hand part of the application screen is taken up by the experiment console consisting of several experiment snippets. Above the console, in a separate window, a plugin for displaying graphical data is shown.

In addition to the basic features available directly in the Experiment Wokbench there are additional mechanisms which can be used in more advanced experiments. The first one is WebGUI, which allows experiments to expose dedicated Web interfaces. Another – semantic integration – enables the construction of domain-specific models and data exchange

formats to facilitate colaboration and data sharing between experiments and users.

A. File management

At the present stage of development, the GridSpace 2 platform provides basic but stable functionallity which presents a sound basis for further expansion. The most fundamental feature is to enable users to manage their files on an experiment host through an HTTPS interface, enabling basic file system operations as well as uploading, downloading and accessing files via URLs. Data elements and experiment files are assigned globally unique URLs, which facilitate access, annotations and linking resources in a weblike manner. The URLs are given as: https://experiment.workbench.name/experiment.host.name/files/username/path/to/a/file. The Experiment Workbench handles these URLs by accessing the remote experiment host in the scope of the authenticated session. An SSH connection is established with the host, using the provided login/password pair. Following authentication, the workbench performs all file system operations via SCP/SFTP on behalf of the end user. Therefore, authorization relies on file access policies of the operating system residing on the experiment host.

B. Visualization openers

Files served by the Experiment Workbech can be downloaded to the end-user's desktop or viewed and edited within a web browser using so-called openers. The mechanism follows and extends the idea URL-accessible files by introducing the HTTPS GET param "opener", yielding URLs such as https://experiment.workbench.name/experiment.host.name/files/username/path/to/a/file?opener=openerName. The Experiment Workbench handles such requests by serving a page with an embedded opener applet instead of the file itself. The opener applet is configured on the fly, using the input URL, so that it is able to get and put a file using the above mentioned HTTPS interface. As the opener applet launches within the web browser, the authenticated session context (implemented using cookies) covers its function as well.

C. Interactive interpretation of experiment script snippets

The Experiment Workbench implements the exploratory programming paradigm through interactive interpretation of experiment parts called snippets. A snippets is an atomic planning and execution unit of an experiment. Exploratory development involves experiment planning and execution, both of which start at the same time and proceed in parallel. During the exploration process snippets can be incremetally added to the experiment plan, which, in turn, can be incrementally executed in a snippet-by-snippet manner. If the experiment plan calls for a change in a snippet which has alrady been evaluated in a run, the experiment needs to be reexecuted or rolled back (the latter functionality is, however, a challanging issue which will be addressed in the scope of further research).

D. Storing and sharing of experiments using the XML format

The experiment plan is modeled as a sequence of snippets. Each snippet is associated with an interpreter required for its execution. Interpreter specification includes a command, a set of environment variables and a prompt character sequence which is required in order to enable identification of script line evaluation completeness. Interpreters can be intaractive (capable of evaluating snippets line by line) or batch-oriented (the whole snippet is sent to the interpreter followed by an EOT character, upon which the environment waits for output). Any executable capable of operating in one of the above modes may be configured as a GridSpace 2 interpreter. The idea of an experiment file is that it presents a complete and standalone artifact sufficient for performing the experiment run. As long as it is contained in a single file, it can be associated with a global URL, which makes the experiment an addressable, shareable and linkable resource within the Web 2.0 space. Along with snippet code and interpreter specifications, the experiment XML file contains metadata including the name of the experiment, its description, its creation date, author names and comments. In addition, each snippet may specify a list of so-called secrets, i.e. data elements (such as passwords) which represent user credentials. This data should not be stored in experiment files but instead retrieved from the local user's wallet each time a given experiment is run. The Workbench provides a user-friendly way to manage secrets and use them in experiments while the GridSpace platform facilitates secure storage of credentials and other sensitive data.

A sample experiment XML file in a simplified notation is shown in Fig. 4. It includes a metadata tag, where user comments can be added during experiment evolution. An interpreter definition is presented in line 26 where it is possible to specify the command to initiate an interactive session using PBS. In lines 31–36 of this "hello world" example we can see the sample code in the specified languages.

36     code: echo "Hello, Bash via PBS"
```

Figure 4. Sample "Hello world" experiment XML file (tags are represented as bold text for clarity).

E. WebGUI

In order to enrich user experience a WebGUI integration tool is available. It provides well-defined frames for incorporating external web applications in the experiment execution flow. The tool enables experiment creators to plan interactions with the end user and either retrieve additional data or present intermediate experiment results. For integration with external web applications simple JSON communication is used, which makes the process of creating new or modifying existing web applications straightforward. For less demanding experiment creators who do not wish to create or reuse external applications, a generic web UI implementation is available. Through a simple JSON-based definition, available from the experiment code, a graphical interface can be spawned and presented during experiment execution. This implementation allows for building web forms using standard controls (e.g. text fields, text areas, radio boxes, etc.) In addition, a rich text editor control is available.

F. Semantic integration

Among the goals of the Virtual Laboratory, as stated in Section III, is the provision of a generic technology, supporting scientists from specific application domains. Since each of the *in-silico* experiments supported by our platform comes from a specific field of science, the need for domain-specific data models is clear. The semantic integration concept [20] is a method of building application-specific data models and cross-combining them with protocols and tools developed for the application environment. In other words, semantic integration helps scientific developers support structures and taxonomic characteristic for a given field of science via generic storage mechanisms and generic information exchange protocols.

The incorporation of semantic integration in the presented Virtual Laboratory provides a means of storing data and metadata for bioinformatics applications (such as protein pocket finding), as well as for computational chemistry applications running Gaussian and GAMESS. In the former case it is used to store and publish several gigabytes of data produced in high-throughput computations involving numerous proteins. In the later case it helps store and exchange metadata for the output files generated by various chemistry packages. Since the Virtual Laboratory application pool is still being extended, we can expect that the semantic integration solution will eventually cater to other scientific domains as well.

VIII. Working with GridSpace and Examples of Usage

Virtual Laboratory defines a specific model of interacting with applications. The main procedure for preparing an experiment is as follows:

1) The user identifies a procedure (process, workflow) that involves manual use of a number of software pieces which could benefit from (semi-)automation, making them easy to use for the user and for the research team.
2) The user writes this procedure in a stepwise fashion where each step is decided upon by viewing the outcome of previous steps.
3) At each step the user takes advantage of one of a number of programming languages, platforms or programs which are the most suitable for the current purpose.
4) Following each step the user may open the retrieved files with the available tools (e.g. display a graph, visualize molecules, show text content etc.)
5) The user can retrace his/her steps in order to find the best path to the solution.
6) The user can save the current sequence of steps (i.e. the experiment) and open it later for further development.
7) Having discovered the right sequence of steps, the user can save the experiment again and specify the group of users who will be allowed to run or further modify that experiment.
8) The user can send a link to the experiment web application to his/her group.
9) The link leads to a page where, following successful login, other users can run the web application or open it in an experiment editor.
10) The user can enrich experiments with custom graphical user interfaces which collect input and display results.

As an example of use we can present an application from the chemistry domain involving the study of aqueous aminoacid solutions. The analysis process is a workflow which involves multiple steps realized using many tools, languages and libraries. First, Packmol [21] is used to perform molecular dynamics simulations for animoacid aggregation in the presence of water. The resulting solution is visualized with Jmol [22] and can be manually checked prior to further processing, i.e. computing a spectrum using the Gaussian [18] tool. In order to extract spectrum-related information from the Gaussian output file we need to use the CCLIB [23] library written in Python. Finally, spectrum information can be visualized as a plot using GnuPlot.

In addition to the above, many other programming languages and tools can be configured in the Experiment Workbench and thus made available for experiment developers.

Our sample installation of the Experiment Workbench supports a set of interpreters and tools including Bash 3.00, Python 2.6.4, Perl 5.8.5, Ruby 1.8.7, Packmol, Gaussian 09 and Gnuplot 4.0. All interpreters can be launched directly on the experiment host or through the Torque Portable Batch System.

IX. Conclusions and Future Work

In this paper we have presented the main requirements, concepts and current status of the Virtual Laboratory based on GridSpace platform. Although based on experience gained in the course of the ViroLab project, GridSpace 2 constitutes a novel framework. Its main advantage is support for exploratory programming, where each experiment consists of snippets programmed interactively in multiple programming languages using a web console. The Experiment Workbench allows interactive experiment development, file manegement and experiment sharing. The Virtual Laboratory also supports web-based graphical user interfaces and semantic integration.

GridSpace 2 has been made available for the users of the Pl-Grid project for beta testing. Preliminary feedback from bioinformatics and computational chemistry applicaiton domains shows promising results. The final release and integration with the PL-Grid infrastructure is planned for the end of 2010. The continuously updated beta installation of the Virtual Laboratory has been made available to the PL-Grid users and is accessible at the Virtual Laboratory website [24]. More information about the GridSpace 2 technology, including demos and presentations can be found at [25].

Future work will focus on enhancing the usability and security features. One of the planned enhancements involves development of a graphical tool for constructing experiments with hierarchical snippet trees. Another will provide handling of multiple security credentials to facilitate access to heterogeneous middleware systems and data sources. We are also adding support for more application-specific gems, interpreters and visualization tools to extend the range of supported application domains.

Acknowledgments

The research presented in this paper has been partially supported by the European Union within the European Regional Development Fund program no. POIG.02.03.00-00-007/08-00 as part of the PL-Grid project (www.plgrid.pl) and ACC Cyfronet AGH grant 500-08. Maciej Malawski acknowledges support from the UDA–POKL.04.01.01-00-367/08-00 AGH grant.

***Abstract*—The paper proposes a model which allows integration of services published by independent providers into scientific or business workflows. Optimization algorithms are proposed for both distribution of input data for parallel processing and service selection within the workflow. Furthermore, the author has implemented a workflow editor and execution engine on a platform called BeesyCluster which allows easy and fast publishing and integration of scientific and business services. Several tests have been implemented and run in BeesyCluster using services for a practical digital photography workflow with and without budget constraints. Two alternative goals are considered: minimization of the execution time with a budget constraint or a linear combination of cost and time.**

I. Introduction

SERVICE integration has become the main focus in distributed environments. Firstly, Service Oriented Architecture (SOA) promoting loosely coupled services interacting with each other, secondly Open Grid Service Architecture in the context of grid computing laid fundamental concepts for modern distributed applications. In both cases, workflow management systems using Web Services and grid middlewares allow composition of individual services into complex workflows. In the classic approaches, tasks are either mapped to available resources or available services are assigned to tasks so that QoS metrics for particular tasks or for the whole workflow are optimized. This can be minimization of the execution time with a budget constraint on the costs of resources or services used. Furthermore, many of the practical workflows are data-intensive and require data partitioning for parallel processing. From this point of view the author proposes a model with data partitioning for parallel execution and service selection, both important for practical workflows.

From the infrastructure point of view, it is desirable for a service provider to publish scientific or business services easily and instantly, define prices and other QoS parameters as well as be able to manage the service. For the client, it is important to be able to integrate such services from various providers. This requires selection of best services considering imposed QoS constraints and the goal followed by execution of selected services. The author has implemented these in BeesyCluster which satisfies all of these requirements for scientific and business environments.

II. Related Work and Motivations

Firstly, *task scheduling* considers mapping of workflow tasks to available resources so that workflow execution time is minimized [1], [2]. In the classic problem, task execution times are known in advance, neither data flows nor other metrics such as costs are usually considered. Some works take into account execution costs of particular resources [3]. Paper [4] considers resource requirements for tasks of the workflow.

Secondly, in *scheduling in utility grids* [5] or *workflow scheduling in grids* [6] for each task t_i we distinguish a set of services S_i out of which only one service is to be chosen to execute t_i. Other attributes such as service costs are considered [7]. As considered by [8] and [5] the goal is to find the best assignment of $t_i \rightarrow (s_k, t_{ik}^{st})$ where s_k is a service able to execute task t_i and t_{ik}^{st} is the starting time of execution of task t_i on service s_k. Execution of t_i and t_j on one s_k must not overlap and the workflow execution time should be minimized while keeping the cost of selected services below a predefined minimum. In the context of typical business interactions, the *QoS service selection/workflow composition* problem is stated. Compared to the scheduling problem, many more quality attributes are considered without dependencies between or overlapping of services executing different tasks. The goal is to select proper services so that a function of QoS metrics such as: execution time, cost, availability [9], [10], [11], accessibility [10], fidelity [12] or conformance [10], security [10], reputation [9] is minimized possibly also with additional conditions imposed on some of them [11], [13]. For instance, the cost of using the services must not exceed the given budget.

There exist several workflow management systems for grid computing. Paper [2] describes and compares Gridbus, Kepler [14], Pegasus [15], Triana [16], P-GRADE [17], Directed Acyclic Graph Manager (DAGMan), ICENI, GridFlow, GrADS, Askalon, UNICORE, Taverna, GridAnt. These grid-oriented systems mainly use middlewares such as Globus Toolkit, Grid Application Toolkit or other resource management systems etc. for running jobs. More business oriented environments focusing on execution of BPEL or semantic service discovery and compositon such as Meteor-S [18] usually do not offer support for HPC environments although [19] presents how to use BPEL for grid environments.

Such workflow management systems support data parallelism and various operations on the data [20], [21]. In Gridbus, input parameters can be defined as parameter values, files or data streams [20]. In Process Networks in Kepler the workflow is driven by data availability and can be used for parallel processing on distributed systems [22]. Since the service may receive data as it runs and possibly from various predecessors, data processing can be defined in many ways on the input data. In the one-to-one composition pattern successive portions of input data from two input sources are processed pairwise [21]. Paper [21] demonstrates that MOTEUR can handle one-to-one and all-to-all patterns as well as workflow, data and service parallelism and is compared to Taverna, Kepler and Triana which lack some of these features. [23] optimizes workflow makespan also considering the possibility of dynamic deployment of services on various resources to save large data communication costs.

From the point of view of the model, the contribution of this work is a combined model (Section III) with both data distribution for parallel computing by parallel tasks and selection of services to optimize various QoS goals and meet QoS constraints. The consumer constructs a workflow i.e. a complex scenario composed out of simple tasks. It is assumed that the workflow graph can contain both sections with parallel tasks for among which input data is distributed for parallel processing. In this case each task has a single service assigned to it. Also, the graph may contain tasks with alternative services out of which one needs to be chosen to perform the given task. As an example, the workflow shown in Figure 1 allows parallel processing of several input digital RAW images by several filters. These can be executed by services created from free applications such as `dcraw`, `RAWtherapee` or possibly offered by companies who offer own paid image processing software. A comparison of RAW converters is available at `http://www.photozone.de/conclusion-on-going`. It finally produces a Web album out of images previously processed in parallel. The problem is to find both: data distribution – partition input data for parallel processing by parallel paths to speed up workflow execution and service selection – a service to execute each task – for each task t_i there may be one or more services (s_{ij}) capable of executing the task at price per unit of data c_{ij} (one out of two web album generation services $s_{19\ 0}$, $s_{19\ 1}$ can be chosen for task t_{19}). The goal is to minimize one of the following: $v_{MIN\_T\_C\_BOUND}$ – minimization of the workflow execution time with a constraint that the total cost of selected services does not exceed the given budget or, v_{MIN_TC} – minimization of a linear combination of workflow execution time and the total cost of services. Services may be offered by independent providers for potentially various prices and each service is installed on a particular cluster or server of a predefined speed. Incompatibility between formats used by various providers is considered as additional cost in the model. If there is a budget constraint set then more tasks will be sent along cheaper paths and more expensive paths will not be used. What is important, the model proposed by the author and presented in Section III considers alternative approaches as to how data is passed between tasks. As discussed in Section III-A, either the next task starts when all data has been processed by preceding tasks or processing data in streams for overlapping communication and computations is proposed. In [24] the author has presented how to choose services at runtime for highly changeable environments rather then before workflow execution considered in this work.

From the infrastructure point of view, the contribution is the author's implementation of the model in BeesyCluster (Section VI) taking advantage of features of the latter. Secondly, the paper demonstrates usefulness of the solution for a real world workflow application (Section VII). BeesyCluster is the middleware for the workflow system described in Section VI in this work. BeesyCluster differs from other middlewares as it accesses services published by users through user accounts via SSH. This means that contrary to many other systems adding new clusters or registering new user accounts is a matter of seconds as requires just corresponding entries in the database regarding access. Similarly, each user can become a provider by publishing their parallel or sequential applications installed on various clusters as services in a matter of seconds in the file manager in BeesyCluster. This allows publication of scientific services from HPC clusters as BeesyCluster hides low level details like queueing systems. Also, businesses can publish services from their own servers attached to BeesyCluster. This also brings pricing for not only business but also scientific services and allows composition of both types.

III. Model of the Workflow Scheduling with Data Distribution

Consequently, the author proposes a model with data distribution in which a directed graph $G(V, E)$ represents a workflow where nodes V correspond to tasks while edges E denote task dependencies. There is at least one starting node with initial data and one termination node which terminates computations. The model allows: a sequence – for connected tasks, a service connected to the successor will be executed only after the service selected for the predecessor has completed (t_1 and t_2 in Figure 1), fork – services associated with tasks following the forked task can potentially be executed in parallel (if run on separate processors – e.g. t_1, t_4, ..., t_{16} in Figure 1), join – the service selected for the task to which other tasks are connected will be executed only after each of the predecessors has finished (in Figure 1 t_{19} will execute only after t_3, t_6, ..., t_{18} have finished).

The model distinguishes the following: a set of services $S_i = \{s_{i0}, s_{i1}, ..., s_{i(|S_i|-1)}\}$ out of which only one must be selected to execute task t_i, c_{ij} – cost of processing a unit of data by service s_{ij}, P_{ij} – the provider of service s_{ij}, N_{ij} – the node service s_{ij} runs on while sp_n the speed of node n, d_{ij}^{in} and d_{ij}^{out} are the size of the input data and the size of the data produced by service s_{ij} bound with $d_{ij}^{out} = f_{t_i}(d_{ij}^{in})$. d_i denotes the size of data processed by task t_i. d_{ijkl} denotes the size of data to be sent from service s_{ij} to service s_{kl}. f_{t_i} denotes how the size of output data for task t_i depends on the size of input data. Then the required

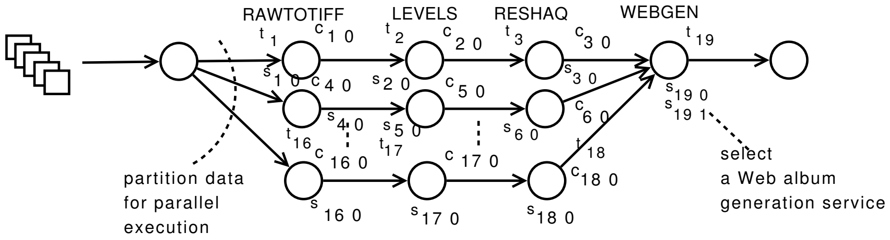

Figure 1: A Parallel Digital Photo Workflow with Budget Constraints

constraints on these variables would include: $d_i = \sum_j d_{ij}^{in}$, $d_{kl}^{in} = \sum_{i,j:(v_i,v_k)\in E} d_{ijkl}$, $d_{ij}^{out} = f_{t_i}(d_{ij}^{in})$. $d_{ij}^{in} > 0$ for only one selected service s_{ij} for task t_i. Output data from a task can be sent and/or partitioned into input files of successors. In particular, the following alternatives are possible: All Fork (AF) task i.e. t_{ij}: $\forall_{k:t_k\in Succ(t_i)} d_{ij}^{out} = \sum_l d_{ijkl}$ or Distribute Fork (DF) task i.e. t_{ij}: $d_{ij}^{out} = \sum_{l,k:(v_i,v_k)\in E} d_{ijkl}$. Then assuming $t_{ijkl}^{comm}(d_{ijkl}) = t_{N_{ij}N_{kl}}^{startup} + \frac{d_{ijkl}}{bandwidth_{N_{ij}N_{kl}}}$ – communication time of data of size d_{ijkl} sent from service s_{ij} and s_{kl}, $t_{ij}^{exec}(d_{ij}^{in})$ – the execution time of service s_{ij}, t_{ijkl}^{tr} – additional time for data conversion between output/input formats if connected services are offered by various providers, $t_i^{st} : i \in |V|$ – the time at which service s_{ij} chosen to execute t_i starts processing it, we have $\forall_{i,k:(v_i,v_k)\in E}\ t_k^{st} \geq t_i^{st} + \sum_j t_{ij}^{exec} + \sum_{j,l} t_{ijkl}^{comm} + \sum_{j,l} t_{ijkl}^{tr}$. t_{ij}^{exec} will be larger than 0 only for one j. Similarly, for the given i and k t_{ijkl}^{comm} and t_{ijkl}^{tr} will be larger than 0 only for one pair of l and k since only one service per node i and one per node k will be selected. Additionally, $t^{workflow} = t_{termination}\ \ not\exists_q(v_{termination}, v_q) \in E$

We consider two alternative minimization goals where $t^{workflow}$ is the time when the last service finishes:

1) min $v_{MIN\_T\_C\_BOUND} = t^{workflow}$ while adding a constraint on the total cost i.e. $\sum d_{ij}^{in} c_{ij} < B$ where B is the budget (problem MIN_T_C_BOUND).
2) min $v_{MIN\_TC} = \alpha t^{workflow} + \sum d_{ij}^{in} c_{ij}$ (problem MIN_TC), $\alpha > 0$.

A. Data Processing

For data processing and communication between tasks, three possibilities are considered:

1) synchronized: as assumed above, before execution of the given task starts, all data processed by previous tasks must be sent and ready,
2) overlapping: instead of $t_i \rightarrow t_j$ we can introduce parallel paths $t_i \rightarrow t_{j'}$, $t_i \rightarrow t_{j''}$, ..., $t_i \rightarrow t_{j'^n}$ such that every $t_{j'^l}$ is in fact the same task as t_j and has the same services assigned to it as t_j and a constraint that the same service is chosen for every one of them. Instead of passing whole data d_i to t_j, $\frac{d_i}{n}$ can be passed to every following task independently. This means that services for $t_{j'^l}$ will be executed faster. Secondly, if copying to every $t_{j'^l}$ is delayed compared to $t_{j'^{l-1}}$ this results in overlapping communication and computations.
3) streaming: after receiving a unit of data, each task processes it and passes to a following task(s) and does so for every unit.

IV. Algorithms

The author has proposed and implemented three different algorithms to solve the problem:

1) genetic algorithm (GA) – a chromosome encodes both the assignment of services to tasks and data distribution among tasks. The algorithm does not impose linearity on the constraints but it comes at the cost of slower convergence compared to MGALP described next.
2) mixed genetic algorithm and linear programming (MGALP) – where the genetic algorithm is used to determine the assignment of services to tasks and fast linear programming [25] is used to determine optimal data distribution for the given schedule; a chromosome encodes just the assignment of services to tasks,
3) mixed integer linear programming (MILP) – the author adopts MILP traditionally used for solving the service selection problem and extends it for scheduling and solving data flows. The algorithm solves the problem optimally but at a high computational cost for large problem sizes. Similarly to [9], [18], [26], integer variables denote which service is selected for the particular task while real or integer variables sizes of data sent between tasks.

GA and MGALP are much faster for larger graphs at the cost of lower quality results. Due to space limitations, only GA is presented in more detail. For large workflows, the algorithm may take more steps to arrive at an acceptable data distribution or even such that make constraint $\sum d_{ij}^{inp} c_{ij} < B$ satisfied for goal MIN_T_C_BOUND. To make the starting solution better, for each of the initial chromosomes, linear programming was used to help find better data flows and following iterations used only crossover and mutation operators.

Each chromosome consists of the representation for the schedule shown in Figure 2.

1) the first $|V|$ numbers contain indexes of selected services for each task i.e. $0 \leq e_i < |S_i|$ $0 \leq i < |V|$. Initial values are chosen by a random selection of services for each task i.e.: $e_i = random()\ mod\ S_i$;
2) the last $|V|$ numbers contain ordering of the $|V|$ tasks. Namely, assuming tasks t_k, t_l are executed on one processor (i.e. services on one processor are chosen to

$$\underbrace{e_0 \cdots e_{|V|-1}}_{e_i \text{ – service for } t_i} \quad \underbrace{e_{|V|} \quad \cdots \quad e_{|2V|-1}}_{e_i \text{ – task id}}$$

Figure 2: GA's Representation

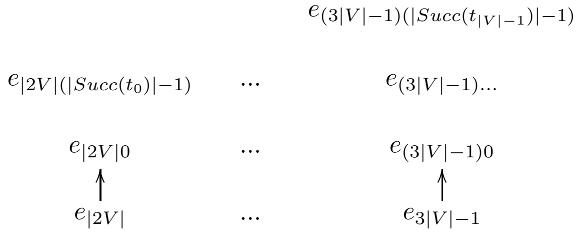

Figure 3: GA's Representation for Flow Distribution

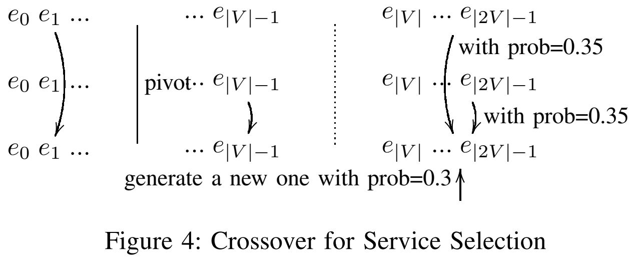
execute them), t_l is executed after t_k iff $e_i = k$ $e_j = l$: $i < j$ $i \geq |V|$. Initial values are chosen randomly out of following tasks starting from the initial task. In the next step its successors are added to the pool of the tasks from which in the next step one will be chosen randomly and the procedure is repeated.

Additionally each chromosome contains a distribution of d_{ij}^{out} into data of the following tasks. For DF tasks data from t_i is simply copied to each task in $Succ(t_i)$. For AF tasks the structure shown in Figure 3 is used. For task t_i, since data is divided into all following tasks, there is an array of $|Succ(t_i)|$ $e_{(2|V|+i)j}$ elements for this task such that $\sum_{j=0}^{|Succ(t_i)|-1} e_{(2|V|+i)j} = 1$ and d_{ij}^{out} $e_{(2|V|+i)y} = \sum_{t_k : t_k \text{ is } y\text{-th successor of } t_i \text{ out of tasks in } Succ(t_i)} d_{ijkl}$ which denotes how output data for task t_i is split into input data of following tasks.

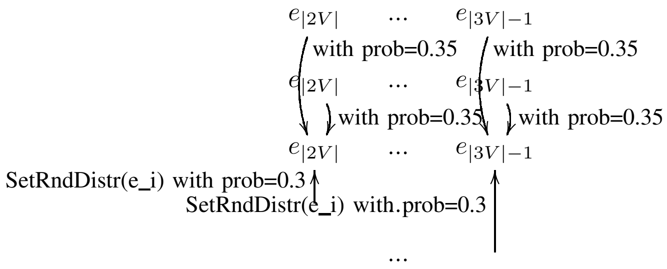
Crossover for service selection works as follows – a pivot (task) is selected randomly and services for tasks smaller than the pivot are taken from the first chromosome and for larger from the second chromosome. The order is taken from one of the two chromosomes with probabilities 0.35 and a new one is generated randomly with probability 0.3 (Figure 4). The algorithm for data distribution is shown in Figure 5. Function `SetRndDistr` assigns the flow to only one successor with probability 0.5 or divides it into more following tasks with smaller probabilities. This ensures that the algorithm can both direct the flow to a small and a large number of following tasks.



$e_0\ e_1 \cdots$
$\cdots e_{|V|-1}$
$e_{|V|} \cdots e_{|2V|-1}$
with prob=0.35
$e_0\ e_1 \cdots$
pivot$\cdots$ $e_{|V|-1}$
$e_{|V|} \cdots e_{|2V|-1}$
with prob=0.35
$e_0\ e_1 \cdots$
$\cdots e_{|V|-1}$
$e_{|V|} \cdots e_{|2V|-1}$
generate a new one with prob=0.3

Figure 4: Crossover for Service Selection

Mutation for service selection is applied as follows – a new service is selected for a task with the probability of 0.1 and a new order is generated with the probability of 0.02. Function `SetRndDistr` is invoked for a new distribution with probability 0.05.



$e_{|2V|}$ $\cdots$ $e_{|3V|-1}$
with prob=0.35
with prob=0.35
$e_{|2V|}$ $\cdots$ $e_{|3V|-1}$
with prob=0.35
with prob=0.35
$e_{|2V|}$ $\cdots$ $e_{|3V|-1}$
SetRndDistr(e_i) with prob=0.3
SetRndDistr(e_i) with.prob=0.3
$\cdots$

Figure 5: Crossover for Data Distribution

This version can be adjusted to use only integer data sizes by rounding d_{ijkl} values which result from $e_{|2V|}$ to $e_{3|V|-1}$ distributions to integer numbers such that constraints III are satisfied and successive evaluation of the chromosome using integers.

V. Optimal vs Heuristic Algorithms

The author has run the three implemented algorithms for workflow graphs with varying numbers of nodes (tasks) and services assigned to each task. The main goal is to assess workflow sizes for which the MILP algorithm is able to return an optimal solution within a reasonable time limit of 20 seconds. For the given number of nodes, out of all possible edges between the nodes, 10% are chosen randomly. Then all nodes without predecessors are connected to the initial node and all without successors connected to the terminating node. For this particular test service costs are random from the $[0, 40]$ range, service execution coefficients $e_{ij} : f_{eij}(d) = e_{ij}d$ are random from the $[0, 4]$ range, the time coefficient $\alpha = 100$.

MILP is able to solve only small problems with a small number of tasks and services optimally. Since e.g. solving for MIN_T_C_BOUND is NP-hard, heuristic algorithms need to be used for large workflows. Since it is not possible to compare to an optimal algorithm, for MGALP and GA, we measure the improvement the algorithm is able to make over an initial value (for goal MIN_T_C_BOUND or MIN_TC) for the first chromosome of the population $v_{initial\ i}$. The improvement is computed as follows:

$$impr[\%] = \frac{100}{sc} \sum_{i=1}^{sc} \frac{v_{initial\ i} - v_{final\ i}}{v_{initial\ i}} \qquad (1)$$

where sc denotes the number of simulations. It must be noted that both for GA and MGALP the initial chromosomes are set using random schedules and data distribution computed using linear programming. This allows GA to have a reasonable start for tuning using only crossover and mutation. $v_{initial\ i}$ is always obtained by taking the value from the initial chromosome of the population. For MIN_T_C_BOUND it may not meet the cost bound though. If this is the case, $v_{initial\ i}$ is obtained using linear programming minimizing the cost and taking the workflow time obtained for the minimum cost (if the minimum cost is lower than the bound set). In the experiments B is set to $bestcost + \frac{worstcost - bestcost}{4}$ where $bestcost$ is the minimum possible workflow cost without considering the workflow time and $worstcost$ is the cost corresponding to minimization of only workflow execution time.

Figures 6 and 7 present which algorithm is best for a workflow with a particular number of tasks and services marked on the two axes respectively. Each algorithm is given 20 seconds and results are compared. Each measured number is an average from 50 runs for a particular input data set. MILP is best for small graphs as it generates optimal results. For larger graphs, either MGALP or GA are preferred. Colors denote the ratio of improvement over the initial solution of GA divided by the improvement for MGALP. The range of input data for which MILP completes in 20 seconds (marked as OPT) and thus is best is limited (white color). Light areas correspond to workflow sizes for which GA gives better results than MGALP.

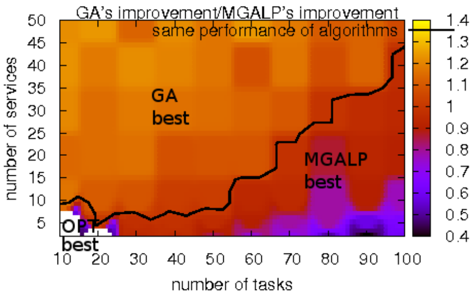


Figure 6: Comparison of OPT, MGALP, GA within 20 seconds vs Task Count and Average Service Count MIN_TC

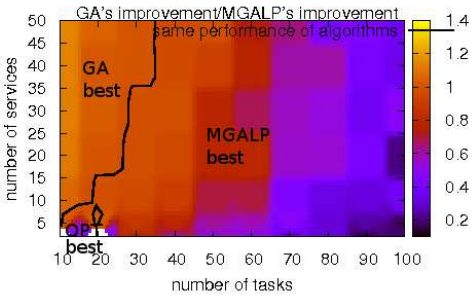

Figure 7: Comparison of OPT, MGALP, GA within 20 seconds vs Task Count and Average Service Count MIN_T_C_BOUND

VI. Modelling, Scheduling and Execution of Workflow Applications in BeesyCluster

The author has created an environment for modelling, scheduling and execution of workflow applications implementing the proposed model and algorithm. It is embedded in BeesyCluster. The latter is a JEE-based front-end and middleware which allows publishing and consuming services offered by various providers and consumers from locations managed by them. BeesyCluster, designed and co-developed by the author, was deployed at Faculty of Electronics, Telecommunications and Informatics, Gdansk University of Technology for integration of clusters and laboratories. It is used for research and teaching high performance computing.

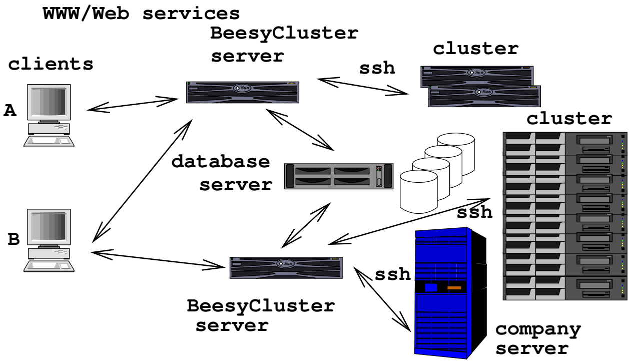

Figure 8: BeesyCluster Architecture

BeesyCluster allows the registered user to access accounts on various clusters or servers via WWW/Web Services (Figure 8). [27] presents details and performance of the Web Service interface. The system accesses these accounts via SSH. It allows to manage resources on these accounts allowing copying, editing files, management of directories and archives in a versioning system, compilation, queueing and even running applications interactively in a graphical mode via the browser.

Advantages of this complete environment with workflow support are as follows:

- the user can publish a sequential or a parallel (e.g. MPI) application from his/her user account as a service This brings business features to the scientific environment,
- companies can publish commercial applications as services from their servers,
- such services can be incorporated into workflows as described by the model,
- if the service is deployed on a cluster with a queueing system (e.g. PBS, LSF), the latter will be used transparently to the user,
- support for a complete workflow creation and execution cycle i.e.: workflow editing using a GUI, workflow optimization (service selection and data distribution), workflow execution in the real distributed environment.

The author has implemented a workflow editor in BeesyCluster shown in Figure 9 implementing the model proposed in Section III. It allows to define a workflow graph including tasks and dependencies, assign services to tasks, define input data which will be partitioned for parallel execution as well as one of the optimization goals. Workflow description

Figure 9: Workflow Editor in BeesyCluster

of input data and data flowing between services correspond to the numbers of files flowing between the services. Data distribution policies mentioned in Section III-A are possible. To run a workflow, BeesyCluster launches one of the algorithms implemented by the author to determine services for tasks and data distribution and executes the selected services handling data transfers between clusters and servers on which the services are installed. [24] and [28] present implementation details of the workflow execution engine which is also used in this work. However, [24] focuses on just-in-time service selection while [28] on incorporation of a checkpoint/restart mechanism for execution of scientific workflows.

VII. Compute and Data Intensive Digital Photography Workflow

The workflow shown in Figure 1 was modelled and tested in BeesyCluster. It shows a scenario in which there are three filters applied on input RAW images to generate a final web album to be published in the photographer's portfolio. Optimization problems include: partitioning a set of input images among services installed on nodes of various speeds, a trade-off between the budget for the execution and the execution time (some services are more expensive than others).

1) Testbed Environment and Services: The environment consists of 16 nodes installed at the Faculty of Electronics, Telecommunications and Informatics, Gdansk University of Technology. The speeds of all the nodes used are identical for this application. One BeesyCluster server located at `https://lab527.eti.pg.gda.pl:10030/ek/AS_LogIn` was used.

The following services were used to execute the tasks (Figure 10): RAWTOTIFF – conversion from a RAW format to TIFF: each service is performed by script `dcraw -T $1` using the well known `dcraw` (`http://cybercom.net/~dcoffin/dcraw/`) converter, LEVELS – level adjustments so that whites, blacks and middle tones are mapped correctly: each service is performed by script `convert $1 -normalize $1` using the `ImageMagick` (`http://www.imagemagick.org/script/index.php`) tool, RESHAQ – resizing, sharpening and saving as a 97% JPEG image for further generation of a web album: each service is performed by script `convert $1 -resize 600x400 -sharpen 1x1.2 -quality 97% $1.jpg` using the `ImageMagick` tool, WEBGEN – generation of a Web album: two services are installed on only one node (are alternative) and performed by applications `album` (`http://marginalhacks.com/Hacks/album/`) and `jigl` (`http://xome.net/projects/jigl/`) respectively.

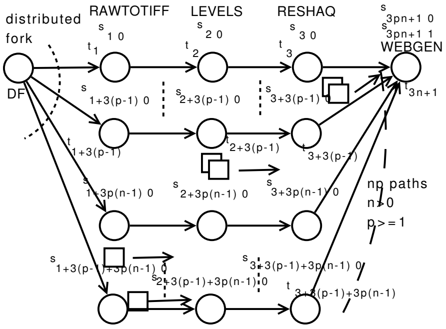

Figure 10: A Parallel Digital Photo Workflow with Several Paths per Node

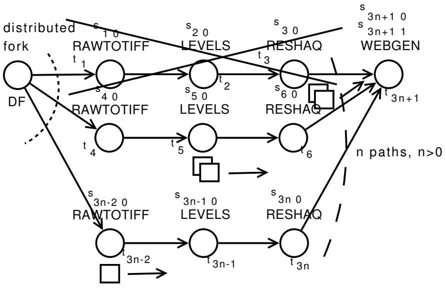

Figure 11: A Parallel Digital Photo Workflow with Budget Constraints

2) Workflow Configurations and Results: The following configurations were tested (optimization goals are noted): **MIN_TC: parallel** (Figure 10) – each filter is cloned into up up to $16p$ ($p \geq 1$) functionally equivalent t_{i+3k} $k \in \{0, 1, ..., 16p-1\}$ $i \in \{1, 2, 3\}$ tasks (Figure 10 also shows nodes the services are installed on). If $p = 1$ then each node waits for its batch of data to start processing. If $p > 1$ there are p services for each filter on a given node and it is possible to start processing faster as a smaller batch of input data can reach the service faster. Execution of services on one node is serialized. Each batch is processed independently allowing computations on the given node to start faster at the cost of running and managing more threads responsible for more paths. Since the cost of each service was set to the same value in this configuration the algorithm effectively minimizes the total execution time. Figures 12 and 13 present execution times and speed-ups obtained for 40, 160 and 560 input images

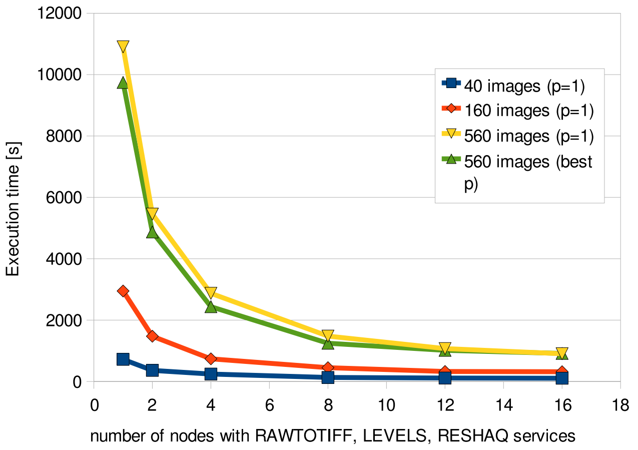

Figure 12: Digital Photography Workflow: Execution Times [s]

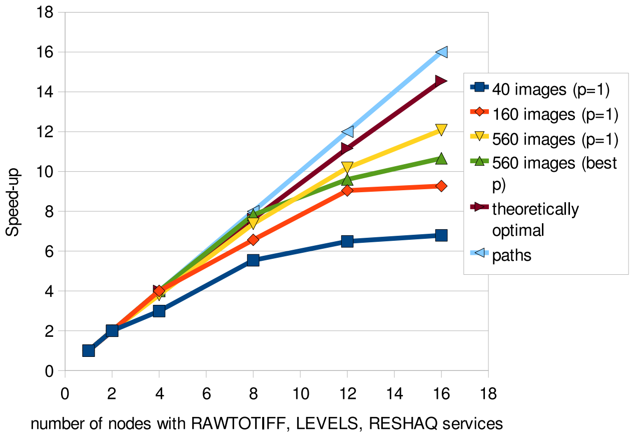

Figure 13: Digital Photography Workflow: Speed-up

Table I: Services and Cost per Processor Second for Testbed Clusters

			cost per second	
Cluster	services	node count	day	night
1	$s_{1\ 0}$ to $s_{24\ 0}$	8	20	10
2	$s_{25\ 0}$ to $s_{36\ 0}$	4	10	20
3	$s_{37\ 0}$ to $s_{48\ 0}$	4	15	15

(500MB, 2GB, 7GB of input data) respectively and from 1 to 16 nodes thus 1 to 16 paths.

As expected better speed-ups are obtained for a larger number of input images. For 560 images there is a comparison between $p = 1$ and best p for the given configuration. In the latter case, the time is lower as services can start processing earlier. BeesyCluster first sends a smaller batch to each service on a different node, then proceeds with following batches effectively overlapping communication and computations. It can be noted that the gain is much smaller for a larger number of nodes because the communication/transfer times between the tasks are much smaller for these configurations. Secondly, the node with the initial data may be a bottleneck for a large number of following tasks.

MIN_T_C_BOUND: parallel with budget constraints on the selection of services (Figure 11) – in this example the goal is to obtain the shortest possible execution time assuming the total cost of selected services does not exceed the given threshold. The literature proposes [29], [30] several pricing methods for services. Following the simplest strategy of charging per processor second and assuming the computational time can be divided between clusters we obtain the same cost irrespective on the number of processors used [31]. However, if costs per processor can vary, we are faced with a non-trivial cost-performance trade-off. Similarly to [30] the author has distinguished services installed on three logical clusters with 8, 4 and 4 nodes with prices for a processor second as shown in Table I. The prices vary depending on the time of day. Two configurations were tested: clusters 1 and 2 (total of 12 nodes), clusters 1, 2 and 3 (total of 16 nodes) both during the day and the night. For each configuration the total allowed budget (for the parallel paths) is varied from the minimum cost allowing full parallelization to through 0.9 to 0.8 of this cost. Figures 14 and 15 show that if the budget is limited then the more expensive paths are not used which results in higher execution times. For day simulations, services from cluster 1 will be ommitted first, for night simulations services from cluster 2.

VIII. Summary and Future Work

The paper formulated a problem on how input data should be distributed among parallel tasks and how services should be selected for other workflow tasks so that a QoS goal is optimized while possibly other QoS constraints are met. Both the model, algorithms and an execution engine were implemented in BeesyCluster allowing to consume distributed services from various providers. As an example, a data and compute intensive digital photo workflow was executed in this environment. It has been demonstrated that the solution achieves good speed-ups and is able to select services in such a way that the execution time is minimized and the total cost of selected services does not exceed the budget. Clearly, the environment can be used for other workflow applications which can be easily constructed from distributed services deployed in BeesyCluster.

Further work will include testing more complex workflows in more distributed environments with services installed on distant clusters.

***Abstract*—The paper presents a concept, implementation and real examples of dynamic parallelization of computations using services derived from MPI applications deployed in the BeesyCluster environment. The load balancing algorithm invokes distributed services to solve subproblems of the original problem. Services may be installed on various clusters or servers by their providers and made available through the BeesyCluster middleware. It is possible to search for services and select them dynamically during parallelization to match the desired function the service should perform with descriptions of services. Dynamic discovery of services is useful when providers publish new services. Costs of services may be incorporated into the selection decision. A real example of integration of a given function using distributed services has been implemented, run on several different clusters without or with external load and optimized to hide communication latency.**

I. Introduction

PARALLEL computing has come a long way from dedicated parallel applications to grid computing allowing to couple clusters to perform distributed computations. Traditionally, parallel computing has been performed either on shared memory machines or within dedicated multi-node clusters. For the former, threads or processes may be spawned and communicate using shared memory which is supported using e.g. Pthreads [1], Java threads [2], OpenMP [3]. For clusters, MPI [4] and PVM [5] allow development and running parallel programs using the message passing paradigm for communication. For fast communication between processes on one node MPI can use shared memory. MPI implementations may offer various support for threads. Furthermore, computational codes may be wrapped into services, discovered and integrated for distributed computations at a higher level.

Section II investigates existing approaches for parallelization among clusters and proposes a framework for multi-level parallelization through dynamic discovery of services in BeesyCluster that can make use of specific features of the latter. Section III presents a concept and an algorithm for parallelization of computations using BeesyCluster services while Section IV presents experimental results including the ability of the solution to hide latency of Web Service calls. Finally, Section V presents a summary and future work.

II. Related Work and Motivations

Grid systems like CrossGrid [6] or Clusterix [7] use grid middleware such as Globus Toolkit [8] to allow the user to manage, access and share various resources. Grid middlewares allow controlled resource sharing and offer uniform interfaces to access various resources in various administrative domains. In turn, parallelization among clusters has become easier especially for the master-slave or divide-and-conquer paradigms as previously used within clusters [9], [10]. Such parallelization is possible either by running grid-enabled MPI applications or composing distributed services.

Grid-enabled versions of MPI such as MPICH-G2 [11], PACX-MPI [12], BC-MPI [13] allow one application to run on more than one cluster using TCP for inter-cluster and usually faster Infiniband or Myrinet within each cluster. MPICH-G2 uses Globus for job control as can PACX-MPI and LAM/MPI [14] to couple remote clusters. BC-MPI can use BeesyCluster [15] for this purpose [13].

There exist several frameworks that allow management of distributed processing and computations. The MW toolkit [16] allows development of a master-worker style application that works in the distributed environment of Condor. [17] studies load distribution methods for a master-slave scheme on a multi-cluster architecture. Tuning of master-slave applications on grids is analyzed in [18]. Nimrod/G [19] allows resource management and scheduling in a global computational grid. It introduces a concept of computational economy that allows the user to specify the cost and the deadline for the work or negotiate for resources to do the job.

Grid or Web Services can be used as a front-end to HPC resources [20]. This allows parallelization using services. [21] and [22] contain an interesting comparison of performance of a computationally intensive application run on MPI and using Web Services as workers rather than front-ends to HPC resources. The latter showed higher execution times but has advantages in case of firewalls and better interoperability in heterogeneous environments. A methodology to migrate from MPI to Web Service base applications is shown in [22]. [23] implements an Application Management System into an MPI application and its ability to balance load in a computational grid is demonstrated for an application which partitions initial data for parallel execution on a three site grid. [24] demonstrates an approach to find and use grid services for parallel solving of matrix multiplication – although sequential in the workers. The framework allows to specify priority QoS parameters like accuracy, speed, bandwidth.

In this paper, using BeesyCluster and combining features of the previous works, the author proposes a dynamic master-slave parallelization approach able to discover and invoke computational services spawning MPI applications on HPC resources. The algorithm finds and invokes ready-to-use possibly geographically distributed computational services derived from MPI applications published by possibly independent providers from various clusters/servers incorporating possibly changing costs of such services. The solution focuses on efficient parallelization of computations among the services with hiding communication latency and parallelization on clusters using MPI. Although the master-slave paradigm has been widely used in parallel programming and distributed processing on grids as discussed above, the contribution of this work is that the proposed scheme benefits from particular features offered by the BeesyCluster middleware:

- parallel and sequential applications created by users can be published instantly as services within BeesyCluster and made available as Web Services accessible from outside BeesyCluster. The publisher can grant rights to other BeesyCluster users to run the service and defines QoS parameters such as cost the client needs to pay to invoke the service. When a BeesyCluster client invokes the service, the cost is subtracted from their account. Our latest work [25] shows how thousands of existing Linux applications distributed in packages such as deb or rpm can be published in BeesyCluster and thus be available to be used in the proposed load balancing scheme.
- searching for services that might then be used in the load balancing scheme. Currently, each service deployed in BeesyCluster is described in the database as well as in a UDDI registry based on JUDDI and used by BeesyCluster. The latter may be queried using the UDDI API. We have also implemented [25] an intelligent search mechanism based on the similarity of the service description and user query that uses Apache Lucene. For instance, a user might request services for numerical integration and those with best matching descriptions are returned.
- incorporation of possibly changing costs when discovering and selecting services.
- access to the services is restricted only to BeesyCluster users to whom it has been granted. Also, services offered by *various* providers can be integrated in one load balancing scheme.
- in case of parallel applications run on clusters with queuing systems such as PBS, LSF, LoadLeveler etc., BeesyCluster can handle queuing transparently to the client.

BeesyCluster (Figure 1) is a middleware and front-end to several clusters and allows users to access their system accounts on clusters or servers using a web browser or web services [26]. BeesyCluster features an easy-to-use WWW interface with a file manager with drag and drop in the browser, ability to launch graphical or text sessions with remote clusters through a browser. Among others, users can publish own MPI applications from their system accounts as services (Figure 2) and assign a price for invoking the service and access rights to particular users or groups. The service can then be invoked on the cluster the provider has installed it through BeesyCluster via a web browser (Figure 3) or Web Services [26]. BeesyCluster uses SSH to access clusters (Figure 1). Moreover, such services can be combined into workflows [15]. Since the standard MPI and PVM allow parallelization within a cluster, an MPI or PVM application may be published as a service (also studied in [27] instantly with a few clicks (Figure 2, [26]) and used as a part of a framework for balancing work between clusters by passing distinct data sets to particular services. BeesyCluster co-developed by the author hides the underlying queuing (PBS, LSF etc.) system on the cluster the application was installed on.

III. Concept and Algorithm for Parallelization of Computations using BeesyCluster Services

For composing services, usually a workflow graph $G(V,E)$ is defined [28] where V is a set of vertexes denoting tasks while E is a set of edges denoting dependencies between the tasks. Out of a set of services for each task one is to be chosen so that certain QoS goals are optimized. As an example, this could be minimization of the workflow execution time with an upper bound on the total cost of selected services.

In this paper, we focus on multi-level parallelization of computations in a dynamic master-slave fashion using services published by independent providers from potentially geographically distributed clusters. Each service is a parallel MPI application.

The parallelization framework is implemented on the client side and thus does not depend on grid middleware and allows access to several BeesyCluster servers handling local computer centers in different administrative domains. The main steps of the strategy are shown in Figure 4:

1) Providers publish parallel MPI applications as BeesyCluster services (Figure 2). In case the cluster on which the application runs uses a queuing system, its usage is handled by BeesyCluster and hidden to the user. Providers specify costs which will need to be paid by the client when invoking particular services. Each BeesyCluster user has a virtual purse, can earn on own services used by others. A description of each BeesyCluster service is stored in BeesyCluster's own UDDI registry based on JUDDI. Thus the balancing thread can query for services using SOAP.
2) The client queries BeesyCluster for services capable of performing the given function [25] also taking into account the costs of available services. The client receives a list of capable services. The recently developed

Figure 3: Running a Service Published by Another User and Derived from an MPI Application (WWW)

module in BeesyCluster allows for advanced search and matching of service descriptions to the user textual query [25] using the Apache Lucene engine. For the desired function expressed in the natural language (e.g. numerical integration etc.), BeesyCluster returns a list of services with numerical matching scores. Furthermore, the aforementioned balancing algorithm can choose services with greatest $clusterspeed/(1+cost)$ ratios.

3) The balancing thread (Listing 1) divides the initial data into a predefined number of parts set by the programmer.

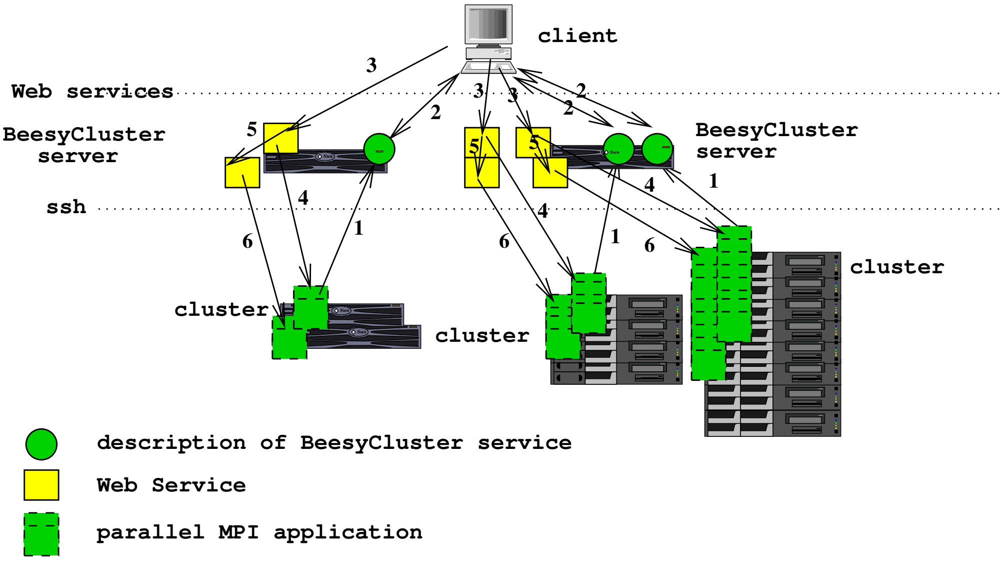

Figure 4: Interactions in the Solution

The thread also checks the speed of each cluster or server on which the services are installed. The balancing thread launches a new thread (Listing 2) for each part which then calls a Web Service in BeesyCluster.

4) The Web Service implementation within BeesyCluster starts an MPI application on a cluster remotely using ssh.
5) The framework launches a second instance of the Web Service for each service which is delayed compared to the first one to hide the communication latency upon termination of the first one.
6) As for the first one, the Web Service in BeesyCluster invokes the MPI application.
7) Then after the first application has terminated, another one is launched (Listing 1) while the one launched as second is still running. This way the cluster is kept busy. The framework proceeds until all data has been processed.

In the integration example considered in this paper the data part corresponds to a range to be integrated.

The algorithm can handle irregular problems taking different amounts of time on data sets of the same size. Examples of such applications include adaptive quadrature integration or $\alpha\beta$ searches [9].

IV. Experimental Results

A. Testbed Application and Environment

As an example, a parallel program for integration of a given function on the given range was used. Initially, the balancing thread divides the range into a predefined number of subranges. Then it launches services on clusters each of which represents a parallel MPI application and passes a single range $[a, b]$ and $accuracy$ which denotes width of polygons used to compute the integral.

The testbed environment used one BeesyCluster server installed at Faculty of Electronics, Telecommunications and Informatics which accesses in particular two clusters:

1) `holk` – a cluster with 288 dual core Itanium 2 processors connected with Infiniband, 2304 GB of RAM, 5.8 TB of disk space,
2) `KASK's cluster n01.eti.pg.gda.pl` – a cluster with 10 Dell PowerEdge 1850 nodes each with 2 dual core Intel Xeon processors, Infiniband interconnect, 40 GB of RAM.

For the tests, the client-BeesyCluster connection was at 2Mb/s while the BeesyCluster-cluster(s) connections were internal university links at 10Mb/s. Two nodes of `holk` and 9 nodes of `KASK`'s cluster were used as 11 virtual clusters on which the client called MPI integration applications as Web Services in BeesyCluster.

B. Hiding latency of the Web Service Calls

The goal of this test was to assess how running two parallel MPI simulations concurrently on one cluster, spawning one with a slight delay can mitigate communication latency. If only one application is run on a cluster (MPI-SA case), after it has terminated, the cluster is idle until a new one is started. If two are run, the second started slightly after the first one (MPI-2A case) the former can keep processors busy after the latter has terminated and a new application is being launched on this cluster. It happens at the cost of context switching between processes. Two nodes (`h001` and `h002`, each node with 2 dual core Itanium2 processors) of cluster `holk` were used. Both MPI-SA and MPI-2A ran with 4 processes per node. The range [1,1000000] with $accuracy$=3e-5 was used. Table I presents execution times for the aforementioned configurations. The variable is the number of ranges to integrate.

```
Vector pending; // with pending WorkRequestResult (cluster + data)
Vector finished; // with finished WorkRequestResult (cluster + data + result)

public void BalancingLoop() {
   // find/discover a certain number of capable services in BeesyCluster based on the
   // required functionality, costs and available budget

   // generate data
   int data_count=COUNT;
   type[] data;
   generate_data_and_store_in_data();

   // prepare data and start processing
   // there are two threads launching each service twice
   for(k=0;k<2;k++)
     for(i=0,j=0;j<services.length;j++) {
       WorkRequestResult wrr=new WorkRequestResult(j,data);
       synchronized(pending) { pending.add(wrr); } // add a request to a queue
       new Thread(this).start(); i++; // spawn a thread to get this data to process
     }
   WorkRequestResult wrr; int finishedcount=0; result=0;

   for(;(i<data_count) || (finishedcount<data_count);i++) { // main loop
     try {
         synchronized(finished) {
           if (finished.size()==0) finished.wait(); // notified by
         } // a notify() from method run()
     } catch (Exception e) { ... }

     // read data from the finished queue and then spawn another thread
     synchronized(finished) {
         wrr=(WorkRequestResult)finished.elementAt(0);
         finished.removeElementAt(0); }
     result=result.add(wrr.result); finishedcount++; // 'add' the result depending on
     // the problem
     if (i<data_count) {
         // now launch another thread for running the same service unless conditions have changed
         // - in the latter case discover next best service
         wrr.data=new data;
         synchronized(pending) { pending.add(wrr); } // add to the pending tasks
         new Thread(this).start(); } // spawn a thread to get this data to process
   } System.out.println("Result="+result);
}
```

Listing 1: Main Load Balancing Loop

```
public void run() {
  WorkRequestResult wrr;
  synchronized(pending) {     // first get a pending request
    wrr=(WorkRequestResult)pending.elementAt(0);
    pending.removeElementAt(0); }
  // process it on the cluster and update the result
  wrr.result=CallService(wrr.service,wrr.data);
  synchronized(finished) { // insert the result
    finished.add(wrr); } //  into the finished queue
  // now wake up the main thread
  synchronized(finished) { finished.notify(); }
}
```

Listing 2: Thread Calling Services

Table I: Hiding Latency of Web Service Calls: Execution Time [s]

ranges	2	4	8	20	30	50
MPI-SA	64	68	76	86	117	156
MPI-2A		64	70	82	85	111

It is clear that launching two MPI applications (with 4 processes) each on a half of the initial range gives best possible results as there are just two calls (one to each cluster) and returning results. However, we obtain the same results for 4 ranges (2 calls to each cluster) run with concurrent applications on each node (MPI-2A). Here, the communication latency is practically hidden by the other applications running on the clusters. Moreover, increasing the number of ranges gives MPI-2A an edge over MPI-SA.

The larger the number of ranges the more perfect balance can be achieved especially if we consider potentially various speeds of clusters or additional load which may appear on some clusters.

For the following tests, the best execution times including hiding communication latency using this technique are considered.

C. Execution Time under External Load

Table II: Execution Time under External Load [s], 11 clusters

ranges	18	36	72	144	288
execution time [s]	174	150	147	167	218

In this case, all 11 clusters were used while node compute-0-0 of KASK's cluster was loaded with computationally intensive processes launched by another user. Table II shows how the execution time of the integration application changes with the number of ranges. A small number of ranges means that the integration processes (on reasonably large subranges) on compute-0-0 were considerably prolonged. On the other hand, a very large number of ranges resulted in a large overhead. 72 ranges turned out to be the best trade-off between the range counts tested. The range [1,1000000] with *accuracy*=3e-5 was used.

D. Scalability Results

For the first test, a single homogeneous cluster (KASK's cluster was partitioned into up to 9 virtual clusters each composed of 4 processing cores. Execution times and speed-ups of the load balancing solution were measured and shown in Figures 5 and 6 given various numbers of ranges from the number of nodes up to 16 times the number of nodes used for the run. The range [1,1000000] with *accuracy*=3e-5 was used.

Similarly, the second test involved a heterogeneous environment with two nodes of cluster holk as 2 virtual clusters and up to 9 virtual clusters defined on the KASK cluster as in the previous experiment. Each processor of the first cluster is approximately 7 times faster than of the KASK cluster for the integration example. The balancing algorithm merges ranges for the faster cluster trying to obtain similar execution times for each requested range for each cluster. Figures 7 and 8 present the execution time and speed-up for integration of ranges [0,2e6], [0,5e6], [0,1e7] with *accuracy*=3e-5. All presented examples confirm good speed-ups (compared to a single fastest processor in the configuration) given the overhead of the client-BeesyCluster Web Service calls, BeesyCluster-cluster SSH communication and management of ranges.

V. Summary and Future Work

The paper presented an idea and an implementation of a framework for parallelization of computations in a dynamic master-slave fashion using distributed services installed in BeesyCluster and derived from MPI applications. The framework can use services published by various users and discover services at runtime for a desired application using service parameters such as cost. The algorithm is able to use the services to solve the problem on subsets of the initial data set and then merge into final results. An example of integration of a given function was presented and run on several modern clusters using services installed on them. Tests with and without external load for up to 11 clusters with varying speeds confirmed good scalability of the approach.

Future work includes testing more applications in the proposed scheme as well as tests of searching of services using ontologies.

Managing Large Datasets with iRODS—a Performance Analysis

Denis Hünich, Ralph Müller-Pfefferkorn
Center for Information Services and High Performance Computing (ZIH)
Technische Universität, Dresden

***Abstract*—The integrated Rule Orientated Data System (iRODS)[3] is a Grid data management system that organizes distributed data and their metadata. A Rule Engine allows a flexible definition of data storage, data access and data processing. This paper presents scenarios implemented in a benchmark tool to measure the performance of an iRODS environment as well as results of measurements with large datasets. The scenarios concentrate on data transfers, metadata transfers and stress tests. The user has the possibility to influence the scenarios to adapt them to his own use case. The results show the possibility to find bottlenecks and potential to optimize the settings of an iRODS environment.**

I. Introduction

TODAY and even more in future scientific research generates and will generate enormous amounts of data. To handle these data they are often stored in distributed locations within a Grid data management systems like the integrated Rule Orientated Data System (iRODS)[3]. iRODS allows a fast and easy access on files and their provenance. As it is used more and more in production environments and with rapidly increasing data sets it is of importance to be able to analyze and optimize the performance of an iRODS installation.

This paper describes a tool and scenarios which enable the measurement of the performance of data and metadata transfers as well as internal parameters of an iRODS system. First measurement with millions of files stored in iRODS show already the potential to optimize the performance. It is based on the benchmark tool BenchIT[1]. The aim of the development was to allow the users to easily optimize an iRODS environment. This paper is structured as follows: section 2 presents related work, section 3 gives an overview of iRODS and BenchIT, section 4 describes the investigated scenarios, section 5 shows the results of measurements and section 6 concludes this paper.

II. Related Work

There exist a variety of tools that define benchmarks and provide performance tests of I/O, e.g. IOZone [5] or IOR [4]. But these focus primarily on POSIX files systems. iRODS is not a POSIX accessible system but provides its own clients to access the storage.

iRODS is a relatively new product (version 1 released in 2008) and there are only a few performance evaluation results published, most of them focus on simple tests. Iida[7] measured the performance of transfers between two iRODS systems. Furthermore, he performed scaling tests for iCAT, concurrent tests for iCAT and a comparison of iRODS and SRB. Baquero[8] tested the performance of iRODS and Hadoop[9] and compared the results. On the iRODS website results of an ”Ingestion Test”[10] and a ”General Query Stress Test”[11] are shown. This are stress tests of the iCAT server. But a systematic performance analysis of iRODS was not done yet nor exist scenarios or a tool for users. Thus, the scenarios and the tool presented in this paper gives the user the possibility to test an iRODS environment and compare it with others.

III. Overview

A. iRODS

iRODS, developed by the Data Intensive Cyber Environment (DICE) group, organizes distributed data up to a range of petabytes. It is released with an Open-Source-Licence. iRODS stores data on heterogeneous storage systems (so-called ”iRODS server”) and the related metadata in a database on a special iRODS server named ”iCAT enabled server” (figure 1). Metadata are for example information on stored data, their locations or user defined information. A set of metadata is created and stored automatically by iRODS for every stored data - e.g. file, location or user. Additional information can be stored as user defined metadata.

An iRODS server has a Rule Engine which interprets rules. A Rule contains Micro-Services, arranged in a workflow, which process special tasks like replicating data or calculating check sums. Microservices can be provided by anyone. Additionally, a rule defines conditions to execute the Micro-Services and has a backup strategy if an error occurs. The definition of rules allows the users to configure the iRODS environment according to their requirements and is also one reason why performance testing is so important for iRODS. iRODS provides a number of clients - e.g. command line clients (the iCommands) or the iRODS explorer - as well as programming interfaces to transfer files to and from an iRODS server for example.

B. BenchIT

BenchIT[1] is a benchmark tool to analyze and optimize computer systems. It was developed at the Center for Information Services and High Performance Computing (ZIH) of the Technische Universität Dresden. BenchIT provides a set of small algorithms (kernels) to measure the performance of a system. The execution of a measurement or a set of

978-83-60810-27-9/09/$25.00 © 2010 IEEE

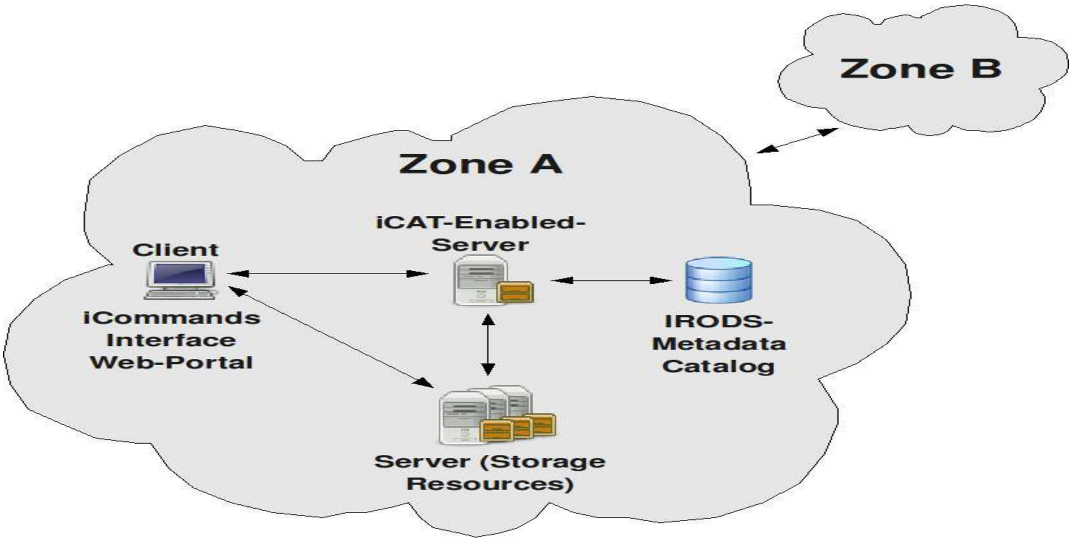

Fig. 1. Schematic representation of an iRODS environment

measurements is driven by a graphical utility providing an interface to the kernels. The interface allows the user to adjust the measurement. Relevant information on the measurement are saved together with the results in a file. The results are evaluated and diagrams of the measurement are generated. Additionally, the result file can be uploaded to a central server via a web interface [2] and can be compared with the measurements of other users.

The scenarios described in this paper were realized as kernels in BenchIT. The advantage of this approach is the use of the existing BenchIT environment with its graphical user interface and the functions to present and analyze the data.

IV. Scenarios

In the following a number of scenarios are defined that describe typical usage profiles when managing large datasets with iRODS. The scenarios are divided into four categories: data transfers with iCommands or Micro-Services, transfer of metadata, stress tests and a scenario to measure the performance of given Micro-Services. They use the client tools of iRODS such as the iCommands iput[1], iget[2], and imeta[3]. To characterize the performance the time for an event in a scenario is measured. Either the time or the derived data transfer rates are used. To avoid outliers in the results, the measurements were repeated several times and the average of the measured time were calculated.

A. Data transfer

1) Different stages of data transfer: The aim of this scenario is the measurement of different stages of a data transfer. A data transfer with iput or iget sets up the transfer environment at first. Then the connection to the iRODS server can be established. After the successful connection the client will be authenticated. If the client has the required rights the transfer starts. Usually, iRODS chooses automatically the number of parallel threads it uses for the transfer if more than one file are to be read or written. This scenario also allows a manual selection.

For the measurement a data transfer is divided in the following stages:

1) Set up of the transfer environment (Environment)
2) Establishing connection (Connection)
3) Authentication and authorization (Login)
4) Data transfer (including metadata writing) (Put File)

For these 4 stages the times are measured. Furthermore, the total time will be determined to set the single stages in relation to it. Thus, the user has the opportunity to see where the main fraction of time is used for the transfer and how it might change e.g. when increasing the number of simultaneously started data transfers. It is also possible to get an idea of how much time is used to write/read the metadata by transferring a one byte sized file because then the runtime for the last stage is mainly used for reading/writing metadata.

2) Parallel transfer of many files: This scenario transfers a defined number of files simultaneously and measures the runtime for the whole transfer process. The number of files transfered at once can be varied. In contrast to the scenario above the user gets no information about a single data transfer. The aim is to find the number of files/parallel transfers for which the iRODS environment works most efficient. The result also depends on the file size and the usable bandwidth.

3) Transfer of directories: The iCommands iput and iget provide the possibility to transfer the content of a whole directory at once. The difference between transferring a directory and transferring a number of single files is that in the first case the iRODS server only has to handle one request for the transfer and he can use all resources for this request. This

[1] iput - transfers files from the client to the iRODS server
[2] iget - transfers files from the iRODS server to the client
[3] imeta - writes metadata to the iCAT server

scenario measures the time for such a transfer with a varying number of files in the directory. The time mainly depends on the bandwidth and the time used to write metadata. The larger the files and the smaller the number of it, the more the runtime depends on the bandwidth. In the opposite case the time is mainly used to write the metadata.

4) Data transfer for varying file sizes: This scenario measures the performance of a transfer for varying file sizes. The workload for the iRODS server is small because only one file will be transfered and the iRODS server can use all resources for it. With small files the user can measure the latency and with large files the bandwidth. Furthermore the user can check the preferences set for parallel data transfers of the iRODS server for different files sizes. Therefore, it is possible to vary the number of threads for a file transfer and to compare the performance results with the results of the automatic settings.

B. Transfer of user defined metadata

To store user defined metadata on the iCAT server iRODS offers two ways. In the parallel case the metadata will be transfered with simultaneously started imeta requests each writing one element. For the performance evaluation the time to transfer all metadata is measured. In the sequential case the metadata are written in a file. The file is transfered to the iRODS server with one request, but then the metadata sets are written one by one sequentially.

The user can vary the number of metadata entries, compare the results and decide which kind of transfer is to prefer. Especially when writing large amounts of metadata these two ways can produce quite different performance results (see section V-D).

C. Stress tests

In the stress tests the iCAT server is analyzed in cases when it is flooded with requests or the number of files to store in iRODS (and thus needs to be managed by the iCAT server) increases dramatically.

1) Requests to the iCAT server: This stress test starts a defined number of parallel imeta requests to the iRODS server. The number of requests is varied to find the number of operations per second the iRODS environment can manage. Additionally, it is possible to get the number of requests the iCAT server refuse. This occurs when the maximum number of requests the database on the iCAT server can handle is exceeded.

2) Management of large metadata sets on the iCAT server: In this test the number of metadata sets the iCAT server has to manage is increased. For that, a directory with a (large) number of files is transfered successively to the iRODS environment. The time for every transfer is measured. With every file arriving in the iRODS environment the iCAT server needs to handle a larger number of metadata. This usually results in an additional time penalty when transferring the next data.

D. Time measurement of Micro-Services

Micro-Services allow the execution of small tasks directly on the iRODS server. They should not put to much workload on the server because this influences its data management capabilities. This scenario was created to measure the runtime of Micro-Services in any user defined rule. It allows developers as well as iRODS administrators to see how the performance of a Micro-Service behaves in different workflows. The scenario introduces three Micro-Services that measure the time before, between or after Micro-Services of a Rule. The results are collected at the iRODS server and moved to the BenchIT environment for analyses.

V. Results

This chapter presents measurement results of the scenarios described above. These were performed to optimize an iRODS installation to be used in production. After some generic measurements and stress tests a real use case from genetics (the future major user of the installation) was simulated.

A. The test system

The measurements were done on an iRODS installation at ZIH. The combined iRODS/iCAT server with 8 Dual Core AMD Opteron 885 (2.6 GHz) CPUs and with a memory of 32 GByte provides the storage resources and the database for the metadata over a 4 GBit/s SAN network. The client ran on a cluster with Intel Xeon Quad Core X5472 (3.00 GHz) CPUs and a 10GBits/s Ethernet network. iRODS version 2.1 was used with a PostgreSQL database for metadata storage.

B. Handling large sets of data

Figures 2 and 3 show the measurements for the single stages (see IV-A1) when 150 files are transfered simultaneously, each of them 1 Byte large. In figure 2 the iRODS environment contained no files (fresh install). Thus, the management overhead of the iCAT server is very small. Most time is used for the connection and for the file transfer including the writing of metadata. The results in figure 3 look quite different. Here, the iRODS environment already contained 13 million files and their metadata. The transfer time increased almost by a factor of 8. The reason is the increased effort to write metadata if the database is already large. This has also an effect on connection and login time. The iRODS server was not able to work off the requests as fast as before. This delay deferred the connection establishing and the login. In average the total time for the transfer increased by a factor of twenty.

C. Comparing the reading and writing of data

This test compares transfers done with iput and iget for three different states of the iRODS environment (empty, 7 million files and 13 million files stored in iRODS). A directory with a varying number of files (each with a size of 1 Byte) was written and read. Figure 4 shows the results. In the empty state reading needed 4 times longer than writing for 150 files. This means that finding the requested metadata and files needed much longer than writing both.

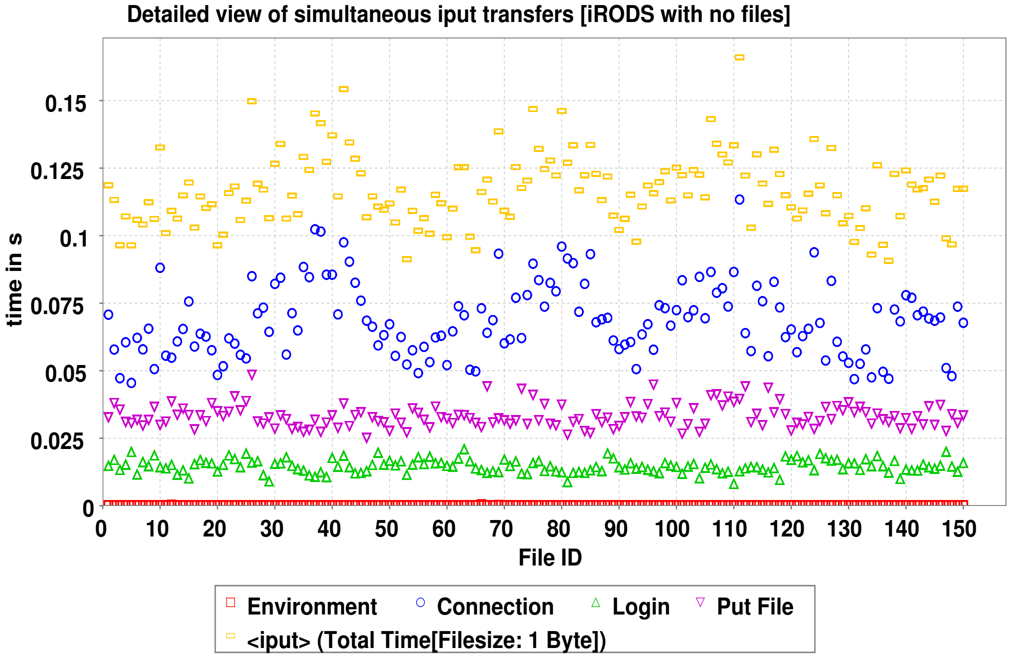

Fig. 2. Simultaneous data transfer of 1 Byte large files with iput. The iRODS environment contains no files. Shown is the time needed for every stage and the overall transfer time (stages, see IV-A1).

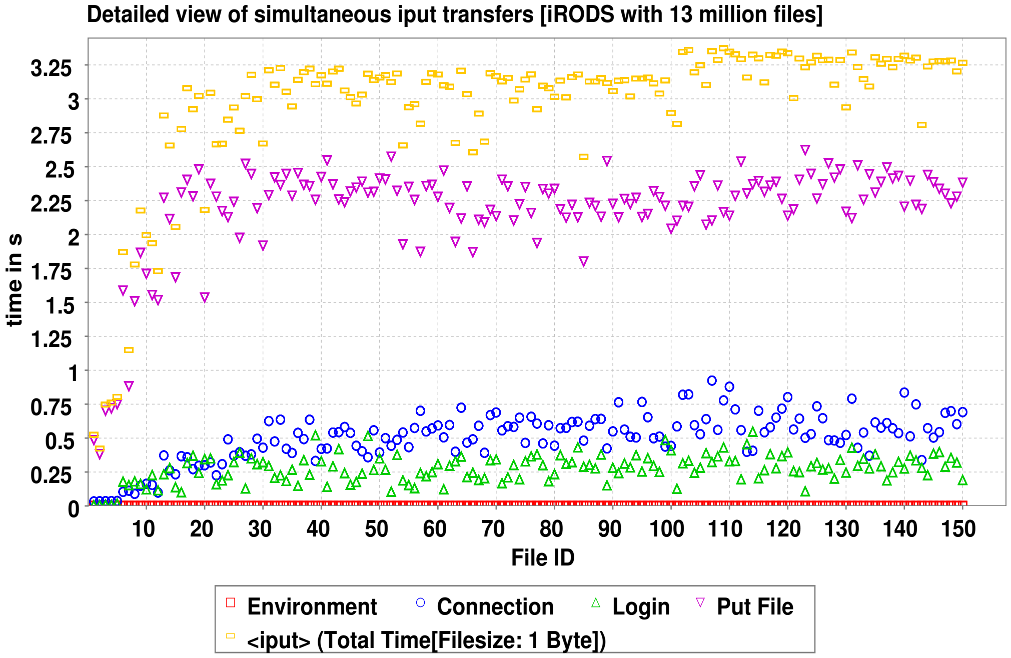

Fig. 3. Simultaneous data transfer of 1 Byte large files with iput. The iRODS environment contains 13 million files. Shown is the time needed for every stage and the overall transfer time (stages, see IV-A1).

In the next state (7 million files) the behavior changes. The time for writing data increased significantly compared to reading, where the increase is small. Nevertheless, the performance of writing was still better than of reading. The time difference between iput and iget decreased by a factor of 1.5 for 150 files written or read.

As expected, in the last case of the filled iRODS environment the performance decreased both for reading and writing. The increase of time iget needed is small compared to iput, which is 7 times slower than in the empty state. Now writing data is slower than reading files.

Summarizing one can say that the results of this test show that writing the standard metadata is an important performance factor and that the number of metadata stored on the iCAT server has more influence on writing than on reading files.

D. Writing user defined metadata

This test wrote the same amount of metadata to iRODS using the two transfer methods described in section IV-B. Furthermore, the measurements were performed with the iRODS environment in two states: empty and filled with 13 million files. Figure 5 shows the results.

In the case of the empty iRODS environment the difference between the performance of simultaneously and sequentially written metadata is small. This changed when the iRODS environment was filled with 13 million files. While the time of simultaneously written metadata increased already significantly (e.g. for a number of 150 metadata elements by a factor of 5), the performance of the sequential method got even worse (e.g. 24 times longer for 150 elements). The reason for the latter is the accumulation of the additional time (originating from the slowdown due to the filled iCAT server) needed for the sequential writing of the metadata (see description in IV-B).

E. Stress tests

On the iCAT server it is possible to configure the maximum number of requests allowed to the database. With scenario IV-C1 it is possible to measure the actual number of requests an iCAT server can handle. Measurements were done for three states - setting the maximum number of simultaneous requests to 200, 700 and 1000, respectively (the default value is 100). Additionally, the shared memory of the database was increased to 2000 MByte - otherwise the database had refused requests. The test varied the number of simultaneously started processes. Each process starts 10 imeta requests. Figure 6 shows the results for the three stages. Up to 100 processes iRODS can handle more than 35 operations per second. Between 100 and 500 processes iRODS finished the requests with about 34 op/sec. This value decreases faster, down to 27 Op/sec.

The second test (see IV-C2) continuously transfers 1000 files at once (each file with a size of 100 Byte) to the iRODS server. With every run the number of metadata to be managed increases. In the empty iRODS environment the transfer time is about 7 seconds and up to 150 files can be written per second (figure 7). With 13 million files already stored on the iRODS server, the time increases to 38 seconds and only 25 files can be transfered per second. The performance decrease is a factor of about 6. The major cause is the metadata handling in the database. The shift of the transfer time between 7 million and 10 million files was probably caused by a process on the iRODS server. Because the overall time of the measurement needed more than one day it was not possible to identify the exact reason for the shift when the measurement was finished.

F. Using the scenarios to simulate a real use case

In the following it is described how the benchmark tool and the scenarios were used to simulate a real use case. In genetics automatic microscopes take a large number of pictures of gene screening processes. For a gene screen ten thousands of pictures needs to be analyzed. The management of the pictures and their metadata is done with iRODS.

To find optimal usage parameters for this use case it was simulated using 10,000 files each with a size of 10 MByte. The transfer was done with one iput request. Figure 8 shows the time of the transfer as function of the different number of threads (parallel transfers) used and for different conditions of the iRODS environment (empty, 7 million files in iRODS and 13 million files in iRODS). The condition of the iRODS environment had more influence on the performance than the used number of threads. For such a large number of files to transfer the performance variation between the thread The difference of the writing time between an empty database and a database filled with metadata for 13 million files is about 20%.

Figure 9 shows how time and bandwidth will change if the files are stored in several directories and these are simultaneously transfered to the iRODS environment. The use of 5 directories instead of one reduces the time by more than the half and when using 10 directories the runtime is about a third. The reason is the better utilization of the bandwidth. That means in this case it is useful to divide the files on more than one directory by using subdirectories. The subdirectories can be transfered simultaneously and reduce the total transfer time to optimize the use of the bandwidth.

VI. Conclusion

In this paper scenarios for iRODS performance measurements were presented, which are integrated in the tool BenchIT. This allows administrators or users of iRODS to measure the performance of an iRODS installation easily and to adopt the usage patterns to an optimal performance. The scenarios provide performance measurements of data transfers, user defined metadata transfers, stress tests of the iCAT server and the runtime of Micro-Services. Furthermore, performance tests done on an existing iRODS environment and simulating a real use case were presented. Among other things the results show that the performance of data transfers decreases when the number of metadata the iCAT server has to manage grows significantly. But the measurement described in section (V-F) also shows that it is possible to optimize the performance by efficiently using the iRODS capabilities.

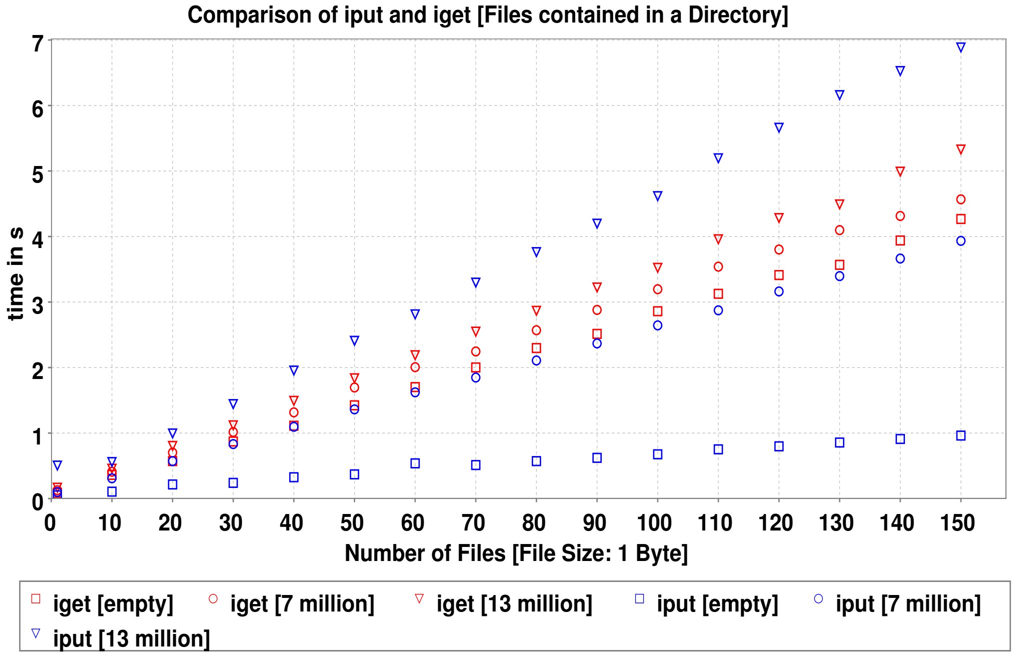

Fig. 4. Comparison of writing (iput) and reading (iget) a varying number of files (each with a size of 1 Byte) transfered at once in a directory. The figure shows the time needed for the transfers with iput and iget for three different states of the iRODS environment (no [empty], 7 million files and 13 million files already stored in iRODS).

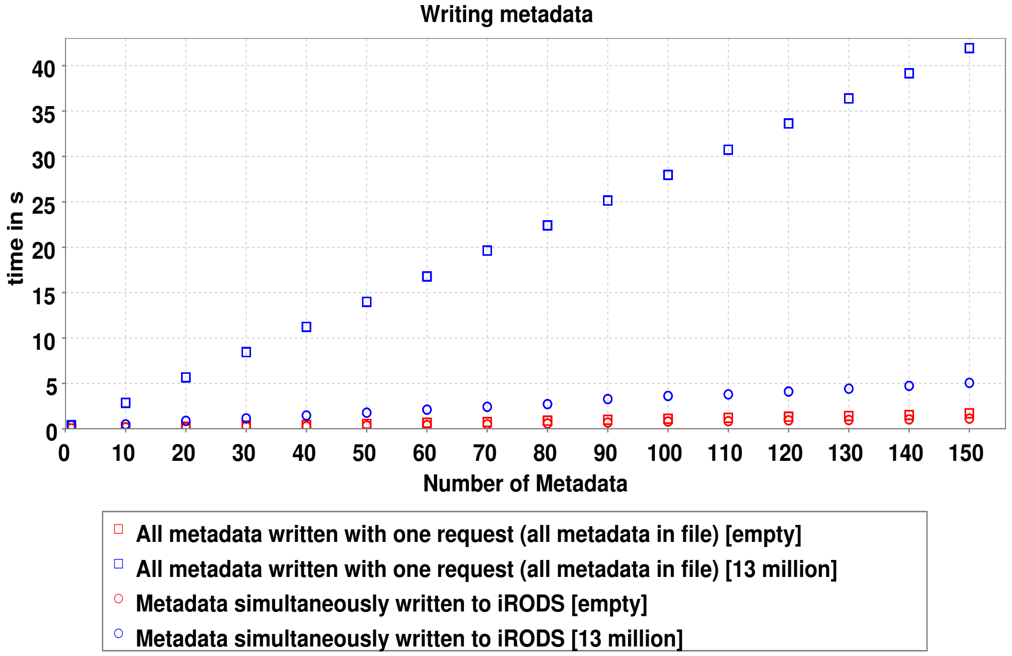

Fig. 5. Comparison of simultaneously (parallel imeta requests) and sequentially (in one file) written metadata. Shown is the time needed for writing a varying number of metadata for two states of the iRODS environment (empty and filled with 13 million files).

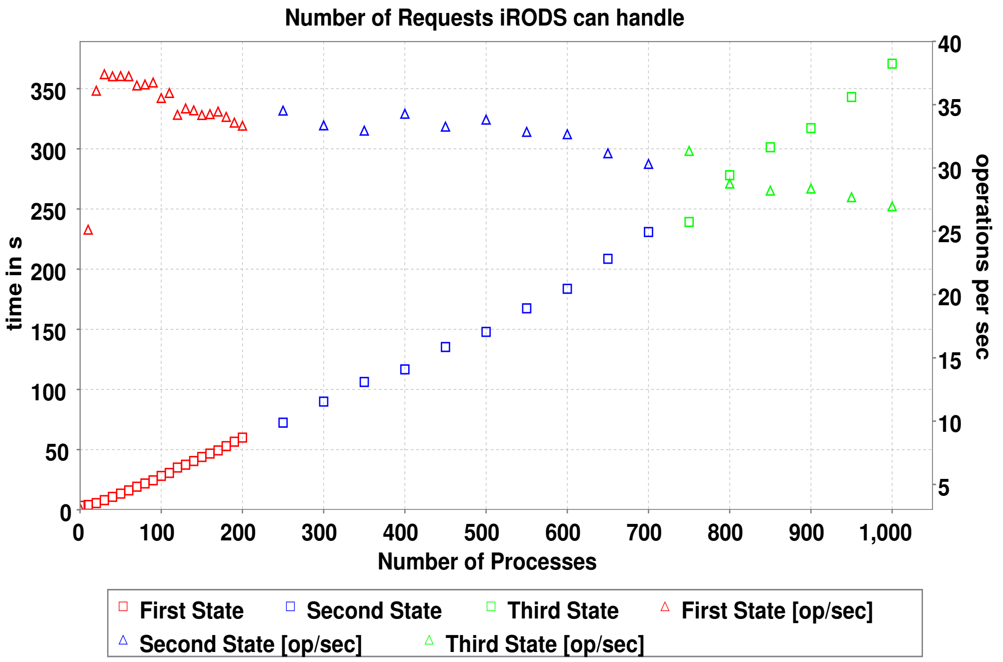

Fig. 6. Number of metadata requests: A varying number of processes were simultaneously started. A process starts sequentially 10 imeta requests. Shown are the time needed to process all requests and the resulting operations per second (op/sec). The three states correspond to the setting of the maximum number of requests allowed on the iCAT server (200, 700 and 1000).

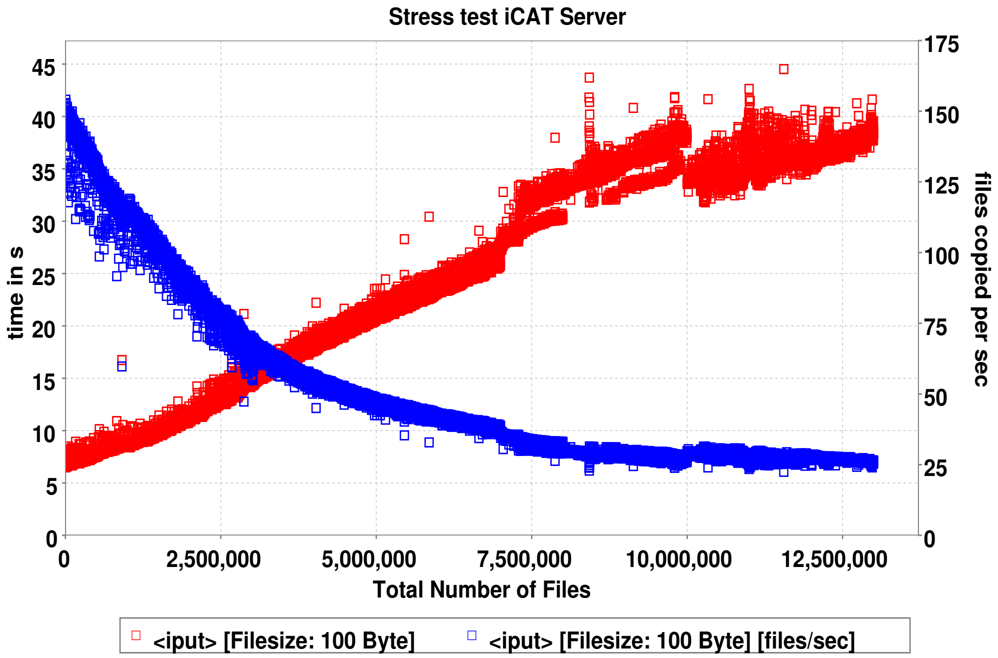

Fig. 7. Stress test: 13 million files (each 100 Byte) are transfered with iput. With each run 1000 files are transfered. Shown are the time for each run and the number of file transfers per second.

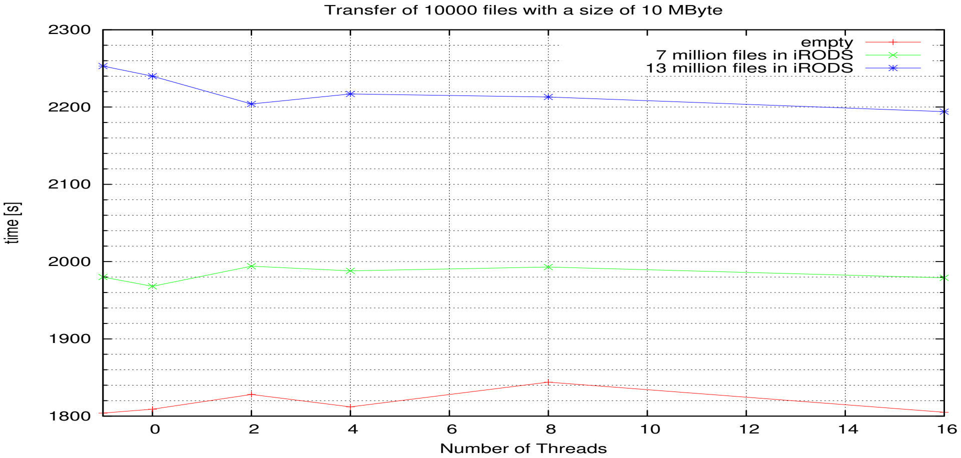

Fig. 8. Use case: 10,000 files (each 10 MByte) were written as part of one directory to the iRODS environment. Shown is the time needed for the transfer as a function of the threads/parallel transfers used. The thread number -1 means automatic thread choice by iRODS and 0 means no threading.

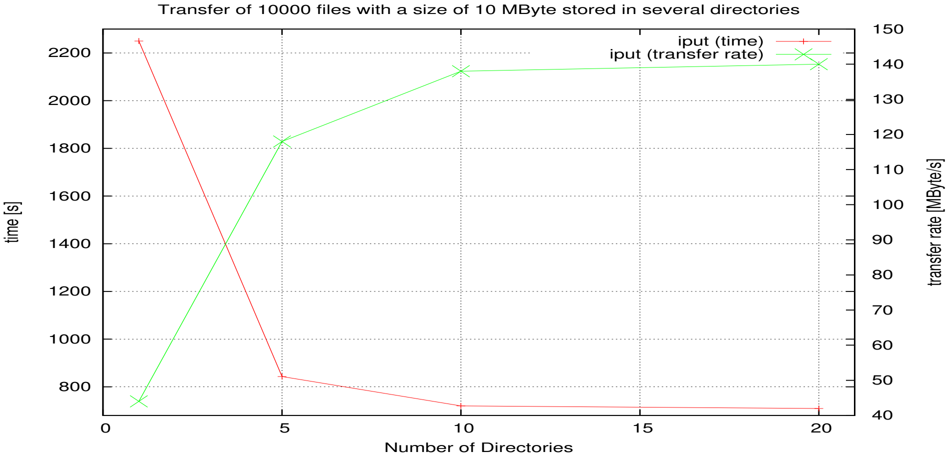

Fig. 9. Use case: 10,000 files are stored in several directories and are then written in parallel. Shown is the time needed for the transfer of the directories containing the 10000 files.

***Abstract*—A key element for outsourcing critical parts of a business process in Service Oriented Architectures are Service Level Agreements (SLAs). They build the key element to move from solely trust-based towards controlled cross-organizational collaboration. While originating from the domain of telecommunications the SLA concept has gained particular attention for Grid computing environments. Significant focus has been given so far to automated negotiation and agreement (also considering legal constraints) of SLAs between parties. However, how a provider that has agreed to a certain SLA is able to map and implement this on its own physical resources or on the ones provided by collaboration partners is not well covered. In this paper we present an approach for a High Performance Computing (HPC) service provider to organize its job submission and scheduling control through long-term SLAs.**

***Index Terms*—Service Level Agreements, High Performance Computing, Cloud Computing**

I. Introduction

FOR High Performance Computing resources scheduling of jobs is still realized in most cases using simple batch queues. While batch queues like OpenPBS [1], TORQUE [2] or others offer a quite comprehensive set of functionality for placing jobs in appropriate queues and optimizing the load of the cluster systems, also across sites, there is no mapping from business level requirements down to the low-level specifications. Low-level specifications are typical elements of a job description, for example desired number of CPUs, maximum wall- or run-time. The provision of such low-level properties requires a high level of expertise of the user and can only be specified if the target platform is pre-determined as different node and CPU architectures require different values. Additionally the number of queues is limited and therefore requirements have to be mapped to a particular queue. While advanced reservation, allowing a pre-defined start time, can be specified the drawback of potentially significantly reduced efficiency due to fragmentation of the schedule is not mapped to potential business penalties such as dynamically adapted pricing for such requests depending on the concrete loss in efficiency.

If an HPC provider wants to offer its services as utilities and aims to map different possible flavors of the services on different queue structures, the following problems can occur:

- Typically the use of certain queues is mapped to Unix credentials and groups. So all users of a certain group can or cannot use e.g. the express queue. However, depending on time of day or load situations, the “express queue service” might not be available to the same group of users all the time.
- While queues for specialized nodes (for example with graphics processing units (GPUs) or high memory nodes) are underutilized and normal nodes are oversubscribed there is no way to allow clients and providers to agree on special “discounts” for them. An automatic movement from normal to premium node queues would require interaction with accounting services.
- Customers might want to differentiate quite fine-grained about the treatment of their jobs. In such cases nowadays manual movement of jobs within the queues to “prioritize” them might be agreed beyond existing queue structures and group memberships. Such manual interactions cannot scale.
- Not all elements describing the Quality of Service (QoS) or Quality of Experience (QoE) can be mapped on queue properties and parameters. The overall service covers a wider range of properties such as the availability of a certain compute environment, application versions and licenses, proper treatment of data or specific configurations of the cluster system such as “require logical partition to isolate from other users”.

This limitation that only a few functional parameters can be specified when submitting a job (also reflected in standards like the Job Service Description Language (JSDL) [3]) means that there is basically no way for the user to express his requirements on a QoS or QoE level. Considering that the HPC provider is offering a utility potentially replaceable with other providers there is a clear gap between the demands from the user side and current offerings.

As a result a significant amount of work has been spent on realizing SLA frameworks allowing to mutually agree on the terms of the service between provider and consumer. However, while these frameworks cover well the necessary steps to realize SLAs also as a legally binding agreement, the concrete content of such an SLA and more important how these terms

978-83-60810-27-9/09/$25.00 © 2010 IEEE

can be guaranteed and provided from the service provider side are not adequately addressed.

So far we have the possibility for the consumer to express the requirements and agree the terms with the provider but

- terms within the SLA are not on the desired business level but mimic the low-level properties of the underlying queuing systems and
- the agreement process is typically detached from the underlying infrastructure such as current load situation of different resources, priority and importance of the consumer in a Customer Relationship Management (CRM) system and the accounting and billing services.

Consequently there is a gap between the demand of defining business level SLAs and their implementation using available methods and tools for the management of them on different type of computing facilities ranging from commodity of the shelf (COTS) clusters over specialized compute systems to cloud computing and storage systems.

Management systems on the provider side between the SLAs agreed with the consumer and the concrete physical resources need to interact with a range of different elements within the providers IT infrastructure and must look beyond individual SLAs to optimize the overall operation of all resources within a HPC computing service provider.

II. Related work

There are various approaches to the usage of service level agreements for job scheduling. While they differ in many respects - detail of the presentation, assumed parameters, implementation level, etc. - they all share the fact that they treat SLAs as agreements on a per-job basis. That means that, for each job to be submitted, a unique SLA is established before the job can be submitted. In [4], Yarmolenko et al., after having identified the fact that SLA-based scheduling is not researched as intensively as it could be, investigate the influence of different heuristics on the scheduling of parallel jobs. SLAs are identified as a means to provide more flexibility, increase resource utilization and to fulfill a larger number of user requests. Parameters either influence timing (earliest job start time, latest job finish time, job execution time, number of CPU nodes) or pricing. They present a theoretical analysis of scheduling heuristics and how they are influenced by SLA parameters and do not investigate how the heuristics might be integrated into an alredy existing setup. The same authors identify in [5] the need to provide greater flexibility in service levels offered by high-performance, parallel, supercomputing resources. In this work they present an abstract architecture for job scheduling on the grid and come to the conclusion that new algorithms are necessary for efficient scheduling in order to satisfy SLA terms but that little research has been published in this area. MacLaren et al. come to a similar conclusion, stating that SLAs are necessary in an architecture supporting efficient job scheduling [6].

SLAs that express a job's deadline as central parameter for deadline-constrained job admission control have been investigated by Yeo and Buyya [7]. The main findings were that these SLAs depend strongly on accurate runtime estimates, but that it is difficult to obtain good runtime estimates from job traces.

Djemame et al. present a way of using SLAs for risk assessment and management, thereby increasing the reliability of grids [8]. The proposed solution is discussed in the scope of three use cases: a single-job scenario, a workflow scenario with a broker that is only active at negotiation-time and a workflow scenario with a broker that is responsible at runtime. It is claimed that risk assessment leads to fewer SLA violations, thus increasing profit, and to increased trust into grid technology.

Dumitrescu et al. have explored a specific type of SLAs, usage SLAs, for scheduling of grid-specific workloads using the bioinformatics BLAST tool with the GRUBER scheduling framework [9]. Usage SLAs are characterized by four parameters: a user's VO and group membership, required processor time and required disk space. The work analyzes how suitable different scheduling algorithm are. Additionally, it comes to the conclusion that there is a need for using good grid resource management tools, which should be easy to maintain and to deploy.

Sandholm describes how a grid, specifically the accounting-driven Swedish national grid, can be made aware of SLAs [10]. It is presented how the architecture can be extended with SLAs and it is stated the greatest benefit would be achieved by insisting on formally signed agreements.

A comprehensive overview of resource management systems and the application of SLAs for resource management and scheduling is given by Seidel et al. [11]. The connection of service level and resource management to local schedulers is clearly shown as a gap in nearly all solutions.

In summary, it can be said that isolated aspects of the usage of SLAs have partly been investigated in detail: scheduling algorithms and heuristics, abstract architectures, parameters which are to be used as service levels, SLA negotiation etc. Gaps, however, can be easily identified: the analysis of the "big picture", that is the composition of individual aspects of SLA usage into a complete system and the integration of SLAs and SLA management with local resource management. This is not only true for the "traditional" field of high performance and grid computing but can also be extended to the field of cloud computing. Furthermore, SLAs are solely treated on a per-job basis, the analysis of SLAs as long-term contracts is not covered.

III. Benefits of SLAs for HPC service provisioning

The current operation model for high-end computing resources is conceptually still the same as fifty years ago where users placed a set of punching cards at the registry desk. The only difference is that users now can submit their compute jobs to a set of different queues and instead of the human operator the scheduling system is picking the jobs from the different queues depending on defined policies aiming for an optimized load of the system partially reaching 99% utilization. The major shortcoming of this approach is that the optimization strategy defined by the queues and the scheduling system policies is oriented towards a global optimization rather than an individual service offer.

If a user needs a special service (e.g. guaranteed start time of a job during a demonstration, interactive visualization or exhibition) beyond regular job submission the negotiation is typically done directly with the system operator and the performed steps are mostly done manually.

The availability of multi-core CPUs will lead to compute nodes with 32 cores and more in the near future, the rise of GPU-based computing with several hundred "cores" per card allows a reasonable number of applications to run on a single node. This is particularly true if the application is not targeting for a high-end simulation e.g. in the area of Computational Fluid Dynamics (CFD) domain with a very fine-grained mesh but more on exploring the problem space. Other examples are cases where the full simulation has been done before and now only small changes in geometry are done interactively demanding much less intensive computing to reach a stable state again as it is based on the previously achieved results.

Driven by the availability of cloud service providers and emerging products such as the Amazon Cluster Compute Instances also high-end computing service providers change their offers to be more *elastic* and realize a more *dynamically changing* infrastructure having certain queues available only during specific time periods or realizing a dynamic allocation of resources to logical partitions depending on the load situations or specific time bound agreements.

The pre-dominant use of high-end computing services will continue to be highly scalable technical simulations demanding a large number of compute nodes for exclusive use. However additional use cases have emerged driven by changes on the hardware level and competition with cloud service providers in particular for small scale simulations. The exclusive access for a user to one single node might even for compute intensive applications become a relic of the past. This substantially more complex management model for HPC service providers that cannot rely anymore on a quite homogeneous user behavior and long running jobs demands for a more complex management solution for operating their resources. The challenge is to integrate the demands of policies from different levels such as business policies (e.g. users with highly scalable and long running jobs should experience a preferred treatment) with more short term policies reacting on the current load situation (e.g. reducing prices or accepting more small jobs to fill gaps in the current schedule) and the demand of the users on a per-job basis.

The following sections aim to cover in examples the three major use cases driving the need for an SLA-guaranteed HPC service provision. Abstracting from concrete cases three different cases can be identified:

A. Interactive Validation

In many areas simulations have already replaced real experiments or physical prototypes during the development process. However at certain control points in the process simulation results have to be verified using physical prototypes. Within the IRMOS project augmented reality techniques are used to overlay real experimental data like a smoke train in the wind channel with a visualization of trace lines from the corresponding simulation. This "hybrid" prototype allows experts to directly compare the behavior of the real prototype with the results of the simulation. Such a design review session typically involving several people of a development team spread around the globe demands a fixed availability of the wind-tunnel, the computing resources, the visualization resources, the corresponding network resources and all involved experts, for example via video-conferencing.

In such a scenario simulation data will be generated continuously by a simulation running on a compute resource that is directly connected to the visualization resources. The current configuration of the wind channel like the air speed will be communicated as boundary condition for the simulation, thus the same parameters for both will be used while the experiment is running. This requires a coordinated and automated provision of the resources involved in the overall setting.

Such a scenario cannot rely on batch queue-based access as the computing and simulation part is just one piece in the overall setting. The demand for a co-ordinated availability also opens questions on how penalties are applied if one of the pieces in the overall setting is failing. For example if the compute resources are not provided as promised in time and the wind tunnel cannot be used the costs for it still accumulate. This applies also the other way around if the wind tunnel is not available or fails to communicate the boundary conditions for the simulations or the network connection is not delivering sufficient bandwidth.

As the resources needed for the full scenario are provided by different organizational entities the different quality levels needed by each individual contributor need to be put in a formal SLA, covering the terms of service as well as the agreed penalties in case of failures.

B. Guaranteed Environment

As outlined in [12] beside quality constraints there is also a demand to ensure a certain environment or other procedural constraints such as data handling, security policies or environmental properties (version of the operating system, available Independent Software Vendor (ISV) applications, etc.).

This is especially necessary for simulations performed as part of an overall design cycle for a complex product such as a car or airplane. A software environment is freezed for a full development cycle in order to ensure reproducible simulation results. This fixed environment is typically ranging from operating system over certain versions of numerical libraries up to application codes. A typical approach to address this requirement is to have beside a paper-based SLA agreed for a design cycle period a dedicated computing resource with the requested environment.

Advances in virtualization technologies as well as the possibility to apply different boot images in diskless cluster environments allow a more flexible treatment. Using such technologies a potentially unlimited number of pre-defined images, or even user-defined images, might be provided. As not all environments can be provided on all compute resources there must be a negotiation process between the user and the provider where a certain environment is demanded (e.g. expressed in a certain SLA bundle such as "Silver") and a corresponding reply about the conditions for the different options from the provider side is delivered.

The increased flexibility would allow to offer customized environments not only to large customers asking for resources for a long time period but also for users looking to meet their peak demands with outsourcing avoiding tedious customization activities of the environment reducing the entry gap.

C. Real-time Constraint Simulations

With the increasing role of simulations in design processes for complex products the demand to have a time-boxed simulation where results need to be delivered in time have emerged. This might be a set of simulations exploring a parameter space as input for a meeting of engineers the other day deciding on the focus for the future (long running simulation jobs). Another possibility is if the results of one single simulation (or a set of simultaneously running simulations) is the input to support an expert in taking a decision.

One important application area demanding for such an operation model is individualized patient treatment. For example in [13] a scenario for using simulations to validate different options to perform a bone implant for a specific patients is presented. In such cases the expert that needs to make a treatment decision has to ensure in advance of starting the simulation at a specific compute service provider that the results will be available in time before the treatment must be executed.

In such a scenario a negotiation with several providers would be started in parallel in order to make a case-by-case decision to which provider the job will be finally submitted. Such a loose binding to a specific provider would also require similarly to the scenario in the previous section a guaranteed or user-provided environment making the different providers interchangeable.

D. SLA Service Provision Benefits

From all the scenarios above it becomes clear that a much higher diversity of the offered services must be expected in the future. The requirements of the different scenarios on the provider's infrastructure are quite diverging. Additionally the consumer requirements are contradictory to the goal of the providers reaching a very high level of utilization of the provided resources.

As a result service providers will need to

- offer a mix of different services in order to combine the benefit of best-effort services (high utilization) with the benefit of special services (high value and price),
- offer a framework allowing consumers and providers to agree on the specific conditions for the service and
- actively manage their resources in a way that agreed SLAs are met, resources are most effectively used and any failures and incidents on the resource level are managed to avoid any impact on the agreed service levels.

The underpinning assumption presented in this section is that the provision of SLA controlled services is beneficial for consumers *and* providers. Consumer can negotiate guarantees and specific properties of the provided services as needed enabling new use models for high-end computing resources as outlined above. The provider perspective is clearly driven by business benefits to deliver as a part of the differentiation strategy specific products rather than aiming for a cost leadership approach. Consequently there is a clear need from the consumer side as well as a clear motivation from the provider side to deliver also in the HPC domain SLA based services. In other words the current model where the user needs to fully adapt to the provided environment and access model is changed to a model where the provider is offering certain possibilities or a kind of toolbox where the consumer can arrange the service offer according to their needs. Realistically this space of options needs to be discrete and limited allowing a management of the service offer from the provider side.

IV. Using long-term service level agreements for job control

Service level agreements, when they are used for the scheduling of compute jobs, are normally assumed to be on a per-job basis. That means that an individual SLA only contains terms for one specific job and a new SLA needs to be established for each job (see for example [14], [7] and [8]). This may be ideal to investigate the influence of SLAs and parameters specified therein on the scheduling of jobs in an isolated environment but does not correspond with the reality of how contracts are handled at HPC providers. At HPC providers, users usually agree to a contract that specifies charges for computational times and storage for available machines [15]. Jobs are then submitted in accordance with the acknowledged charges which therefore can be thought of as a long-term contract. This contract is, however, missing a specification of service levels. There may be some service level-related parameters specified - for example the availability of different machines to users and their characteristics, for example CPUs per compute node and memory size per node, but these are only specified in order to compute the amount finally billed to the user. By adding service levels to this contract, a long-term service level agreement is formed.

Long-term SLAs add the missing specification of service levels but keep the familiar contract behavior used by HPC providers intact. A simple specification of priorities, for example, might be realized through the following service levels:

Bronze Computational time is cheap, but there is no assurance on the scheduling of a job. This corresponds to the best-effort services provided today at HPC centers.

Silver Moderate prizing for computing time due to prioritized scheduling. Silver jobs can have timing

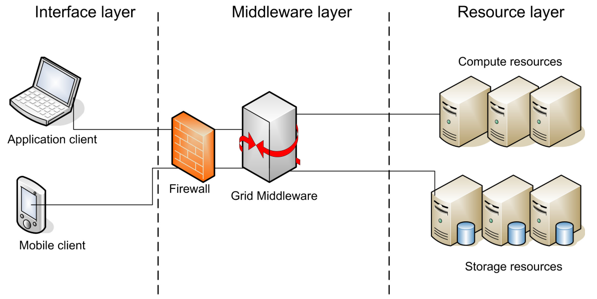

Fig. 1. Layered architecture

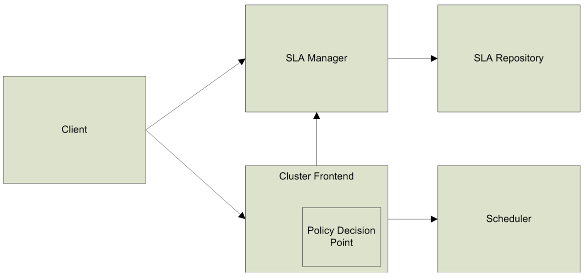

Fig. 2. High-level SLA management components

guarantees and might preempt best-effort jobs. The increased prize is justified since guarantees on the job's scheduling are given.

Gold High-prized jobs that are only rarely used, for example for urgent computing when computations need to be started immediately.

In contrast to the current situation the possibility of providing different service levels allows users to potentially have multiple contracts in place in parallel. On job submission time, a user decides which contract to reference in the submission depending on the current requirements and conditions such as urgency of the simulation result, load situation of the provider(s) etc. This can be seen as a using the middle way between using SLAs on dynamic, per-job basis and solely having singular long-term contrasts. In contrast to dynamic, per-job SLAs, this approach reduces the amount of negotiation as only few contracts are in place. Additionally, it avoids the problem that an urgent job cannot be submitted due to a failed negotiation. In contrast to having only singular contracts, this approach is more flexible and allows users to choose necessary priorities depending on the prize they like to pay.

V. An integrated approach to service level management

The basic service level approach given above can be realized with current techniques, for example the usage of specialized priority queues; however, providing more complex service levels cannot be realized that easily but requires the integration of service level management techniques across interface, middleware and resource layer.

Figure 1 shows the typical three-layered setup that is used by HPC providers. The left-hand sides shows clients of the HPC provider, either static or mobile[1]. The middleware layer is positioned between the client and the low-level resources and serves as a central entry point to the HPC provider's system and provides access through grid middlewares, for example the Globus Toolkit. The Grid middleware takes jobs submitted by the client and passes them on to low-level resources by means of a resource manager which employs a job scheduler in order to determine which jobs are placed on which resources.

A. *Service level selection by the client*

Enhancing the client with the ability to select service levels is very straightforward. This can be either done by changing the job submission client, adding SLA information to the message sent to the middleware or by integrating SLA functionalities into the application, if job submission is performed directly out of it.

B. *Enhancing the middleware*

SLA management on a middleware level has been investigated by various research projects and therefore different components and solutions already exist [16] [17] [18] [19] [20]. As these solutions often have the drawback of being very complex, a simpler solution is preferable, as it eases the amount of work necessary for installation, integration and maintenance.

Figure 2 is a diagram depicting how easily SLA management can be implemented on a middleware level and the underlying resource layer. The client thereby can either communicate with the SLA Manager, a central component on the HPC provider side responsible for SLA management, or submit jobs to the cluster front-end in the manner already explained.

The SLA Manager provides data regarding the long-term SLA contracts, for example contract information, accounting pertaining to contracts etc. It uses an internal SLA Repository for storing the contracts and other relevant information and is the central point that is queried by other components regarding SLAs. The cluster front-end, for example, on submission of a job, can query the SLA Manager for the validity of SLAs and can, after job completion, send accounting data to the SLA Manager.

[1] Mobile in this context should not be mixed with cellular phones and is understood as a nomadic user that is connecting from different locations without pre-defined IP addresses

The SLA functionality for the cluster front-end in the grid middleware can be realized in a non-intrusive way, for example through a policy decision point (PDP) that checks incoming requests and their SLA specification for validity. Incoming requests that do not contain SLA specifications can be mapped internally to a default SLA specifying a best-effort style service level, thereby realizing complete SLA-functionality and being backwards-compatible to clients.

C. Acknowledgement of SLAs

Honoring service levels of submitted jobs depends on the software used on this low level. Very simple schedulers, like the default scheduler supplied with the TORQUE resource manager, cannot honor service levels and need to be replaced by an SLA-enabled scheduler. This can be implemented by the provider itself, but this is a time-consuming and error-prone job. Rather, an SLA-enabled scheduler, for example the Moab Cluster Suite, should be used. It allows the formulation of quality of service levels for resource access, priority and accounting.

The providers main task is then to express the high-level SLAs offered to customers in such a way that the scheduler can implement them on the resource layer. Additionally, the incoming job requests have to be mapped to the corresponding service levels.

VI. From high-performance to cloud computing

In the previous sections we have elaborated a concept to enhance "classical" high-performance computing with service levels through the use of long-term service level agreements. Cloud computing, in many terms similar to the previous scenarios, seems like a logical step for the provisioning of services and can be a sensible offer to provide for HPC providers besides their usual role. Even though the term cloud computing is not clearly defined, it can be seen as distributed computing with virtual machines. Virtualization allows for more flexibility, scalability and abstraction of the underlying resources. Accounting and billing are usage-dependent. [21]

Cloud computing brings benefits both for consumers and providers. Virtualization allows the provider to use free resources for the execution for virtual machines as the underlying hardware is mostly irrelevant, although requirements specified by the user of course still need to be met. The usage of virtual machines means that the provider can offer a multitude of different environments tailored to customers, which was previously infeasible. Users might even be allowed to provide their own virtual machines, therefore giving them control over the complete environment.

Cloud computing began on a best-effort basis and many solutions provided today don't offer any more service [22] [23]. Service level agreements for cloud computing are, however, provided by some service providers, but they provide only minimal service levels [24] [25].

It has been shown that both Infrastructure as a Service and Platform as a Service - two types of cloud computing where the first one offers the concept described above and the second one offers a scalable, flexible but pre-defined environment to users - can benefit from service level agreements as well [26].

VII. Conclusions

The preceding work has described how an integrated approach to using service level agreements for the control of compute jobs allows HPC providers to offer support for various quality of service levels. Due to the solution including both high-level SLA management and low-level resource management and job scheduling, service providers can take advantage of service level agreements through the complete infrastructure. This is even valid for the recently introduced cloud computing paradigm.

The concept described above has been partially realized for an HPC scenario where the SLA management layer has been implemented and a simple integration with the grid middleware and resource layer has been achieved. Following the trend to provide Infrastructure as a Service solutions, we have decided to adapt the general concept for the Gridway meta-scheduler which is compatible with the OpenNebula cloud toolkit. This will enable HPC providers to offer IaaS with distinct service levels, which is not possible at the moment.

The offering of service levels can be a distinctive advantage for HPC providers as current contracts normally do not foresee the provision of service levels. Customers gain flexibility by having the possibility to choose between different service levels when submitting jobs. This also allows providers the option of offering previously unsupported service models, for example for urgent computing, which can generate a new revenue stream.

***Abstract*—BOINC (*Berkley Open Infrastructure for Network Computing*) is a framework for solving large scale and complex computational problems by means of public resource computing. Here, the computational effort is distributed onto a large number of computers connected by the Internet. Each computer works on its own workunits independently from each other and sends back its result to a project server. There are quite a few BOINC-based projects in the world. Installing, configuring, and maintaining a BOINC based project however is a highly sophisticated task. Scientists and developers need a lot of experience regarding the underlying communication and operating system technologies, even if only a handful of BOINC related functions are actually needed for most applications. This limits the application of BOINC in scientific computing although there is an ever growing need for computational power in this field. In this paper we present a new approach for *model-based development* of BOINC projects based on the specification of a high level abstraction language as well as a suitable development environment. This approach borrows standardized modeling concepts from the well-known *Unified Modeling Language (UML)* and *Object Constraint Language (OCL)*.**

I. Introduction

VOLUNTEER computing technologies allow to realize low-cost high-performance computing projects in certain application areas. A very prominent framework based on the principle of Public-Resource Computing (PRC) is BOINC (*Berkley Open Infrastructure for Network Computing*). BOINC provides an Application Programming Interface (API) with about one hundred functions of different categories, e.g. *filesystem operations*, *process controlling* and *status message handling* [1], [2]. A few of the most important functions are listed in section I-B. PRC is based on a server-client communication infrastructure mechanism. Here, the client retrieves a project specific application from the server along with a so-called workunit, i.e. a number of parameters usually provided in data files of simple ASCII or binary format that are optionally needed by the application to perform a specific task. BOINC is strongly focused on autonomic applications, each BOINC project has its own server, applications and tasks. The client executes the application, i.e. performs the calculations and sends its results back to the server which assembles these into a “global” result or stores these results at specific places.

The setup of a BOINC project heavily relies on the use of file-based scripting techniques. For instance, the programming language *Python* is utilized for the creation of a standard BOINC server infrastructure with database initialization, website and administration interface configuration and an optional BOINC test application. A few scripts are implemented using GNU BASH to sign executable files with encryption keys and yet another script uses the C shell (csh) to monitor network traffic. Extensible Markup Language (XML) files are used for the runtime server configuration. *All* files have to be edited *manually* by the project developer, scientist or administrator which bears the risk of making a large number of typical errors. For example, wrong spelling of parameter names or simulation relevant values as shown in I-A would have a significant effect on the system’s integrity and the application’s performance [8]. One way to cope with these problems is to provide a tool support which allows to automate the manipulation, generation, and checking of all necessary scripts.

In this paper we discuss a model-based approach for the development of BOINC projects that makes it possible to implement application specific changes while always keeping a valid configuration of the BOINC infrastructure. We give an idea on how to create a proper high-level domain specific language (DSL) in order to develop and maintain a complete BOINC application. This DSL forms the basis of an easy-to-use programming environment along with a high-level programming language and a suitable development process. Additionally, we present a way to model a complete BOINC installation including the client application for different target computer architectures and processor types. Aspects of single- and multicore processor units (CPU) and graphics processing units (GPU) are also discussed.

This project is funded by the German Federal Ministry of Education and Research

A. Typical errors during the BOINC server configuration process

The following list shows examples of typcial errors that can occur due to manual editing of the BOINC server configuration files. As a consequence of these errors one can expect a significant effect on the system's integrity and application performance.

- *uldl_dir_fanout* is the parameter that contains the number of subdirectories inside the upload and download directories on the server computer. A wrong value set here may dramatically slow down the system's server performance because of too many hard disk drive accesses.
- *shmem_key* names the allocated memory that is needed for the interprocess communication (IPC) between all BOINC applications on every BOINC project server. It is required that this value is unique, never changed during the runtime and is used by all BOINC server applications.
- *msg_to_host* must be included in the BOINC server configuration to enable sending of trickle-down messages[1] to the BOINC client nodes.
- *tasks* describes a set of parameters for applications which should execute in a cycle period, i.e. a crontab. Suitable values are needed to avoid problems like extremely large logging files or a outdated statistics, i.e. how many workunits are left for working or have errors during the computation.
- *daemon* contains a set of command descriptions. It is useful to start more than one daemon process to get a good load balancing of user requests, e.g. when the BOINC projects are much in demand.

One of our goals is the automatic determination of these most important parameters for different target computer architectures and processor types [20].

B. The BOINC Application Programming Interface

BOINC offers few example applications in which the number of lines of code range from 38 to 308. The first one only includes some elementary functions and no BOINC specific commands, e.g. a for-loop which just keeps the processor busy for one second. The second one is a more useful example since it contains BOINC specific function calls, e.g. how to retrieve the name of the checkpoint file or the actual processing state. Implementing a complex scientific application using BOINC is far more complicated and requires a broad experience of the developer. However, one can show that only 23 different BOINC functions are necessary to create a successfully running research relevant distributed computing application [23], [21].

II. State of the Art

Model-driven engineering (MDE) is becoming the dominant software engineering paradigm to specify, develop and maintain software systems. For example, Brunelière *et al.* [6] propose a *Modeling as a Service* (MaaS) initiative for cloud computing projects with an emphasis on topics like scalability, tool interoperability, and the definition of modeling mash-ups as a combination of MDE services from different vendors. Moreover, the definition of domain-specific languages (DSL) [10], [26], [27] along with the development of tools which support the developer during the DSL conception [9], [17], [26] are currently under investigation. However, none of the above mentioned approaches is related to public resource computing nor can it be directly used for the modeling process of BOINC projects. In the following chapters we therefore propose a first modeling language approach for the abstraction of the BOINC framework.

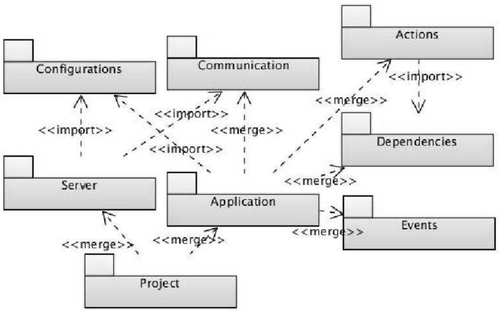

Fig. 1. Logical packages and dependencies of the BOINC functionalities

III. Abstraction of the BOINC Framework

The BOINC framework offers many very useful functionalities that help the developer to create his application. As a first step towards our modeling language approach we have subdivided the BOINC functionalities into different logical packages as shown in Fig. 1. Each package contains functions that cover a specific aspect during the development process [22] and can be used independently from functions of other packages which minimizes the number of dependencies. The whole BOINC project including the server installation components and application specific implementations is contained in the package *Project*. This package directly depends on the packages *Server* and *Application*. The package *Application* contains all application specific implementations and depends on the following child packages:

- *Events* - This package describes the abstractions for all possible events that can occur during the execution, e.g. exceptions like *'File not found'* or *'Segmentation fault'*. It contains routines for clearly defined error handling.
- *Actions* - Every execution statement is gathered within this package including wrapper routines to call third-party applications, i.e Matlab, or other domain-specific simulation tools.
- *Dependencies* - All libraries that are needed for the whole project are contained in this package. This includes the BOINC libraries as well as application specific runtime libraries and external sources.

[1] Trickle messages are asynchronous, ordered, and reliable messages between the BOINC server/clients and let applications communicate with the server during the execution of a workunit.

- *Communication* - This package includes the BOINC core client component which is the interface between the client installations and project servers and performs the information exchange between them.
- *Configurations* - In this package one keeps all system relevant parameters coded in XML files.

The complete server installation and maintenance process is provided by the package *Server*. This package describes the relationships between all components of a complete BOINC server installation, i.e. all configuration files, a list of the parameters for the workunits, description of installed applications with the corresponding architecture and processor targets. The package *Server* imports its required information from the contents of the *Configurations* and *Communication* packages.

IV. The modeling language approach for the abstraction of BOINC

Nowadays, models and model-based techniques are the fundamental means by which engineers are able to cope with otherwise unmanageable complexity and reduce design risk. In particular, software models have the distinct advantage that they can be *evolved* from high-level views of possible designs into actual implementations.

The *Unified Modeling Language (UML)* – a widely adopted, widely supported and customizable industry standard – plays a key role in modern software development. With the possibility of creating standardized UML profiles it provides the fundamentals for a true engineering-oriented approach to the construction of software. That is, system models can be used to understand and assess designs and predict design risks in meaningful (e.g., quantifiable) ways. Full automatic code generation from UML models facilitates preservation of proven model properties in the final implementation.

In our approach to a model-based development of BOINC projects we focus on the use of quasi standard software tools available within the Eclipse development environment. These tools enable us to develop all necessary components, like diagram editors, including graphical representations of modeling elements, code generators, etc. in one and the same development environment. Specifically, the code generation should be realized using a template engine which could also be used to generate important documentation files.

A. Graphical modeling environment

Throughout our project we exclusively use the Eclipse Modeling Framework (EMF) as released by the Eclipse Model Development Tools (MDT) project [26]. A detailed description of all components can be found in [9]. A key feature of our approach is the definition of a suitable standardized UML2 profile [22]. Here, we make use of the EMF-based implementation of the *UML2* and *UML2 Tools* subproject. EMF specifically allows implementing of constraints based on the Object Constraint Language (OCL) [18].

Fig. 2 gives an overview about a simplified modeling process. Here, the developer uses graphical modeling elements within diagrams to design an application as described in Sec. IV-B below. For a more detailed modeling of the application logic the developer is required to use a textual DSL as described in Sec. IV-D. The *Graphical Model* will be implemented using the Graphical Modeling Framework (GMF). GMF includes EMF, the Graphical Editing Framework (GEF) and Draw2D. GEF is a framework built upon the Model-View-Controller (MVC) pattern and handles the view and logical components with own instances. The controller handles the logic between these instances. The *Textual Model* and the *Graphical Model* are synchronized, i.e. every change in one of the models causes changes in the other one and each model will automatically be adjusted. Both models will be transformed into one (yet to be defined) so-called *VisualGridML Genmodel*. This can be done by exploiting the model-to-model transformation framework Query/View/Transformation (QVT). The QVT operation mapping language is capable of dealing with multiple input and output models and also supports OCL statements.

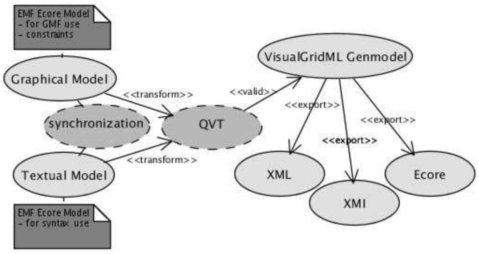

Fig. 2. Simplified view of the modeling process

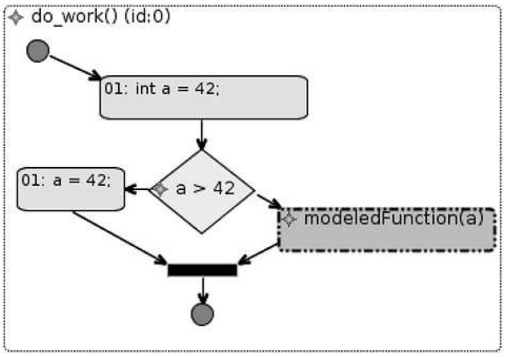

Fig. 3. Example flowchart diagram for instruction sequences.

One of the key issues of our approach is to define a proper *VisualGridML Genmodel*. The *VisualGridML Genmodel* can be exported into different other formats, e.g. XML, XML Metadata Interchange (XMI), or Ecore. The *VisualGridML Genmodel* will only be generated when the previously created models are valid. In order to support the developer during the verification and validation process adequate error messages and output comments will be created.

B. Graphical modeling elements

The proper definition of suitable graphical modeling elements is vital for our modeling language approach for the

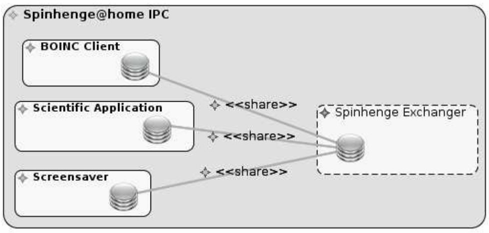

Fig. 4. Interprocess Communication within a BOINC application

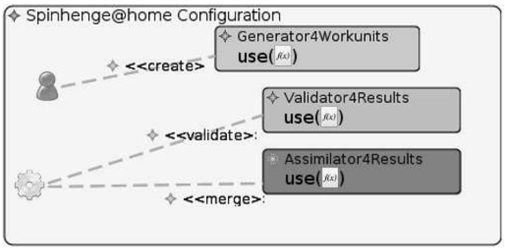

Fig. 5. Elements for configuration purpose

abstraction of BOINC. In the following we present some examples along with sample modeling fragments. Fig. 3 shows a flowchart of a high-level description of instruction sequences. The graphical notation is adapted from the UML2 flowchart definition [17, Fig. 12.36].

Fig. 3 shows an example that uses seven graphical modeling elements. As mentioned above these modeling elements are defined in the *Actions* package and have the following meaning [22]:

- *Start*, which describes the entry point of an application.
- *Stop*, which defines the end of execution, i.e. after that no other instructions will be executed and the application will shut down.
- *Action* is a modeling element which can execute native C/C++ instructions.
- *Decision* describes an `if-else` condition.
- *Join* merges two or more subdivided instruction sequences.
- *Execute* executes external C/C++ functions which are implemented in header and source files.

In Fig. 4 we show an adapted version of a UML2 collaboration diagram [17, Tab. 9.1, 9.2]. The dashed rounded rectangle on the right hand side specifies a shared data space. This data space is defined using one ore more port descriptors. Different ports could include different data descriptions and could also be connected with different so-called handlers. The three elements on the left hand side are examples of such handlers. Each handler handles a specific functionality and is connected with one application implementation. This example contains handlers for the *BOINC Core Client*[2], a scientific application, and a component for a screensaver session [1]. The handler can have only one data port. Data ports can only be connected to data ports of shared data space. Connections between ports may also be named as shown in this example.

In Fig. 5 we show an adapted version of a UML2 Use-Case diagram [17, Fig. 16.10] which contains elements of the *Configuration* package [22]. The elements on the left hand side are the actors for the use cases of the right hand side. The use cases contain a reference to predefined functions which can be modeled with a flowchart diagram. The dashed line connects the use cases with the appropriate actor and defines the type of execution. The lower actor describes the BOINC server which could be a cronjob. The upper actor describes a user. In this example the user defines workunits.

C. Aspect-Oriented Programming and Feature-Oriented Programming

Aspect-Oriented Programming (AOP) aims at separating and modularizing cross-cutting concerns [12]. The idea behind AOP is to implement so-called cross-cutting concerns as *aspects* and the core (non-cross-cutting) features are implemented as *components* [5]. Using *pointcuts*[3] and *advices*[4], an aspect weaver glues aspects and components at *join points* together. Fig. 6 shows on the left hand side (1) two aspects (A1 and A2) which extend the class definitions (C1 and C2). In AOP aspects can be added to the programming logic where ever functions are called. It is also possible to replace any functionality dynamically or to define the order of execution by precedence.

In Feature-Oriented Programming (FOP) the program functionalities can extended during the compilation and execution process, e.g. two or more functions can be combined to create extented features [7]. Fig. 6 shows on the right hand side (2) a simple overview of FOP. Here, F4 inherits the properties and methods of F1. Additionally, F6 refines F4, which can be done during runtime or while the compiling process creates the application.

Aspects and features in their current representation are intended for solving problems at different levels of abstraction [4], [14], [16]. Whereas aspects in AspectC++ [24] act on the level of classes and objects in order to modularize cross-cutting concerns, features act on the software architecture level [3].

For our approach, we are expecting that AOP and FOP are suitable methodologies for dynamic binding of applications as stated in Sec. IV-E. For example, the BOINC project result file format must be defined and created manually by the scientist or developer for a specific scientific application. This file can be generated during the code generation process as soon as definitions of the BOINC validator and BOINC assimilator are existing. After that, the BOINC project can be deployed with error-free validator and assimilator configurations.

D. Domain-specific language for BOINC

Domain-specific languages (DSL) are language definitions tailored to the development needs of specific problem domains

[2] The BOINC Core Client communicates with schedulers, uploads and downloads files, and executes and coordinates applications.

[3] The point of concern to execute an *advice*.

[4] Additional code that should apply to the existing model.

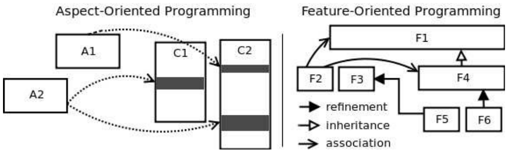

Fig. 6. (1) Two aspects extend two classes, (2) Two features refine two other features

[10]. For example the Structured Query Language (SQL) is designed for database queries. Another vital part of our modeling language approach to BOINC is a proper definition of a DSL for BOINC applications. Here, a key issue is the use of Xtext which allows to create an application by code generation. Xtext offers in combination with Xpand a template-based code generation engine [26]. By using Xtext and Xpand is has been shown that it is possible to create a complete BOINC application [21].

Generally speaking, all BOINC functionalities can be defined using a set of specific language elements. Our model-driven approach allows to develop applications independently of the target type, i.e. for CPU or GPU targets. Furthermore, BOINC offers various diagnostic parameters which enable or disable checks, e.g. *memory leaks* or *heap violations*. With the help of DSL statements these specific options can enabled or disabled for a subsequent automatic code generation. For example, the following code fragment defines a single processor environment which enables the above mentioned diagnostic flags:

```
target cpu single;

diagnostics {
 dumpcallstack
 heapcheck
 memoryleakcheck
 redirectstderr
 tracetostderr
}
```

In order to create applications with multicore or GPU computing support the following statement can be used:

```
target cpu mode multi with 10;
  // or
target gpu dim(10) block(4);
```

The first line describes a multi-thread application with up to 10 threads. The last statement enables the support of GPU computing. In GPU computing the process is splitted into *dim* threads, executed in 4 *blocks* [13]. It is also possible to include manual implementations or third-party libraries. The following examples show this in more detail. The required dependencies to third-party libraries or functionalities could be also defined with only a few lines of code. This code is used for the "make" process of an executable application. On Linux or Unix like operating systems a makefile is generated whereas on Windows systems it is possible to generate different project files which can be imported by integrated development environments like Visual Studio or Eclipse. Using this feature one can realize a *platform-independent* approach.

```
includes AppInclude {
 "~/boincadm/framework"
 "~/boincadm/src/api"
 "~/boincadm/src/lib"
}

libraries AppLibrary {
 "/lib", "pthread"
 "~/boincadm/framework", "visualgrid"
 "~/boincadm/src/api", "boinc_api"
 "~/boincadm/src/lib", "boinc"
}
```

It is common to use parameter files for the BOINC applications. The native way of doing this is to create *mapping files* on the server with a few parameters. Whenever clients connect to the server, they retrieve the application and all necessary parameter files. The following DSL fragment describes this procedure using the `infile` statement. The content is specified as an XML tree and could be iterated with a reference, e.g. `ObjectName1`. As a consequence of, binary data must be base64 encrypted [25]. Each reference contains the parameter as a *struct* or *class* definition.

```
infile "metropolis_data.xml"
                  as ObjectName1;
infile "param.jj" as ObjectName2;
infile "param.nn" as ObjectName3;
infile "param.ww" as ObjectName4;
```

After the execution of the client application the results are stored in *result files* defined by the statement `outfile` and are uploaded to the server.

```
outfile "metropolis_out.erg"
                  as ObjectResult1;
```

In general there exist several ways using a modeling process to develop a certain client application. As a matter of fact, every developer differs in his way to develop applications and it is necessary that the DSL supports this variety. For example, it is possible to link third-party libraries to the application using DSL statements. Furthermore, the application code can also be directly implemented into the `worker` part. The following DSL fragment contains an example which is used in [21]. Here, the `worker` starts the environment for execution instructions with the name `Spinhenge`. The statement `exec` defines pointcut expressions which are used by the AOP weaver process to deploy the scientific application. In this definition, the pointcut expression describes the working function in Fig. 8.

```
worker Spinhenge {
 exec "void %::Spinhenge::doWork(...)";
}
```

This statement could be replaced by other instructions, e.g.

```
worker Spinhenge {
 cpp {
  int a = 42;
 }
 action(modeledFunction(a));
}
```

Here, `cpp` starts an inline code area which contains native C/C++ statements. The variable `a` is available right after its definition and optional initialization within the context. It can be used by DSL defined functions like `modeledFunction(variable)`. Third-party applications can be executed using the DSL statement `wrapper`. It allows to call an external application, so called *legacy application*, and only one call is allowed to realize. Optional parameters for the application can be set in the *Configuration* package.

```
worker Spinhenge {
  wrapper("Matlab", "Argv[1] Argv[2]" [,
       weight, checkpoint_filename,
       fraction_done_filename, ...]);
}
```

These optional parameters are defined by the wrapper interfaces [11], [15], [19].

```
screensaver Spinhenge {
  render "% Screensaver
              ::Spinhenge::doWork(...)";
}
```

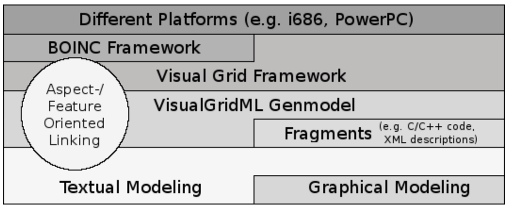
During the execution of an application different events can occur, e.g. events which could also be logged for diagnostic analysis in the above mentioned definitions. Furthermore an exception handling is described by the following DSL definition:

```
handle TypeOfException (: optionalName) {
 /* to be defined handler */
}
```

Predefined exception handlers are reusable by other exceptions. This is enabled by using the `ref` statement which uses the optional name `optionalName` of the previous example.

```
handle AnotherTypeOfException
   ref optionalName;
```

The BOINC framework uses interprocess communication (IPC) to exchange data between different application instances, e.g. scientific application, and screensaver. The native way to use IPC needs the definition of shared variables, e.g. in a C/C++ `struct` or `class` definition and furthermore different functions which handles these variables. A strict well-formed definition would be easier to use and reduces the effort of changing code parts in the source files. The DSL statement `exchange` describes the structure of the IPC with C/C++ language elements like datatypes which are usable in every application. The keyword `feature` defines an AOP pointcut expression which is used to assign values to the variable on the left hand side, e.q. `update_time` keeps the delta in milliseconds between the value updates. The listed AOP pointcut expressions are implemented in the *Visual Grid Framework* which is described in Sec. IV-E.



Different Platforms (e.g. i686, PowerPC)
BOINC Framework
Visual Grid Framework
Aspect-/ Feature Oriented Linking
VisualGridML Genmodel
Fragments
(e.g. C/C++ code, XML descriptions)
Textual Modeling
Graphical Modeling

Fig. 7. *Visual Grid Framework* Abstraction Layer

```
exchange {
 double update_time :
   feature "% Boinc::updateTime(...)";
 double fraction_done :
   feature "% Boinc::fractionDone(...)";
 double cpu_time :
   feature "% Boinc::cpuTime(...)";
}
```

To handle BOINC Trickle Messages the `TrickleUp` and `TrickleDown` commands are stated in the following listing. The `TrickleUp` needs two AOP pointcut expressions to check if a trickle up must handled and the trickle up handler itself.

```
 TrickleUp "bool checkTrickleUp(...)"
     do "% handleTrickleUp(...)";
 TrickleDown "% handleTrickleDown(...)";
```

The handler defined by `TrickleDown` is called frequently to manage the incoming messages by the BOINC server, e.g. command to abort one workunit or informations of the current BOINC credit points.

Furthermore, general descriptive information about the application can be defined with the statement `info`.

 description="Spinhenge@home Example";
 project="Spinhenge@home";
 version="3.16";
}
```

E. Visual Grid Framework

Fig. 7 shows the proposed *Visual Grid Framework* layer which is defined between the layer that describes the underlying computer hardware, the BOINC framework, and the *VisualGridML Genmodel*. The *Visual Grid Framework* offers a less complex access to the BOINC functionalities and handles the creation of applications for different platform targets, e.g. Intel 686 based 32-bit or 64-bit architectures.

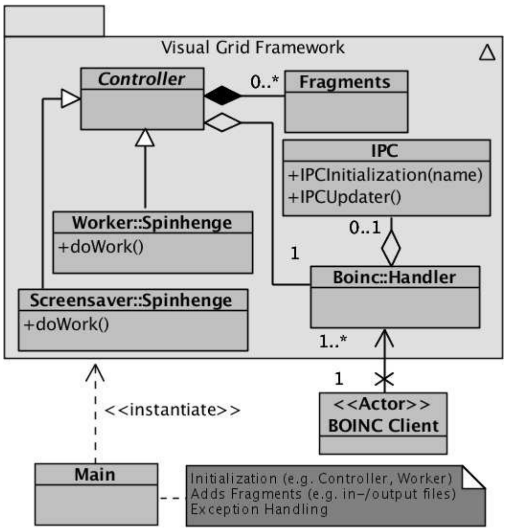

Fig. 8. Composition of the Visual Grid Framework Approach

The left side describes one approach to generate the function calls and logical program parts between the textual-/graphical modeling tools, fragments, *VisualGridML Genmodel*, *Visual Grid Framework*, and BOINC Framework. In Fig. 8 we show how the *Visual Grid Layer* works.

The `Main` class is generated by the code generation process and contains the implementation of the starting routines. This routine instantiates the interface to the BOINC framework as well as to the scientific application. The entry point of the scientific application is called using the *doWork()* functions of the *Worker::Spinhenge* and *Screensaver::Spinhenge* classes. These two classes are specializations of the abstract *Controller* class. The *Controller* class keeps track of all necessary data management, e.g. input, and output data files, checkpoint definitions, etc. The *IPC* class (Interprocess-Communication) is completely generated and implements the initialization and update routines. This class is used by the *Worker::Spinhenge* and *Screensaver::Spinhenge* classes for the exchange of data. The external *BOINC Client* class is an actor and therefore represents just the interface to the client. The BOINC Client has the full control of the executed applications and processes.

As a consequence, there exist two ways to generate an application within the *Visual Grid Framework*, (1) creation of a class which is derived from the abstract *Controller* class, (2) the definition of AOP *joinpoints* and *advices* as defined by the DSL in Sec. IV-D.

As a first test of our approach we have created an application which is similar to the BOINC sample to perform a transformation of lowercase to uppercase texts. The BOINC sample is based on approximately 400 lines of code, including the makefile, C++ header, source files, and 31 BOINC specific function calls. In contrast to this, our generated application contains only about 90 lines of code, including 60 lines of DSL code, and 30 lines of application specific code which performs the transformation. All defined dependencies, e.g. for the initialization of the process or exception handling, are resolved by generating files. Furthermore, a makefile is generated which on execution builds the complete application for the defined client platform architecture.

V. Conclusion

We have presented a first modeling language approach for developing Public Resource Computing applications on the basis of BOINC. We have demonstrated that the complete BOINC framework can be divided into a few logical packages that provide the necessary graphical and textual model elements to allow for a model-based development of applications with subsequent source code generation. Our approach is technically realized by using standardized and well-defined technologies [26]. Thus far, we have just implemented a small part of the BOINC functionalities. Key features like graphical and textual modeling elements, the *VisualGridML Genmodel* have been defined to an extent that we could show the general feasibility of our approach. However, further investigations with regard to the abstraction of the system architecture, dependencies, error checking, and the transformation to different target languages are needed. We have successfully performed a first test of our approach by modeling an existing BOINC application with just a few lines of DSL code using external libraries for the core computational routines and abstraction of the BOINC functionalities. However, most steps of our modeling process are still performed manually, and we are currently working on the creation of a unified development environment that supports the wide range of technologies, including a one and only graphical modeling framework which minimizes the need of textual modeling fragments, automatic dependencies resolving, completely error-free code generation, and higher support for legacy applications.

***Abstract*—Desktop-Grids have been around since the very early days of Grid computing, scaling into the millions of PCs, well established as regular distributed computing infrastructure for many research projects. Desktop-Grids collect CPU cycles from PCs contributed by donors, by volunteers who are willing to support science and research. This paper focusses on the energy efficiency aspects of Desktop Grid computing: the Green Desktop Grid, as a task of the EU-FP7 DEGISCO project [20].**

The key advantage of Desktop-Grids with regards to Green-IT over service Grids and data centres based on clusters of servers is the minimal heat density. Compute Clusters without energy intensive air-condition would run into thermal disaster within minutes. PCs participating in Desktop-Grids usually do not make use of any air-condition.

We will have a closer look on several aspects of energy consumption and computational performance in Desktop-Grids describing several distinct Green Methodologies to optimize compute unit specific energy consumption.

I. The need for Green Desktop-Grids

DESKTOP-GRIDS provide compute-power to scientists by contributions of resource owners, typically individuals at home but also institutions and companies. Compute time harvested this way does not request large upfront investment by the scientist; it is a low cost approach towards significant scientific output. Typically implemented using BOINC [17], sometimes XtremWeb [19] or other packages, Desktop-Grids are found among the largest Distributed Compute Infrastructures (DCI) [1]. Also known as Volunteer-Computing, Desktop-Grids have been around since the very early days of Grid computing [18], scaling into the millions of PCs contributing compute time every day. The aggregations of so many machines result in significant performance well beyond Petaflop/s for selected applications. For example: BOINC network averages about 5.1 Petaflop/s as of April 21, 2010 [2]. Key difference to service Grids like EGEE (now EGI) is the voluntary character of the resources – citizens contribute their PC's compute time to the Desktop-Grid projects in order to support scientific challenges of their choice. The FP7 project DEGISCO aims to support Desktop-Grid deployments in and beyond Europe, especially countries that strongly collaborate with the European Union. A focus topic of DEGISCO is the energy efficient handling of Desktop-Grid workload and management of resources, provided as configuration advice to Desktop-Grid operators. DEGISCO is accompanied by the EDGI project that continues to maintain and further develop the EDGES-Bridge [3], a gateway transparently connecting gLite, Unicore, and KnowArc based infrastructures (Service-Grids) to Desktop-Grids by automated translation of the job-languages.

Why Green-Desktop-Grids? As stated above, Desktop-Grids can aggregate hundred-thousands of machines. Power consumption of such large amounts of devices should be considered when making use of them. And yes, when used for computation energy consumption of PCs (like of any other computer) goes up. In the end, the contributor, the volunteer, who allows and enables the use of her or his machine, not only provides compute time for free but also pays for the additional electrical energy to cover the computation induced power consumption. Key advantage of Desktop-Grids is the minimal power density compared to conventional data centres. Typically, PCs participating in Desktop-Grids in Europe are not hosted in air-conditioned environments. Without the energy burden of air-conditions, Desktop-Grid are intrinsically “greener” than data centre based clusters and thereof built Service-Grids.

Green IT has been a hype topic claimed by the hardware vendors: buy new, buy more power efficient machines and you will become “Green”. Supported by the EC (European Commission) issued “Code of Conduct on Datacenters” [4], the massive refurbishment or fresh built of data centres has been encouraged. The effective outcome in order to “Green” our planet lags behind expectations: number one reason is the lack of investment budget. Number two reason might be lack of interest – maybe due to the fact that energy is still too cheap: some data centre CIOs still do not know their energy-bill nor -cost structure. Efforts to improve the energy efficiency of data centres by minimal impacting methods, by reorganization of usage and workload distribution [5] have been presented in the course of OGF Green-IT working group, but not led to significant uptake yet.

The need for compute power, the progress of Computer Aided Science (CAS), is massive and unstoppable. Researchers from all sectors are urgently looking for more compute power. By today and well ahead of operations start, PRACE resources are already overbooked by a factor of 5 [6]. Although Desktop-Grid suitable workload is *not* HPC and only the lean data fraction of all HTC, significant scientific

DEGISCO is supported by the FP7 Capacities Programme under grant agreement nr RI-261561

output has been, is, and will be produced with their help [7]. With the growing importance of Desktop-Grids in the scientific process and the significantly growing deployments, the need to optimize the use of energy is obvious both for general environmental considerations as well as for the attraction of contributors. Citizens providing their machines are interested in finding their contribution used in the most optimal way, producing more science and less waste-energy.

II. DEGISCO Green Desktop-Grid Methodologies

The environmental impact of IT and its specific usage patterns have been investigated in the recent years manifold. In the course of the roadmap consultation process, DEGISCO gathers analysis and best practices on Green aspects of distributed computing, focused on Desktop-Grids, but also comparing to classical technologies like clusters and data centres. Conceptually different methodologies will be investigated, based on technology means like Desktop-Grid client based ambient metrics, application profiling or adjustment of energy consumption per time interval, exploitation of natural ambient conditions, and possibly more. Some of those methodologies are technological, some are pure organizational. DEGISCO will promote this methodology inside the International Desktop-Grid-Federation [8] especially as part of a road map. This federation will offer consulting and advice based on these methodologies, continuing the roadmap process to reflect and integrate future findings and developments. One focus topic in the roadmap process is the application of Green Methodologies to achieve reduction in carbon dioxide footprint of research infrastructures.

A. Aims of Green IT: CO$_2$ footprint and the energy mix

Green IT aims were originally formulated to reduce CO2 footprint of IT activities. As extended scope reduction of energy consumption in general and especially thermal emissions in metropolitan areas, both impacting a) global climate b) local (micro) climate and c) human quality of life. Production of CO2 and accordingly the reduction of CO2 footprint are difficult to measure from the perspective of a concrete IT activity like computation.

Even if energy consumption as such is accounted for, it depends on the local energy mix how much CO$_2$ this is equivalent to. The electrical energy mix, the combination of electrical energy sources, depends on national specifics. The electrical energy mix (Table 1) in Germany [9] includes a nuclear energy portion of 27,5%, scheduled to be phased out, while the French [10] one (78,3%) is stable on a higher level. Denmark [11] produces 25% of its electricity consumption from wind – sometimes up to 150% (when strong winds produce more electricity that the Denmark needs) causing negative energy prices at the spot market [12]. Neither the single PC owner who contributes compute time to a scientific project nor the operator of the Desktop-Grid server that offers the respective workload item is in control of the energy source used to produce electricity consumed by the computational effort. Desktop-Grids are natively internationally or globally dispersed. While a specific Desktop-Grid server and its hosted projects may be presented to users from specific communities, there is no effective mechanism in place to "steer" or "control" the workload to contributors of a specific location or region. And it seems completely beyond the means of Desktop-Grid computing to control the workload may be executed only on machines supplied with energy of a "Green" qualified source. It seems to be possible to offer workload for the execution in a specific region – given that the contributing person takes into account and chooses to comply with the according recommendations. Nevertheless, the contributors have little control or even knowledge on the energy mix of their regional electricity providers. With a more general understanding of environmental protection, it is difficult to prefer nuclear power plants with their unresolved radioactive waste issues over natural gas powered electricity generation, although emitting carbon dioxide. As being in control only for the second half of the energy life cycle, IT activities can still use environmental friendly policies targeting to reduce energy consumption in general. It seems adequate to rephrase the core aim of Green IT to: Save energy!

Table I.
Zero CO2 electricity sources by 2007

Energy Mix	**Total**	**Nuclear**		**Renewables**	
Electricity	[TWh]	[TWh]	%	[TWh]	%
Germany	607,0	167,1	27,5%	58,2	9,6%
France	572,2	448,2	78,3%	66	11,50%
Denmark	40,5	0	0,0%	10,2	25,2%

B. € - metrics for Green IT success

In order to measure the effectiveness of energy saving policies and methods, we need to introduce a metric that can be "metered". The obvious advantage of "kWh" as the base metric for Green IT is the simplicity of measurement: electricity is metered everywhere. Different from data centres and conventional Service-Grids, policies and methods are applied and executed in Desktop-Grids only by the volunteer effort of the resource contributor. As success metric for Green IT, the translation into cost, into money, is helpful to connect to business considerations and propel motivation. With € (for kWh) as metric, contributors can relate their choice of workload and policy-compliance to the personal electricity bill: Green Desktop-Grids help the planet and your budget!

III. Six Green Desktop-Grid Methodologies

DEGISCO starts with a shortlist of 6 methodologies which are collection of best practices, techniques and policies:

- Ambient metrics based Green optimization
- Cool strategy: avoid air-condition use
- Energy profiling of applications

- CPU speed steps
- Exploitation of natural ambient conditions
- Time-of-day dependent energy tariffs

In the course of the roadmap process these methodologies will be challenged, refined or replaced, according to feedback and feasibility tests supported by contributors.

A. Ambient metrics based Green optimization

In order to tune DEGISCO connected Desktop-Grids towards saving of energy suitable configurations and parameters are to be identified enabling the Desktop-Grid client to intelligently select adequate workload. A regular PC [13] almost doubles its power consumption from idle 160W to 300W under full CPU load. Ambient temperature measurement or at least estimation (compare below: On the Difficulties of Temperature Measurement) could be used to control and potentially prevent download of workload items if the PC and its environment are too hot for comfortable or safe operations. The measurement and observance of ambient conditions, mainly temperature, is essential for several advanced Green Methodologies, too.

B. Cool strategy: avoid air-condition use

Desktop-Grids are the real Green Grids: lower energy density than clusters results in less energy wasted for cooling. However, this may not longer be true if air-conditions are used to assure proper operation of Desktops. Principles of cooling: Energy consumption by air-conditions range from 30% to >200% of the energy dissipated by the IT device (payload), depending on the cool-reservoir temperature the heat pump can utilize to get rid of the heat. The Code of Conduct on Datacenters quotes that most European data centres are actually worse: they consume more than 200% of the IT related energy for cooling, UPS and power distribution losses. The prime advice to configure Desktop-Grids: avoid air-condition use! Selection criteria for the “maximum temperature” as described above could be that temperature which would just not yet trigger the start of the local air-condition.

What if air-condition is unavoidable?

Should we recommend to participate in Desktop-Grids when resources are located in hot ambient? The answer clearly depends:

- If the additional workload by Desktop-Grids would cause proportional air-condition power consumption, a different strategy could be considered. Maybe by restricting the acceptance of workload to night times would help.
- If the air-condition is in full power use anyway – like in tropical ambient – the additional heat dissipation during compute load processing may not impact the total energy balance too much.

Example: light building structures with poor thermal insulation and continuously running air-conditions are de-facto standard in sub-tropical and tropical regions globally. If we assume a 3,5kW air-condition (2-3 room flat, small house) to run non-stop in order to keep the ambient temperature 15°C below the 40°C outside, additional heat dissipation of a standard office PC (60W idle, 120Watts fully loaded) would raise the ambient temperature by ~1°C (assumed 50% efficiency of the air-con). The 120 Watts compare to the 100W approximate basal metabolic rate + 20-40W brain activity of the human body – so the user of the PC will raise the ambient temperature for another 1°C. The raise in room or ambient temperature is minimal since the thermal balance in this example is dominated by the heat flow through the building structure. Massively higher impact on the room temperature is caused by cooking activities (in the n*kW range). This discussion is not finalized. We explicitly ask for support either by pro or contra arguments and references.

C. Energy profiling of applications

Applications will be investigated with regards to their energy profile. Different applications and codes consume more or less CPU at any given time, resulting in different energy consumption per time interval; they behave differently in raising machine and ambient temperature. According to our findings within the DEGISCO available pool of applications (The inherited EDGeS pool of applications: [14]), these are classified accordingly with a heat index as +, ++ and +++ for example. We refrain from using “green”, “orange”, and “red” at this point: The +++ index marks an application that makes maximum use of a given machine, is raising its temperature, but finishes the computation quickly. This behavior may total in less “energy consumed”/computation than the application which creates less heat/time. Still heat/time is an important parameter from a green operations point of view. As PC owners can select the project and by this the application they want to contribute to, they can take into account their specific knowledge of local operations conditions, primarily how much additional heat they can accept.

Limitations and implementation risk mitigation: If the energy profiles of the applications within DEGISCO and partner projects happen to be too similar, the demonstrated impact of the approach become less obvious. Means to adjust application energy consumption per time interval have been discussed and could be used for demonstration.

D. CPU Speed Steps

A similar effect could be achieved by exploiting processor speed steps, avoiding additional preparation work on the application side. Current processors provide multiple steps (8-16) for CPU speed, thus controlling energy consumption. Gruber and Keller discuss the use of “SpeedStep” among other methods in order to use the minimal CPU frequency to run an application at full memory bandwidth [15]. Different from the application, the OS and tools installed at the PC are not under control of the Desktop-Grid operator but the contributor, rendering the applicability of methods like “SpeedStep” questionable due to lack of resource control. Whether reduced preparation work on the application level balances the lack of control on the resource level needs to be found out. DEGISCO will call for volunteers supporting the installation of CPU speed step tools and monitoring and report about the benefits and difficulties.

E. Exploitation of natural ambient conditions

A completely independent green strategy we are going to investigate exploits a DEGISCO specific advantage: the aggregation of partners from various different geographies allows benefiting from differences in regional weather situations in order to save energy. Workload indexed as "+++" may systematically be offered to contributors located in low temperature areas while those in sunny summer weather will be offered to contribute for "+" workload.

Different locations yield different climates

- Kazakhstan, Amaty: http://worldweather.wmo.int/070/c00152.htm
- Russia, Moscow: http://worldweather.wmo.int/107/c00206.htm
- Hungary, Budapest: http://worldweather.wmo.int/017/c00060.htm
- Denmark, Copenhagen: http://worldweather.wmo.int/173/c00190.htm
- Spain, Zaragoza: http://worldweather.wmo.int/083/c01240.htm

Recruit regions with opposite weather conditions! Only "+++"-workload today? Sorry Zaragoza, Copenhagen is cooler! DEGISCO partners from Kazakhstan, Russia, and Spain confirmed the weather conditions reported on "world-weather" as already averaged – the peak temperatures exceed both into heights and lows significantly. Again, as DEGISCO just started so is this discussion – and your contributions are welcome!

F. Time-of-day or weather dependent energy tariffs

The value of electrical energy is usually changing according to the conditions of generation as well as by changing consumption. Accordingly, the tariffs for electricity are changing.

While in Germany electricity prices are high during lunch time, in Kazakhstan the energy prices go up in the evening – in both cases dependent on consumption.

Energy prices at the Spot markets vary depending on excess production capacity. Since wind energy can deliver significant amounts of energy, these spot market prices can even turn negative [12].

To improve the energy cost situation and to take advantage of excess Green electricity, advice could be given to contributors how to configure their Desktop-Grid-Clients to prefer workload during low tariff times.

IV. Desktop-Grid – the anarchistic virtual data centre

A major difference between a data centre situation and volunteer based Desktop-Grids is the almost complete lack of central control over the compute resources. Further, Desktop-Grid applications are executed as user with limited permissions (no root rights). Accordingly, installation of support tools, in our case for temperature and energy consumption measurement, is not possible without active voluntary contribution by the resource owner, installing tools with administrator (aka "root") rights. This cannot be done as regular Grid job: different from service Grids, Desktop-Grids implement highest security standards also on the execution side. Applications that are downloaded and executed on the contributed Desktop-Grid client are security validated and, dependent on the Desktop-Grid technology used, even rewritten to execute exactly that computation as described – and nothing more. Any activity beyond the sandbox, e.g. accessing local HW devices like sensors, is off limits for Desktop-Grid jobs. When DEGISCO is looking to gather detailed temperature and energy consumption data we will ask for volunteers to download and install tools and allow the upload of resulting metric data.

V. Difficulties of temperature measurements

In order to apply the Green Methodologies described, it is necessary to adequately understand the ambient conditions of the PC, especially the ambient temperature. Least effort would be the use of PC's built in temperature sensors – but there are difficulties to overcome. The temperature sensors built into PCs and laptops are optimized to support energy management of the PC and its components – not to provide ambient conditions, the kind of information we need. Mainly the position of the sensor determines what is measured. On-die temperature sensors may reflect the CPU internal temperature quite precisely while "system" temperature sensors are placed "somewhere" on the mainboard – delivering temperature measurements that cannot be interpreted meaningful without precise and detailed knowledge of the individual board. Although this seems doable in a lab situation, it is completely beyond scope and capabilities in case of real world deployed Desktop-Grids. The situation is not very much better in regular data centres: depending on the placement of the temperature sensor in the rack, a hot spot will be detected or not. A detailed temperature measurement at several positions in the rack is not commonly found. For safety reasons, the single temperature sensor is placed to detect the (known or anticipated) hot spot, caused by poor local airflow – delivering information misleading with regards to average, typical, or total (=full rack) energy consumption. Further complication is deriving from the application of temperature aware fan speed controls embedded in the systems. Originally developed for Desktops in order to keep their operations noise level convenient for living room conditions, meanwhile regular servers are controlling their fan speeds to provide exactly that amount of cooling needed to keep board temperature within the targeted operations range while enhancing the lifetime of the fans. Side note: The formerly already mentioned "Code of Conduct on Datacenters" explicitly requests control of fan speeds also on the data centre level. The result for our aim to understand the ambient conditions of a machine by reading its temperature sensors gets complicated by these features.

Still the information retrieved may well be sufficient for our aims:

1) Understand values delivered by PC internal temperature sensors as non-linear non-calibrated relative information on machine cooling effectiveness.
2) For ambient temperature use meteorological data by independent sources.

3) To calibrate and QA the methods, call for participation by contributors in a temperature measurement campaign.

Even qualitative temperature information is suitable to distinguish condition “too hot for workload” from “cool and ready to work”. To verify our understanding on ambient conditions, we started working with Mathias Dalheimer, Fraunhofer Institute ITWM, Kaiserslautern. Mathias developed a simple and low cost temperature sensor [16] that can be connected to the desktop or laptop (USB) and delivers proper ambient metrics. This temperature sensor may be offered to Desktop-Grid volunteers by mail-order, requesting the commitment to provide temperature measurement data for automated upload.

The sensor implements an USB1.1-device. The whole USB stack is implemented in software and does not rely on dedicated hardware, keeping the component count low. Digital temperature sensors provide high accuracy measurements. Since the sensors are attached via the Onewire bus, a single USB dongle can query up to eight different temperature sensors which can be placed at different locations around the PC. The software stack is available for Windows, Mac OS and Linux and allows users to query the temperature sensors. Both the hardware and software components are open source and can be modified to accommodate additional requirements.

Currently sponsors are looked for. If the device is produced in a small batch, the cost of an individual device should be around 10 Euro.

VI. Call for contributions: join the Desktop-Grid-Federation

Due to the specific character of Desktop-Grids as voluntary effort, the personal contribution of individuals is of prime importance and very welcomed. In order to improve Desktop-Grid service for science, the dear reader may consider joining the International Desktop-Grid-Federation, described in detail below. Especially welcome are your contributions to Green optimization of Desktop-Grids. To advance the Green optimization beyond the described basic methods, we need support by individuals, institutions, and projects. Contact: mail to green@desktopgridfederation.eu

Looking forward to hear from you!

Appendix: The International Desktop-Grid-Federation

Desktop Grids, Desktop Clouds, allow to employ otherwise idle computing time of Desktop computers for large computational programs.

Desktop Grids can be used inside an organization, or they can collect computing time from volunteers all over the country, or even all over the world. However, operating a desktop grid and developing programs for desktop grids poses specific challenges. That is why the International Desktop Grid Federation is formed.

A. Who should become member?

Organizations and persons can become member of the International Desktop Grid Federation. When should you consider joining? Your organization is operating a Desktop Grid and would like to share experiences with operators, get support and trainings Your organization has a lot of Desktop computers, and would like to make better use of them You want to develop computation programs for Desktop Grids Your organization wants to install a volunteer Desktop Grid, and wants to know how to attract volunteers You are interested in further developing Desktop Grid and Desktop Cloud technology You would like to integrate a Desktop Grid with other Service Grids (for instance based on gLite, KnowArc or Unicore). Your organization has large computational needs, and wants to know whether Desktop Grids could be used. You care about the environment and want to know how Desktop Grid can contribute to a Green ICT infrastructure with less power consumption.

B. Services offered by the International Desktop Grid Federation

The Federation offers several services for its member: Meetings, workshops and conferences: were you can meet and discuss with other members Training sessions and tutorials. Technical support in operation Desktop Grids Technical support in connecting Desktop Grids with other Grids and Clouds Web site and information centre. Material will be available in several languages.

C. Supporting projects

The services offered by the International Desktop Grid Federation are supported by two European projects: EDGI and DEGISCO. EDGI focuses on Europe and on integrating clouds, DEGISCO has an international approach.

D. How to become member

All services are available to all members. So become a member today. We have several options, for companies, research organizations, and persons. More information: http://desktopgridfederation.org

***Abstract*—With the growing amount of computational resources not only locally (multi-core), but also across the web, utility computing (aka Clouds and Grids) becomes more and more interesting as a means to outsource management and services. So far, these machines still act like external resources that have to be explicitly selected, integrated, accessed etc. - much like the concept of "Virtual Organisation" prescribes. This paper will describe how the development of dealing with increased scale and heterogeneity of future systems will implicitly open the door for new ways if integrating and using remote resources through a kind of web-based "fabric".**

I. Introduction

OVER the last few years distributed computing has gained in relevance, not only as a concept, but – more importantly – as a commercial reality: through "Clouds" and multicore processors which make concurrent compute units available for the average user [1, 2]. Notably, usage of these two environments differs significantly: Cloud systems are essentially server-like machines available over the internet and accessed accordingly (via e.g. remote desktop or SSH); as opposed to that the capabilities of multicore machines are locally available – implicitly there are no specific means needed to access the resources.

What is more, cloud systems typically deal with scaling a specific service or application multiple times according to access and availability needs, i.e. perform scale by replication. As opposed to this, multicore systems, just like high performance computers deal with scaling a single application "vertically" across the resources in the form of instantiating multiple processes that *together* form the application logic, as opposed to individually [3]. It should be noted in this context though that desktop systems and high performance computing systems differ in this respect: whilst the latter typically only deal with execution of one single process or thread per core at a time, desktop usage typically implies concurrent execution of multiple applications in a time-sharing manner.

In both the cloud and the multicore case we talk of "distributed systems" in the sense that the system on which the service / application is being executed consists of multiple resources connected via a communication and / or messaging link. From this perspective, we can specifically note that essentially clouds and multicore systems just provide different capabilities on essentially the same environment. Section II will elaborate how a common "denominator" of such a system could look like.

By exploiting the commonalities, rather than focusing on the differences, it would in particular become possible to exploit remote resources as if local, thus truly realising the grid's original concept [4, 5]. For example, an application could be replicated beyond the restriction of the local system, and new applications executed remotely without interfering with any local executions, thus competing over resources. What is more, even simple laptop systems would be enabled to execute demanding applications in the same fashion as on a home or office PC [6]. Whilst this is not a new idea as such (see [4]), its realisation has many impacts not only on a middleware, but more importantly on operating system and programming model. Sections III and IV of this paper will highlight in particular to how such a "resource fabric" could be realised and to which specific technological issues apply, respectively.

By overcoming these obstacles, new systems and implicitly new types of applications would become possible that allow following the worldwide trend of internet integration, dynamic outsourcing etc. in short, the future internet. Section V will describe these application areas in more detail.

As will be shown, it is not yet possible to overcome all technical issues easily, in particular since the "natural" technological development (i.e. the industrial provisioning) follows the laws of stepwise development, rather than disruptive (r)evolution. We will conclude this paper with an analysis of the main outstanding issues in section V.

II. The "New" Von Neumann Architecture

"Distributed systems" in their widest sense , i.e. including multi-core processors, clusters, clouds and grids all have in common that they integrate compute units over a communication link. The main difference thereby being the specifics of the linkage: whilst communication between cores in a multi-core system has a very low latency; cloud and grid systems in particular use the intra- / internet for communication, meaning high latency but considerably large bandwidth; and finally, HPC systems integrate different levels of linkage, ranging from multi-core interconnects to fast, broadband networks (100GB Ethernet, Infiniband).

This work supported by the S(o)OS project under FP7 grant agreement no. 248465 – http://www.soos-project.eu

In principal, latency can be compensated by bandwidth, i.e. if the delay is l and the bandwidth b, the effective data d_{eff} communicated in a set of messages over a time-frame t is

$$d_{eff}(t) = t * \left(\frac{b}{l}\right) * seconds$$

In other words, latency is anti proportional to bandwidth: if latency is high, bandwidth should be large too, respectively a low latency can compensate a small bandwidth, in order to reach the same effective data throughput.

However, an important factor has been subsumed in this calculation, namely the numbers of communications within that time-frame. Obviously latency impacts only per individual invocation, respectively message exchange (actually leading to half the throughput per communication side), meaning that the full throughput depends on the number of invocations, which is accordingly high if the latency is small, and low with a large latency.

$$Number\ of\ invocations = \frac{t}{l}$$

For non interactive systems this does not play a major role, the delays in communication are not noticeable as such – however, in applications that directly interact with the user (such as a word processor), any delay occurring between user input and system reaction beyond 0.1 seconds leads to the impression of a "non-reactive" system, and beyond 1 second, it will even disrupt the user's flow of thought [7].

Browsers in particular take a position somewhere between interactive and non-interactive and users show a slightly higher tolerance towards waiting time than in local applications (4 seconds for maintaining the flow of thoughts according to [8]). Implicitly, offering applications *via* the web typically leaves an impression of being slow and unresponsive.

Latency is always a source for problems, when task execution is *synchronously* dependent on communication, i.e. when the querying task is blocked whilst it is waiting for a response. This affects in particular parallelised applications where the individual processes need to synchronise data.

The average developer however is not aware of the connection details – not only are they difficult to acquire, but even more difficult to represent in the program in some form. The general tendency is therefore to make use of asynchronous messaging in the web domain (clouds, grids) and synchronous messaging in compute clusters.

However, embarrassingly parallel applications scale well in any environment and by removing the interactive from the processing part, web based systems can even be exploited for demanding user applications. To achieve this, we do no longer need to distinguish between different resource types, but between their connectivity. From this perspective, the different notions of distributed systems fall together as a complex system consisting of computation resources connected over a communication link. Modern systems are therefore no longer building up a strict von Neumann architecture, but a modular system that connects any amount of von Neumann *like* units.

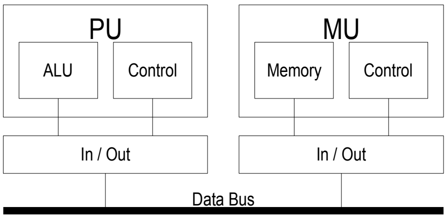

Figure 1: A modified von Neumann architecture that depicts any form of distributed machine as a type of linked compute units.

In particular from a programming perspective, we can therefore derive a modified von Neumann architecture as depicted in Figure 1: in particular the I/O moves closer to the PU (processing unit) thus allowing for connectivity between multiple PUs without an explicit single central instance. We also distinguish between processing and memory units (MU), which are connected through a dedicated I/O. It must be noted that current multi-core systems do not make use of an explicit I/O unit for core-2-core communication – whilst this is expected to change, the according I/O will most likely differ from the one connecting outside the processor. It must also be mentioned that cache access is not linked to an I/O as such, but to a memory controller – again, long-term developments (e.g. ring over caches) will impact here. All this however, has no impact on the programming layer.

In this view, clusters, multi-core processors and cloud or grid based systems are essentially identical. So far this model is essentially realised through according means on the middleware level (with the highest level of abstraction being represented through distributed workflows).

A. Data management in the "new" model

The massive distribution of data over multiple machines (i.e., storage points) as provided by this new architecture fundamentally changes current data management concepts, too, in particular data generation, exchange and storage. These phases are usually extremely time-consuming, and thus require new mechanisms, strategies and tools that manage the movement of particular data sets (similar to [9]) automatically across a storage hierarchy.

Similar to the code (see below), data must therefore be managed in a more intelligent fashion, according to the points of access and the degree of synchronisation, respectively coherency across usage points (see also [10]). As such, data that is frequently used shall be moved to highly parallel dynamic storage (e.g. parallel file systems like Oracle's Lustre (http://www.lustre.org/) or virtual distributed file systems like GFS [11] or a combination of both), while archived data shall reside in "passive" storage devices (e.g. low-cost storage devices or robotic tape libraries). To allow for this separation, a fundamental requirement is the ad-hoc allocation, use and release of particular storage space. Hence, algorithms shall automatically request necessary space but also track and delete unused data from these dynamic storages, so as to minimise storage costs and increase throughput.

Similarly, replication of data represents a key issue to increase data locality and availability. Management of replicas has to carefully consider lifetime issues to remove outdated pieces immediately. New replicas should be dynamically created, distributed and / or destroyed based on users' and applications' needs but also according to technical requirements [12]. In shared environments, i.e. where multiple access points require the same data, serious consistency issues across nodes have to be addressed [13].

Of particular relevance is also that data source and applications are not necessarily directly coupled. Collections of data sets shall be organised as hierarchical directories. Such abstraction will essentially change the way the I/O is expressed by applications and will involve data exchange and storage management in a form that maps data sets into physical devices without affecting the application's behaviour.

III. Weaving Resource Fabrics

The classical approach towards dealing with distributed systems consists in providing a form of middleware that translates function invocation, instantiation etc. into a set of remote procedure calls or web service calls. The actual details depend not only on the realisation but also on the domain applied to:

In multicore systems, the actual transaction logic is encapsulated and realised via the hardware; supercomputer clusters employ some form of dedicated communication programing model (with either explicit (e.g. MPI) or implicit (e.g. PGAS) messaging) that is translated into ports and sockets at compile time and the grid / cloud support typically builds on http protocols that are typically translated into ports and sockets at run-time.

In other words, the actual type of communication bridge is transparent to the user, though he will still have to use it in different ways, depending on use case and environment. Though there are ways of controlling and configuring the communication link, there is little possibility to exploit this dynamically for maintaining distributed code – in other words, parallel programming models that use synchronisation for control base on the assumption that the underlying infrastructure is effectively homogeneous.

Considering however that neither the resource infrastructure, nor the program is effectively homogeneous: typical applications, even in the strong scaling based HPC domain, the actual algorithm consists of both parallel and sequential segments that interchange during execution. What is more, e.g. in typical (unstructured) grids algorithms (such as blood--flow simulation etc.), the communication relationship between the parallel processes is not symmetrical, meaning that the code would benefit from a distribution on the infrastructure aligning the connectivity between compute units with the neighbourhood model of the code.

The classical means to developing parallel applications consists in either segmenting the work or the data by identifying natural partitions to either of those [14]. Whilst this is the most common approach, it suffers from the drawback that it a) requires good knowledge about the program and the concurrency in work and data, necessitating additional development work; b) the partitioning may be too small or to big to be efficient, in particular if the communication exchange between segments is not considered properly; c) heterogeneity and structure of the underlying system are mostly unused – what is more, if the according effort is undertaken to adapt code to the specific system, it will become less portable; and finally d) not all kind of segments can be identified this way. Heterogeneity and architecture of the system are typically regarded as obstacles, but program execution can actually benefit from this structure by reflecting the "natural" behaviour of an application.

We can identify the following key aspects of any algorithm:

1. Concurrency – some functions are executed without explicitly sharing data or resources. In this case these segments can be executed in parallel.
2. Parallelism – similar to concurrency, some functions operate on a common data set, but the actions they perform are not directly dependent on one another. This is typical for loops over large grids ("loop unrollment").
3. Interactivity – in particular in desktop applications, the interface towards the user can be easily defined by the connectivity to external input resources.
4. Background Tasks – are tasks waiting for specific events to execute and with little relationship to the main execution (regarding data dependency).

Similarly, the communication needs are not the same between all these parts, though there is no general statement about the relationships possible: concurrency and parallelism do not necessarily imply high connectivity (low latency), as e.g. embarrassingly parallel applications show; on the other hands, events processed in the background may require immediate response and interactivity does not mean that all processing on the input data has to be executed immediately (cf. word count and spell-checking in modern word editors: even though they react "immediately" to any input, the delay until the actual results are available is of no concern to the user and hence typically not even noticeable. Again, keep in mind that if the result is in some form relevant (in the sense of often checked by the user), the time frame for maintaining a flow of work is 1 second [7].

A. The structure of applications

The structure of an application can therefore be used as an indicator for its distributability (and, to a degree, parallelisability). The (runtime) behaviour provides additional information about the actual connectivity between the individual segments and thus its requirements towards the communication model, i.e. the relationship of latency versus bandwidth.

Implicitly, runtime *behaviour* effectively provides more information about the potential code distribution than the programmer can currently encode in the source code. This is simply due to the fact that this is not in-line with our current way of writing programs and is implicitly not directly supported by programming models. The foundation is however laid out by integration of remote processes (web services) and dedicated synchronisation points in parallel processes – this does not always reflect the best distribution though, as the according invocations are mainly functionality- rather than communication-driven.

A way of identifying and exploiting the "behavioural" structure of the application for distribution purposes consists in run-time analysis and annotation of the code and data memory to produce a form of dependency graph (cf. Figure 2) which depicts the invocations of memory locations (code) and read / write operations on data.

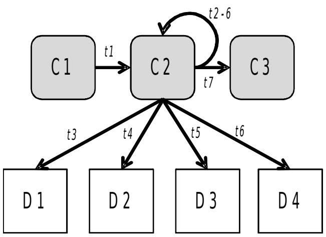

Figure 2: A simple code (C) and data (D) dependency graph of a sequential application with a loop over an array (C2). The graph denotes a sequence of actions with t_x representing the x^{th} transition, respectively access action.

In order to acquire the according code and data blocks, the basic starting point consists in identifying jumps and non-consecutive data accesses. Figure 2 exemplifies how the graph information can be used to identify an unrollable loop (C2) that consecutively accesses unrelated memory blocks to produce a result. In this simplified case there is no data dependency between C1 and C2, or even between C2 and C3, which means that the unrolled C2 blocks do not even have to be synchronised. An example of such a loop would be

C2: for (int i=0; i<4; i++) a[i]=0;

As opposed to this, Figure 3 depicts the example of a loop that can not be unrolled due to dependency issues in C2. This loop could look like

*C2: for (int i=1; i<3; i++) a[i]=a[i-1]*2;*

Notably, the examples given are not sensible for parallelisation, as the actual work load per iteration is too small to compensate the overhead for spreading out, communication etc. All analysis so far is based on the simple fact of data relationship and dependency – not unlike to the approach pursued in StarSS [15]. Accordingly, even though a pattern based approach like the one presented above does principally provide information about the distribution and parallelisabilty, it does not actually increase the execution performance.

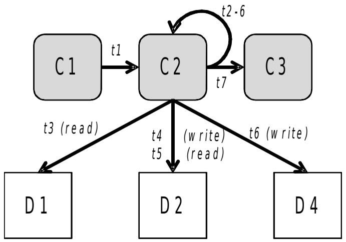

Figure 3: Example of a loop that is not unrollable and its representation in a dependency graph.

In order to not only identify principle points of distribution and parallelisation, but to also make code execution more efficient, so as to exploit the specific benefits of a parallel infrastructure, further information about the code behaviour is needed – in particular the “strength” of code / data relationships, and the size of the segment. Note that timing can be derived through more detailed sequential information (i.e. in Figure 2 or Figure 3 by storing actual timestamps in t_n). Strength of relationship is thereby proportional to amount of invocations divided by the full execution time.

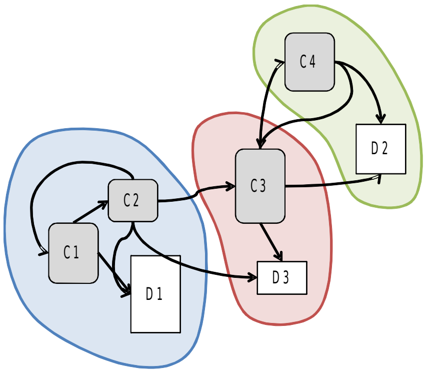

Figure 4: A dependency graph with implicit relationship strength (length of the vector) and size information (size of the block). The three areas depict potential areas of segmentation.

With this information, we can derive a graph (Figure 4) where the the strength of the relationship (e.g. C2 calls C3 less often than C1 calling C2) and the size of the underlying code / data is encoded as weights of vertices and edges. For simplicity reasons we left out timing information in the figure and concentrated on a very simple code structure (without loops or similar) – according data will be provided in future publications.

The dependency information in this graph, in combination with the size information can be used to extract different segments in the form of subgraphs according to nearness (connection strength) and combined size. Or to put it in computational terms again: according to the number of memory accesses with fewer accesses implying a potentially good cutting point. Each segment reflects the code to be executed on one compute unit (core, node etc.) and connections across segments need to be realised through a cross-process communication link. Information about the bandwidth and latency of the system's specific communication links can thereby serve as an indicator for cutting point identification, if it is respected that access across segments is effectively identical to data passing – accordingly, the temporal sequence and dependency of access constrains the segments' independency and hence concurrency. In order to not exceed this paper's limitation, we will not elaborate the segmentation algorithm in detail here.

It is obvious that one of the major problems for an efficient segmentation consists in the right data gathering granularity: whilst too fine data will cause memory and algorithm to go over bounds, too coarse information will lead to too strong relationships and too large segments, so that the effective gain through distribution is counterweighed by the overhead for communication and memory swaps.

B. Life-cycle of applications in a resource fabric

As noted, the major part of the information about the code is acquired at actual run-time – implicitly, the distribution information may change during execution, leading to potential instabilities. In this section we will examine the full lifecycle of an application executed in such an environment and implicitly the steps involved to better exploit a scalable (and potentially dynamic) environment can be captue:

1. Analysis of the application behaviour ("Analyse"): In an initial step (first time the application is executed), there is little to no dependency information available, unless an according programming extension (such as StarSS) was applied. This means that initially the application is executed locally in a virtual memory environment that logs the run-time behaviour and hence the dependencies between code partitions. Implicitly first time invocation is effectively identical to sequential execution – even though user provided parallelisation (if any) can still be exploited.

2. Identification of appropriate resources ("Match"): The dependencies in the application graph reflect the communication needs between segments and thus implicitly indicate the required infrastructure architecture, including type and layout of interconnects. But also specific core types can be exploited to a degree – e.g. Figure 2 shows clear vectorizable behaviour and other microarchitecture specific patterns can be identified, which would exceed the given space though.

3. Distribution and adaptation of code and data ("Distribute"): When appropriate resources could be identified, the code segments can be distributed across the infrastructure accordingly. In the simplet case, all partitions will be uploaded prior to actual execution, in which case no additional data has to be distributed at runtime (besides for the data transported during communication). However, in principle, it is possible to distribute the segments in their order of invocation, though this runs the risk of potential delays.

4. Execution and run-time analysis ("Execute"): Actual execution is principally identical to any distributed program execution with explicit communication between process instances. However, as opposed to an explicitly developed parallel program, the source code in this model has not been altered and the communication points and tasks are unknown to the algorithm itself. Accordingly, the infrastructure has to take care of communicating the right data at the appropriate time. This is principally identical to the PGAS approach (http://pgas.org/), which provides a virtual shared memory and deals with the communication necessary to enable remote data access. Effectively the system for enabling distributed execution in the model proposed here must enact the same tasks directly on the (virtual) memory environment of the operating system, rather than on the programming level.

During execution, the system may continue analysing behaviour (cf. step 1 "Analyse") in order to further improve the segmentation information and granularity. As program behaviour changes according to code dependency, the main problem to avoid in this phase consists in ensuring and maintaining an *efficient* stability of the distribution. Monitoring and segmentation must therefore not only consider the dependencies, but also higher-level parameters that implicitly define the stability of a given segmentation. Though there is some relationship to SLA based monitoring, these parameters should not be confused with common quality metrics.

5. Information storing (Store): Behaviour and distribution information should be stored after execution in order to be retrieved in the next iteration, thus allowing to skip step 1 and thus improving the process.

The main issues in the life-cycle consist obviously data exchange and synchronisation of the segments which are treated as distributed processes. If data and execution are not carefully aligned, inconsistency may lead to serious crashes, deadlocks, or serious efficiency issues due to overhead. It is therefore not only relevant, from where data is accessed, but also when and in which order. Ideally, data is being transported in the "background" whilst the segment is mostly inactive. Due to lack of space, we will not elaborate these issues here – suffice to say that by treating the segments completely isolated and swapping all memory during execution pass-over, coherency and consistency is ensured.

IV. A Middleware for Resource Fabrics

In order to achieve this goal, the execution environment must accordingly provide some capabilities to capture memory access and intervene with code progression so as to pass the execution point at the boundary of the individual segments. Effectively this means that the system provides a virtual environment in which to host and execute the code – a full virtual system however would impact on execution performance. Whilst this may be acceptable for some type of applications where simplicity of development ranks higher than performance, in particular in scalable environments, efficiency typically ranks higher.

The system does not necessarily need to provide a *full* virtual machine, but in particular a virtual memory environment and a set of interfaces to access (shared) resources – in other words, an operating system. Since effectively in all execution parts memory access needs to be controlled, a centralised operating system approach would create a serious non-scalable bottleneck and additional delays due to message creation and communication would turn out a major performance stopper. This relates to the major reasons why monolithic, centralised operating systems show bad horizontal scaling capabilities [16].

In order to achieve better scalability the individual compute units hence need some local support to reduce overhead and enable virtual memory management in a form that can also identify and handle segment passover. The S(o)OS project (http://www.soos-project.eu) funded by the European Commission investigates into new operating system architectures that can deal with exactly this type of scenarios. The approach thereby essentially bases on a concept of distributed microkernel instances that fit into the local cache of a compute unit (processor core) without obstructing it, i.e. leaving enough space for code and data stack.

We can essentially distinguish between two types of OS instances in a resource fabric: firstly, the main instance that deals with initiating execution and distribution, as well as scheduling the application as a whole. Secondly, the local instances that effectively only deal with communication and virtual memory management. In effect, all instances could have the same capabilities [16], which would make them larger and more complex to adapt to specific environments though. In S(o)OS the principle is extended with on-the-fly

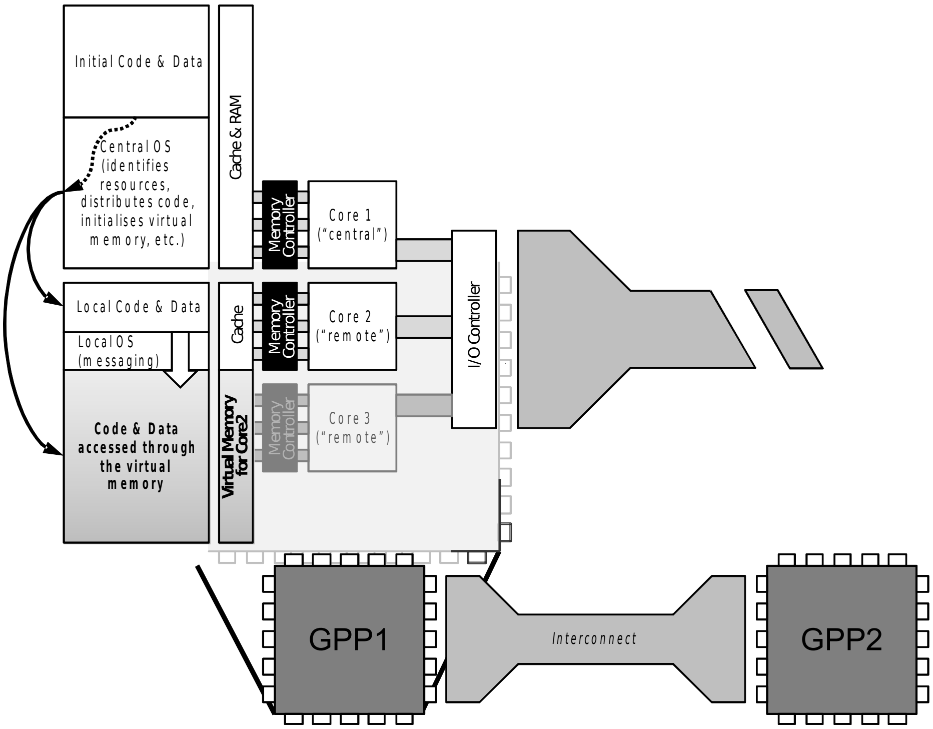

Figure 5: A distributed micro operating system and its relation to the individual compute units in the system. "Remote" cores can be hosted within the same processor or principally a remote machine.

adaptation of local OS instances according to application requirements and resource capabilities – this way, the kernel can even support adaptation to resource specifics without the central instance having to cater for that [17].

In Figure 5 we depict the principle of such an operating system with respect to the relationship between cores (or compute units, comes to that): typically one selected unit will take over the initial responsibility for code and data, i.e. loading it from storage, analysing it (respectively retrieving the annotations) and distributing it accordingly. The segmentation information (i.e. the memory structure derived from the dependency graph) will be passed with the code segments, allowing the local instance to build up the local virtual memory and implant system invocations at the appropriate time (during segment pass over).

A. Distributed execution

Pure distributed (as opposed to parallel) execution is effectively similar to context switching during time-sharing, only that the "new" state is not uploaded from local memory, but provided over the communication link between the initiating unit and the one taking over. However, parts of the state (code and base data) can principally already be available at the destination site due to predistribution according to the dependency graph (cf. above).

Similar to context switching, the application itself does not have a dedicated point at which to perform the switch (or even enable it), though with additional programming effort context switching can be avoided (thus leading to single-task execution, up to a point). As opposed to multi-tasking operating systems, however, a S(o)OS like system must initiate the context switch (execution pass-over) at a dedicated point, according to the segmentation analysis (cf. Figure 4).

This point is effectively the end of the local segment and can thus be initiated by a simple *jmp* (jump) command into the virtual memory address space of the new segment and can thus simply be appended to the partition. Just like with any access to remote data (be that due to branching or data access), the operating system has to intercept the request prior to its execution, similar to classical virtual memory management. The MMU (Memory Management Unit) of modern processors supports this task already, but would need to be extended to also cater for the specific needs of a distributed (cross-unit) memory virtualisation.

B. Access across

Modern systems supporting a fully distributed environment will hence not only need to check for *local* accesses to virtual memory addresses, but also for remote ones. Whilst a classical local cache miss would lead to a page swap, in the environment promoted here, a cache miss could indicate that the actual endpoint is hosted remotely. Accordingly, the destination address needs to be matched against the dependency graph based distribution to identify the real endpoint.

In principle, this endpoint may not be known to the local instance (in particular true for dynamic environments) in which case the memory address resolution request needs to be forwarded to other OS instances – though this could be the central one (cf. Figure 5), a broadcast to available instances may be more effective due to concurrency issues.

Far more important, the operating system needs to identify whether the remote access is a data access request (*mov, in, out* etc.) or a code branch (*jmp, call*). In the latter case, local execution will be halted and the overall execution point be passed over to the remote instance (cf. above). The destination therefore must be able to interpret the entry point like a local jump (out of virtual space).

C. Data Maintenance

As opposed to passing over execution, data access across the units means that the remote information needs to become locally available in some form. The OS instance has principally 3 options to deal with data access:

1. preemptive distribution: provide the data to all requestors, before they actually try to access it
2. context switch: pass all status data when passing over the execution point to a remote instance (does not apply to parallel processes)
3. on demand: make data available and accessible the moment the remote process requests it

The actual decision will not only depend on time of access (in particular for parallel processes), but also on size of the data and on outstanding tasks of the processing segment. For example, if the data will only be ready by the end of the segment's processing, there is not point in distributing it earlier. However, if the data size is too large for single provisioning without introducing unnecessary delays, partial data updates according to the data segments (cf. above) may be distributed ahead of time (pre-emptive). Note that current processor architecture does not allow for easy background data transmission and in most cases the communication will stall execution of the main process.

As noted, a particular issue in this context consists in ensuring data coherency across segments and avoiding deadlocks. Intel's MESIF protocol over the Quick Path Interconnect [18] is one means to ensure cache coherency in a distributed environment at the cost of access delays. The basic principle of this approach consists in checking the consistency of a datum at access time by verifying it against all other replicated instances. Obviously this protocol does not scale very well and requires a specific type of architecture that will most likely not be supported in future large scale environments any more [19].

V. Exploiting Resource Fabrics

Since the system primarily caters for distribution of an application across a (potentially large-scale) environment for effectively sequential execution, how would this approach help solve the problem of dealing with future infrastructures? The system offers two major contributions that will be discussed in more detail in this section:

A. Supporting High Performance Computing

Though the primary concern is distribution and not parallelisation, the features and principles provided by a S(o)OS like environment deal with essential issues in large scale high performance computing: namely (1) exploiting cache to its maximum, (2) providing a scalable operating system, (3) matching the code structure with the infrastructure architecture and (4) managing communication and synchronisation in a virtual distributed shared memory environment.

Whilst the system does not explicitly provide a programming model that deals with scalability over heterogeneous, hierarchical infrastructures, it does support according models by providing additional and enhanced features to deal with such infrastructures. In particular it implements essential features as pursued e.g. by StarSS and PGAS (Partitioned Global Address Space): the concurrency information extracted from the memory analysis is consistent with the dependency graph that StarSS tries to derive [15] and could be used as an extension along that line. The main principle behind PGAS on the other hand consists in providing a virtual shared memory to the programmer, with the compiler converting the according read / write actions into remote procedure calls, access requests etc.

B. Office@World

A slightly different use case supported by the S(o)OS environment consists in the current ongoing trend of resource outsourcing into the web (see Introduction). As has been noted before, an essential part for web exploitation consists in maintaining interactivity whilst offloading demanding tasks. As we have shown, this does not only affect code, but equally data used in an application – accordingly, the features are of particular relevance in a future environment where most code and personal data will be stored in the web.

As discussed in detail in [6], the system thus not only allows that code and data becomes accessible and usable from anywhere at any time (given internet connectivity), but also virtually increases local performance of the system. This enables in particular frequent travelers to exploit a local system environment for their applications whilst using data and code from the web – future meeting places could thus offer compute resources that can be exploited by a laptop user, but also the other way round, i.e. a home desktop machine could replicate the full environment of the laptop. A low-power, portable device could thus turn into a highly efficient system by seamlessly integrating into the "resource fabric" without requiring specific configuration or development overhead [6]. This is similar to carrying an extended secure full work, respectively private profile with you.

VI. Conclusions

We have presented in this paper an approach to dealing with future distributed environments that span across the internet, multiple resources and multiple cores, but also across different types of usage and applications (such as High Performance Computing and Clouds).

"Resource Fabrics" are thereby an effective means to integrate compute units non-regarding their location and specifics. We have shown how a general view on computing resources can serve as basis for such a development, enabling higher scalability. To this end, a more scalable operating system is required that enables the explicit usage of resource fabrics as discussed here.

The according OS is still in a highly experimental stage, and more data is needed for concrete performance estimations – however, the basic principle has already been proven implicitly by in particular the Cloud Platform as a Service movement, where the dichotomy of interactive and "executive" part of the application is used to exploit remote resources. Many issues still remain speculative, though, for example regarding the execution of parallel applications where time-critical alignment is crucial. Along this line in particular the concurrent exploitation of remote resources, leading to potential time sharing of individual units (and their resources, such as I/O) still needs to be assessed more critical. With the general movement towards multi-cores, it can however generally expected that time-sharing during execution time is no longer a valid execution model.

In this paper we have used a lot of simplifications, mostly due to size-constraints. It will be noticed however, that we did not even touch upon the issue of security, which will be a major concern in scenarios such as the "office@world" one. So far, we did not touch upon this as other more technological issues need to be solved first - according concepts are expected in the near future.

2nd International Workshop on Medical Informatics and Engineering

MI&E 2010 will bring researchers, developers, practitioners, and users to present their latest research, results, and ideas in all areas of medical informatics, engineering, and artificial intelligence in medicine and health care.

MI&E 2010 will provide a forum for the exchange of ideas between physicians and computer scientists and engineers to address the important issues in those areas. Papers related to methodologies and applications in medical informatics, telemedicine, and eHealth are especially solicited.

The topics of interest include, but are not limited to:

- Health Care Information Systems
- Clinical Information Systems
- Medical Image Processing and Techniques
- Medical Intelligent Systems for different medical tasks
- Medical Expert Systems
- Applications in Medical and Health Sciences
- Artificial Intelligence Techniques in Health Sciences
- Medical Databanks, Databases, and Knowledge Bases
- Neurocomputing in Medicine
- Ontology and Medical Information Science
- Bioethics and Health informatics
- Web-Based Medical Diagnosis
- Health Care Process Management
- Intelligent Agents

Agile methodology and development of software for users with specific disorders

Rostislav Fojtik
University of Ostrava, Department
of Computer Science, 30.dubna
22, Ostrava, Czech republic
Email: rostislav.fojtik@osu.cz

Abstract—**The paper deals with possibilities of information technologies when improving communicative skills of children with specific disorders, such as autistic spectrum disorders, Down syndrome, mental retardation, etc. The development of an application stemming from the communication system PECS (The Picture Exchange Communication System) and its Czech variant VOKS is the base of this paper to show specificity of the development and verification of software for the given group of handicapped users. The paper shows suitability of using agile methods of software development for a concrete application which is designed for users with specific disorders. It tries to show advantages and disadvantages of new methodologies, particularly Extreme Programming. Agile methodologies of software development appeared in the second half of the 90's of the last century. Thus it concerns new ways which have not been spread massively yet.**

***Key words*: Agile methodology, autism, Down syndrome, Extreme Programming, mental retardation, VOKS, RUP, testing**

I. Introduction

USE OF information and communication technologies has reached massive expansion recently. Computer users are to be found in every social and professional group. Computers simplify a lot of work tasks, make methods of communication easier and more accessible, intermediate new information, etc. These modern technologies can play a role of important supporting and compensational means for a group of users with specific needs. It is mainly people with some mental and health problems who face difficulties with communication, and common means of communication are usually unusable for them. Computers can act as a positive agent in such cases. However, hardware and software must be adjusted to the specific needs and it is not possible to implement experience gained and applied with common groups of users.

There is a potential group of users with specific disorders who could make use of the development of communication skills. E.g. people with autistic spectrum disorders, Down syndrome, forms of mental retardation and other development defects which cause problems to learn and use spoken language, written text, and other commonly used means of communication. Various methodics bringing interesting results have been worked out to develop communication skills of people with the above mentioned disorders. For instance, such methodics is the system PECS (The Picture Exchange Communication System) and its Czech variation VOKS. The base is a use of pictures representing particular concepts, things, activities. The user gradually becomes familiar with new concepts – pictures, which are then incorporated in their list. Choosing pictures and placing them on a sentence strip helps them learn to create even simple sentences. [7]

II. Metodics for learning

Based on the requirements from special school, we are developing an application which should facilitate communication with a child with specific disorders such as autism, Down syndrome, mental retardation and others. Autism is a mental handicap which demonstrates in worsened communication skills. Speech formation of people with an autistic spectrum disorder is delayed and some of them do not speak all their life or they use only limited number of words, frequently corrupted. Several methodics to improve their communication skills have been developed. [15]

One of them is the PECS methodics created in 1985. It is an alternative education and communication method for communication between an adult and a child handicapped by autism, mental retardation, and other specific disorders. [16] The fundamental principle is an exchange of a picture representing a particular thing for a real one. Continuous practice leads the child to learn how to use concepts correctly and improve its communication skills. The whole process is emphasised by stimulation. For instance, the child gets a chocolate if it brings the correct picture. Follow-up education leads not only to knowledge of pictures – concepts, but also to composing a short sentence from the pictures. The last phase of education encourages the children to comment independently the action around them and to answer direct questions. The system also helps some pre-school children to develop speech. An elaborate methodics of work with a system provides six training phases with examples, manuals, and advice [3] [2].

The Czech system VOKS mainly stems from the methodics and principles of PECS. However, it brings some improvements and it tries to adjust to particularities of the Czech language. Unlike PECS, it emphasises visual support of speech of both communicating partners. Thus there are changes to basic situations in all lessons. The methodics is divided into two basic parts. The first contains important information concerning teachers of the VOKS system and training environment. In addition, it describes preparation of individual tools for communication and the way of reward choice before the whole training of the communication begins. The second part contains educative lessons, which form the backbone of the education. The client learns to ask spontaneously for a favourite thing in exchange for a picture, to go on his own to the symbol container to get a picture and then to hand it in subsequently to the partner. They learn to ask different people about anything in an unfamiliar environment, to choose appropriate symbol from several pictures, to complete correctly a simple sentence on a sentence strip using pictures and then to ask by help of the sentence strip. Finally, they learn to react to various questions and to comment on the environment around them. The supplementary lessons then develop picture inventory and syntax [13].

III. Application voks

When designing a new application environment, it was necessary to get rid of all control features which were not directly related to the main use of the programme, and which could lead to early closing, new configuration, initialisation of new actions, etc. A lot of children find difficult to concentrate on realizing the needed performance. They frequently unwillingly click the mouse or wander the cursor round the screen. Thus it is highly important that children could not consciously or by mistake initiate functions indirectly related to the course of the programme.

The application control must not be demanding, unclear, or complicated at all. Generally common activities (such as double-click on a mouse) are almost impossible for numerous users with specific disorders. The control features of the programme must be conveniently large and their start-up and control as easy as possible. An ideal case would be if the application, having been opened, took up the whole screen of the desktop, being maximized all the time with no possibility of any change. The use of the mentioned software counts with the use of special hardware to control the computer. Users with motor handicap are e.g. supplied with IntegraSwitch, which works as an aspiration-expiration switch. Classical mice and keyboards are replaced by alternative positioning devices and keyboards, such as BickTrack, KidTrack, Roller Joyistick, BigKeys, IntelliKeys, various sensor buttons, and others. The main advantages are larger control features and more robust construction. On the other hand, the disadvantage is usually the price which exceeds several times the price of commonly used hardware. Purchase of such special devices can become unaffordable for many families with handicapped children. The solution could be use of touch screens, e.g. in new types of computers generally called nettops. It is a kind of cheaper computers containing all parts in one case together with a touch screen. The user can control the applications directly on the touch screen, which seems to be more convenient especially for children with specific disorders than using mouse or other positioning devices. Some children have motor problems when using mouse, moreover they have problems with moving the mouse while concentrating on another place - on the screen. Nevertheless, despite all of the above mentioned special hardware tools, it is convenient to create the developed software in a way to be usable even on common desktops, or notebooks with their usual peripherals.

IV. Agile methodologies

Current software development is characterised by shorter and shorter lifecycle. In addition, the development reflects running changes and dynamic technological development. It can be seen not only when developing complex and extensive information systems, but when developing specialised applications as well. Traditional software development methodologies do not meet current conditions, therefore those are agile methodologies that have taken up their place in recent years. Despite a certain difference, they have similar principles, which were expressed in Agile Manifesto in 2001 [9]

- Individuals and interactions over processes and tools
- Working software over comprehensive documentation
- Customer collaboration over contract negotiation
- Responding to change over following a plan

Apart from extensive projects with clear and detailed assignment solved by large development teams, there are also small projects. Their development is secured by a small group of developers. In many of these projects, we cannot pre-define all requirements for the application, or the customer cannot do it. An example can be specialised applications for a targeted group of end-users. We could class here educational software for users with specific disorders.

Recent years have proved that so-called agile methods of software development can be used for this purpose. They were created on the basis that traditional rigorous methodologies are no longer suitable due to their formality and hugeness. It typically concerns web applications and closely specialised software. Customers are not usually willing to wait for months for a web application to be created. They prefer fast implementation even at the cost of continuously created modules. [1] [5]

Basic requirements on agile methodology cover:

- development is controlled by current requirements on functionality
- emphasis on continuous communication between the development team and customer
- emphasis on teamwork and team self-organisation
- regular and frequent transition of completed work to the customer
- not to avoid changes in the programme
- emphasis on the output programme quality before documentation
- changes should be actively followed and commented by the customer
- customer can actively interfere into the development

Agile methodologies include

- Dynamic Systems Development Method (DSDM),
- Adaptive Software Development (ASD),

- Feature–Driven Development (FDD),
- Extreme Programming (XP),
- Lean Development,
- Scrum,
- Crystal Methodology,
- Agile Modeling.

TABLE 1
COMPARISON OF BASIC DIFFERENCES BETWEEN TRADITIONAL AND AGILE METHODOLOGIES.

Agile methodologies	Traditional methodologies
Requirements on the application change frequently	Requirement do not change in the course of the development, or only minimally
Principle of freer cooperation of the development team	The development principle is based on fixed order
Developers should have experience needed for process adaptation	Less experienced developers
Emphasis on team communication	Directive management
High tolerance to changes	Low tolerance to changes
Testing throughout the whole course of the development	Testing is usually done at the end of the development
Documentation and models do not play the most important part in the development process	Documentation and the created model have high importance and the developers must follow them
The customer must be a part of the team	Customer's role is reduced to only the starting and final stages of the development
Smaller teams (2 to 10 developers)	Designed rather for larger teams

Agile methodologies are not suitable for all types of projects and all types of developing teams. Therefore there is a frequent combination of these two approaches. As for example, we can take methodology RUP, which gradually incorporates lots of agile techniques. RUP is currently representing a kind of a framework including both traditional and agile methodologies.

Despite the fact that the use of agile methodologies is increasing, their expansion is not still common. For example, 66% out of 3061 respondents of an inquiry held in 2008 said that they used at least some of agile procedures, such as iteration planning, unit testing, daily standup, release planning, continuous integration. [12] The most frequently accepted methodologies are XP, Scrum, Agile MSF, Agile Unified Process. On the other hand, according to inquires made in the Czech Republic, the situation is much worse. Only 43% of the respondents are aware of agile methodologies, but majority of companies do not use these methodologies at all. [4]

V. AGILE DEVELOPMENT OF VOKS APPLICATION

Initial efforts in the development stemming from the waterfall model have proved unusable. The customer (health staff of special school) did not have a clear idea about all functionalities and qualities of the developed communication software. Lots of the requirements had to be corrected, specified, and re-defined. Thus we proceeded to change the strategy and the software was developed according to an agile methodology. Elements and processes of Extreme Programming were taken as the basis. The basis of the whole XP software development is code-writing and testing. XP methodology is primarily designed for smaller teams with two to ten members, who work on frequently or less known assignments. Projects which take long or have difficulties in getting feedback (e.g. from technological point of view) are not suitable for this methodology. Automatic testing or version assembly is necessary for its implementation. XP is a flexible agile methodology emphasising interconnection of the proposal and implementation stages.

Basic activities are

1. Planning and Managing
2. Designing
3. Coding
4. Testing

XP has the following characteristic qualities:

- Continuous revision of the program code – frequent use of pair programming, when a pair of programmers works together on one code. Application of the principle led to removal of previously occurring problems in the code of the developed application.
- Testing – apart from unit tests, continuous testing by the customer was also successful. In our case, it was primarily health staff, but also children with specific disorders. Only the health staff from special school could define whether the application was suitable.
- Short iterations – classic methodologies usually transit the application to the customer after a long period, usually at the end of the development. This approach in the development of the educational application did not prove to be suitable. When an agile development methodology started to be used, we tried to make the shortest and most frequent iterations. They were given by time possibilities of the participants and we can see from the acquired experience that it would be convenient to make iterations more often than have been made so far.

Extreme Programming consists in five values:

- *Communication* – a large number of development problems lie in incorrect communication, not only among the team members, but with the customer as well. If XP is used, large teams assign a special role, so-called coach, who detects communication failures and secures correct communication. However, small teams should not underestimate good, continuous communication. Frequent communication is important not only among the developers, but with the customer as well.
- *Simplicity* – the methodology tries to develop software as easy as possible, not to deal with functionalities that are not currently important and that might be used in future. XP methodology says we should not create a more robust architecture than necessary for the moment. It also proved crucial in the development of the PECS application. With respect to frequently unclear customer's requirements, it was the most effective to solve the application for future needs. The development required more time and energy and

certain functionalities frequently proved to be unnecessary or unusable for a specific group of users.

- *Feedback* – is very important for correct development. It runs at several levels. One of them is testing, which should be performed at all development stages and not after the implementation stage. When developing program PECS, it proved necessary to test it continuously by its users. The main reason was the need of the developers to become familiar with possibilities of users with specific disorders. Many of commonly used approaches (particularly in the area of program control) are not usable for this group of users. Thus it was necessary to test more frequently and in all stages of the development what suits the users or what does not. The second target group of users was the health staff of special school that had to define and set up in the configuration part of the program an individual educational program for individuals. The configuration program requires simple control, still it offers a wide range of possibilities of individual setting according to specific requirement of the tutored child.
- *Courage* – A very important value of XP is courage to correct and remove errors at all costs. It even means removing a great part of the code or fundamental re-doing of the so-far architecture design. According to experience with the practical use of XP in companies, it seems that this requirement is difficult to be applied (more difficult in Europe than in the USA). The developers feel that removal of a great part of the code signs their failure and they are less likely to try further. [12] In the case of the PECS application development, it was necessary to remove a part of already created code several times because the corresponding application functionality proved to be unsuitable for a user with specific disorders. Despite those fundamental changes, it appears that the process helps to achieve the objective better than traditional methods.
- *Respect* – The team members should be interested in their colleagues' work. In case individuals work alone, with no close relations to others, XP will be unusable. This XP value closely corresponds to the emphasis on communication.

Why is agile methodology suitable for developing educational and communication software for users with specific disorders?

- The submitter does not have a clear idea about functionality of the application. Because there is a lack of experience with similar software, the development is frequently changed or corrected.
- A closely specialised group of future users requires frequent communication with submitters as well as continuous testing on by the developers and future users.
- The number of developed similar applications is very small, therefore there is a lack of experience with similar projects. Traditional development processes cannot be used in many aspects, particularly in the area of program control.
- The developers must get thoroughly acquainted with the environment and users, with whom they do not often get in touch and thus they do not know their abilities and requirements.

The used methodology has its disadvantages and risks. The requirement on frequent iterations proved to be hardly realisable. With respect to the nature of the solved project, direct communication of the developing team and the staff of the special school was necessary. It was quite a difficult task to secure this way of communication (taking into consideration time possibilities and distances between the participants). In order to achieve faster advance in the development of educational software, it would be necessary to communicate n shorter intervals, which was not possible to carry out successfully.

VI. Testing of voks application

Hand in hand with an increase in requirements and properties of software tools, there is a need of appropriate and profound testing. Despite the fact that the above described programme does not include any complicated functional structures or algorithms, and work of complicated and expensive devices is independent of its activity, it is necessary to secure its high reliability. Children suffering from e.g. autism find difficult to get used to a new environment and unfamiliar things. The time needed for the child to accept the programme and learn to work with it is usually very long. In case of serious disorders, there is a danger that the child will decline it or refuse to work with it. During testing of an application by children, there should not be any fundamental adjustments of the graphical interface and its control. Apart from classical procedures of testing of the programme functionality, it is important to observe how the child masters the application. It is not enough to use only usual static and dynamic testing means, analysis of the source code, monitoring by testing programme, special tests on memory usage or load, etc. [6] Thus the application incorporates internal mechanisms which monitor user's activities. Monitoring data about manipulation with programme objects are stored in XML files. The application contains an interface designed purely for parents and health workers which enables to evaluate both child's skills to work with the programme and its functionality. The output data then acts as a feedback for the creators of the programme as well as for parents and health workers, who can adjust the process of education more effectively. Another way to verify the programme functionality is methods used in quality oriented pedagogical research. It primarily concerns the method of observation [10]. The children use the application together with the parents or health workers. The adults act both as a pedagogue, who teaches the child to use and communicate with the programme, and an observer, who check for reactions and skills of the child. The observation results are very important not only for the educational process, but also for the development of the programme.

Unlike commonly used software, there are specific problems when testing:

- The target group of users is not large enough.
- The target group of users is very diverse and the level of the disorder considerably influences ability to work with the programme. It is necessary to take into consideration individual needs of the users and to enable more possibilities of setting and adjustment.

- The phase of learning how to use the programme is very time consuming. This results in longer period of testing than with usual applications. Children with higher level of disorder can take months to pass from one phase of the programme to another.

It is important to largely cooperate with parents and health workers because the children find difficult to get used to changes in environment and unknown people.

VII. Conclusions

Extreme Programming and other agile development methods have been implemented more and more in the past decade. It does not concern methodologies that would be suitable for all projects, they find their place in smaller developing teams. They can be used in projects with no clear initial definition, where the customers do not have a clear idea about the output product. Extreme Programming does not emphasise documentation of the development and its strict control. The basic element is a high level of communication among all team members and customers as well as frequent iterations. An advantage of this methodology was its possibility to react fast on customer's changes in requirements and possibility to adapt the program to users with specific disorders, even at the cost of removal of a great part of already written code. The methodology prefers fast reaction to a change before the plan completion, which proved to be important in the case of the developed software. There were plenty of changes and new requirements during the development, and their solution was more important for the output quality than following the time schedule of the development.

3^{nd} International Symposium on Multimedia—Applications and Processing

Multimedia—Applications and Processing (MMAP'10) will be organized within the framework of the International Multiconference on Computer Science and Information Technology.

MMAP'10 will be organized by Software Engineering Department, Faculty of Automation, Computers and Electronics, University of Craiova, Romania ("Multimedia Applications Development" Research Centre).

Conference Background and Goals

Multimedia information has become ubiquitous on the web, creating new challenges for indexing, access, search and retrieval. Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices – such as laptops, iPods, personal digital assistants (PDA), and cellular telephones – have stimulated the development of intelligent pervasive multimedia applications. These key technologies are creating a multimedia revolution that will have significant impact across a wide spectrum of consumer, business, healthcare, and governmental domains. Yet many challenges remain, especially when it comes to efficiently indexing, mining, querying, searching, and retrieving multimedia data.

The Multimedia – Processing and Applications 2010 (MMAP 2010) Symposium addresses several themes related to theory and practice within multimedia domain. The enormous interest in multimedia from many activity areas (medicine, entertainment, education) led researchers and industry to make a continuous effort to create new, innovative multimedia algorithms and application.

As a result the conference goal is to bring together researchers, engineers and practitioners in order to communicate their newest and original contributions on topics that have been identified (see below). We are also interested in looking at service architectures, protocols, and standards for multimedia communications – including middleware – along with the related security issues, such as secure multimedia information sharing. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages offered by multimedia computing techniques, including home-networked entertainment and games. However, innovative contributions that don't exactly fit into these areas will also be considered because they might be of benefit to conference attendees.

Topics of interest

Topics of interest are related to Multimedia Processing and Applications including, but are not limited to the following areas:

- Image and Video Processing
- Speech, Audio and Music Processing
- 3D and Stereo Imaging
- Distributed Multimedia Systems
- Multimedia Databases, Indexing, Recognition and Retrieval
- Data Mining
- Multimedia in E-Learning, E-Commerce and E-Society Applications
- Multimedia in Medical Applications
- Multimedia Authentication and Watermarking
- Entertainment and games
- Multimedia Interfaces

***Abstract*—This paper presents a system for segmentation of images into regions and annotation of these regions for semantic identification of the objects present in the image. The unified method for image segmentation and image annotation uses an hypergraph model constructed on the hexagonal structure. The hypergraph structure is used for representing the initial image, the results of segmentation processus and the annotation information together with the RDF ontology format. Our technique has a time complexity much lower than the methods studied in the specialized literature, and the experimental results on the Berkeley Dataset show that the performance of the method is robust.**

I. Introduction

The hypergraph data model and object-oriented model make join to define the spatial relations between regions from images and the features of them; the composite model is called hypergraph object-oriented model ($HOOM$). Hypergraph data structure inherit the characteristics of the object model. Depending on hypergraph structure the complex spatial relations can be described easily and the attributive data can also be integrated more efficiently. Using hypergraph structures allows more advantages: using a single form for the representation of the combinations of classes and structural inheritance; allowing to avoid data redundancy (inherited values for sub-objects are taken from the super-objects) and to define complex objects (using undirected hyperedges) and functional dependencies (using direct hyperedges); support mechanism for identification through OID's and offers mechanisms for specifying multiple inheritance. In [1] was presented an overview of a hypergraph-based image representation that considered Image Adaptive Neighborhood Hypergraph ($IANH$) model.The proposed segmentation and annotation methods use a virtual graph structure constructed on the image pixels in order to determine the regions from the image and to allocate the labels for these which can give the semantic signature of the each region. Thus the image segmentation is treated as a hypergraph partitioning problem. The predicate for determining the set of nodes of connected components is based on two important features: the color distance and syntactic features [2], that are geometric properties of regions and their spatial configurations. The schema for the prototyping system is presented in Fig. 1:

Initial Image
Segmentation and Contour Detection
Hypergraph of Regions
Geometric Characteristic Extraction
Annotated HyperGraph of Regions
Topological Relations Extraction
Annotated Graph of Regions and Topological Dual Graph

Fig. 1. The image processing system architecture

In the following sections there are discussed the next topics: in Section II we describe the image segmentation based on hypergraph structure; in Section III presents the method of the image annotation; Section IV describes the results of our experiments and Section V concludes the paper.

A. Related Work

In this section we briefly consider some of the related work that is most relevant to our approach. In the image segmentation area, the most graph-based segmentation methods attempt to search a certain structures in the associated edge weighted graph constructed on the image pixels, such as minimum spanning tree [3], or minimum cut [4]. The major concept used in graph-based clustering algorithms is the concept of homogeneity of regions. For color segmentation algorithms, the homogeneity of regions is color-based, and thus the edge weights are based on color distance. For image annotation, an approach based on graph is presented in [5], where the learning model is constructed in a simple manner by exploring the relationship among all images in the feature space and among all annotated keywords. The Nearest Spanning Chain method is proposed to construct the similarity graph that can locally adapt to the complicated data distribution. Object oriented database models [6] are based on the object-oriented techniques and their goal is representing by data as a collection of objects that are organized in hierarchy of classes and have complex values associated with them. The [7] describes the use of the $OODB$ in content-based medical images retrieval and the proposed approach accelerates image retrieval processing by distributing the workload of the image processing methods in the storing time.

II. Image Segmentation Technique Based on Hypergraph Structure

A. The Image Hypergraph Model

The construction of the initial hypergraph is based on an utilization of pixels from the image that are integrated into a network type graph. We used a hexagonal network structure on the image pixels for representation of the hypergraph $HG = (V, HE)$ and we considered two hyperedges of graph joining the pseudo-gravity centers of the hexagons belongs to hexagonal network as presented in Fig. 2.

The introduction of the hypergraph structure was in [8] and is a generalization of graph theory. The main idea refers to consideration of sets as edges and then a hypergraph is the family of these edges (called hyperedges). This concept represent more general data than graph structure and the theory of hypergraphs has proved to be of a major interest in applications to real-world problems such is image processing. The object model used for storing images, is based on the complex and different structure for each image that does not allow a simple data model using predefined data structures such as those used in relational databases. Relational databases have several limitations in representing an image: from the perspective of data representation model, in the relational database, links between two records are achieved through attributes primary key and foreign key. The records have the same values for foreign keys, primary that are logically related, although they are not physically linked (logical references). The object-oriented model allows to define the methods by which messages are exchanged between objects and to implement the inheritance mechanism which offers classes which have new definitions based on existing definitions.

In an object-oriented database, each object in the real world can be modeled directly as an instance of a class; each instance has an OID and is associated with a simple or complex object. The OID stored in the database is not changed, while other fields associated object can be modified. This identity provides a good support for object sharing updates and simplifies management. Inheritance offered by object-oriented paradigm provides a powerful mechanism for organizing data, it allows to the user to define classes in an incremental way by specializing existing classes. As you can see, is achieved a triangulation of the image, which is in fact a decomposition of the image in a collection of triangles whose edges form the set V of nodes of the hypergraph HG. The condition for achieving a triangulation is satisfied, namely collection of triangles is mutually exclusive (no overlapping triangles) and fully exhaustive (all triangles meeting covers the original image). If it considered the edges which join the gravity pseudo-centers of the hexagons, it obtain a Delaunay triangulation [9]; the grid-graph is a Delaunay graph and based on planarity graph condition ($no\_edge \leq (3 * no\_vertex - 6)$) we demonstrated that the time complexity of segmentation algorithm is $O(nlogn)$. The algorithms for segmentation and the demonstration for complexity are presented in [10]. In the hexagonal structure, for each hexagon h in this structure there exist 6-hexagons that are neighbors in a 6-connected sense and the determination of indexes for 6-hexagons neighbors having as input the index of current hexagon is very simple. The main advantage when using hexagons instead of pixels as elementary piece of information is the reduction of the time complexity of the algorithms. The list of hexagons is stored such as a vector of integers $1 \ldots N$, where N, the number of hexagons, is determined based on the formula:

$$N = \frac{H-1}{2} \times (\frac{W-(W\%4)}{4} + \frac{W-(W\%4)-4}{4}) \quad (1)$$

where H represents the height of the image and W represents the width of the image.

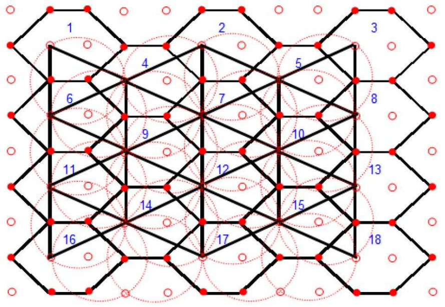

Fig. 2. The hexagonal structure on the image pixels

Each hexagon from the set of hexagons has associated two important attributes representing its dominant color and its pseudo-gravity center. For determining these attributes we use eight pixels: the six pixels of the hexagon frontier, and two interior pixels of the hexagon. For RGB space, the dominant color of a hexagon is determined as follows: is extracted three components (r, g, b) for each pixel of the hexagon; next step is sorting of the three vector components; last phase involves choosing as dominant components of media components located in positions 3 and 4 in the vectors, and dominant color calculation using the formula:

hexagon_color =

$$(r\_d\_color << 16)|(g\_d\_color << 8)|b\_d\_color \quad (2)$$

where r_d_color is the dominant color for the red component, g_d_color is the dominant color for the green component and b_d_color is the dominant color for the blue component of the RGB colorspace. We split the pixels of image into two sets, a set of pixels which represent the vertices of hexagons and a set of complementary pixels; the two lists will be used as inputs for the algorithm which construct the initial hypergraph of the initial image. The mapping of pixels network on the hexagons network is immediately and it is not time consuming in accordance with the following formula which determines the index for the first vertex of hexagon:

$$fv = 2 \times h + \frac{2 \times (h-1)}{columnNb - 1} \quad (3)$$

where fv represent the index of the first vertex, h the index of the hexagon and $columnNb$ represent the column number of the hexagon network. For representing the output of the image segmentation process we used the Attributed Relational Graph (ARG) [11]. The result of segmentation algorithm is stored as a graph where the nodes represent the regions and the edges represent the neighborhood relations: G = (V_r, E_r), where V_r is the set of vertices corresponding regions detected and E_r is the set of edges that describes the neighborhood relations. The spatial relations between regions are divided into 3 categories: distance relations, direction relations and topological relations. For determining these types of relations we choose for each region the following relevant geometric features: the pseudo-center of gravity; the distance between two neighboring regions; the length of common boundary of two regions and the angle which is formed by two regions.

B. The Image Segmentation Methods

In this subsection there is shown the algorithms for determining the initial hypergraph and the segmentation method. By using as unit element a hexagon, any two neighboring elements have in common two vertexes (an edge). The function $createHG$ which is describes in algorithm 1 produce the initial hypergraph for the initial image.

Algorithm 1: Create the initial hypergraph

```
Input: The list of color pixels from the hexagonal
       network: $L = \{p_1, \ldots, p_{6n}\}$
Output: The initial hypergraph $HG$ which correspond to
        the initial image
Procedure createHG($L$ ; $HG$);
* init $crtHyperEdge$;
for $i \leftarrow 1$ to $sizeof(L)$ do
    $hcrt \leftarrow L(i)$;
    * init $indexN$ as indexes from $L$ for the neighbors
    of $hcrt$;
    $indexM \leftarrow -1$;
    for $k \leftarrow 1$ to $6$ do
        $distRef \leftarrow colorDist$ ($L[indexN[k]]$, $L[hcrt]$);
        if $distRef$ are minimum value then
            $indexM \leftarrow k$;
        end
    end
    if !mark(edge[$L[indexN[indexM]]$, $L[hcrt]$]) then
        * add ($crtHyperEdge$,
        $edge[L[indexN[indexM]]$, $L[hcrt]]$];
        * mark $edge[L[indexN[indexM]]$, $L[hcrt]]$];
    end
    else
        * add $crtHyperEdge$ to $HG$;
    end
end
```

The output of segmentation algorithm 2 is the hypergraph corresponding to the segmentation image and it is computed based on the hexagonal grid-graph and the distance between the two colors for the RGB color space. The variable $colorsHexagon$ represents the vector colors of the hexagon and the others attributes of the class $Hexagon$ are $indexHexagon$ in the hexagonal structure of the virtual graph and $visitedHexagon$ which is used in the crossing network algorithms.

Algorithm 2: Determination of the segmentation hypergraph

```
Input: The total number of hexagons from hexagonal
       grid $n$
The hypergraph representation for an image ($HG$),
obtained with algorithm 1
Output: The hypergraph with the hexagons of regions
        $HG = \{\{he_1\}, \ldots, \{he_k\}\}, he_i =$
        $\{color, \{r_1, \ldots, r_p\}\}$
Procedure HGSegmentation ($N$, $HG$; $HG$);
* initialize the stack of hyperdges;
* get $indexH$ as index of unmarked hexagon
while ($indexH$ != -1) do
    * mark as visited the hexagon $indexH$;
    * push ($hyperdge[indexH]$);
    $HERegionItem \leftarrow newHyperEdgeRegion$;
    while !empty(stack) do
        $crtColorHyperedge \leftarrow pop()$;
        for each $crtColorHexagon$ from the set of
        $crtColorHyperedge$ do
            if (!mark($crtColorHexagon$) then
                * add $crtColorHexagon$ to
                $HERegionItem$;
                * push ($hyperdge[crtColorHexagon]$);
                * mark as visited the hexagon
                $crtColorHexagon$;
            end
        end
    end
    * add object $HERegionItem$ to list $HG$;
    * get $indexH$ as index of unmarked hexagon
end
```

The procedure $HGSegmentation$ returns the hypergraph with the hexagons of regions; the elements of hypergraph (the hyperedges) are determined for each distinct color from the input image as a list of regions that contain hexagons which have the same dominant color. The $HERegionItem$ is an instance of the class $HyperEdgeRegion$ and represents the data structure corresponding to an item from the output list. The attributes of the class $HyperEdgeRegion$ are: the color of the region and the list of hyperedges which represent the hexagons with the same color.

III. Image Annotation Technique Based on Hypergraph Structure

The management of ontologies, used for annotate of images, has two hierarchical levels that are closely associated. On the one hand, the low-level image contains specific properties as color, texture, shape, and the second level, which contains sematic of image that can be perceived human user. An ontology management system should model the low level that supports retrieval and inference level of their content. One scenario of using such a system can be that a user loads all ontologies in a given area, and allows selection of different objects in images and their correlation with the concepts of ontologies.

A. Ontologies and RDF format

For specifying the ontologies and the corresponding graph structure of the images segmented and annotated format we used RDF (Resource Description Framework). The RDF is a specification defined $metadata$ processing, providing interoperability between different applications such as an exchange of information, the purpose of understanding the semantics. To use the method of reasoning described in the ontology-based knowledge bases, we used $RDF2Jess$ model, a hybrid model that can be used to fill the gap between RDF and $Jess$. Based on domain knowledge and using Protégé [12] ontology editor, this method turns the RDF format in $Jess$ facts using XSL transformations on XML syntax and additional rules in Jess. For these rules redefined based on RDF semantics $Jess$ inference system is used to implement the reasoning. Predefined rules are used to check consistency and to determine the characteristics of RDF vocabulary. Deducted $Jess$ assertions are helpful for phase domain ontology modeling to assess and refine ontology. According to different levels of expressiveness, $RDF2Jess$ could be extended to new $SWRL2Jess$ where $SWRL$ extends the set of axioms to include Horn rules. The conversion of syntactic and semantic RDF in $Jess$, allows replacement of ontology in RDF format using $Jess$ reasoning engine. Ontology conversion into Jess facts and rules is done in four steps:

- first step is the ontology construction, ontology editor used $Protege$, provides a plug-in RDF ontology to support development. The taxonomy of knowledges into classes, features, restrictions was accepted by experts in the field and by software developers, because this paradigm is very similar to object-oriented modeling (UML). Lately, most ontologies have been formalized using standardized $RDF(S)$ and can be reused to extend the rules, if necessary;
- the second step is to represent the transformation of RDF syntax in $Jess$ syntax using $XSLT$, the output file consists of $Jess$ facts. If support ontology language semantics is specified as $Jess$ rules, matching specific keywords is no longer necessary in the transformation;
- the third step is to combine file $Jess$, including $XSLT$ transformation result, and RDF predefined rules. Moreover, external queries and $Jess$ rules can also be added to the composition similar properties;
- the last step is running the system of rules $Jess$ inference system. The rules defined, is the classification and consistency checking characteristics. The output containing erroneous messages indicating the presence of incorrect syntax in RDF ontology processed.

To implement the RDF, semantics are defined to represent the additional facts and their relations with $RDFS$ primitives such as $rdfs : Class$. This approach prevents duplication of semantic information in the database, and an overview of how to store links between visual concepts/concepts domain and related regions is given by Fig. 3.

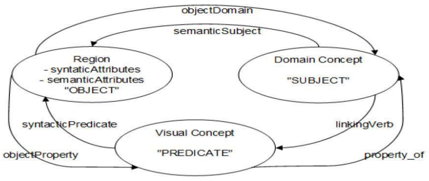

Fig. 3. Triple link: visual concept/semantic concept/Region

In Fig. 4 are presented the classes which are used for specification of the $HOOM$ in the image annotation processus:

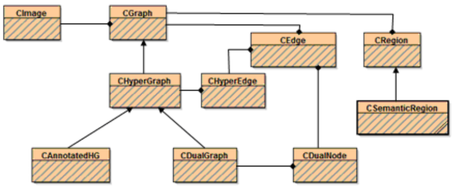

Fig. 4. The hypergraph object data model

B. The Image Query Specification

To specify queries we have expanded the query language $GOQL$ using data structures of type hypergraph - $HGOQL$ (Object Query Language Hyper-Graph). In [13] is proposed $GROOVY$ model (Graphically Represented Object-Oriented Data Model with Values) which represents a proposal to formalize the object-oriented model based on hypergraph structures type. It defines a set of data structures for object model data: (I) Value diagram that defines the attributes that contain a class of objects. Items can be atomic or multi-value, (ii) The court: defines a lot of items under the diagram. An object is a pair $O = < id, v >$, where id is the identifier of the object and v is the value of the object (his properties), (III) Dependency of functional values: are used in the scheme to check that the value of a set of attributes determine in a unique way the value of another attribute; (IV) Object diagram: is a triplet $< N, F, S >$, N - diagram value, F a lot of dependency of functional values for N and S - a lot of subsets of N. This structure is defined using hypergraphs by establishing a corresponding one-to-one between object diagram $< N, F, S >$ and an interpretation where N is the oriented nodes of a hypergraph, F is its direct hyperedges, and S, undirect hypeedges. A manipulation language of hypergraph (HML - Hypergraph Manipulation Language) for query and update them has with two operators querying based on identifier or value, eight operators for inserting and deleting the hypernodes and the hyperedges. During the developed language ($HGOQL$) we implemented only operators who refers to the query. The grouping of the indexes attributes (which includes enable/disable attributes through facet $index - propagation$) is achieved by Algorithm 3 based on a function implemented in the states of each class. The function $hyperGraphGroup$ that does clustering indexes, used as support for storing and linking indexes a $hypergraph$ [14], implemented by the $CHypergraph$ class, subject to the previous result that output algorithm ($indexThis$) is an instance of $CHypergraph.$ Choosing $hypergraph$ type structure to represent indexes was made because this type of structure is very good for browsing and retrieving images corresponding graph processed. The function $HyperGraphGroup$ properly algorithm is presented in Algorithm 4.

IV. Experiments

In this section experimental results are highlighted demonstrating that the method presented produces a good image segmentation and annotation, and extraction of outlines for visual objects from different images without the need for parametrization of the method depending on image processing. For this purpose, we used human segmentation for color image from Berkeley Segmentation dataset ($BSDB$).

A. Image Segmentation Experiments

After problem examination of validating the quality of segmentation, we proposed an effective evaluation system which shows the comparative results of segmentation both obtained with the algorithm implemented and the three alternatives segmentation methods: the "Mean-Shift" method (MS) [15], the "Local-Variation" method (LV) [3] and the "Normalized-Cuts" method (NC) [4]. In the last part is presented an analysis performed for a set of synthetic images. The $BSDB$ database contains two sets of images: a lot of training with 200 images and a lot of test 100 images. For each image is available a set of human segmentations. This set contains between four and eight segmentations specified in the form of images labeled using a special format. In [16] showed that human segmentation, although vary in detail, are according with each other for the segmented regions by humans are exposed to a finer level of detail and in this situation can merged so as to appear as to extracted regions a coarse level of detail. To assess performance of segmentation method were segmented images of crowds test and were used two measures of quality: the value function harmonic mediation ($F - measure$) and performance value ($P - measure$) [17]. Value of $F - measure$ [18] determined by a combination of precision values (P) and re-call (R) is calculated for each segmentation and number the correct segmentation comparing to the wrong. In Fig. 5 are the results of contour detection for a group images, considering the four methods of segmentation. In the three methods chosen for comparison was considered when the result value is the measure of $F - measure$ is the maximum, namely: MS method, DW = 10 and PW = 8, for the LV method, the value used was k = 900, for NC method, the value used was $nTresh$ = 25. In the second part of experiments was considered a set of synthetic images generated so the RGB colorspace to be presented with non-null value a single channel of the three. In figure Fig. 6 are examples of such images generated. The purpose of generate and use this set of images was to determine the optimal formula for calculating dominant color of a hexagon (formula

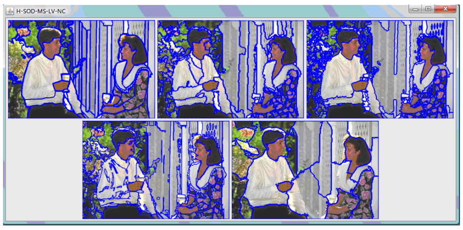

Fig. 5. Results for image segmentation: human segmentation, SOD segmentation, MS segmentation, LV segmentation and NC segmentation

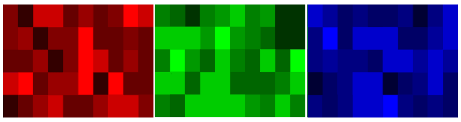

Fig. 6. Samples of synthetics images

2) and on the other side validation formulas used to determine threshold values used in the two stages of segmentation. To achieve these goals we generated for each image, an attached file in XML format. File picture represented in XML as a list of rectangles, for each rectangle specified coordinates of points on the left/top, that right/down, channel number and the value for that channel with values between [0 . . . 255]. After segmentation a synthetic image is comparing the list of regions obtained with the rectangles list extracted from the XML file by using a parser. As a result of comparison the aim is to modify channel values after considering the dominant color from the level of a hexagon. The closest values were obtained for two experiments that have used the formula 2 for calculation of hexagon color. threshold values used in the two stages of segmentation.

B. Image Annotation Experiments

The following phase after the segmentation step involves the addition of labels to the semantic regions. There are two phases of this stage, manual annotation (training phase) and automatic annotation. For the first phase, representative images are selected for the considered domain. Manual annotation scenario assumes that the first step, loading the domain ontology. In the next step, the user selects the regions of the segmented image and put them in correspondence with the ontology domain concepts. While the regions are manually annotated, an XML file with the annotated information is generated. To identify a region in space of the image is stored in the XML file the hexagons list region which are founded on its border. This information is necessary to establish a visual correlation between the XML node for a region and this; this is done by double selection: when selecting a region already annotated in the tree view of XML corresponding node is selected automatically. Fig. 7 presents the corresponding GUI of the annotation phase.

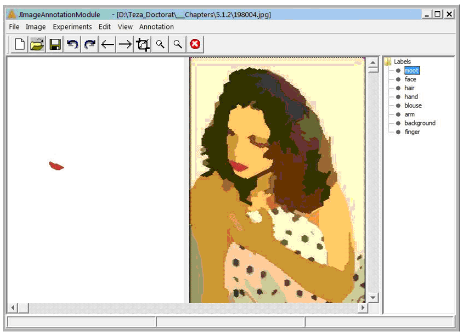

Fig. 7. Graphical user interface subsystem for image annotation

Based on syntactic and semantic properties of manually annotated images is constructed a decision tree which is translated into a set of rules used for automatic annotation of image regions segmented test. We used to add semantic tags the decoration technique of the hypernodes of the hypergraph in accordance with the RDF format representation. The obtained hypergraph as a result of the processing steps is serialized as a system of objects, which have links in accordance with existing relationships (inheritance or composition) on the all classes which are implemented.

V. Conclusion

In this paper presents an hypergraph object-oriented model for image segmentation and annotation when is considered as the input the information extracted from the image. The unified method for image segmentation and image annotation uses an hypergraph model constructed on the hexagonal structure. The hypergraph structure is used for representing the initial image, the results of segmentation processus and the annotation information together with the RDF ontology format. The hypergraph representation of images is the output of all the phases of system: the segmentation phase and the annotation phase. Our technique, which combines the hypergraph model with the object oriented model, has a good time complexity and the experimental results showed that the method can be yielded with good results regardless of the area of the images that come.The future work implies the using of the hypergraph theory with the goal of searching and retrieving complex images based on the complex query formulated in a symbolic language.

***Abstract*—This paper introduces and comprehensively evaluates a new approach for classification of image regions. It is based on the so called *wavelet standard deviation descriptor*. Experiments performed for almost one thousand images with region segmentation given provided reasonable results for a very general application domain: "holiday pictures".**

I. Introduction

In the field of research dealing with image classification and understanding we follow a multi-layered concept. Image data is described in high level and low level semantics. High level semantics are represented by ontologies and low level semantics in feature comparison techniques. This paper is focused on wavelet features following the proposal of the *Wavelet Standard Deviation Descriptor (WSD)* [1] used for the classification of texture patterns. Here it is used in order to classify regions of previously segmented images. The task at hand is to find a label for each region in any given holiday photo that can later be used in image management applications or retrieval systems e.g. to automatically tag inserted photos. The major motivation for this research work lies in the two following statements:

1) finding adequate region labels can improve the research on high-level semantics (narrowing the semantic gap)
2) the problem of image region classification can be reduced to a problem of texture pattern classification

Indications on the first assumption can be found in [2] but in general it is task of the high-level domain. The second assumption is analyzed in detail. Therefore two implementations using the WSD are presented each tested under different modalities. Both classification algorithms compare the WSD of an image region to the WSD of each pre-defined concept. The concepts used are shown in table I. They were trained using a subset of the available images. The region-labels of those images were manually annotated beforehand providing ground truth.

This introduction is followed by a brief overview of similar research in II. Section III introduces the environment of the performed tests followed by the implementation of the mathematical constructs in IV. The results are shown in V with a view on issues, proposals and future developments in VI

II. Related Work

The field of image region classification offers many approaches. In [3] seven feature extraction and comparison methods are compared in their performance of correct image retrieval out of the WANG[1] and the IRMA[2] databases. The evaluated feature extraction methods are image features ($\widehat{=}$ pixel values), color histograms [4], invariant feature histograms [5], Gabor feature histograms [6], Tamura texture feature histograms [7], local features [8] and region based features [9]. As the IRMA database contains too specific medical images, the images of the WANG database get close to the sources of this paper though it is not limited to the loosely defined class of holiday photos. The provided ground truth is also more focused on semantic classes, e.g. "Africa," "food," "monuments," than on elementary texture patterns like "sand," "sky" or "foliage."

In many cases features are generated using an entire image without providing information about specific regions in the image. As soon as regional features are provided the focus lies on object detection. A task very similar to this paper though using different features is presented in [2]. Also similar is [10] using Gabor features [11] on segmented satellite images which provide optimal conditions for texture analysis as they barely suffer from perspective distortion. The idea of this study is to ignore the perspective distortion and reduce the problem of identifying image regions to a problem of identifying textures. The publication closest to this work is [12]. It also faces the task of concept similarity measures in an even larger scale and therefore affiliation estimation. The features used are two-dimensional hidden Markov models.

III. Design

A set of 922 RGB-images with a resolution of 800 by 600 pixels was provided to represent "holiday images". They

TABLE I

[2] http://ganymed.imib.rwth-aachen.de/irma/index_en.php

originate in the available Database of the K-Space Project[3]. To avoid an *over-fitting* of the (to be generated) concept descriptors the data was separated into three subsets. One for the training of the concept classifiers, a second one to validate parameter changes in the algorithm and a third one to test the final classification performance. For the training- and validation-subset 230 images were each randomly chosen out of the provided images. The remaining 462 photos were used as test-subset.

A. *Concept Training*

The aim of this study is to enable a comparison of image regions against a set of pre-defined concepts using WSDs. Therefore a WSD-representation of the concepts must be developed. As a WSD is a feature vector of invariant length (for identical image resolutions) it was chosen to represent each of the features by mean and standard-deviation. To generate the concept-descriptors the following steps were taken:

1) Compute the WSDs of each image region within the training-set and select one representative per region.
2) Group the representative WSDs of all the images within the training-set by their concept label using a manually annotated affiliation list.
3) Calculate the mean and standard-deviation of each feature value of a WSD over the given concept.
4) Store mean and standard-deviation as representative for the corresponding concept in a concept descriptor.

A concept is now defined by a label (e.g. sailing-boat) and a corresponding descriptor which is a mean and standard-deviation value for each computable feature value.

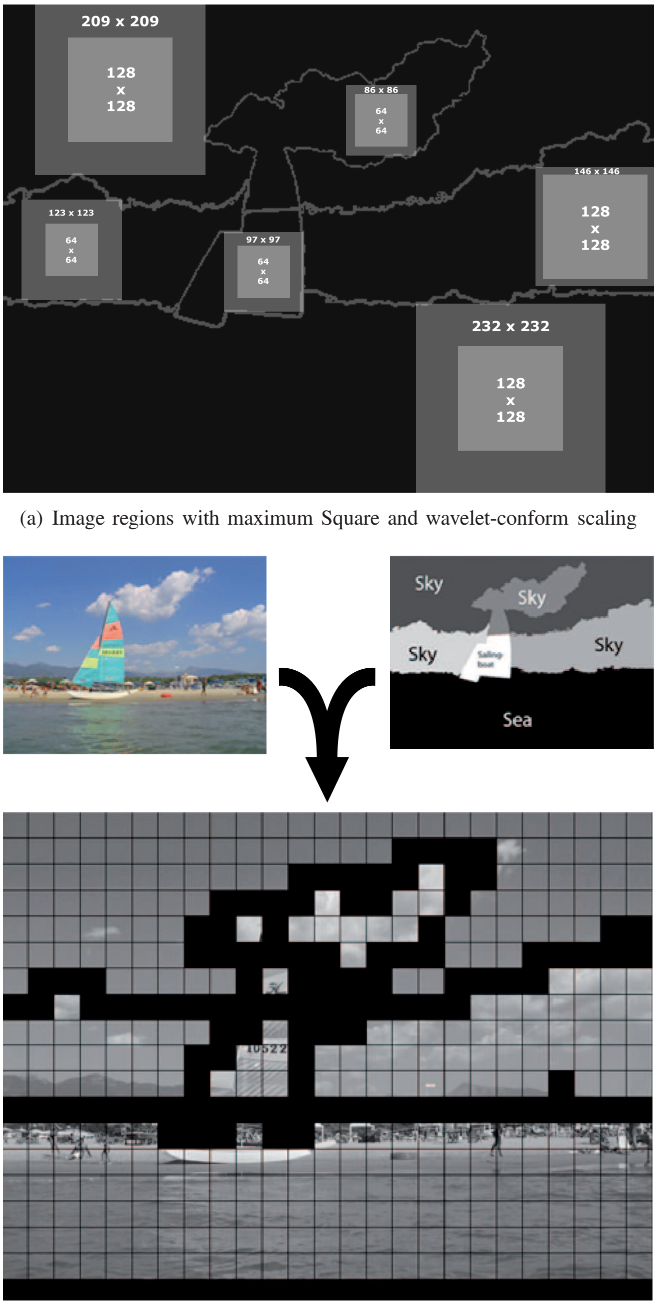
B. *Modalities & Validation*

When dealing with texture data there's usually no need to provide color information as it multiplies the processing time at least by the number of color-channels used. There is also the problem that color information is strongly dependant on the environment's illumination. However color channels can include patterns that supply additional information of the structural character. During the validation it showed that e.g. the concepts snow and sand tend to be very similar in their structural consistency. Here a separate analysis of the color channels can add additional precision to the results. Therefore three different color-spaces were tested - gray-scale, RGB, and YC$_r$C$_b$. The gray-scales are obviously representing structure-only information. RGB was chosen in regard to the simplicity of the approach as the available images are provided in this format and it is to be expected that most of the sources of ”holiday images” (e.g. cameras) have the same output. In case of satisfying results without color-space transformations the run-time performance would benefit. YC$_r$C$_b$ was chosen as proposed in [1] with the argument of describing structural information in the Y-component and the distribution of color information in the C$_r$- and C$_b$-components.

When working with wavelet transformations the image or region to be processed must fulfill the conditions

$$(x = y) \wedge (x = 2^n : n \in \mathbb{N}_{>0}) \tag{1}$$

where x and y define the pixel resolution. As image regions mostly don't fit these requirements it is necessary to choose a representative for every region in order to compute the WSD-features. To meet these conditions two approaches were tested.



(a) Image regions with maximum Square and wavelet-conform scaling

(b) Determination of valid patches using a 32 by 32 pixels grid

Fig. 1. maximum Square 1(a) and grid overlay 1(b) feature selection methods

a) maximum square: The first approach finds the largest square fitting in an image region and scales it down to the

[3] http://kspace.qmul.net:8080/kspace/

next valid wavelet-conform resolution as shown in fig. 1(a). Then the WSD was computed stopping after the third level of the wavelet transformation (see IV-A) in order to assure a common vector size for later comparison. This limits the patch resolution from 8^2 up to 512^2 pixels using 800 by 600 pixel images.

b) grid overlay: The second approach uses a square grid overlay to create a pattern with wavelet-conform patches. The size of the grid's patches was set to 32^2 pixels. When using YC$_r$C$_b$ color-space a resolution of 8^2 pixels was additionally tested. Only patches lying completely within a single region were considered for the WSD computation. The process of finding out the valid patches ist depicted in figure 1(b). To determine a single representative for an image region different methods were used:

- *first patch:*
  when processing the image, the first found patch of an image region was selected as representative (dummy implementation).
- *mean value:*
  the WSD of each patch was computed. All WSD features of an image region were merged into a representative WSD for the image region using mean for every feature (per filter and level).
- *maximum affiliation:*
  the WSD of each patch was computed. Then they were compared to each concept resulting in 10 affiliation values[4] per patch. The patch with the largest affiliation value[4] was selected as representative.
- *largest difference:*
  similar to *max. affiliation*. Though the representative was selected by the largest difference of the highest two affiliation values[4] per patch.

Table II lists the modes and combinations the validation was performed in. The rows show the representative selection method, the columns show the colorspace. Content is the used patch size of the specific method. The *maximum square* entry refers to the first selection approach and therefore doesn't use a static patch size. All parts of the algorithm were validated against the validation-set of images concerning error handling and parameter optimization.

maximum affiliation			
largest difference			
maximum Square	8^2 to 512^2	-	-

C. Algorithm Testing

In order to avoid bias due to overtraining of the algorithms on a specific set all presented results in this paper were created using the images of the test-set with the unaltered parameters or fixes created during the validation process.

IV. Implementation

The implementation of this study covers four partial tasks.

- create the wavelet-transformation for the input images
- compute the WSD out of the wavelet-transformed images
- describe any pre-defined concept using WSDs
- a *concept-to-WSD* comparison method must be developed

As the descriptor for the WSD values was decided to be the mean and standard-deviation over the computed features in the training set, there won't be a more detailed description for point three. The implementation of the wavelet-transformation, the WSD computation and the selected comparison method are presented in the following.

A. The Wavelet Standard Deviation Descriptor

The wavelet-transformation computes the frequencies within different levels of a signal. In case of image processing it is interpreted as the frequencies of a single channel's discrete values within the input image—most likely gray-scale images. The implementation uses the Haar wavelet [14] following the proposal of [1]. It results in a transformed image like the example in figure 2. Every level of the wavelet transformation a partial HL-, LH-, HH- and LL-image is created where H is a high-pass filter and L a low-pass filter. The partial images are created following:

1) Apply the horizontal filter to the input image (e.g. H).
2) Eliminate every second column.
3) Apply the vertical filter (e.g. L).
4) Eliminate every second row.
5) In case of HL-, LH- and HH-images store the result in the specific position shown in figure 2 (e.g. top-right for HL). in case of an LL-image compute the next wavelet-level using the LL-image as input.
6) Repeat this process until the desired wavelet-level is reached or the LL-image has a resolution of 1 by 1 pixels.

The *wavelet standard deviation descriptor* (WSD,[1]) is a vector that uses the weighted standard deviation of each partial HL-, LH- and HH-image as feature values. The weighted standard-deviation of the LL-image and its mean are used as final feature values in the vector. The *maximum Square* approach uses a depth of three wavelet-levels as its WSD. In the *grid overlay* approach all level-features were calculated and used as WSD. In the second case the size of the feature vector is therefore always:

$$\varepsilon = 3 \cdot \#_k + 2 \tag{2}$$

Where $\#_k$ is the number of computed levels.

[4] described in IV-B

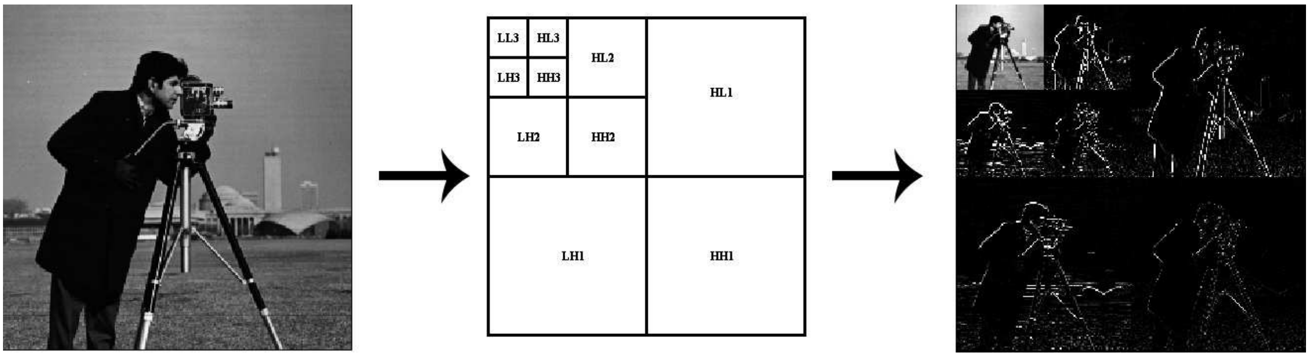

Fig. 2. Wavelet transformation with three levels on an image by [13]. The intensities in the LL-image on the right were normalized for visualization purposes.

The WSD vector is then defined as:

$$WSD = \{\frac{\sigma(LH_k)}{2^{k-1}}, \frac{\sigma(HL_k)}{2^{k-1}}, \frac{\sigma(HH_k)}{2^{k-1}}, \dots, \frac{\sigma(A)}{2^{k-1}}, \mu(A)\} \quad (3)$$

$LH_k, HL_k, HH_k =$ the partial image of the k-th level
$\sigma(image) =$ standard deviation of the image
$\mu(image) =$ mean value of the image
$k =$ the index of the specific level $[1..(\varepsilon - 2)/3]$
A = the approximation image (the lowest LL-image)

B. Comparison Method

In [1] a similarity measure for WSDs is offered based on the weighted difference of the corresponding features. It was decided to implement a probabilistic measure similar to the offered approach. As after section III-A each feature of a concept is represented by mean μ and standard-deviation σ, it is possible to compute a relative similarity ρ for each feature f of a WSD using the probability distribution:

$$\rho_k = exp(-\frac{(f_k - \mu)^2}{2\sigma^2}), k \in [1..\varepsilon] \quad (4)$$

The final concept affiliation was tested with two different aggregation modes - the sum of the single values and their product.

$$\gamma_{sum} = \Sigma_1^{\varepsilon} \rho_k \quad (5)$$

$$\gamma_{product} = \Pi_1^{\varepsilon} \rho_k \quad (6)$$

V. Results

Within the 462 images of the test-set a manual annotation was provided for 2960 of the contained regions. Any result presented in this paper is referencing to this number of regions providing ground truth. Applying the grid presented in section III-B with a patch size of 32^2 pixels results in 2521 classifiable regions. The remainder of the regions didn't fit the grid in so far as none of its patches were completely located within its boundaries and therefore no features could be extracted. A patch size of 8^2 pixels could cover each region. Anyway these circumstances make it necessary to distinguish between two types of results. First there is the *feature classification rate* (feature rate) which represents the classification performance only in regard to all computable features. And second there is the *task classification rate* (task rate) which shows the overall classification performance treating ignored regions as falsely classified.

The computed classification rates are presented in Table III. It shows that a region representative is best selected by creating a mean WSD over all the region's patches. The feature aggregation to be favored is summing up the feature values (compare equation 5). Using color information doesn't strongly influence the classification rates though using RGB shows slight advantages. Applying the smaller sized grid improves the results by less than one percent when comparing the best classification rates of each size. Instead the algorithm's run time increases a lot as there are 16 times as many features to be computed, merged and compared. The *maximum squares* approach delivered results worse than the task rates of a 32^2 pixel sized grid, both using gray-scale converted images.

It showed up that none of the patches provided any data in the partial images after the fourth level of the wavelet-transformation. And also the fourth level only contained data in a very few cases. This was not tested with patches larger than 32^2 pixels but the computation speed of implementations as used in this study can be enhanced when stopping feature computation after the third wavelet level. Table II includes an entry for a *first patch* method on 32^2 pixel gray-scale patches. This method was only implemented as an early placeholder for better founded methods and is therefore not listed in the results table.

VI. Conclusion

This paper is based on the wavelet standard-deviation descriptor [1] that uses texture images from the Brodatz texture database [15] containing 1856 samples. Their algorithm reaches an average classification rate of up to 70.30% when used in an image retrieval scenario. Compared to the extended classification approach in this paper the maximum task rate of 36.45% is to be rated rather moderate. The maximum feature rate of 42.12% also shows that a classification system (e.g. an automated image tagging system) can't solely be based on this algorithm. Nevertheless in 76.74% of the cases the

- *feature rate* represents the classification performance in regard to all validated regions
- *task rate* represents the classification performance in regard to the total number of regions
- 1st / 2nd / 3rd ≙ searched concept is contained in best / best two / best three affiliation result(s)
- all classification rates are percentage values, bold text shows the column's maximum
- $\sum$, $\prod$ reference to equations 5 and 6

correct concept can be found within the best three affiliated concepts out of ten. This can be used as a weighting factor for algorithms dealing with similar tasks. The results show two major problems when using texture descriptors on segmented images of natural scenarios. First the shape or size of the segments can strongly counter-act the requirements of the texture descriptor - in case of wavelets this is the square-sized base shape. And second texture patterns in natural images underly a perspective distortion as you most likely don't watch top-down onto the surface (like in satellite photography). The extension of the original approach brings up one more issue. Instead of comparing two images directly, an image is compared to a trained descriptor representing a group of texture patterns. This affects the capabilities of the algorithm as it adds additional noise to the results. Considering those problems the results appear sufficient as base for upcoming studies and the presented knowledge gaps require further investigation. The following paragraphs propose approaches to be validated in order to improve the classification performance.

A. Segment WSD selection

The determination of a segment's WSD can be dealt with in very different ways. The grid-based process used in this paper (see section IV-B) was chosen to make sure the input for the wavelet-transformation has always the same resolution. Another aspect was a predictable computation duration. However this demands for a selection or aggregation of data as most likely many WSDs can be computed for a single segment. The larger the grid's patch size is compared to the segment size the more data is lost in the border regions of the segments. It also increases the possibility to find no single patch being completely located within the segment. The smaller the grid's patch size is chosen the less representing the data found in a single patch becomes. This also increases the computation time a lot as much more wavelet-transformations and comparisons to the concepts must be performed per segment. Upcoming studies can therefore focus on the problem of finding an optimal patch size depending on the image resolution, the segment size and shape.

The selection or creation of a representative patch currently favors the mean value methods presented in section III-B. A method yet unevaluated would be to count the appearances the patches' concept affiliations favor a specific concept within a single segment. Saying a segment consisting of 10 patches favors 2 times ”sand”, 3 times ”water” and 5 times ”snow”. Then you can select the ”snow”-patch with the highest affiliation value to the concept snow as representative. An extension to this idea would be to connect positioning values to a patch's concept affiliation values. Saying the highest value scores 10 points (when having 10 concepts), the next highest value scores 9 points and so on. In the end you sum up the concept affiliation scores and pick the concept with the highest score as representative.

Another Idea that was tested is the *maximum square* approach. This approach increases the computation speed a lot as only one feature vector has to be calculated as soon as the maximum square area was identified. Unfortunately the results show a worse performance than a grid sized approach on gray-scales.

An even more sophisticated approach would be to identify subregions within the image segments that are oriented almost planar to the camera's viewpoint. Those subregions provide data that is just slightly altered due to perspective distortion. You can also think of finding a segment's world plane in order to create a planar representation through perspective back projection (e.g. an ocean layer or a wall). The assumption here is that the distortion a perspective back projection creates is smaller than the information value generated in terms of WSD similarity.

B. Similarity Measure

The similarity measure presented in this paper is based on a probabilistic approach using mean and standard deviation to create a similarity value for each of the feature's levels. Finally the similarities of each level were either summed up or multiplied to create a value expressing the patch's affiliation to a concept.

In literature there are a lot more similarity measures offered for vector- and histogram-like comparisons. Implementations using (e.g.) the vector angle, a support vector machine, the earth mover's distance or the kullback-leibler divergence might improve the results a lot.

C. Usage of color values

The implementation as proposed in [1] currently only uses the standard deviation of each color channel as color information. This means only the structural character of the color is taken into account when creating a concept representation. A more promising approach would be to use the color intensities and a comparison method based on their mean value as an additional factor in the process of calculating a concept affiliation. This could be realized e.g. using the HSV or Lab color space. A WSD-conform vector on the S,V or L channels is created to represent the structure of a segment and additionally the H or a and b channels create a similar vector including the color mean values. This should at least improve distinguishing concepts like snow, sand or sea from each other.

***Abstract*—Barcodes enable automated work processes without human intervention, and are widely deployed because they are fast and accurate, eliminate many errors and often save time and money. In order to increase the data capacity of barcodes, two dimensional (2D) code were developed; the main challenges of 2D codes lie in their need to store more information and more character types without compromising their practical efficiency. This paper proposes the High Capacity Colored Two Dimensional (HCC2D) code, a new 2D code which aims at increasing the space available for data, while preserving the strong reliability and robustness properties of QR. The use of colored modules in HCC2D poses some new and non-trivial computer vision challenges. We developed a prototype of HCC2D, which realizes the entire Print&Scan process. The performance of HCC2D was evaluated considering different operating scenarios and data densities. HCC2D was compared to other barcodes, such as QR and Microsoft's HCCB; the experiment results showed that HCC2D codes obtain data densities close to HCCB and strong robustness similar to QR.**

I. Introduction

Barcodes have become widely popular because of their reading speed, accuracy, and functional characteristics. As barcodes became popular and their convenience universally recognized, the market began to call for codes capable of storing more information, more character types, and that could be printed in smaller space. As a result, various efforts were made to increase the amount of information stored in barcodes, such as increasing the number of barcode digits or laying out multiple barcodes. However, these improvements have some negative effects, such as enlarged barcode areas, complicated reading operations, and increased printing costs. Barcodes may be referred to as linear or one-dimensional (1D) codes. However, barcodes are available also in patterns of square, dots, hexagons and other geometric patterns within the image; such a kind of barcodes are referred to as matrix or bidimensional (2D) codes. Although 2D systems use symbols other than bars, they are generally referred to as barcodes as well. In order to increase the available data space, 2D codes introduce the capability of storing information in two directions. 2D codes contains information in both the vertical and horizontal dimensions, whereas 1D codes contains data in one dimension only. Figure 1 shows examples of 2D (a) e 1D (b) codes.

Available 2D codes solutions span from repeating a single 1D code over multiple rows to exploiting bidimensional shapes to represents data. Figure 2 illustrates the evolution of barcode technology. In particular, Figure 2 (a) shows the multiple barcode layout: the main disadvantage related to this simple 2D layout is the need of multiple scans in order to get all the information contained in the barcode. Figure 2 (b) illustrates the stacked barcode layout: in this case one single scan is enough to obtain the stored information but the scanning equipment must be carefully aligned with the code orientation. Finally, in Figure 2 (c), the matrix barcode layout is presented: this layout enables to acquire information with one single scan and does not require the accurate alignment of the scanning equipment.

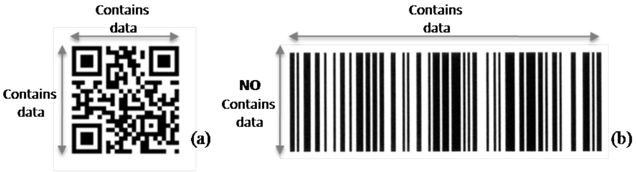

Fig. 1. Dimension for storing data in 2D (a) e 1D (b) codes

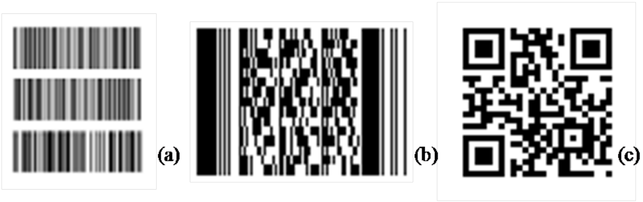

Fig. 2. Evolution of barcodes: multiple barcode layout(a), stacked barcode layout (b) and matrix barcode layout (c)

There are more than 20 types of conventional 2D codes. Figure 3 illustrates some examples of 2D codes; the main difference among the presented codes is in terms of the amount of data which can be stored in a single code. For example, Quick Response (QR)[1] code is able to store more than 7,000 decimal digits, while Maxi Code is able to store only 138 decimal digits. QR Code is a type of 2D codes developed by Denso Wave, a division of Denso Corporation at the time, and released in 1994 with the primary aim of being easily interpreted by scanner equipment.

The capability of storing more data in the same space taken by a classical two dimensional code represents one of the main challenges of the next generation barcodes. In order to increase

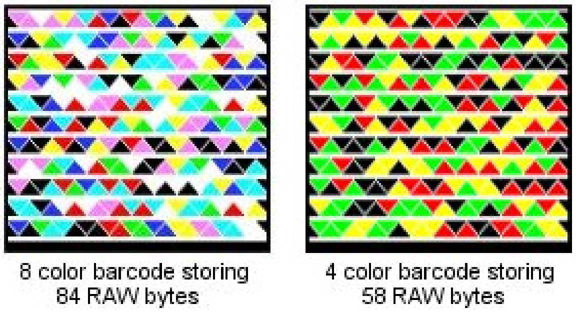

Fig. 4. An example of the Microsoft High Capacity Color Barcode (HCCB) (Viewed better in color)

data capacity, some 2D barcodes use colors to create more symbols, resulting in larger data capacity within the same size. Examples of such barcodes are the Color Bar Code System of Imageid Ltd [1] and the more widely diffused Microsoft's High Capacity Color Barcode (HCCB) [2], [3], [4]. While HCCB may be used for a variety of applications, its most immediate application is for marking univoquely commercial medias such as motion pictures, video games, broadcasts, digital video recordings, etc... We now describe briefly the main features of HCCB (see Figure 4). It consists of rows of strings of symbols (triangles) of four different colors: black, red, green and yellow, and consecutive rows are separated by a white line. While the number of rows in a HCCB code may vary, the number of modules in each row is always a multiple of the number of rows. A module represents the basic entity for storing information in a 2D code. HCCB has a black boundary around it, further surrounded by a thick white band. These patterns are designed to act as visual landmarks in order to locate the barcode in an image. The black boundary at the bottom of HCCB is thicker than the boundaries on the other three sides: the bottom boundary acts as an orientation landmark, as barcodes may be at an arbitrary orientation in the image. The last 8 symbols on the last row are always in the fixed order of black, red, green and yellow (2 symbols per color) and can be used as a color palette during the scan. The main limitation of the HCCB code is related to the fragility of the detection and alignment mechanisms. Indeed, the detection process works as follows: it starts from a point which is supposed to be at the interior of the code and proceeds on squares of larger sizes until it recognizes the white border around the code; after the white border has been located, it starts the alignment process by looking for the thick bottom boundary. The fragility of the detection process derives from the fact that not all the images inside a white border are necessarily codes (thus giving rise to delayed failures, which will be explained later), while the weakness of the alignment process derives from the facts that different slopes in the scan phase might result in failures to properly recognize the thick bottom boundary [5].

The increased data density obtained with the usage of colors comes at an additional cost. Today a Print&Scan process is commonly used for image reproduction and distribution. Indeed, often images are converted between printed and digital formats. A rescanned image may look similar to the original, but it may have been distorted during the process. Indeed, reading 2D color codes poses significant computer vision challenges [5], [6], [7]. This is due to several factors, and we cite only few of them in the following. First, the color balance may be drastically different in different code readers. Second, the images containing codes may be taken by unexperienced users, and thus the location of the barcode in the image, its orientation, its slope, etc. can be mostly unconstrained. Furthermore, possible transformations in the prospective can distort the geometry of the barcode. Last but not least, the light conditions under which the images are taken can vary dramatically.

Not all the scenarios where black and white 2D codes are currently exploited may benefit from the introduction of colors; in many scenarios 2D codes have to be copied or transmitted through fax, and fast color printers and color fax machines are not yet widely diffused in today's offices. On the other hand, the availability of new low cost hardware may solve some of the problems that arise in the Print&Scan process. Since in many cases the Print operation is executed once while the Scan operation is likely to be repeated many times, we can consider that replacing ad-hoc hardware for scanning 2D codes by inexpensive mobile phones equipped with a megapixel camera may dramatically boost the adoption of colored 2D codes.

The contribution of this work is a new 2D code technology, named HCC2D (High Capacity Colored Two Dimensional), which use colors to increase the code data density. The introduction and recognition of colored modules in HCC2D poses some new and non-trivial computer vision challenges, such as handling the color distortions introduce by the hardware equipment that realizes the Print&Scan process. The HCC2D codes presented in this paper are able to support different types and sizes of data input, and adapt smoothly the code dimension to the actual input size. In order to support all those scenarios in which the Print&Scan process imposes the usage of only two colors (i.e., Black&White) HCC2D considers Black&White codes as codes with exactly two colors. In particular, HCC2D has been designed so as to be fully compatible with the standard QR code, which is currently the most widespread 2D code technology (a standard QR code represents the simplest case of our 2D colored code). The main advantage of HCC2D over QR is that HCC2D is able to store substantially more data than QR, while preserving the strong reliability and robustness properties of QR.

We developed a prototype of HCC2D, which realizes the entire Print&Scan process, tested this prototype in many experiments considering different operating scenarios and data densities, and compared it to QR and HCCB. In our experiments, HCC2D codes obtained data densities close to HCCB and strong robustness similar to QR. In particular, HCC2D resulted to be very robust, and capable of resisting to dirt, damage and distortion, and introduced little computational overheads compared to QR.

II. Standard QR Code

Standard QR codes as well as other black and white 2D codes store data using a graphical representation; the core of this representation is based on the arrangement of multiple simple geometric shapes over a fixed space. A generic 2D code is required to perform efficiently at least the following three functions:

- the position detection function is critical; elements that serve as position detection function give to the acquisition process the capability of identifying the presence of a 2D Code in the acquired image;
- the alignment function is required to synchronize the Scan process on the right position of a 2D code. This function exploits some alignment patterns placed by the Print process in a well known position. Hence, the Scan process focuses on retrieving these well known patterns in order to position correctly the 2D code.
- the data function is required to encode the input data in a specific graphical representation. Some additional goals may be reached by the data function; error correction and data masking are examples of these functions for strengthening the 2D code.

In particular standard QR codes adopt an arrangement of black and white squares of different sizes for all the required functions. In the following, some of the features provided by QR codes will be discussed.

A. High Capacity Encoding of Data

While conventional 1D codes store up to 20 decimal digits, QR Code is able to store from several dozen to several hundred times more information. QR Code can handle a large variety of data, such as binary, numeric and alphabetic characters, Kanji, Kana and Hiragana (Japanese) symbols, and control codes. If the input is represented by decimal digits, one code can encode up to 7,089 decimal digits (see Figure 3).

B. Small Printout Size

Since QR code carries information both horizontally and vertically, it is capable of encoding the same amount of data in approximately one-tenth the space of a traditional 1D code.

C. Dirt, Damage and Distortion Resistant

QR code has error correction capability. Data can be restored even if the symbol is partially dirty and damaged (see Figure 5). A maximum of 30% of the codewords can be restored. A codeword is a unit that constructs the data area. In the case of QR code, one codeword is equal to 8 bits. Thanks to its alignment function, QR Code is resistant to distorted acquisitions.

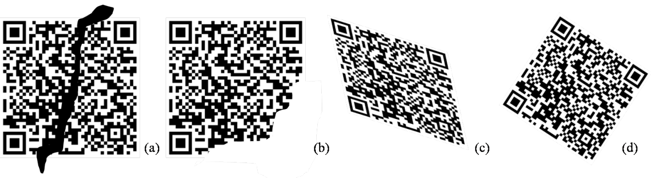

Fig. 5. Samples of QR Code dirty (a), damaged (b), distorted (c), and rotated(d).

D. Readable from any direction in 360 degrees

QR code is capable of 360 degrees (omni-directional) reading. This task is accomplished through position detection patterns located at the three corners of the symbol. These position detection patterns guarantee stable high-speed reading, circumventing the negative effects of background interference.

E. Structured Append Feature

If a single QR code is too large for the print space available, a splitting function may be applied to obtain smaller QR codes containing the same data. One data symbol can be divided into up to 16 codes, which can be printed in smaller areas (see Figure 6).

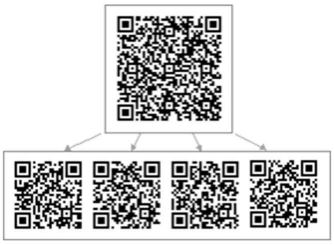

Fig. 6. Single QR Code splitted in four smaller QR Code

F. Standardization Process

QR codes have become widely used for two reasons: QR code specifications are clearly defined and made public and the QR codes can be freely usable. QR code is open in the sense that the specification of QR code is disclosed and that the patent right owned by Denso Wave is not exercised.

III. High Capacity Colored QR Code

The main goals of our HCC2D code are to increase the space available for data and to preserve strong robustness and error correction properties similar to the original QR standard. HCC2D increases the storage space by generating each module of the data area with a color selected from a color palette. Figure 7 illustrates samples of HCC2D with 4 colors HCC2D (Figure 7 (a)) and 16 colors (Figure 7 (b)).

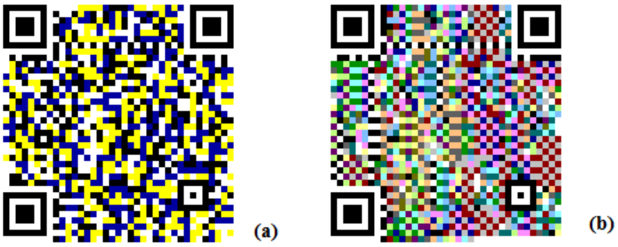

Fig. 7. Samples of the High Capacity Colored Two Dimensional Code (HCC2D) version 5 and error correction level H: 4 colors (a) and 16 colors (b) (Viewed better in color).

In the standard QR code each module represents a single bit following a simple rule: black squares store 1 and white squares store 0. To ensure robustness, we have designed similar mechanisms to those available in the standard QR code; in particular, we have applied the Reed Solomon error correction codes for correcting code modules that represent more than one single bit. This way, HCC2D defines a superset of the standard QR code set, and thus it is able to maintain fully compatibility with QR.

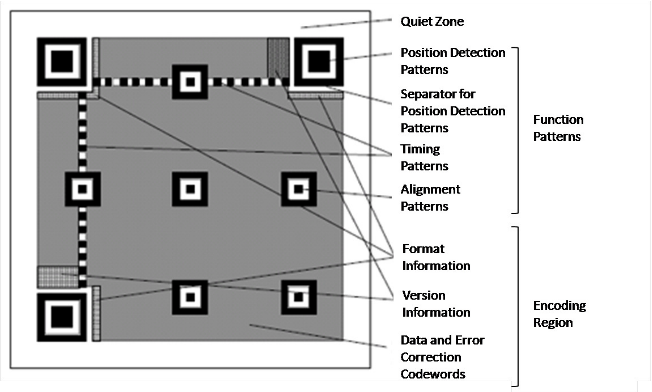

Fig. 8. Structure of a generic QR Code

A standard QR Code can be represented as shown in Figure 8; the structure is composed of some elements that perform the various functions. The available space in each symbol may serve as *Function Patterns* or as *Encoding Region*. The *Position Detection Patterns*, the *Alignment Patterns*, the *Timing Patterns*, and the *Separators for Position Detection Patterns* support the Scan process in detecting the presence, the right orientation and the correct slope of a QR code into an image. The *Format Information* describes the error correction level used in the code; it is possible to use four different error correction levels in the HCC2D code: the lower level (i.e., Level L) is able to correct about 7% of the data, the Level M restores about 15% of the data, the Level Q is able to fix about 25% of the data, and the higher level (i.e., Level H) corrects approximately 30% of the data. The *Version Information* contains the real size of the code; it is possible to generate QR codes starting from Version 1 (i.e., 21x21 modules) to Version 40 (i.e., 177x177 modules). Finally the *Data and Error Correction Codewords* contains input and error correction data.

We designed the HCC2D code preserving all the *Function Patterns*, the *Format Information* and the *Version Information* defined in the standard QR code. Saving the structure and position of such critical information allows HCC2D code to preserve compatibility with the standard QR code. Furthermore, the space required by all this information is small, so we did not reduce this space to increase the data density. Any modification to such information may led to failures in the recognition process. The most important changes are gathered in the Data and Error Correction Codewords area. The most noticeable difference with a standard QR code is that the modules may be of different colors; in a code with a palette composed by at least 4 colors each module is able to store more than one bit. Introducing colors in the data and error correction area requires to address some issues, which will be analyzed next.

A. *HCC2D Code Tables*

The HCC2D Code Tables contain some information such as the total codewords count, the symbol version, the error correction level, the Reed-Solomon block type, etc. The aim of these tables is to support users in selecting the best code once the size and kind of the input data and the desired error correction level are known. In order to define the table it is possible to refer to those published in the ISO/IEC 18004 document that contains the definition of the standard QR code. The Bits per Module (BpM) can be defined as the number of bits that a single module is able to store:

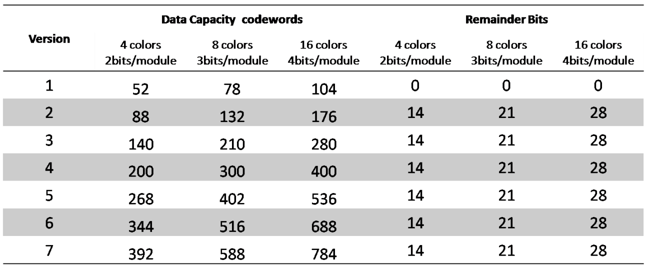
$$BpM = \log_2(\text{number of colors})$$

The more colors available, the more data can be stored into the code. In Figure 9 the data capacity for the smaller versions of QR Code are detailed.

Version	No. Of Modules/Side	Function Patterns Modules	Format and Version Information Modules	Data Modules	Data Capacity (codewords)	Remainder Bits
1	21	202	31	208	26	0
2	25	235	31	359	44	7
3	29	243	31	567	70	7
4	33	251	31	807	100	7
5	37	259	31	1079	134	7
6	41	267	31	1383	172	7
7	45	390	67	1568	196	0

Fig. 9. Data capacity for smaller version of standard QR Code

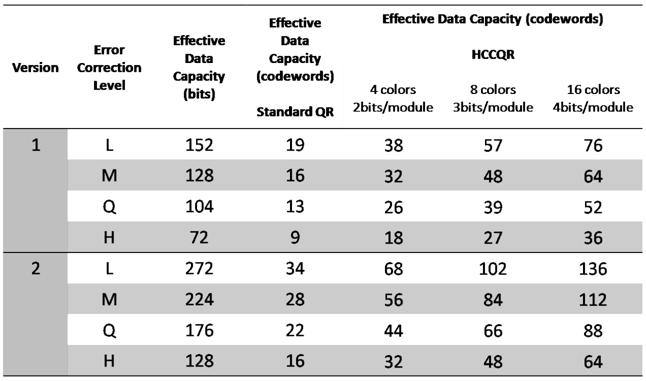
When considering values for BpM greater than one, values contained in the Data Capacity column vary. In particular, since each module is able to store exactly BpM bits each value has to be multiplied by the BpM value as shown in Figure 10. The *Remainder Bits* are bits used to fill empty positions of the symbol encoding region after the final symbol character in the standard QR codes. They follow the same simple rules: the new value of *Remainder Bits* is obtained by multiplying the old value by the BpM value.



Version	Data Capacity codewords			Remainder Bits		
	4 colors 2bits/module	8 colors 3bits/module	16 colors 4bits/module	4 colors 2bits/module	8 colors 3bits/module	16 colors 4bits/module
1	52	78	104	0	0	0
2	88	132	176	14	21	28
3	140	210	280	14	21	28
4	200	300	400	14	21	28
5	268	402	536	14	21	28
6	344	516	688	14	21	28
7	392	588	784	14	21	28

Fig. 10. New values for data capacity for smaller version of HCC2D codes

Figure 11 illustrates the effective data capacity for version 1 and version 2 of QR and HCC2D when considering the use of a specific error correction level. The new effective capacity is obtained by multiplying the old values by the BpM value. Starting from these values and choosing the data type that will be encoded in the HCC2D code we can compute the real code capacity.

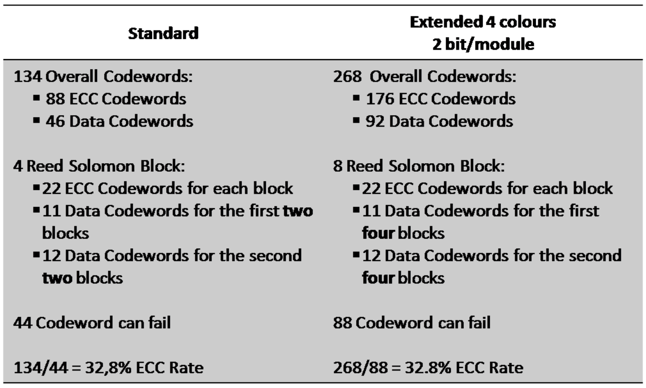


Version	Error Correction Level	Effective Data Capacity (bits)	Effective Data Capacity (codewords)	Effective Data Capacity (codewords)		
				HCCQR		
			Standard QR	4 colors 2bits/module	8 colors 3bits/module	16 colors 4bits/module
1	L	152	19	38	57	76
	M	128	16	32	48	64
	Q	104	13	26	39	52
	H	72	9	18	27	36
2	L	272	34	68	102	136
	M	224	28	56	84	112
	Q	176	22	44	66	88
	H	128	16	32	48	64

Fig. 11. Error Correction Level for version 1 and version 2 of standard QR codes and HCC2D codes

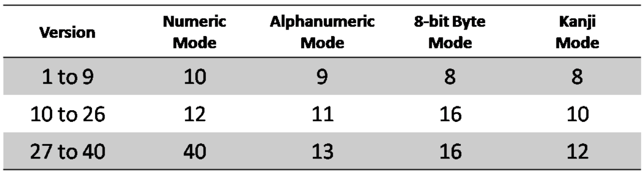
Figure 12 illustrates the situation for version 5 of HCC2D with the highest error correction level (i.e., level H). The *Character Count Indicator* value gives the number of elements of a specific data type that are encoded in the code. Conversely, the *Mode Parameter* expresses the specific data type contained in the code. Since the main goal of HCC2D is to increase the number of elements that can be encoded in a single symbol, it is important to verify if this value fits in the space reserved by the standard.

Note that QR code version from 1 (i.e., 21x21 modules) to 9 (i.e., 53x53 modules) in alphanumeric mode reserves 9 bits for the *Character Count Indicator*, thus allowing for at most 511 (i.e., $2^9 - 1$) characters. However, with the increase of data density, HCC2D codes may contain more than 511 elements, and thus 9 bits are no longer sufficient. Hence, the space reserved for the *Character Count Indicator* in a HCC2D code is defined according the following rules:



Standard	Extended 4 colours 2 bit/module
134 Overall Codewords: ▪ 88 ECC Codewords ▪ 46 Data Codewords	268 Overall Codewords: ▪ 176 ECC Codewords ▪ 92 Data Codewords
4 Reed Solomon Block: ▪ 22 ECC Codewords for each block ▪ 11 Data Codewords for the first **two** blocks ▪ 12 Data Codewords for the second **two** blocks	8 Reed Solomon Block: ▪ 22 ECC Codewords for each block ▪ 11 Data Codewords for the first **four** blocks ▪ 12 Data Codewords for the second **four** blocks
44 Codeword can fail	88 Codeword can fail
134/44 = 32,8% ECC Rate	268/88 = 32.8% ECC Rate

Fig. 12. Comparison between standard QR code and HCC2D code considering version 5 and error correction level H



Version	Numeric Mode	Alphanumeric Mode	8-bit Byte Mode	Kanji Mode
1 to 9	10	9	8	8
10 to 26	12	11	16	10
27 to 40	40	13	16	12

Fig. 13. Number of bits reserved for the *Character Count Indicator* for the various standard QR Code version

- 16 bit are reserved in the 8-bit Byte mode, regardless of the HCC2D Code version;
- for the remaining modes, a simple rule that combine the old *Character Count Indicator* length, $Length_{old}$, and the bit per module, BpM value is applied:
  - $Length_{old} + (BpM/2)$ if the number of bits per module is even
  - $Length_{old} + ((BpM + 1)/2)$ if the number of bits per module is odd

Those rules are valid if and only if the color palette is composed by at least four colors; otherwise, the space for the *Character Count Indicator* can be defined as in QR codes (see Figure 13).

B. The Color Palette

If the *Encoding Region* is composed of colored modules, the Scan process needs to know the complete color palette in order to decode the symbol. In the standard QR code during the Scan process only the brightness information is taken in account. A simple solution is to consider the color palette as an *a priori* shared knowledge between the Print and the Scan processes; in such a scenario handling the distortions introduced by the specific hardware (e.g., scanner, camera, ...) represents a critical issue. Hence, in the HCC2D code we have introduced an additional field (i.e., the color palette) to ensure that the Scan process is able to know how many and which colors are used in the scanned code. Encoding the color palette directly in the HCC2D code helps in reducing failures in the acquisition process due to the color distortions related to the specific hardware.

In image processing, it is important to define some quick failure criteria that avoid unnecessary computations if the Scan process delays a successful recognition. Forcing the start of a new Scan process instead of trying to recognize low quality images can reduce the delayed failure. Sorting the colors that compose the color palette according to the brightness value may represent a simple criterion to overcome the delayed failure problem. The Scan process starts recognizing only the color palette, if colors in the palette are not sorted as expected the process terminate with a quick failure, otherwise the Scan process can continue.

Furthermore, if the color palette is replicated around the bidimensional code, the quick failure rate can be further reduced. Each color palette that does not respect the expected color sorting should be discarded. If a minimum number of color palettes is successfully recognized, the Scan process can build the color palette for decoding the code by computing the average of the valid color palettes. In HCC2D the repeated color palettes are placed on the right side of the code; this single line will be adjacent to the *Encoding Region* for preserving compatibility. Considering version 1 of HCC2D code we introduce an overhead of about 4,76 %, i.e., one line of 21 modules over 441 modules. The overhead is reduced to 0,56% for version 40, i.e., one line of 177 modules over 31329 modules.

Analyzing the color palette extra field in the HCC2D code, the Scan process is able to build a model for evaluating each module in the *Encoding Region*. In the standard QR code the problem of distinguishing between light and dark modules is addressed by handling only the brightness information; exploiting the *Quiet Zone* to calibrate the Scan process, an appropriate threshold is chosen. In HCC2D a more complex similarity function is needed for handling colored modules. Since colors in computer graphics are usually represented as vectors in multidimensional space (e.g., the Red Green Blue model, the Cyan Yellow Magenta Key model, the Hue Saturation Lightness model, etc.), we solve the identification problem by using Euclidean distances between such vectors. In particular, modules in the encoding region are considered as vectors according to the specific color model used by the scanning equipment; the color recognized is given by the color in the palette which minimizes the vector distance.

C. Data Masking

The main purpose of data masking in the standard QR code is to reach an appropriate balance between dark and light areas and to avoid that patterns similar to those used for *Position Detection*, *Alignment* and *Timing* appear in the *Encoding Region*. The HCC2D needs a similar function for preserving the Scan process in recognizing the *Function Patterns* and increasing the code robustness. The standard QR code defines eight different masks; each mask is generated according to a simple rule that mimics the *Function Patterns*. The Print process has to select the mask that obtains the best score according to a scoring rule that is based on some bitwise XOR operations. Switching the brightness of some modules (i.e., light modules become dark modules and vice versa) is the result of data masking.

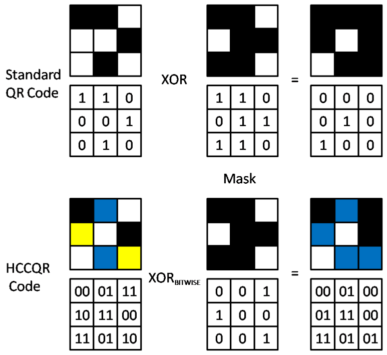


Fig. 14. Sample application of data masking in standard QR code and HCC2D code

Since HCC2D increases the number of bits per module (BpM), the standard scoring rules are no longer useful and we need to define new bitwise operations that are able to handle more than one bit per module. As far as the mask selection step is concerned, the HCC2D code is considered as a binary matrix composed simply of dark (i.e., the darkest colors) and light (i.e., the lightest colors) modules; the score for each mask is computed as in the standard QR code without taking in account the chromatic information of modules which is disjoint by the brightness information. Once the best mask is identified, each bit of the mask has to be used for switching the color of the module in the *Encoding Region*. For each module a bitwise operation between the bit in the mask and each bit that is stored in the module has to be performed. Figure14 shows an example of how the data masking process works for a 3x3 modules grid with 4 colors, considering both the standard QR code and the HCC2D code.

To preserve the balance between dark and light areas, we need to properly organize the palette. The colors are sorted in descending order according to the brightness information, the lighter colors first and the darker colors last; the color palette is then splitted in two halves and the second part is sorted in reverse order. As shown in Figure 15, this simple reorganization of colors in the palette results in increasing the minimum brightness distance between switched colors from 10% up to 35%.

IV. Experimental Results

We developed a prototype that implements the Print&Scan process for HCC2D codes. In particular, we implemented two different applications, the encoder and the decoder, for generating and acquiring HCC2D codes. The HCC2D code encoder was realized with the help of *libqrencode* [8], a C library for encoding data in standard QR code symbols, while the decoder was built with the help of *zxing* [9], an opensource Java project for improving the processing of 1D/2D barcodes. In our implementation, the decoder is

able to recognize standard QR codes as well; some of the operations executed in the acquisition process are preserved: recognizing the position detection pattern, recognizing and exploiting the alignment patterns, and reading the version and format information. After all these operations have been carried out, the decoder tries to detect the color palette. If the color palette is succesfully detected, the decoder tries to process a HCC2D code. Otherwise, it tries to decode a standard QR code. The image processing phase ends by returning a matrix representation of the scanned code; in the standard QR code a bitmatrix is sufficient to represent the modules whose brightness is greater (i.e., bit 0) or lower (i.e., bit 1) than the threshold value determined by analyzing the *Quiet Zone*. In HCC2D a bitmatrix is not adequate to represent the chromatic information of the modules. The acquisition process ends with a matrix of vectors that describe the scanned modules according to the color model used by the scanning equipment. In the HCC2D code design data are unmasked using the brightness information only; each scanned module is represented as a vector in the color model: a color distance rule is applied, the most similar (i.e., the closest) color in the palette is found and the associated bitstream is updated. Once the complete bitstream is reconstructed, the Reed-Solomon correction may be executed and the decoding process can retrieve the original input.

We now turn to the experimental results. We executed some performance tests using our prototype. We aimed at measuring the increase of the space available for data and the time computational overhead introduced by the use of colors, and thus we measured the time needed to convert all modules in a binary representation according to the color palette considered. Finally we reproduced the Print&Scan process for different code versions and different print qualities using widely diffused and low-cost print and scan equipment.

The first issue we address is the increase of data density, and a general comparison is illustrated in Table I. Like most 2D codes, the QR Code data-density depends on several factors. The module size depends heavily on the printing and scanning resolutions. Microsoft offers its HCCB in black and white, with four and eight different colors. Currently Microsoft laboratory tests have yielded using eight colors, 16,000 bits per square inch in its highest density form using a 600dpi business card scanner (cfr. [2]). Conversely, if a standard QR code symbol is printed with a resolution of 600 dpi, 4-dot printer, the module size is 0.17mm and will therefore require a scanner resolution of less than 0.17 mm (cfr. [10]). Using Version 19 of the standard QR code and the M correction level (i.e. about 15%) it is possibile to store 5,016 bits per square inch. Introducing a color palette composed of 8 colors, a HCC2D code of Version 19 and with the M correction level, is able to store 15,048 bits per square inch. HCC2D data density is slightly lower than Microsoft's HCCB data density but while our solution preserves similar robustness in detection, alignment, and error correction of the standard QR code HCCB has no patterns that strongly support the detection and alignment process. Our solution increases the data density of standard QR code by a factor proportional to the BpM as mentioned in Section III-A and reaches a similar capacity to Microsoft HCCB.

30H	338	416 (18.75%)	506 (33.20%)
40L	430	483 (10.97%)	550 (21.81%)
40M	415	481 (13.72%)	540 (23.15%)
40Q	420	500 (16.0%)	566 (25.79%)
40H	373	485 (23.09%)	552 (32.42%)

Afterwards, we address the computational overhead for processing HCC2D codes by comparing the average time taken by the scan process. As far as standard QR codes are concerned, the time required for the automatic recognition of a code may be considered as a measure for the Scan process. Selection of a proper binarization method is critical to the performance of barcode recognition system. Binarization of gray scale images is the first and important step to be carried out in pre-processing system. In binarizing an image, a simple and popular method is thresholding. Sahoo et al. [11] concluded that, among more than 20 thresholding methods, the Otsus method [12] which chooses the threshold that minimizes within-group variance, gives better results. A goal-directed performance evaluation of eleven popular locally adaptive thresholding algorithms were performed in [13] for map images. The experimental results indicated that Niblacks method with postprocessing step appears to be the best. Since our solution preserves the binarization for recognizing position detection and alignment patterns, the results mentioned in [11], [12], [13] are still valid.

In Table II we report results of an experiment focused on the recognition of more than 100 barcode images. To measure the overhead introduced by colors, times were taken after the alignment and detection phase. The experiment was run on a machine equipped with a Linux Slackware 13.0 operating system running on 1.73 GHz Intel dual core with 1 GB of RAM. The results report the average time in milliseconds for QR codes, HCC2D with 4 colors and HCC2D with 16 colors, and the overhead (in parenthesis, percentual values) introduced by HCC2D over QR. Our experiments show that, although the overhead introduced by HCC2D over QR tends to increase, as expected, with the number of colors and the code size, it seems to remain always within reasonable values (ranging from a minimum of about 3% for HCC2D version 1H with 4 colors to a maximum of about 38% for HCC2D version 20L with 16 colors). In particular, the average overhead introduced by HCC2D with 4 colors is about 15%, while the average overhead introduced by HCC2D with 16 colors is about 25%. The dependendence of the overhead on the error correction levels appears to be more complicated: in HCC2D with 4 colors the overhead (for the same code size) tends to decrease with the error correction levels for all versions except for version 40, while our experiments did not show a very strong correlation between the overhead of HCC2D with 16 colors and the error correction levels. In any case, the slowdown implied by the use of higher levels of error correction appears always limited (within about 5% of the total time).

Finally, in order to evaluate the usability of HCC2D code in a real setting, we realized a common Print&Scan scenario using a widespread inkjet multifunction equipment with print and scan capabilities. The equipment is able to print and to scan at different resolutions; in the test scenario we decide to fix the scan resolution while varying the print resolution. We have considered four different print resolutions: Draft Mode (i.e., 180 dpi), Text Mode (i.e., 360 dpi), Text and Photo Mode (i.e., 720 dpi), Text and Photo Mode (i.e., 720 dpi) and Photo (i.e., 1440 dpi). We experimented with a small print size (1 square inch) for different versions of the 4-colors HCC2D codes with the L error correction level; the Print&Scan process is repeated for the code versions: Version 5 (i.e., 37x37 modules), Version 10 (i.e., 57x57 modules) and Version 15 (i.e., 77x77 modules). Table III shows that only codes printed at poor quality levels (i.e., Draft Mode with a resolution of 180 dpi) fail to complete successfully the Print&Scan process. When the print resolution increases, the success rate depends on the HCC2D version: at 360 dpi only Version 15 (77x77 modules) failed on print sizes of 1 square inch.

TABLE III
USABILITY OF DIFFERENT VERSIONS OF THE HCC2D CODE VARYING THE PRINT RESOLUTION

Print resolution	180dpi	360dpi	720dpi	1440dpi
Version 5	No	Yes	Yes	Yes
Version 10	No	Yes	Yes	Yes
Version 15	No	No	Yes	Yes

V. CONCLUSIONS

In this paper we have proposed High Capacity Colored QR codes, a new 2D code which aims at increasing the space available for data, while preserving similar robustness, error correction and without loosing compatibility with the original QR standard. Our results show that HCC2D leads to larger data density compared to QR at the price of a small computational overhead. Though the data density is slightly lower than in HCCB, HCC2D does not suffer from the problems in detection and alignment of the 2D code.

***Abstract*—The present paper is aimed to compare the efficiency of a new segmentation method with several existing approaches. The paper addresses the problem of image segmentation evaluation from the error measurement point of view.We are introducing a new method of salient object recognition with very good results relative to other already known object detection methods. We developed a simple evaluation framework in order to compare the results of our method with other segmentation methods. The experimental results offer a complete basis for parallel analysis with respect to the precision of our algorithm, rather than the individual efficiency.**

I. Introduction

The problem of segmentation is an important research field and many segmentation methods have been proposed in the literature so far ([1],[3],[4],[7]). The aim of image segmentation is the domain-independent partition of the image into a set of regions which are visually distinct and uniform with respect to some property, such as grey level, texture or color.

Image segmentation is one of the most important operations performed on acquired images. Image segmentation evaluation [2] focuses on two main properties: objectivity and generality. Objectivity means that all the test images in the benchmark should have an unambiguous ground-truth segmentation so that the evaluation can be conducted objectively. Generality means that the test images in the benchmark should have a large variety so that the evaluation results can be extended to other images and applications.

The main objective of this paper is to emphasize the very good results of image segmentation obtained by our segmentation technique, $Graph-Based\ Salient\ Object\ Detection$, and to compare them with other existing methods. The algorithms that we use for comparison are: $Normalized\ Cuts$, $Efficient\ Graph-Based\ Image\ Segmentation$ $(Local\ Variation)$ and $Mean\ Shift$. All of them are complex and well known algorithms, with very good results in this area and building the knowledge based on their results represents a solid reference.

The experiments were completed using the images and ground-truth segmentations in the Berkeley segmentation dataset [8]. Since the ground-truth segmentation may not be well and uniquely defined, each test image in the Berkeley benchmark is manually segmented by a group of people.

The segmentation accuracy is measured taken into consideration the global consistency error and the local consistency error. We will provide comparative results that reflect a well-balanced behavior of the algorithm we propose.

The paper is organized as follows. In Section III we briefly present previous studies in the domain of image segmentation and the segmentation method we propose. The methodology of performance evaluation is presented in Section IV. The experimental results are presented in Section V. Section VI concludes the paper and outlines the main directions of the future work.

II. Related Work

Image segmentation evaluation is an open subject in today's image processing field. The goal of existing studies is to establish the accuracy of each individual approach and find new improvement methods. The segmentation methods require ground truth image segmentations as reference. The main drawback of providing such reference is represented by the resources that are needed. However, after analyzing the differences between the image under study and the ground truth segmentation, a performance proof is obtained.

Region-based segmentation methods can be broadly classified as either model-based [13] or visual feature-based [14] approaches. A distinct category of region-based segmentation methods that is relevant to our approach is represented by graph-based segmentation methods. Most graph-based segmentation methods attempt to search a certain structures in the associated edge weighted graph constructed on the image pixels, such as minimum spanning tree [3], or minimum cut [15].

Berkeley image segmentation benchmark is the reference that we use for our study. Using the same input, the provided image dataset, we are developing a customized methodology in order to efficiently evaluate our algorithm.

The closest work to ours is [3], in which an image segmentation is produced by creating a forest of minimum spanning trees of the connected components of the associated weighted graph of the image. The novelty of our contribution concerns two main aspects: (a) in order to minimize the running time we construct a hexagonal structure based on the image pixels, that is used in both color-based and syntactic-based segmentation algorithms, and (b) we propose an efficient method for segmentation of color images based on spanning trees and both color and syntactic features of regions.

III. Segmentation Methods

We will compare four different segmentation techniques, the Mean Shift-Based segmentation algorithm [4], Efficient Graph-Based segmentation algorithm [3], Normalized Cuts segmentation algorithm [7] and our own region-based segmentation method. We have chosen Mean Shift-Based segmentation because it is generally effective and has become widely-used in the vision community. The Efficient Graph-Based segmentation algorithm was chosen as an interesting comparison to the Mean Shift. Its general approach is similar, however, it excludes the mean shift filtering step itself, thus partially addressing the question of whether the filtering step is useful. Due to its computational efficiency, Normalized Cuts represents a solid reference in our study. We use all these algorithms as terms of comparison for the evaluation we performed.

A. Graph-Based Salient Object Detection

We present an efficient segmentation method that uses color and some geometric features of an image to process it and create a reliable result [10]. The used color space is RGB because of the color consistency and its computational efficiency.

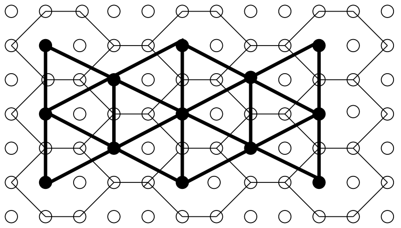

Fig. 1. The grid-graph constructed on the hexagonal structure of an image

What is particular at this approach is the basic usage of hexagonal structure instead of color pixels. In this way we can represent the structure as a grid-graph $G = (V, E)$ where each hexagon h in the structure has a corresponding vertex $v \in V$, as presented in Figure 1. Each hexagon has six neighbors and each neighborhood connection is represented by an edge in the set E of the graph. For each hexagon on the structure two important attributes are associated: the dominant color and the coordinates of the gravity center. Basically, each hexagonal cell contains eight pixels: six from the frontier and two from the middle.

Image segmentation is realized in two distinct steps. The first step represents a pre-segmentation step when only color information is used to determine an initial segmentation. The second step represents a syntactic-based segmentation step when both color and geometric properties of regions are used.

The first step of the segmentation algorithm uses a color-based region model and will produce a forest of maximum spanning trees based on a modified form of the Kruskal's algorithm. In this case the evidence for a boundary between two adjacent regions is based on the difference between the internal contrast and the external contrast between the regions. The color-based segmentation algorithm builds a maximal spanning tree for each salient region of the input image.

The second step of the segmentation algorithm uses a new graph, which has a vertex for each connected component determined by the color-based segmentation algorithm. In this case the region model contains in addition some geometric properties of regions such as the area of the region and the region boundary. The final segmentation step produces a forest of minimum spanning trees based on a modified form of the Borůvka's algorithm. Each determined minimum spanning tree represents a final salient region determined by the segmentation algorithm.

B. Efficient Graph-Based Image Segmentation

Efficient Graph-Based image segmentation [3], is an efficient method of performing image segmentation. The basic principle is to directly process the data points of the image, using a variation of single linkage clustering without any additional filtering. A minimum spanning tree of the data points is used to perform traditional single linkage clustering from which any edges with length greater than a given threshold are removed [6].

Let $G = (V, E)$ be a fully connected graph, with m edges $\{e_i\}$ and n vertices. Each vertex is a pixel, x, represented in the feature space. The final segmentation will be $S = (C_1, ..., C_r)$, where C_i is a cluster of data points. The algorithm [3] can be shortly presented as follows:

1) Sort $E = (e_1, ..., e_m)$ such that $|e_t| \leq |e'_t| \forall t < t'$
2) Let S^0=$(\{x_1\}, ..., \{x_n\})$ in other words each initial cluster contains exactly one vertex.
3) For $t = 1, ..., m$
    a) Let x_i and x_j be the vertices connected by e_t.
    b) Let $C^{t-1}_{x_i}$ be the connected component containing point x_i on iteration $t-1$ and $l_i = max_{mst} C^{t-1}_{x_i}$ be the longest edge in the minimum spanning tree of $C^{t-1}_{x_i}$. Likewise for l_j.
    c) Merge $C^{t-1}_{x_i}$ and $C^{t-1}_{x_j}$ if:

$$|e_t| < min\left\{ l_i + \frac{k}{C^{t-1}_{x_i}}, l_j + \frac{k}{C^{t-1}_{x_j}} \right\} \quad (1)$$

4) $S = S^m$.

C. Normalized Cuts

Normalized Cuts method models an image using a graph $G = (V, E)$, where V is a set of vertices corresponding to image pixels and E is a set of edges connecting neighboring pixels. The edge weight $w(u, v)$ describes the affinity between two vertices u and v based on different metrics like proximity and intensity similarity. The algorithm segments an image into two segments that correspond to a graph cut (A, B), where A and B are the vertices in the two resulting subgraphs.

The segmentation cost is defined by:

$$Ncut(A,B) = \frac{cut(A,B)}{assoc(A,V)} + \frac{cut(A,B)}{assoc(B,V)} \qquad (2)$$

where $cut(A,B) = \sum_{u \in A, v \in B} w(u,v)$ is the cut cost of (A,B) and $assoc(A,V) = \sum_{u \in A, v \in V} w(u,v)$ is the association between A and V. The algorithm finds a graph cut (A,B) with a minimum cost in $Eq.(1)$. Since this is a NP-complete problem, a spectral graph algorithm was developed to find an approximate solution [7]. This algorithm can be recursively applied on the resulting subgraphs to get more segments. For this method, the most important parameter is the number of regions to be segmented. Normalized Cuts is an unbiased measure of dissociation between the subgraphs, and it has the property that minimizing normalized cuts leads directly to maximizing the normalized association relative to the total association within the sub-groups.

D. Mean Shift

The Mean Shift-Based segmentation technique [4] is one of many techniques dealing with "feature space analysis". Advantages of feature-space methods are the global representation of the original data and the excellent tolerance to noise [9]. The algorithm has two important steps: a mean shift filtering of the image data in feature space and a clustering process of the data points already filtered. During the filtering step, segments are processed using the kernel density estimation of the gradient. Details can be found in[4]. A uniform kernel for gradient estimation with radius vector $h = [h_s, h_s, h_r, h_r, h_r]$ is used. h_s is the radius of the spatial dimensions and h_r the radius of the color dimensions. Combining these two parameters, complex analysis can be performed while training on different subjects.

Mean shift filtering is only a preprocessing step. Another step is required in the segmentation process: clustering of the filtered data points $\{x'\}$. During filtering, each data point in the feature space is replaced by its corresponding mode. This suggests a single linkage clustering that converts the filtered points into a segmentation.

Another paper that describes the clustering is [5]. A region adjacency graph (RAG) is created to hierarchically cluster the modes. Also, edge information from an edge detector is combined with the color information to better guide the clustering. This is the method used in the available EDISON system, also described in [5]. The EDISON system is the implementation we use in our evaluation system.

IV. Region-based performance evaluation

We present comparative results of segmentation performance for our region based segmentation method and the three alternative segmentation methods mentioned above.

Our evaluation measure is mainly related to the consistency between segmentations. We use segmentation error measures that provide an objective analysis of the segmentation algorithms.

A potential problem for a measure of consistency between segmentations is that there is no unique human segmentation of an image, since each human perceives the scene differently. In this situation you could declare the segmentations inconsistent. However, if one segmentation is a refinement of the other, then the error should be small. Therefore, the measures are designed to be tolerant to refinement. Some other aspects to be taken into account are that error measure should not depend on the pixelation level and should be tolerant to noise along region boundaries.[12]

We used two metrics in order to provide an objective comparison between the four segmentation methods and the human segmentation. The two error measures are described below. We applied the measures to the Berkeley segmentation database and the segmentation results of the four algorithms.

In order to describe the segmentation errors, we considered two different segmentations S_1 and S_2 and calculated a value in the range $[0..1]$ where 0 represents no error. For a given p_i we considered segments S_1 and S_2 that contain the pixel. If one segment is a proper subset of the other, then the pixel lies in an area of refinement, and the local error should be zero. Otherwise, the two regions overlap in a inconsistent manner and we should calculate the corresponding error. We use \to denote the set difference and $|x|$ for cardinality of set x.If $R(S, p_i)$ is the set of pixels corresponding to the region in segmentation S that contains pixel p_i, the local refinement error is defined as:

$$E(S_1, S_2, p_i) = \frac{|R(S_1, p_i) n R(S_2, p_i)|}{|R(S_1, p_i)|} \qquad (3)$$

This local error measure is not symmetric. It encodes a measure of refinement in one direction only: $E(S_1, S_2, p_i)$ is zero precisely when S_1 is a refinement of S_2 at pixel p_i, but not vice versa. Considering this local refinement error in each direction at each pixel, there are two methods to combine the values into an error measure for the entire image. We apply two error measures as follows: $Global\ Consistency\ Error$ (GCE) that forces all local refinements to be in the same direction and $Local\ Consistency\ Error$ (LCE) that allows refinement in different directions in different parts of the image.[11] For a given n as the number of pixels we have:

$$GCE(S_1, S_2) = \frac{1}{n} min \left\{ \sum_i E(S_1, S_2, p_i), \sum_i E(S_2, S_1, p_i) \right\} \qquad (4)$$

$$LCE(S_1, S_2) = \frac{1}{n} \sum_i min\{E(S_1, S_2, p_i), E(S_2, S_1, p_i)\} \qquad (5)$$

We will evaluate the performance of our algorithm on the Berkeley Segmentation Database (BSD) [8]. We will refer the characteristics of the error metrics previously defined by Martin et al. [2], explore potential problems with these metrics in order to evaluate the quality of each segmentation and to characterize its performance over a range of parameter values.

The current public version of the Berkeley Segmentation Database is composed of 300 color images. The images have a size of 481×321 pixels, and are divided into two sets, a training set containing 200 images that can be used to tune the parameters of a segmentation algorithm, and a testing set containing the remaining 100 images on which the final performance evaluations should be carried out.

We built a custom benchmark framework, that processes the Berkeley dataset, converts it to our proprietary format and preforms parallel analysis. Additionally, we adapted the other mentioned algorithms to the same evaluation format for unitary purposes.

The human segmented images provide the ground truth boundaries. Therefore, any boundary marked by a human subject is considered to be valid. Since there are multiple segmentations of each image by different subjects, it is the collection of these human-marked boundaries that constitutes the ground truth. Based on the output of the previously presented algorithms for a set of images, we will determine how well the ground truth boundaries are approximated.

In order to determine an algorithm's efficiency by comparing it to the ground truth boundaries, a threshold of the boundary map is needed.

We are providing an additional evaluation based on histogram representation of the error density characteristic for each algorithm.

V. Experimental Results

Our study of segmentation quality is based on experimental results and uses the Berkeley segmentation dataset provided at [8].

A. GCE and LCE Metrics

In order to proper evaluate the segmentation method we propose, we first need to better understand how the GCE and LCE error metrics work. Given two extreme cases:an under-segmented image, where every pixel has the same label (i.e. the segmentation contains only one region spanning the whole image), and a completely over-segmented image in which every pixel has a different label.

From the definitions of the GCE and LCE we can see that both measures evaluate to 0 on both of these extreme situations regardless of what segmentation they are being compared to. The reason for this can be found in the tolerance of these measures to refinement. Any segmentations is a refinement of the completely under-segmented image, while the completely over-segmented image is a refinement of any other segmentation.

In order to have a better analysis result and a more complete description for the errors we considered, we have performed 10 different tests for each subject per algorithm - Fig. 2.

More precisely, by varying several key parameters, we have obtained 10 distinct points that define the errors for each approach. For $Normalized\ Cuts$ [7] we have modified the $number\ of\ segments$ in the range of $\{5, 10, 12, 15, 20, 25, 30, 40, 50, 70\}$. The variable parameter for $Efficient\ Graph - Based\ Image\ Segmentation$ [3] was the scale of observation, k , in range {100, 200, 300, 400, 500, 600, 700, 800, 900, 1000}. For Mean-Shift [4] we have made 10 combinations from $Spatial\ Bandwidth$ {8, 16} and $Range\ Bandwidth$ {4, 7, 10, 13, 16}.

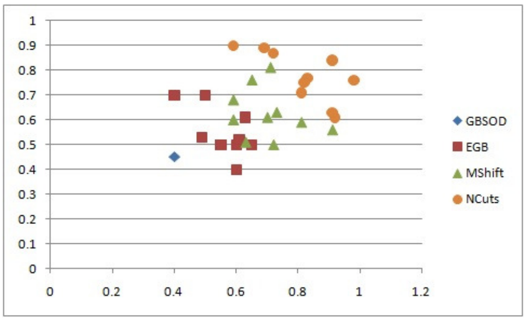

Fig. 2. Average GCE vs. LCE for Berkeley test images

We calculated the GCE and LCE average values for the 100 test images provided by Berkeley. Figure 2 illustrates the GCE vs. LCE graphic representation.

In the resulting diagram (Fig. 2) we can see that the GCE vs. LCE error metric for our proposed method, denoted $GBSOD - Graph\ Based\ Salient\ Object\ Detection$ is situated below the values for the other algorithms indicating a better performance result, a smaller average error and a balanced algorithm. Analyzing the set of results for each parameter per algorithm, it's easy to distinguish which algorithm is generating better results; the smaller the error it is, the better is the accuracy of the respective algorithm.

B. Histogram based evaluation

We elaborated a histogram-based evaluation mechanism aimed to compare the segmentation results for the studied algorithms via the errors metrics.

In order to achieve this, we considered the human segmentation as the ground-truth segmentation and compared each algorithm with it, measuring the error metrics GCE and LCE.

For each algorithm we analyzed the 100 test images from Berkley and calculated the corresponding GCE and LCE. The histograms presented below illustrate this approach (Fig.3 - Fig. 10).

For a better description of the histogram based analysis, in Fig.3 and Fig.4 we have depicted the distribution of the the values of GCE respectively LCE for the 100 images processed using $GBSOD - Graph\ Based\ Salient\ Object\ Detection$ algorithm. It is very important that these value are more concentrated on smaller error values, which gives us the confidence that the presented method has good results. In Fig.5 and Fig.6 it can be seen the same analysis for $Normalized\ Cuts$, in Fig.7 and Fig.8 for $Efficient\ Graph - Based\ Image\ Segmentation$ and in Fig.9 and Fig.10 for $Mean - Shift$ algorithm.

Figures Fig.11 and Fig.12 are illustrating a comparison between all the four presented algorithms; it gives a good

perspective on the what error values generates each studied algorithm.

VI. Conclusion

In this paper we presented a new graph-method for image segmentation and extraction of visual objects. Starting from a survey of several segmentation strategies, we aimed at performing an image segmentation evaluation experiment.

Our segmentation method and other three segmentation methodologies were chosen for the experiment, and the complementary nature of the methods was demonstrated in the results. The study results offer a clear view of the effectiveness of each segmentation algorithm, trying in this way to offer a solid reference for future studies.

Future work will be carried out in the direction of integrating syntactic visual information into a semantic level of a semantic image processing and indexing system.

***Abstract*—We consider a scenario where an attacker is able to receive a stegosignal only over a Gaussian channel. But in order to provide security of this channel noise–based stegosystem under the very strong condition that an attacker may know even the cover message, it is necessary to establish a very low signal-to-noise ratio in the channel. The last requirement is very hard to be implemented in practice. Therefore we propose to use spread-time stegosystem (STS). We show that both security and reliability of such STS can be guaranteed and their parameters can be optimized with the use of error correcting codes. We show some simulation results with an own STS implementation for digital audio cover messages presented in WAV format.**

***Index Terms*—Digital audio signal, error correcting codes, noisy Gaussian channel, relative entropy, stegosystems.**

I. Introduction

Steganography (SG) is the information hiding technique that embeds the hidden information into an innocent *cover message* (CM) under the conditions that the CM is not corrupted significantly and that the presence of the additional information into the CM may not be detected.

In order to prevent statistical detecting attacks on SG systems, it should be guaranteed the following principle: the statistics of the CM and the SG signal have to be indistinguishable for the time limited analysis.

But in order to implement this principle, the designer of the SG system should know at least the statistics of the CM. At the same time, it is a rather hard problem to study completely the CM distribution. In order to be successful within this risky situation (which is, indeed, a bottleneck of any SG system), it has been proposed in [1] to move into another concept of SG system setting, namely to SG system *based on noisy channels*.

This setting can be justified only if there exists in a natural manner a noisy channel and the attacker is able to receive the stegosignal just over this channel, and nothing else. Then the attacker's problem consists in statistically distinguishing the CM after its passing over the noisy channel and the SG signal passing over the same noisy channel. It should be emphasized that such model is even stronger than conventional SG systems since CM can be publicized. Thus the steganalysis problem reduces to channel noise recognition within the sum of the channel noise and the embedded signal. Since the channel noise distribution is, as a rule, known much better than the CM distribution, the problem to design SG systems which are resistant to their detection is simplified.

In the current paper we adopt only a Gaussian channel from the two models given in [1]. The embedding of an information bit b can be provided as

$$\forall n=1,\ldots,N: \quad C_W(n)=C(n)+(-1)^b\sigma_W\pi(n) \tag{1}$$

where $C=(C(n))_{n=1}^N$ is the CM, $\pi=(\pi(n))_{n=1}^N$ is a zero-mean Gaussian pseudorandom i.i.d. reference sequence with variance 1, N is the length of both sequences and σ_W is the depth of embedding. After a passing of the watermarked signal through the Gaussian channel we get

$$\forall n=1,\ldots,N: \quad C'_W(n)=C_W(n)+\varepsilon(n)$$

where $\varepsilon=(\varepsilon(n))_{n=1}^N$ is a zero-mean Gaussian i.i.d. noise sequence with variance σ_ε^2. It has been proved in [1] that, under the condition that an attacker knows even the CM, the *relative entropy* D (introduced in [2]) can be expressed, for the current SG-system model, as

$$D=0.72\ N\left[\ln\left(1+\frac{1}{\eta_W}\right)-\frac{1}{1+\eta_W}\right] \tag{2}$$

with $\eta_W=\frac{\sigma_\varepsilon^2}{\sigma_W^2}$. In order to provide a good hiding of secret information into the channel noise, η_W should be taken large. Hence, the relative entropy given by (2) is approximated as

$$D=0.36\ \frac{N}{\eta_W^2}. \tag{3}$$

We recall that in line with Information Theory [2], for any hypothesis testing rule, the following inequality should hold:

$$P_{fa}\ \ln\frac{P_{fa}}{1-P_m}+(1-P_{fa})\ \ln\frac{1-P_{fa}}{P_m}\le D, \tag{4}$$

where P_{fa} is the probability of *SG signal false alarm* and P_m is the probability of *SG signal missing*. Let us assume, for simplicity, $P_{fa}=P_m=P$. Then, by (4), we get $(2P-1)\ \ln\frac{P}{1-P}\le D$. From eq. (3) it follows that

$$\eta_W=0.6\ \sqrt{\frac{N}{D}}. \tag{5}$$

The optimal decision rule for the embedded bit b, in the case of a Gaussian channel and decoder's CM knowledge (*informed decoder*), is

$$\Lambda = \sum_{n=1}^{N} (C'(n) - C(n))\, \pi(n) \;\Rightarrow\; \tilde{b} = \begin{cases} 0 & \text{if } \Lambda \geq 0 \\ 1 & \text{otherwise} \end{cases} \qquad (6)$$

It is easy to show that for a Gaussian reference sequence $\pi = (\pi(n))_{n=1}^{N}$ the error probability of the decision rule (6) is

$$P_e = Q\left(\sqrt{\frac{N}{\eta_W + 2}}\right) \leq \exp\left(-\frac{N}{2(\eta_W + 2)}\right) \qquad (7)$$

where $Q : x \mapsto Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{+\infty} e^{-\frac{u^2}{2}}\, du$. If $\eta_W >> 1$ (which is a rather common situation in SG systems) both security and reliability can be pooled together in one expression:

$$P_e = Q\left(1.29\,(ND)^{\frac{1}{4}}\right) \leq \exp\left(-0.83\,(ND)^{\frac{1}{2}}\right). \qquad (8)$$

From (8) there follows that for any security level D there can be chosen an appropriate N such that the SG system provides any given reliability P_e.

But this apparent good design of the SG system has one defect. Namely, if one wants to embed many secret bits into the CM in such a way that they can be reliably decoded by a legal user, it is necessary to increase the parameter η_W and this may not be possible in practical implementation. In order to see sharply this negative property, let us consider the following:

Example 1: Let $D = 0.1$ (that provides an acceptable level of security) and let $m = 10$ be the number of secure embedded bits. For multiple bit embedding, (8) should be posed as

$$P_e \leq \exp\left(-0.83\,\frac{(ND)^{\frac{1}{2}}}{m}\right). \qquad (9)$$

Let us choose then $N = 10^5$. From (9), the probability of error is bounded as $P_e \leq 2.5 \times 10^{-4}$ which is acceptable. But $\eta_W = 600$, by (5). Now, if the CM signal-to-noise ratio has been taken also within an acceptable, say $\frac{\sigma_C^2}{\sigma_\varepsilon^2} = 10^2$, where $\sigma_C^2 = \text{Var}\left((C(n))_{n=1}^{N}\right)$, then $\frac{\sigma_\varepsilon^2}{\sigma_W^2} = 6 \times 10^4$ which is indeed unacceptable for the most practical digital applications.

In order to overskip this unfortunate situation, we propose in section 2 the so called *spread-time stegosystem* (STS). The security and reliability of STS are proved in that section jointly with an optimization of parameters. An improvement of the cost of using error correcting codes is also given there. Section 3 presents the results of STS simulation for digital audio signal with a CM in the WAV format. Section 4 consists of some conclusions and open problems in this direction.

II. Description of STS and its performance evaluation

Let us consider initially an uncoded stegosystem. Let us embed secret bits b as a random modification of the embedding rule (1), namely, $\forall n = 1, \ldots, N$:

$$\begin{array}{rcl} \Pr\left[C_W(n) = C(n) + (-1)^b \sigma_W \pi(n)\right] & = & P_0 \\ \Pr\left[C_W(n) = C(n)\right] & = & 1 - P_0 \end{array} \qquad (10)$$

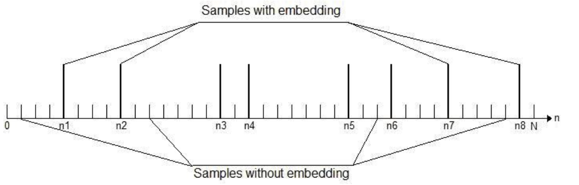

Fig. 1. Pseudorandom samples for STS system embedding, with $N_s = 8$, $N = 38$, $P_0 = 8/38 = 4/19$.

In practical implementation of the modified embedding rule (10), we can simply use a pseudorandom subsequence of samples. Let $(n_m)_{m=1}^{N_s}$ be an increasing sequence of indexes, $N_s \leq N$, generated also as a secret stegokey K, determining the samples in which the WM's are to be embedded (see Fig. 1). Then for a large value of N we may assume that $P_0 = N_s/N$. For uncoded SG, the same secret bit b is used at N_0 consecutive chosen samples for embedding. Hence the total number of secret bits embedded into N_0 samples for STS is $N_t = N_s/N_0$. Any legal user should know the stegokey K, hence he knows exactly the samples with embedding, and is able to extract one-by-one all the N_t secret bits using the decision rule (6). The error probability can be found by (7) (by considering the N appearing there as the current N_0).

An attacker A ignores the stegokey and hence the samples with the WM embedding. In order to take a decision about presence or absence of the SG system under the condition of a known $C = (C(n))_{n=1}^{N}$, the attacker A has to perform a testing of two hypothesis. Let

$$\delta = \left(\delta(n) = C'_W(n) - C(n)\right)_{n=1}^{N} \qquad (11)$$

and $\sigma_s^2 = \sigma_\varepsilon^2 + \sigma_W^2$. Then the two hypothesis to be tested are:

$$H_0 : \left[\delta \in \text{N}(0, \sigma_\varepsilon^2) \text{ and is an i.i.d}\right] \qquad (12)$$

$$H_1 : \begin{cases} \Pr\left(\delta \in \text{N}(0, \sigma_s^2) \text{ and is an i.i.d}\right) = P_0 \\ \Pr\left(\delta \in \text{N}(0, \sigma_\varepsilon^2) \text{ and is an i.i.d}\right) = 1 - P_0 \end{cases} \qquad (13)$$

The hypothesis testing can be done using the *maximum likelihood ratio*

$$\Lambda\left(\Lambda_1 | \Lambda_0\right) = \frac{P\left(\delta | H_1\right)}{P\left(\delta | H_0\right)}$$

where $P\left(\delta | H_j\right)$ is the probability distribution of the random variables $\left(\delta(n)\right)_{n=1}^{N}$ under the condition that hypothesis H_j is valid, $j = 0, 1$. Namely, the *optimal hypothesis testing* based on maximum likelihood ratio [3] is

$$\begin{array}{lcl} \Lambda\left(\Lambda_1 | \Lambda_0\right) \geq \lambda & \Longrightarrow & H_1 \\ \Lambda\left(\Lambda_1 | \Lambda_0\right) < \lambda & \Longrightarrow & H_0 \end{array} \qquad (14)$$

where λ is some fixed threshold. By substituting into (14) the probability distributions (12)-(13) we get after simple transforms

$$\Lambda\left(\Lambda_1 | \Lambda_0\right) = \prod_{n=1}^{N} \left[P_0 \sqrt{\frac{\sigma_\varepsilon^2}{\sigma_s^2}} \exp\left(\frac{\sigma_W^2}{2\sigma_s^2 \sigma_\varepsilon^2} \delta(n)^2\right) + (1 - P_0)\right]$$

By changing λ in (14), it is possible to pass to the logarithmic likelihood ratio, $\Lambda_L\left(\Lambda_1|\Lambda_0\right) = \log\Lambda\left(\Lambda_1|\Lambda_0\right)$, and it equals

$$\sum_{n=1}^{N}\log\left[P_0\sqrt{\frac{\sigma_\varepsilon^2}{\sigma_s^2}}\exp\left(\frac{\sigma_W^2}{2\sigma_s^2\sigma_\varepsilon^2}\delta(n)^2\right)+(1-P_0)\right] \qquad (15)$$

The application of the transformed decision rule based on $\Lambda_L\left(\Lambda_1|\Lambda_0\right)$ using (15) is rather hard. We will consider it again something later.

But so far let us consider a suboptimal decision rule based on some further reasonable conditions. First of all let us assume, in line with a good security guarantee, $\sigma_W^2 << \sigma_\varepsilon^2$. Then, a normalization of (15) expresses $\Lambda_L\left(\Lambda_1|\Lambda_0\right)$ as

$$\frac{1}{N}\sum_{n=1}^{N}\log\left[P_0\exp\left(\frac{1}{2\eta_W^2\sigma_\varepsilon^2}\delta(n)^2\right)+(1-P_0)\right] \qquad (16)$$

The series expansion of $x\mapsto\log(1+x)$ up to its linear term produces

$$\Lambda_L\left(\Lambda_1|\Lambda_0\right) = P_0\left[\sum_{n=1}^{N}\exp\left(\frac{1}{2\eta_W^2\sigma_\varepsilon^2}\delta(n)^2\right)-N\right].$$

The series expansion of $x\mapsto\exp(x)$ up to its linear term renders the following decision rule:

$$\left[\tilde{\Lambda}\geq\tilde{\lambda}\implies H_1\right] \quad ; \quad \left[\tilde{\Lambda}<\tilde{\lambda}\implies H_0\right] \qquad (17)$$

where $\tilde{\Lambda} = \frac{1}{N}\sum_{n=1}^{N}\delta(n)^2$ and $\tilde{\lambda}$ is some new threshold. The decision rule (17) is sufficiently reasonable because $E[\delta^2|H_1] > E[\delta^2|H_0]$ as we will show later.

Let us estimate the missing and false alarm probabilities, P_m and P_{fa} respectively, for the hypothesis H_1 (presence of the SG system) against hypothesis H_0 (absence of the SG system) under the decision rule given by (17).

For enough large N, by the Central Limit Theorem [4], $\tilde{\Lambda}\in\mathrm{N}(\mu_j,\sigma_j^2)$ for H_j, where $\mu_j = E[\tilde{\Lambda}|H_j]$ and $\sigma_j^2 = \mathrm{Var}\left(\tilde{\Lambda}|H_j\right)$, for $j=0,1$. Since $\sigma_1^2 > \sigma_0^2$ we get:

$$P_m \geq \frac{1}{\sqrt{2\pi\sigma_0^2}}\int_{-\infty}^{\tilde{\lambda}}\exp\left(-\frac{(x-\mu_1)^2}{2\sigma_0^2}\right)dx \qquad (18)$$

$$P_{fa} \geq \frac{1}{\sqrt{2\pi\sigma_0^2}}\int_{\tilde{\lambda}}^{+\infty}\exp\left(-\frac{(x-\mu_0)^2}{2\sigma_0^2}\right)dx \qquad (19)$$

Let us select the threshold $\tilde{\lambda}$ in such a way that the condition $P_m = P_{fa} = P$ is fulfilled. After simple transforms of eq's (18)-(19) it is obtained

$$P\geq Q\left(\frac{\mu_1-\mu_0}{2\sigma_0}\right). \qquad (20)$$

Necessarily the following identities should hold:

$$\mu_0=\sigma_\varepsilon^2\ ;\ \mu_1=\sigma_\varepsilon^2+P_0\sigma_W^2\ ;\ \sigma_0^2=\frac{2}{N}\sigma_\varepsilon^4. \qquad (21)$$

By substituting (21) into (20), we get

$$P\geq Q\left(\sqrt{\frac{N}{2}}\frac{P_0}{2\eta_W}\right),$$

or equivalently,

$$P\geq Q\left(\frac{N_s}{2\sqrt{2N}\eta_W}\right),$$

where, as introduced at the beginning of the current section, N_s is the number of samples with embedding. Consequently if asymptotically $N_s\sim\sqrt{N}$, then $P\sim\frac{1}{2}$ and an undetectable stegosystem results.

TABLE I
SETS OF PARAMETERS FOR STS PROVIDING $P_0\geq 0.4$ AND $P_e\leq 10^{-3}$ GIVEN DIFFERENT VALUES OF N AND η_W.

In order to embed m secret bits into N_s samples, $N_0=\frac{N_s}{m}$ samples should be selected for embedding each bit. Then the error probability P_e after extraction of one bit by a legal informed decoder is expressed by (7) (with N_0 playing the role of N). It is necessary to note that in order to extract the secret bits, the legal decoder has to be synchronized with both the reference sequence π, appearing in relation (1), and the pseudorandom sequence determining the samples with embedding.

In Table I we show the calculation results for some values of parameters N_s, N_0, m, P_0 providing $P_e\leq 10^{-3}$ and $P\geq 0.4$, given some values of N and η_W. For enough large N, it is possible to provide a good undetectability ($P_0\geq 0.4$) and reliability ($P_e\leq 10^{-3}$) of the STS and embed up to 232 secure bits.

In order to improve the STS efficiency it is possible to use *coded STS*. Then an embedding procedure such as (10) has to be replaced as follows: Given a CM $C=(C(n))_{n=1}^N$, let $C_W=(C_W(n))_{n=1}^N$ be such that for each sample index n_j with embedding

$$\begin{aligned}\Pr\left[C_W(n_j)=C(n_j)+(-1)^{b_{ij}}\sigma_W\pi(n_j)\right] &= P_0\\ \Pr\left[C_W(n_j)=C(n_j)\right] &= 1-P_0\end{aligned}$$

where b_{ij} is the j-th bit in the i-th codeword of length $N_0 = N_s/\ell$, with ℓ a positive integer value.

We will restrict our attention to binary linear systematic (N_0,k,d)-codes, varying i in the interval $\{1,2,\cdots,2^k-1,2^k\}$, with d the minimal code distance. In this setting the informed decoder takes a decision about the embedding of the i-th codeword by making

$$i = \arg \max_{1 \le i' \le 2^k} \sum_{j=1}^{N_0} \left(C'_W(n_j) - C(n_j) \right) (-1)^{b_{i'j}} \pi(n)$$

The total number of secure embedded bits is $m = k\ell$ and the block-error probability P_{be}, based on well known union bound [5], can be expressed as

$$\begin{aligned} P_{be} &\le (2^k - 1)\, Q \left(\sqrt{\frac{d}{2 + \eta_W}} \right) \\ &\le \exp \left(- \frac{d}{2(2 + \eta_W)} + R\, N_0 \ln 2 \right) \end{aligned}$$

Since signal-to-noise ratio η_W^{-1} is typically small, we will restrict our consideration only to two classes of linear error correcting codes: the simplex codes (SC) and the Reed-Muller codes (RMC) [5]. For the first class the main parameters are $N_0 = 2^\nu - 1$, $k = \nu$, $d = 2^{\nu-1}$, $R = \frac{\nu}{N_0}$, where ν is some integer; whereas for the second class: $N_0 = 2^\nu$, $k = \sum_{i=1}^{r} \binom{\nu}{i}$, $d = 2^{\nu - r}$, where $\nu \ge 3$ and r is an integer, the so called *order of the* RMC.

Now we can fix the total number of samples N, the security level P, the block-error probability P_{be}, the parameter η_W and then to optimize the code parameters N_0, ν and r in order to provide the maximum possible number m of secure and reliable embedded bits.

Example 2: Let us take $N = 10^7$, $P \ge 0.4$, $P_{be} \le 10^{-3}$, $\eta_W = 20$. Then we get for the class of SC the optimal parameters $\nu = 10$, $k = 10$, the total number of secret bits $m = k\frac{N_s}{N_0} = 442$. If we require more reliable extraction then we get, for the class of RM codes, the optimal parameters $\nu = 14$, $r = 2$, $k = 105$ and for the same restrictions $P \ge 0.4$, $\eta_W = 20$, the total number m of embedded secret bits is about 290 with $P_{be} \le 10^{-9}$. So, we can conclude that the use of error correcting codes results in either an increment in the number of secure embedded bits or in an improvement of reliability.

Let us find out whether the use of the optimal decision rule (16) can provide an appreciable improvement of STS detecting in comparison with the suboptimal decision rule (17).

Since N is sufficiently large, we can apply the Central Limit Theorem to the sum in (16). Then similar to the proof of (20) we get for such a choice of the threshold λ, which provides $P_m = P_{fa} = P$ the following upper bound

$$P \ge Q \left(\frac{\tilde{\mu}_1 - \tilde{\mu}_0}{2\tilde{\sigma}_0} \right) \tag{22}$$

where, for $j = 0, 1$,

$$\tilde{\mu}_j = E \left[\left(\log \left(P_0 \exp \left(\frac{\delta(n)^2}{2\eta_W \sigma_\varepsilon^2} \right) + (1 - P_0) \right) \right)_{n=1}^{N} \middle| H_j \right]$$

and

$$\begin{aligned} \tilde{\sigma}_0 &= \frac{1}{N} \mathrm{Var} \left((s(n))_{n=1}^{N} \middle| H_j \right) \\ &= \frac{1}{N} \left(E \left[\left((s(n))^2 \right)_{n=1}^{N} \middle| H_j \right] - \tilde{\mu}_0^2 \right) \end{aligned}$$

where

$$s(n) = \log \left(P_0 \exp \left(\frac{\delta(n)^2}{2\eta_W \sigma_\varepsilon^2} \right) + (1 - P_0) \right)$$

and the random values $\delta(n)$ have the probability distributions given by (11). Since it is very hard to find analytically the values $\tilde{\mu}_0$, $\tilde{\mu}_1$ and $\tilde{\sigma}_0$, we will estimate them just by the simulation of the above described procedure.

In Table II there are presented the simulation results for $\tilde{\mu}_0$, $\tilde{\mu}_1$ and $\tilde{\sigma}_0$ and the calculation of P by (22) for typical values of σ_ε^2, η_W and P_0. It can be seen that the use of the optimal decision rule does not break undetectability of STS, hence it can be declared as a secure SG system indeed.

η_W	N_0	P_e	$\tilde{P}_e$
20	210	$5.0 \cdot 10^{-4}$	0.001
50	496	$6.0 \cdot 10^{-4}$	0.001
100	973	$5.5 \cdot 10^{-4}$	0.001

TABLE III
THE RESULTS OF CALCULATIONS FOR THE ERROR PROBABILITY P_e OBTAINED AFTER DECODING BY RULE (6) AND THE THEORETICAL ERROR PROBABILITY $\tilde{P}_e$ CALCULATED BY EQ. (7), WITH $N = N_0$ FOR DIFFERENT PARAMETERS η_W AND N_0.

III. SIMULATION OF STS FOR AUDIO COVER MESSAGES

We use an audio music file in format WAV where the sample frequency is 44.1 kHz with duration about 29 sec. The CM signal-to-noise ratio η_c has been taken as 10 dB, whereas watermark-to-noise ratio (WNR) η_W^{-1} was 20 dB. The embedding rule was taken as (10), where $P_0 = 0.1$. In Fig. 2 the wave forms of the original audio signal, audio signal after passing over a noisy channel and after secret message embedding are presented at the same time interval. One can see that the noise corrupts slightly the audio signal and this fact can also be appreciated by human ear, whilst, at the same time, the embedding procedure is not observable.

Moreover, in Fig. 3 the waveforms of channel noise are shown, as well as this noise after embedding with straining in time confirming this fact. (Of course we do not claim that the impossibility to detect the SG system either by ear or by eye, is enough to prove its security by the best statistical methods. We have proved indeed this fact in the previous section).

In Table III we present the results of simulation for the error probability P_e versus the block length N_0 and η_W. The error probability $\tilde{P}_e$ calculated by eq. (7) is also presented in this Table. There, we can see that the reliability of STS obtained by simulation is even better than the theoretical estimated bound.

IV. CONCLUSIONS

In the current paper we proposed some modification of the stegosystem based on noisy channel called spread-time stegosystem (STS). The goal of the STS is to provide such a WNR able to be implemented in practice, especially with digital cover messages. We prove that both STS security

N	σ_ε^2	η_W	$P_0 = \frac{N_s}{N}$	$\tilde{\mu}_0$	$\tilde{\mu}_1$	$\tilde{\sigma}_0$	$P = Q\left(\frac{\tilde{\mu}_1 - \tilde{\mu}_0}{2\tilde{\sigma}_0}\right)$

and reliability of secure bit extraction can be provided by an appropriate selection of the system parameters. The main defect of the proposed stegosystem is its low embedding rate which entails longer times for the embedding of a limited number of secret bits. The used error correcting codes improve this situation but only slightly. However this is a generic property "sacrificed on the altar of undetectability" and an attacker's knowledge of the CM.

We show that the suboptimal SG system detection (see eq. (17) is practically as much efficient as the optimal (based on the maximum likelihood ratio). Simulation of the STS with audio CM shows that its detection by ear and eye is impossible, whereas the embedded bits can be extracted reliably.

The first of open problems which we are going to consider in the near future is to specify security of STS for digital CM and after saving the stegosignal in digital formats. The second problem considers an extraction of secret bits by a blind decoder (in particular using the improved spread spectrum modulation [6]) while keeping a good undetectability of STS.

***Abstract*—Building personalized high quality multimedia interfaces represents a great challenge. This paper presents a custom procedure of buiding personalized interfaces within e-Learning environments. The procedure has an interdisciplinary approach since the following domains are met: multimedia interfaces, data mining and e-Learning. A large variety of learners with possible very different background and goals may access an e-Learning system. This situation yields to the necessity that the interface to by dynamically build according with the current state of the learner. The business logic that decides which resources are available for the learner is based on Bayesian network learning.**

Introduction

THIS paper presents a custom procedure for building high quality personalized multimedia interface within an e-Learning environment.

E-Learning domain has received great amount of effort in last decade. E-learning represents a modern form of conducting education. The e-Learning domain developed greatly due to enormous development of Internet technologies. There are many areas in which e-Learning has progressed. One of the most important areas regard building storing and delivering e-Learning materials, assessment and monitoring of student progress, building recommender systems for learners. This paper is closely related with the last domain.

One of the main characteristics of traditional learning lays in the guidance offered by the professor to the learner. With time, professors gain experience and thus are able to guide learners according with their background and abilities. In education, this ability is highly appreciated and can make the difference in a context where learning resources are similar.

In same manner, e-Learning tries to emulate the experience and the ability of the real professor. Of course, human characteristics are very hard to be modeled and that is why the goal of the presented work is not an easy one yet very challenging.

The first step that needs to be accomplished represents setting up the input and the output. The input is represented by various types of data. The e-Learning context is represented by the e-Learning resources. This also regards the way e-Learning materials are structured. Another important input is represented by the actions performed by learners. All performed actions are important in the way that they will provide important information regarding the behavior of the learners. This will represent in a hard and the structured form the experience of the crowd. The core idea of the paper is represented by a custom representation of this data such that high quality personalized interface may be obtained. Thus, the output of the presented procedure has as output the obtained interface and more exactly a list of resources that need to be accessed. There will be obtained also a ranking of needed resources thus leading to a dynamic learning path that may be created for a certain learner. Under these circumstances the following issues need a great deal of attention: the employed methods, the e-Learning infrastructure, the input data and the analysis process itself.

The main analysis methods are Concept Maps [1, 2, 3] and Bayesian Network Learning [4, 5]. These methods are presented in second section. The e-Learning infrastructure is represented by Tesys e-Learning platform [6]. It is presented in third section along with the procedure of obtaining input data for the analysis process. Fourth section will present the analysis process in detail. Section five presents a sample experiment where real data are processed. Finally, in section six there will be presented conclusions and future works.

Analysis Methods

Concept Maps

Concept mapping may be used as a tool for understanding, collaborating, validating, and integrating curriculum content that is designed to develop specific competencies. Concept mapping, a tool originally developed to facilitate student learning by organizing key and supporting concepts into visual frameworks, can also facilitate communication among faculty and administrators about curricular structures, complex cognitive frameworks, and competency-based learning outcomes.

To validate the relationships among the competencies articulated by specialized accrediting agencies, certification boards, and professional associations, faculty may find the concept mapping tool beneficial in illustrating relationships among, approaches to, and compliance with competencies [7].

The usage of concept maps has a proper motivation. Using this approach, the responsibility for failure at school was to be attributed exclusively to the innate (and, therefore, unalterable) intellectual capacities of the pupil. The learning/teaching process was, then, looked upon in a simplistic, linear way: the teacher transmits (and is the repository of) knowledge, while the learner is required to comply with the teacher and store the ideas being imparted [8].

Usage of concept maps may be very useful for students when starting to learn about a subject. The concept map may bring valuable general overlook of the subject for the whole period of study.

It may be advisable that a concept map should be presented to the students at the very first meeting. This will help them to have a good overview regarding what they will study.

Bayesian Networks

A Bayesian network [5] encodes the joint probability distribution of a set of v variables, $\{x_1, x_2, ..., x_v\}$, as a directed acyclic graph and a set of conditional probability tables (CPTs). In this paper we assume all variables are discrete. An instance is represented by a learner from the e-Learning environment. Each instance is described by a set of features which in this context represent the variables. Each node corresponds to a variable, and the CPT associated with it contains the probability of each state of the variable given every possible combination of states of its parents. The set of parents of x_i, denoted π_i, is the set of nodes with an arc to x_i in the graph. The structure of the network encodes the assertion that each node is conditionally independent of its non-descendants given its parents. Thus the probability of an arbitrary event $X = (x_1, x_2, ..., x_v)$ can be computed as

$$P(X) = \prod_{i=1}^{v} P(x_i|\pi_i)$$

In general, encoding the joint distribution of a set of v discrete variables requires space exponential in v; Bayesian networks reduce this to space exponential in $max_{i\in\{1,...,v\}}|\pi_i|$.

Bayesian networks represent a generalization of naïve Bayesian classification. In [9] it was proved that naïve Bayes classification outperforms unrestricted Bayesian network classification for a large number of datasets. Their explanation was that the scoring functions used in standard Bayesian network learning attempt to optimize the likelihood of the entire data, rather than just the conditional likelihood of the class given the attributes. Such scoring results in suboptimal choices during the search process whenever the two functions favor differing changes to the network. The natural solution would then be to use conditional likelihood as the objective function.

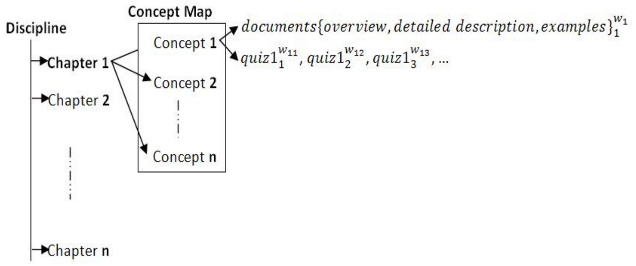
That is why, when using Bayesian networks conditional independence of used variables needs a great attention.

E-Learning Infrastructure

So far, e-Learning platforms are mainly concerned with delivery and management of content (e.g. courses, quizzes, exams, etc.). An important feature that misses is represented by the intelligent characteristic. This may be achieved by embedding knowledge management techniques that will improve the learning process.

For running such a process the e-Learning infrastructure must have some characteristics. The process is designed to run at chapter level. This means a discipline needs to be partitioned into chapters. The chapter has to have assigned a concept map which may consist of about 20 concepts. Each concept has assigned a set of documents and a set of quiz questions. There are three tree documents that may be attached to each concept: overview, detailed description and examples. Each concept and each quiz has a weight, depending of its importance in the hierarchy.

Figure 1 presents a general e-Learning infrastructure for a discipline. Once a course manager has been assigned a discipline he has to set up its chapters by specifying their names and their associated concept maps. For each concept managers have the possibility of setting up three documents and one pool of questions.



Discipline
Concept Map

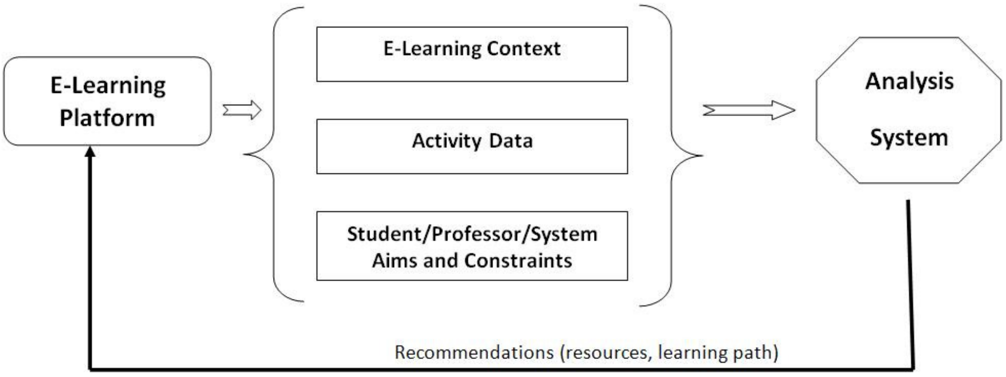
Concept 2
Concept n
$documents\{overview, detailed\ description, examples\}_1^{w_1}$
$quiz1_1^{w_{11}}, quiz1_2^{w_{12}}, quiz1_3^{w_{13}}, ...$

Fig. 1. General structure of a discipline

When the discipline is fully set, the learning process may start for learners. Any opening of a document and any test quiz that is taken by a learner is registered. The business logic of document retrieval tool will use this data for determining the moment when it is able to determine the document (or the documents) that are considered to need more attention from the learner. The course manager specifies the number of questions that will be randomly extracted for creating a test or an exam.

Let us suppose that for a chapter the professor created 50 test quizzes and he has set to 5 the number of quizzes that are randomly withdrawn for testing and 15 the number of quizzes that are randomly withdrawn for final exam. It means that when a student takes a test from this chapter 5 questions from the pool of test question are randomly withdrawn. When the student takes the final examination at the discipline from which the chapter is part, 15 questions are randomly withdrawn. This manner of creating tests and exams is intended to be flexible enough for the professor. This means, the professor may easily manage the test and exam questions that belong to a chapter. Also, tests and exams composition may be easily managed by professors through custom settings. The difficulty of created test and exam may be controlled with the weights that were assigned to concepts and quizzes.



E-Learning Platform
E-Learning Context
Activity Data
Student/Professor/System Aims and Constraints
Analysis System
Recommendations (resources, learning path)

Fig. 2. General view of analysis process

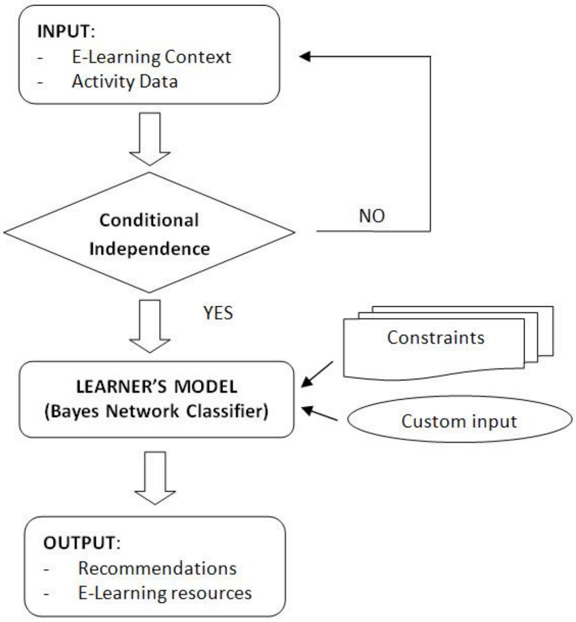


Fig. 3. Detailed view of analysis process

Analysis Process

The analysis process runs along the served e-Learning platform. The e-Learning platform is supposed to be able to provide in a standard format data regarding the context, the performed activity by learners and the aims/constraints provided by learners, professors or system administrator itself.

The e-Learning context represents the set of e-Learning resources that are available for a certain chapter of a discipline. The data that represents the context regards the concept map associated with the chapter along with resources associated to each concept or phrase from the concept map. The resources are represented by documents and quizzes as presented in section three.

The analysis system works as a service that loads the e-Learning context provided by the e-Learning platform and performs updates in a scheduled manner regarding performed activities and the constraints provided by learners, professors or administrator of the e-Learning platform. The constraints work as threshold within the analysis process.

The first step regards checking the conditional independence of attributes. If this condition does not hold than the input must be reviewed. This might mean changes regarding the attributes or even data pruning.

Once the conditional independence of attributes is met the learner's model is build. It will represent the "ground truth" against which any custom request will be evaluated. The custom input regards personal data of a certain learner. It may be regarded as the current status of the learner.

The final outcome of the analysis process is represented by the recommendations and/or a list of resources that need more attention from the learner.

The interface of the learner will be dynamically loaded with links to needed resources thus obtaining a personalized interface

Setup and Experiment

The presented experiment consists in an off-line step by step running of the analysis procedure with real data obtained from Tesys e-Learning platform.

The context has an xml representation. Below it is presented a sample of the xml file representing Computer Science program, Algorithms and Data Structures discipline, Binary Search Trees and Height Balanced Trees chapters.

```

It may be observed that each chapter has associated a set of concepts and each quiz has associated a certain concept.

Figure 4 presents the concept map associated with the Binary Search Tree chapter.

The data representing the activities performed by learners needs to be obtained. Firstly, the parameters that represent a learner and their possible values must be defined. For this study the parameters are: *nLogings* – the number of entries on the e-Learning platform; *nTests* – the number of tests taken by the learner; *noOfSentMessages* – the number of sent messages to professors; *chapterCoverage* – the weighted chapter coverage from the testing activities. Their computed values a scaled to one of the following possibilities: VF – very few, F – few, A – average, M – many, VM – very many. The number of attributes and their meaning has a great importance for the whole process since irrelevant attributes may degrade classification performance in sense of relevance. On the other hand, the more attributes we have the more time the algorithm will take to produce a result. Domain knowledge and of course common sense are crucial assets for obtaining relevant results.

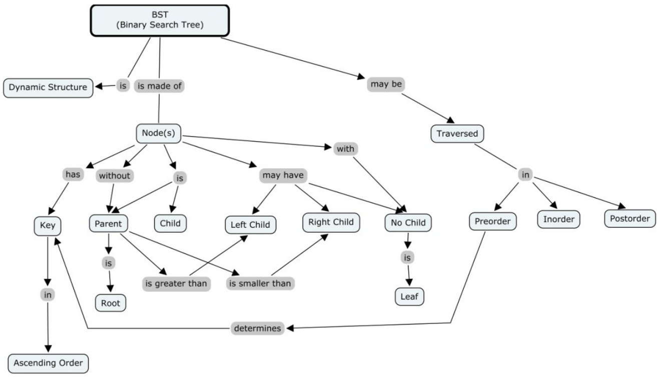

Fig. 4. Binary Search Tree Concept Map

The preparation gets data from the database and puts it into a form ready for processing of the model. Since the processing is done using custom implementation, the output of preparation step is in the form of an *arff* file. Under these circumstances, we have developed an offline Java application that queries the platform's database and crates the input data file called *activity.arff*. This process is automated and is driven by a property file in which there is specified what data/attributes will lay in *activity.arff* file.

For a student in our platform we may have a very large number of attributes. Still, in our procedure we use only four: the number of logings, the number of taken tests, the number of sent messages and the weighted chapter coverage from the testing activities. Here is how the arff file looks like:

```
@relation activity
@attribute nLogings {VF, F, A, M, VM}
@attribute nTests {VF, F, A, M, VM}
@attribute noOfSentMessages {VF, F, A, M, VM}
@attribute chapterCoverage {VF, F, A, M, VM}
@data
VF, F, A, A,
F, A, M, VM,
A, M, VM, A, V,
VM, A, VM, M,
```

As it can be seen from the definition of the attributes each of them has a set of five nominal values from which only one may be assigned. The values of the attributes are computed for each student that participates in the study and are set in the @data section of the file. For example, the first line says that the student logged in very few times, took few tests, sent an average number of messages to professors and had average chapter coverage.

In order to obtain relevant results, we pruned noisy data. We considered that students for which the number of logings, the number of taken tests or the number of sent messages is zero are not interesting for our study and degrade performance; this is the reason why all such records were deleted.

Once the dataset is obtained the conditional independence is assessed. This is necessary because the causal structure of attributes needs to be revealed. If conditional independency is identified between two variables then there will be no arrow between those two variables.

As metric regarding the conditional independence there are estimated expected utilities. This metric will specify how well a Bayesian network performs on a given dataset. Cross validation provides an out of sample evaluation method to facilitate this by repeatedly splitting the data in training and validation sets. A Bayesian network structure can be evaluated by estimating the network's parameters from the training set and the resulting Bayesian network's performance determined against the validation set. The average performance of the Bayesian network over the validation sets provides a metric for the quality of the network.

Running Bayes Net algorithm in weka [10] produced the following output:

```

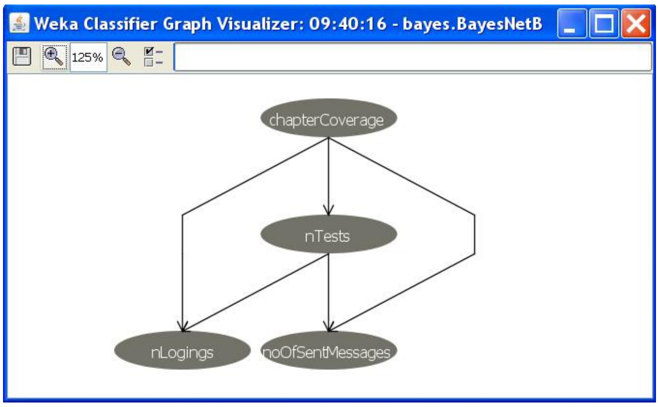
```

The Bayesian network obtained in weka has the following graph.



Weka Classifier Graph Visualizer: 09:40:16 - bayes.BayesNetB
125%
chapterCoverage
nTests
nLogings
noOfSentMessages

Fig. 5. Detailed view of analysis process

As it can be seen in above figure the chapter coverage is the variable with greatest conditional dependence towards all other variables. On the other hand, variables *nLogings* and *noOfSentMessages* are conditional independent which means they need to be used in further developments.

Once the Bayes Net has been obtained it may be used for obtaining the items that compose the interface for the learner. The procedure *findItems* determines the needed resources.

```
Items procedure findItems (LearnerModel LM, Constrtaints CS, Lerner l) {
    Class C = classify (l,LM);
    Class D = findClass (LM, C, CS);
    Items items = determineItems(C, D);
    return items;
}
```

Firstly, the learner is classified against the current learner model. Thus, the actual class to which the learner belongs is determined. Secondly, the destination class D is determined taking into consideration the current learner model, the class of the learner and the constraints set up by system professor or learner himself. Finally there is determined the set of items that need to be accessed by learner by analyzing classes C and D. As general idea, there are determined the items where class D is better representation than in class C. Such a metric may also rank the resources. Firstly, there are presented the resources with smaller distance between classes. It is supposed that these resources need immediate attention from the learner.

Conclusions and Future Works

This paper presents custom data analysis process which has as main outcome obtaining a personalized interface for an e-Learning platform.

The main inputs of the process are: the context of the platform, the activity data, the constraints of the involved parties and data regarding the learner for which the personalized interface is built.

The activity data managed by the analysis process is represented by actions performed by learners within the e-Learning environment. From the great variety of performed actions there were taken into consideration only four: the number of entries on the e-Learning platform, the number of tests taken by the learner, the number of sent messages to professors and the weighted chapter coverage from the testing activities.

The business logic uses Bayes Network Classifier implemented in weka for building the learner's model against which any learner is classified. For obtaining sound classification results the conditional independence is verified.

Once the conditional independence is met there may be started the procedure for obtaining the items that will be recommended. The procedure classifies the learner, finds the destination class and determines the items. Each item represents a resource (document or quiz) that needs attention from the learner.

As future works, there are some issues that need to be addressed. One issue regards the conditional independence assessment of variables. When this condition is not met the procedure for data pruning and feature selection may need improvement.

Another issue regards the granularity with which items are obtained by *findItems* procedure. Optimization of complexity calculus for determining the destination class and especially the set of items is needed.

Abstract—**Image segmentation has an essential role in image analysis, pattern recognition and low-level vision. Since multiple segmentation algorithms exists in literature, numerical evaluations are needed to quantify the consistency between them. Error measures can be used for consistency quantification because are allowing a principled comparison between segmentation results on different images, with differing numbers of regions, and generated by different algorithms with different parameters. This paper presents a graphical interface for evaluating three graph-based image segmentation algorithms: the color set back-projection algorithm, an efficient graph based image segmentation algorithm known also as the local variation algorithm and a new and original segmentation algorithm using a hexagonal structure defined on the set of image pixels.**

I. Introduction

IMAGE segmentation is one of the most difficult and challenging tasks in image processing and can be defined as the process of dividing an image into different regions such that each region is homogeneous while not the union of any two adjacent regions.

The consistency between segmentations must be evaluated because no unique segmentation of an image can exist. If two different segmentations arise from different perceptual organizations of the scene, then it is fair to declare the segmentations inconsistent [3].

This paper presents a graphical interface used for an objective and quantitative evaluation of three graph-based segmentation algorithms that will be described further. For each of these algorithms three characteristics are examined [4]: correctness, stability with respect to parameter choice, stability with respect to image choice.

The evaluation of the algorithms is based on two metrics (GCE, LCE) defined in [3] which can be used to measure the consistency of a pair of segmentations. These measures allows a comparison between segmentation results on different images, with differing numbers of regions, and generated by different algorithms with different parameters. In order to establish which algorithm produces better results these are compared with manual segmentations of the same image.

For searching certain structures graph-based segmentation methods such as minimum spanning tree [6] [7], or minimum cut [8] [9] are using an edge weighted graph constructed on the image pixels. The Graph-based clustering algorithms use the concept of homogeneity of regions. For color segmentation algorithms the homogeneity of regions is color-based, and thus the edge weights are based on color distance.

For obtaining the image regions early graph-based methods have used fixed thresholds and local measures. Using these values larger edges belonging to a minimum spanning tree were beaked. The problem of fixed threshold [10] can be avoided by determining the normalized weight of an edge using the smallest weight incident on the vertices touching that edge.

Other methods presented in [6] [7] use an adaptive criterion that depends on local properties rather than global ones. The methods based on minimum cuts in a graph are designed to minimize the similarity between pixels that are being split [8], [9]. An alternative to the graph cut approach is to look for cycles in a graph embedded in the image plane [11].

The color and texture models are used by most graph-based segmentation approaches but these homogeneity criteria have some drawbacks for object extraction.

In [12] a source of additional information denoted by the term of syntactic features is presented, which represent geometric properties of regions and their spatial configurations such as homogeneity, compactness, regularity, inclusion or symmetry.

II. The color set back-projection algorithm

The color set back-projection algorithm proposed in [5] is a technique for the automated extraction of regions and representation of their color content. This algorithm is based on color sets which provide an alternative to color histograms for representing color information. Their utilization is possible only when salient regions have few equally prominent colors. Each pixel from the initial image is represented in the HSV color space. The quantized colors from 0 to 165 are stored in a matrix that is filtered by a 5x5 median filter for eliminating the isolated points. The back-projection process requires several stages:

a) Color set selection - candidate color sets are selected first with one color, then with two colors, etc., until the salient regions are extracted

b) Back-projection onto the image - a transformation from the RGB color space to HSV color space and a quantization of the HSV color space at 166 colors is performed for each segmented image.

c) Thresholding and labeling image - insignificant color information is reduced and the significant color regions are evidentiated, followed by the generation, in automatic way, of the regions of a single color, of the two colors, of three colors.

In the implementation of the color set back-projection algorithm that can be found it in [1] [13]. After processing the global histogram of the image, and the color set are provided. The process of regions extraction is using the filtered matrix and it is a depth – first traversal described in pseudo-cod in the following way:

```
Procedure FindRegions (Image I, colorset C)
    InitStack(S)
    Visited = ∅
    for *each node P in the I do
    if *color of P is in C then
        PUSH(P)
        Visited ← Visited ∪ {P}
        while not Empty(S) do
            CrtPoint ←POP()
            Visited ← Visited ∪ {CrtPoint}
              For *each unvisited neighbor S of CrtPoint do
                if *color of S is in C then
                   Visited ← Visited ∪ {S}
                   PUSH(S)
              end
            end
        end
    *Output detected region
      end
    end
```

The total running time for a call of the procedure FindRegions (Image *I*, colorset *C*) is $O(m^2 * n^2)$ where *m* is the width and *n* is the height of the image [1][13].

III. LOCAL VARIATION ALGORITHM

This algorithm described in [6] is using a graph based approach for the image segmentation process. The pixels are considered the graph nodes so in this way it is possible to define an undirected graph G = (V, E) where the vertices v_i from V represent the set of elements to be segmented. Each edge (v_i, v_j) belonging to E has associated a corresponding weight $w(v_i, v_j)$ calculated based on color, which is a measure of the dissimilarity between neighboring elements v_i and v_j.

A minimum spanning tree is obtained using Kruskal's algorithm. The connected components that are obtained represent image's regions. It is supposed that the graph has *m* edges and *n* vertices. This algorithm is described also in [14] where it has four major steps that are presented below:

1) Sort $E=(e_1,...,e_m)$ such that $|e_t|<|e_{t'}| \;\forall t<t'$

2) Let $S^o=(\{x_1\},...,\{x_n\})$ be each initial cluster containing only one vertex.

3) For $t=1,...,m$

   a) *Let* x_i *and* x_j *be the vertices connected by* e_t

   b) *Let* $C_{x_i}^{t\text{-}1}$ *be the connected component containing point* x_i *on iteration t-1 and* $l_i = max_{mst}\, C_{x_i}^{t\text{-}1}$ be the longest edge in the minimum spanning tree of $C_{x_i}^{t\text{-}1}$ .Likewise for l_j.

   c) *Merge* $C_{x_i}^{t\text{-}1}$ *and* $C_{xj}^{t\text{-}1}$ *if*

   $$|e_t| < \min\{\, l_i + \frac{k}{C_{x_i}^{t\text{-}1}}, l_j + \frac{k}{C_{x_j}^{t\text{-}1}} \} \textit{ where k is a constant.}$$

4) $S=S^m$

The existence of a boundary between two components in segmentation is based on a predicate D. This predicate is measuring the dissimilarity between elements along the boundary of the two components relative to a measure of the dissimilarity among neighboring elements within each of the two components. The internal difference of a component C ⊆ V was defined as the largest weight in the minimum spanning tree of a component MST(C, E):

$Int(C) = {}_{e\in MST(C,E)} max\, w(e)$. The difference between two components $C_1, C_2 \subseteq V$ is defined as the minimum weight edge connecting the two components:

$$Dif(C_1,C_2)=min(w(v_i,v_j))$$
$$v_i \in C_1, v_j \in C_2, (v_i,v_j) \in E$$

A threshold function is used to control the degree to which the difference between components must be larger than minimum internal difference. The pair wise comparison predicate is defined as:

$$D(C_1,C_2)=\{ \begin{matrix} \textit{true if } Dif(C_1,C_2)>MInt(C_1,C_2) \\ \textit{false otherwise} \end{matrix}$$

where the minimum internal difference Mint is defined as:

$$MInt(C_1,C_2)=min(Int(C_1)+\tau(C_1), Int(C_2)+\tau(C_2)).$$

The threshold function was defined based on the size of the component: $\tau(C)=k/|C|$.The k value is set taking into account the size of the image. The algorithm for creating the minimum spanning tree can be implemented to run in $O(m\log m)$ where m is the number of edges in the graph.

IV. IMAGE SEGMENTATION USING A HEXAGONAL STRUCTURE DEFINED ON THE SET OF PIXELS

The technique is based on a new and original utilization of pixels from the image that are integrated into a network type graph [2]. The hexagonal network structure on the image pixels, as presented in figure 1 was selected to improve the running time required by the algorithms used for segmentation and contour detection.

The hexagonal structure represents a grid-graph and for each hexagon h in this structure there exist 6-hexagons that are neighbors in a 6-connected sense. The time complexity of the algorithms is reduced by using hexagons instead of pixels as elementary piece of information. The index of each hexagon is stored in a vector of numbers $[1..N]$, where *N*, the number of hexagons, is calculated using the formula [2]:

$$N = \frac{height - 1}{2} * (\frac{width - width \bmod 4}{2} - 1)$$

where *height* and *width* represent the height and the width of the image.

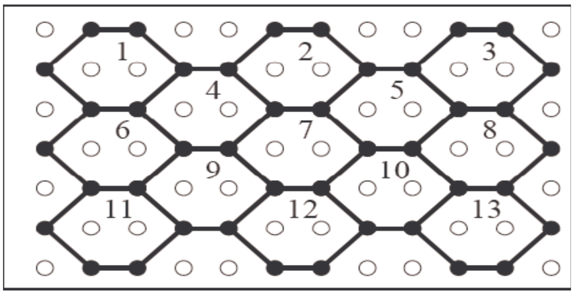

Fig.1. Hexagonal structure constructed on the image pixels

With each hexagon two important attributes are associated:

a) The dominant color - eight pixels contained in a hexagon are used: six pixels from the frontier and two from interior

b) The gravity center

The pixels of image are split into two sets, the set of pixels representing the vertices of hexagons and the set of complementary pixels. These two lists are used as inputs for the segmentation algorithm.

Based on the algorithms proposed in [2] the list of salient regions is obtained from the input image using the hexagonal network and the distance between two colors in HSV space color. The color of a hexagon is obtained using a procedure called *sameVertexColour*. The execution time of this procedure is constant because all calls are constant in time processing. The color information is used by the procedure *expandColorArea* to find the list of hexagons that have the same color. To expand the current region it is used a procedure containing as input:

a) The current hexagon h_i ,

b) L_1 and L_2 lists,

c) The list of hexagons V

d) The current region index *indexCrtRegion*

e) The current color index *indexCrtColor*.

The output is represented by a list of hexagons with the same color *crtRegionItem.* The running time of the procedure *expandColourArea* is $O(n)$ where n is the number of hexagons from a region with the same color.

The list of regions is obtained using the *listRegions* procedure The input of this procedure contains:

a) The vector V representing the list of hexagons

b) The lists L_1 and L_2

The output is represented by a list of colors pixels and a list of regions for each color.

```
Procedure listRegions ( $V, L_1, L_2$ )
colourNb ←0;
for i ←1 to n do
    initialize crtRegionItem;
    if not(visit( $h_i$ )) then
        crtColorHexagon ←sameVertexColour ( $L_1, L_2, h_i$ );
        if crtColorHexagon.sameColor then
            k ← findColor(crtColorHexagon.color);
            if k < 0 then
                add new color $c_{colourNb}$ to list C;
                k ←colourNb++;
                indexCrtRegion ←0;
            else
                indexCrtColor ←k;
                indexCrtRegion ←findLastIndexRegion(indexCrtColor);
                indexCrtRegion++;
            End
            hi.indexRegion ←indexCrtRegion;
            hi.indexColor ←k;
            add $h_i$ to crtRegionItem;
            expandColourArea( $h_1, L_1, L_2, V$ ,indexCrtRegion,
                indexCrtColor; crtRegionItem);
            add new region crtRegionItem to list of element k from C
        end
    end
end
```

The running time of the procedure list Regions is $O(n^2)$, where n is the number of the hexagons network [2].

V. Segmentation error measures

To evaluate a segmentation algorithm it is needed to measure the accuracy, the precision and the performance. When multiple segmentation algorithms are evaluated some metrics are needed to establish which algorithm produce better results.

In [3] are proposed two metrics tolerant to refinement that can be used to evaluate the consistency of a pair of segmentations. A segmentation error measure takes two segmentations S_1 and S_2 as input, and produces a real valued output in the range [0..1] where zero signifies no error. For a given pixel p_i two segments S_1 and S_2 containing that pixel, are considered. If one segment is a proper subset of the other, then the pixel lies in an area of refinement, and the local error should be zero. If there is no subset relationship, then the two regions overlap in an inconsistent manner. In this case, the local error should be non-zero. Let \ denote set difference, and $|x|$ the cardinality of set x. If $R(S,p_i)$ is the set of pixels corresponding to the region in segmentation S that contains pixel p_i, the local refinement error is defined in [3] as:

$$E(S_1,S_2,p_i)=\frac{|R(S_1,p_i)\setminus R(S_2,p_i)|}{R(S_1,p_i)}$$

This local error measure is not symmetric and it encodes a measure of refinement in one direction only. Given this local refinement error in each direction at each pixel, there are two natural ways to combine the values into an error measure for the entire image. Global Consistency Error (GCE) forces all local refinements to be in the same direction. Local Consistency Error (LCE) allows refinement in different directions in different parts of the image. Let n be the number of pixels [3]:

$$GCE(S_1,S_2)=\frac{1}{n}\min\{\quad {}_i E(S_1,S_2,p_i),E(S_2,S_1,p_i)\}$$

$$LCE(S_1,S_2)=\frac{1}{n}\quad {}_i \min(E(S_1,S_2,p_i),E(S_2,S_1,p_i))$$

$LCE \leq GCE$ for any two segmentations and it is clear that GCE is a tougher measure than LCE. In [3] are shown that, as expected, when pairs of human segmentations of the same image are compared, both the GCE and the LCE are low; conversely, when random pairs of human segmentations are compared, the resulting GCE and LCE are high. If the pixel wise minimum is replaced by a maximum it is obtained a new measure named Bidirectional Consistency Error (BCE) that is not tolerating the refinement. This measure is evaluated using

$$BCE(S_1,S_2)=\frac{1}{n}\quad {}_i \max(E(S_1,S_2,p_i),E(S_2,S_1,p_i)).$$

If an image is interpreted as a set *O* of pixels and the segmentation as a clustering of *O* we can apply measures for comparing clusters. As described in [17] we can have two types of distances available for clusters: the distance between clusters evaluated by counting pairs and the distance between clusters evaluated using set matching. For the first case are assumed two clusters C_1 and C_2 belonging to a set *O* of objects and also all pairs of distinct objects (o_i,o_j) from *OxO.*

Each pair can be found into one of the four categories:

a) in the same cluster under both C_1 and C_2 (the total number of these pairs is represented by *N11*)

b) in different clusters under both C_1 and C_2 (*N*00),

c) in the same cluster under C_1 but not C_2 (*N*10),

d) in the same cluster under C_2 but not C_1 (*N*01).

Based on these assumptions the following statement is obtained: $N_{11}+N_{00}+N_{10}+N_{01}=n(n-1)/2$.

Based on these numbers multiple distances of the first type were defined. One of the distances described in [18] is the Rand index evaluated as $R(C_1,C_2)=1-\frac{N_{11}+N_{00}}{n(n-1)/2}$.

A perfect matching between two clusters is implied by a 0 value. Another index called the Jacard index [19] is evaluated as $J(C_1,C_2)=1-\frac{N_{11}}{N_{11}+N_{10}+N_{01}}$

For the second type the comparison criteria is based on the following term $a(C_1,C_2)=\quad {}_{ci\in C_1}\max_{cj\in C_2}|c_i\cap c_j|$.

This term measures the matching degree between C_1 and C_2 has a value of *n* when the two clusters are equal. The Dongan index [20] is evaluated as $D(C_1,C_2)=2n-a(C_1,C_2)-a(C_2,C_1)$.

VI. EXPERIMENTAL RESULTS

For each image three major steps are required in order to calculate GCE, LCE, BCE, Dongen index and Rand index values:

a) Obtain the image regions by applying segmentation algorithms (color set back-projection – CS, the algorithm based on the hexagonal structure – HS, the local variation algorithm – LV) and the regions manually segmented -MS

b) Store the information obtained for each region in the database

c) Use a graphical interface to easily calculate GCE and LCE values and to store them in the database for later statistics

All algorithms are using a configurable threshold value to keep only the regions that have a number of pixels greater than this value. In this way only representative regions are saved in the database and used later in the experiments.

The experiments were made on a working set containing 300 images selected from IAPR-TC12 [15] and Berkeley [16] segmentation datasets. All values were calculated using the graphical interface presented in figure 1.

This application is offering to the user a list containing the name of all images that were segmented and that have regions stored in the database. After selecting from the list the name of an image the user needs to press *GetInfo* button to retrieve de information stored in the database for that image. In that moment the text boxes containing the number of regions obtained with each algorithm are filled.

For each algorithm a button named *ViewRegions* is available. By pressing this button a new form is shown containing the obtained regions as presented in image 2. This form helps the user to view the regions detected by each algorithm and to make an empirical evaluation of the performance. Because this evaluation is subjective we need a numerical evaluation.

Since the information about regions is available the user can press Calculate button. In this moment the error measures will be calculated and shown to the user. If the user decides that these values are needed later he can choose to store them in the database by pressing *Store results* button. To compare the obtained results with previous results stored in the database *View stored results* button should be pressed. In this way it is possible to evaluate what algorithm is producing better results.

2	0.18	0.12	0.17
3	0.17	0.07	0.08
4	0.09	0.11	0.09
5	0.05	0.08	0.10
6	0.04	0.02	0.02

Bellow is presented the regions obtained for the third image after applying manual segmentation and the three algorithms presented above.

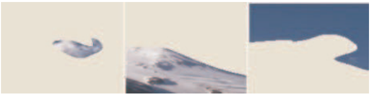

Fig.3. Regions from manual segmentation

Fig.4.Regions from the color set back-projection algorithm

Fig.5. Regions from hexagonal structure segmentation

Fig.6. Regions from the local variation algorithm

The error measures presented in tables three and four are calculated in relation with manual segmentation which is considered the ground truth. It can be observed that the values for GCE and LCE are lower in case of hexagonal segmentation. For example for the first analyzed image GCE = 0.09 and LCE =0.07 in the case of hexagonal segmentation, GCE=0.18 and LCE=0.11 for the color set back-projection algorithm, GCE=0.24 and LCE=0.15 for the local variation algorithm. The error measures, for almost all tested images, have smaller values in case of the hexagonal segmentation so this algorithm is a good refinement of the manual segmentation.

VI. Conclusion

In this paper it is proposed a graphical interface for evaluating three graph-based image segmentation algorithms: the color set back-projection algorithm, the image segmentation using a hexagonal structure defined on the set of image pixels and the local variation algorithm. Error measures like GCE, LCE are used to evaluate the accuracy of each segmentation produced by the algorithms. The values for the error measures are calculated using the described application specially created for this purpose. The proposed error measures quantify the consistency between segmentations of differing granularities. Because human segmentation is considered truth segmentations the error measures are calculated in relation with manual segmentation. The GCE and LCE demonstrate that the image segmentation based on a hexagonal structure produces a better segmentation than the other methods. In the future work the comparative study will be effectuated on medical images.

Abstract—**Re-encoding of once compressed files is one of the difficult challenges in measuring the efficiency of coding methods. Variable length coding with a variable source delimiting scheme is a promising method for improving re-encoding efficiency. Analyses of coded files with fixed length delimiting and with variable length delimiting are reviewed. Motion vector codes of MPEG-2 encoded files are modified as a variable-to-variable coding point of view. Length, bit-rates, and varieties of videos are examined. The largest file is 16 seconds of D1 full size at 720 ×480 among five video files. By entropy evaluation, an improvement of almost 20% in coding efficiency over the conventional MPEG-2 is obtained.**

I. Introduction

In this paper, for coded files, such as MPEG-2 encoded ones, redundancy will be evaluated to provide re-encoding information. There are four frameworks of encoding according to whether input event length and output bit length is fixed or variable. One example is fixed length input and fixed-length output that is an F-F type. In the same manner, there are three other types of F-V, V-F and V-V. Among these types, V-V is the most general and has the greatest possibilities in realizing the most efficient encoding method [1-2]. However, the V-V type has the difficult problem of how to delimit the input events into most efficient length. Universal coding and arithmetic coding are flexible methods. But they are basically still F-V types. Based on several examples of V-V trials, we will show an example of V-V re-encoding. The method improves a compression ratio of 20% compared to the MPEG-2 standard method.

Examples of V-V coding methods are reported in several papers. Jacob presented that the V-F codes are better than the F-V codes for finite alphabets of K-th order ergodic Markov sources [1]. Yamamoto et al mentioned that a VF code is called proper if the set of parse strings of the code satisfies the prefix condition [3]. He also described that non-proper VF codes should be considered in order to realize efficient VF coding. This implies that variable parsing without considering prefix condition has a large possibility to enhance coding efficiency. Abrahams presented a survey paper on the theoretical literature on fixed-to-variable-length lossless source code trees, called code trees, and on variable-length-to-fixed lossless source code trees, called parse trees [4]. He focused on Huffman coding and Tunstall V-F coding for parsing and making tree methods with a large bibliography for further investigation of algorithmic and performance perspectives. Matsui et al examined the compression ratio of the Tunstall-Huffman code. The Tunstall-Huffman code is a variable-to-variable code. They obtained better results by the Tunstall-Huffman V-V coding than with standalone coding methods such as the Tunstall V-F coding or the Huffman F-V coding [5].

All these V-V coding are theoretical not for video files. MPEG-2 coding of video files is not proved to be an optimum method. In fact one of the authors has shown reduandancy of coded MPEG-2 files using FV codes. In this paper, we will try to enhance to use VF codes for MPEG-2 coded files. Though the aplication is restricted to motion vector parts, coding efficiency of the VV codes is much larger than that of the FV case.

The proposed method is an improvement of the MPEG-2 coding. So it is not compatible with the standard methods.

As for V-V coding, there have been few papers. The reason may be that it is difficult to parse sequences at optimal delimiting points. To cope with this problem, an example of review trials will be presented in this paper. A fixed length analysis of sequences was first implemented. The length of the fixed parsing was incrementally examined. Many heuristic trials were carried out and problems with this analysis will be listed.

To conduct variable parsing of sequences, the T-code generating method [6] was taken up. T-code was introduced by Titchener in 1984 [7]. Though the generating process is only a parsing process, it may be an influential tool to optimal variable length coding. It generates codes by copying pregenerated shorter codes. T-code generating experiments were carried out for more than 50 different video sequences. Efficient parsing is itself efficient coding. How to combine efficiency conditions with a parsing algorithm will be a further problem.

According to coding of motion vectors, Yu et al presented two-dimensional motion vector coding for low bit-rate video phones. However, their Huffman coding was generated by the JPEG procedure and the number of motion vector bits were about only one-frame for full D1 digital video size, 720×480 [8]. Shimizu et al proposed a method using representation of norm and angle for motion vectors. The method was complicated and still two separate codes were used [9]. Matsuda et al proposed a lossless re-encoding scheme for MPEG-1 video. They used an arithmetic coder for both DCT and motion vector data for the MPEG-1 coder [10]. In the following sections, an exemplified review of the fixed parsing method, and a variable parsing method with T-code are

978-83-60810-27-9/09/$25.00 © 2010 IEEE

presented for long-term investigation. Then a practical variable length coding will be presented with several variations of construction parameters.

II. Re-Encoding of MPEG-2 coded files

I. Fixed Length Analysis

Before considering V-V coding, we will review F-V coding to evaluate actual entropy. There is redundancy in the MPEG coded bit-stream. There are two problems in evaluating redundancy for coded bit-streams as statistical data with a long interval. These are quantity and quality. How much coded data should be prepared? How many kinds of pictures should be prepared? For this problem, we introduce a new inverted distribution model. Based on the model, we analyze entropy space and show that the distribution is symmetrically uniform on a distorted circle at isentropic space cut out by the same entropy plane. Though the model is uniformly distributed, actual random samples of coded bit-stream statistics are not uniformly distributed as in the case of the model. They are located in a small region by our experimental results. We conclude that the MPEG coded bit-stream is not random, but is very much correlated. Based on these results, we evaluate entropy of coded bit-streams. For the interval of 20bit, the entropy value is 0.9.

If the encoder is an ideal one, the output of the encoder should be a perfect random number, which cannot be re-compressed at all into a file of smaller size. For evaluating ideal encoder performance, random number analysis is one of the most effective methods. Among several methods of random number analysis, entropy evaluation is used.

How much bit data is needed to get reliable results? A relation between the length of the bit stream and the bit pattern interval was obtained as formula (1),

$$n \simeq m \cdot 2^{L} \cdot \log_{e} 2 \ , \qquad (1)$$

where L is an interval length of the bit pattern, 2^{-m} is the level of significance, and n is the required length of the bit stream to be analyzed. Using the formula (1), we can obtain a relation between the length of a bit stream and the interval of a bit pattern to be analyzed with a probabilistic parameter "m". For a coded bit stream with a certain length, using the formula (1), we can get the length of interval "L", which assures accuracy of the result with a risk probability of $\frac{1}{2^m}$.

To consider how many kinds of pictures and coding parameters we should prepare for valid results, we introduced entropy space and cut it with an equi-entropy plane. The entropy per bit is Ent(R) =1.0. The probability distributions give a specific entropy value between 0<Entropy<1.

Fig. 1 shows isentropic curves that are plotted with probability points with the same entropy values. This figure is the case of a computational low dimension. We can utilize this idea for higher dimensional cases because we cannot exactly analyze all cases but some sample cases among all. If we take two points at random on one of these isentropic curves, these two points are not always close at hand, but rather located on symmetrically opposite each other in many cases. The two points that locate in completely symmetrical positions with each other have inverted probability distributions. If we make a sum set of the distribution of these two points with respect to their occurrence frequency, the distribution of the sum set is flat and its entropy should be 1.0. To observe these behaviors, we choose all patterns on the isentropic curves. Then, taking two samples from this pattern set at random, we put them together to form a new point. The new point locates midway between two points in Fig.1, whose entropy increases because the new point moves in an inner direction in entropy space. This method is formalized as an evaluating method 1

```
Method 1:
S1. Evaluate entropy of files, F1,F2,….
S2. Select files, Fs1,Fs2,…,Fsn, with the same entropy
  value E, e.g. E=0.9
S3. Make combined files Cp=U(Fsi,Fsj), i≠j
S4. Evaluate Entropy of Cp
S5. Evaluate increase of Entropy from S1 to S4.
```

If there is no difference between the entropy values of S1 and S4, then the original files are strongly correlated located in a narrow region. If there is a difference, the maximum value indicates the distribution of the original files. If the maximum value is not 1.0, then there should be redundancy in the set of original files.

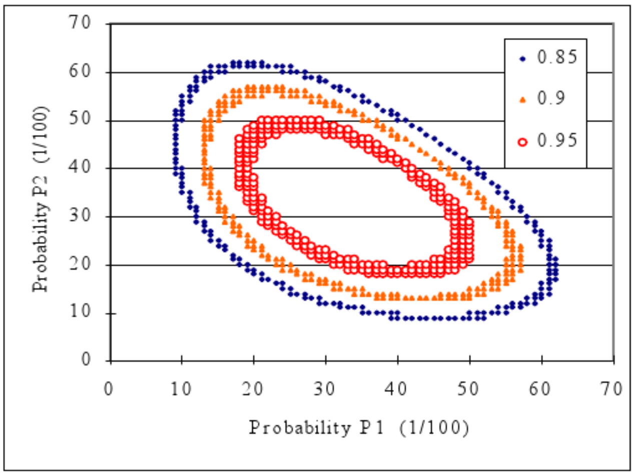

Fig. 1 Isentropic curves for all probabilistic data.

II. Variable Length Analysis

To construct an optimal V-V coding, analysis of input sequences and parsing of the sequence is important. Savari et al presented an analysis of variable-variable length codes [11]. It found that The Tunstall V-F codes can be considered to have an equi-probable code set. Then, combining the Tunstall V-F code with Huffman F-V code will provide higher efficiency. Matsui experimentally proved the concept using text files [5]. In this section, T-code analysis which was carried out in [12] will be introduced.

Fig. 2 shows an example that accomplishes better performance for the V-V encoding scheme than for the F-V encoding scheme. There is a 44-bit sequence in the number column of Fig. 2(d). Parsing this sequence by the fixed length of two bits, we get Fig. 2(a). For three events, allocating one and two bit codes, we get in total 35 coded bits. Next, parsing this sequence by the fixed length of three bits, we get Fig. 2(b). For four events, allocating two bit codes, we get in total 28 coded bits. On the other hand, in the variable coding case, Fig. 2(c) shows variable code example. There are 20 coded bits in total. Fig. 3 shows another four bit fixed code case. The total number of bits is either 21 or 22. Still the variable case has a smaller number of bits.

This example shows that there is at least a better performance variable code than that of all fixed codes within a designated code length.

An example of the T-code generation is described in Fig. 4. The result after parsing is not necessarily the prefix condition. However, the parsed codes represent the original sequence and may provide an influential tool to design a variable parsing code set. According to the T-code generation rule [6], detaching the rightmost bit "1", at first code the second bit "1" from the right. In this case, "1"appears twice and proceeds to two bits to the left. Next, for the "0", code newly "0". Further, the "0" appears three times and counts three for the "0". Then, another "0" appears, which is the fourth time. But in this case, as there is another "1", "10" becomes a newly defined code as an extended new code from the previous generated codes. Further, this "10" code appears four times. The detailed generation rule is described using recursive formulation.

III. Experimental Results

A. Fixed Length Coding

The authors analyzed MPEG-2 coded files to re-encode them. The length of the fixed delimiting interval is more than 20 bits. The variety of 20 bit data is about one million. The file length in which these 20 bit patterns appear once is about 2.5 Mbytes. For valid statistical evaluation, at least 10 instances of each pattern should appear on average, which means that an input file needs to be about 25MB. Table I shows the necessary sizes of file and corresponding original video lengths needed for measuring bit length by assuming a ten times occurrence for the files.

Table I
Necessary sizes of file and corresponding original video lengths needed for measuring bit length by assuming ten time occurrence for the files.

bit	Number of patterns (2^{bit})	Size of files	Video lengths（6Mbps)
20	1048576	26MB	35 Sec
30	1073741824	40GB	15 hour
40	1099511627776	55TB	848 days

B. T-code Analysis

Here, to obtain optimal delimiting methods of unknown bit streams in general, for the first step, T-code analysis is carried out. This is only half of the total coding design. But as the first step, we analyze bit streams by T-code and investigate the resultant entropy behavior. Table II shows entropies of generated T-codes for 50 different videos. The values are about half. This implies that the T-code generates codes in a balanced manner. Table III shows increase behaviors when combining two files. Table IV shows further results of combining three files and five files. These values are all normalized to input single bit, and the entropy value of 0.5 means the compressed size is 1/2 of the original size. This entropy is not the so-called T-entropy in [6].

Fig. 5 shows the increasing tendency of T-code entropy when combining a number of files. At the number of five files, the saturation tendency can be seen. The calculation time for T-code analysis takes a long time, and it is limited to evaluation for longer files.

C. Re-encoding of MPEG-2 Coded Files

Based on the concepts above, the coding efficiency of MPEG-2 coded files is shown as a V-V coding paradigm. Fig 6 shows a V-V coding design and coding execution.

According to coding of motion vectors, Yu et al presented two-dimensional motion vector coding for low bit-rate video phone. However, their Huffman coding was generated by a JPEG procedure and the numbers of motion vector bits were equivalent to about only one-frame for full D1 digital video size, 720×480 [8]. Shimizu et al proposed a method using representation of norm and angle for motion vectors. The method was complicated and still two separate codes were used [9]. Matsuda et al proposed a lossless re-encoding scheme for MPEG-1 video. They used an arithmetic coder to both DCT and motion vector data for the MPEG-1 coder [10].

To realize the whole system, we will propose a re-encoding method that integrates two existing variable codes into a single code as the first step. Based on the information theory, blocking source inputs brings efficiency to the lower bound of entropy. For the Markov source, blocking gains more efficient results. In actual MPEG-2 encoding, 2D-VLC is the only example of blocking source events with run-length of zeros and amplitude in DCT coefficient coding. We constructed block coding for motion vector coding in this paper. Motion vectors of MPEG-2 consist of a set of symmetrical 16 variable-length-codes from 1-bit to 10-bit and one bit code for a zero vector. In the following parts of this section,

several experiments are carried out to improve the coding algorithm.

I. Symmetrical coding

In this subsection, 16 different non-zero events and a zero event are coded in a pair of two consecutive original VLCs. There is another sign bit to represent positive or negative for non-zero motion vectors. In this experiment, the sign bit is a fixed one bit, and is excluded for the calculation of efficiency. This scheme is called "Symmetrical coding" because positive and negative evens are coded by the same codes. The motion vectors appear as a pair of horizontal and vertical vectors as shown in Fig.7. For this format, we can block the horizontal vector and the vertical one in a single code.

Table V shows the frequency of motion vectors in encoding a video by MPEG-2 encoder, TM-5. The video size is full D1 (720×480) and the length is half a second.

Table VI shows entropy of coded bits with improving ratios of compression rates. The entropy of blocked motion vectors is reduced 27% at most from the original MPEG-2 coded bits. Table VII shows a part of the constructed codes.

The Huffman codes are generated using free software by Marcus Geelnard available at http://bcl.comli.eu/. Table VIII shows a part of the constructed codes.

II. Influence of Video Length

In this subsection, we examine the necessary length of input video for these experiments. It is better to use video test sequences as far as possible to examine the performance pre-

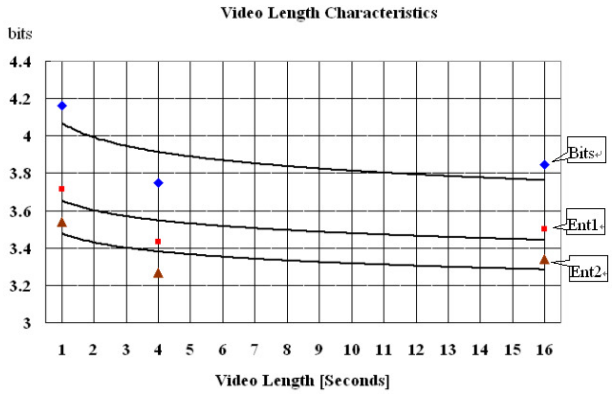

Fig.8 Video length influence of MPEG-2 re-encoding for the video No. 4, at 8Mbps.

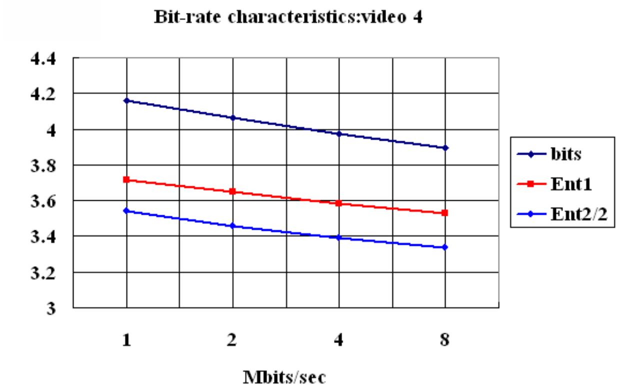

Fig. 9 Bit rate characteristics for the video No.4 with a duration of four seconds.

cisely. On the other hand, it is better to keep time and data volume to a minimum. New results of re-encoding for several cut-out partial sequences from a single video are listed in Table 8. Fig. 8 is a graph showing re-encoding. From the start of 0.5 seconds, information decreases gradually toward 16 seconds. The least squares regression lines on the graph can be gradually decreased and nearly converge. The videos used in this paper are listed in Table 9. The video used to examine of the influence of video length is No.4 "autobahn". The size of the motion picture is 720x480.

The bit-rate of encoding is 8Mbps. Sixteen different non-zero events and a zero event including the sign bit to represent positive or negative for non-zero motion vectors (MV) are coded in a pair of two consecutive original VLCs. In this experiment, the sign bit is included in newly generated VLCs and for the calculation of efficiency.

Viewing these behaviors, we choose the video length of 4 seconds for the following experiments.

III. Influence of bit-rate

In this subsection, the influence of bit-rate is examined. There are many choices of bit-rates in MPEG-2 encoding. It is important to check the effects of bit-rate to re-encoding code design. Fig. 9 shows bit-rate characteristics with log-scale for the horizontal axis. Bits mean the original MPEG-2 motion vectors. Ent1 means entropy of motion vectors of MPEG-2. Ent2/2 means entropy of motion vectors obtained by the proposed re-encoding method. In general, a decrease can be seen with bit-rates. But improving ratios from MPEG-2 to re-encoding may be the same. The entropy is larger for low bit-rates, which means a role of motion vectors is large and may require more bit-rate for describing videos. For high bit-rates, the smaller entropy means that there may be redundancy and all motion vectors are not necessarily required. These understandings coincide with the former comments that improvement of motion vector coding is effective for low bit-rates in references [8] and [9].

IV. Evaluation of a variety of videos

Table VIII and Fig 10 show overall comparison of re-encoding efficiency. The first column of Table VIII is the numbers of coded bits of motion vectors for the case of the original MPEG-2. Ent1 means entropy of motion vectors of MPEG-2. Ent2/2 means entropy of motion vectors in the case of the re-encoding method. In Fig.10, improvement ratios from MPEG-2 to re-encoding are large for videos No. 1, No.4 and No.5, but are small for videos No.2 and No.3. The characteristic of videos No.2 and No.3 is relatively smaller motion. On the other hand, videos No.1, No.4 and No.5 have large motion scenes. Ave in Fig. 10 means the average of five results. Table IX are videos used in these experiments.

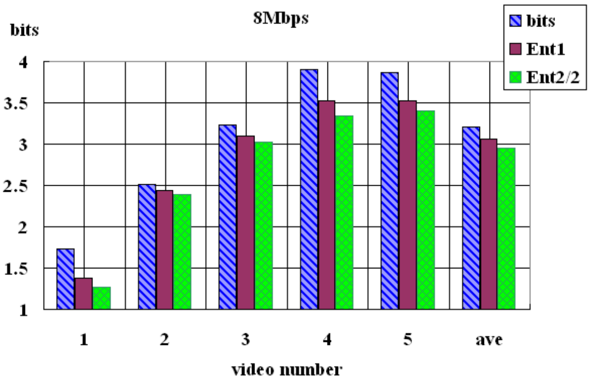

Fig. 10 Overall comparison of re-encoding efficiency.Video length is four seconds for No. 1-5. Bit-rate is 8Mbps.

V. Comparison of quantity of the number of MVs

Table X shows increased bits of motion vectors used in our experiments in this paper. A large number of video data are used to analyze the methods in detail and to improve reliability of the experiments. About 30 times more than the conventional experiments carried out by Yu et al. [8].

Fig.11 (a)-(d) are sample pictures of videos used in these experiments except (e) which is a rugby game on television. The former four videos are presented at author's homepage [13].

IV. Conclusion

A new re-encoding paradigm is reviewed and a two dimensional semi-optimization is examined. A large number of

Car Phone	14961	4.autobahn	246924
Foreman	22105	5.rugby	615714
total	58565	total	1782830

video data are used to analyze the methods in detail and to improve reliability of the experiments. By two-dimensional Huffman re-encoding by V-V codes, 5-26% coding efficiency is obtained. Though the result is restricted to the motion vector parts, the efficieny improves much comparing to the conventional methods using F-V codes for MPEG-2 with 5% coding efficiency.The results may be stable as to length of video and bit-rates. However, for the variety of video contents, the result may still not be convergent. This implies that a larger variety of videos, including still scenes and large motion ones should be tried in the future.

Abstract—**The paper presents an original dedicated integrated software system for managing and querying alphanumerical information and images from medical domain. The software has a modularized architecture controlled by a multimedia relational database management server. The server is designed to manage database creation, updating and complex querying based on several criteria: simple text-based or content-based image query on color or texture feature, extracted from color and gray-scale image.**

Keyword—**smultimedia; database server; content based retrieval; insert operations.**

I. Introduction

ONE of the domains where a large quantity of alphanumerical and visual information is acquired daily is the medical one. This information is obtained during the patients' diagnosis and treatment process. Some of the imagistic medical data sources are:

- Electronic medical sheets: these files contain information about patients' name, birth date, medical antecedents, signs, main diagnosis, secondary diagnosis, values of the analysis and treatment.
- Medical images that are stored in digital format or images stocked on different media (X-ray film, paper, etc).
- Digital Imaging and Communications in Medicine (DICOM) files – these standard files are produced by the most part of medical devices (echographs, endoscopes, magnetic resonance imaging devices) which are used in patients diagnosis. A DICOM file contains alphanumerical information (patient name, doctor name, consulting date, diagnosis) and one or several images stored in different formats, compressed or uncompressed.

That is why the problem of storing the medical images collections in digital format along with the associated information (patient name, diagnosis, consulting date and treatment), managing the database and executing efficient queries, it is intensely studied in order to find new and more efficient solutions.

There are only few systems on the market that have already integrated algorithms for image processing and features extraction into the medical diagnosis process. Most of the applications use classic Database Management Systems, like: Microsoft SQL Server, MySQL or Interbase.

The problem is that almost none of these servers offer support for multimedia data. The users have to implement their own algorithms and methods for images processing.

It is presented in this paper an original solution that integrates both the methods needed to process the images and methods for executeing complex queries, based on the content.

The paper has the following structure: Section 2 presents a short overview of the images format, Section 3 describes the algorithms used for characteristics extraction, in Section 4 it is described the system and made an analysis of the images processing performances and Section 5 presents the conclusions.

II. An original Implementation of a Multimedia Database Server

In order to manage content based retrieval for images collections there have been implemented a series of applications. Most of them are using classic Database Management Systems, like: Microsoft SQL Server, MySQL or Interbase.

The main drawback of these systems is that, most of them offer no support for multimedia data (neither for processing, nor for searching).

In [5][6] it is presented an original solution for managing visual information from images. This solution implemented in Visual C++ is a multimedia database management system (MMDBMS) that includes algorithms for extracting texture and color characteristics and for executing content-based visual queries.

This server is designed to manage medium sized personal digital collections having at most few tens of thousands of records. Over this number of records it should be redesigned the indexes system in order to enhance the execution time.

The implementation includes both a server and a client application that can be executed from any internet browser.

An element of novelty for this implementation is that the client application has the possibility to build visual content-based queries directly from the interface.

The elements of this window which permit content based retrieval are (figure 2):

– Similar With – opens the window for choosing the query image

– Select – permits to choose the field (or fields) that will be presented in the results of the query

– From – it represents the tables in database, that will be used for the query

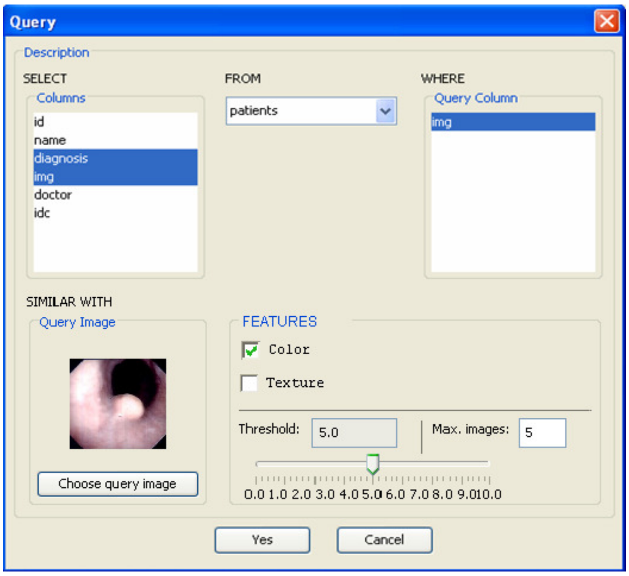
Fig. 1. Main page of the client application

- Where – the image type column used for content-based image query
- Features – it is chosen the characteristic used for content based visual query – color, texture or a combination of them
- Threshold – it is chosen a threshold of accepted similitude between query image and target image. An image with a similitude under that threshold will not be added into the resulted query images



SELECT Columns: id, name, diagnosis, img, doctor, idc

FROM: patients

WHERE Query Column: img

☑ Color

☐ Texture

Threshold: 5.0

Max. images: 5

Fig. 2. The window implementing content-based queries

- Maximum images – specify the maximum number of images returned by the query

Based on these options, it is generated a modified SQL command for content-based retrieval that is sent to the server along with the query image.

The client communicates with the server through messages exchange using sockets. The client sends SQL commands and receives the results. The results can be either strings (responses to queries or error messages), or multimedia files in which case it is needed to return images to client.

The execution time for content based queries is influenced by two factors: the time needed to process the query image and the time needed to search similar images into the database.

Each image is processed before being stored into the database and extracted color and texture characteristics. That is why it is needed in this step to process only the query image. Depending to the size of the image, this can take an important time.

Only after this step is finished the server can apply specific algorithms in order to find the most similar images.

An original aspect of the server is that it includes all the methods needed to extract the characteristics and compare the similitude of the images.

III. Characteristics Representation and Extraction

The server is intended to be used especially with medical images. The studies have shown that not all the methods used to extract characteristics give the best results in any circumstances [10][11]. That is why it is important to know the domain where the server will be mainly used.

In our experiments there were considered images from gastric tract. For these images the best results were obtained using histograms for color characteristics and Gabor filters for texture characteristics [10][11].

A. Color characteristics representation

Image processing is a technique used to increase the images quality in order to be easily understood by the human eye, or to help extract some important characteristics. In order to succeed it is necessary to identify pixels groups that are interconnected by common characteristics. Some useful information can be extracted from colors repartition in pixels, obtaining the color histogram. For that it is measured and represented the number of pixels for each color. The histogram does not say anything about the geometric relations between pixels. The image-histogram relation is not mutual, meaning that there can be several images with the same histogram [3].

If the measured characteristics can have k_1 values for the first coordinate, k_2 values for the second…, and k_n for the last, then the resulted histogram will have the size:

$$size=\prod_{i=1}^{n} k_n \tag{4}$$

A major disadvantage of the histograms is that they need a lot of space, especially if the number of colors is high. A good solution would be to store only characteristics that have a non-zero value, or the value is above a specified threshold.

The histograms are invariant to translations, rotations, and they have only small variations when the viewing angle is changed.

The following definition can be given: a histogram represents the colors distribution in an image, region or object. It is calculated using the following formula:

$$h_c[m]=\sum_{x=0}^{X-1}\sum_{y=0}^{Y-1}\left\{\begin{array}{ll}1, \text{ if } :Q_c(T_c I[x,y])=m \\ 0, & otherwise\end{array}\right\} \tag{5}$$

Another disadvantage of the histograms is they do not specify the geometric relations between pixels. That means several images might have the same histogram, although they are totally different.

B. Texture characteristics representation

The texture is the second important characteristic of the images that can be used in content-based retrieval. It is hard to give an exact definition of texture. Usually the word “texture” is used to define the touch feeling of objects, without touching them.

The dictionary definition is: the internal organization of an object, the association modality of an object, characterized by its shape, size of each element and by the geometric relations between each component.

A texture is created by regularly repeating an element or a model on a surface. This model/element is called texture point (textel). The computer graphic techniques define two types of textures: deterministic (regular) and statistic (random).

The deterministic textures are created by repeating the same specified geometric form (e.g.: circle or rectangle). An example of such a deterministic texture is the bricks in the wall.

The statistical textures are obtained by modifying the patterns using specified statistic properties (e.g.: the texture of wood or rocks). They are typically specified by properties of the spatial frequencies.

In order to extract the texture characteristics there have been studied a series of methods. The most representative are Gabor filters and Coocurence matrix. Although there are a lot of other available techniques, there is no one to be considered the best. This depends especially by the type of images used (from nature, medical, etc.).

C. Extracting texture characteristics using Gabor filters

Starting from HSV color space representation, the color can be represented in complex. Any point from the HSV cone can be computed using the formula [4]:

$$z_M = S\,(\cos H + i \sin H) \tag{6}$$

The saturation can be interpreted as size, the hue as the phase of the complex value. There are a lot of advantages of such a representation. First, it is simple due to the fact that color is a scalar and not a vector and the combination between channels is made before filtering. In conclusion, the color can be represented in complex using:

$$b(x,y)=S(x,y)\times e^{iH(x,y)} \tag{7}$$

To compute the Gabor characteristics for an image represented in HS-complex it is used a method similar as computing the monochromatic Gabor characteristics. This is due to the fact that the color channels are combined before filtering [4]:

$$C_{f\phi}=\left(\sum\left(FFT^{-1}\left\{P(u,v)\times M_{f,\phi}(u,v)\right\}\right)\right)^2 \tag{8}$$

The Gabor characteristics are created using the value $C_{f,\varphi}$ computed for 3 scales and 4 directions:

$$f = (C_{0,0}, C_{0,1},\ldots\ldots, C_{2,3}) \tag{9}$$

The similitude between these characteristics is defined by the metric:

$$D^2(Q,T)=\sum\sum d_{f,\phi}(Q,T)\text{,whered}_{f,\phi}=(f^Q-f^T)^2 \tag{10}$$

IV. Experiments and Results

Because it is a client-server application, the execution time depends on two aspects: the network speed that is used to send data to the network and the data processing speed.

Table 1.
Time needed to transfer images

N o	Image resolution	Image size	Time needed
1	160 ×160	75 KB	0,30 s
2	240 × 240	172 KB	0,75 s
3	480 × 480	675 KB	2,90 s
4	640 × 640	1204 KB	5,20 s
5	1200 × 1200	4220 KB	18,30 s

Usually the information sent to server is based on strings, less than 100KB in size. Nowadays the network speed is high enough that the sending time can be considered close to zero.

In our case, an important role in data transfer is represented by the images data. Depending to the resolution and compression used, they might have a size up to several MB. In this case it is very important the speed used to send data to the network.

Taking into account that the size of a BMP image with resolution of 100×100 pixels, is 30 KB it can be deducted the time needed to send images to the server:

The time effectively needed by the server for an insert operation is higher than presented above because the server uses a handshaking communication technique for client communication and data sending: the client sends to the server the insert command, the server responds with an OK confirmation. It analysis the data next and if needs more data (such as receiving an image), sends to the client a data request. The client responds sending the image. To the last step, the server acknowledges receiving the image. If one of them does not receive an acknowledgement it will resend the information.

After all the information is receive, before making the insertion in the database, the server has to process the image received and extract the color and texture information.

In order to extract the characteristics, the image colors have to be translated from RGB to HSV color space, quantized to 166 colors and after that applied the algorithms presented above to extract histogram and texture. These operations are made to the pixel level and need a high processing power and important execution time.

In the tested version, the server process only BMP images. If the image would be compressed (e.g.: JPEG), it should be decompressed first and only after that processed as the BMP images.

In Table 2 it is presented the time needed to extract the color and texture characteristics from images having different resolutions.

The graphic resulted from the above table is presented in figure 2.

It can be noticed a linear growth of the execution time with the image size, due to the linearity of the algorithms used.

Table 2.
Time needed to process the images

No	Image resolution	Time for color characteristics	Time for texture characteristics	Total time
1	160 ×160	0,45 s	14 s	14,45 s
2	240 × 240	0,60 s	14,5 s	15,10 s
3	320 × 320	0,70 s	15,30 s	16 s
4	480 × 480	1 s	63,70 s	64,70 s
5	640 × 640	1,50 s	108,50 s	110,50 s

For an image having the 160 × 160 pixels resolution it is necessary approximate 15 seconds to extract the characteristics. For an image of 640 × 640, the time will increase to almost 2 minutes.

Taking into account that there are cases when several users want to execute insert operations simultaneously, it was considered to be useful to limit the images resolution to 500×500 pixels. This will give the possibility to finalize the insert operations in a reasonable time.

V. Conclusions

The paper presented a new solution for managing and querying multimedia images collections. The implemented multimedia relational database management system includes an original data type, called IMAGE used to store all the characteristics extracted from images. These characteristics are used in content based retrieval.

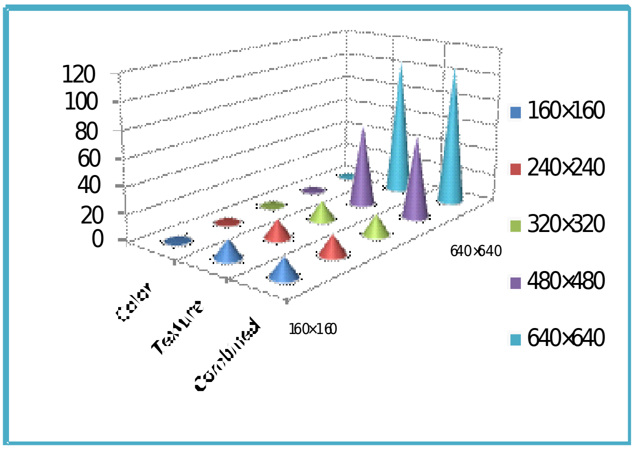


Fig. 3. Time vs. Image resolution

It is created for managing and querying medium sized personal digital collections that contain both alphanumerical information and digital images (for examples the ones used in private medical consulting rooms). The software tool allows creating and deleting databases, creating and deleting tables in databases, updating data in tables and querying. The user can use several types of data as integer, char, double or image.

The quality of the server is tested from the execution point of view. It is tested the time needed to process the insert queries, namely the time needed to extract color and texture characteristics.

This software can be extended in the following directions:

- Adding new types of traditional and multimedia data types (for example video type or DICOM type - because the main area where this multimedia DBMS is used it is the medical domain and the DICOM type of data is used for storing alphanumerical information and images existing in a standard DICOM file provided by a medical device)
- Studying and implementing indexing algorithms for data inserted in the tables in order to enhance the execution time.

***Abstract*—In this article we intend to present a method of obtaining high complexity sinthetic scenes by using simple volumes as the building blocks. The below described method can be used to obtain both homogenous and heterogenous volumes. This is done by combining volumes of different voxel densities.**

***Index Terms*—volumetric data, voxel, constructive solid geometry, volume modelling, constructive volume geometry.**

I. Introduction

THE VOLUMETRIC data imaging technology has greatly improved sice the 1990's. Before this many fields had to work with data images that used the depth or field effect known from 2D screens.

Because of the improved graphical representation, the volumetric data has found extensive use in medical applications such as 3D ultrasound, CAT (Computed Axial Tomography) or MRI (Magnetic Resonance Imaging). Other fields putting the technology to use include geological surveying, security scanning and, potentially, 3D gaming.

Given the importance of volumetric data, a lot of research has been done lately in the field, ranging from volumetric generation and rendering to volumetric segmentation, indexing and compression. This research was mainly done using data that resulted from real medical cases. Only recently did researchers start to use data obtained by scanning physical objects using lasers. Even so, volumetric data is stil scarce and not readilly available.

Because volumetric data is in general obtained through medical imaging devices it is usually hard to come by. Given the ease with wich sinthetic scenes can be manufactured, the sinthetic senes are somtimes prefered for volumetric analysis. It must be said that the sinthetic scenes offer less diversity than the real medical data but they can be custom made to the precise needs of the desired field of analysis. Volume segmentation and indexing can greatly take advantage of sinthetic scence tailormade for its needs.

II. Constructive volume modeling

The constructive volume generation technology is not a new thing and many articles have been written on this topic. For example the Constructive Volume Geometry (CVG) [1] article presents an algebraic framework for modelling complex spatial objects using combinational operations. In this article we present another approach for volume generation. We will use basic volumes like spheres, prisms, cylinders, cones, tori, etc. as building blocks for more complexe volumes. These volumes are combined using boolean operators like union and intersection. The resulting volumes can be combined with other volumes to form more complex objects.

The volumes that we are using are made up of voxels that have a position in the volumetric spece they are defined in and a density, with values in the interval [0,1]. The density can later on be interpreted as a color in a given spectrum. For the examples given in this article we chose a palette consisting of shades of green ranging from light green for density 0 to dark green for density 1.

A volume is stored in a 3D matrix of densities, where a voxel is represented by its position in the matrix and the density stored at that position.

contenta-images2eps.com

Fig. 1. Sphere and cone union.

In order to combine their volumetric data, all volumes must be defined in the same subspace.For example we consider a 256x256x256 cube made up of voxels. Each voxel in the cube has a density between 0 and 1. Let us take two such cubes, A and B, which contain the volumetric data for a homogenous sphere of radius 100, centered in (100, 100, 100) and a homogenous cone of radius 100 and height 50, centered in (100, 200, 100) respectively. Both volumes have the density equal to 1. The union of A and B will be another 256x256x256 cube of voxels as presented in Fig. 1.

When we make a union between two volumes, we actually add the densities of corresponding voxels in the cubes containing these volumes, caping the densities at a maximum of 1, thus obtaining a valid new cube, with all densities between 0 and 1. The resulting cube can be used in subsequent operations.

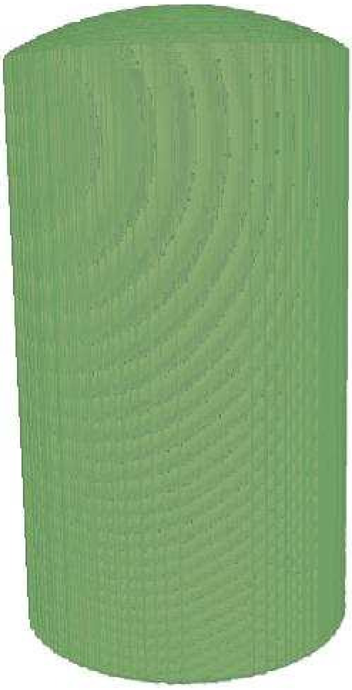

Fig. 2. Sphere and cylinder intersection.

For the intersection of two volumes we compute the product of all corresponding densities in the cubes containing the volumes. Given that the densities of voxels have values in the interval $[0, 1]$, after multiplication the resulting densities also have values in the $[0, 1]$ interval. An example of an intersection between a sphere and a cylinder is given in Fig. 2.

The difference of two volumes is obtained by subtracting the corresponding densities of voxels in the cubes containing the volumes. Because the resulting densities can fall below 0, we need to limit these values at 0. An exemple of a difference is given in Fig. 3.

The complement of a volume can be obtained by subtracting from 1 the voxel densities of the cube containing the volume. The resulting cube has all densities in the $[0, 1]$ interval.

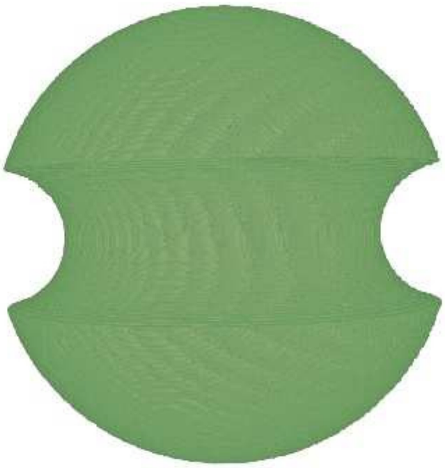

Fig. 3. Sphere and torus difference.

These operations have the potential of creating realy complex volumes. In Fig. 4. there is a volume created from a sphere and three cylinders.

The basic volumes used in these operations are created using their parametrized equations. For example, a sphere is defined by the equation (1).

$$\begin{aligned} x&=x_0 + r\sin\theta\cos\phi \\ y&=y_0 + r\sin\theta\sin\phi \quad (0 \leq \phi \leq 2\pi \; and \; 0 \leq \theta \leq \pi) \\ z&=z_0 + r\cos\theta \end{aligned} \qquad (1)$$

By taking discrete values from the intervals $[0, 2\pi]$,$[0, \pi]$, and $[0, r]$ we are able to build our sphere voxel by voxel. The

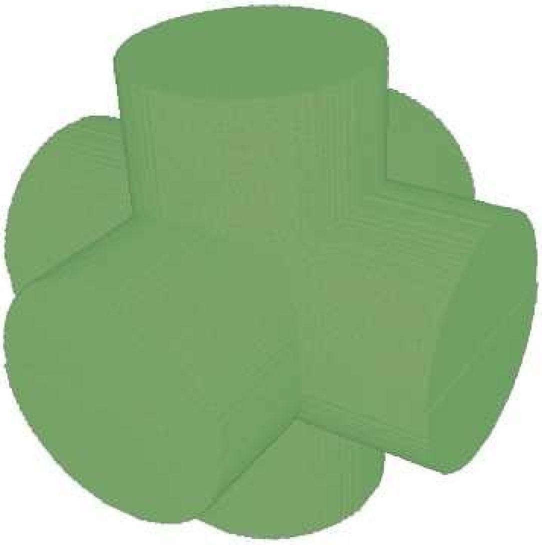

Fig. 4. Union of three cylinders.

algorithm for constructing a homogenous sphere is given in Algorithm 1.

Algorithm 1 Generating voxels for a homogenous sphere of density 1.

```
Require: $r > 0$
  $r \leftarrow 1$;
  while $r <= radius$ do
    $theta \leftarrow 0$;
    while $theta \leq 2\pi$ do
      $phi \leftarrow 0$;
      while $phi \leq \pi$ do
        $x \leftarrow x_0 + r * \sin(theta) * \cos(phi)$;
        $y \leftarrow y_0 + r * \sin(theta) * \sin(phi)$;
        $z \leftarrow z_0 + r * \cos(theta)$;
        $volume_{x,y,z} \leftarrow 1$;
        $phi \leftarrow phi + \arcsin(1/r)$;
      end while
      $theta \leftarrow theta + \arcsin(1/r)$;
    end while
    $r \leftarrow r + 1$;
  end while
```

In order to obtain a heterogenous volume we can combine homogenous volumes using the operations defined previously. For example a sphere with three layers of density d_1, d_2 and d_3 can be obtained by making a union between a homogenous sphere with density d_1, a homogenous sphere shell with density d_2 and another homogenous sphere shell with density d_3. A section through the resulting sphere can be seen in Fig. 5.

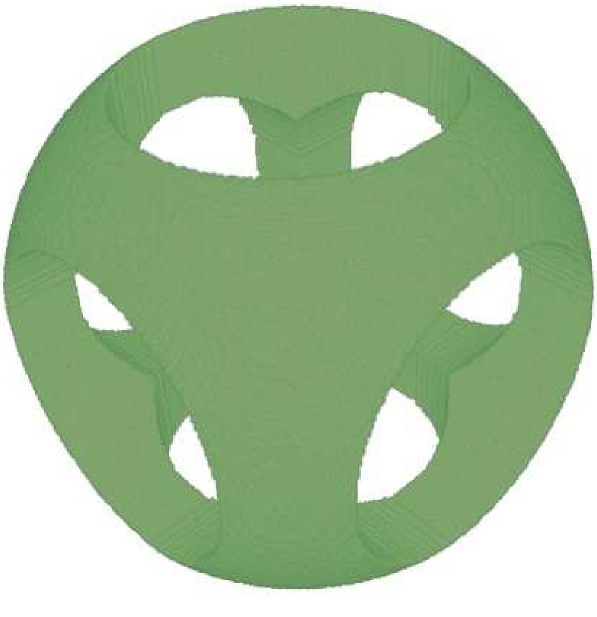

Fig. 5. Sphere and cylinders difference.

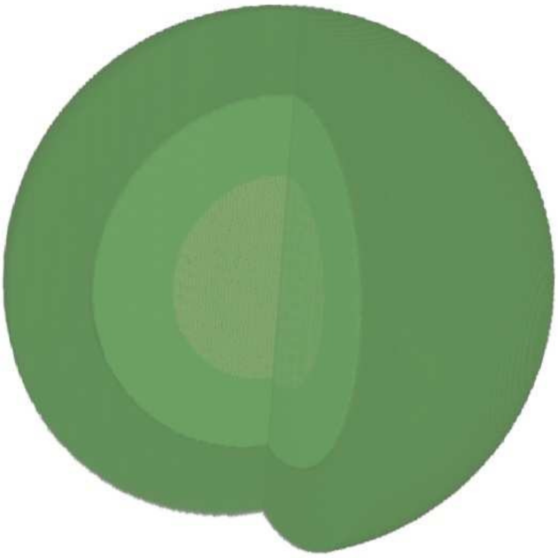

Fig. 6. Heterogenous sphere obtained by combining three basic homegenous volumes through union. The section through the sphere was made by means of a difference with a prism.

III. Conclusion

We have shown that more complexe volumetric objects can be obtained by combining basic volumes using boolean operators. This is very helpful in obtaining synthetic data for other volume related fields of research like volumetric segmentation and indexing, and volume compression.

The simple sinthetic data can be combined into more complex forms thus giving a large colection of objects from where to choose when performing volumetric analysis.

The method that we have used is a very simple but an ingenious one as presented above. We will use this method in our future work.

Abstract— **The main idea of this paper is the real-time implementation of the Fault Detection Kalman Filter Estimators (FDKFE) in a satellite's Reaction Wheels during its scientific mission. We assume that the satellite's reaction wheels are subjected to several failures due to the abnormal changes in power distribution, motor torque, windings current as well as the temperature caused by a motor current increase or friction. The proposed real-time FDKFE strategies consist of two embedded multiple model bank of nonlinear Kalman Filter (Extended/Unscented) estimators. This research work is based on our previous results in this field and we intend to extend this approach by real-time implementations of the developed FDKFE strategies (FDDM-EKF and FDDM-UKF). Furthermore we will construct a benchmark to compare their results to have an overall image how perform these strategies.**

I. Introduction

THE most important faults in the aerospace satellite's systems are the result of unexpected failures, interferences as well as the age of their crucial components. Also the defective measurement and control loops equipment, in particular some of the sensors and actuators should be considered. Whenever these critical situations come out the satellite's systems could lose the control, require much more energy, and could operate harmfully. Therefore to operate in real-time at high energy efficiency and to guarantee the equipment safety and reliability it is important to develop suitable FDKFE strategies able to detect and diagnose any time every faulty satellite's system components and consequently corrective and reconfiguration actions should be initiated promptly. Up to date for the majority part of the satellites, the onboard measurements data acquisition is sent to the land stations relatively frequently. However the operators still remain implicated to monitor some of the telemetry measurements and to diagnose the inconsistency of the operating equipment. Effectively the existing methods to identify and to adjust the equipment failures are mostly labor-intensive task, and consequently sustained, rhythmic and error-prone. In the majority situations the operators inspect telemetry plots manually to determine the satellite's reaction wheels health motors current. Also they use statistical evaluation that still necessitates considerable human knowledge, consequently error-prone that could generate harshly equipment operation. In these circumstances the problem of satellite monitoring and fault diagnosis becomes a critical issue, very complex that need to be implemented in mainframe environment using more sophisticated control systems and artificial intelligent strategies. Therefore the objective of our research is to develop more proficient, accurate and reliable real-time FDKFE strategies based on the nonlinear estimation techniques.

II. REACTION WHEEL's DYNAMICS

The Reaction Wheel (RW) model is developed based on detailed schematics shown in Figure 1 [3]. In a state-space representation associated to the RW actuator healthy mode (j=1) or its faulty modes ($j=\overline{1,N}$) we could write

(i) State Equation:

$$\begin{bmatrix} x_{j,1}(k+1) \\ x_{j,2}(k+1) \end{bmatrix} = \begin{bmatrix} T_s G_d \omega_d (f_1(x_{j,1}(k), x_{j2}(k)) - f_3(x_{j,2}(k)) \\ \dfrac{T_s[k_f x_{j,1}(k)(1+f_2(x_{j,2}(k))) - \tau_c f_4(x_{j,2}(k))]}{J} + (1 - \dfrac{T_s \tau_v}{J}) x_{j,2}(k) \end{bmatrix} + \\ T_s \begin{bmatrix} G_d \omega_d u(k) \\ \dfrac{\tau_{noise}}{J} \end{bmatrix} + w_j(k) := F_j(x_{jk}, u_k) + w_{jk} \tag{1}$$

(ii) Output equation:

$$\begin{bmatrix} y_{j,1}(k) \\ y_{j,2}(k) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_{j,1}(k) \\ x_{j,2}(k) \end{bmatrix} + \upsilon_j(k) := H_j(x_{jk}, u_k) + v_{jk} \tag{2}$$

where the j-state vector mode is defined as:

$$x_j(k) := x_{jk} := \begin{bmatrix} x_{j,1}(k) \\ x_{j,2}(k) \end{bmatrix} = \begin{bmatrix} I_{m,j}(k) \\ \omega_{w,j}(k) \end{bmatrix} \tag{3}$$

The input command $u(k) = V_{com}$ is generated by the attitude controller, and it represents the command voltage applied to the reaction wheel motor axis. The functions H_s, H_b, H_f that appear in the reaction wheel diagram shown in Figure 1 represent the discontinuous Heaviside functions and the sign (.) block function represents the sign function. Also T_s is the sampling period of the discrete-time model of the reaction wheel actuator, w_{jk} and v_{jk} that appear in Figure 2 are the process and measurement noise, assuming that they are independent white Gaussian random processes with zero mean and covariance matrices:

$$E[w_n w_n^T] = \begin{cases} Q_w, n = k \\ 0, n \neq k \end{cases} \quad E[v_n v_n^T] = \begin{cases} R_v, n = k \\ 0, n \equiv k \end{cases} \tag{4}$$

The other parameters indicated in the model are identical to the reaction wheel parameters that are used in [3], and [6]-[9].

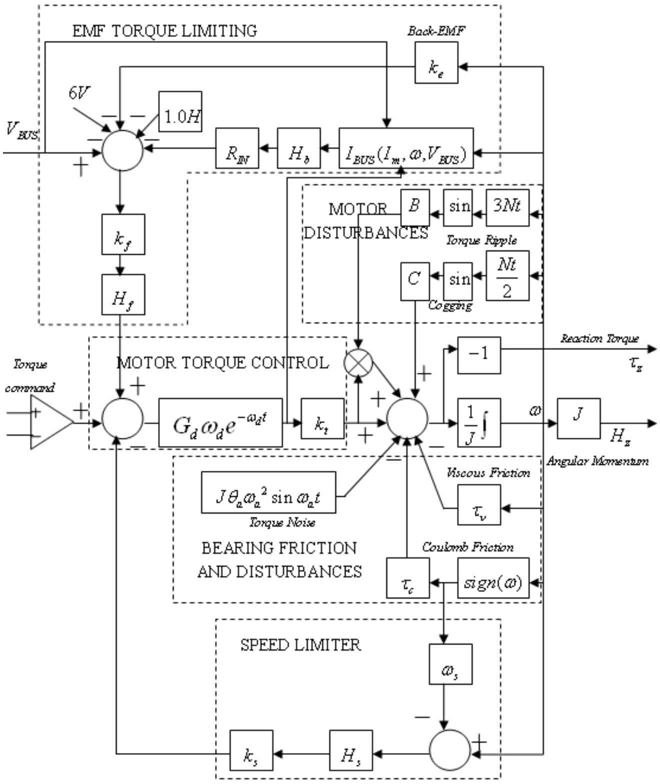

Fig.1 A detailed block diagram of a high fidelity reaction wheel model

III. Extended Kalman Filter Estimator (EKF)

Consider the dynamics of a linear stochastic system expressed in the state-space difference representation

$$x_{k+1} = Fx_k + Gu_k + w_k \tag{5}$$

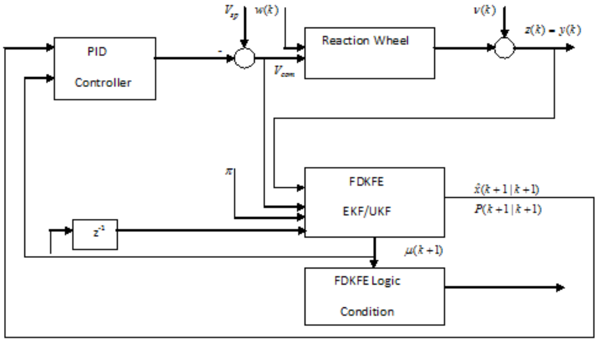

Fig. 2 The satellite's embedded FDKFE integrated structure

$$y_k = Hx_k + v_k \tag{6}$$

The process and measurement noise have normal probability distributions governed by

$$p(w) \sim N(0, Q_w)$$

$$p(v) \sim N(0, R_v) \tag{7}$$

The covariance matrices Q_w (process noise covariance) and R_v (measurement noise covariance) might change with each time step or measurement, but in our approach we assume that they are constant. Due to the process noise injected in the state space equation (5)-(6), the state vector $x_k \in R^n$ becomes random variable with its distribution approximated by a Gaussian distribution function $p(x) \sim G(\hat{x}, P_x)$.

Considering the nonlinear model of a reaction wheel as given by (1)-(2), the linearized state transition and observation matrices are defined according to the following Jacobeans

$$\begin{aligned} F_k &= \frac{\partial f(x_k, u_k)}{\partial x_k}\Big|_{\hat{x}_{k-1|k-1}, u_k} = \begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix} \\ H_k &= \frac{\partial h(x_k, u_k)}{\partial x_k}\Big|_{\hat{x}_{k|k-1}, u_k} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \end{aligned} \tag{8}$$

where G is an identity matrix. The EKF algorithm used for the state estimation of this dynamical system is now given according to the following steps [2]:

Step1. Initialization: for $k = 0$, set:

$\hat{x}_{0|0} = E[x_0], P_{0|0} = E[(x_0 - \hat{x}_{0|0})(x_0 - \hat{x}_{0|0})^T]$ representing the distribution of initial state estimate and its covariance matrix

Step2. Prediction step: Predict the state and the estimated covariance according to

$$\begin{aligned} \hat{x}_{k|k-1} &= f(\hat{x}_{k-1|k-1}, u_k) \\ P_{k|k-1} &= F_k P_{k-1|k-1} F_k^T + Q_w \end{aligned} \tag{9}$$

Step3. Update step:

3.1 Innovation or measurement residual

$$\tilde{y}_k = z_k - h(\hat{x}_{k|k-1}, u_k) \tag{10}$$

3.2 Innovation or residual covariance

$$S_k = H_k P_{k|k-1} H_k^{\ T} + R_v \tag{11}$$

3.3 Optimal Kalman filter gain

$$K_k = P_{k|k-1} H_k^{\ T} S_k^{\ -1} \tag{12}$$

3.4 Update state estimate

$$\hat{x}_{k|k} = \hat{x}_{k|k-1} + K_k \tilde{y}_k \tag{13}$$

3.5 Update estimate covariance

$$P_{k|k} = (I - K_k H_k) P_{k|k-1} \tag{14}$$

The covariance matrices Q_w (process noise covariance) and R_v (measurement noise covariance), together with the initial error covariance $P_{0|0}$ are the three tuning parameters in the EKF algorithm.

The matrices Q_w and R_v are determined empirically and account for uncertainty in the tracking data. Setting these matrices "properly" significantly contributes in making the EKF filter robust. The error covariance matrix P indicates uncertainty in the state estimate and provides criterion for the error bound.

IV. The unscented kalman filter estimator (UKF)

The Unscented Kalman Filter (UKF) is based on the unscented transformation (UT) which addresses the general problem of state estimation of a system that is governed by a nonlinear stochastic difference state-space representation [2], [4]-[5]:

$$\begin{aligned} \mathbf{x}_{k+1} &= F(\mathbf{x}_k, \mathbf{u}_k) + \mathbf{w}_k \\ \mathbf{y}_k &= H(\mathbf{x}_k, \mathbf{u}_k) + \mathbf{v}_k \end{aligned} \tag{15}$$

The critical operation that is performed in the Kalman filter is propagation of a Gaussian random state variable $\mathbf{x}_k \in \mathbf{R}^n$ through the system dynamics. In the Extended Kalman Filter (EKF) estimator the Gaussian random state variable is propagated analytically through the first-order linearization of the nonlinear system. This can introduce large errors in the true *a posterior* mean and covariance of the transformed Gaussian random state variable, leading to sub-optimal performance and sometimes divergence of the EKF estimator.

The UKF estimator is developed as an alternative to the EKF estimator and addresses this problem by using a deterministic sampling approach.

Using the principle that a minimal set of carefully chosen weighted sample points, called sigma points, can be used to parameterize mean and covariance, the UKF estimator yields superior performance when compared to the EKF estimator, especially for nonlinear systems.

These sigma points should completely capture the true mean and covariance of the Gaussian random state variable, and are propagated through the true nonlinear system dynamics. In it was shown that a random n-dimensional state variable x with mean $\overline{x}$ and covariance P could be approximated by $2n+1$ weighted sigma points X_i, $i = 1,....,2n+1$, that are given by:

$$\begin{aligned} X_0 &= \overline{x}\ , \ W_0 = \frac{k}{n+k} \\ X_i &= \overline{x} + (\sqrt{(n+k)P})_i\ , \ W_i = \frac{1}{2(n+k)} \\ X_{i+n} &= \overline{x} - (\sqrt{(n+k)P})_i\ , \ W_{i+n} = \frac{1}{2(n+k)} \end{aligned} \tag{16}$$

where k is a scalar that provides an extra degree of freedom for "fine tuning" the higher order moments of the approximation, and can be used to reduce the overall prediction error, $(\sqrt{(n+k)P})_i$ is the i-th row or column of the matrix square root of $(n+k)P$, and W_i is the weight associated with the $i-th$ point X_i.

The cloud of the transformed sigma points distribution X_{k+1} given by

$$X_{k+1} = F(X_k, u_k) \tag{17}$$

captures the *a posterior* mean that is given by the weighted average of the transformed sigma points:

$$\overline{x} = \sum_{i=0}^{2n} W_i X_{k+1,i} \tag{18}$$

and the covariance (the weighted outer product of the transformed sigma points) given by

$$P = \sum_{i=0}^{2n} W_i (X_{k+1,i} - \overline{x})(X_{k+1,i} - \overline{x})^T \tag{19}$$

In some applications the sampling rate could be an important source of degrading the UKF estimator performance.

The main advantage of the UKF estimator is that it is suitable for most general class of process models, due to the fact that the mean and covariance are calculated using standard vector matrix operations, and the implementation is extremely fast since UKF does not require calculation of Jacobean matrices that could in certain cases lead to numerical complications and difficulties.

Also the sigma points capture the mean and the covariance irrespective of the choice of matrix square root that is used.

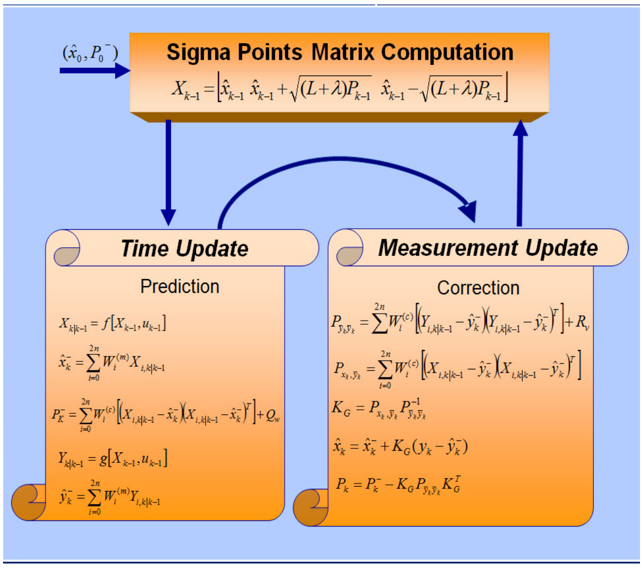
Numerically efficient and stable methods such as the Cholesky decomposition [5] can be used for this purpose.

Similar to EKF estimator the UKF estimator design steps for the both phases (prediction and correction) are well presented in figure 3.

V. Fault Detection Strategy Design

The multiple model approach for fault detection and diagnosis assumes that the actual system at any time can be modeled sufficiently accurately by the following jump Markov hybrid nonlinear system [1]:

$$\begin{aligned} & x(k+1) = F(k, m(k+1), x(k), u(k)) + T(k, m(k+1)) w(k, m(k+1)) \\ & x(0) : N(\hat{x}_0, P_0) \\ & z(k) = G(k, m(k), x(k), u(k)) + v(k, m(k)) \end{aligned} \tag{20}$$



$(\hat{x}_0, P_0^-)$
Sigma Points Matrix Computation
$X_{k-1} = \left[\hat{x}_{k-1}\ \hat{x}_{k-1} + \sqrt{(L+\lambda)P_{k-1}}\ \ \hat{x}_{k-1} - \sqrt{(L+\lambda)P_{k-1}}\right]$
Time Update
Prediction
$X_{k|k-1} = f[X_{k-1}, u_{k-1}]$
$\hat{x}_k^- = \sum_{i=0}^{2n} W_i^{(m)} X_{i,k|k-1}$
$P_K^- = \sum_{i=0}^{2n} W_i^{(c)} \left[(X_{i,k|k-1} - \hat{x}_k^-)(X_{i,k|k-1} - \hat{x}_k^-)^T\right] + Q_w$
$Y_{k|k-1} = g[X_{k-1}, u_{k-1}]$
$\hat{y}_k^- = \sum_{i=0}^{2n} W_i^{(m)} Y_{i,k|k-1}$
Measurement Update
Correction
$P_{\bar{y}_k \bar{y}_k} = \sum^{2n} W_i^{(c)} \left[(Y_{i,k|k-1} - \hat{y}_k^-)(Y_{i,k|k-1} - \hat{y}_k^-)^T\right] + R_v$
$P_{x_k, \bar{y}_k} = \sum_{i=0}^{2n} W_i^{(c)} \left[(X_{i,k|k-1} - \hat{y}_k^-)(X_{i,k|k-1} - \hat{y}_k^-)^T\right]$
$K_G = P_{x_k, \bar{y}_k} P_{\bar{y}_k \bar{y}_k}^{-1}$
$\hat{x}_k = \hat{x}_k^- + K_G(y_k - \hat{y}_k^-)$
$P_k = P_k^- - K_G P_{\bar{y}_k \bar{y}_k} K_G^T$

Fig. 3 The block scheme of the UKF estimator

The mode of the system (normal or faulty) at time k is selected by a discrete process m_j and modeled as a s-state, first-order Markov chain with transition probabilities $\pi_{ij}(k)$ given by:

$$\pi_{ij}(k) = P\{m_j(k+1) \mid m_i(k)\},\ \forall m_i, m_j \quad S \qquad (21)$$

and

$$0 \le \pi_{ij}(k) \le 1,\ i = \overline{1,N}, j = \overline{1,N}, \qquad \sum_j \pi_{ij}(k) = 1,\ \ i = \overline{1,N} \qquad (22)$$

The initial state distribution of the Markov chain is $\pi(0) = [\pi_1\ \pi_2\ \pi_3 \ldots\ldots \pi_N]$, where

$$0 \le \pi_j \le 1,\ \forall j = \overline{1, N},\ \sum_{j=1}^{N} \pi_j = 1 \qquad (23)$$

and where $x(k)$ is the state vector, $z(k)$ is the mode-dependent measurement vector, and $u(k)$ is the control input vector. The process and measurement noise vectors $w(k)$ and $v(k)$, respectively, are mutually independent, additive, white Gaussian of zero mean and covariance matrices $Q_w(k)$ and $R_v(k)$, and are independent of the initial state $x(0)$. In expression (44), P{.} denotes the probability operator. The event that m_j is in effect at time k is denoted as $m_j(k) = \{m(k) = m_j\}$, and $S = \{m_1, m_2, \ldots, m_N\}$ represents the set of all possible system modes. The system may jump from one such system to another at a random time. It can be observed from that the state vector observations are in general noisy and dependent. Therefore, the mode information is embedded in the measurement sequence. The system mode sequence is an indirectly observed Markov chain, from which the transition probability matrix $\pi = \{\pi_{ij}\}$ represents a design parameter. The simulation results and our comparative studies are presented in the next section.

The root-causes of faults injected in the reaction wheels are due to the following sources:

(i) unexpected viscous friction changes generating anomalies in the temperature *T*,

(ii) unexpected changes in the bus voltage V_{bus},

(iii) loss of effectiveness in the motor torque as represented by unexpected changes in the coefficient k_t.

The FDKFE strategy for the hybrid system can be stated as that of determining the current model state. In other words, it involves determining whether the normal or a faulty mode is currently in effect from a sequence of noisy observations. How to design set of modes to represent the possible system modes is a key issue in multiple model approach, which is problem-dependent. This design should be achieved by attempting to have models (approximately) that represent or cover all possible system modes at any given time. This represents the model set design that is critical for multiple model based FDKFE. To design a good set of models requires *a priori* knowledge of possible faults in the system. In application of multiple model estimation techniques for fault detection and diagnosis, the following tasks should be implemented [1]:

a) model set design,
b) filter selection,
c) estimate fusion, and
d) filter re-initialization.

Filter selection deals with the problem of selecting a model-based recursive filter such as Kalman Filter for each model of the nonlinear system. The estimate fusion task combines model-conditional estimates to obtain an overall estimate. Towards this end, three approaches could be investigated, namely soft, hard and random decisions. The procedure for reinitializing each single-model based filter from time to time is of significant importance for multi-model estimation. The simplest approach for reinitializing each filter is to use its previous state estimate and filter covariance at the current cycle. In this case filters are operating in parallel and no interactions exist among them.

However, this may lead to unsatisfactory performance when the system structure or its mode changes. For this reason, it would be more appropriate to reinitialize each filter using the previous overall state estimate and covariance matrix which does lead to an interacting multiple model estimation technique. For each faulty mode corresponding to a set of possible ACS reaction wheel faults and a normal operating mode, one can apply an unscented Kalman filter based on measurements collected from reaction wheels angular velocity vector ϖ. The input considered can be taken as the torque command voltage vector *u* that is generated by, e.g. a PID controller. The dynamics of an unscented Kalman filter associated with each mode is described by the following nonlinear state space representation:

$$\begin{aligned} x_j(k+1) &= F_j(k, x_j(k), u_j(k)) + T_j(k) w_j(k) \\ z_j(k) &= G_j(k, x_j(k), u_j(k)) + v_j(k) \end{aligned} \qquad (24)$$

where $x_j = \varpi(k)$ and the subscript j denotes the quantities pertaining to mode m_j. The nonlinear functions F_j, G_j and the weighting matrix T_j may have different structures for different values of j. The process noise and measurement noise vectors w_j and v_j are white Gaussian of zero mean with covariance matrices Q_{wj} and R_{vj}, respectively. In principle the probability of a given model matches the system mode provides the required information for the fault detection and diagnosis. Taking into account historical behavior of modes at time $\boldsymbol{k}$ ensures that the interacting multiple model algorithm yields a good estimate.

Consequently, exponential increase in complexity of a detection algorithm is avoided by mixing previous estimates at beginning of each cycle.

The model probabilities provide an indication of the mode in effect at any given time, and therefore can provide an indication of the reaction wheel actuator fault. By using model probabilities information, both fault detection and diagnosis can be achieved. This decision making process is formally stated according to:

$$\begin{aligned} &\mu_j(k+1) = \max_j \, \mu_j(k+1) = \mu \\ &\textit{If } \; \mu > \mu_T \; \textit{then } \; \text{mod}\,e \;\; j \;\; \textit{is faulty} \\ &\textit{Otherwise no fault occurs} \end{aligned} \tag{25}$$

where $\mu_{Threshold}$ represents the fault detection threshold value. The interacting estimation algorithm runs each parallel filter banks only once in each cycle. Each of these filters at time $t_{k+1} = k+1$ has its own input, the state estimate at time t_k, $\hat{x}^0(k|k)$, and its own covariance matrix, $P^0(k|k)$, which form a valid quasi-sufficient statistics of all the past information, under the assumption that model of each filter matches the system mode.

The above decision rule yields not only fault detection capability but also information about the type (sensor or actuator), the location (which sensor or actuator), the size (total failure or partial failure with fault severity), and the fault occurrence time.

VI. Nhe Embedded Fault Detection Kalman Filter Estimators Interacting Strategy

The embedded structure of an Interactive Multiple Model algorithm and EKF/UKF estimators is included in the references [1]-[2], [4]-[9]. Due to space limitations only the UKF based procedures is described below, the algorithm steps remaining almost the same for the both cases.

Step 1: Interaction and mixing of the estimates [1]

1.1 Compute the predicted mode probability from k to $k+1$

$$\hat{\mu}_j(k+1|\,k) = \sum\nolimits_1^N \pi(i,j)\mu_i(k) \tag{26}$$

1.2 Compute the mixing probability at k:

$$\mu_{ij}(k) = \frac{\pi(i,j) \;\; \mu_i(k)}{\hat{\mu}_j(k+1|\,k)} \tag{27}$$

1.3 Compute the mixing estimate at k:

$$\hat{x}_{j0}(k \mid k) = \sum\nolimits_1^N \hat{x}_i(k \mid k) \times \mu_{ij}(k) \tag{28}$$

1.4 Compute the mixing covariance at k, that is, P_0

$$P_{j0}(k|k) = \sum\nolimits^N [P_i(k|k) + (\hat{x}_{j0}(k|k) - \hat{x}_i(k))(\hat{x}_{j0}(k|k) - \hat{x}_i(k|k))^T] \times \mu_{ij}(k) \tag{29}$$

Step 2: Model conditional filtering [1]

(i) Prediction step [2], [4]-[5]:

2.1 Compute the global state sigma points matrix:

$$X_{k|k} = [\hat{x}(k|k) \;\; \hat{x}(k|k) + \sqrt{(L+\lambda)P(k|k)} \;\; \hat{x}(k|k) - \sqrt{(L+\lambda)P(k|k)}] \tag{30}$$

where the state covariance matrix $P(k|k)$ is updated for each time increment.

2.2 Compute the transformed global state sigma points matrix from k to $k+1$:

$$X_{k+1|k} = F(k, X_{k|k}, u_k) \tag{31}$$

2.3 Compute the predicted global state from k to $k+1$:

$$\hat{x}(k+1 \mid k) = \sum_{i=0}^{2n} W_i^{(m)} X_{i,k+1|k} \tag{32}$$

2.4 Compute the global predicted covariance from k to $k+1$:

$$\begin{aligned} P(k+1|\,k) = {} & (W_0^{(c)} + 1 - \alpha^2)(X_{0,k+1|k} - \hat{x}(k+1|\,k))(X_{0,k+1|k} - \hat{x}(k+1|\,k))^T + \\ & + \sum_{i=1}^{2n} W_i^{(c)}[(X_{i,k+1|k} - \hat{x}(k+1|\,k))(X_{i,k+1|k} - \hat{x}(k+1|\,k))^T] + Q_w \end{aligned} \tag{33}$$

2.5 Compute the transformed global output sigma points matrix from k to $k+1$:

$$Y_{k+1|k} = G(k, X_{k+1|k}, u_k) \tag{34}$$

2.6 Compute the predicted global output from k to $k+1$

$$\hat{y}(k+1 \,|\, k) = \sum_{i=0}^{2n} W_i^{(m)} Y_{i,k|k-1} \tag{35}$$

2.7 Compute the measurement residual for each mode j at $k+1$:

$$v_j(k+1) = z(k+1) - \hat{y}_j(k+1 \,|\, k) \tag{36}$$

where $\hat{x}_j(k+1 \,|\, k)$ represents the j-th component of the global predicted state $\hat{x}(k+1 \,|\, k)$ (the mode j), and $z(k+1)$ represents the new available measurement for the active mode in effect, let say i, namely

$$z(k+1) = z_i(k+1) \tag{37}$$

2.8 Compute the global predicted output covariance matrix $P_{\tilde{y}\tilde{y}}(k+1 \,|\, k)$

$$\begin{aligned} P_{\tilde{y}\tilde{y}}(k+1 \,|\, k) = {} & (W_0^{(c)} + 1 - \alpha^2)(Y_{0,k|k-1} - \hat{y}(k+1 \,|\, k))(Y_{0,k|k-1} - \hat{y}(k+1 \,|\, k))^T + \\ & + \sum_{i=1}^{2n} W_i^{(c)}[(Y_{i,k|k-1} - \hat{y}(k+1 \,|\, k))(Y_{i,k|k-1} - \hat{y}(k+1 \,|\, k))^T] + R \end{aligned} \tag{38}$$

2.9 Compute the global cross-covariance matrix

$$\begin{aligned} P\tilde{x}\tilde{y}(k+1|\,k) = {} & (W_0^{(c)} + 1 - \alpha^2)(X_{0,k|k-1} - \hat{x}(k+1|\,k))(Y_{0,k|k-1} - \hat{y}(k+1|\,k))^T + \\ & + \sum_{i=1}^{2n} W_i^{(c)}[(X_{i,k|k-1} - \hat{x}(k+1|\,k))(Y_{i,k|k-1} - \hat{y}(k+1|\,k))^T] \end{aligned} \tag{39}$$

2.10 Compute the global Kalman filter gain at *k*+1:

$$K_G(k+1) = P_{\tilde{x}\tilde{y}}(k+1 \mid k)(P_{\tilde{y}\tilde{y}}(k+1 \mid k))^{-1} \quad (40)$$

(ii) Correction step:

2.11 Update the state estimated at k+1

$$\hat{x}_j(k+1 \mid k+1) = \hat{x}_j(k+1 \mid k) + K_{G,j}(k+1)\nu_j(k+1) \quad (41)$$

2.12 Update the state covariance matrix

$$P_j(k+1|k+1)=P_j(k+1|k)-K_{G,j}(k+1)(P_{\tilde{y}\tilde{y}}(k+1|k)^{-1}(K_{G,j}(k+1))^T \quad (42)$$

<u>**Step 3:** Update the mode probability at *k*+1</u>

3.1 Compute the likelihood function at *k*+1

$$L_j(k+1)=\frac{1}{\sqrt{|(2\pi)P_{j,\tilde{y}\tilde{y}}(k+1|k)|}}\exp[-\frac{1}{2}\nu_j^T(k+1)(P_{j,\tilde{y}\tilde{y}}(k+1|k))^{-1}\nu_j(k+1)] \quad (43)$$

3.2 Update the mode probability at *k*+1:

$$\mu_j(k+1) = \frac{\mu_j(k+1 \mid k)L_j(k+1)}{\sum_{1}^{N} \mu_j(k+1 \mid k)L_j(k+1)} \quad (44)$$

<u>**Step 4:** Fault detection at *k*+1</u>

4.1 Compute the mode probability vector at *k*+1:

$$\vec{\mu}(k+1)=\left[\mu_1(k+1)\ \ \mu_2(k+1)\ \ \mu_3(k+1)\dots\mu_N(k+1)\right] \quad (45)$$

4.2 Obtain the maximum value of the mode probability vector:

$$\mu_{FDD\ \max} = \max_j \{\mu_j(k+1))\ , \quad (46)$$

4.3 Determine the index of the maximum value of mode probability vector

$$j = find(\vec{\mu} == \max(\vec{\mu})) \quad (47)$$

and subsequently assign:

$$index = j \quad (48)$$

<u>**Step 5**: Fault decision – FDD logic</u>

if $\mu_{FDD\max} > \mu_{Threshold}$ the fault occurs, (49)

Otherwise no fault occurs.

VII. Real-Time Control and FGKE Strategy Implementation

The control system literature rarely includes extensively the real-time software and hardware implementation aspects, and it doesn't pay attention beyond algorithms and sampling time selection. Normally the implementation aspect and real-time system design are connected together but in the most cases this connection is always ignored. Moreover the real-time system design is treated from control perspective ignoring the implementation aspects of the control algorithms. However in the last years the real-time implementation and design aspects get more transparency to control engineering field due to advent of software tools like MATLAB/SIMULINK with its RTW (Real-Time Workshop) and the RTWT (Real-Time Windows Target) Toolboxes. Definitely these new real-time platforms do the implementation of real-time experiments easier and save much time but on the other hand they have some drawbacks regarding a good insight view of the real-life problems that could emerge during the real-time implementation of the control system. Building a real-time ACS requires normally two stages: PID controller and estimators design as well as their digital implementations. At controller and estimators design stage some performance indices are defined and the PID controller and EKF and UKF estimators are designed to optimize these indices.

At implementation stage, multiple control tasks should be scheduled to run the FPGA (*Field-Programmable Gate Array*) onboard microprocessor or controller module. We have to take care about task scheduling taking into account the limited available computing resources. Firstly to select the sampling time T_s, it should take into account the limited computation time provided by the hardware such that to avoid the conflict with its computation time delay (control latency). Since the control latency is typically affected by control jitter, delay and loss can occur alternatively in the system at different instants of time. The loss of the ACS control signal $u(k)$ leads to the controller computer failure, unable to update its output during any one sampling interval, and accordingly the one step delayed input $u(k-1)$ it will be applied again. Since this situation may well occur accidentally at any instant of time, the failure to deliver a control signal can be treated as a casual ACS input disturbance $u_p(k)$. Anyway this interaction between control performance and task scheduling will be investigated in the future work.

VIII. Simulation Results

The real-time platform used to perform these real-time simulations was a MATLAB R2007b with SIMULINK running on the two processors WINDOWS OS machine. The simulation results are obtained for a sampling time T_s equal to 1s, but a carefully selection of it and the interaction between control performance and task scheduling will be done in the future work. In spite of a large number of scenarios, to have an overall image about the estimator's performance, we present in figures (4)-(5) only the partial simulation results for the both real-time embedded fault detection strategies. In these figures we will present in terms of the mode probability index the transient and the steady state of different fault modes occurrences in a multi-fault sequence. These figures reveal in the same time the robustness of the both estimators to the noise level and to the probability matrix. Also the estimator's performance comparison is available in the benchmark presented in Table 1.

IX. Conclusions

In this paper, we have studied the possibility of using two interactive multiple models based on Extended and Unscented Kalman Filter estimators to detect and diagnose the faults in reaction wheels of the attitude control system (ACS) in a satellite. The main contributions in our research are summarized briefly as follows:

(a) Detection and identification of reaction wheel faults of the ACS due to a number of possible

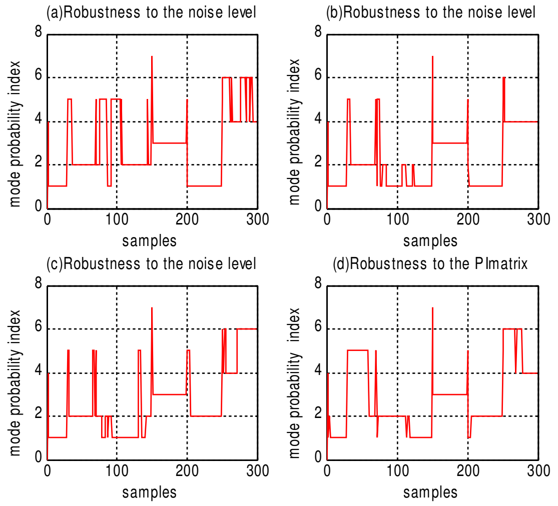


Fig. 4 The performance in terms of mode probabilities index for robustness analysis using the FD-EKF strategy

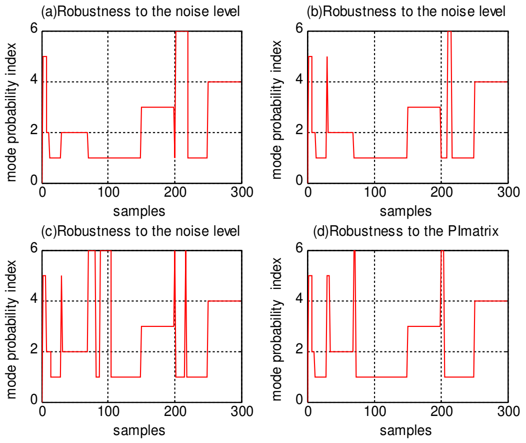

Fig. 5 The performance in terms of mode probabilities index for robustness analysis using the FD-UKF strategy

TABLE 1
THE PERFORMANCE COMPARISON OF THE FDKFE STRATEGIES

Item	Performance	KF	EKF	UKF
1	Accuracy Degree for modeled faults	Very good	Good	Very Good
2	Accuracy Degree for un-modeled faults	Small	Small	Good
3	Robustness to R ,Q matrices	Not Robust	Not Robust	Robust
4	Robustness to the matrix probabilities, π	Not Robust	Not Robust	Robust

*Embedded estimators: KF-Standard Kalman Filter, EKF-Extended Kalman Filter, UKF-Unscented Kalman Filter.

sources that generate soft and hard anomalies during a scientific mission of a satellite,

(b) Implementation of a bank of real-time parallel Kalman filters for faulty modes covering a quite large set of the most likely and commonly possible scenarios of reaction wheel failures,

(c) Detection and diagnosis of both partial and significant reaction wheel failures for different scenarios using the real-time EKF and UKF estimation algorithms,

(d) Comparison of performance capabilities and advantages of real-time UKF estimation algorithm with respect to the real-time EKF estimation algorithm, and

(e) Robustness analysis of both real-time estimation algorithms to the selection of model transition probabilities, modeling errors, and noise statistics under different scenarios.

The approach proposed in this paper is probabilistic in nature and yields results that are more accurate and having good fault classification capabilities than the spectral analysis that is well studied in the literature. Based on fault identification analysis that is carried it can be observed that the real-time UKF estimation algorithm is robust to modeling uncertainties, and to statistics of noise measurements and process noise. The both real-time algorithms work similar to a real-time neural network estimator and classifier employed to perform satisfactory FDKFE. Compared to a real-time neural network estimator and classifier, the real-time UKF estimation algorithm doesn't need an on-line training that takes an extensive amount of computational resources. Compared to the above approaches and real-time EKF estimation algorithm, the real-time UKF estimation algorithm performs better and has a much less computational burden and complexity, and it furthermore operates much faster. Perhaps the biggest drawback of predictive model-based approaches is the need for a suitable quantity of data for training and testing the system during the development phase [10], [13]. Moreover, stability of the real-time UKF estimation algorithm still remains an open question, which needs further investigation. Also, the behavior of the real-time UKF estimation algorithm for diagnosis in a fast or rapidly changing process dynamics needs to be explored further.

***Abstract*–This paper describes a proposition of the method for optimal adjustment parameters of the adaptive filter with LMS algorithm in the practical application of suppression of additive noise in a speech signal for voice communication with the control system. By the proposed method, the optimal values of parameters of adaptive filter are calculated with guarantees the stability and convergence of the LMS algorithm. The DTW criterion is used for the quality assessment of speech signal processing obtained from output of adaptive filter with LMS algorithm. In the experimental section is described the way of verification of the proposed method on the structure of the adaptive filter with LMS algorithm and on the structure of the adaptive filter with LMS algorithm in application of suppressing noise from speech signal by simulations in MATLAB software and implementation on DSK TMS320C6713.**

***Keywords*–LMS adaptive filter (Least Mean Square), DTW criterion (Dynamic Time Warping), noise canceller.**

I. Introduction

FOR optimum settings of a step size parameter μ and the length M of the adaptive filter with the LMS algorithm is necessary ensuring the stability and convergence of the LMS algorithm. As a result of appropriate setting of the adaptive filter parameters is correct speech signal processing and subsequent correct the isolate words recognition through the use of the DTW criterion.

II. The Adaptive Filter With LMS Algorithm

A. LMS algorithm

Least mean – square (LMS) algorithm was developed by Widrow and Hoff in 1960. This algorithm is a member of stochastic gradient algorithms [2]. The LMS algorithm is a linear adaptive filtering algorithm, which, in general, consists of two basic processes:

a) filtering process, which involves

- Computing the output $y(n)$ of adaptive filter in response to vector input signal $\mathbf{x}(n)$ (1),
- Generating an estimation error $e(n)$ (Fig.5) by comparing this output $y(n)$ with desired response $d(n)$ (Fig.2) (2),

b) An adaptive process (3), which involves the automatic adjustment of the parameters $\mathbf{w}(n+1)$ of the filter in accordance with the estimation error $e(n)$ [3], [1]

$$y(n) = \mathbf{w}^{\mathrm{T}}(n)\,\mathbf{x}(n) \tag{1}$$

$\mathbf{w}(n)$ tap – weight vector,

$$e(n) = d(n) - y(n) \tag{2}$$

$$\mathbf{w}(n+1) = \mathbf{w}(n) + 2\mu e(n)\mathbf{x}(n) \tag{3}$$

$\mathbf{w}(n+1)$ tap – weight vector update,
μ step size parameter.

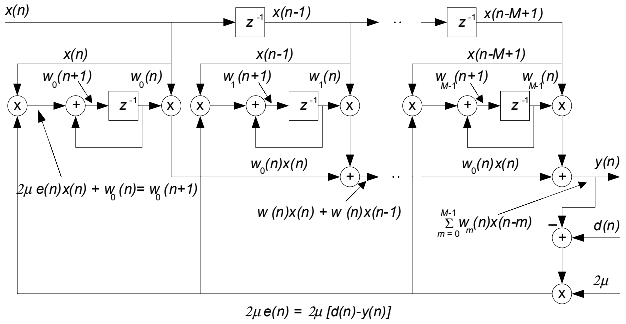

Fig. 1 FIR LMS adaptive filter realization [2].

B. Settings of a step size parameter μ

a) Calculating of a step size parameter μ to ensure the stability of adaptive filter with the LMS algorithm.

For determination, when the LMS algorithm remains stable is necessary find the upper bound of $\mu_{\max}$, that guarantees stability of LMS algorithm (4) [1]

$$\mu_{\max} < \frac{1}{3\operatorname{tr}[\mathbf{R}]} \tag{4}$$

tr[**R**] trace of **R**, which mean sum of the diagonal elements of **R**,

R Toeplitz autocorrelation matrix calculated from vector of input signal $\mathbf{x}(n)$, size **R** is M x M.

Toeplitz autocorrelation matrix **R** is calculated by equation (5)[2]

$$\mathbf{R} = \mathrm{E}[\mathbf{x}(n)\mathbf{x}^{T}(n)]. \tag{5}$$

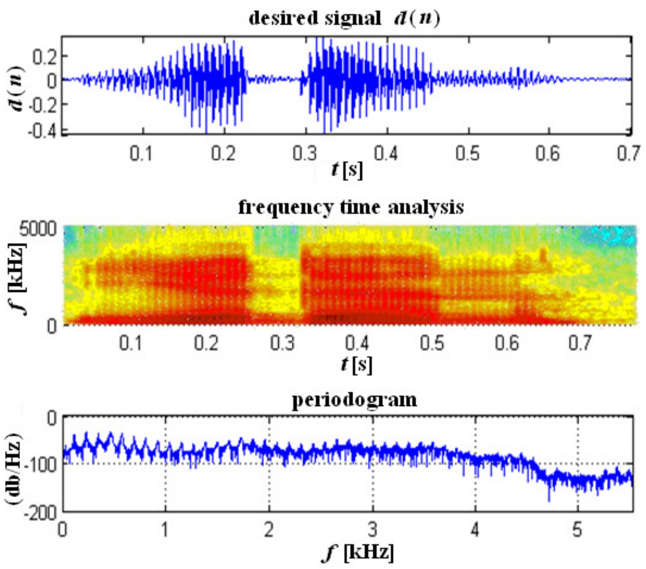

Fig. 2 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of desired speech signal $d(n)$ of isolated czech word "jeden" to the input of adaptive filter with LMS algorithm.

The significance of the upper bound of μ, which is provided by (4), is that it can easily be calculated from the filter input samples. Range of μ that is provided by (4) is sufficient for the stability the LMS algorithm, but is not necessary [1].

b) Calculating of a step size parameter μ to ensure the convergence of adaptive filter with the LMS algorithm

Convergence behaviour of LMS algorithm is directly linked to the eigenvalue spread of the autocorrelation matrix **R** and the power spectrum of $\mathbf{x}(n)$. Convergence of the LMS algorithm is directly related to the flatness in the spectral content of the underlying input process. E[$\mathbf{v}(n)$] converges to zero when μ remains within the range of formula (6). E[$\mathbf{v}(n)$] is expectation of weight – error vector $\mathbf{v}(n) = \mathbf{w}(n) - \mathbf{w}_0$.

$$\mu_{\mathrm{conv}} \leq \frac{1}{\lambda_{\max}} \qquad (6)$$

$\lambda_{\max}$ maximum eigenvalue of autocorrelation matrix **R** of the input vector $\mathbf{x}(n)$.

The above range does not necessarily guarantee stability of LMS algorithm. The convergence of LMS algorithm requires convergence of the mean of $\mathbf{w}(n)$ towards $\mathbf{w}_0$ and also convergence of the variance of the elements of $\mathbf{w}(n)$ to some limited values [1]. Vector $\mathbf{w}_0$ is calculated by Wiener – Hopf equation and the superscript "$_0$" indicates the optimum Wiener solution for the Wiener filter [2].

c) Calculating of optimal value of a step size parameter μ_{opt} of adaptive filter with the LMS algorithm

Determination of a step size parameter μ_{opt} value is important to conduct an algorithm LMS. When selecting parameter μ_{opt} terms of a compromise between the two aspects. On the one hand, large values μ can leads quickly to the optimal settings the LMS algorithm for speech signal processing. On the other hand, may increase the value μ of a mistake in the speech signal processing in further steps. Small value μ, on the contrary, ensure the stability and the convergence of LMS algorithm [1].

As a result small value μ is the slowdown in the convergence of LMS algorithm and, consequently, increasing the inaccuracies in the filtration non-stationary signals [9]. For the optimal value of the parameter μ_{opt} is the following equation (7) [1]

$$\mu_{\mathrm{opt}} = \frac{M}{(1+M).\mathrm{tr}[\mathbf{R}]}, \qquad (7)$$

tr[**R**]trace of **R**, which mean sum of the diagonal elements of **R**, M parameter misadjustment.

Parameter misadjustment M is defined as ratio of the steady – state value of the excess mean-square error (MSE) ξ_{excess} to the minimum mean square (MSE) error $\xi_{\min}$.

$\mu_{\mathrm{opt}}=1,08.10^{-2}$ (M=20%)	$\mu_{\mathrm{opt}}=1,18.10^{-2}$ (M=20%)	$\mu_{\mathrm{opt}}=1.10^{-2}$ (M=20%)	$\mu_{\mathrm{opt}}=7,5.10^{-3}$ (M=20%)
$\mu_{\mathrm{opt}}=14,99.10^{-3}$ (M=30%)	$\mu_{\mathrm{opt}}=1,63.10^{-2}$ (M=30%)	$\mu_{\mathrm{opt}}=1,38.10^{-2}$ (M=30%)	$\mu_{\mathrm{opt}}=1,04.10^{-2}$ (M=30%)

$$M = \frac{\xi_{excess}}{\xi_{\min}} = \mu\,\mathrm{tr}[\mathbf{R}]. \qquad (8)$$

The misadjustment M is a dimensionless parameter that provides a measure of how close the LMS algorithm is to optimality in the mean - square – sense.

The smaller M is compared with unity, the more accurate is the adaptive filtering action being performed by the LMS algorithm. Values of misadjustment M are usually the 10%, 20% and 30% (Tab.I), (Tab.III), (Tab.V), (Tab.VI), (Tab.VII) [1].

A value of M = 10% means, that the adaptive system has an MSE only 10 percent greater than $\xi_{\min}$ [8].

III. Determination of the LMS adaptive filter length *M* by way of Widrow method [8]

Time constant τ_{mse} is calculating

$$\tau_{\text{mse}}=\frac{1}{4\mu\lambda}=\frac{M}{4\mu\,\mathrm{tr}[\mathbf{R}]}, \qquad (9)$$

λ eigenvalue of autocorrelation matrix **R** of the input vector **x**(*n*),
tr[**R**]trace of **R**, which mean sum of the diagonal elements of **R**.

When the eigenvalues λ are sufficiently similar for the learning curve to be approximately, fitted by a single exponential, its time constant τ_{mse} may be applied to (9) to give an approximate value of *M* [8].

Values of order *M* LMS adaptive filter can be calculated from input signal **x**(*n*) to adaptive filter (Tab.III)

$$M=\frac{\mathrm{tr}[\mathbf{R}]}{\lambda}. \qquad (10)$$

IV. Using DTW criterion for determination of the adaptive filter length *M*

The correct determination of the adaptive filter length *M* is very important. When the length *M* of the adaptive filter is low, the speech signal processing as a result of a small number of parameters of the adaptive filter is inaccurate. High value of the adaptive filter length *M* lead to inaccurate speech signal processing by influence of the estimator variance increase. In draft method in this work was used DTW criterion for determining value of length *M* of the LMS adaptive filter.

By way of DTW criterion is compare two sequences of vectors: reference vector **P** = [p(1), . . . p(P)] of the length P and test vector **O** = [o(1), . . . o(T)] of the length T [6].

Value of the LMS adaptive filter order *M* is determined by setting values of the order *M* in interval {0 to 150} and calculating of the minimum distance *d* (similarity) between the reference vector **P** (desired signal *d*(*n*) (Fig.2)) and the test sequence vector **O** (error signal *e*(*n*) (Fig.5)). Words are almost never represented by the sequence of the same length P$\neq$ T. The distance *d* between the sequences **O** and **P** is given as minimum distance over the set of all possible paths (all possible lengths, all possible courses) [4]. When the distance *d* was ***d*<0,2**, the word **was recognized**. This value ***d*<0,2** was determined empirically from the measured results of implemented experiments (Tab.II), (Tab.III), (Tab.V), (Tab.VI), (Tab.VII), (Tab.VIII).

Minimum distance computation

$$D(\mathbf{O},\mathbf{P})=\min_{\{C\}} D_c(\mathbf{O},\mathbf{P}) \qquad (11)$$

is simple, when normalization factor N_c is no function of path and is possible write N_c=N for $\forall_c$

$$D(O,P)=\frac{1}{N}\min_{\{C\}}\sum_{k=1}^{Kc} d\left[o\left(t_c(k)\right),p\left(r_c(k)\right)\right]W_c(k) \qquad (12)$$

V. Using of the additive noise in experiments with speech signal

For implementation of experiments are used additive noises with calculated segmental SNR (Signal to Noise Ratio) – SSNR (Tab.IV) for speech signal processing [5]

$$\mathrm{SSNR}=\frac{1}{K}\sum_{i=0}^{L-1}\mathrm{SNR}_i VAD_i, \qquad (13),$$

L is the number of segments of speech signal,
K the number of segments in speech activity,
VAD_i is information about speech activity (values 1 and 0) in *i*-th segment, SNR_i is local (short term) SNR.

Table II.
The values of distance *d* are calculated by comparing of the czech isolated words "jeden" (one) with the words "dva" (two) for up to "pět" (five) and compared the word "dva" (two) with the words "jeden"(one), "tři" (three) for up to "pět"(five).

jeden–jeden	jeden–dva	jeden–tři	jeden–čtyři	jeden–pět
***d* = 0**	*d* = 0,713	*d* = 1,218	*d* = 1,415	*d* = 0,552
dva–jeden	dva–dva	dva–tři	dva–čtyři	dva–pět
d = 0,713	***d* = 0**	*d* = 0,406	*d* = 0,568	*d* = 0,373

Table III.
The values of order *M* of adaptive filter and distance *d* between desired speech signal *d*(*n*) to adaptive filter and error signal *e*(*n*) from adaptive filter calculated by way of widrow methods (simulated in MATLAB).

	SSNR$_a$=6,731(dB)	**SSNRw1=18,187(dB)**	**SSNR$_{w2}$=3,119(dB)**	**SSNR$_{w3}$=–1,783(dB)**
Widrow M=10 %	μ_1=5,9.10^{-3}; ***M*=19** ***d*=9,919.10^{-2}**	μ_1=6,4.10^{-3}; ***M*=17** ***d*=1,697.10^{-1}**	μ_1=5,4.10^{-3}; ***M*=21** *d*=2,919.10^{-1}	μ_1=4,09.10^{-3}; ***M*=26** *d*=2,908.10^{-1}
Widrow M=20 %	μ_2=1,08.10^{-2}; ***M*=19** ***d*=1,181.10^{-1}**	μ_2=1,18.10^{-2}; ***M*=17** *d*=2,54.10^{-1}	μ_2=1.10^{-2}; ***M*=21** *d*=4,152.10^{-1}	μ_2=7,5.10^{-3}; ***M*=26** *d*=4,011.10^{-1}
Widrow M=30 %	μ_3=14,996.10^{-3}; ***M*=19** ***d*=1,357.10^{-1}**	μ_3=1,63.10^{-2}; ***M*=17** *d*=3,194.10^{-1}	μ_3=1,38.10^{-2}; ***M*=21** *d*=4,907.10^{-1}	μ_3=1,04.10^{-2}; ***M*=26** *d*=4,645.10^{-1}

In the paper were used following additive noises for compare of the results of the proposed methods:

- Additive noise $n_a(n)$ (Fig.3) with the ratio of the desired signal $d(n)$ (Fig.2) of isolated czech words "jeden" to noise $n_a(n)$ **SSNR$_a$=6,731(dB)** (Tab.IV).
- White noise $n_{w1}(n)$ with the ratio of the desired signal $d(n)$ (Fig.2) of isolated czech words "jeden" to noise $n_{w1}(n)$ **SSNR$_{w1}$=18,187(dB)** (Tab.IV).
- White noise $n_{w2}(n)$ the ratio of the speech signal of isolated words "jeden" (Fig.2) to noise $n_{w2}(n)$ **SSNR$_{w2}$=3,119(dB)** (Tab.IV).

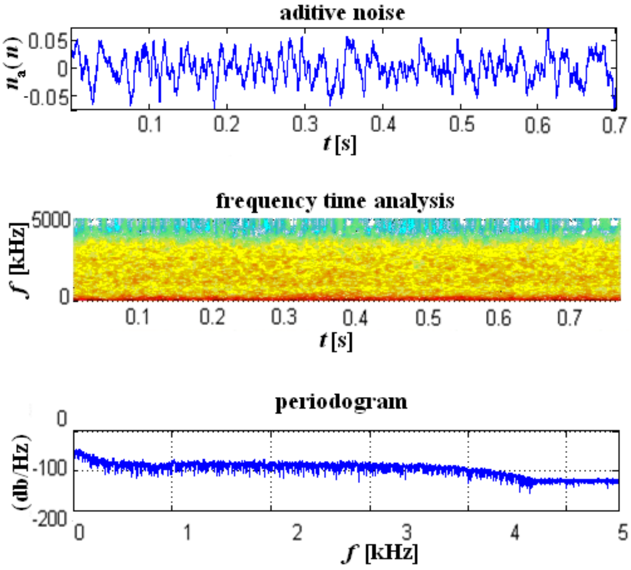

Fig. 3 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of desired speech signal $d(n)$ of additive noise $n_a(n)$ with SSNR$_a$=6,731(dB).

TABLE IV.
SEGMENTAL SIGNAL TO NOISE RATIO VALUES CALCULATED FOR THE SPEECH SIGNAL WORD "JEDEN" (FIG.1) TO ADDITIVE NOISE AND TO ADDITIVE WHITE NOISE.

Noise signification	Calculated values of ratio signal to noise
additive noise $n_a(n)$	SSNR$_a$=6,731(dB)
additive white noise 1 $n_{w1}(n)$	SSNR$_{w1}$=18,187(dB)
additive white noise 2 $n_{w2}(n)$	SSNR$_{w2}$=3,119(dB)
additive white noise 3 $n_{w3}(n)$	SSNR$_{w3}$= –1,783(dB)

- White noise $n_{w3}(n)$ the ratio of the speech signal of isolated words "jeden" (Fig.2) to noise $n_{w3}(n)$ **SSNR$_{w3}$=-1,783(dB)** (Tab.IV).

VI. DRAFT DTW METHOD

Draft method for optimal adjustment of a step size parameter μ_{opt} and the length M of the LMS adaptive filter was applied in next steps [7]:

1. Calculation of a step size parameter μ_{opt} optimal value (7) from input signal $x(n)$ (with SSNR) to the LMS adaptive filter (M=10%, M=20%, M=30%) (Tab.I).

2. For reference vector **P** is used desired signal $d(n)$ (Fig. 2) to the LMS adaptive filter.

3. As a test vector **O** was chosen error signal $e(n)$ (Fig.5).

4. Next was calculated the distance d (11), (12) between the signals $d(n)$ and $e(n)$ for sets values of LMS adaptive filter lengths M in interval {1 to 150}.

5. As the optimal value of the LMS adaptive filter order M was chosen value of the adaptive filter length M for minimum distance d (Fig.4) between two compared signals $d(n)$ and $e(n)$.

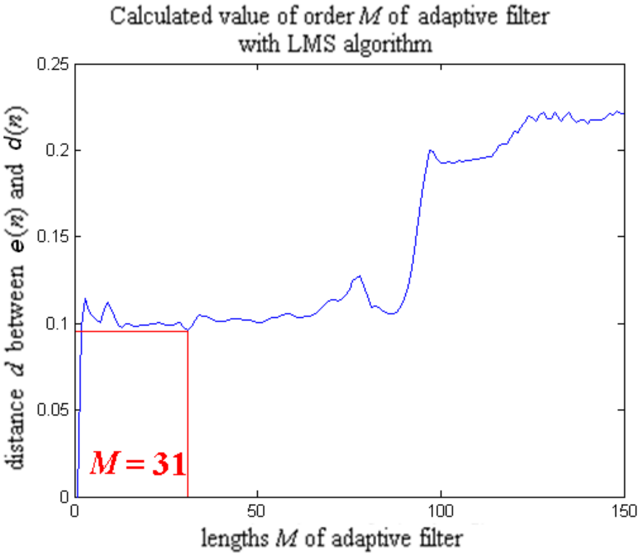

Fig. 4 Calculated values M=31 and d=9,61.10^{-2} of the LMS adaptive filter (μ=5,9.10^{-3}, SSNR=6,731(dB), M =10%).

TABLE V.
THE VALUES OF ORDER M OF ADAPTIVE FILTER AND DISTANCE d BETWEEN DESIRED SPEECH SIGNAL $d(n)$ TO LMS ADAPTIVE FILTER AND ERROR SIGNAL $e(n)$ FROM LMS ADAPTIVE FILTER CALCULATED BY WAY OF DRAFT METHOD WITH DTW CRITERION (SIMULATED IN MATLAB).

	SSNR$_a$=6,731(dB)	**SSNR$_{w1}$=18,187(dB)**	**SSNR$_{w2}$=3,119(dB)**	**SSNR$_{w3}$=–1,783(dB)**
M=10 %	μ_1=5,9.10^{-3}; ***M*=31** ***d*=9,61.10^{-2}**	μ_1=6,4.10^{-3}; ***M*=16** ***d*=1,691.10^{-1}**	μ_1=5,4.10^{-3}; ***M*=17** d=2,902.10^{-1}	μ_1=4,09.10^{-3}; ***M*=88** d=2,784.10^{-1}

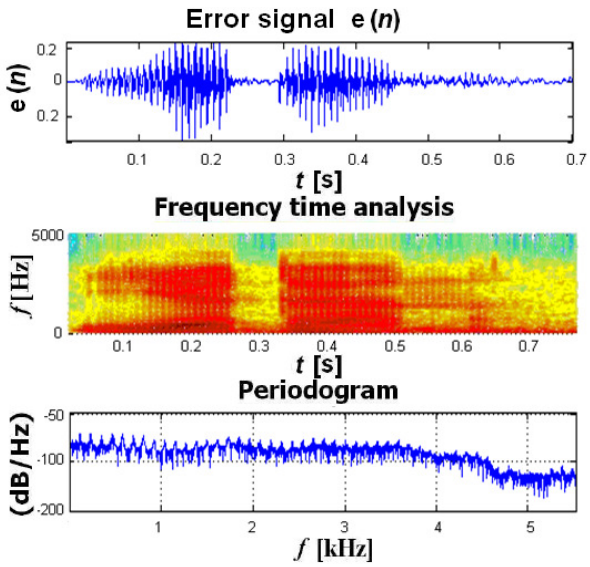

Fig. 5 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of error signal $e(n)$ (LMS adaptive filter – first iteration, M=31, μ=5,9.10^{-3}, simulated in MATLAB) [7].

In Table V can be seen, that the speech signal $e(n)$ at the output of the LMS adaptive filter **was recognized** (***d*<0,2**) from first iteration for SSNR$_a$=6,731(dB) (μ_1=5,9.10^{-3}; M=31, **M**=10%), (μ_2=1,08.10^{-2}, M=12, **M**=20%), (μ_3=14,996.10^{-3}, M=12, **M**=30%) and for SSNR$_{\text{w1}}$=18,187(dB) (μ_1=6,4.10^{-3}; M=16, **M**=10%). When the additive noise values SSNR$_w$ in speech signal were higher, the speech signal was not recognized.

VII. Using of the Draft Method with DTW criterion for LMS adaptive Noise Canceling from speech signal

B. Matlab simulation

The draft method with DTW criterion was used for the LMS adaptive noise canceling from speech signal, simulated in MATLAB in two channel structure of the adaptive filter with LMS algorithm in an application for the suppression of additive noise (Fig.6). A primary input contains desired signal $d(n)$, and an additive noise $n(n)$. A noise reference input is assumed to be available containing $n''(n)$, which is correlated with the original corrupting noise $n(n)$. As shown figure 6 the LMS adaptive filter receives the reference noise, filters it, and subtracts the result from the primary input. From the point of view of the adaptive filter, the primary input ($d(n)$+$n(n)$) acts as its desired response and the system output acts as its error. The noise canceller output $e(n)$ (Fig.7) is obtained by subtracting the filtered reference noise $n(n)$ from the primary input. Adaptive noise canceling generally performs better, than the classical approach since the noise is subtracted out rather than filtered out [8].

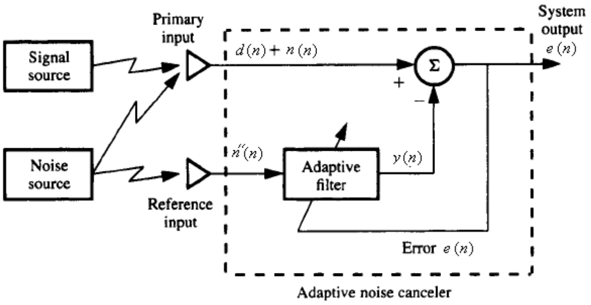

Fig. 6 Separation of signal $d(n)$ and noise $n(n)$ LMS adaptive noise-canceling approach [8].

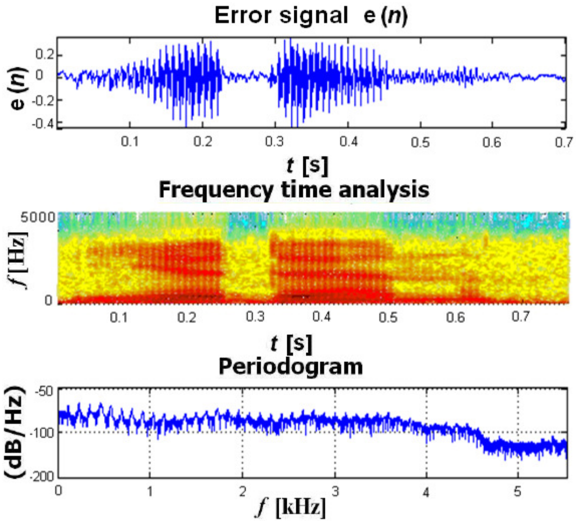

Fig. 7 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of error signal $e(n)$ (LMS adaptive noise canceller – first iteration, M=17, μ=5,9.10^{-3}, simulated in MATLAB) [7].

The draft DTW method was used for optimal settings values of the adaptive filter length M and a step size factor μ of

M=10 %	μ_1=5,9.10^{-3}; ***M*=17** ***d*=9,9.10^{-2}**	μ_1=6,4.10^{-3}; ***M*=43** ***d*=5,421.10^{-1}**	μ_1=5,4.10^{-3}; ***M*=149** ***d*=9,142.10^{-1}**	μ_1=4,09.10^{-3}; ***M*=74** ***d*=1,473**
M =20 %	μ_2=1,08.10^{-2}; ***M*=10** ***d*=9,8.10^{-2}**	μ_2=1,18.10^{-2}; ***M*=99** ***d*=5,409.10^{-1}**	μ_2=1.10^{-2}; ***M*=103** ***d*=1,127**	μ_2=7,5.10^{-3}; ***M*=74** ***d*=1,42**
M =30 %	μ_3=14,996.10^{-3}; ***M*=7** ***d*=9,87.10^{-2}**	μ_3=1,63.10^{-2}; ***M*=99** ***d*=5,405.10^{-1}**	μ_3=1,38.10^{-2}; ***M*=103** ***d*=1,111**	μ_3=1,04.10^{-2}; ***M*=74** ***d*=1,374**

the adaptive filter with LMS algorithm in the application of the suppression of additive noise from the speech signal. Calculated optimal values – the order M of the LMS adaptive noise canceller and distance d between desired speech signal $d(n)$ (Fig.2) and error signal $e(n)$ (Fig.7) from the LMS adaptive noise canceller are calculated in Table VI. The speech error signal $e(n)$ from the output of LMS adaptive noise canceller **was recognized** (***d*<0,2**) from first iteration only for the SSNR$_a$=6,731(dB) (μ_1=5,9.10^{-3}; M=17, M =10%), (μ_2=1,08.10^{-2}, M=10, M =20%), (μ_3=14,996.10^{-3}, M=7, M =30%).

When additive noise values SSNR$_w$ in speech signal are higher, speech signal was not recognized.

C. Implementation LMS adaptive noise canceller on DSK TMS 320C6713

The draft method with DTW criterion for determining of the order M of the adaptive filter with LMS algorithm was used in an application to suppressing noise $n(n)$ from the speech signal $x(n)$ in implementation of two channel structure of LMS adaptive noise canceller on DSP (Digital Signal Processor) Starter Kit (DSK) TMS320C67113 (Fig.10) [11].

Input signal $x(n)$ (Fig.8) is composed from desired signal $d(n)$ (Fig.2) + additive noise $n(n)$. The segmental signal to noise ratio of input signal $x(n)$ (Fig.8) is SSNR=6,676(dB).

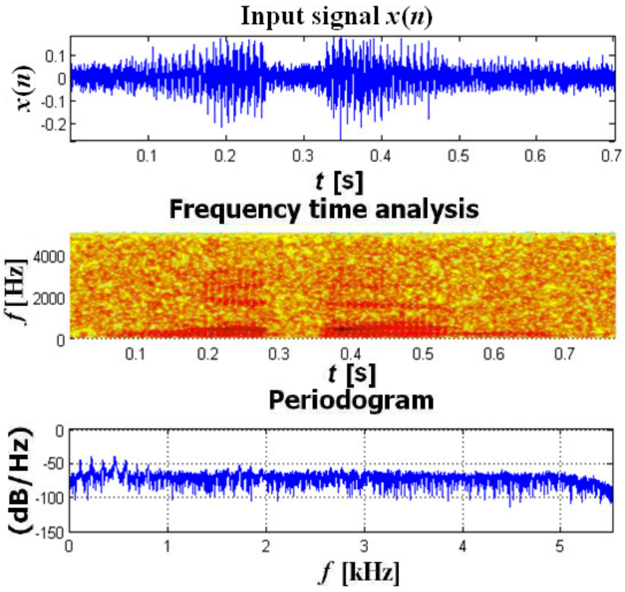

Fig. 8 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of input signal $x(n)$ (desired signal $d(n)$ + additive noise $n(n)$ - SSNR=6,676(dB)) to LMS adaptive filter in an application to suppress noise from the speech signal – first iteration, implemented on DSK TMS320C6713) [7].

Applications of the draft method with DTW criterion was carried out in several steps:

1. step - calculation of a step size parameters μ (M =10%, M =20%, M =30%) (Tab.VII) with guarantees the stability and convergence of the LMS algorithm by using of input signal $x(n)$ (Fig.8) SSNR=6,6756(dB) to LMS adaptive noise canceller (simulated in MATLAB).

2. step - the calculation values of the LMS adaptive filter order M (Tab.VII) for sets a step size parameters μ (M =10%, M =20%, M =30%) by using of input signal $x(n)$ (Fig.8) SSNR=6,6756(dB) to the LMS adaptive noise canceller (simulated in MATLAB).

In the Table VII are calculated values d between output signal $e(n)$ (Fig.9) from adaptive filter with LMS algorithm and desired signal $d(n)$ (Fig.2) for the values parameters set of the LMS adaptive filter order M.

The calculated values of distance d (Tab.VII) in MATLAB shows, that an isolated word "jeden" (Fig.9) from adaptive filter output **was recognized** **<u>*d*=0,184</u>** (***d*<0,2**), when optimal set parameters of adaptive filter with LMS algorithm are M=21, μ_1=0,103 for M =10%.

Table VII.
The calculation values of distance d, length M and a step size parameter μ of the LMS adaptive noise canceller for (M =10%, M =20%, M =30%) SSNR=6,676(dB), (simulated in MATLAB).

M	M =10%	M =20%	M =30%
μ	μ_1=0,103	μ_2=0,188	μ_3=0,26
M	***M*=21**	M=40	M=99
D	**<u>*d*=0,184</u>**	d=0,265	d=0,307

3. step - empirically was found, that the parameter μ for the LMS adaptive noise canceller, implemented on the DSK TMS320C6713 allow set only in the range μ=1.10^{-8} to μ=1.10^{-12} . The length M of the LMS adaptive noise canceller can be set only in the range M=16 to M=52.

Optimal settings values of a parameter μ and the order M was M=21 and μ=1.10^{-8} for the LMS adaptive noise canceller implemented on the DSK TMS320C6713 (Tab.VIII).

The speech error signal $e(n)$ from the output of LMS adaptive noise canceller (implemented on DSK TMS320C6713) **was recognized** (***d*<0,2**) from first iteration for the SSNR$_a$=6,676(dB) (μ=1.10^{-8}; M=21).

Table VIII.
The Calculation values of distance d for settings of length ***M*=21** and parameters μ ($x(n)$) (Fig.8) with SSNR=6,676(dB)) (LMS adaptive noise canceller was implemented on DSK TMS320C6713).

Settings of parameterμ	μ=1.10^{-12}	μ=1.10^{-10}	μ=1.10^{-8}
Calculated value of d	d=4,266.10^{-1}	d=3,475.10^{-1}	**<u>*d*=8,97.10^{-2}</u>**

VIII. Using LMS adaptive noise canceller in voice communication with control BUS system Nikobus

The draft method with DTW criterion was used for optimal settings parameters of LMS adaptive noise canceller, implemented on DSK TMS320C6713, applied in voice communications with control BUS system NIKOBUS (Fig.10). System NIKOBUS was implemented in simulation of visualization operational control of the technical features of the building through visualization software Promotic. For speech recognition in voice communication with control BUS system has been used software My Voice (Fig.10)

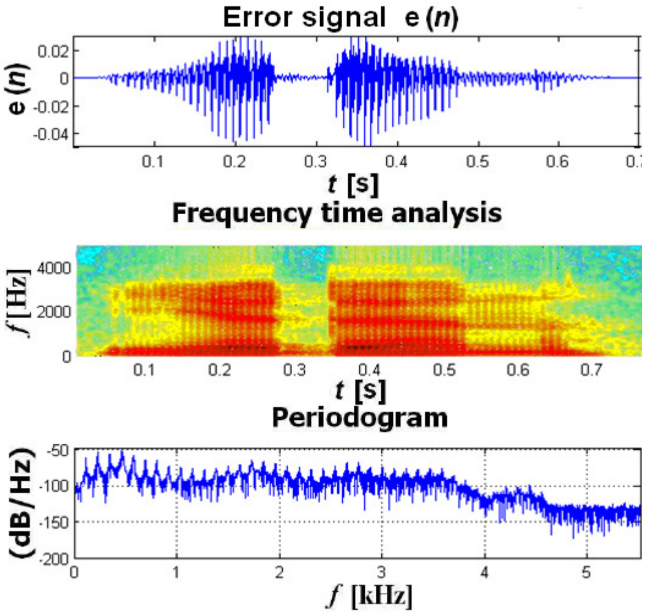

Fig. 9 Waveform, spectrogram (frequency time analysis) and periodogram of power spectral density estimate of error signal *e*(*n*) (LMS adaptive Noise Canceling from the speech signal – first iteration, *M*=21, μ=1.10^{-9}, implemented on the DSK TMS320C6713) [7].

linked with software Promotic. By using of software My Voice is done voice control of operational technical functions in the buildings.

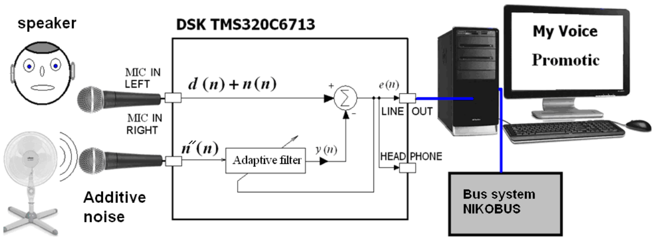

Fig. 10 Implementation of the LMS adaptive noise canceller for voice communications with control system NIKOBUS (Xcomfort) [7].

The aim of the experiment was to determine the success of the detection of selected voice commands. A microphone for capturing speech was located at a distance of about 5 cm from the mouth, according to the manufacturer's instructions. The second microphone was directed to the source of additive noise.

As source of additive noise were used the blower noise and loud radio on (radio station in D major, with classical music). The fan was placed in a distance of 25cm from the microphone. Radio speakers were placed approximately 70 cm from the microphone.

One order was one-word command "boiler" (wash-boiler) is for switching on and off the boiler.

Conditions for the experiment were the following (Fig. 11):

1. 100 x spoken command “boiler” without the LMS adaptive noise canceller:

- Measure 1 without additive noise – 99% successfully speech recognition.
- Measure 2 with additive noise – 81% successfully speech recognition.

2. 100 x spoken command “boiler” with the LMS adaptive noise canceller implemented on DSK TMS320C6713:

- Measure 3 without additive noise – 99% successfully speech recognition.
- Measurement of 4 with additive interference – 99% successfully speech recognition.

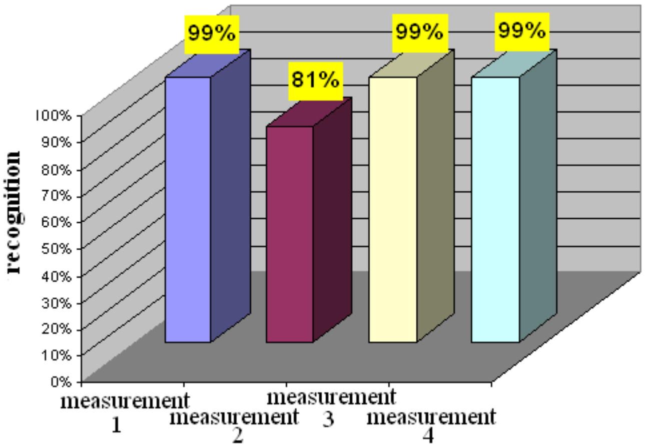

Fig. 11 Evaluation of recognition of isolated czech word - the command "boiler" (wash - boiler) by way of recognition software MyVoice.

Conclusion

In this paper was described the way of verification of the proposed method on the structure of adaptive filter with LMS algorithm in application of suppressing noise from speech signal by way of simulation in MATLAB software.

Through the use of DTW criterion was obtained a tool for determining the quality of speech signal processing using in optimal settings step size parameter μ and order *M* of the LMS adaptive filter or the LMS adaptive noise canceller

The proposed method was verified by way of the practical realization of the structure of the LMS adaptive noise canceller in the application for suppressing additive noise from speech signal by implementation on the DSK TMS320C6713 (Fig.12). This implementation was used for voice communication with control BUS system NIKOBUS for simulation controlling of operating technical functions in buildings.

***Abstract*—This paper describes a new obfuscation method with two techniques by which both computational complexity can be controlled and semantic obfuscation can be achieved. The computational complexity can be strictly controlled by using the technique of encryption. The computational complexity can be arbitrarily specified by the impossibility of factorization of prime numbers by length from one second to about one year. Semantic obfuscation is achieved by transforming a function into a table function. A nonlinear, arbitrary function can be incorporated into the functions, while only linear functions are used in the conventional methods. Because the explicit function form is hidden, it is thought that analysis takes time. The computational complexity technique and semantic technique can be used at the same time, and the effect of integrated obfuscation with both techniques is great.Introduction.**

I. Introduction

OBFUSCATION is used for protecting software copyright and hiding ID and passwords when you disclose the software program. Barak showed the impossibility of obfuscation with theoretical proof [1]. Using a virtual black--box, the proof was carried out for an unnatural function. The idea was restricted to such an unnatural function. It is still meaningful to consider obfuscation of software programs beyond the impossibility discussion. Moreover, obfuscation requirements have been upgraded to keep the calculation process secret in public areas. This is called the white-box scheme.Chow et al presented the white-box obfuscation scheme in [3]. document template contains different styles for appropriate text elements. Most of styles are divided into two classes: paragraph styles and symbol styles.

Pa In this paper, we will present both controlling accurate calculation amounts and creating semantic difficulty in conversion from a plain software program to an obfuscated version. For evaluating the calculation amounts of a obfuscated program, we will introduce a cipher method to obtain an accurate evaluation. As for semantic obfuscation, we will introduce a table for a function used in the program. The table function does not present the method of calculation explicitly

Monden [4] presented obfuscation methods according to loops, branches and control of orders. Hachez [5] and Myles [6] presented a wide variety of obfuscation methods including opaque predicates, computation, quality evaluation and applications to watermarking. We studied the loops and branches and then transformed these into complex functions [3]. But these methods were not suitable for reverse-engineering analyses. In this paper, we provide two different methods. One is to control calculation amounts of a software program. The other is to produce semantic obfuscation. We can use both methods in one software program because the two methods correspond to different parts of programs. The former is used for constant values in the program, while the latter is used for numerical functions such as Fourier transform etc. A basic discussion of the former method for calculation amounts has been carried out in technical reports in Japanese [7][8]. Brief results of the former method were presented in [9]. The basic idea of the latter method of semantic obfuscation was presented in [3] but it was a basic method with the name of the ROM function. ROM means 'read only memory'. This means that the function output values are all pre-calculated for a limited number of input discrete variables. Therefore the data of the function operation can be written in read-only-memory (ROM). As a result, the explicit function description disappears and only numerical values can be seen in the program. If the function is a simple linear one, reconstruction of the function formula is easy. But if the function is of second order or more, reconstruction of the function is done by numerical calculation. We can also add fake data into the ROM at the function values of unused input variables. In this paper, the basic method in [3] is implemented by giving a specific function and making part of a table.

In the following section of this paper, we present the obfuscation method by controlling calculation amounts in section 2. Then semantic obfuscation by using table function is presented in section 3.

II. Controlling calculation amounts

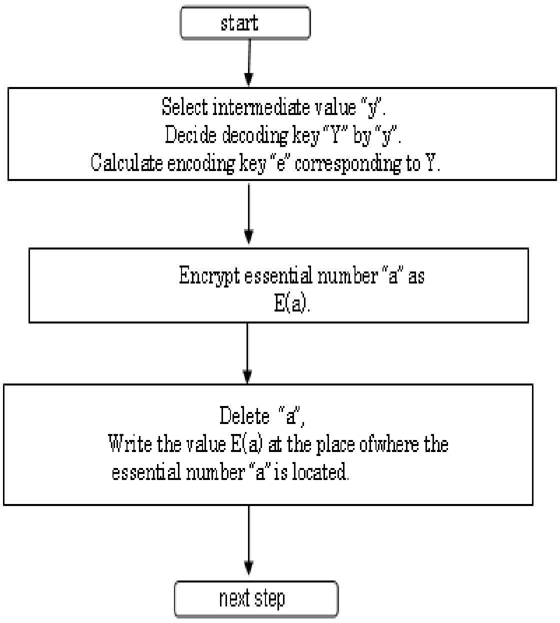
A. *Encrypting Essential Number (EEN)*

It is important to measure the number of calculations needed to analyze and break an obfuscated program. If we can prove the required number of calculations, which is the minimum number, it would be very useful as a component of obfuscation. The method to realize this is that using an intermediate result for a decoding key of RSA encryption, an essential number needed for processing the following calculation is encrypted by an encoding key that corresponds to the decoding key. This method is effective because it cuts the serial calculation flow. No parallel analyses are effective. Consequently, only after obtaining the intermediate value, can the program proceed to the next step by decoding the en-

This work was supported by Universal Robot Corporation.

crypted essential number. The method is called Encrypting Essential Number (EEN).

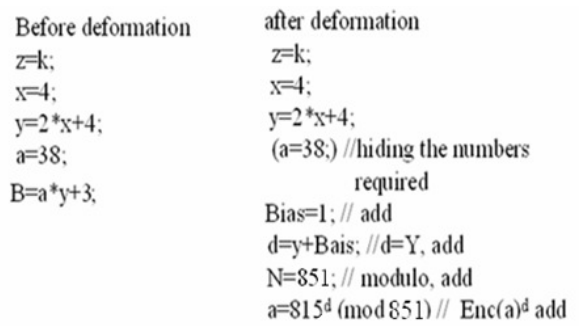
Fig. 1 shows a block diagram of the ENN software program flow. At first, an appropriate intermediate number "y" is selected. Then decoding key "Y" is decided in relation to "y". If the value "y" is a large prime number, Then Y=y is sufficient. If "y" is not a large prime number, we search for a large prime number Y and get the difference between Y and y as Bias, and decide Y=y+Bias. Then, encoding key "e", which corresponds to "Y", is obtained. To obtain the encoding key, we should decide p, q N in the same way as the RSA encrypting method in the background. Then the essential number "a" is encrypted using encoding key "e", and we get E(a). Next, the essential number - usually it is a constant in the program - is removed from the program, and instead encrypted value E(a) is written where the essential number "a" existed.



start
Select intermediate value "y".
Decide decoding key "Y" by "y".
Calculate encoding key "e" corresponding to Y.
Encrypt essential number "a" as
E(a).
Delete "a",
Write the value E(a) at the place ofwhere the
essential number "a" is located.
next step

Fig.1 EEN obfuscation block diagram

Fig. 2 shows a transformation from the original program to the proposed method of encrypting essential number (EEN). The numbers of k, z and x are given. The value "y=12" is an intermediate number, which is calculated from the values in the upper part. The value "a=38" is an essential number. To transform the original program first, a prime number 13 related to the value y=12 is selected. The difference between y and 13 is described as Bias, and "Bias=1" is written in the transformed program. Based on the prime number 13, P=38 q=23 are selected in the same manner as the RSA method. Also, the least common multiplier of p-1 and q-1 is calculated as n=396. From N=p*q=851, encrypting key Y=e=61 is obtained. The essential number a=38 is encrypted as a message. In fact, the 61-th power of "a=38" yields an encrypted value as E(a)=3861 (mod 851) =815. In an operation after transforming, the intermediate value y=12 is first obtained. Then the bias value "Bias=1" is added to the intermediate value, and decoding key "d=13" is obtained. The encrypted value "N=815" is raised to 13th power, yielding "a=38".



```
Before deformation        after deformation
z=k;                       z=k;
x=4;                       x=4;
y=2*x+4;                   y=2*x+4;
a=38;                      (a=38;) //hiding the numbers
                                   required
B=a*y+3;                   Bias=1; // add
                           d=y+Bais; //d=Y, add
                           N=851; // modulo, add
                           a=815^d (mod 851) //  Enc(a)^d add
```

Fig.2 Transform from the original program to EEN form

In this way, the hidden essential number can only be obtained by proceeding to the intermediate value position. The minimum required number of calculations is equivalent to calculating E(a)e raised to the d-th power for hidden essential number E(a)e. This kind of exponential calculation can be reduced to a known level by Montgomery multiplication etc.

B. Evaluation of Calculation Amounts

Evaluation of the obfuscation degree in a quantitative way is very difficult. Hachez said that there were several evaluation methods of software complexity, but they were qualitative methods [5]. In the proposed method in this paper, the number of calculations is specified. RSA is used by the fact that there is no way at this moment to decompose the arbitrary number into a product of prime numbers. So the evaluation of this EEN can be described by the number of multiplications. In this EEN method, encoding key "e" need not be disclosed, on the contrary, RSA does not disclose an encoding key. This means that this method is more difficult than RSA. At this moment the excess part is not considered and put forward for further study.

Table I
Examples of decoding key values

intermediate value	digit number of power r	after being raised to the r-th power	decoding key	Bias	index
3.19584	5	319584	319733	-149	i
	5.1	351542	355753	-4211	ii
	5.5	479376	479371	5	iii
	6	3195840	3195869	-29	iv

The evaluation of EEN is carried out by the following rule;

> "Amounts of calculation required to decode the encrypted value" (i)

Table 1 shows examples for several specific numbers of large decoding key values. In these examples is a real fractional value of the intermediate number. The intermediate number can be such a real and fractional number. The intermediate number value "3.19584 is shifted to several large numbers by digit number “r” by an exponential operation. For the case of r=5 at the top row, 3.19584 is raised to the 5-th power to 319584. The exponent values can be fractional as 5.1 or 5.5 as seen in the second and third rows. Next, a decoding key value is selected from an associated value of 319584. In this example, 319733 is selected as an associated value. But it is easy to understand that this value can be freely selected from the intermediate value because they are related to each other by the Bias value. The Bias value is the difference between 319584 and the decoding key value 319733.

Figs. 3(a),(b) show examples of transforming EEN methods of (i) and (ii) in Table 1. Based on these examples, we confirmed actual encoding keys derived from decoding keys, intermediate values in excecution.

For small values of decoding keys, the obtained results are shown in Table 2. A relation between an encoding key and a decoding key is,

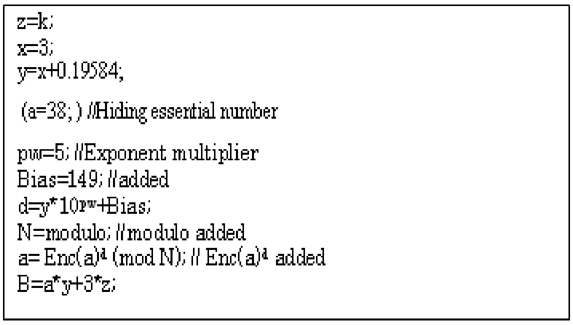
$$e \cdot d = 1 \quad (\mathrm{mod}\ N)\ . \qquad (2)$$

Obtaining an encoding key from a decoding key is done using the same process as obtaining a decoding key from an encoding key in the RSA method. In obtaining the encoding key, two prime numbers p and q are arbitrary selected. There are many choices in selecting p and q. Also after deciding p and q and the least common multiplier N of (p-1,q-1), there are many choices for selecting an encoding key.

The calculation amounts for this part of the program are decided according to the size of decoding key “d=Y” and the size of module value N. To design the system, it is sufficient to adjust these two sizes.

A detailed transform flowchart of EEN obfuscation from the original software program is shown in Fig. 4. That expression above was described for one unit of obfuscation. Within the frequency of occurrence of the intermediate numbers, requisite times of units can be arranged.

Figure 5 shows a block diagram of the digital watermark system with the type of detector that is disclosed to the public. As for the digital watermark of the image, there are various attacks, and it is difficult to insist on authenticity.



```
z=k;
x=3;
y=x+0.19584;

 (a=38; ) //Hiding essential number

Ref [3] proposed by the idea that credibility is sure to be improved in this method to the extent that it opens the detector to the public compared with copyright owners secretly verifying it by themselves. The execution module is obfuscated, though the detector of the digital watermark is a software program. The operation verification is made more difficult by increasing the load in the computational complexity corresponding to an attack that executes the operation analysis coping with slow down in the execution speed. Moreover, semantic obfuscation is being examined as the method replacing the complicated calculation method and the table by ROM function [3]. This uses the input value as is at used positions and uses fake functions at not-used positions. This is different from the DES calculations of Chow [2] with a table realizing as an affine-transformation.

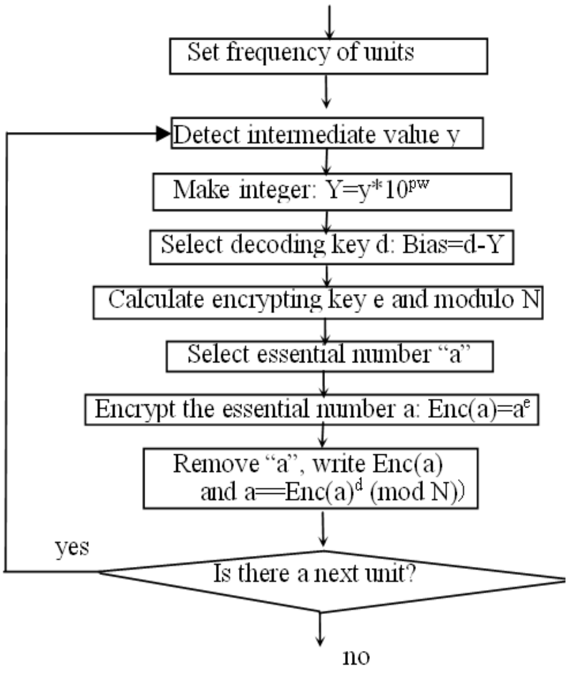
Table Ⅱ
Calculated encoding keys and decoding keys

d	e	p	q	N	lcm
13	61	23	37	851	396
17	233	23	37	851	396
19	667	23	37	851	396
29	437	23	37	851	396
31	511	23	37	851	396
41	425	23	37	851	396
43	571	23	37	851	396
47	455	23	37	851	396

Finally, even if a minute error margin is included, it is a thing that the device such as becoming a correct value can be included because the output of the function of the input value not used is adjusted to the value of the imitation, and it will quantize the result where a discrete calculation is done.

Estimation from the calculation and the example of the execution time of the calculation frequency in obfuscation that provides for the computational complexity, and the design data of the length of the decoding key matched at the required operation time are made. Fig. 6 shows the design time when searching for the encoding key versus the length of the designed decoding key.

Searches for the prime number by the calculation, enable to assume the further estimation for the larger required length of calculation. The value of encoding key e, prime numbers of p and q are selected as each of resembling length comparable to the decoding key length. They are not neces-



Set frequency of units

sarily united because they are made as a design procedure for which it searches from the small number.

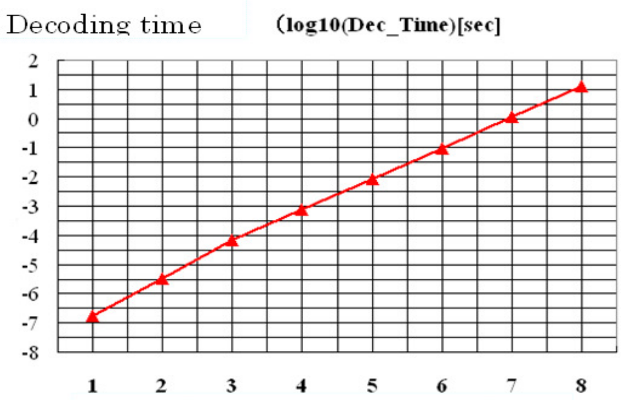

Fig.7 Decoding time vs. length of key number

Fig. 7 shows the decoding times versus the lengths of the decoding keys. The message length had the same length as the decoding key though the message length also influenced the decoding time.

The decoding time for a number composed of eight digits is about one second. The computer specification used was a Pentium 4, 3.2GHz with C language. Modulo operation was used for each multiplication and speed-up processing such as the Montgomery multiplication etc. was not used. The vertical axis was a logarithm at time, and the result for a longer digit number can be worked out by extending the graph if it is almost considered as a straight line.

When Fig. 7 was calculated for 1-3 of the horizontal axis, the digit numbers of decoding key d, encoding key e, and p, q, lcm, N, and the message were calculated as shown in Table 3. For one of four or more of the horizontal axes, almost maximum prime number was used for the digit number of p, q, and decoding key d.

It is on a regular, actual measuring evaluation because the computational complexity depends on the number of digits and the number of multiplies, divisions of modulo.

It is possible to contribute to the improvement of credibility by making the detector of the digital watermark available to the public instead of processing the secret by the closed-door method. It focused only on the increase of computational complexity as the technique for carrying out obfuscation when the detector was disclosed to the public, and the amount was estimated. The program cannot be analyzed in parallel by dividing it, which provides computational complexity of the decoding key.

In this construction, an accurate estimate can be given for computational complexity with exponent power and the modulo calculation. For a computer that uses it to experiment, about one year will cost 13-14 digits since it will cost a day and one month every 12 digits every 10-11 digits from about 10 seconds by eight digits and seconds it about ten times a digit when fast computation is not used.

III. Semantic Method by Table Function

Table 4 shows a comparison of the methods using the table function. Method (i) is a method of [3], and obfuscates the DES operation processing. The DES operation consists of permutation and xor. Because the method of permutation

processing is known beforehand, it is possible to decipher it by examining the concealed relation of the I/O and examining the law of permutation. Method (ii) obfuscation is for general, arbitrary functions [3]. An example of the shape of the function is shown in [3]. Moreover, the relation of I/O is not understood for those not used only from observing input and output values because of the error incorporated. Method (iii) is proposed in this paper, basically the same as case of (ii). The example of the function is concretely given, and the shape of the table function for obfuscation is considered in this paper.

To transform a linear function to a table function is not effective obfuscation because the transform unknown coefficients can be obtained from as many numbers of relations between the input and output as those of the unknown coefficients. To transform quadratic polynomial functions or general non-linear functions to table functions can be effective obfuscation because the calculation amounts become huge even though input and output relations are obtained.

In this paper, the function of the Fourier transform etc. is considered for embedding digital watermarks. Because the Fourier transform is a linear transformation, a modified version of a nonlinear transformation that provides pseudo frequency components is newly developed. Examples of the nonlinear transformations are (1) RGB-HSV color conversion, and (2) a non-linear pseudo frequency transform with exponent multiplication.

First, the original RGB-HSV color conversion:

Max=MAX(R,G,B), Min=MIN(R,G,B)

H=undefined if Max=0

$$H = \begin{cases} C_{60} \times \dfrac{G-B}{\text{Max}-\text{Min}} + C_0, & \text{if } \text{Max}=R \\ C_{60} \times \dfrac{B-R}{\text{Max}-\text{Min}} + C_{120}, & \text{if } \text{Max}=G \\ C_{60} \times \dfrac{R-G}{\text{Max}-\text{Min}} + C_{240}, & \text{if } \text{Max}=B \end{cases}$$

H=H+360 if H<0

$$S = \frac{\text{Max}-\text{Min}}{\text{Max}}$$

$$V = \text{Max}$$

H=H+360 if H<0

$$S = \frac{Max - Min}{Max}$$

$$V = Max$$

C_* are constants.

Next, a pseudo-frequency transform with exponent multiplication for the case of the least number of I/Os, which has two inputs (x,y) and two outputs (p,q) is introduced;

$$p = a \cdot x^e + b \cdot y^f$$

$$q = c \cdot x^g + d \cdot y^h$$

Here, a, b, c, d, e, f, g, and h are hidden constants. Examples of these are a=1.01, b=0.98, c=1.02, d=-0.99, e=1.01, f=1.02, g=0.997, and h=0.996, as are likewise as the Hadamard transform.

This transform converts signals into a kind of pseudo frequency region. As the exponent part is set to a number near one, the behavior of this transform resembles the Fourier transform. While, the analysis of this transform is still difficult because it is non-linear, the amount of the operation of the analysis of this transform increases remarkably compared with a linear case. For the use of a digital watermark, it need not be an accurate Fourier transform, and quantizing can use pseudo frequency components.

IV. Conclusion

This paper presents a new obfuscation method with two techniques by which both the computational complexity can be controlled and the semantic obfuscation can be achieved. Decoding keys and encrypting keys are actually calculated by using intermediate values and essential values in a software program. Among many choices of selecting encrypting keys from the decoding key, the one whose length is the same as the decoding key is selected. Actual computing times are obtained for the small sizes of encrypting key numbers. For the large sizes of them are obtained from the tendency to a extended graph for smaller sizes. The computational complexity can be arbitrarily specified by the impossibility of factorization on prime numbers by lengths from 1 second to about 1 year. Semantic obfuscation is achieved by transforming a function into a table function. A nonlinear, arbitrary function can be incorporated into the functions, while

Table Ⅳ
Comparison of table functions

method	(i) [2]	(ii) [3]	(iii)
type	permutation XOR	General	Linear Non-linear
error data	non	incorporable	incorporable
object	DES operation with Key	General functions	Matrix Fourier Transform Higher order functions

only linear functions are used in conventional methods. Two functions of the form with exponential power terms are shown. These proposed table functions effectively provide quasi-frequency components like the Fourier transform though these are nonlinear functions. These obfuscation processing methods can be applied also to many applications in signal processing such as embedding digital watermarks etc.

International Workshop on Real Time Software

International Workshop on Real Time Software will be held within the framework of the International Multiconference on Computer Science and Information Technology, and will be co-located with the XXVI Fall Meeting of Polish Information Processing Society.

Proliferation of computers interfacing with real world and controlling their environment requires careful investigation of approaches related to the specification, design, implementation, testing, and use of modern computer systems. Timing constraints, dependability, fault-tolerance, interfacing with the environment, reliability and safety constitute integral components of the software development process. Appropriate education of engineers developing such systems, working in interdisciplinary teams and in a global environment is of paramount importance.

In addition to traditional papers, we plan to organize a round table discussion forum on safety critical aspects of the education/training. We are soliciting brief one-page position papers on education and training of engineers developing dependable software intensive systems – presenting the views of academia and industry (in the submission clearly identity the "position paper" for the engineering education round table discussion). The accepted position papers will be a base for 10 minutes presentation followed by a discussion.

The workshop is planned around three main focus areas:

- Real-Time Control
- Safety, Reliability, and Dependability
- Real-Time Education

Traditional Papers topics include but are not limited to:

- Real-time system development
- Scheduling
- Safety
- Reliability
- Dependability
- Fault-tolerance
- Feedback control real-time scheduling
- Hardware-software co-design
- Standards and certification
- Control software
- Robotics and UAV
- Software development tools
- Model-based development
- Automatic code generation
- Real-time systems education
- Related engineering curricula
- Laboratory infrastructure
- Internet-based support

Computationally effective algorithms for 6DoF INS used for miniature UAVs

Jan Floder
VSB – Technical University of Ostrava, Department of Measurement and Control, 17. listopadu 15, 70833
Ostrava, the Czech republic
Email: jan.floder@vsb.cz

***Abstract*—The article aims at 6 degrees of freedom inertial navigation systems for miniature UAVs. It shows a new filter design which replaces standard solutions represented by EKF/UKF filters. The new filter is designed to significantly reduce filter complexity and processing power requirements (but keeping estimation accuracy) to be useful in small embedded systems with minimum processing power.**

I. Introduction

DEVELOPMENT in semiconductor technologies in past several decades brings technologies which used to belong to military/hi-tech domain to everyday use in variety of fields.

This includes also a development of inertial measurement related sensors like MEMS technology sensors (accelerometers, gyrometers), tiny but powerful GPS modules, small magnetometers, barometric sensors and of course fast and small processors. The sensors are used for inertial navigation systems which provide information about vehicle orientation and movement in space. These navigation systems are used for example in autonomous robots, ground, underwater and aerial vehicles.

Although all sensors mentioned above undergo rapid development accuracy is still far beyond their high-end counterparts and traditional technologies. So the sensors themselves used in inertial measurement units (abbreviation IMU) are not able to provide acceptable navigation results over a longer period of time. To solve the issue GPS measurements have to be integrated to the INS measurements to keep navigation results usable (in contrary to INS output errors, GPS measurement errors are not function of time). This solution is known as a GPS aided inertial navigation. The sensor integration and INS information calculation is usually handled by an EKF (Extended Kalman Filter) or an UKF (Unscented Kalman Filter) with adaptive gain. But these filters have drawbacks in certain situations. Major drawback is their relative complexity and requirements of powerful processors.

The article tries to describe and explain ways how replace traditional INS algorithms (represented by EKF, UKF) by algorithms which are more suitable for miniature unmanned aerial vehicles (UAVs) which have limited processing power. The article continues in development of the vector filter algorithm presented in [1].

A. INS

The INS does estimate orientation, acceleration, velocity and position of a vehicle moving anywhere on earth (or close to its surface). This is done by measurement and integration of several motion parameters. There are several types of inertial navigation but the article is aimed at a GPS aided tightly coupled inertial navigation for systems with 6 degrees of freedom of motion. Six degrees of freedom of motion means that vehicles, where the navigation is applied on, can “virtually freely” move and rotate in any direction. The only omitted parameter are huge long term centripetal accelerations because UAVs the article is aimed at do not undergo them.

The motion equations for a UAV are (presented in form prepared for inertial sensors)

$$\begin{aligned}
&\dot{\boldsymbol{q}}_{RPY\to ENU}=\boldsymbol{q}_{RPY\to ENU}*\frac{1}{2}\boldsymbol{\omega}_{RPY}\\
&\dot{\boldsymbol{v}}_{ENU}=-\boldsymbol{g}_{ENU}+\boldsymbol{C}_{RPY\to ENU}(\boldsymbol{q}_{RPY\to ENU})\cdot\boldsymbol{a}_{RPY}\\
&\dot{\boldsymbol{p}}_{ECEF}=\boldsymbol{C}_{ENU\to ECEF}(\boldsymbol{p}_{ECEF})\cdot\boldsymbol{v}_{ENU}\\
&\boldsymbol{p}_{LLA}=\begin{bmatrix}\varphi_{WGS84}\\ \lambda_{WGS84}\\ h_{WGS84}\end{bmatrix}=\boldsymbol{f}_{ECEF\to WGS84}(\boldsymbol{p}_{ECEF})
\end{aligned}\tag{1}$$

Vehicle motion parameters velocity vector $\boldsymbol{v}_{ENU}$ and position vector $\boldsymbol{p}_{ECEF}$ (and $\boldsymbol{p}_{LLA}$) are derived from vehicle acceleration vector $\boldsymbol{a}_{RPY}$ which is measured by a MEMS accelerometer (measurement contains gravity acceleration part which has to be subtracted - $\boldsymbol{g}_{ENU}$). Vehicle orientation quaternion $\boldsymbol{q}_{RPY\to ENU}$ is derived from angular rate vector $\boldsymbol{\omega}_{RPY}$ measured by a MEMS gyrometer.

The quaternion $\boldsymbol{q}_{RPY\to ENU}$ stores rotation between vehicle local frame RPY and earth local frame ENU [2]. The position is calculated in earth global frame ECEF and alternatively in LLA (longitude, latitude, altitude) coordinates (usually the WGS84 Earth model). For coordinate systems and transformations ($\boldsymbol{C}_{RPY\to ENU}$, $\boldsymbol{C}_{ENU\to ECEF}$) consult next section.

As shown above accelerometer and gyrometer are enough to calculate all parameters of the inertial navigation. But this is valid for ideal sensors only. In the real world there are many sources of errors which cripple navigation results. In the equation you can see that acceleration and angular rate are integrated to provide vehicle orientation, velocity and

978-83-60810-27-9/09/$25.00 © 2010 IEEE

position. So measurement errors (like offset) are integrated too and do rise in time. That is why magnetic field and GPS measurements have to come to stage.

B. Coordinate Systems and Transformations

The equation 1 represents INS parameters in several coordinate systems. They can be divided in 3 groups.

1. Vehicle local Cartesian coordinate system RPY (Rol-l-Pitch-Yaw) is fixed to vehicle with center in its center of gravity.

2. Earth local Cartesian coordinate system ENU/NED (East-North-Up / North-East-Down). This is a local coordinate system related to earth.

3. Earth global coordinate system ECEF, LLA (Earth-Centered-Earth-Fixed and Longitude-Latitude-Altitude). The ECEF is a Cartesian coordinate system and the LLA is a spherical (or elliptical) coordinate system.

For complete definitions consult for example [2] and [7].

Coordinate transformations transform a vector represented in one coordinate system to another and vice versa (for example $RPY \rightarrow ENU$), so they can describe vehicle orientation in space (when considering rotations only).

There are several ways to calculate/represent coordinate transformations. The best suited (for INS systems) are [2]:

- Rotation matrix $\boldsymbol{C}_{\boldsymbol{from \rightarrow to}} = \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix}$

- Quaternion $\boldsymbol{q}_{\boldsymbol{from \rightarrow to}} = \begin{bmatrix} q_1 & q_2 & q_3 & q_4 \end{bmatrix}^T$

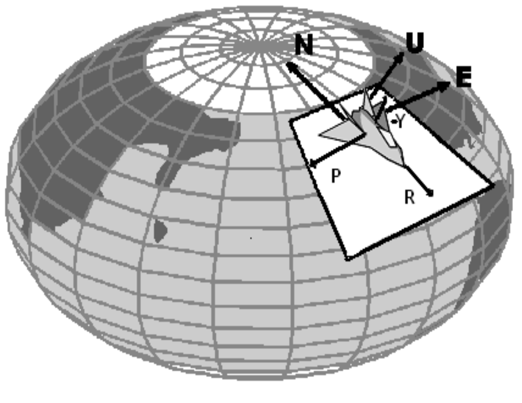

Fig 1. Illustration of coordinate systems relations (RPY, ENU, LLA).

The figure 1 illustrates RPY, ENU and LLA coordinate systems.

II. Sensors

Modern MEMS sensors are small in size (usually below 1cm2) require minimum external components (supply filter capacitor and some output low-pass single pole filters), single voltage supply and consume minimum power (below 1mA). But they also have drawbacks. As said before they are not accurate enough for classical INS.

The main sources of INS error related to MEMS sensors are additive white noise $\boldsymbol{\eta}$, temperature, random and high frequency vibration bias drift and offset $\boldsymbol{b}$, scaling error $\boldsymbol{s}$ and cross axis sensitivity $\boldsymbol{c}$.

A. MEMS Accelerometers

Bearing in mind the equation 1, accelerometer output is transformed from vehicle coordinates (RPY) to local earth coordinates (ENU) and integrated to obtain vehicle velocity (and position). Ignoring possible attitude estimation error $\delta \boldsymbol{q}_{\boldsymbol{RPY \rightarrow ENU}}$ (see section *INS Algorithms*) there are three types of accelerometer errors which corrupt velocity estimation in time. It is a drift & offset, mis-scaling and cross-axis sensitivity. According to practical measurements (3 axis ADXL335) these errors may lead up to 0.3 $\mathrm{m \cdot s^{-2}}$ (each axis) ignoring high frequency vibrations drift - in helicopter-like UAVs, where powerful engines are needed to create enough lift, there is a danger of strong vibration bias drift due to motor vibrations (close to resonant frequency of sensor's mechanical parts). The only way to avoid it is a mechanical damping.

B. MEMS Gyrometers

Gyrometer outputs are integrated to obtain attitude information from angular rate. The most important error, which is usually estimated and compensated by the INS filter, is a bias drift $\boldsymbol{b}_{\boldsymbol{g}}$. For modern gyrometers overall drift does not usually exceed 0.5 deg/s (MLX90609) but initial bias may differ on every run so it is worthy to estimate it. There may also be a danger of a high frequency vibration drift but as long as resonant frequencies of gyrometer mechanical parts are higher compared to accelerometers the danger is smaller.

C. Magnetometers

Modern magneto-resistive or magneto-inductive magnetometers are size and power consumption friendly too. But in their case another type of errors is most important. It is a hard iron distortion and a soft iron distortion. The distortions are caused by close sources of magnetic field (like DC motor magnets) or magnetic materials (chassis, shielding, etc.). Without compensation these errors lead in overall error that may exceed even 20 degrees. But ways how to compensate these errors are not subject of the article.

D. Miniature GPS Modules

GPS modules just receive and process navigation data from geostationary satellites (and in some cases additional navigation data from ground stations too). They are also small (especially models with integrated antennas) and may weight even less than 20 grams. They output actual position and velocity information with accuracy of several meters (RMS) for position and tenths of meters per second for 2D/3D velocity (later GPS chipsets, like µBlox-5, provide 3D velocity estimations).

III. INS Algorithms

At first a standard tightly coupled INS based on the multiplicative EKF (MEKF) design is presented. It was chosen

due to its elegance (relatively "linear" model) and "simplicity" (sparse matrices reduce number of arithmetic operations needed for calculations) which enables it to be used in non-powerful processors unlike some other solutions (like for example GP-UKF). The MEKF also represents a standard navigation solution which is used as a reference to the navigation algorithm proposed in this article. The figure 2. shows a tightly coupled INS diagram.

A. Error Model

The MEKF INS filter, which can be found for example at [4] is based on an error model where the motion model itself is calculated alone and only model errors are subject of estimation (by the MEKF). So using accelerometer and gyrometer measurement and equation 1 the INS estimates vehicle orientation in space $\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU}$, velocity in local earth coordinates $\tilde{\boldsymbol{v}}_{ENU}$ and vehicle position on earth $\tilde{\boldsymbol{p}}_{ECEF}$ (and in more common longitude, latitude and altitude coordinate system $\tilde{\boldsymbol{p}}_{LLA}$). Because there are errors which corrupt INS outputs, estimation errors are calculated according to [4]

$$\begin{aligned}
&\delta\dot{\boldsymbol{q}}_{RPY\rightarrow ENU}=\frac{1}{2}\delta\boldsymbol{b}_{RPY}\times\delta\boldsymbol{q}_{RPY\rightarrow ENU}-\frac{1}{2}\delta\boldsymbol{b}_{RPY}-\frac{1}{2}\boldsymbol{\eta}_g\\
&\delta\dot{\boldsymbol{b}}_{RPY}=\boldsymbol{\eta}_b\\
&\delta\dot{\boldsymbol{v}}_{ENU}=-2\boldsymbol{C}(\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU})\boldsymbol{a}_{RPY}\times\delta\boldsymbol{q}_{RPY\rightarrow ENU}-\boldsymbol{C}(\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU})\boldsymbol{\eta}_a\\
&\delta\dot{\boldsymbol{p}}_{ECEF}=\boldsymbol{C}_{ENU\rightarrow ECEF}(\boldsymbol{p}_{ECEF})\delta\boldsymbol{v}_{ENU}
\end{aligned}\tag{2}$$

The filter is constructed of 4 state vectors (12 state variables) which serve to estimate: attitude error vector $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ which contains only vector part of the quaternion because for small errors the scalar part is ≈ 1 – see [4], gyrometer bias drift $\delta\boldsymbol{b}_{RPY}$, velocity estimation error $\delta\boldsymbol{v}_{ENU}$ and position estimation error $\delta\boldsymbol{p}_{ECEF}$. $\boldsymbol{\eta}_g$ for a gyrometer, $\boldsymbol{\eta}_b$ for a gyrometer bias drift, $\boldsymbol{\eta}_a$ for an accelerometer represent sensor white noise acting on the error model. The filter is updated (every step) by a magnetometer measurement $\boldsymbol{m}_{RPY}$ [4] which is compared to expected magnetic filed vector $\boldsymbol{m}_{ENU}$ for given location,

$$|\boldsymbol{m}_{RPY}|=\boldsymbol{A}(\delta\boldsymbol{q}_{RPY\rightarrow ENU})\cdot\left(\boldsymbol{C}(\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU})^T\cdot|\boldsymbol{m}_{ENU}|\right)\tag{3}$$

$$\boldsymbol{A}(\delta\boldsymbol{q})=\begin{bmatrix}1 & 2\delta\boldsymbol{q}[3] & -2\delta\boldsymbol{q}[2]\\ -2\delta\boldsymbol{q}[3] & 1 & 2\delta\boldsymbol{q}[1]\\ 2\delta\boldsymbol{q}[2] & -2\delta\boldsymbol{q}[1] & 1\end{bmatrix}\tag{4}$$

When a GPS measurement is available the filter is also updated by a measured velocity vector in ENU frame $\boldsymbol{v}_{ENU}$ and a position vector $\boldsymbol{p}_{ECEF}$ in ECEF frame.

$$\begin{bmatrix}\boldsymbol{v}_{ENU}\\ \boldsymbol{p}_{ECEF}\end{bmatrix}=\begin{bmatrix}\tilde{\boldsymbol{v}}_{ENU}+\delta\boldsymbol{v}_{ENU}\\ \tilde{\boldsymbol{p}}_{ECEF}+\delta\boldsymbol{p}_{ECEF}\end{bmatrix}\tag{5}$$

These estimated INS solution errors have to be used to correct INS data (the INS data are calculated using equation 1). The correction is

$$\begin{aligned}
&\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU}=\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU}*\delta\boldsymbol{q}_{RPY\rightarrow ENU}\rightarrow\delta\boldsymbol{q}_{RPY\rightarrow ENU}=0\\
&\tilde{\boldsymbol{v}}_{ENU}=\tilde{\boldsymbol{v}}_{ENU}+\delta\boldsymbol{v}_{ENU}\rightarrow\delta\boldsymbol{v}_{ENU}=0\\
&\tilde{\boldsymbol{p}}_{ECEF}=\tilde{\boldsymbol{p}}_{ECEF}+\delta\boldsymbol{p}_{ECEF}\rightarrow\delta\boldsymbol{p}_{ECEF}=0
\end{aligned}\tag{6}$$

The errors can be transformed from the filter to INS parameters estimations and the errors themselves are set to zero [4], [5] after (every) filter step. The $\tilde{\boldsymbol{q}}*\delta\boldsymbol{q}$ may be rewritten as (derived from [4])

$$\tilde{\boldsymbol{q}}*\delta\boldsymbol{q}=\begin{bmatrix}-\tilde{\boldsymbol{q}}[2] & -\tilde{\boldsymbol{q}}[3] & -\tilde{\boldsymbol{q}}[4]\\ \tilde{\boldsymbol{q}}[1] & -\tilde{\boldsymbol{q}}[4] & \tilde{\boldsymbol{q}}[3]\\ \tilde{\boldsymbol{q}}[4] & \tilde{\boldsymbol{q}}[1] & -\tilde{\boldsymbol{q}}[2]\\ -\tilde{\boldsymbol{q}}[3] & \tilde{\boldsymbol{q}}[2] & \tilde{\boldsymbol{q}}[1]\end{bmatrix}\delta\boldsymbol{q}+\tilde{\boldsymbol{q}}\tag{7}$$

According to the general rule in quaternion calculations the quaternion $\tilde{\boldsymbol{q}}$ should be normalized always after several calculations to avoid accumulation of floating-point round-off errors (valid especially for 32-bit floating-point).

B. (M)EKF/UKF

The error model merits of relatively simple and quite "linear" equations, and sparse matrices when using EKF. But besides this there is one more advantage. Because motion model and error estimation are separated they can be calculated with different sampling periods (bearing in mind S-N-K theorem) – motion model can be calculated for example 100 times per second and the error estimation just 20 times per second. This does reduce arithmetic operations requirements even more. The MEKF is an EKF variant where the attitude estimation error quaternion is multiplied (not added) to the model [5] when every other filter aspect remains the same.

The EKF and UKF (adaptive versions) equations are well known and can be found among literature. The UKF has one disadvantage and this is that it cannot take advantage of spare matrices. Some example INS solution can be found for example at [6] or [9].

C. Vector Filter

First of all complete explanation of the vector filter is too long to fit in the article so it is described only briefly. Some basic principles are described in [1]. The EKF/UKF filter is a working solution proven by time and experience (used over 40 years) but for purposes of miniature UAVs there are some drawbacks. Embedded systems for these UAVs tend to be very cheap, small and light and all processing (basic signal processing, navigation and control) is usually done by a single System on Chip processor which should also have minimum power consumption. This means that processing power for the navigation is significantly reduced. Besides this hurdle EKF/UKF configureability is somewhat limited (it is easy to alter $\boldsymbol{Q}$ and $\boldsymbol{R}$ matrices but impossible to adjust convergence mechanisms freely).

This is the main reason why the vector filter was developed. First stage was development of an IMU filter to provide orientation estimation for a loosely coupled INS filter (described in [1]). This article describes enhancement to a tightly coupled and mixed solution INS. The filter has these main features:

a) It is based on vectors rather than single variables. It means that $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$, $\delta\boldsymbol{b}_{RPY}$, $\delta\boldsymbol{v}_{ENU}$, $\delta\boldsymbol{p}_{ECEF}$ are taken directly as 4 variables (not 12 as in the EKF).

b) Equation searching for solution of $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$, $\delta\boldsymbol{b}_{RPY}$, $\delta\boldsymbol{v}_{ENU}$, $\delta\boldsymbol{p}_{ECEF}$ to approach measured values is solved directly. It does not matter if it is solved analytically, iteratively, using gradient or any other way. The goal is to find a proximate solution to reach measured values and distance between estimation and measurement.

c) The criteria to reach measured values can be/are defined for any vector independently and can by customized any way and also changed during run.

d) Almost all criteria of the filter are accessible and can be changed on run.

1) Equation solution

The filter is based on the same principles as presented in previous work in [1]. Firstly the bias drift $\delta\boldsymbol{b}_{RPY}$ is excluded from equation 2 because it can be estimated from $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ directly:

$$\delta\boldsymbol{b}_{RPY}(k+1)=\delta\boldsymbol{b}_{RPY}(k)-\alpha_b(k)\delta\boldsymbol{q}_{RPY\rightarrow ENU}(k) \tag{8}$$

(α_b = correction size, see section *Correction Size Calculations*) and angular rate is corrected outside the error equation

$$\boldsymbol{\omega}_{RPY,compensated}=\boldsymbol{\omega}_{RPY}-\delta\boldsymbol{b}_{RPY} \tag{9}$$

So the modified equation 2 now consists of $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$, $\delta\boldsymbol{v}_{ENU}$ and $\delta\boldsymbol{p}_{ECEF}$ only. There are more ways how to find proximate solution of this modified equation. The solution presented here solves $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ and $\delta\boldsymbol{v}_{ENU}$, $\delta\boldsymbol{p}_{ECEF}$ separately (because it involves minimum of arithmetic operations).

a) $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ by quaternion math

Unlike in the [1], now the main vector is the measured magnetic field vector $\boldsymbol{m}_{RPY}$ and measured velocity $\boldsymbol{v}_{ENU}$ is the second vector. $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ is calculated (using superposition in each axis (Roll, Pitch and Yaw)) as

```
for $k=1$ to 3
  $c_{rot,\pm}=\left(\boldsymbol{C}_{rot}(\boldsymbol{\omega}_{search}(k))|\tilde{\boldsymbol{m}}_{RPY}|\right)\cdot|\boldsymbol{m}_{RPY}|$
  if $c_{rot,+}\geq c_{rot,-}$ then $s=1$
   else $s=-1$
  $\boldsymbol{\omega}_{corr}[k]=s\left[acos(|\tilde{\boldsymbol{m}}_{RPY}|\cdot|\boldsymbol{m}_{RPY}|)-acos\left(max(c_{rot,+},c_{rot,-})\right)\right]$
end
$\delta\boldsymbol{q}_{RPY\rightarrow ENU}=-\frac{1}{2}\alpha_{\delta q,m}|\boldsymbol{\omega}_{corr}|$
```

$$\boldsymbol{C}_{rot}\left(\begin{bmatrix}\alpha\\ \beta\\ \gamma\end{bmatrix}\right)=\begin{bmatrix}\cos(\beta)\cos(\gamma) & -\cos(\beta)\sin(\gamma) & \sin(\beta)\\ \sin(\alpha)\sin(\beta)\cos(\gamma)+\cos(\alpha)\sin(\gamma) & \cos(\alpha)\cos(\gamma)-\sin(\alpha)\sin(\beta)\sin(\gamma) & -\sin(\alpha)\cos(\beta)\\ \sin(\alpha)\sin(\gamma)-\cos(\alpha)\sin(\beta)\cos(\gamma) & \cos(\alpha)\sin(\beta)\sin(\gamma)+\sin(\alpha)\cos(\gamma) & \cos(\alpha)\cos(\beta)\end{bmatrix} \tag{10}$$

Where $\boldsymbol{C}_{rot}$ is a rotation matrix [10]

$\boldsymbol{\omega}_{search}$ is a search rotation vector – for separate rotations in R, P and Y axis respectively (for k =1, 2, 3)

$\boldsymbol{\omega}_{corr}$ is a correction vector

$\alpha_{\delta q,m}$ is a magnetic vector correction size (see section *Correction Size Calculations*)

In case a new GPS measurement is available, $\delta\boldsymbol{q}_{RPY\rightarrow ENU}$ is updated using second pair of vectors (the velocity vector $\boldsymbol{v}_{ENU}$ and the model velocity estimation $\tilde{\boldsymbol{v}}_{ENU}$). These two vectors are not compared directly because there is a singularity when the vehicle is not moving (→ zero velocity vector). So the vectors are taken with added gravity and subtracted previous estimation

$$\begin{aligned}\tilde{\boldsymbol{v}}_{ENU,mod}&=\tilde{\boldsymbol{v}}_{ENU}(t)+\Delta t_{GPS}\cdot\boldsymbol{g}_{ENU}-\tilde{\boldsymbol{v}}_{ENU}(t_{previousGPS})\\ \boldsymbol{v}_{ENU,mod}&=\boldsymbol{v}_{ENU}(t)+\Delta t_{GPS}\cdot\boldsymbol{g}_{ENU}-\tilde{\boldsymbol{v}}_{ENU}(t_{previousGPS})\end{aligned} \tag{11}$$

The estimated (modified) velocity $\tilde{\boldsymbol{v}}_{ENU,mod}$ vector is rotated around measured magnetic field vector $\boldsymbol{m}_{\boldsymbol{RPY}}$ by angle $\alpha_{\delta q,v}$ towards the measured (modified) velocity vector $\boldsymbol{v}_{ENU,mod}$. The sequence of calculations is:

$$\begin{aligned}
&\delta \boldsymbol{q}_{ENU\rightarrow RPY}=\boldsymbol{C}\left(\tilde{\boldsymbol{q}}_{RPY\rightarrow ENU}\right)\delta \boldsymbol{q}_{RPY\rightarrow ENU}\\
&\boldsymbol{q}_{corr,+}=\left[\cos\left(\frac{\alpha_{\delta q,v}}{2}\right)\quad \sin\left(\frac{\alpha_{\delta q,v}}{2}\right)\left(\boldsymbol{C}\left(\boldsymbol{q}_{RPY\rightarrow ENU} * \delta \boldsymbol{q}_{RPY\rightarrow ENU}\right)\left|\boldsymbol{m}_{RPY}\right|\right)^T\right]^T\\
&\boldsymbol{q}_{corr,-}=\left[\cos\left(\frac{\alpha_{\delta q,v}}{2}\right)\quad -\sin\left(\frac{\alpha_{\delta q,v}}{2}\right)\left(\boldsymbol{C}\left(\boldsymbol{q}_{RPY\rightarrow ENU} * \delta \boldsymbol{q}_{RPY\rightarrow ENU}\right)\left|\boldsymbol{m}_{RPY}\right|\right)^T\right]^T\\
&\boldsymbol{v}_{rot,+}=\boldsymbol{C}\left(\boldsymbol{q}_{corr,+} * \delta \boldsymbol{q}_{ENU\rightarrow RPY}\right)\left|\tilde{\boldsymbol{v}}_{ENU,mod}\right|\\
&\boldsymbol{v}_{rot,-}=\boldsymbol{C}\left(\boldsymbol{q}_{corr,-} * \delta \boldsymbol{q}_{ENU\rightarrow RPY}\right)\left|\tilde{\boldsymbol{v}}_{ENU,mod}\right|\\
&\text{if } \left|\boldsymbol{v}_{ENU,mod}\right|\cdot\boldsymbol{v}_{rot,+}\geq\left|\boldsymbol{v}_{ENU,mod}\right|\cdot\boldsymbol{v}_{rot,-}\\
&\quad\text{then } \delta \boldsymbol{q}_{ENU}=\boldsymbol{q}_{corr,+} * \delta \boldsymbol{q}_{ENU\rightarrow RPY}\\
&\quad\text{else } \delta \boldsymbol{q}_{ENU}=\boldsymbol{q}_{corr,-} * \delta \boldsymbol{q}_{ENU\rightarrow RPY}\\
&\delta \boldsymbol{q}_{RPY\rightarrow ENU}=\left[\delta \boldsymbol{q}_{ENU}[1]\quad \boldsymbol{C}\left(\boldsymbol{q}_{RPY\rightarrow ENU}\right)^T \delta \boldsymbol{q}_{ENU}[2:4]\right]^T[2:4]
\end{aligned}\tag{12}$$

As mentioned before $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$ is a vector part of quaternion and is used for small correction angels (→ scalar part of quaternion ≈ 1). If the angles are huge (usually than ten degrees per step) transform $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$ to quaternion and calculate with pure quaternions.

This method is used because it is very fast (less than 500 arithmetic operations per step) and is easy to implement.

b) $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$ by gradient

Usage of a minimum-squared-error (MSE) criterion and gradient (or Hessian) calculations is another way to find $\boldsymbol{q}$ or $\delta\boldsymbol{q}$ for two sets of vectors. The approach how estimate quaternion from two sets of vectors using Gauss-Newton or Newton method was presented by Marins *et al* in [3] (article available on web). But this method is not as efficient as the previous because it involves several matrix calculations (including inversion).

c) $\delta \boldsymbol{v}_{ENU}$ and $\delta \boldsymbol{p}_{ECEF}$ calculations

Velocity and position correction direction and size calculation is much easier. It involves subtraction and distance calculation of two vectors only (no transformations are necessary).

$$\begin{aligned}
\delta \boldsymbol{v}_{ENU}&=\alpha_v\left(\boldsymbol{v}_{ENU}-\tilde{\boldsymbol{v}}_{ENU}\right)\\
\delta \boldsymbol{p}_{ECEF}&=\alpha_p\left|\boldsymbol{p}_{ECEF}-\tilde{\boldsymbol{p}}_{ECEF}\right|
\end{aligned}\tag{13}$$

The formula shows that $\delta \boldsymbol{v}_{ENU}$ is calculated regarding distance between measurement and estimation while $\delta \boldsymbol{p}_{ECEF}$ not. This is because different correction calculations were used for each case.

2) Solution "distance" calculations

"Distance" calculations (estimation to measurement) serve to find a distance between estimated and measured values. They are much simpler than direction (or gradient) calculations and involve vector angle and vector distance calculations. General equations are as follows

$$\begin{aligned}
d_{vec1}&=acos\left(\frac{\boldsymbol{v}_1\cdot\boldsymbol{v}_2}{\|\boldsymbol{v}_1\|\|\boldsymbol{v}_2\|}\right)\\
d_{vec2}&=\|\boldsymbol{v}_1-\boldsymbol{v}_2\|
\end{aligned}\tag{14}$$

d_{vec1} represents vector angle calculations for the magnetic vector and modified velocity vector. d_{vec2} is used for velocity and position error distance calculations.

3) Correction Size Calculations

The first section of the filter gives only information which direction correct to (to the measurements) and about distance between estimation and measurement. So the aim of the second section is to find a correction size to keep estimation on INS sensors (accelerometer and gyrometer) in short term but also lock them to GPS and magnetometer measurements in long term. The function can be defined any way according to user specification. This part is under development but even in an early stage it provides good results (see *Results* section). In this case it was defined as

1. Bias drift $\delta \boldsymbol{b}_{RPY}$ accumulation. The $\alpha_b=0.1$ except initialization time ($\alpha_b=0$). This setting says that the bias accumulation is directly dependent on the attitude correction. But this simple accumulation algorithm works as proven in the [1].

2. $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$. In this case situation is a bit complicated. $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$ consists of two parts and it is the magnetic vector $\boldsymbol{m}$ and velocity vector $\boldsymbol{v}$. The are treated separately to calculate $\alpha_{\delta q,m}$ and $\alpha_{\delta q,v}$ to form final $\delta\boldsymbol{q}$. These gain coefficients are calculated according to the following general formulas

$$\alpha_{vec}(k+1)=\alpha_{vec}(k)-T_S\, d_{vec}(k)\,\beta_{fall}\tag{15}$$

or

$$\alpha_{vec}(k+1)=\alpha_{vec}(k)+T_S\, d_{vec}(k)\,\beta_{rise}\tag{16}$$

The equations show that actual gain depends on previous gain α_{vec} and actual measurement to estimation error d_{vec}. Decision whether to accumulate (equation 12) or de-accumulate (equation 13) gain depends on sensor noise, actual gain size, error between measurement and estimation and time. β_{rise} and β_{fall} are constants which determine speed of accumulation and de-accumulation (set respecting sensor drifts/offsets). The gain α_{vec} is limited by an upper border to prevent filter from divergence/oscillations (which may occur in EKF/UKF designs when coefficient are set improperly).

3. $\delta \boldsymbol{v}_{ENU}$. For most situations $\alpha_{v_{ENU}}=0.5$ is sufficient enough. This converges to measurement for all cases.

4. $\delta\boldsymbol{p}$. The calculations are based on the same principles (equations 15-16) as $\delta \boldsymbol{q}_{RPY\rightarrow ENU}$ size calculations.

As can be seen from equations above it is very easy and simple to calculate correction sizes but the algorithm still is very efficient (as proven by simulations shown in chapter IV).

4) Higher Level of Control

Because the vector filter calculates correction direction and correction size there can be some superior control which can bypass lower levels of the filter and set corrections , this is sufficient for example during initialization when the filter settles its estimation within one or several consecutive steps (figure 5., *Higher Level of Control* sub-section). Or when the GPS looses fix for several seconds - in this case all the correction may by zeroed for that time or the INS can be switched to a loosely coupled version to keep at least attitude estimation valid.

D. Mixed Solution

Another possible filter design is to leave some parameters for the smaller EKF and the rest calculate by the vector filter. In this case $\delta \boldsymbol{q}_{RPY \rightarrow ENU}$ and $\delta \boldsymbol{v}_{ENU}$ are estimated by the 6 state MEKF and $\delta \boldsymbol{b}_{RPY}$ and $\delta \boldsymbol{p}_{ECEF}$ are estimated by the vector filter (using rules from above). This reduces filter complexity dramatically but still the MEKF is used for crucial parts of the INS.

IV. Results

In this chapter results and filter comparisons are presented. The comparisons are based on simulated data which are set to represent sensor errors during UAV flights as close as possible or with worse parameters for stress tests. Simulated data were chosen because in this case true values are known and many variations can be tested. The sensor errors were set to exceed measured errors of real sensors during flight conditions to test filter limits.

Three INS solutions are compared. The first one is a "full" MEKF – it means 12 state EKF, the second one is a combined solution with 6 state EKF estimating attitude and velocity error with the rest being estimated by a vector filter and as the last one is the full vector filter (without higher level of control).

A. Simulated Data

The flight itself was simulated by these parameters: UAV accelerations were simulated by a quarters of sinusoids (simulating acceleration of an vehicle with some momentum) with random amplitudes which did not exceed ±4 m·s^{-2} and random periods which did not exceed 10 seconds. Resulting speed and position were calculated by integrations. Vehicle rotation was simulated similar way with maximum angular rates of ±250 deg·s^{-1} and random periods with less then 10 seconds. In fact these conditions cannot be reached during a flight because the UAV has limits in freedoms of motion (cannot rotate upside down etc.) and length ans size of acceleration but the values are suitable to test filter limits.

B. Sensor Errors

Every sensor included additive white noise, bias drift, offset, mis-scaling and quantization error (simulating ADCs). Besides these errors, magnetometer included uncompensated hard and soft iron distortion and GPS included measurement delay. Here is a short list of (proximate) parameters.

Table I.
Sensor parameters (errors)

White noise for each axis (std. deviation)	**offset/bias/other for each axis**	**Mis-scaling for each axis**	**quantization**
accelerometer [m·s^{-2}]			
< 0.3	< 0.25 , constant	< 1% , constant	0.01
Gyrometer [deg·s^{-1}]			
2.7	< 1.5 , changing	< 2% , constant	0.15
Magnetometer (46μT vector size) [μT]			
0.2	< 0.5 , constant	< 10% , constant	0.2
GPS ENU velocity [m·s^{-1}]			
0.3	0.25 sec measurement delay	-	0.01
GPS ECEF position [m]			
2.5	< 3 changing	-	0.01

As can be seen from previous data simulated sensors contain significant errors. For example overall error between real and measured magnetometer data may reach up to 4 degrees. Such a big error was set to simulate partially uncompensated iron distortions. With GPS velocity, 2D velocity error does exceed 0.7 m·s^{-1}.

C. Simulation Results for Extreme Conditions

The sub-chapter presents results of simulations constructed with parameters mentioned in table I. In table there are presented the most important estimation INS outputs: gyro bias drift estimation, attitude estimation and velocity estimation. Position estimation is not considered (as being estimated from velocity). Estimation errors during filter initialization are excluded. The simulation is considered to be a "worst condition" scenario. It means that in a real flight INS should perform considerably better (the maximum error should be less than maximum error presented in table II). So the table has to be treated that way.

Table II. shows that the vector filter performs a little bit better in this case but it is caused by more proper selection of parameters compared to the EKF. The 12 state EKF does not perform better compared to the mixed 6 state EKF solution. So the table shows that the vector filter can replace the EKF without any problem. Large attitude estimation error is caused by uncompensated hard and soft iron distortions which are in this case equal to 4 deg (compare with table III. where the distortion error is roughly 1.5 deg).

For a short comparison, table III shows attitude estimation error for the 6 state EKF (mixed filter) and the vector filter for more common conditions. Maximum magnetometer error is set to 1.5 deg and the rest of errors are lowered to a half (except quantization errors and GPS velocity and position errors which were kept the same).

TABLE II.
INS ESTIMATION ERRORS FOR EXTREME CONDITIONS

Filter	average	standard deviation	maximum
Attitude estimation error [deg]			
12 state EKF	3.59	1.64	10.66
Mixed Filter	3.49	1.56	10.23
Vector Filter	3.21	1.33	9.81
Bias drift vector estimation error [deg/s]			
12 state EKF	0.49	0.2	1.4
Mixed Filter	0.41	0.16	1
Vector Filter	0.41	0.17	0.95
velocity vector estimation error [m/s]			
12 state EKF	0.38	0.16	1.16
Mixed Filter	0.37	0.16	1.15
Vector Filter	0.36	0.16	1.16

TABLE III.
INS ESTIMATION ERRORS FOR MORE COMMON CONDITIONS

Filter	average	standard deviation	maximum
Attitude estimation error [deg]			
Mixed Filter	1.53	0.98	5.86
Vector Filter	1.35	0.81	5.25

D. Simulation Results - Figures

Here are several examples of INS filter estimations. These figures were taken for common conditions simulation.

Figure shows that both two filters tend to overact a bit. This is caused by $\boldsymbol{Q}$ and $\boldsymbol{R}$ matrices set for extreme conditions for the EKF and rise β_{rise} and fall β_{fall} coefficients for the vector filter.

E. Simulation Results – Filter Complexity Calculations

As shown before both the MEKF and the vector filter can reach about the same estimation results and the MEKF can be replaced by the vector filter. The table below tries to show the main merit of the vector filter and this is its complexity (when it comes to number of arithmetic operations per filter step). The data are calculated for for filter frequency of 100 Hz and floating point operations are taken in single precision (one double precision FP operation was approximated as two single precision operations). Model calculations and ECEF to LLA transformations were omitted. Results were rounded.

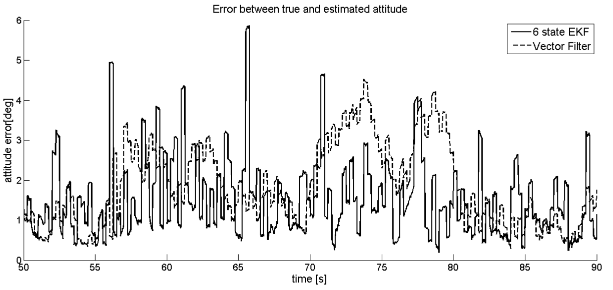

Fig 3. Example plot of attitude error for the mixed filter (6 state EKF) and the vector filter

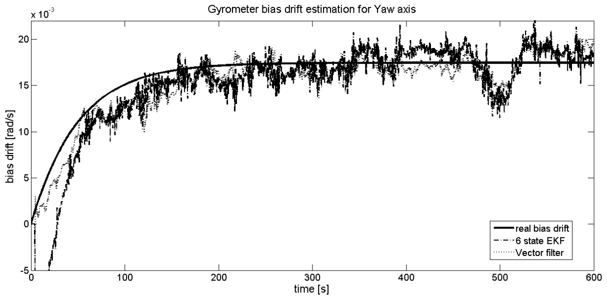

Fig 4. Example plot of a bias drift estimation

Matrix optimizations were calculated for the 12 state EKF only to show the huge difference between unoptimized and optimized calculations with sparse matrices. The table shows that the 12 state EKF needs really huge processing power and without optimizations and lowering filter frequency it is not suitable for miniature INS systems. The mixed solution and the vector filter are much better suited. The vector filter needs less than 4% of processing power compared to the (unoptimized) 12 state EKF and 20% of the processing power compared to the mixed solution.

F. Vector Filter - Higher Level of Control

The above simulations were done using the vector filter without higher level of parameter control – in this case the filter behaves like the corresponding EKF. As the vector filter calculates direction and distance of convergence to the measured values the higher level of control can take these data and for example during filter initialization it can estimate correct filter outputs in one or several consecutive steps.

V. CONCLUSION

The article shows that a standard tightly coupled GPS aided inertial navigation can be easily replaced by much more efficient solutions keeping the estimation as accurate as for

TABLE IV.
FILTER COMPLEXITY

Filter	FLOPS	FLOPS, matrix optimizations	FLOPS, full optimizations + 25 Hz filter frequency
12 state EKF	1896000	640000	190000
Mixed Filter	348000	-	-
Vector Filter	70000	-	-

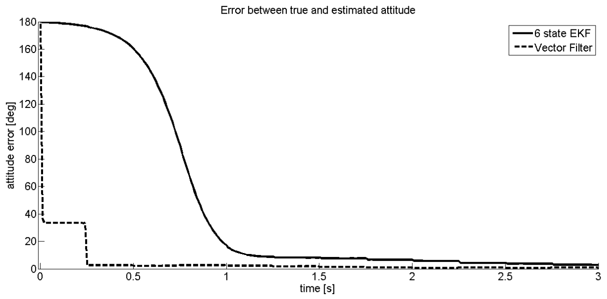

Fig 5. Example plot of a higher level control functionality (attitude estimation error). Compared vector filter and mixed solution.

the standard solutions. This may be done either by the hybrid solution where the KF is used to estimate some parameters while other are estimated by the custom filter. Or it may by done by the custom filter only. The main benefit of this approach is significant reduction in complexity (see table IV) and better system control-ability. Besides this benefit the nature of the vector filter implementation enables it to switch from tightly to loosely coupled system and back without any impact on the system which is vital in cases when GPS measurement is not present for longer period of time and INS attitude estimation would become corrupted due to present sensor errors.

These merits are vital especially in miniature embedded system where their price, size and power consumption is very limited (the system is being developed for the miniature UAV where the whole embedded system weights less than 100 grams and consumption is less than 1Watt (including wireless communication)).

***Abstract*—OPC (OLE for Process Control) protocol was developed as a solution which fulfills requirements of open data integration architecture for industrial control. OPC standard is not primarily intended for feedback control or communication with high-bandwidth hard real-time requirements. Adding OPC to a process could influence the dynamics of the control loop and could cause problems in controller design and implementation. The experiments presented in this paper have shown that OPC if properly configured, is capable of providing a loop time shorter than the time constants of many industrial processes.**

I. Introduction

THERE are three major trends observed in contemporary industrial control systems:

- distributing and decentralizing structures of automation,
- increasing integration of communication through all the levels of the control systems supported by application of wired and wireless networks,
- growing demand for application of IT standards.

Most of the contemporary industrial automation systems adopts multilevel, vertical control architecture [1], [2]. The hierarchical, multilevel approach to industrial process automation is a well accepted method able to cope with complexity of the process and multiple criteria of operation. The structure from Fig. 1 represents a functional decomposition, as it is based on defining functionally different control objectives for vertically dependent layers.

Logically, a typical complex, industrial control system is structured into three levels (Fig. 1), which are: the direct (device) control level, supervisory level and process optimization and management level. Basic objective of the direct (device) control level is to maintain the process states in a safe operations mode according to the prescribed set values. Device controller level provides interface to the hardware, either as separate modules or as microprocessors incorporated in the equipment to be controlled. A number of embedded control nodes and Programmable Logical Controllers (PLC) are used as the front-ends to take the control tasks.

The supervisory level comprises workstations and industrial PCs providing, the high-level program support, database support, graphic man-machine interface, alarming and general management of computing resources. The partial objective of this level is to keep set values of device controllers or process inputs on prescribed values in order to meet demands of product quality or other economical constraints.

The supervisory level often interacts with optimization level. The objective of this level is to calculate the best values of process inputs. Its structure can be very complex and include such modules as identification module, simulation module or optimization module [2].

Usually direct control level operates with an intervention frequency significantly higher (i.e. sampling period is shorter) than the intervention frequency of the supervising level. In direct control sampling intervals can be in the range of miliseconds, whereas sampling interval of the process optimization level can be in the range of seconds or even minutes. This effect is justified by slow-varying disturbances shifting optimal high- level set-points, when compared to the device level feedback control dynamics.

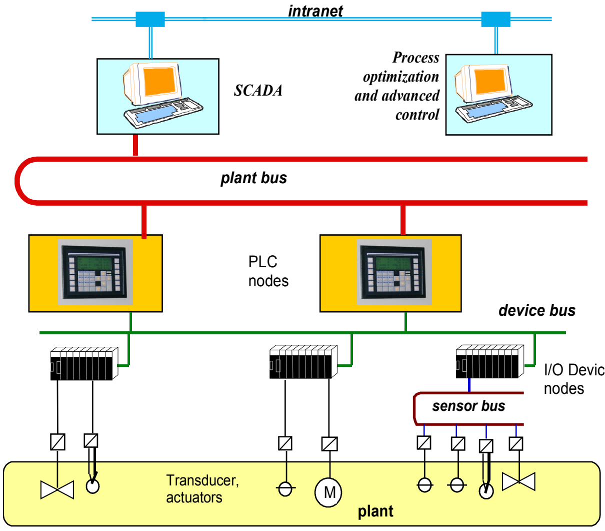

Fig.1 Multilevel structure of the industrial automation system

The ability to easily integrate information from control systems and „plant floor" measurements with supervisory and optimisation levels is a critical issue. It is very difficult to share data between various devices and software manufactured by different vendors without a common industrial communication protocol and integration standard to facilitate interoperability [3], [4].

This work was supported by the European Regional Development Fund Grant no. UDA-POIG.01.03.01-12-171/08/00.

The key is an open and effective communication and integration architecture concentrating on data access, not on the types of data. Ethernet comes as a solution to the data transmission problems mentioned above, while the OPC (OLE for Process Control) protocol was developed as a solution which fulfills requirements of open data integration architecture [5], [6].

In determining the capability for improving the plant operation through control methods implementation, it is important to understand where the delays occur and how these individual delay components contribute to the end-to-end communication. As a first step in this delay analysis, the impact of the network is assessed.

It is well known that the introduction of data transmission networks into the feedback loop in many cases violates conventional control theories assumptions such as non-delayed or evenly spaced sampling sensing and actuation. The computer network is characterized by its maximal throughput. This parameter limits the amount of data that can be sent within a time unit. Network-induced delays may vary depending on the network load and medium access protocol. Generally, networked control often introduces some additional temporal non-determinism. For distributed control systems variable queuing delays, transmission delays, transport layer ACK delays and the lost of data, leads to the deterioration of the quality of control [7]. Various methodologies were proposed for compensation of such the effects [8].

When using networks for control, it is often important to assess determinism as a QoS parameter. For example, evaluating whether end-to-end message communication times can be predicted exactly or approximately, and whether these times is bounded. Total end-to-end delay between network nodes is the sum of pre-processing time (microprocessor), waiting time (network protocol – MAC), transmission time (data rate & length), post-processing time (microprocessor).

Very little was said about the impact of OPC data processing on the dynamics of a control loop [9]. The overhead associated with OPC is included in pre (post) processing times and might be significant and variable for some configurations of this interface. Most of this delay is due to the software implementation of the OPC protocol, as OPC was not intended for hard real-time applications.

J. T. Parrott et al. from the University of Michigan [16] had investigated more deeply the delays induced by the application layer in three types of communication:

- UDP, User Datagram Protocol, a simple transport layer protocol,
- OPC, OLE for Process Control, an open application level communication protocol,
- VPN, virtual private networks, which create secure “tunnels” to transfer data between networks.

The Authors concluded that application layers delays are more important than network delays.

The main focus of this paper is in the usage of OPC in real-time control loop. It has already been mentioned that OPC has been designed to help with the interoperability problems inherent in a market with different propriety devices, protocols and industrial network standards. The question that needs to be asked is, which costs does this interoperability incur on the system in terms of performance? In order to achieve these goals a number of experiments was planned and performed. The results are given in the following sections.

II. Networks

Current communication systems for automation implements different protocols. This is a substantial disadvantage, leading to necessity of using vendor-specific hardware and software components, which increase installation and maintenance costs. Moreover, presently used fieldbus technologies make vertical communication across all levels of the automation systems difficult. Gateways need to be used to establish connections between different kinds of fieldbus systems used in the lower level, and Ethernet used in the upper levels.

Ethernet provides unified data formats and reduces the complexity of installation and maintenance, which, together with the substantial increase of the transmission rates and communication reliability over the last years, results in its popularity in the area of industrial communications.

Ethernet, as defined in IEEE 802.3, is non-deterministic and thus, is unsuitable for hard real-time applications. The media access control protocol, CSMA/CD with its backoff algorithm, prevents the network from supporting hard real-time communication due to its random delays and potential transmission failures. In real-time systems, delays and irregularities in data transmission can very severely affect the system operation. Therefore, various techniques and communication protocol modifications are employed, in order to eliminate or minimise the undesired effects.

To employ Ethernet in industrial environment, its deterministic operation must first be assured, which can be accomplished in several ways. Coexistence of real-time and non-real time traffic on the same network infrastructure remains the main problem. This conflict can be resolved in several ways, by [10]:

- embedding fieldbus or application protocol on TCP/IP – the fieldbus protocol is tunneled over Ethernet, and full openness for “office” traffic is maintained,
- using special Data Link layer for real-time devices – special protocol is used on the second OSI Layer, implemented in every device. The real-time cycle is divided into slots, one of which is opened for regular TCP/IP traffic, but the bandwidth available is heavily limited down,
- using application protocol on TCP/IP, direct MAC addressing with prioritization for real-time, and hardware switching for fast real-time,
- maintaining real-time on TCP/IP is achieved by prioritized messaging and time synchronization – the

synchronized devices assign higher priority and timestamp real-time messages,

All the specific techniques allow a considerable improvement in terms of determinism. The desire to incorporate a real-time element into this popular single-network solution has led to the development of different real-time Industrial Ethernet solutions, called Real-time Ethernet, as PROFINET, EtherCAT, Ethernet/IP [11], [12] and many more. The conditions for the industrial use of Ethernet are described by international standard IEC (*International Electrotechnical Commission*) IEC 61 784-2 *Real Time Ethernet,* Fig.2.

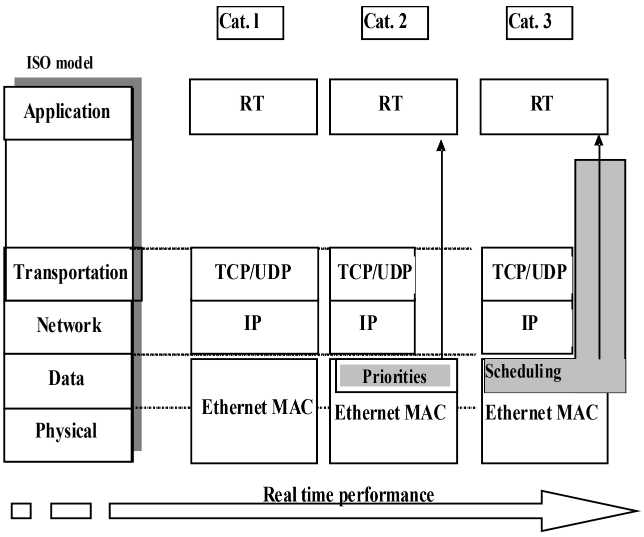

Fig.2 Classification of industrial Ethernet (IEC 61 784-2)

III. OPC

OPC [6] is a widely accepted open industrial communication standard that enables the exchange of data without any proprietary restrictions between multi-vendor devices and control software (horizontal integration) as well as between different software applications (vertical integration, Fig.3). Currently, most of plant-level control systems can be configured to be the OPC servers for supervisory control levels of the factory.

OPC is based on the Microsoft DCOM specification. Although OPC actually consists of many different data exchange specifications, its most commonly used form is Data Access (OPC DA), which supports both client-server and publisher-subscriber data exchange models. OPC DA deals only with current process data - not historical data or alarms.

An OPC client can be connected to several OPC servers provided by different vendors. Important feature of OPC is that the client is able to connect the OPC server which is located in other computer in the network. This is possible because of DCOM (Distributed COM) the COM standard extension which enables client running on one computer to create instances and invoke methods of servers on another computer within the network.

The OPC standard defines numerous ways to communicate between the server and its clients to satisfy different OPC applications. The client can specify that some operations should be performed on "cache" or "device". If "device" is chosen, operation directly on the physical device will be requested. If "cache" is selected data will be read from server's internal memory where server keeps a copy of device data received during the last OPC refresh cycle.

Both reading and writing can be done synchronously or asynchronously:

- OPC synchronous functions run to completion before returning. It means that the OPC client program execution is stopped till operation is over.
- OPC asynchronous functions use callback mechanism to inform the requested OPC operation is over. The client program execution is not stopped while waiting for OPC operation completed.

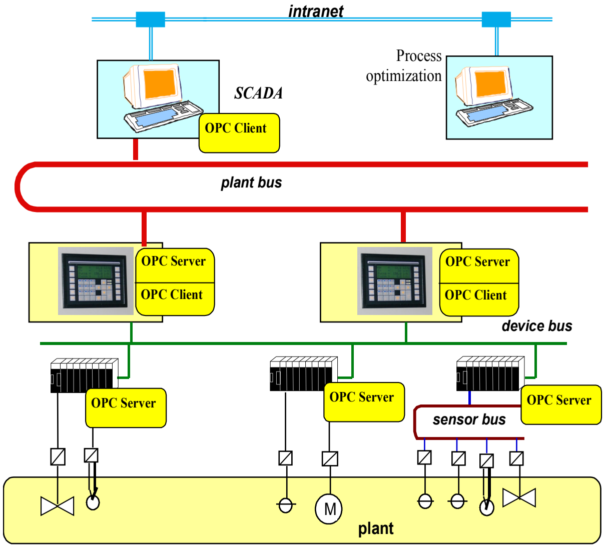

Fig. 3 Vertical integration with OPC

The OPC standard was not primarily intended for feedback control or communication with high-bandwidth, hard real-time requirements. However, many of I/O devices require real-time capabilities that are specific to the hardware and essential to proper operation of the high-level SCADA application. Therefore, one of the most important issues for communication between devices is to the assure proper configuration and synchronization.

IV. Experiments

The control algorithm must be designed according to a specification that provides the required performance when changes occur at the input or in the disturbances. For distributed control systems variable delays are considered to be the most important disturbances. For longer delays observed in the control loop it is much difficult to ensure the stability of the system within the response specification. Another factor that affects the operation of the control system is the variability of the delays, which again cannot be too large without making the system unstable.

The control system considered in this paper has two data processing modules (Fig. 4): the OPC server and OPC client. The main objective of these experiments was to investigate how fast the OPC server responds to a client request and what is uncertainty associated with such a data exchange? The configuration shown in Fig. 4 describes idea of the experiments. Analogue Process Simulator (PS) have been used as a model of real controlled process. The device can simulate a third order linear process with different time constants.

The PS has two current inputs (4..20 mA) and one current output. The process control value was calculated in real-time in Simulink and send to PLC (Siemens) during the next OPC server cycle. In this configuration PLC was only a bridge between PC and Process Simulator. During each PLC controller program cycle process variables are read from PS and control variables are send to PS. The OPC server makes the variables available for OPC clients operating in the upper layer.

The Matlab OPC Toolbox™ was applied at the upper layer. It is a set of functions which make able to connect with an external OPC server from Matlab/Simulink programming environment. For the experiments described in in this paper only Simulink part of the OPC Toolbox was used. The PID controller block of Simulink was running using *pseudo real-time simulation* mode.

To configure the reading or writing block of the OPC client it is also important to decide the method how data will be captured from the OPC server. We had selected one of two options:

Synchronous read – MATLAB stops simulation and wait for the server to return data from a read request before continuing processing. The data returned by the server can come from the server's *cache*, or the server read values directly from the *device* that the server item refers to. Reading from the device can be slower but data are more time accurate.

Asynchronous read – MATLAB client sends a request to read data from the server. Ones the request is accepted it continue processing without waiting to receive values from server. Server will use callback to inform MATLAB about new data occurrence. MATLAB will handle that event as soon as it is able to perform that task.

With each OPC data read time stamp value is associated. Theoretically, distinction in time between successive time stamps should be equal to OPC item refresh rate (T_{ITEM}). In reality it varies depending synchronization method and CPU load.

Default server's cycle time T_{SERVER} for Siemens PLC was set as 00ms. OPC item refresh rate is specified in OPC Client and should be multiplication of OPC Server cycle time. OPC performance was calculated as sum of absolute errors between two successive OPC item read time stamps and OPC item refresh rate (T_{ITEM}) and divided by number of time stamps. The results of this calculation will presents the average time deviation of OPC item reading:

$$OPC_{Perform}=\frac{1}{N}\sum_{i=1}^{N-1}|(TimeStamp_{i+1}\text{-}TimeStamp_i-T_{ITEM})|$$

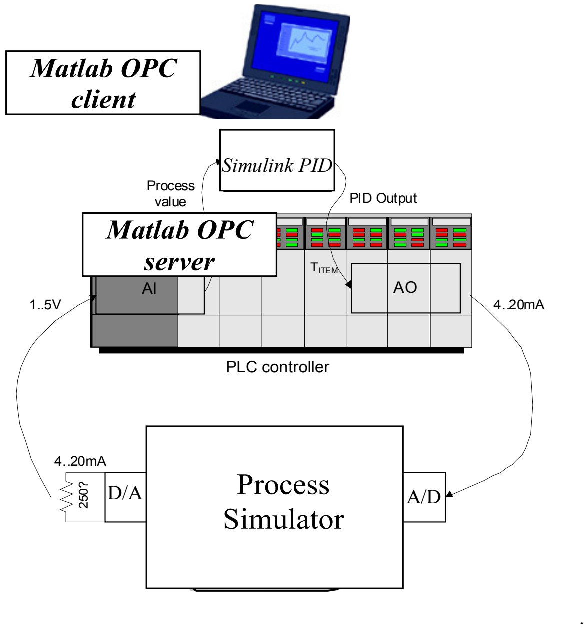

Fig. 4 Laboratory control system

The results of the above experiment are summarized in Table 1.

TABLE 1. OPC PERFORMANCE [13]

Configuration	OPC item rate T_{ITEM}=100ms, OPC server rate T_{SERVER}=100ms
	OPC performance
Synchronous cache read, synchronous write	8,72
Asynchronous cache read, asynchronous write	162,80
Asynchronous device read, synchronous write	162,39
Synchronous cache read, asynchronous write	13,31
Synchronous device read, synchronous write	6,99
Synchronous device read, asynchronous write	6,39

It can be seen for the delay of 100ms between readings, that the values of jitter (i.e. average of the deviation from the data mean delay) obtained for synchronous read are much lower compared to asynchronous operations. As it can be seen in Fig.5d the OPC client very often needs 500ms or even 700ms to asynchronously read data from the PLC (see Fig.6b). Notice, that while waiting for this event processing the controller is running and obsolete data are used for control. If one looks in details into asynchronous time stamps vector, he will recognize also, that several items have the same time stamp.

The lower jitter values obtained for synchronous mode indicate the significance of proper configuration of OPC interface.

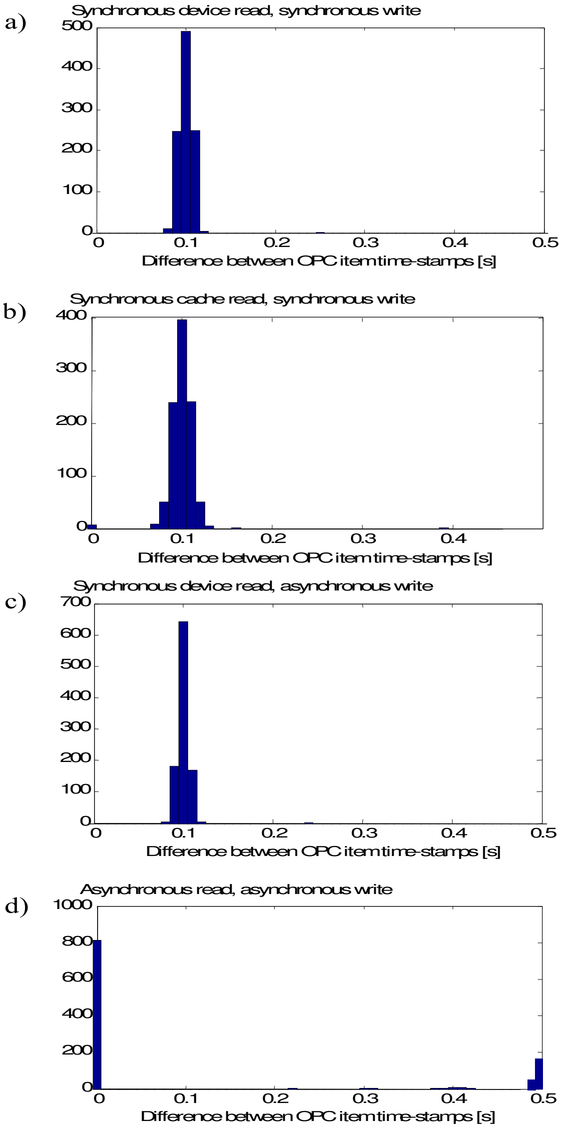

Fig.5 OPC jitter

V. Influence of network traffic

In this part impact of network traffic on data delivery was tested. PLC and PC with MATLAB were connected each other via hub and additionally, three other computers were connected to the hub. Between additional computers artificial TCP traffic was generated. OPC Server refresh rate and OPC item refresh rate were set to $T_{ITEM}=$ $=T_{SERVER}=100$ms. One of the tests was performed using wireless (WiFi) connection. The results are presented in Table 2.

Digital control systems are based on periodic operations. A shortest sampling period is limited by OPC server refreshment rate. It must guarantee acceptable control performance. The network communication delays and jitters will be added to the OPC delays and jitters, creating total delays and uncertainty in the control loop. General conclusion after this experiment is, that low network traffic is not influencing very much the time accuracy of data delivery. In this case OPC jitter is more significant.

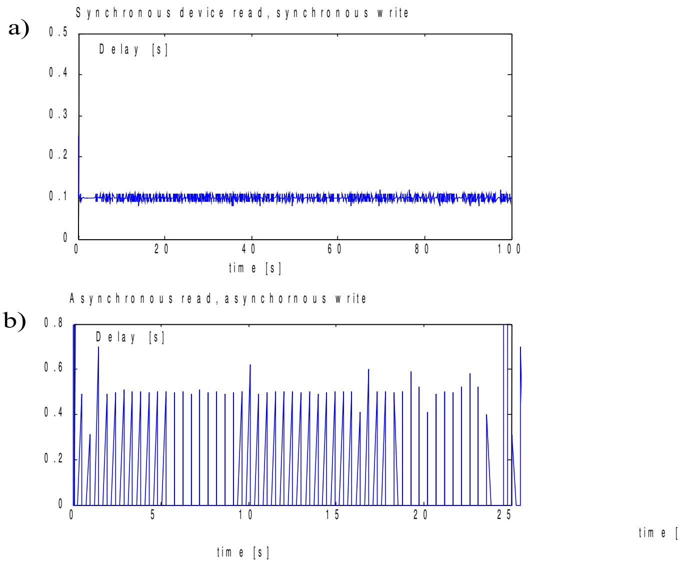

Fig.6 Time delays for synchronous and asynchronous modes

Table 2. Jitter introduced by network [13]

Network	Synchronous		
	Mean jitter [ms]	Jitter highest [ms]	Jitter lowest [ms]
Ethernet	0.4231	0.4323	0.493
Wireless	0.7222	0.8889	1.7778
TCP Ethernet with traffic 50%	5.7105	20.7895	24.4737

Network type jitters and delays dominate for heavy traffic. In this case the highest jitter gets 20% of T_{ITEM} time and might influence on control quality i.e. to violate conventional control theories assumptions such as evenly spaced sampling sensing and actuation.

VI. Conclusions

Various requirements for distributed, real-time control of a process in process automation can be formulated, for example stability, speed of response etc. Most important is to ensure that the data required by the controller are delivered to the controller and for the data from the controller to the process again, in less time that it takes for the any appreciable change to occur in the output of the process. With the industrial network speeds that increase application layer delays can become more important than network delays. As a consequence, application layer delays must be taken into account but they are often not specified.

OPC is a standard that has been developed to help with inoperability problems with the number of different devices and communications protocols in the process industry. OPC was never intended for a hard real-time operation. The latency and jitter associated with OPC (and DCOM in general) is significant. Even though data read from an OPC server bears timestamps, there is no guarantee that the client will receive them in a reasonable time. Therefore, adding OPC to a process could influence the dynamics of the control loop and could cause problems in controller design and implementation.

There are a number of researches focused on COM technology to demonstrate that the COM/DCOM model after some extensions can guarantee real-time communication to industrial control systems [14], [15].

Our experiments have shown that standard OPC DA in asynchronous mode has slow and unpredictable read times. However, if properly configured, the OPC is capable of providing a loop time less than the time constants of many industrial processes. Especially, it is useful for supervisory control level, where sampling intervals can be in the range of seconds or even minutes. It can be also used to send set-point commands down from the SCADA to the device level. OPC standard has its place in the distributed control configurations of all processes that do not have fast responding outputs.

{hagner, goltz}@ips.cs.tu-bs.de

***Abstract*—The complexity of embedded systems and their safety requirements have risen significantly in recent years. Models and the model based development approach help to keep overview and control of the development. Nevertheless, a support for the analysis of non-functional requirements, e.g. the scheduling, based on development models and consequently the integration of these analysis technologies into a development process exists only sporadically. The problem is that the analysis tools use different metamodels than the development tools. Therefore, a remodeling of the system in the format of the analysis tool or a model transformation is necessary to be able to perform an analysis. Here, we introduce a scheduling analysis view as a part of the development model, which is a MARTE annotated UML model to describe a system from the scheduling behavior point of view. In addition, we present a transformation from this annotated UML model to the scheduling analysis tool SymTA/S and a treatment of the analysis results to integrate scheduling analysis into a development process. With our approach it is not necessary to remodel the system in an analysis tool to profit from the analysis and its results. Additionally, we illustrate our approach in a case study on a parallel robot controller.**

I. Introduction

Model based development is widely appreciated in the embedded systems domain to cope with the complexity. As a generic and standardized approach, UML [1] has established as one of the most important notations for modeling software. The MARTE profile (UML Profile for Modelling and Analysis of Real-Time and Embedded systems) [2] makes domain specific ideas, relevant for real-time and embedded systems design, available in a unified modeling framework. Based on this profile, we have defined the UML scheduling analysis view [3] as a part of the design model that concentrates on the scheduling analysis aspects and leaves out all unnecessary information to help the developer focusing on these aspects. This approach is based on the cognitive load theory [4], which states that human cognitive productivity dramatically decreases with the amount of different dimensions to be considered at the same time.

Besides specification and tracing of timing requirements through different design stages, the major goal of enriching models with timing information is to enable early validation and verification of design decisions. As designs for an embedded or safety critical systems may have to be discarded if deadlines are missed or resources are overloaded, early timing analysis has become an issue and is supported by a number of specialized analysis tools like SymTA/S [5], MAST [6], and TIMES [7]. However, the metamodels on which analysis models of the tools are based differ from each other and in particular from UML models used for design, especially the UML scheduling analysis view. Thus, to make an analysis possible and to integrate it into a development process, the developer has to remodel the system in the analysis tool. To avoid this major effort, an automatic model transformation is needed to build an interface that enables automated analysis of a MARTE extended UML model using existing RT analysis technology.

In this paper, we introduce a method to integrate the scheduling analysis into a UML based development process. With our approach it is possible to add scheduling parameters to a UML model and to perform scheduling analysis based on this model. Therefore, we demonstrate a model transformation (realized with the Atlas Transformation Language - ATL [8]) from our proposed UML scheduling analysis view as an extension of Papyrus for UML[1] to the scheduling analysis tool SymTA/S. After the analysis, the results are published in the UML development model to give the developer a feedback concerning the scheduling behavior such that he/she can draw the right conclusions. Consequently, the developer does not need to see SymTA/S or to know how to use the analysis tool to profit from scheduling analysis.

This paper is structured as follows: Section II gives an introduction over the integration of scheduling analysis into the development process, Section III presents the UML scheduling analysis view, in Section IV, SymTA/S

[1] http://www.papyrusuml.org

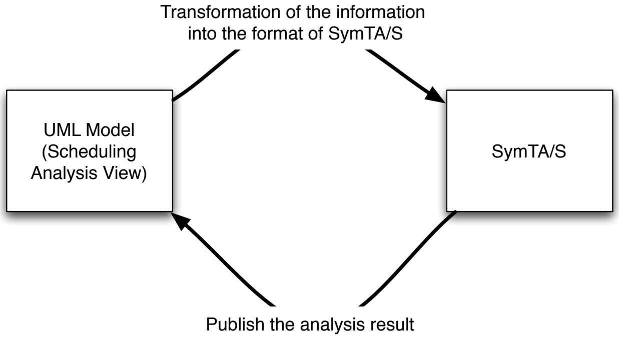
978-83-60810-27-9/09/$25.00 © 2010 IEEE

is explained, Section V and VI present the transformation from the UML scheduling analysis view to SymTA/S and the recirculation and publication of results of the analysis. In Section VII we apply our approach to a case study of our Collaborative Research Centre 562. Section VIII concludes the paper.

II. Integration of Scheduling Analysis into a Development Process

The idea of performing scheduling analysis based on UML models assumes that all the information that is needed for the analysis is already part of the UML model. There is no scheduling analysis tool that is based on UML models or that uses UML models as an input. Therefore, the transformation described in Section V is necessary. But for this transformation, it is necessary that all information needed is already part of the UML development model. If this is the case, the data/necessary information of the system is transformed into the format of the analysis tool.

After the transformation is done, the analysis examines the response times of the tasks and the utilization of the resources. It checks if task chains are executed fast enough or deadlines are missed. Following the analysis, the results are published again in the UML scheduling analysis view (see Figure 1 for the workflow). These steps are done automatically and the developer only has to start the workflow and gets back the analysis results immediately. Afterwards, he/she just has to interpret the analysis results. Consequently, the developer does not need to see or use the analysis tool, as he/she can model and parameterize the system in the UML development model. Even the analysis results are published using UML and the MARTE profile.



Transformation of the information into the format of SymTA/S
UML Model (Scheduling Analysis View)
SymTA/S
Publish the analysis result

Fig. 1. Illustration of the transformation flow

This approach is independent from the point in time during the development process, as long as the system under consideration is completely described to meet the criteria of a scheduling analysis. It is useful at the beginning of a development process to help making decisions concerning the number of resources or the distribution, even if at this time mainly estimated values must be used and the system is not completely designed (e.g. tasks are still combined and not yet broken down). At a later stage of development, more exact/measured (execution) times can be used to determine more accurate analysis results. Regardless of the development stage, the workflow, described in Figure 1, is the same.

III. The UML Scheduling Analysis View

The UML scheduling analysis view [3] was designed regarding the information required by a number of scheduling analysis tools (e.g. SymTA/S). Therefore, it concentrates on and highlights timing and scheduling aspects. Unlike usual design models, it contains all necessary information for an analysis (priorities, scheduling algorithms, task execution times, etc.).

The view consists of three different UML diagram types and a selection of MARTE stereotypes and tagged values (see Figure 2). The diagram types are class diagrams as an architectural view (to describe the structure, associations, and allocations of the systems' elements), object diagrams as a view on the runtime system (to instantiate the concrete system that should be analyzed based on the architectural view), and activity diagrams as a workload view (to describe workload situations, flows, and dependencies of tasks).

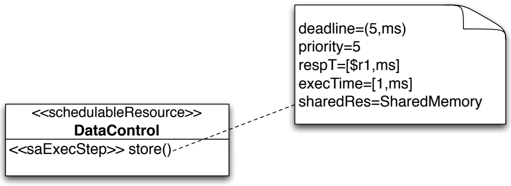


Fig. 2. Example of MARTE stereotypes and tagged values

The stereotypes and the tagged values are based on the MARTE UML profile. We only used a small amount of the defined elements for the scheduling analysis view. One goal of the view is to keep it as simple as possible. Therefore, only elements are used that are necessary to describe all the information that is needed for an analysis. In Table I all used stereotypes and tagged values are presented.

Class diagrams are used to describe the architectural view/the structure of the modeled system. The diagrams show resources, tasks, and associations between these elements. Furthermore, schedulers and other resources, like shared memory, can be defined. Figure 3 shows a class diagram of the scheduling analysis view that describes the architecture of a sample system. The functionalities/the tasks and communication tasks are represented by methods. The tasks are described using the «saExecStep» stereotype. The methods that represent the communication tasks (transmitting of data over a bus) are extended with the «saCommStep» stereotype. The tasks or communication tasks, represented as methods, are part of schedulable resource classes (marked with the «schedulabeResource» stereotype), which combine tasks

TABLE I
ELEMENTS OF THE SCHEDULING ANALYSIS VIEW

Stereotype	used on	Tagged Values
«saExecHost»	Classes, Objects	Utilization, mainScheduler, isSched
«saCommHost»	Classes, Objects	Utilization, mainScheduler, isSched
«scheduler»	Classes, Objects	schedPolicy, otherSchedPolicy
«schedulableResource»	Classes, Objects	
«saSharedResources»	Classes, Objects	
«saExecStep»	Methods	deadline, priority, execTime, usedResource, respT
«saCommStep»	Methods	deadline, priority, execTime, msgSize, respT
«saEndToEndFlow»	Activities	end2endT, end2endD, isSched
«gaWorkloadEvent»	Initial-Node	pattern
«allocated»	Associations	

or communications that belong together, e.g. since they are part of the same use case or all of them are service routines. Processor resources are represented as classes with the «saExecHost» stereotype and bus resources are classes with the «saCommHost» stereotype. The tasks and communications are mapped on processors or busses by using associations between the schedulable resource and the corresponding bus or processor resource. The associations are extended with the «allocated» stereotype. Scheduling relevant parameters (like deadlines, execution times, priorities, etc.) are added to the model using tagged values.

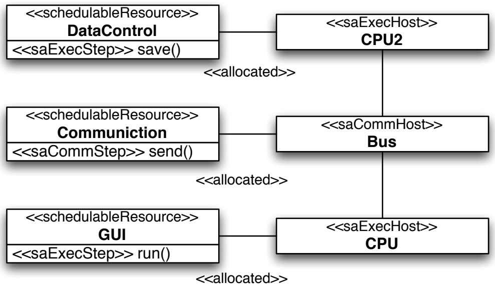

Fig. 3. The architectural view of the scheduling analysis view

The object diagram or runtime view is based on the class diagram/architectural view of the scheduling analysis view. It defines how many instances are parts of the runtime system respectively what parts are considered for the scheduling analysis. It is possible that only some elements defined in the class diagram are instantiated. Furthermore, some elements can be instantiated twice or more (e.g. if a processor is redundant). Only instantiated objects are taken into account for the scheduling analysis and, consequently, for the model transformation.

Activity diagrams are used to describe the behavior of the system. Therefore, workload situations are defined that outline the flow of tasks that are executed during a certain mode of the system. The dependencies of tasks and the execution order are illustrated. The «gaWorkloadEvent» and the «saEnd2EndFlow» stereotypes and their corresponding tagged values are used to describe the workload behavior parameters like the arrival pattern of the event that triggers the flow or the deadline of the outlined task chain. For example, in Figure 4, it is well defined that at first *cpu.run()* has to be completely executed, before *communication.send()* is scheduled etc.. There are restrictions like that no decision nodes are allowed, because the analysis tool SymTA/S does not support these model elements.

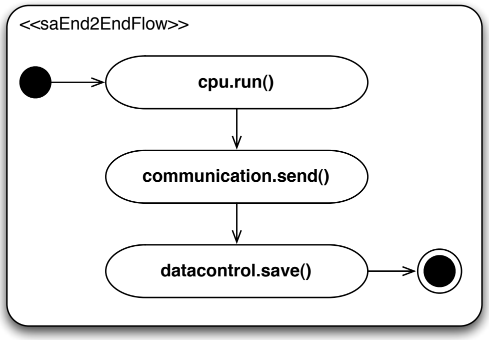

Fig. 4. A workflow description of the scheduling analysis view

The scheduling analysis view can be easily be extended, if necessary. If a scheduling analysis tool offers more possibilities to describe or to analyze a system (e.g. a different scheduling algorithm) and needs more system parameters for it, these parameters have to be part of the scheduling analysis view. Therefore, the view can be extended with new tagged values that offer the possibility to add the necessary parameters to the system description (added to Table I).

Another advantage of using the scheduling analysis view is that the tagged values help the developer to keep track of timing requirements during the development, as these parameters are part of the development model. This especially helps to keep considering them during refinement.

IV. SCHEDULING ANALYSIS WITH SYMTA/S

We use SymTA/S (**Sym**bolic **T**iming **A**nalysis for **S**ystems) [4] for the scheduling analysis. The example depicted in Figure 5 is the SymTA/S representation of the system described in Section III and illustrated in Figure 3 and Figure 4. There is one source (trigger), two CPUs (CPU and CPU2), which run two tasks (run and save), and a bus (Bus) with one communication task (send). All tasks are connected using event streams, representing task chains.

SymTA/S links established analysis algorithms with event streams and realizes a global analysis of distributed systems. At first, the analysis considers each resource on its own and identifies the response time of the mapped tasks. From these response times and the given input event model it calculates the output event model and propagates it by the event stream. If there are cyclic dependencies, the system is analyzed from a starting point iteratively until reaching convergence.

V. Transformation and Analysis

During the transformation, the information is taken from the UML metamodel of the scheduling analysis view and is placed in the metamodel of SymTA/S. The scheduling analysis view is modeled in Papyrus for UML and saved as an XMI[9] file. SymTA/S files are also based on XML. Therefore, the ATL transformation [8] has to read the XMI file and create a, for SymTA/S valid, XML file containing the system represented in the scheduling analysis view.

First, the transformation checks whether the model is suitable at all for a transformation. After that, the hardware components are transformed. The transformation searches for all objects with the «saExecHost» stereotype and generates CPU objects for them in the SymTA/S model. The same happens with objects with the «saCommHost» stereotype for busses.

Thereafter, the activity diagrams/workflow descriptions are considered, and, depending on the parameters of the initial nodes, corresponding source elements in the SymTA/S model are created. In the next step, all tasks and communication tasks (all methods with a «saExecStep» or «saCommStep» stereotype) are created as often, as the class/schedulable resource they belong to is instantiated in the scheduling analysis view (e.g. if a class "Calculate" with the «schedulableResource» stereotype has a method *calculateValues()* that has the «saExecStep» stereotype, and the "Calculate" class is instantiated two times in the scheduling analysis view, there will be two calculateValues tasks in the SymTA/S model).

Analyzing the «allocated» stereotypes does the mapping: For example, if there is an «allocated» marked association between a resource and a class with a «schedulabeResource» stereotype, all methods/tasks of the «schedulabeResource» class are mapped on this resource in the SymTA/S model. The corresponding parameters of the tasks (annotated with tagged values in the UML scheduling analysis view) are entered into the SymTA/S model.

In the last step of the transformation, the event streams in SymTA/S are created based on the dependencies described in the activity diagrams/workflow descriptions. The activity diagrams of the UML scheduling analysis view are observed and the dependencies are added to the SymTA/S model. It is only necessary to detect which actions are connected in the UML view and to reproduce these connections using Event Streams in SymTA/S. As SymTA/S does not offer decision nodes, these elements are not supported during the transformation.

After the complete transformation, SymTA/S is used for the analysis. For this, the tool is started with the created XML file as a parameter. SymTA/S analyses the system and writes back the results into the XML file.

VI. Publishing the Analysis Results in the Scheduling Analysis View

After the analysis is finished, the results are published in the scheduling analysis view. The developer gets the information whether there are tasks or paths/task chains that are not schedulable or that miss their deadlines. Some of the tagged values of the scheduling analysis view are used to give the developer a feedback about the analysis results. For example, in Figure 2 the respT tagged value is empty before the analysis and has a variable ($r1), which means that the response time of the corresponding task is entered at this point after the analysis. There are also other parameters, which give a feedback to the developer (see also Table I):

a) respT: The respT tagged values gives a feedback about the response time of the (communication) tasks and is offered by the «saExecStep» and the «saCommHost» stereotype.

b) end2endT: As the respT, the end2endT tagged values offers the response time, in this case of a path/task chain and is offered by the «saEnd2EndFlow» stereotype. It is not a summation of all response times of the tasks that are part of the path, but a worst case calculated response time of the whole path examined by the scheduling analysis tool (for more details see [5]).

c) Utilization: The «saExecHost» and the «saCommHost» stereotype offer a utilization tagged value that gives a feedback about the load of the CPU or the bus. The value is given in percent. If the value is higher than 100%, it is obvious that this resource is not schedulable (and the isShed tagged value is false too), but even if the value is only slightly under 100% , this is a warning for the developer that this resource is nearly overloaded.

d) isShed: This tagged value gives a response whether the tasks mapped on this resource are schedulable or not (false or true) and is offered by the «saExecHost» and the «saCommHost» stereotype. The tagged values are connected to the Utilization tagged value (e.g. if the utilization is higher than 100%, the isShed tagged value is false). This tagged value is also offered by the «saEnd2EndFlow» stereotype. As the «saEnd2EndFlow» stereotype defines parameters for a path/task chain, the

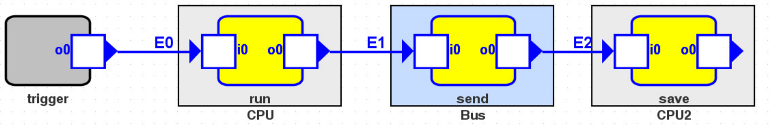

Fig. 5. A sample of a system described in SymTA/S

isShed tagged value gives a feedback whether the deadline for the path is missed or not.

After an analysis is finished, the developer can check if the system is schedulable. For this, the developer checks if the paths/tasks chains are schedulable (isShed tagged value of the «seEnd2EndFlow» stereotype). If this is false, the developer has to find the reason why the scheduling failed. The end2EndT tagged value shows to what extent the deadline is missed, as it gives the response time of the path/task chain. The response times of the tasks and the utilization of the resource give also a feedback where the bottleneck might be (e.g. a resource with a high utilization and tasks scheduled on it with long response times is more likely a bottleneck as resources with low utilizations).

VII. Case Study

The aim of the Collaborative Research Centre 562 (CRC 562)[2] is the development of methodological and component-related fundamentals for the construction of robotic systems based on closed kinematic chains (parallel kinematic chains - PKMs), to improve the promising potential of these robots, particularly with regard to high operating speeds, accelerations, and accuracy [10]. This kind of robots features closed kinematic chains and has a high stiffness and accuracy. Due to low moved masses, PKMs have a high weight-to-load-ratio compared to serial robots. The demonstrators which have been developed in the research center 562 move very fast (up to 10 m/s) and achieve high accelerations (up to 100 m/s^2). The high velocities induced several hard real-time constraints on the software architecture that has been designed to control the robots. The latest version is *PROSA-X* (**P**arallel **R**obots **S**oftware **A**rchitecture - e**X**tended) which uses multiple control PCs to distribute its algorithmic load. *PROSA-X* is a generic architecture which is used to control several different robots. A specifically tailored middleware (*MiRPA-X*) and a bus protocol that operates on top of a FireWire bus (*IAP*) realize communication satisfying the hard real-time constraints [11]. The architecture is based on a layered design with multiple real-time layers within QNX[3] to realize e.g. a deterministic execution order for critical tasks [12].

The robots are controlled using cyclic frequencies between 1 and 8 kHz. If these hard deadlines are missed, this could cause damage to the robot and its environment. To avoid such problems, a scheduling analysis on the basis of models ensures the fulfillment of real-time requirements. The case study presented below has been performed in this context and is based on [13].

In Figure 6 a scheduling analysis view representation of the software architecture, PROSA-X [14], is presented. It consists of a control PC ("Control_PC1"), which performs various computing tasks ("CP1_Tasks"). The control PC is connected via a FireWire (IEEE 1394) data bus with a number of other processors ("DSP_1-7"). The DSPs supervise and control the machine.

The methods represent the following tasks:

- *IAP_D*: This instance of the *IAP* bus protocol receives the *DDTs (Device Data Telegram)* that contain the instantaneous values of the DSP nodes over the FireWire bus.
- *HWM*: The *Hardware Monitoring* takes the instantaneous values received by the *IAP_D* and prepares them for the control.
- *DC*: The *Drive Controller* operates the actuators of the parallel kinematic machine.
- *SMC*: The *Smart Material Controller* operates the active vibration suppression of the machine.
- *IAP_M*: This instance of the bus protocol *IAP* sends the setpoint values, calculated by DC and SMC, to the DSP node.
- *CC*: The *Central Control* activates the currently required sensor and motion modules (see below) and collects their results.
- *CON*: *Contact Planner*. Combination of power and speed control. For the end effector of the robot to make contact with a surface.
- *FOR*: *Force Control*, sets the force for the end effector of the robot.
- *CFF*: Another *Contact Planner*, similar to CON.
- *VEL*: *Velocity Control*, sets the speed for the end effector of the robot.
- *POS*: The *Position Controller* sets the position of the end effector.
- *SAP*: The *Singularity Avoidance Planner* plans paths through the work area to avoid singularities.
- *SEN*: An exemplary *Sensor Module*.

Next we explain the real-time demands on the system. There is no deadline on a specific task, but there are deadlines on task chains/workflows. The first task chain receives the instantaneous values and calculates the new setpoint values (IAP_D, HWM, DC, SMC). The deadline

[2] http://www.tu-braunschweig.de/sfb562
[3] QNX Neutrino is a micro kernel real-time operating system.

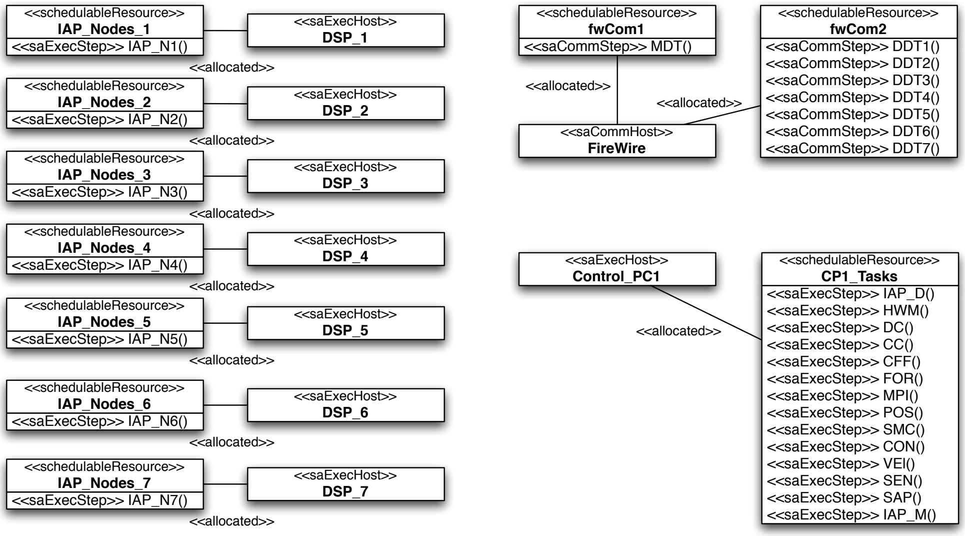

Fig. 6. The architectural view of the PROSA-X system

for this is after 250 microseconds (see Figure 7 for the scheduling analysis view description).

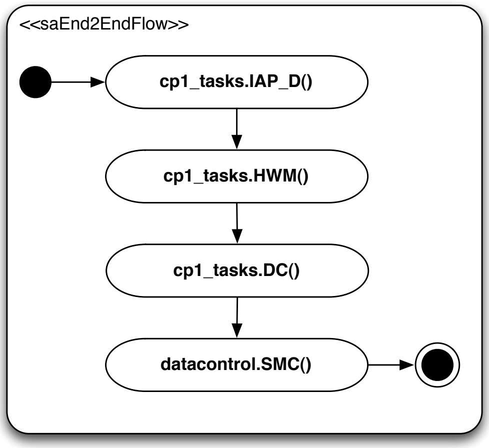

Fig. 7. The receiving of the instantaneous values and the calculation of the new setpoint values

The second task chain contains the sending of the setpoint values to the DSPs and their processing (IAP_M, MDT, IAP_N1, …, IAP_N7, DDT1, …, DDT7). This must be finished within 750 microseconds (see Figure 8).

Finally, the third chain comprises the control of the sensor and motion modules (CC, CON, FOR, CFF, POS, VEL, SEN, SAP) and has to be completed within 1945 microseconds (see Figure 9).

The system was modeled in Papyrus for UML as a Scheduling Analysis View. Every element of the architectural view (depicted in Figure 6) is instantiated once in the runtime view.

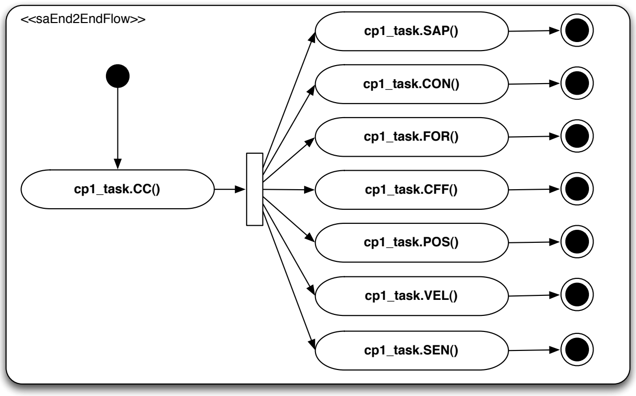

Fig. 9. Control of the sensor and motion modules

The ATL transformation creates a corresponding SymTA/S model and makes it possible to analyze the system. The transformation was successful, the output model was analyzed by SymTA/S and confirms to the expectations: The analysis was successful, all paths keep their real-time requirements, the resources are not overloaded. The SymTA/S model is depicted in Figure 10.

After the successful analysis, the results are published back into the scheduling analysis view (see section VI).

The analysis has confirmed that the system is schedulable. We also integrated this analysis into our approach for finding the best distribution using graph partitioning [15].

VIII. Conclusion and Further Work

We have presented a model transformation from a MARTE annotated UML model to the scheduling analysis tool SymTA/S to make a scheduling analysis based

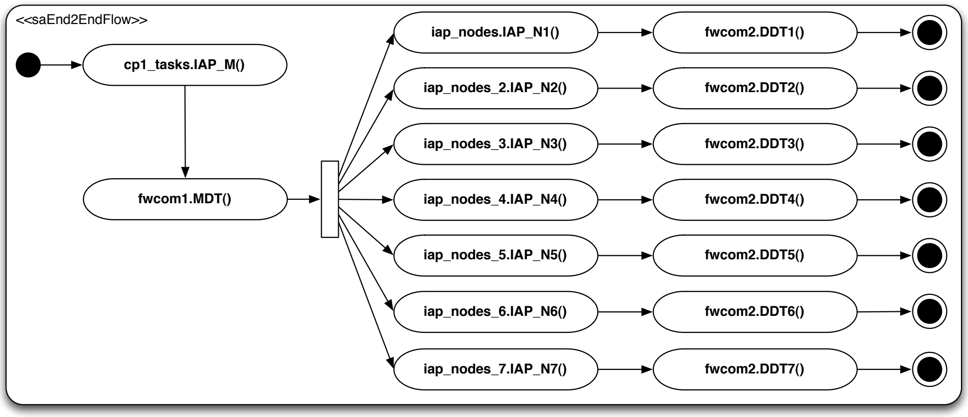

Fig. 8. Sending of the setpoint values to the DSPs

on UML design models possible and to limit the effort for a developer to get feedback concerning the timing/scheduling behavior. We have demonstrated this transformation on a parallel robot controller of our CRC 562. Further steps would be to create more model transformations for other non-functional parameters to corresponding analysis tools.

Another extension of this approach would be to describe a method how to create the scheduling analysis view and how to add the necessary and typically missing parameters to this view to make a scheduling analysis possible (we have made first approaches in [16] and [17]). It is also possible to integrate further tools into the method (e.g. aiT [18]).

Furthermore, a method to help finding the bottleneck if an analysis fails would be of great benefit.

Abstract—**The paper is an attempt to interest the reader how to control real-time mechatronic systems under the MS Windows operating system. The authors refer to solutions that combine a software part and a hardware using the FPGA technology, together forming a comprehensive platform for the control purposes in the real-time. The main emphasis is placed on the authors' own designs and constructions. Lectures and laboratory experiments must be conducted hand in hand. Such is the message to facilitate the *Automatic Control* education. Research works have been carried out in the Department of Automatics at the University of Science and Technology (AGH).**

I. Introduction

THE paper presents important aspects of education provided with the use of laboratory experiments. How to facilitate the teaching of control theory which can not go without a control experiment performed in the real-time? Researcher, scientist, teacher, engineer should use the laboratory computer controlled systems. That is the systems that we create and by which we teach young people. These systems are the subject of further considerations. The work focuses on:

❍ development of software to enable a control in real time involving a popular MS Windows operating system,

❍ construction of simple and also advanced mathematical algorithms for control purposes in the real-time,

❍ implementation, verification and tests of the developed algorithms in the self-designed and constructed complete mechatronic systems such as: the gantry crane, tower crane, magnetic levitation, magnetic bearings, anti-lock braking system, pendulum on a cart, the multi tank, etc.,

❍ usability of the same software and hardware platform to perform simulations and real-time experiments.

While teaching the automatic control it is reasonable to intertwine lectures and laboratory experiments. In particular this field of knowledge requires to be exposed through demonstrative laboratory tools. A prominent pedagogue equipped only with chalk and his knowledge can be under a misapprehension that a pure theory presented at the lecture is just what was expected by the audience. In fact, such a lecture may become as interesting as watching grass grow. One has to be far from impression that he is just presenting electro-mechanical toys in motion even quite complex due to involved preprogrammed control algorithms. In fact, one may notice a smell of mechatronic systems and it is not bad. However, our address has a different goal, namely how to facilitate the automatic control education.

II. Real Time Control

A. Real-time services in MS Windows systems

MS Windows can not be considered as robust hard real-time operating systems. However some features of the system can be applied to develop a soft real-time platform. The main parameter of the real-time control systems is the sampling time period – its maximum frequency and accuracy. The timing services built into the MS Windows systems are:

❍ system timer message (WM_TIMER),

❍ multimedia timer events,

❍ kernel mode services. The RTWT kernel driver is considered in this comparison.

The system timer is posted to a thread's message queue when a timer expires. The minimum sampling period of this service is 1 millisecond. In fact, the system processes the WM_TIMER message at low priority influencing the performance. Also, the minimum sampling in multimedia services is 1 ms. But the performance, considered as the timer jitter, seems to be much better. The best performance, both in the sampling period and the jitter, is achieved by kernel mode services.

Fig. 1, presents the histograms of three services. In all cases a 10 millisecond timer event has been started. The horizontal axis presents the duration of the sampling period. The duration was measured by a hardware timer with a 25 ns resolution. The vertical axis shows the number of sampling periods of a given duration.

One can observe that the WM_TIMER service behaves in a very poor way. The period was set to 10 ms but most of the sampling periods last much longer. Even a 260 ms period was observed. It is unacceptable for electrical and mechanical control systems. On the opposite side of the time regimes appear the RTWT service. Here the accuracy and jitter of the sampling periods i less then 15 ms. The multimedia timer can be located as an in-between solution. The

This work was supported by AGH. Project no. 11.11.120.768

average value of the sampling period follows the timer period setup, but a few millisecond jitter can be observed as well.

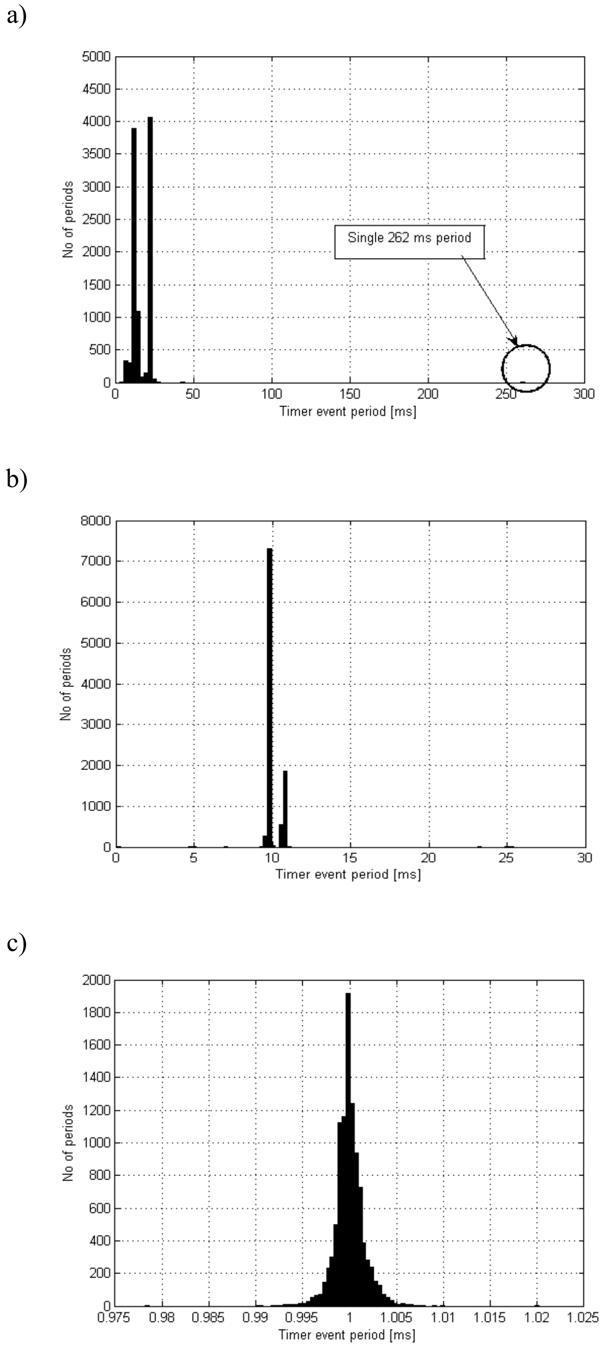

Fig.1. Histograms of the durations of the timing services: a) WM_TIMER, b) multimedia, c) RTWT timer

The timer services are executed in interrupt mode between operating system services and usually are not allowed to call all operating system functions. In the investigated timers the exception is the WM_TIMER procedure, where any OS call can be executed. The multimedia service disallows call only to a very limited set of OS functions. Such API functions like file I/Os, network functions or access to the USB stack, which are crucial to applications of measurement and control systems, can be executed in a timer service routine. The most restricted policy enforces RTWT timer. In this case the timer routine is executed at the kernel level and most of the OS API function may crush the system. The RTWT platform can be applied to cooperate with I/O boards plugged-into PCI or ISA buses but Ethernet or USB devices are unavailable.

Some functions of the control system may require a reaction faster than the response time of the presented timers. An interface to incremental encoder of safety functions can be given as an example. In such a case an additional hardware has to be used. The FPGA technology seems to be an ideal solution due to its flexibility.

III. Hardware implementation

A. RTDAC-Board

Standard PC computers are used most often as a control hardware in educational field. This solution has some advantages and disadvantages. The most important disadvantage is that PC hardware is not dedicated for control application. In most cases an additional hardware is needed. A control and/or measurement PCI or USB board is a good choice for educational usage. Control and measurement board should provide some basic features like analog inputs, analog outputs, digital inputs, digital outputs and communication with computer operating system. Some extra features e.g., incremental encoders counters are necessary for special mechatronic system like Inverted Pendulum or Crane.

Typically control and measurement hardware is used with many dynamical systems. This is the reason, that some kind of reconfigurability of the measurement board is necessary. This feature can be provide by using FPGA techniques. One of the FPGA control board is RT-DAC4/PCI [5] presented in Fig. 2.

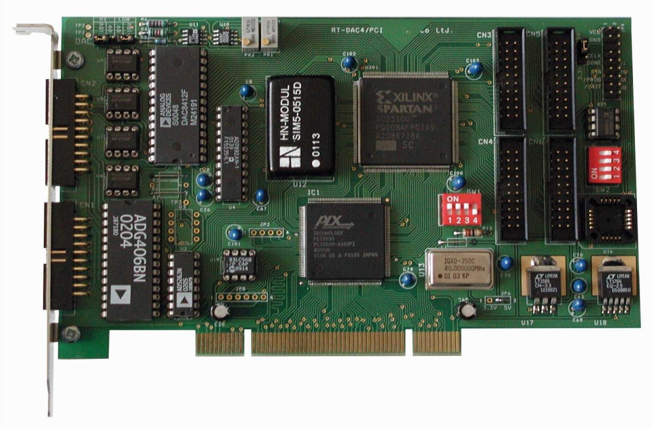

Fig. 2. RT-DAC PCI I/O board

The block diagram of this board is presented at the Fig. 3. The FPGA circuit can be reprogrammed from the PC computer level. This unique function guarantees flexibility of the device and a whole control system. User can manage configuration of the FPGA circuit by special software executed in the PC computer. Hardware functions can be modified by changing FPGA configuration.

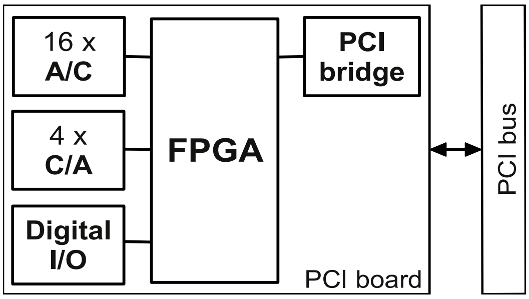

Fig 3. RT-DAC4/PCI block diagram.

FPGA control and measurement boards can work in three main modes that can be changed by reprogramming FPGA.

1. Basic mode. In this mode the board is equipped only with elementary functions. They support only simple operations with analog to digital and digital to analog converters and digital I/Os.
2. Advanced measurement mode. In this mode, the board is equipped with analog I/O operation functions, digital I/O operation functions, and some advanced measurements and control signal operation functions like incremental encoder counters, PWM functions, digital filter blocks, linearisation operation for analog signals. The control loop is closed by PC computer in this case. A designer can save additional processor time for calculations of the most advanced control algorithms in the computer by moving some operations from the software layer (PC computer control task) to the hardware layer (FPGA circuit).
3. Hardware control mode. In this type of operation the hole control task is located in the hardware layer. This is useful for time-critical dynamical systems. A high-speed control system is necessary in this case and PC computers are to slow to execute control tasks [9][8]. In this mode, only monitoring and supervisory operations are performed in a PC computer. Hierarchical high-speed control system can be also build with measurement and control board equipped with FPGA circuit. Direct control algorithms can operate in a hardware layer (FPGA) and optimisation or adaptation algorithm can operate in a software layer (PC software).

B. *Power Interface*

The power interface is an electronic device that provides connections between mechanical system and the controller (computer, PLC, microcontroller etc.). The typical structure of the power interface is shown in Fig. 4. It contains:

❍ power controller to activate the actuators,
❍ electronics for measurement signal conditioning,
❍ other electronics including optical insulation, protection against overvoltage and short circuit.

The main function of the power controller is to guarantee the required current and voltage range for actuators (DC motors, valves). The power controller operating in the PWM mode utilizes integrated bridge circuits supported by a control logic and protection system. Current and temperature are measured by integrated sensors. Depending on the controlled systems is used from one (the cart & pendulum case) to four (the tanks case) power modules. The power module provides required by the actuators voltages in the 12-24 V range and currents up to 16 A (the ABS case).

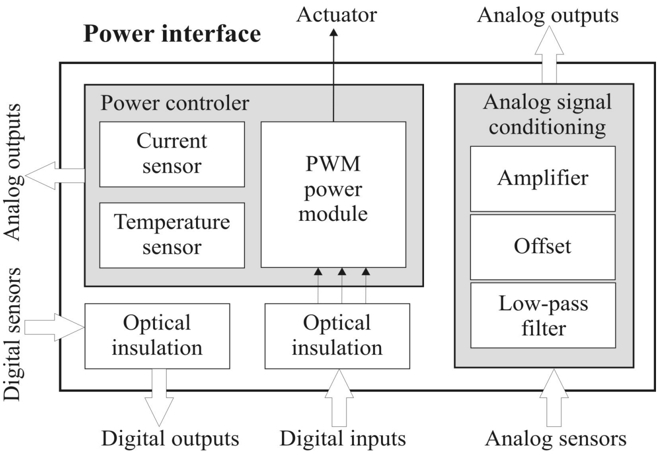

Fig. 4. Structure of the power interface

The analog sensors are connected to conditioning analog circuits. They provide the required measurement signal properties for a high quality A/D conversion. The analog signal conditioning block has an independent bipolar stable supply. Analog output signals from the conditioning block can be established as a unipolar or bipolar in the 0-10 V or ±10 V range respectively. These circuits are utilized to:

❍ increase or decrease the amplitude of the signal,
❍ filter the signal,
❍ decrease the signal output impedance,
❍ reduce the measurement signal bandwidth,
❍ provide a variable gain and offset control.

Optical insulation is used to protect the external I/O interface from overvoltage and overcurrent. It also provides a matching voltage levels.

In addition to these electronics circuits, power interface may also contains circuitry to handle voltage, pressure and strain gauge sensors.

The following sections present implementations of mechatronic systems that use the hardware just described.

IV. One Rotor Aerodynamical System (ORAS)

ORAS shown in Fig. 5 is a laboratory set-up designed for control experiments performed in the real-time. In certain aspects its behavior resembles the special type of one rotor helicopter. From the control point of view it exemplifies a high order nonlinear system with significant cross-couplings. ORAS consists of a beam pivoted on its base in such a way that the beam can rotate freely both in the horizontal and vertical planes.

At the end of the beam there is the rotor driven by a DC motor. The rotor position can be changed by the geared DC motor (see Fig. 6 and 7).

The state of the beam is described by four process variables: horizontal and vertical angles measured by encoders, and two corresponding angular velocities. Two additional

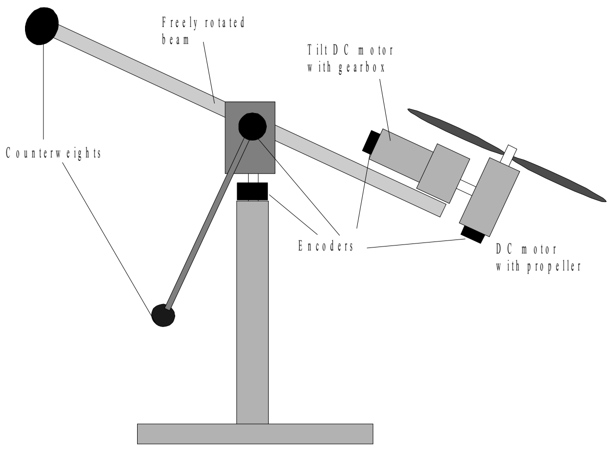

Fig.5 **O**ne **R**otor **A**erodynamical **S**ystem

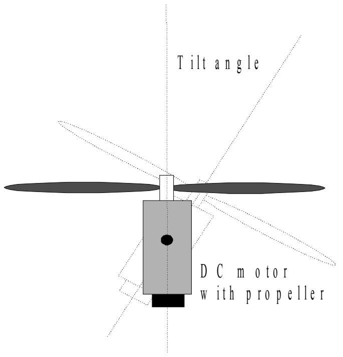

Fig. 6 Propeller tilt angle

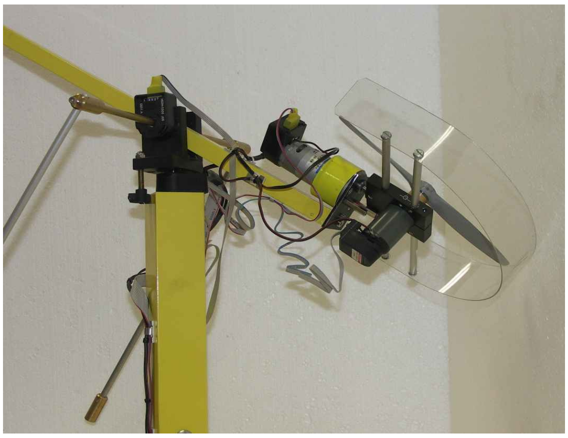

Fig.7 Laboratory set

state variables are the angular velocity of the rotor and the tilt angle. The ORAS system has been designed to operate with an external, PC-based digital controller. The control computer communicates with the position, speed sensors and motors by a dedicated I/O board and power interface. The I/O board is controlled by the real-time software which operates in the MATLAB/Simulink RTW/RTWT environment.

V. Tower Crane

Fig. 8 illustrates a general view of the model. The crane may hoist or lower a suspended payload and also move the payload along the rail and around the basis. The crane is controlled in the real-time in the MATLAB & Simulink environment [6][7].

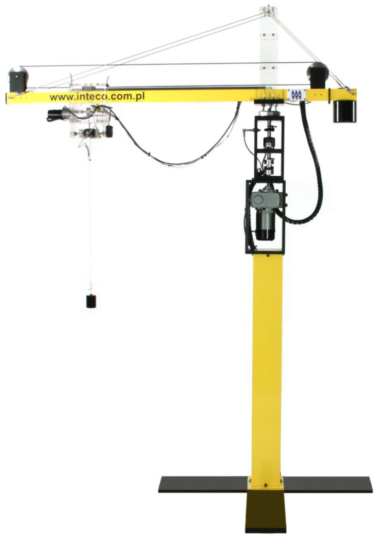

Fig. 8 General view of the tower crane

A PC computer is equipped with an analog-digital board (RT-DAC USB [5]) to transfer data between the tower crane and a controller running on the PC. Digital outputs of RT-DAC are connected to the crane power interface, where the calculated by the control algorithm value of control is converted into a PWM type voltage signal and then distributed to one among three DC-gear motors.

There are two encoders mounted on the shafts to measure rotary positions. Subsequent two encoders are placed in the trolley mechanism for measuring a deviation of the rope from the vertical position. The measurements are performed in two planes (see Fig. 9). The third gear motor is placed directly inside the crane body. The shaft that transfers the motor torque is equipped with the next encoder that measures rotary position of the crane arm with respect to the basis. The Simulink driver has three inputs: XPWM, TPWM and ZPWM to control three motions: a trolley progressive, crane rotary and payload up or down. The control values may vary from 0 to 1. The value 0 refers to no control, value 1 means full control. The control is the PWM type. A value between 0 and 1 refers to the duty cycle of the control square wave. The switch “Reset” sets the encoder counters to value 0. It is used for calibration purposes.

There are five outputs: *X Position* is the trolley position related to the jib length, *T Angle* is the jib angular position related to the crane basis, *Z Position* is the rope length of the suspended payload, *X Angle* is the angle deviation of the

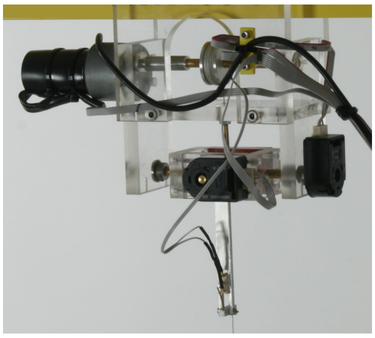

Fig. 9. Tower crane trolley

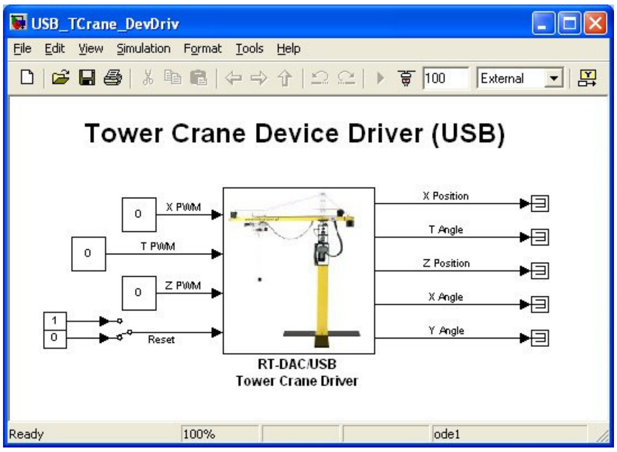

Fig. 10. Tower crane Simulink device driver

payload in the jib plane, *Y Angle* is the angle deviation of the payload in the plane, directed perpendicularly to the jib.

The laboratory model is not a copy of any existing industrial tower crane. It is a tool for research to examine phenomena that occur during motion of a suspended payload and to design control algorithms assuring a safe transport.

VI. Active Magnetic Levitation Systems (AMLS)

AMLS [14] represent structurally unstable systems where the system dynamics is adjusted by the operating controller. The performance of the controlled AMLS depend on the applied hardware and realized control strategy. A key point is to satisfy real-time conditions that allows to close the control loop with frequencies higher than 200Hz depending on the applied hardware and control tasks. Nowadays, AMLS are controlled in the digital form usually, where a number of hardware-software architectures is used, to satisfy mentioned requirements. The real-time controller processing time, computational effort and numerical representation of the processed digital system must be considered for the real-time application.

The AMLS candidates are available now in two designs: single and dual electromagnet (Fig. 11). Both of them contain the electromagnet, ferromagnetic object, position sensors, signal conditioning unit and power interface. The electromagnetic actuator is driven by PWM or current controller. In the first case the high frequency voltage signal is applied to the coil, while in the second one the coil current is kept at the desired level by the hardware current feedback. Both solutions affect the real-time control architecture. For the current driven systems the lower sampling frequency (200-400Hz) allows to control the AMLS using UBS based board [5]. The AMLS are connected to the PC via PCI based board usually equipped with the FPGA unit where the custom logic is implemented [5]. For the real-time control purposes the parallel signal processing board has been developed. The real-time control system performance can increase due to the parallel sampling. [10].

The basic principle of AMLS operation is to control an electro-magnet to keep a ferromagnetic object levitated. The object position is determined through a distance sensor or state observers. The equilibrium stage of two forces (the gravitational and electro-magnetic) has to be maintained by the controller to keep the sphere in a desired distance from the magnet. A number of real-time controllers has been developed to realize stabilization, program system dynamics (see Fig. 13), tracking and satisfy robustness.

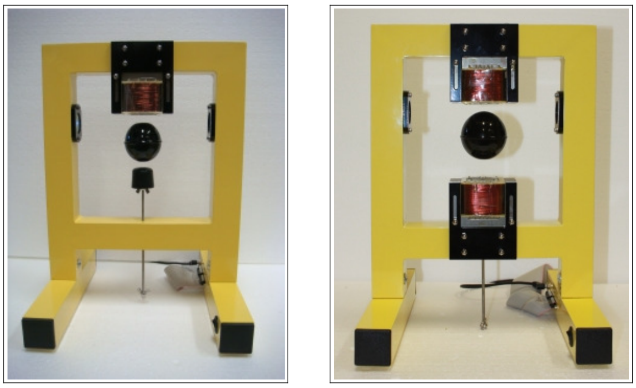

Fig. 11. AML Systems in a single and dual electromagnets versions [3].

From the real-time control point of view a time slot reserved for the application controller vary with respect to the controller architecture. The computational effort, control algorithm structure and numerical representation limit the execution time. For example a nonlinear robust fuzzy based controller [12] consumes more processing power that self tuning neural controller [11] and optimally tuned PID. The dual electromagnets AML can be used to check performance of the real-time controller. The lower electromagnet suits as an extra excitation signal (see Fig. 13) or increases the electromagnetic forces to speed up the system dynamics. The digital hard real-time realized in the form of custom FPGA embedded PID controller is mostly limited by the A/D converters speed. For the analog sampled hard-real time control the Dynamically Programmable Analog Signal Processor has been applied [13]. This solution allows to process sampled analog signals with tunable option of gains fast sampling rate up to 2MHz limited by the controller architecture.

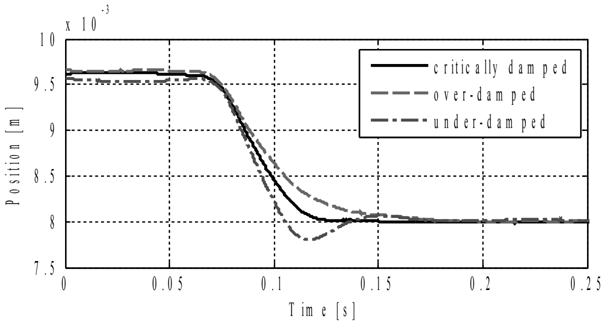

Fig. 12. Programmable dynamics of the AML System

AMLS are one of best tools to learn the control theory and real-time control due to the time-critical execution requirements of AMLS and its dynamics programming ease. Note, that limits of the real-time control systems or limited sampling frequency could make the system unstable.

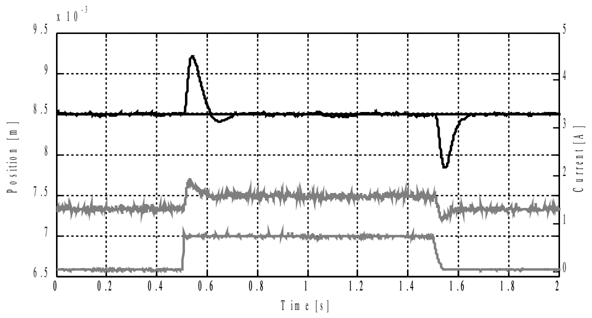

Fig. 13. Object stabilization at external square pulse excitation realized by the lower electromagnet [11]

VII. Multitank system

The Multitank System consists of three water tanks placed above each other (Fig. 14). The uppermost tank is rectangular, the middle one is prismatic and the lowest is a quarter of a cylinder. The first tank thus has a constant cross section, while the cross sections of the two others vary with the water level. Water is pumped into the upper tank from a supply tank by a pump driven by a DC motor. The water flows out from the tanks only due to gravity. The orifices act as flow resistors. The outflow rate from each tank can be adjusted by a manual valves or proportional.

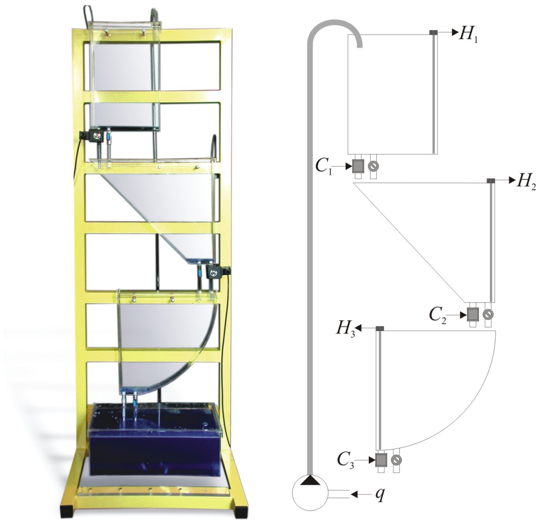

Fig. 14. General view of the tanks system

The levels in the tanks are measured with pressure transducers, which offers analog (0-10) V or digital interface (frequency signal from 100-200 kHz). The speed of the pump motor and proportional valves are controlled by PWM signals via power interface [4].

The goal of the Multitank System design is to study and verify in practice linear and nonlinear control methods. The general objective of the control is to reach and stabilise the level in the tanks (mainly the lower tank) by an adjustment of the pump operation or/and valves settings. The other control problems are: minimizing of the fluid level oscillations and stabilization of the outflow from the tank. These control problems can be solved by a number of level control strategies ranging from PID to adaptive and fuzzy logic controls [1][2].

The Multitank System has been designed to operate with following hardware control platforms:

❍ PC-based equipped with dedicated I/O board,

❍ PLC/PAC controller provided with PWM generator and analog (or high-speed counter) input modules,

❍ other FPGA/microcontroller based platform able to measuring analog or high-speed frequency signals and generating PWM signals.

Such a platform works as an external controller. The control system communicates with the level sensors, valves and pump by a dedicated I/O interface and the power interface.

The mathematical model of the process can be obtained by means of mass balance [15]:

$$\frac{dH_1}{dt}=\frac{q-C_1\sqrt{H_1}}{\beta_1(H_1)} \quad (1)$$

$$\frac{dH_2}{dt}=\frac{C_1\sqrt{H_1}-C_2\sqrt{H_2}}{\beta_2(H_2)} \quad (2)$$

$$\frac{dH_3}{dt}=\frac{C_2\sqrt{H_2}-C_3\sqrt{H_3}}{\beta_3(H_3)} \tag{3}$$

where: H_1, H_2 and H_3 are the water levels; $\beta_1(H_1)$, $\beta_2(H_2)$ and $\beta_3(H_3)$ are the cross sectional area of the tanks; C_1, C_2 and C_3 are the outflow coefficients and q is the flow into the first tank (control variable). The tank cross sectional areas are:

$$\beta_1(H_1)=a\cdot w \tag{4}$$

$$\beta_2(H_2)=w(c+b\frac{H_2}{H_{2\max}}) \tag{5}$$

$$\beta_3(H_3)=w\sqrt{R^2+(H_{3\max}-H_3)^2} \tag{6}$$

where a, b, c, w, $H_{2\max}$, $H_{3\max}$ and R are constants. The control and state components are bounded:

$$0\leqslant q(t)\leqslant 200\,cm^3/s \tag{7}$$

$$0\leqslant H_1(t),H_2(t),H_3(t)\leqslant 40\,cm \tag{8}$$

For the model (5), for fixed q=q_0 we can define an *equilibrium state (steady-state points)*, given by:

$$q_0=C_1\sqrt{H_{10}}=C_1\sqrt{H_{20}}=C_1\sqrt{H_{30}} \tag{9}$$

Figure 15 shows the equilibrium states for the real tank system.

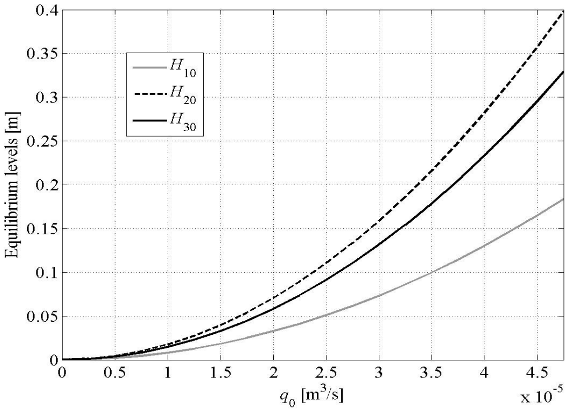

Fig. 15. Equilibrium levels for real system

Several issues have been recognised as potential difficulties for a high accuracy control of the tanks level or flow:

❍ nonlinearities caused by the tank shapes, the valve geometry and flow dynamics, the pump and valves input/output characteristic curve,

❍ state constraints, introduced by the maximum and minimum allowed levels in the tanks.

VIII. Pendulum on a cart system

A favourite laboratory system is the pendulum on a cart (see Fig. 16). We may have a lot of fan while experiment with it.

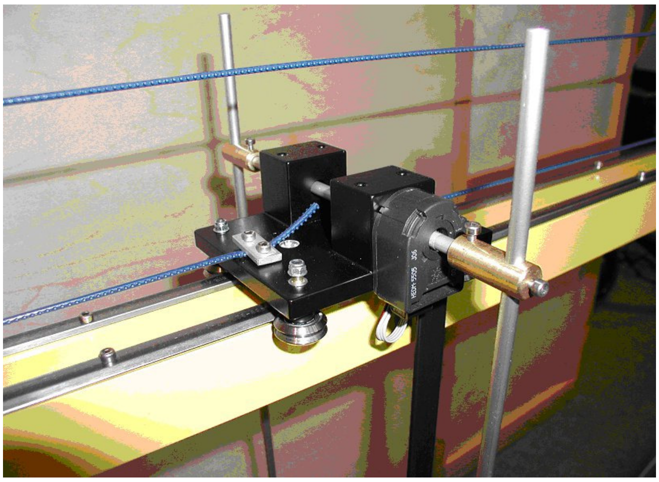

Fig.16 Pendulum on a cart system

To swing and to balance the pendulum the cart is pushed back and forth on a rail of limited length. The purpose of the control algorithm is to apply a sequence of forces of constrained magnitude to the cart such that the pendulum starts to swing with an increasing amplitude and the cart does not override the ends of the rail. The pole is swung up to achieve a vicinity of its upright position. Once this has been accomplish, the controller is maintaining the pole vertical and is bringing the cart back to the center of the rail. The pendulum in its upright position behaves as a circus acrobat. We have to be aware also that this non-trivial fourth order, unstable mechanical system can be used to conduct very serious research corresponding to the complex time-optimal control algorithm. To facilitate education does not mean to give a facile example. Hence, a short presentation of time-optimal and rule-based controls is shown.

The time-optimal controller requires analysis and synthesis based on a mathematical model [16][17]. The approach is laborious and time consuming. However, the good quality of control can be a reward. The so called canonical equations – state (forward) and conjugate (backward) – are solved. A variable parameter optimization method is used. The horizon, a number of switchings and the sign of the first "bang-bang" control are the variables of the quadratic performance index. A final snapshots of the state trajectories, control and anti-gradient of the performance index corresponding to the numerical optimization are shown in Fig. 17. The numbers correspond to the following variables: 1 → x_1 is the cart position with respect to the rail center, 2 → x_2 is the angle between the vertical upright direction and a current angular position of the pendulum, 3 → x_3 is the cart velocity, 4 → x_4 is the pendulum angular velocity, 5 → u is the control force acting horizontally on the cart and 6 → ψ is the anti-gradient of the performance index.

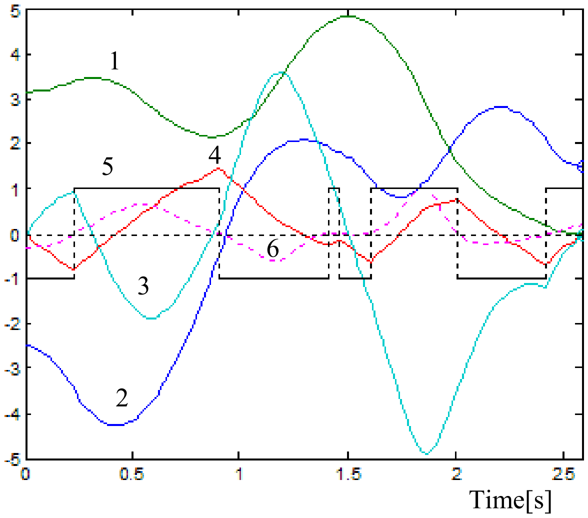

Fig. 17 The state trajectories, control and anti-gradient of the performance index at the end of the numerical optimization

The rule-based controller in a simple form is shown below.

```
                    Stabilization
If  $|x_2|-S<0$   Is pendulum in the stabilization zone?
   then  $u_r=K_1(x_1-x_1^f)+K_2x_2+K_3x_3+K_4x_4$
              Calculate an auxiliary linear control $u_r$.
    if  $|u_r|+F_s>u_{max}^{STAB}$   Does the auxiliary control plus
              friction exceed the limit?
    then  $u=u_{max}^{STAB}\operatorname{sign}u_r$   Calculate the ultimate control
                  that attains the limits.
    else  $u=u_r+F_s\operatorname{sign}u_r$   Calculate the ultimate linear
                  control contained in the limits.
   end
          Enlarging magnitude of the pendulum
elseif
   $\frac{1}{2}x_4^2+9.81\cdot 3.2(\cos x_2-1)>0$   Is pendulum kinetic energy
                  larger then potential energy?
  then u = 0   Set control to zero – perform soft landing in
               the stabilization zone.
  else
     $u=-u_{max}^{POST}\operatorname{sign}\left[x_4\left(|x_2|-\frac{\pi}{2}\right)\right]$   Apply the „bang-bang”
                  control to enlarge oscillations.
end
```

where: $K_{1,} K_{2,} K_{3,} K_4$ are constant gains, x_1^f is the final cart position, F_s is the static friction force and u_r is the auxiliary control.

Alas, rule-based control cannot predict the time-optimal strategy. In turn the time optimal control is sensitive to disturbances and without the soft landing (the control is set to zero when there is an excess of kinetic energy of the pendulum) it would be difficult to achieve the control goal.

IX. Conclusions

There are several critical terms to become an effective educator in the *Automatic Control* field. One must has access to facilities generally called mechatronic systems. Algorithms constructed on the basis of mathematical simulation models should be used in the same software environment to control the actual devices. It is a known complication of such a transfer, namely the real-time control regime. This is the biggest challenge in the education of engineers. It is satisfied mainly due to parallel (FPGAs) and software extensions.

Abstract*—This paper deals with possibilities of manual control of wheeled robots. The problem is tested on a robot-soccer application. The manual computer-assisted control module creates an interface between game controller and controlled robot. There are several ways of steering implementation. The simplest is a differential steering. The module currently uses semi-automatic steering which provides a capability to move with the robot as a point. This functionality requires interaction with vision system, usage of Kalman or similar filter and compensators. Next logical step is a fully-assisted steering. This steering system interacts with strategy and motion control module and provides additional functionality such as tracking the ball and shot. The objective is the control of many robots by only one player.

I. Introduction

The robot-soccer is a popular application that has ability to attract young people and to popularize technical branches on the faculties of mechanical engineering, electrical engineering and computer science. It is also used as a test bed to evaluation and testing of new methods, algorithms and solutions in different technical branches.

Current solution of robot-soccer application consists of the Vision module, the Strategy module (divided into Higher strategy and Motion control), the Wireless transceiver and the Communication module. The Communication module provides interface for distributed data exchange among the other modules of the system [1].

This paper describes the development of computer-assisted Manual control module as the part of the 3rd generation of robot-soccer strategy system for VŠB-TUO robot-soccer team. The module has been developed for two reasons – strategy testing against human opponents and for attraction of young people to study at technical universities.

II. Manual control module interface

The manual control module allows a player to control the robots using connected game controllers or joysticks. It cooperates with other robot-soccer modules so it makes an interface between the game controller and controlled robot.

A. Wheeled robot

The robot with basic parameters is in the Fig. 1. The relationship between velocities, angular velocity and radius of rotation is defined [2]

$$v=\frac{vl+vr}{2}\ ,\ \ \omega=\frac{v}{r}=\frac{vr-vl}{d} \qquad (1)$$

B. Game controller

After testing several types of controllers, the gamepad was chosen. It allows quick control of associated values.

The selected gamepad (Fig. 2) has

- 2 analog sticks
- 8-way POV (point of view) hat
- 12 buttons.

These controls can be utilized to comfortably support both left-hand and right-hand mode.

The position of main stick has coordinates $jx, jy \in \langle -1;1 \rangle$ in axis x, y respectively and button values $b_0, b_1, .. b_N \in \{0;1\}$.

III. Analysis of control methods

There are several ways of how manually control the robot – differential steering, semi-automatic steering, fully-assisted steering and group-assisted steering, from the simplest one to the most advanced.

A. Differential steering

The first generation of manual control used the simple differential steering. Its principle is based on direct

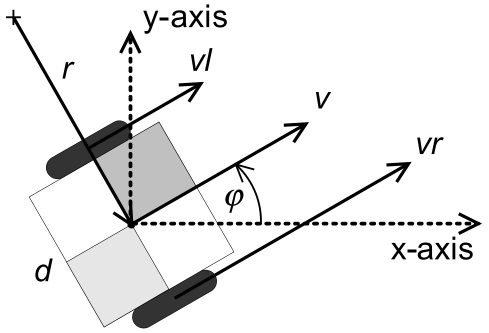

Fig 1. Basic motion parameters of the robot.

This work is being solved at the VSB-Technical University of Ostrava, Czech Republic. The project is supported by GAČR project 102/08/1429 and also by the internal grant SP/2010165 „Development and using new methods for design and realization of embedded systems".

Fig 2. Gamepad controller.

conversion of desired velocity v_d and angular velocity ω_d of robot into the movement of stick

$$jx=\frac{\omega_d}{\omega_{max}}\,,\ \ jy=\frac{v_d}{v_{max}} \qquad (2)$$

Than, the velocities of robot's left and right wheel are defined

$$vl=jy\cdot v_{max}-jx\cdot(\omega_{max}\cdot d)/2$$
$$vl=jy\cdot v_{max}+jx\cdot(\omega_{max}\cdot d)/2 \qquad (3)$$

This principle is shown in the Fig. 3. The computer-assisted control (CAC) block in this case is very simple and the control loop is opened. It leads to very difficult manual control of the robot to move it into desired position or orientation. Human is unable to both accurately and quickly control the rotation of the robot and to adjust its relative position. That is why this steering is unsatisfactory.

B. Semi-automatic steering

Current solution of the computer-assisted manual control is based on automatic control of the robot according to the desired direction and speed. This requires closer cooperation with the vision system. See the Fig. 4. The vision system supplies a position of the robot *rx*, *ry* in axis x, y of the playground and angular position *rφ*.

The objective of this control is to allow moving with the robot as it was a 2D point

$$jx=\frac{vx_d}{v_{max}}\,,\ \ jy=\frac{vy_d}{v_{max}} \qquad (4)$$

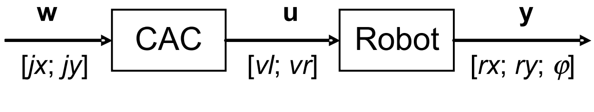

Fig 3. Schema of differential steering.

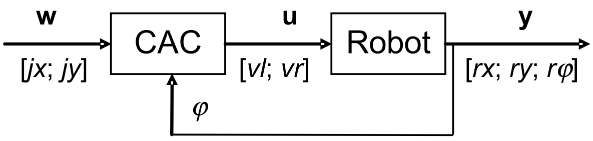

Fig 4. Schema of semi-automatic steering without filter.

where vx_d, vy_d are desired speeds along the axis x and y. There are two possible configurations, without a filter (Fig. 4) and with a filter (Fig. 5). The filter reconstructs the precise position and the speed of the robot. It also allows the CAC to compensate the error from the trajectory due to rotation of the robot. Currently, there is used an extented Kalman filter [1][3].

The schema of the CAC block is in the Fig. 6. Suppose that a player wants to move the robot to given direction with certain speed.

If the robot does not move it should first rotate around its vertical axis to a desired direction and then it should start moving with a desired speed. This will ensure following of a desired trajectory. This function is implemented in the Stationary rotation block. If actual velocity *v* of the robot is smaller than predefined minimum velocity v_0 and absolute value of angle error $\Delta\varphi$ is greater than a predefined maximum angle error $\Delta\varphi_0$ then desired speed v_d is zeroed. Simulated trajectories are shown in the Fig. 7.

If the robot is already moving, it is not possible to change the desired direction and to maintain the planned trajectory.

First, the robot has to rotate to the desired direction while it is still moving. Then it can gradually approach the trajectory that it would move as a mass point from the time of direction change in an ideal case. The tracking of ideal

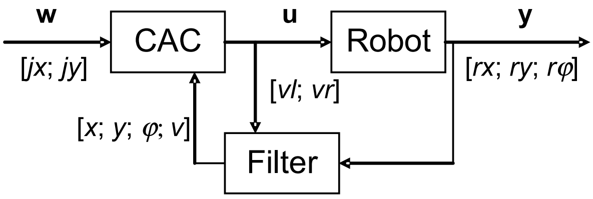

Fig 5. Schema of semi-automatic steering with filter.

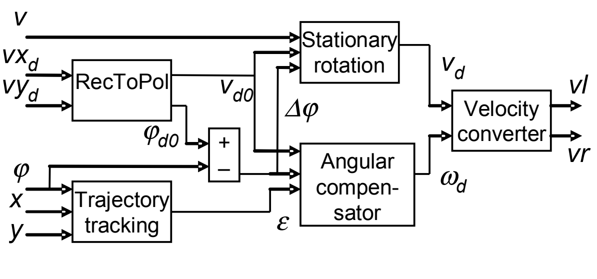

Fig 6. Schema of CAC for semi-automatic steering.

mass point is encapsulated in the Trajectory tracking block. The control requirements – direction (angle error $\Delta\varphi$) and position control (parameter ε) act against each other and this must be reflected by compensators design including system non-linearity and bounds of centripetal acceleration. The compensators are placed in the Angular compensator block. The Velocity converter block converts the pair of desired velocity v_d and angular velocity ω_d into the desired velocities *vl*, *vr* of left and right wheel. Simulated trajectories are shown in the Fig. 8.

If the robot is standing or moving, it is possible to invert the direction of robot. This reduces the required angle of rotation. This functionality is not shown in Fig. 6. If the robot is moving, the range of desired directions suitable for the inversion of robot direction is significantly lower. This is because gradual approach to the desired trajectory is more time efficient than stopping the robot and turning the direction of motion by 180 degrees.

C. *Fully-assisted steering*

This steering is next logical step in evolution of manual control module. See the Fig. 9. It requires cooperation with the Higher strategy and the Motion control module. The higher strategy controls all robots except the manually controlled ones and instructs them the desired positions and velocities [4]. The CAC block overrides the position and velocity for manually controlled robots. The motion control plans trajectory in real-time and controls position of the robots by changing the desired wheel velocity [5].

There are three modes of operation

- Free movement
- Tracking the ball
- Shot.

The free movement mode allows similar movement of the robot as semi-automatic steering. The difference is in this mode the robot will cooperate with other robots and avoid collision with them.

The tracking ball mode causes the robot to start catching the ball. It is activated by pressing the button b_0. If the stick is also applied, it controls the direction in which to meet the ball.

The shot mode makes the robot to shoot to the direction specified by stick.

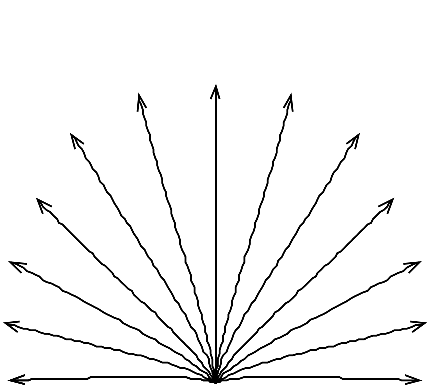

Fig 7. Robot trajectories for particular desired directions with step of 15 degrees and zero speed in the beginning.

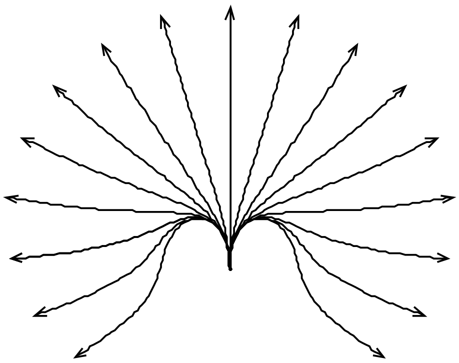

Fig 8. Robot trajectories for particular desired directions with step of 15 degrees and constant velocity.

D. *Group-assisted steering*

This steering will be the final extension of fully-assisted steering. The basic principle is same as previous except a fact that one player is controlling all of the robots.

Only one robot is controlled at the moment, so the capability of robot switching has to be developed. There are several possibilities of making such capability

- The robot nearest to the ball – the robot is selected automatically or by a button.
- Switching to a next robot – selection of the next robot in sequence.
- Select robot by POV-hat or stick – the robot is selected by analysis of current positions of robots on the playground.

It may be difficult for player to quickly recognize the selected robot on the playground. This can be solved by

- External lighting of the robot by LEDs.

IV. Additional functions

There are several additional requirements on the computer-assisted manual control. Some of them are general extensions, others are important for concrete type of steering.

A. Collision Detection

In the robot motion control, a collision detection is necessary. When a collision occurs, it leads not only to stagnation of the robot but it also causes that the underlying mathematical model of the robot gives false output. The model is part of the filter block in the motion control module and provides the predicted position and the speed of the robot based on control requirements. The information about collision can be used to the resetting of the model.

Another problem occurs if there is a permanent obstacle in the way. Then the described motion control is not able to react properly and rotate the robot. The solution is to stop the robot until it rotates and gets out of the collision.

Collision detection is performed in two ways

- A priori – detection is made on the basis of the position of the robot to known bounds (of the playground) and the direction of the velocity vector,
- A posteriori – detection is made on the basis of significant difference between the predicted robot position and its actual position.

B. Game controls

In addition to the control of the direction of the robot in two axes, there are more features important for the strategy testing. Some of these functions apply only on semi-automatic steering

- Acceleration – the possibility of a short-time increase of robot speed, this function is useful for shooting the ball.
- Brake – allows rotation of the robot in place.
- Tracking the ball – robot automatically targets towards the ball, allowing its easy hitting.

C. Force feedback

When the robot gets stuck, typically due to an impact of the robot or an attempt to pass through the barrier, the game controller vibrates strongly for a brief moment.

V. Conclusion

In this paper we described the Manual control module of the robot-soccer system. This module provides interface between the game controller and robot. Currently there is used the principle of semi-automatic steering, which is the step between the simple differential steering and the fully-assisted control method. The manual control module also uses additional functions as the collision detection and force feedback. Next research will focus on design of fully-assisted control. The requirements for the upcoming CAC methods were also described.

Abstract— **The deployment of IEC61850 standard in the world of substation automation system brings to the use of specific strategies for architecture testing. To validate IEC61850 architecture, the first step consists in validating the conformity of the object modeling and services implementation inside devices. The second step consists in validating IEC61850 applications compliance according to the project specifications. A part of the architecture can of course be tested "physically"; however in the design phase or when the actual architecture cannot be checked directly, modeling is helpful. In our research study we propose a co-simulation approach based on several components allowing the realization of advanced tests. This paper describes the need and the design implementation of software and hardware in the loop components as well as the object modeling concept of IED models**.

I. List of Abbreviation

The following table 1 contains the definition of acronyms used in this paper.

Table I.
Abbreviation List

Acronym	Definition
IED	Intelligent Electronic Device
SAS	Substation Automation System
FAT	Factory Acceptance Test
HITL	Hardware In The Loop
SITL	Software In The Loop
UCAIUG	Utility Communications Architecture International Users Group
GOOSE	Generic Object Oriented Substation Event
MICS	Model Implementation Conformance Statement
PICS	Protocol Implementation Conformance Statement
ICD	IED Configuration Description
MX	Measurand analogue value X
SCL	Substation Configuration language
RTG	Run Time Generation

II. Introduction

In the early 1990s communication technologies and protocols began to appear in SAS application. In 2004, a new worldwide standard of communication IEC61850 was introduced in the majority of substation automation systems carrying out new innovation prospects. The interoperability between devices from different manufacturers as well as the insurance of the overall security of SAS architecture through its communication network becomes now attainable with this new communication standard [1]. In addition, object data modeling is used inside IEC61850 equipments to replace the aspect of non significant addresses. The standard provides a stack of services in order to obtain a self description of the internal objects and communication capabilities of the device; this leads to reduce the time of developing supervision control and data acquisition applications.

IEC61850 authorizes the distribution of functionalities between devices. This aspect permits the exchange of real time inter-equipment messages over the communication network to provide advanced services for electrical substation process which was done previously via hardwiring (e.g. interlocking, load shedding, auto transfer switch, etc...). The real advantage behind consists in reducing the amount of cables inside a substation which can be very long due to the distance between the substations (i.e. installation price). However this new aspect of configuration relies on a peer to peer device messages sent over the communication network. Thus it must be well verified before any implementation [2].

Being the unique standard used in the SAS network, devices from different manufacturers are be able to dialog in order to exchange information and services. This feature brings to the engineering staff more liberty in choosing their IED (e.g. protection relay, power meter …). However, the heterogeneity of IEDs inside SAS architecture yields complexities to the FAT which becomes difficult to realize due to the dispersed location of the switchboards suppliers. An exhaustive FAT must be provided with each project development in order to minimize time of site commissioning. This point is an essential key demanded by the end users.

End Users must have a realistic view about the demanded SAS architecture tests according to their desired requirements. Thus they should comprehend the limitation scope of the conformance tests provided by the international certification organizations such as Kema [3] versus a complete successful implementation of IEC 61850 SAS architecture which should be well coordinated by all involving parties.

This work was supported by Euro System Company and GIPSA Laboratory

III. Limitations Scope of Standard Certification Tests

A generic testing plan for an IEC61850 SAS architecture shall include four testing categories: the conformance testing of a device, the distributed functionalities testing, the interoperability testing and the global system performance evaluation [4]. Witness and hold points shall be specified in the testing plan for carrying out inspections that verify the quality of tests.

UCAIUG has established a conformance testing program for IEDs which permits the certification of the internal object data modeling, communication oriented services and the global configuration online testing.

These conformance tests could be considered as parts of the device conformance testing. Therefore distributed functionalities, interoperability and global system performance evaluation tests are still left unanswered. Guidelines are given by the international certification organization to accomplish these advanced tests.

New tools and advanced models should be provided to fill the gap of tests. These tools should also permit the cohabitation of real devices of a switchboard supplier with virtual device of the missing switchboard to ensure an advanced FAT in a heterogeneous SAS architecture.

Based on the guidelines of advanced tests proposed by international certification organization, our work deals with a Co-Simulation Platform to accomplish a complete IEC 61850 advanced test. This platform is constituted of a simulation software and other additional components. Virtual IEDs will be modeled inside the simulation platform by implementing real communication IEC61850 services and data objects. The additional components are used in order to ensure the overall utility of the simulation platform. As shown in Fig. 1 additional component are divided into three categories: the standard simulation configuration component, external process interface component and Hardware in the loop component.

The major purpose of the Standard simulation configuration is to generate and configure any IED model by importing its device configuration file. Using this component our simulation platform will be able to simulate an heterogeneous architecture containing IEDs from different suppliers.

In this paper we show the purpose and the implementation detail of the external process interface and hardware in the loop component.

IV. OPNET Network Simulator

Modeling and simulating a networked system requires a network simulator that takes into account all major contributions including protocols, medium access control technology, network load, communication imperfections, timeouts and packet losses etc. Popular network simulators include NS2, OMNET, Qualnet, OpNet etc. OpNet Modeler is chosen in our research because it implements a large number of libraries of standard equipment (e.g. switches and link models) as well as proprietary models, which is useful for simulation and reduces the development time [5]. Object oriented modeling approach fitted into many programming editors is used in OpNet in order to facilitate the construction of models (Fig. 2).

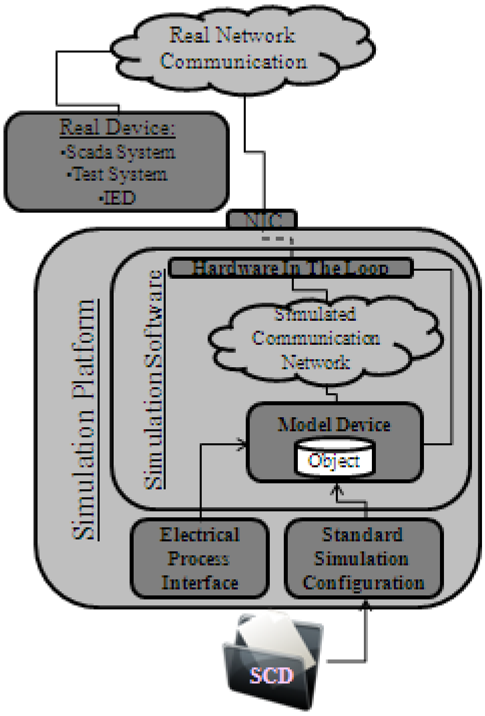

Fig. 1 Co-Simulation platform architecture

A network device is modeled as a node which is composed of many modules connected by packet streams or static wires. Each module aims to represent specific aspect of the node's behavior such as data creation, data storage, data processing or routing (IP layer), data transmission (Transport layer), etc. Thus the modeling of each layer of the TCP IP stack is made in OpNet modules.

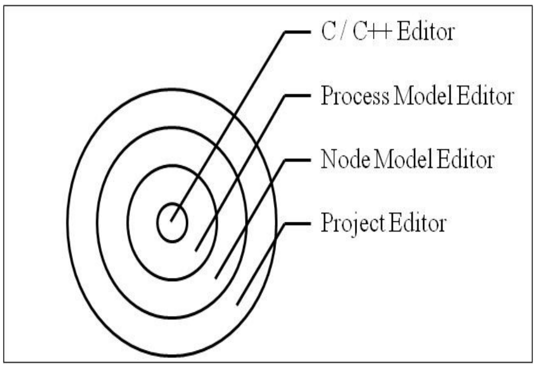

Fig. 2 Simulation software editors

The process is programmed using the finite state machine (FSM – Technology). This approach facilitates the supporting of the implementation of applications, algorithms and queuing policies. States and transitions graphically define the progression of a process in response to events. Each state in process model contains embedded C/C++ code, supported by an extensive library of functions designed for network programming.

Two kinds of states are used in OpNet Modeler: red states and green states.

A red state in the process model is an unforced state. Unforced states allow a pause between the enter executives and exit executives, and thus can model true states of a system. After a process has completed the enter executives of an unforced state, it blocks and returns control to the previous context that invoked it. When an interrupt occurs and invokes the process, the exit executive will be treated as well as the test of the transition to the next state.

A green state in the process model is a forced state. Forced states are so called because they do not allow the process to wait. In other words, the exit executives of a forced state are executed by a process immediately upon completion of the enter executives.

V. Co-simulation Components

This paragraph shows the importance of the presence of the external process interface and the hardware in the loop components inside our Co-Simulation platform in different phase of IEC61850 project.

A. *Typical architecture of an IEC 61850 switchboard under test*

Each IEC61850 server (i.e. device or model) is delivered with its Model Implementation Conformance Statement 'MICS' and Protocol Implementation Conformance Statement 'PICS'. MICS documentation describes the capabilities of the device in term of functionalities described in object format. However PICS is another documentation which describes the IEC61850 services supported by the device. The conformance tests of a device [6] is based on tests that cover the conformity of object data modeling as well as the conformity to IEC 61850 Abstract Communication Services Interfaces 'ACSI' according to PICS and MICS documentations.

Three types of services can be found inside each IEC61850 server:

- Client/Server pooling services which are initiated by the IEC61850 client.
- Peer To Peer services (via IEC61850 GOOSE message). These services are generated by the server on event. It provides the sharing of functionalities between devices.
- Reporting services which are heavy load generated periodically or on event by the server. This kind of services permits to decrease the network load by reducing the number of pooling services.

It is shown in Fig. 3 an image of a typical IEC61850 future substation. The substation is divided into three switchboards including each a group of IEDs coming from different device supplier. The switchboard S1 is the one under test inside S1 factory placement. The switchboard S2 shares functionalities with the switchboard S1. This switchboard is considered absent in our architecture for the fact that it comes from another device supplier. The last switchboard S3 doesn't share any functionality with the other switchboards but is connected to the same communication network. IEDs of the switchboard S3 are also missed during FAT of S1 thus it can be considered that all physical IEDs that belong to S2 and S3 will be replaced by their models inside the simulation platform.

In order to validate the functionalities of the switchboard S1 two different kinds of tests should be provided:

- Test of the functional part of the switchboard's IED,
- Test of the communication part of the switchboard's IED.

Functional part aims to test all the protection and control parameters of IED inside S1. This is done by connecting an electrical process board to S1 and injecting the process values on the inputs of its IEDs.

The most critical point in the communication test consists to verify the exchanging of peer to peer messages between switchboards that shares functionalities. Therefore three different tests should be provided:

- Testing the publisher part of the peer to peer messages from the switchboard S1 to S2 according to the configuration of S1 IEDs.
- Testing the subscriber part of peer to peer messages from S2 to S1 which consists to verify that the IEDs inside S1 accept the peer to peer messages coming from the S2.
- Verifying that the end to end time of the peer to peer message doesn't exceed the time specified in the specification of the project.

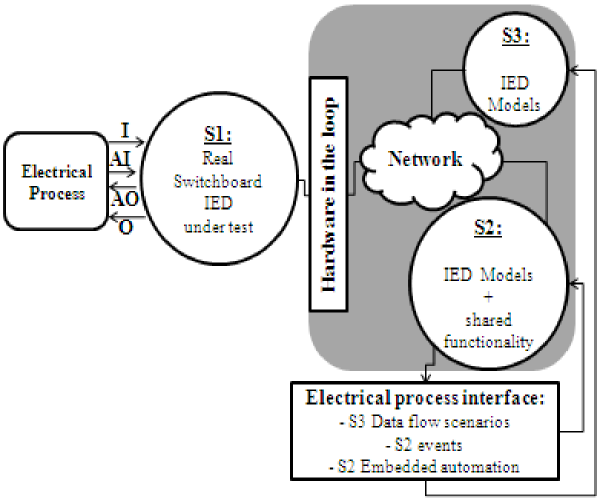

Fig. 3 Typical IEC61850 architecture under test

B. *Hardware and software in the loop during FAT*

To test the publisher part of S1, an electrical process board must inject real inputs to the IEDs inside S1 in order to publish the peer to peer messages. Hardware in the loop component is developed in our study in order to route the real network message from the real world into the simulation platform. Once arrived to the simulation world, the peer to peer message enters the simulation network and reaches at the end to the virtual IED subscribing to this message.

In the factory acceptance test stage, a punctual study of the end to end time parameter of the peer to peer messages must be given for the reason that these messages are used to solve time critical electrical applications. The dynamicity of this parameter comes from the network delays due to the data flows sharing the same network. Real IEC61850 data flows scenarios must be generated as configured inside the IEDs of S1, S2, and S3. Therefore it is crucial to have an electrical process interface inside the simulation platform which corresponds to the electrical process board inside the real world. This component is connected to the simulation platform in order to produce real IEC61850 data flow scenarios for S3 and generate planning events to test the peer to peer message sent from S2 to the switchboard under test S1 (Fig. 3).

C. Hardware and software in the loop during platform development

Our Co-Simulation platform is based on the modeling of device communications. The increase of confidence in the platform is an important point in our research study. To accomplish this point, compliance tests should be provided to IEDs models according to the IEC 61850 flowchart tests. Thus, in order to test the compliance of IED services according to PICS documentation, the software in the loop and hardware in the loop component must be used with the simulation platform. The software in the loop will be used in this case in order to generate Inputs/ Outputs simulated process value (e.g. voltages and currents exceeding values, status trip and default) to the IED model and check its behavior (i.e. reports and peer to peer message transmission). However the hardware in the loop component will be used in order to connect the model under test to a test external system to validate the services declared in its PICS documentation.

VI. Hardware in the Loop Module Implementation

A HITL node is based on an edge Router interface which is used inside the simulation platform in order to provide the workflow for exchanging packets between simulated and real devices. The detailed of this workflow is shown in Fig. 4.

The first important job of the edge interface router is the mapping of external network interface of the simulation machine to the network interface of the appropriate device model. HITL allows multiple interfaces to map different network addresses in the simulated network.

The HITL module has many associated attributes that permit to describe the HITL behavior. One of these attribute is used for filtering packets received by HITL in order to reject unexpected packets and allocate memory for expected real world packets. If the packet is accepted, the edge router enter the creation phase where it constructs the skeleton of the simulated or real packet weather if the packet received is real or simulated.

To succeed in the phase of copying the contents of packet fields between the two formats, HITL requires a predefined well-known protocol format included in the Standard Model Library. Otherwise, if the packet received is not a part of the library, a custom code must be written for providing the conversion of the unsupported protocol format packets else it will be dropped by the edge router and will not enter the simulation world. The protocols format packets supported or partially supported by HITL are the ones associated to standard TCP/IP layers as shown in Fig. 5.

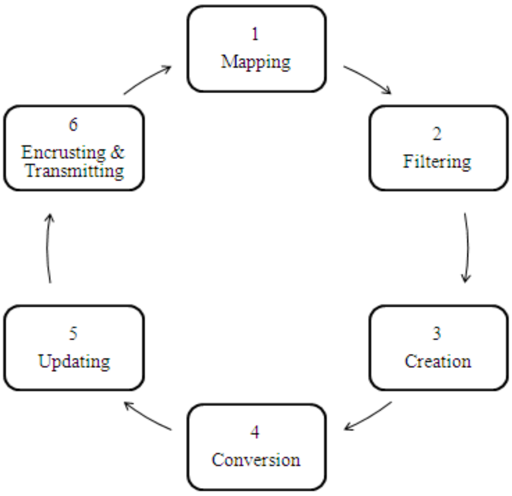

Fig. 4 Hardware in the loop workflow

As described in the introduction, the Simulation Platform is used for solving Power Management System ‘PMS’ issues, thus HITL must provide conversion of protocols associated to PMS more particularly the IEC 61850 standard. IEC 61850 packets format and other industrial protocols are not included inside the Standard Model Library Packets thus the conversion of application layer packets are not provided with a nominal HITL.

Our customized user code is developed to provide the conversion of protocol application packets. In addition, the code is also used to fill in uncompleted conversion points of transport packets by updating (i.e. phase 5 of the HITL workflow shown in figure 6) TCP missing fields which are associated to the application (e.g. data length field).

A surplus point of our custom code is that it has been developed in a way to make use of HITL with any industrial hardware device taking into consideration that it is possible to have heterogeneous power management architecture combining the IEC 61850 and other industrial protocols such as Modbus or others.

After a successful conversion and updating of partially supported packets format, the HITL encrusts real or simulated packet into a SITL conversion block and routes it finally to the appropriate model if the original packet is real or to the external world if the original packet is simulated.

VII. Software in the loop module

A. OPNET Problematic

In OpNet modeler, C functions can be placed in three different placements:

- Process model states,

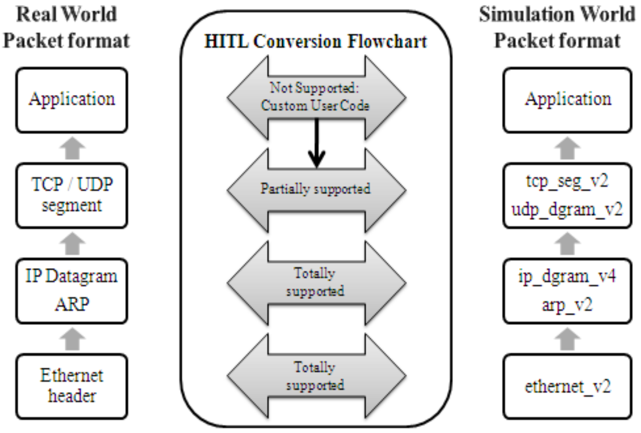

Fig. 5 Hardware in the loop conversion supported packets

- Function blocks attached to a process model,
- External OpNet Library.

When a function is defined inside a function block, it can only be used by the process associated to the function block. External OpNet libraries differ from the function block because when a C function is defined in an external library it can be shared with different process models. Finally if the C function is defined inside a state, only the state can have access to this function.

Three types of variables can be found for particular use inside the OpNet process model: the state, the temporary and the global variable. The table 2 shows which kind of functions can have access to these variables.

Table II.
Variables visibility inside simulation

		Visibility			
		Opnet State executive	Opnet Function block	Opnet External Library	External application
Type of variables	Temporary	X			
	State	X	X		
	Global	X	X	X	

What should be concluded is that only OpNet functions can have access to the simulation variable environment. Electrical process interface is considered as an external application to the simulation software. Therefore as shown in the table 1 this application will not be able to exchange variable values with the simulation on run time. For this reason a software in the loop package [7] is developed in this study in order to make this point feasible.

B. *Software in the loop package constitution*

Software in the loop consists on a package associating three different modules: C predefined research library, Data base, electrical process software. The purpose of this package is to provide an access method which authorizes the electrical process interface to exchange information with the simulation variables.

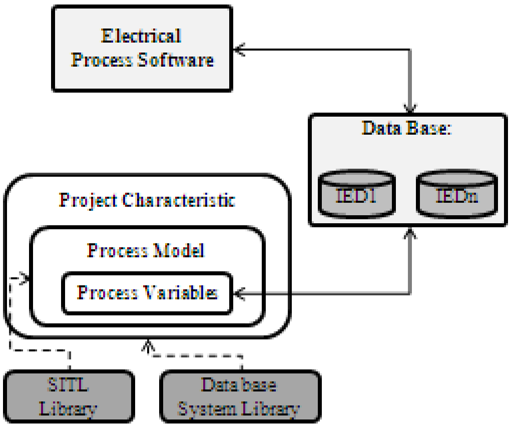

Fig. 6 Software in the loop package

The data base shown in Fig. 6 is used as an intermediate component between the OpNet process and the electrical process interface. Each IED electrical process values is included as a table inside this database in order to have at the end all the electrical process values of all the IEDs integrated inside the modeled switchboards.

In order to ensure a real time exchange between the OpNet process variables and the data inside the database, two libraries are integrated inside the simulation software. The first one is a system library which is implemented in the project properties to provide a communication language between simulation software acting as a data base client and the data base server. The SITL library is developed in our research in order to authorize the simulation to read and write values inside the data base. The read procedure is programmed in a periodical mode in order to collect the changes of the process values. The period of generation will depend on the cycle time of the real IED which will be modeled. On each process value changes, this library generates the appropriate OpNet process interrupt to invoke the state that corresponds to the changes. The collected values will be then placed inside the simulation environment variable. The writing procedure is programmed in event mode. This function is invoked by the library when an external client sends a writing request to an IED model inside the simulation.

VIII. Hardware and Software in the Loop Test

The simulation test described in this paragraph shows how HITL module is used in order to test the compliance of data modeling inside an IED model.

A. *IEC61850 modeling concept*

The IEC61850 includes a comprehensive set of data models for substation (and beyond) functionality. The models are, in general, constructed from a set of common data classes (defined in part 7-3 of the standard). The common data classes are used to build data objects, which are then clustered in logical node classes. Each logical node class represents some basic application function. Instances of the logical node classes are then combined to construct logical devices. A physical network device may contain an arbitrary number of logical devices. The set of classes (common data classes, data objects, and logical node classes) define the network visible data types (network interface), along with some standardized behavior, definitions, and configuration parameters [8]. One of the most important points in testing a physical or model device is to verify the compliance of its data object modeling. The paragraph below describes how HITL module is used for accomplishing this point.

B. Hardware in the loop for testing object modeling

When a physical or a model IED is developed, it is delivered with its PICS and MICS documentation which describe the capability of the IED in term of functionalities and services. Before delivering the IED, it is crucial to verify the conformity of these two documentations according to the IEC61850 specification to increase confidence in implementation (i.e. interoperability). Verifying the MICS of the IED consists to check:

- The existence of the functionalities defined in the MICS
- The compliance of the object modeling according to IEC 61850 standard dictionary (i.e. part 7.3 and 7.4)

The testing of IEC 61850 implementations is potentially a large task, given the large scope of the standard services and data models. IEDScout is a universal IEC 61850 test systems [9] that can be connected to any IEC 61850 device (server) and provides many useful functions for verifying data model, reading and writing data, reporting, along with GOOSE publishing and subscribing.

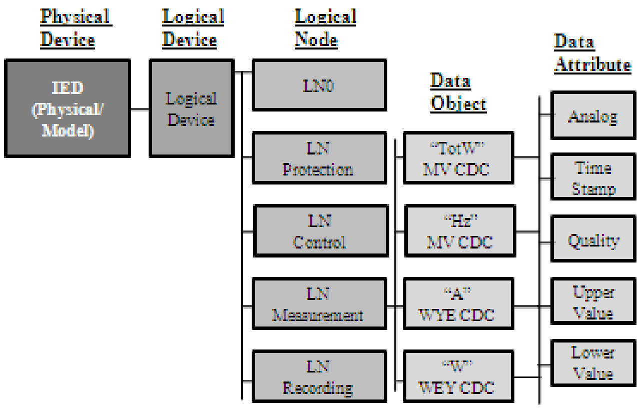

Fig. 7 Simple server MICS representation

A simple IEC 61850 measurement unit functionality has been implemented in our IED model to test the data object implementation. The model IED does not implement the functionality, but it is important to note that even unmapped model elements are implemented in the IEC61850 side of the model. The MX logical node contains four standard measurement unit data objects: TotW, A, W, Hz which permits to calculate the energy, current, power and frequency. Fig. 7 shows the MICS representation of the IED model.

Fig. it is explained that the generation of IEC61850 dictionary relies on the implementation of essential points:

- An ICD configuration file which describes the content of the server (i.e. simple server in our example). This file is generated by the SCL standard editor that produces IEC61850 configuration files.
- SCL RTG Library which includes predefined IEC 61850 code that aims to generate on run time the IEC61850 object dictionary according to the ICD configuration file and to implement the auto discover functionality.

For testing the conformity of implementing the server data model, HITL is used to connect the real IEDScout test system to the IED model using real to simulated scenario. The aim idea consists on showing the content of the IED model and identifying the object included in the model that are conformed or not to the standard dictionary. The test system sends an auto discover query to the configured IED model in order to discover the content of its standardized data object. This query passes through the HITL component as shown in Fig. 8. At its turn, the IED model sends back a file transfer response containing its entire data object content, the response reaches the real world also through the HITL component. In our example, the test system shows clearly the content of the simple server included in Fig. 8. This allows us to certify the implementation of simple server data object.

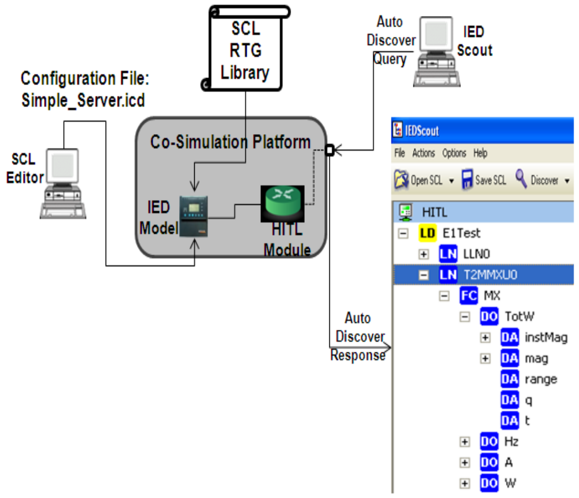

Fig. 8 Object modeling testing platform

C. Software in the loop Test

In order to validate the functionality of the SITL package, a small application is developed in our study. Inside this application, the electrical process software is developed in order to support 1 IED containing 4 categories of process values: Current, voltage, frequency measurements and finally the status position.

In order to validate the SITL package, a simple OpNet modeler node is developed. This node contains a simple module that implements one process model. This process model will be further implemented inside the application OpNet module of the final IED IEC61850 model. The first state 'red' is an unforced state which waits for an interruption coming from the process in order to execute the output transitions. This interrupt will be generated periodically from the SITL library. On the exit executive of the initial state, many states can be invoked depending on the condition calculated by the SITL Library. The activation of a condition depends weather the process value has changed or not. Each process measurement (i.e. current, voltage, frequency, and status) is associated to a forced state in order to run the control procedure associated to the measured value. In order to give a demonstration of the SITL package, the measurements are printed in the OpNet debugger console 'ODB' inside each forced state. As shown in the OpNet Debugger Interface 'White Window' in Fig. 9, when the voltage value changes to 220kV, this value is inserted inside the data base and printed on the OpNet debugger 'Output Consol of OpNet'.

IX. Conclusion

The paper shows the development of a co-simulation platform, for the evaluation of IEC61850-based architectures. The use of OpNet Modeler, which is an event-based simulation tool for networks, is interesting in such a context. A HITL/SITL gateway has been developed, allowing interfacing physical actual components, and virtual components, altogether to constitute a whole "hybrid" architecture.

The whole set of tests, required by the IEC 61850 standards, can be executed on this hybrid architecture, which allows the evaluation of architectures, in the design phase, as well as existing architectures but which require off-line validations.

The preliminary tests of the approach are promising; the next stage will be the validation of the approach on an actual existing architecture.

Acknowledgment

We are thankful to OpNet Technologies, Inc. for their active support under OpNet University Program (OUP).

Real-time controller design based on NI Compact-RIO

Maciej Rosol, Adam Pilat, Andrzej Turnau

***Abstract*—The paper is focused on NI Compact-RIO configured as a controller for the active magnetic levitation used here as a benchmark for time-critical systems. Three real-time configurations: soft, soft with IRQ and hard FPGA are considered. The quality of the real-time control has been tested for each configuration.**

***Index Terms*—real-time control, magnetic levitation, CompactRio, scheduling.**

I. Introduction

THREE different NI Compact-RIO (cRIO) configurations are designed and verified in control experiments performed in the real-time. The main attention is focused on real-time deterministic behavior of the PID controller constructed in a different way for a particular configuration. cRIO is recommended and promoted by National Instruments company as a rugged industrial control and acquisition system that incorporates a real-time processor and reconfigurable FPGA for reliable stand-alone embedded applications. The active magnetic levitation used here as a benchmark is a time-critical system. Therefore, a punctual and fully determined control algorithm is required. The quality of the control algorithm execution depends strongly on a used platform: Power PC or FPGA and the execution mode: software timing loop, interrupt event, hardware timing loop. A desirable design goal is usually the construction of the so-called ”hard real-time” system. We do not always manage to meet this goal. In principle, to develop the hard real-time controller a certain level of familiarity with cRIO and skill is required. Control experiments that have been performed illustrate several timing aspects: jitter, execution time of control algorithm, determinism of data exchange, ect. It is important to answer to the following question. How far one can dimnish the sampling period not disturbing the system performance?

II. Real-Time Control Application Design

The reconfigurable control system may contain the following components:

1) cRIO FPGA core application for input, output, communication, and control,
2) time-critical loop for floating-point control, signal processing, and point-by-point decision making
3) normal-priority loop for embedded data logging, remote Web interface, and Ethernet communication
4) networked host PC for remote graphical user interface, historical data logging, and postprocessing

Depending on requirements of an application, one can implement particular components. The RIO FPGA chip is connected to the I/O modules in a star topology, for direct access to each module for precise control and unlimited flexibility in timing, triggering, and synchronization. A local PCI bus connection provides a high-performance interface between the RIO FPGA and the real-time processor. The magnetic levitation control system structure is shown In Fig. 1.

A PC is dedicated to data acquisition and monitoring. The cRIO-9014 controller is equipped with two hardware platform: the Power PC microcontroller operating under the real-time the VxWorks operating system and FPGA (a Spartan-3 XILINX chip containing 3 milions gates). Power PC is triggered by a 400 MHz clock. FPGA is triggered by a 40 MHz clock. The PWM generator of the control signal is implemented in FPGA. There are also two modules: NI 9401 digital I/O and NI 9215 analog I/O. The PWM signal is transfered from FPGA through the NI 9401 output digital module and the PWM power interface to the electromagnet that operates as the actuator. The signal proportional to the sphere position is transfered from the sensor to the sensor conditioning circuit and farther to the NI 9215 input analog module.

III. Time-critical experiments of two cRIO configurations

Three cRIO configurations shown in Fig. 2 have been built to be tested:

1) Power PC soft real-time,
2) Power PC Interrupt ReQuest (IRQ),
3) FPGA hard real-time.

The PID controller operating in a hard real-time loop is built inside the FPGA chip (Fig. 3). The sampling period can be changed.

However, its minimal value has to be set to 10 ms due to the conversion time of the analog signal (the maximal value is equal to 100 kHz per chanel). The real-time platform is responsible for communication with FPGA and the application that runs on PC and is responsible for changing the parameters of the generator PWM and PID controller. If we use Power PC and VxWorks as a real-time control platform then FPGA is only used to receive the measurment signal and transfer the control signal and measure the so-called jitter signal. The timing loop operating at the 40 MHz frequency is responsible for generating the PWM resolution signal. It generates also the 32-bits counter (in ticks) for the jitter measuring. The measurement accuracy is the clock triggering frequency dependent and is equal to 25 ns. The time-critical while loop executes the PID control algorithm. The position signal related to the sphere position is scaled in meters due to the one-dimensional

look up table. Calculations of the controller are expressed as fixed-point numbers wit the accuracy equal to $1.5259 \cdot 10^{-5}$. The output signal of the controller is a number from the range $0 \div 1$. It is scaled and becomes a duty cycle in the range $0 \div 4095$ as far as the 12-bits resolution is concerned. The sampling period for the FPGA hard real-time configuration has been verified and the 25 ns value has been confirmed. This is obvious due to the hardware paralel implementation of the PID algorithm. In Fig. 4 the logging sessions of primary work parameters corresponding to the operational VxWorks system (the upper frame) and to the realization of the user application (the lower frame) are shown. During the Power PC

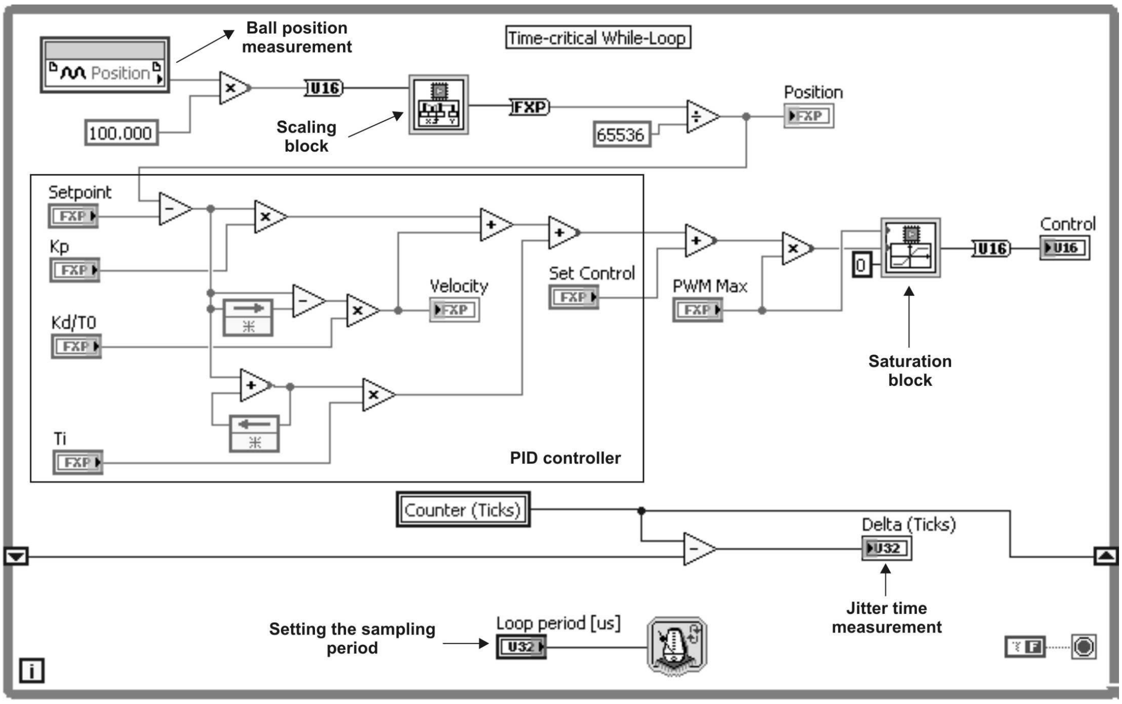

Fig. 3. The PID controller operating in a hard real-time loop running on FPGA chip

session calculation procedures have been executed with data exchange with the FPGA system. This was done to check the performance of this platform with the overhead time devoted to communication. The grey area in Fig. 4 corresponds to one complete execution of the loop which lasts 1 ms. Four interesting signals can be noted in the lower frame, namely: 0-SquareGener, 1-PositionScale, 2-PD_Controller, 4-Saturation. The first one provides square wave signal generator. The second one is devoted to scaling of the sensor signal. Next one implements the PID controller and the last one limits the control signal to the physical bounds. The execution times of these procedures are 28.1334 ms, 22.8882 ms, 30.0407 ms and 16.2125 ms respectively. It means that the time of calculations together with the context switching time between the procedures is equal to 355.84 ms. Hence, the maximal theoretical sampling frequency, without taking into account VxWorks time overhead, is equal to 2.81 kHz. In practice one should not go beyond 1 kHz. Similarly to the Power PC soft real-time configuration the performance of the Power PC Interrupt ReQuest control structure was check by running the Real-Time Execution Trace Toolkit session.

In Fig. 5 the logging data are presented. As can be seen the real-time task is IRQ triggered. The PowerPC platform waits for interrupt generating by FPGA. The execution times of the calculation procedures are comparable to Power PC soft real-time configuration. However the total time of calculations is shorter (equal to 253.27 ms). Hence, the maximal theoretical sampling frequency, without taking into account VxWorks time overhead, is equal to 3.95 kHz. In practice one should not go beyond 2 kHz.

IV. Experimental jitter of two configurations

The real-time controllers have been tested in three cases. However, the jitter has not been illustrated in the third case. This is not a mistake. There is nothing to show. Only the third case is characterized by high accuracy and repeatability of execution determined by 25ns resolution. The FPGA chip is triggered by the hardware timer. In contrast to this case, the first two have different triggering mechanisms. Usually, they introduce uncertainty into the real-time execution. The time stamps in the number of control task events 650 were registered for jitter analysis. The histograms are scaled in the full range of the available data. The results corresponding to two experimental cRIO configurations (see Fig. 2) are shown in Fig. 6 and Fig. 7. Let us define the following factors for further results analysis:

- min - is the minimal time instant registered for an event,
- max - is the maximal time instant registered for an event,
- N - is the maximal number of requests at the same time interval.
- xs [μs] - is the time instant related to the maximal number of events, alas different to the nominal (desired) time instant,
- DN [%] - is the negative deviation from xs,
- DP [%] - is the positive deviation from xs,
- DNn [%] - is the negative deviation from the nominal (desired) time instant,
- DPn [%] - is the negative deviation from the nominal (desired) time instant.

A. *Configuration 1*

One can notice that the sampling frequency equal to 1 kHz is a critical value for the soft real-time. Decreasing the sampling period (from 1 ms to 0.5 ms) is not feasible. The system operates at 995 ms (see Fig. 6c). This demonstrates that the clock mechanisms used by LabView and VxWorks do not cooperate correctly in the Power PC timing loop configuration. Moreover this environment shows also a lack of punctuality for 1 and 2 ms sampling periods (see the histograms in Fig. 6a and Fig. 6b).

c	963.333	1026.092	80

In the case of timing events triggered by the FPGA clock. when tasks are executed at Power PC (illustrated in Fig. 7) we are also surprised by the fact that the system triggered by the FPGA interrupt responds in a strange way. There is a large distribution of single events fortunately quantitatively

insignificant. It is surprising, as if the interrupt handler poorly managed IRQ despite the existence of the acknowledgment mechanisms. Of course, one could neglect the events that occurred fewer times than 10% of the 650 recorded events. Then statistics would be beneficial for the IRQ. As far as Configuration 2 is concerned we can notice a significant improvement in control quality, much of the tasks is executed in the vicinity of the desired time. However, even at such a small number of events as 650 there was a significant time variation (jitter) resulting from the interrupt handler (interrupt routines).

B. *Configuration 2*

Analysing the collected data it should be noted that in both cases (the Configurations 1 and 2), the magnetic levitation system steered by PID controller, where the derivative of the error is determined, would pay a high risk of loss of stability in the worst case, at best, the occurrence of oscillations. Uneven course of events has influence on the rate of change of the error signal fed to the input of the differentiating controller part. Unfortunately, a value calculated in such a way is incorrect and inconsistent with reality.

V. Conclusion

With this research it has been shown that the real-time control development must be considered precisely and with specific attention to the used hardware. The designed controller must be checked and verified how operates. Especially the punctuality of the control task call must be satisfied. The timing loop mechanism with time-critical priority is a fine mechanism for triggered tasks, but is limited to 1kHz of the sampling frequency. The timing events are condensed around the requested sample period. In the case of IRQ driven task, generated on the base of FPGA clock, the events are handled at the desired sample time, but sometimes a few events are called with a distance of about 25% far away from the nominal trigger time. The observed jitter gives a number of inequalities in the controller calculation. Note, that the error derivative calculation is very sensitive for incorrect timing. The tested National Instruments CompactRIO hardware gives a number of possibilities to develop a wide range of control configurations. The PowerPC is dedicated to data management and exchange between hard time-critical layer realised in the FPGA. Summarising, the control task should be implemented in the FPGA and the Power PC used for data acquisition and controller adjustment task only.

***Abstract*—There is presented control system design with autonomous control elements focused on field of automotive industry in this paper. The main objective of this document is description of the control and monitoring system with integrated image processing from the camera. The images obtained from the camera are used for recognizing routing and traffic situation. During system proposal we focused our attention on integration of components for the car localization using GPS and navigation system as well. The implemented embedded system communicates with other car control units using CAN bus and industrial Ethernet. The communication interface between driver and car integrated system is carried out by process visualization on the LCD touch panel.**

I. Introduction

Results for automotive industry development has been the main aim of the presentation in this paper. Our research has focused on process control and monitoring of a process states and values and the specific solution for intelligent car control with autonomous elements has been presented in this contribution. The solution was implemented in a prototype of an electric car, where video-cameras for image processing and objects recognition in a real time were used. Stream data of the recognized objects allow identify route lane, people, other cars, traffic signs and situations. In addition to objects recognition, the accurate position must be obtained from GPS module and then transferred to control system. Information of exact position is useful for the car localization process and system navigation. The position data can be helpful during estimation of a distance between car and surrounding objects where supersonics sensors cannot be used.

The actuators, sensors, control units and video-cameras communicate with each other using industrial interfaces. Implemented industrial interfaces are CAN bus, wire or wireless industrial Ethernet and Bluetooth for extended features. The communication system is able to transfer secured data from one car to another by using open wireless industrial network. Car view information, captured on the camera, is transferred from the car to intelligent highway system. There is also space and possibility to use wireless communication connection for remote diagnostic test. [6]

Information of the system is displayed on the touch screen panel that is connected into central development board based on 32.bits processor i.MX35. This type of processor is suitable for communication, graphic and multimedia applications. In virtue of using a lot of hardware interfaces and due to complexity of realization, we made a decision to use two types of operating system. Both of them are based on Unix platform. The first one is RTAI Linux which supports a lot of drivers for devices like cameras or modules for wireless connection or Bluetooth. On the other hand there is a lack of preferable memory protection. The kernel runs in the same memory space like drivers and the bug in driver can consequently cause the failure of the whole operating system. The new Linux reboot lasts rather long and it is annoying for a car driver or other passengers in the car. The second solution offers applying the system with great memory protection and memory adaptive partitioning management. The micro-kernel and drivers or other processes run in separate memory space. The failure of one driver or process does not cause operating system crash but only automatic process restart in milliseconds. Subject of concern is the operating system QNX Neutrino RTOS. Disadvantage of QNX Neutrino RTOS is weak support for wireless network drivers.[4]

II. Car System Architecture Design

The system architecture design is composed of embedded modules with special or universal function for the car control process. The central control embedded unit has many functions such as the system for battery management, motion control system, image recognizing system, global position system and others. In this paper we have focused our attention to the system for image processing and recognition of objects. The system embedded design is proposed for mobile devices like robots, car or industrial devices for product testing or measurement. Actual development design is composed of low cost products.

I. Embedded Car System

We propose embedded car system with 8.bits, 16.bits and 32.bits processors according to its functionality. The central unit is based on ARM architecture with build-in 32.bits processor i.MX35. This embedded central unit is reserved for graphic applications, image processing with objects recognition and communication processes. We prefer low power

This work is supported by grant of the Grant Agency of the Czech Republic GA102/08/1429 - Safety and security of networked embedded system applications.

consumption for all our embedded units and that is why we have chosen ARM architecture. [5]

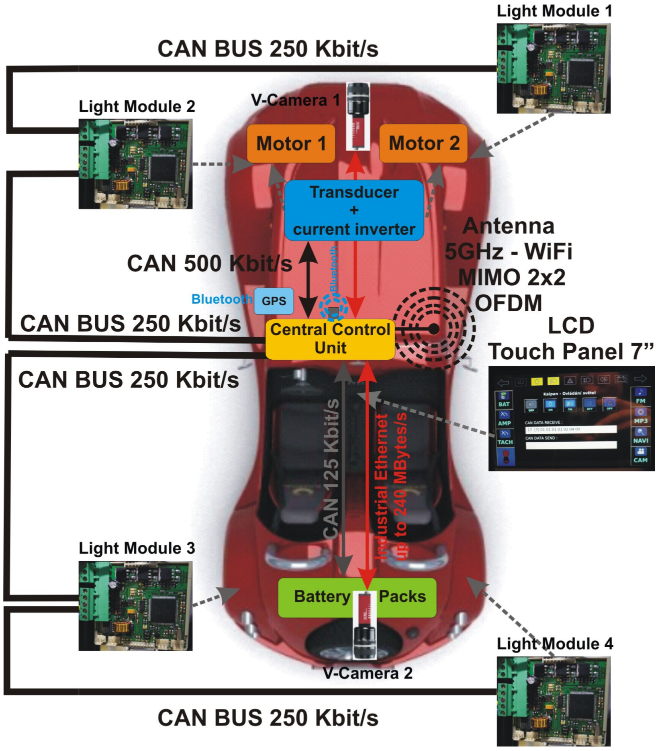

Fig. 1 Embedded car system architecture

Figure 1 presents some of the basic embedded modules implemented in the car control and monitoring system.

II. Software Implementation for Vision Car System

The vision system capability is to react to various types of traffic situations. Together with processing image data there has to be artificial intelligence implemented with ability to predict a critical traffic situation. Our development has been divided into 3 phases. The first one is testing our objects recognition algorithms design in Matlab with cheap webcam on platform x86. Standard USB interface was used for webcam connection. The next development phase was a test on mobile devices like PDA. The last phase was a transfer of the recognition system in embedded device that is part of car system. A new communication interface was used. We decided to choose a new camera with GigaEthernet interface on industrial Ethernet protocol. There is high data stream of data for a new 4 Megapixel camera with resolution up to 2336 x 1752l therefore we need very fast communication interface.

III. Real Time Operating System Implementation

Central control unit carries many functions which present a lot of processes running at the same time. Therefore we decided to use the real time operating system. There are 2 types of operating system mentioned in this paper – RTAI Linux and QNX Neutrino RTOS. [1]

RTAI Linux was modified for our purpose and for our hardware architecture. For this operating system, communication drivers have been adjusted for wire and wireless connection, based on industrial protocols - FlexCAN, EtherCAT and Bluetooth.

QNX Neutrino RTOS was rather easier to implement due to BSP supplied by QNX Company, but there was a problem with wireless communication driver. We still continue working on it with QNX community cooperation. Following figures 2 and 3 show the difference between Embedded Linux and QNX.

IV. QT cross-platform graphic framework

The software Qt is the cross-platform application and UI framework used for embedded applications. Graphics interface was chosen with regards to both operating systems. Our selection was influenced by our experiences with graphical QT system from Nokia. QT embedded graphical interface is applicable for Linux and QNX as well. Figure 4 shows the example of car graphic user interface.

III. Recognition Driver System

The recognition driver system was developed for traffic signs and traffic lanes detection. The system processes real-time image captured by a camera. Implemented algorithms are based on the idea of standardized form and appearance of traffic signs.

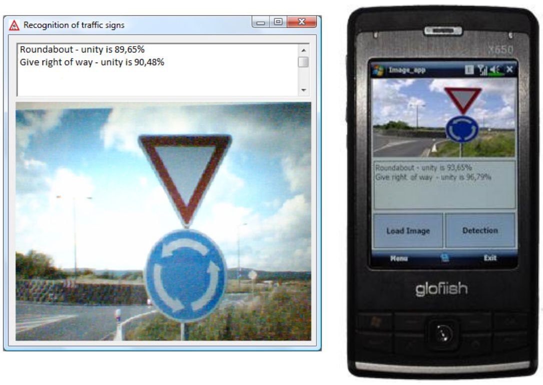
Nowadays there are two production technologies of image scanners available, namely scanners based on CMOS and CCD technologies. Better quality cameras use scanners based primarily on CCD technology. The advantage of this technology is a high luminous sensitivity ensuring better image quality with low brightness. In comparison, the CMOS technology is much cheaper, because it is based on standard technology, which is used in mass production of memory chips. By virtue of this technology, the scanning element can be placed on one chip together with other electronic circuit elements. Moreover, the advantage of CMOS technology is lower energy consumption in comparison with CCD technology. Generally, there is a reasonable argument that when the scanner is heated up, the undesirable noise increases and reduces the quality of final record.

For the presented application determined for image recognition, the VGA camera has satisfactory resolution. Better resolution would extend the process time, as each point of image matrix prolongs recognition process. In this case, a web camera with VGA resolution based on CMOS technology is used for image recording. These cameras communicate with in-built systems with the help of multi-purpose standard interface. The advantage of these cameras is a low price and very good availability, while undesirable disturbance, which can be fixed by developed software, is a disadvantage. Methods for reducing the undesirable noise disturbance are based on using filters, such as linear and median filters, which are very simple, reliable and quickly implemented.

The developed system retrieves images in real time directly from a webcam and they are evaluated immediately. Webcams Logitech with resolution 352 * 288 pixels were used for the test. Image quality reflects necessary quality of traffic signs identification. Low image resolution of traffic signs causes that recognition success will decrease to 90%. It is about 5% less than if the original high resolution image is evaluated. Application speed is convenient, as it is able to process more than 10 frames per second with presented camera resolution.

An application is created for Linux, Windows CE, Windows Mobile QNX. Testing was performed on a development kit i.MX35. Use of 32-bit multimedia applications processor based on iMX357 ARM11 ™ core is run on 532MHz frequency and size of RAM is 128 megabytes.

Implemented algorithms are suitable for wide range of applications in existing PDA devices and mobile phones. These devices are limited by low frequency computing power and memory space compared to being commonly used in desktop computers. The application was tested in devices E-TEN Glofiish X650. This device contains a Samsung S3C2442 processor 500 of MH, 128 MB Flash ROM, 64 MB RAM and a VGA TFT display 2.8-inch. The device has also a camera 2Mpix. Installed Operating System is Windows Mobile 6 Professional. Testing has shown that reduced performance of the device has largely affected algorithms time consumption. Acceleration of algorithms is likely by more efficient use of resource devices and optimizing memory management. The developed application shows examples of detection system for traffic signs in Fig.5.



Roundabout - unity is 89,65%

Roundabout - unity is 93,65%
Give right of way - unity is 96,79%

Fig. 5 Application for devices with operating system Windows CE and Windows Mobile

Execution time for implemented algorithms depends on several parameters. The first parameter is size of the input image, size and number of objects that are inside image. Number of inside objects is input criteria which affects the number of cycles that must be done during patterns comparison. The execution time, which consumes the algorithm, depends on the performance of computer on which it has been executed. Processing time code implemented in C on a desktop PC in test events, did not exceed the period of 1 second.

The verification of the developed software was accomplished approximately on 50 traffic signs. The majority of test results are correct, i. e. in majority of cases traffic signs were detected correctly, but rarely there was not detected any traffic sign. This error was caused by damage to traffic signs, the excessive pollution or poor light conditions. Traffic signs were successfully recognized with patterns in range from 90 to 95%.

During the recognition process, the distance of traffic signs from the camera plays a big role. Due to a small number of pixels of traffic sign that is located too far, it cannot be guaranteed that the system will find the required consensus. Threshold for identifying traffic signs is approximately equal to 50 meters, if the camera zoom value is set to 1:1.

IV. Algorithms for Traffic Signs Recognition

The algorithms are based on ideas of standardized appearance and shape of traffic signs. Parameters are defined by traffic signs in the Czech Republic, which are stated in the regulation no.30/2001, Ministry of Transport The algorithms consist of two main parts. The first part implements correction and segmentation of the input image. The second part implements object searching, analysis and user information system.

V. Image segmentation and conversion

The basic aim of image segmentation is to search continuous parts in whole figure from a camera. From these analysed parts the objects are created, which are explored by parameters and the similarity of the patterns. The method chosen for continuous parts searching is based on conversion of the input colour image into the binary structure, taking into account the colour matrix with limited number of colours. Converted traffic signs image is composed of 5 basic colours, where 4 colours (red, blue, black and yellow) determine the motive of the label and white colour is chosen as the background of the label. The analysis of algorithms also solves the segmentation problem of traffic signs, which are composed just of red and blue colours, so it is converted to only one object, which has to be divided to separated objects. There are not green colour analyses, because traffic signs do not contain this color. For converting the image to a binary algorithm defined by next presented function is used. The example of image segmentation is presented in Fig.6.

$$f\left(p_{(x,y)}\right)=\begin{cases}0 & for \quad R_{(x,y)},G_{(x,y)},B_{(x,y)}>=h\\ 1 & for \quad R_{(x,y)},G_{(x,y)},B_{(x,y)}<h\end{cases} \tag{1}$$

where: p is pixel
h is colour limit
R,G,B are colour components

Fig. 6 Continuous parts searching (left) and Individual part segmentation with different number of each segment (right)

VI. Image rotation and angle correction

The camera images, which are obtained from real camera output, can be rotated to incorrect angles. Rotation is related to one point by an angle α. The simplest cases are: $\alpha=90^{\circ}$, $\alpha=180^{\circ}$, $\alpha=-90^{\circ}$. In these cases it is practical and easy to change the representation of x and y axis. In reality, the angle α does not take exactly predictable values, thus we need to use trigonometric functions conversion to new pixel location. Special situation occurs when the traffic signs not only need to correct their orientation, but also to determine the angle of which are deflected from the vertical position. Traffic signs are not always installed completely vertically. This fact leads to lower conformity of recognition. The solution image has to be rotated to known angle. This angle can be calculated by algorithms based on symmetry of traffic signs as shown in Fig.7.

The figure shows the geometric layout of the problem where the presented trigonometric functions is used for determination the angle α. The presented algorithm for rotation calculation cannot serve for traffic signs of circular shape. Angle α is calculated by next equation. [3]

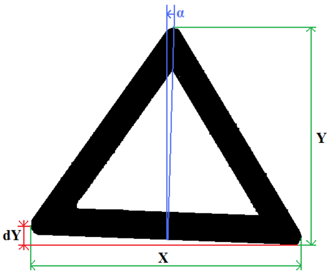

Fig. 7 Geometric expression of rotation traffic signs

$$tg\,\alpha=\frac{dY}{X} \tag{2}$$

The algorithm for rotation chooses reference point, which is located in the lower left corner of the editing image. The calculation of new coordinates is based on the next presented equations, where x‘,y‘ are new coordinates and x, y are current coordinates.

$$x'=\cos\left(\alpha+tg^{-1}\frac{y}{x}\right)\cdot\sqrt{x^2+y^2} \tag{3}$$

$$y'=\sin\left(\alpha+tg^{-1}\frac{y}{x}\right)\cdot\sqrt{x^2+y^2} \tag{4}$$

The rotation method gets images of traffic signs in a vertical position. New calculated pixel coordinates appear in the original matrix, but not always. Therefore there is necessary to consider boundary data fields so as not to exceed their limits.

VII. Image pattern analysis

After image segmentation and image rotation, there is possibility to analyze patterns with the actual edited image from camera. Traffic signs patterns are stored in a binary matrix. Each of the patterns is size-standardized at 100 x 100 pixels. The resolution is chosen on the basis of compromise between size of the matrix patterns and quality of the patterns.

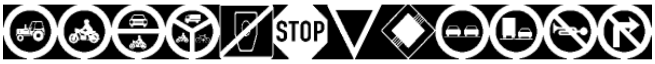

Fig. 8 Example of binary matrix with patterns of traffic signs

Each object has location in the original matrix and is given its size. In order to apply the correlation function, size unification securing of objects and patterns is needed. Function re-calculates the object's size on defined dimension. The resize algorithm can be used after object continues parts recognition. The captured image can contain more traffic labels with other recognized noise, which is not desirable. Therefore, the method for object segmentation is supplemented with object centres identification. In case the centre is outside the other object area, it is solved separately. This recognition method eliminates problems with noise parts of objects, which disturb object comparison with patterns by correlation. This is processed by analyzing the geometric centre of coordinates and objects. The example of described method object separation is shown in Fig.9.

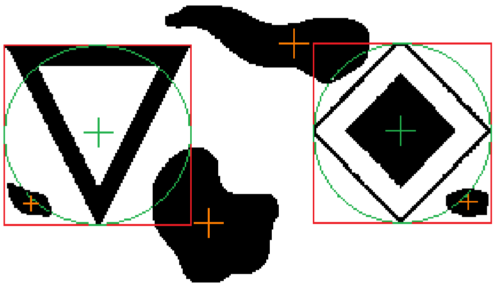

Fig. 9 Example of recognition basic points of image objects

Obtained object is then compared with correlation function used to all patterns. In this process the biggest matching of the object with patterns in percentage is expressed. The correct result is evaluated from the chosen pattern, which is the most identical to traffic sign in actual image. Practical tests have found that matching in more than 87% is sufficient to search traffic signs.

Learning the patterns number and rate of compliance is an adequate criterion for the correct formulation of the result recognition. Each number corresponds with specific patterns traffic signs.

Correlation function is used to determine the relationship between two signals (in this case signal represents the analysed image), the similarity of their histories, depending on their mutual displacement. Correlation can be expressed for linear and discrete signals. These signals cannot just be one-dimensional (vector) signal, but can be expressed by multidimensional signals. Correlation function of two signals is called a peer or cross-correlation functions. The result of correlation is a new signal, which has been displaced amplitude proportions have similar signals. This fact can be expressed as correlation coefficient R, which takes values between zero and one and reflects the similarity of two signals. For discreet binary two-dimensional signals can be expressed by the correlation coefficient R values range from zero to one.

$$R=\frac{\sum_{x=1}^{x}\sum_{y=1}^{y} f(x,y)\cdot g(x,y)}{x\cdot y} \qquad (5)$$

Function f(x,y) represented examined image and g(x,y) represented image pattern. Multiplying the correlation coefficient value by 100 represents the unity signal in percentage. Correlation is often used for the detection of known signals. [2]

VIII. Number recognition and analysis from image

Optical character recognition OCR is a method that enables the digitization of texts from retrieved images. The developed program converts the image either automatically or must learn to recognize characters. The converted text is almost always dependent on the quality of the draft should undergo thorough proofreading, because OCR program does not recognize all the letters correctly.

For the detection of traffic signs that inform about the maximum speed limit a simplified version of OCR algorithms are applied. OCR algorithm is applied to each traffic sign that is probably found with the help of the correlation function in comparison to the patterns. Segments of the traffic signs are systematically compared with known patterns of numbers. [3]

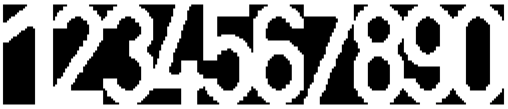

Fig. 10 Patterns for implemented OCR algorithm

Neural networks are useful for solving problems in image and signal recognition or diagnosis. The neural network is generally designed for a structure of spread parallel processing information, which consists of certain (usually very high) number of simple computing elements. Each element is named as the neuron. Neuron receives a finite number of inputs and their input information and passes its output to a finite number of outputs information. Formalized algorithm model of neuron is shown in Fig. 11.

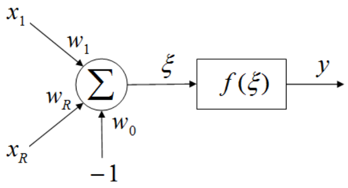

Fig. 11 Formalized algorithm model

Activity of this neuron can be expressed by:

$$y=f(\xi)\,, \qquad (6)$$

where y is input of neuron and ξ is so-called potential, which may be expressed by equation

$$\xi=\sum_{j=1}^{R} w_j x_j - w_0 \qquad (7)$$

In this relationship x_j symbol indicates the value of j-th entry of the neuron, w_j denotes the value of j-th entry, and w_0 denotes the threshold of neurons and the function $f(\xi)$ shows generally nonlinear signal transfer function of neurons.

Neurons are arranged in networks, this arrangement is known as network topology. Neural network does not contain any information about finding the object.

At the moment, neural methods and algorithms for OCR analyses are prepared, but implemented and successfully tested OCR recognition by correlation function is available. The problem of correlation function, compared to other method, is insufficient speed of algorithm execution, which increases with number of patterns.

V. Algorithms for Traffic Lanes Recognition

For the detection of lanes on a road, Hough transform is implemented. At the moment the implementation is solved in MATLAB environment and it is prepared for implementation to embedded system. This transformation is analytical method used to find a parametric description of the objects in the picture. This method is used for the detection of simple objects in the picture, which are example lines, circles and ellipses. The main advantage of this method for lane detection is robust against irregularities and infringements looking curve, which is particularly suitable for the detection of dashed centre line. To find a mathematical model of the object in a picture we used Hough transform as an input pixel input image. For example, detection of lines in the image edited by the Hough transform was used in the equation:

$$x \cdot \cos \theta + y \cdot \sin \theta = r \qquad (8)$$

Where:

r – Length of normal from the origin of coordinates to the line.

θ - Angle between the normal and the *x*.

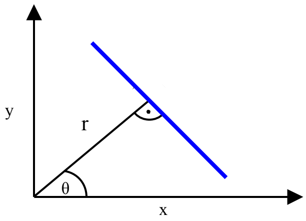

Fig. 12 Parametric description of detected traffic lane

Hough transform is applied here, by an adjustment of the input image. The adjustment consists of the image transfer to binary image, and finding local maxima using edge detector. One of the most important edge detection is Canny edge detector, which is implemented by algorithm for edge detection in two-dimensional discrete image.

VI. Conclusion

The main goal of this paper is to show development of car system for object recognition. The basic car system architecture and algorithms for traffic signs and lanes recognition are presented here. Neural networks were used in order to solve problems in image and signal recognition or diagnosis. The problem of image processing and object recognition was discussed in this contribution. We presented development stages of recognition system.

4rd International Workshop on Secure Information Systems

The SIS workshop is envisioned as a forum to promote the exchange of ideas and results addressing complex security issues that arise in modern information systems. We aim at bringing together a community of security researchers and practitioners working in such divers areas as networking security, antivirus protection, intrusion detection, cryptography, security protocols, and others. We would like to promote an integrated view at the security of information systems.

As information systems evolve, becoming more complex and ubiquitous, issues relating to security, privacy and dependability become more critical. At the same time, the global and distributed character of modern computing – typically involving interconnected heterogeneous execution environments – introduces many new and challenging engineering and scientific problems. Providing protection against increasingly sophisticated attacks requires strengthening the interaction between different security communities, e.g. antivirus and networking. New technologies lead to the emergence of new threats and attack strategies, involving smart mobile devices, peer-to-peer networks, instant messaging, VoIP, mesh networks or even networked consumer devices, such as house appliances or cars. Furthermore, the increasing openness of the communications infrastructure results in novel threats and can jeopardize critical enterprise and public infrastructure, such as industrial automation and process control systems. Not only it is estimated that half of all Web applications and Internet storefronts still contain some security vulnerabilities, but secure commerce applications are also exposed to increasingly elaborate attacks, including spyware, phishing and other social engineering methods.

In order to develop a secure system, security has to be considered in all phases of the lifecycle and adequately addressed in all layers of the system. At the same time, good engineering has to take into account both scientific and economic aspects of every solution: the cost of security has to be carefully measured against its benefits – in particular the expected cost of mitigated risks. Most companies and individuals treat security measures in information system as a necessary, but often uncomfortable, overhead. The increasing penetration of computing in all domains of everyday life means that security of critical business systems is often managed and maintained by personnel who are not knowledgeable in the field. This highlights the importance of usability and ease of configuration of security mechanism and protocols.

Covered topics include (but are not limited to):

- Access control
- Adaptive security
- Cryptography
- Copyright protection
- Cyberforensics
- Honeypots
- Intrusion detection
- Network security
- Privacy
- Secure commerce
- Security exploits
- Security policies
- Security protocols
- Security services
- Security evaluation and prediction
- Software protection
- Trusted computing
- Threat modeling
- Usability and security
- Viruses and worms
- Zero-configuration security mechanisms

***Abstract*—Nowadays, computer users especially run their applications in a complex open computing environment which permanently changes in the *running* time. To describe the behavior of such systems, we focus *solely* on externally observable execution traces generated by the observed computing system. In these extreme circumstances the pattern of sequences of primitive actions (execution traces) which is observed by an external observer cannot be designed and/or forecast in advance. We have also taken into account in our framework that security policies are partial-natured.**

To manage the outlined problem we need tools which are approximately able to discover secure or insecure patterns in execution traces based on *presupposes* of computer users. Rough set theory may be such a tool. According to it, the vagueness of a subset of a finite universe U is defined by the difference of its lower and upper approximations with respect to a partition of the universe U. Using partitions, however, is a very strict requirement. In this paper, our starting point will be an *arbitrary* family of subsets of U. Neither that this family of sets covers the universe nor that the universe is finite will be assumed. This new approach is called the *partial approximative set theory*. We will apply it to build up a new security model for distributed software systems solely focusing on their externally observable executions and to find out whether the observed system is secure or not.

I. Introduction

NOWADAYS, computer end users especially run their applications in a complex open computing environment which as a rule consists of software components of finite numbers. Each component has an individual behavior, and the global behavior of the whole system is a collection of individual ones.

Personal users watch their applications, work with one of them, and, in general, also follow details of other applications with attention. Moreover, the open computing environment permanently changes in the *running* time. Consequently, the pattern of the sequence of primitive actions, which is observed by an external observer, cannot be designed and/or forecast in advance. Nevertheless, from an execution trace which is actually observed during a short observation time interval someone ought to decide whether the system works safely or not, of course, with respect to a certain security specification.[1]

Under these peculiar circumstances, organizations first of all have to understand what has to be protected, and why. The answers determine the choice of the organization's *security strategy* which is, in turn, expressed in *security policies* [6]. Security policies *prescribe* and *proscribe* behaviors of software systems specifying acceptable and unacceptable execution traces of applications.

In corporate information security management there have been many approaches for security policy specification. Traditionally, security policies are formulated along the so-called CIA taxonomy [18] which sees security as the combination of three attributes—confidentiality, integrity, and availability.

However, there are different challenges between corporate information security management and personal information security management. Under the personal information security we do not exclusively mean the privacy. Under the information security from personal point of view we also mean, among others, the protection of personal desktop PCs or notebooks from the intrusion, applications and data from the damage, etc.

Users in personal computing environment are inundated by recommendations how they should use and operate their system. In headwords only: strong password creation tips and maintenance, virus protection, software downloading and installation, removable media risks, encryption and cryptographic means, system backups, incident handling, e-mail and internet use best practices, etc. Non-professionals, of course, cannot convert these pieces of good advice into security policies, particularly into a formal one.

Arising from the human thinking [26], all computer users have *anticipated hypotheses* how an application or the whole computer system should or should not work. This may range from informal expected behaviors of the system, their elements might be called expected 'milestones', to more formal ones described in user manuals. Without any knowledge about

[1] This strange situation is smartly described by Schneier: "You have to imagine an intelligent and malicious adversary inside your system (the 'Satan' of Satan's computer), constantly trying new ways to subvert it. You have to think like an alien." ([3], from the Foreword by B. Schneier)

running application or having either some informal behaviors and/or more formal descriptions about it, we have to make an attempt to build up an information security management model which is approximately able to discover secure or insecure patterns in execution traces of the running system. Thus, in contrast to the traditional approach mentioned above, in order to describe the behavior of distributed software systems in a personal computing environment, we focus *solely* on externally observable executions generated by the observed computing system.

As usual, the software components can operate with each other. Their interconnections may be intended or *ad hoc*. Notice, however, that in both cases, the mechanisms of these interconnections mostly remain concealed from the external observers. In particular, based on only external observations, we cannot model these synchronization mechanisms.

II. Related Work

Our approach partly relates to the theory of a very special class of security policies called *properties* proposed by Lamport [20]. Informally, a security property is a set of execution traces which is defined exclusively in terms of individual execution traces, or, in other words, a property may not specify a relationship between possible execution traces of an application [21]. Access control or availability are properties, while information flow policy is typically not, the latter is a more general one. According to another terminology, properties are *point-wise* in nature, while the information flow policy is *point-free* in nature. Methods for specifying and reasoning about properties are well understood. Alpern and Schneider have shown [1] that every property is the intersection of a so-called *safety* and a *liveness* property. For more details about properties see, e.g., [20] [30], [21], [22].

We also partly relate to the theory of *hyperproperties* proposed by Clarkson and Schneider in [7]. In this approach *every* set of execution traces is a property. Thereupon, the hyperproperty is a set of properties, or simply, a set of sets of execution traces. In other words, both properties and hyperproperties are defined in a *point-wise* manner—properties based on their elements, the execution traces, and hyperproperties based on their elements, the properties.

Analogous to safety and liveness property, Clarkson and Schneider defined the notions of *hypersafety* and *hyperliveness*. They have proved that every hyperproperty is the intersection of a hypersafety and a hyperliveness [7]. This generalizes Alpern and Schneider's result about properties.

Both theories of properties and hyperproperties have a characterization in terms of topology. In the Plotkin topology on properties, safety and liveness correspond to *closed* and *dense* sets, respectively [1]. In [7], this topological characterization is generalized to hyperproperties, showing that hypersafety and hyperliveness also correspond to closed and dense sets in the lower Vietoris topology which is a construction on Plotkin topology [31], [32].

It is an interesting question of the relation between the traditional approaching to the security policies based on CIA taxonomy and the formulation of them based on properties or hyperproperties. This is an open question. Clarkson and Schneider [7] think that the language of confidentiality, integrity, and availability is orthogonal to hypersafety and hyperliveness. Whereas Benenson et al. worked out a framework which, in their opinion, offers a new perspective onto the CIA taxonomy [5]. Namely, to some extent, confidentiality has a large overlap with information flow, integrity has parallels with safety, and availability has some resemblance to liveness.

However, our approach to hyperproperties as sets of sets of execution traces is different from the Clarkson and Schneider's one [7]. Namely, in contrast to their notion, we do not consider *every* set of execution traces as a property. Our proposal is characteristically a *point-free* approach. We deal with the set of execution traces *per se*, and the same is true for hyperproperties. Of course, in some special cases, a point-free feature can coincide with a feature defined in a point-wise manner. Avoiding the ambiguities, in our framework we will not use the terms 'property' and 'hyperproperty'.

We model distributed software systems as semantic system model, so-called *traced-based model*. A traced-based model describes the behavior of a system as a set of execution traces where a trace models a possible execution sequence of the whole system or its some components. To our notion the Mazurkiewicz' trace theory stands the nearest [23], [13]. We, however, at least temporarily, use it in a very simple form.

III. Problem Statement

We briefly sum up our framework informally as follows.

We model security policies as sets of sets of execution traces. We also have taken into account in our framework that security policies are partial-natured. Typically some policies may apply only to a specific application or type of information. For example, the average response time policy would be practical to be applied to the whole observed system. But, in an open computing environment, we *cannot* influence the response time of unknown applications, such as a database's query via the internet. As another example, probably it is enough to enforce the information flow policy on such software processes which handle confidential information.

To manage the outlined problem we need tools which are approximately able to discover secure or insecure patterns in execution traces. By applying some sort of knowledge discovery method it is possible to some extent to reveal the secure or insecure nature of the observed system. However, the result, obtained from the execution traces in this way, cannot be precise (exact) due to the permanent changes of the open computing environment and insufficient knowledge about it.

Rough set theory is a relatively new data-mining technique used in the discovery of patterns within data. This theory provides a powerful foundation to reveal and discover important structures in data and to classify complex objects. One of the main advantages of rough set theory is that it does not need any preliminary or additional information about data.

The rough set theory was introduced by the Polish mathematician, Z. Pawlak in the early 1980s [27], [28]. It was a new mathematical approach to *vagueness* [29]. According to Pawlak's idea, the vagueness of a subset of a finite universe U is defined by the difference of its upper and lower approximations with respect to a partition of the universe U.

Using partitions, however, is a very strict requirement. In this paper, our starting point will be an *arbitrary* family of subsets of an *arbitrary* set U. Neither that this family of sets covers the universe nor that the universe is finite will be assumed. Within this new framework, our concepts of lower and upper approximations are straightforward *point-free* generalizations of Pawlak's ones [9]. This is called the *partial approximative set theory*. This new approach suits the partial nature of security policies, as well. We will apply this theory to build up a new security model for distributed software systems *solely* focusing on their externally observable executions and to find out whether the observed system is secure or not.

The rest of the paper is organized as follows. In Section IV we summarize the basic notations. Section V will outline a general approximation framework. Sections VI and VII briefly present the basic principles of the rough set theory and the partial approximative set theory, respectively. In Section VIII we will describe the behavior of distributed software systems by means of partial approximative set theory.

IV. Basic Notations

Let U be any set. Let $\mathfrak{A} \subseteq 2^U$ be a family of sets of which elements are subsets of U. The union of $\mathfrak{A}$ is $\bigcup\mathfrak{A} = \{x \mid \exists A \in \mathfrak{A}(x \in A)\}$, and the intersection of $\mathfrak{A}$ is $\bigcap\mathfrak{A} = \{x \mid \forall A \in \mathfrak{A}(x \in A)\}$. If $\mathfrak{A}$ is an empty family of sets we define $\bigcup\emptyset = \emptyset$ and $\bigcap\emptyset = U$.

The number of elements of the set U is denoted by $\#U$.

If ϵ is an arbitrary binary relation on U, let $[x]_\epsilon$ denote the ϵ-related elements to x, i.e., $[x]_\epsilon = \{y \in U \mid (x, y) \in \epsilon\}$.

Let $\mathcal{A}$ be a finite set of *symbols* called the *alphabet*. A *string* is a finite or infinite sequence of symbols chosen from $\mathcal{A}$. We denote strings by small Greek letters $\sigma, \varrho, \tau, \ldots$, with possible sub- or superscripts. String containing no symbols is called the *empty string* and is denoted by λ.

If $\sigma = a_1a_2\ldots a_n$ is a finite string, $n = |\sigma| = |a_1a_2\ldots a_n|$ is called the *length* of σ. In particular, $|\lambda| = 0$.

Let $\mathcal{A}^*$ and $\mathcal{A}^\omega$ denote the set of all finite and infinite strings made up of symbols chosen from $\mathcal{A}$, respectively. We also use the following notations: $\mathcal{A}^+ = \mathcal{A}^* \setminus \{\lambda\}$, $\mathcal{A}^\infty = \mathcal{A}^* \cup \mathcal{A}^\omega$.

For any finite strings $\sigma_1 = a_1a_2\ldots a_n$, $\sigma_2 = b_1b_2\ldots b_m$, the *concatenation* $\sigma_1 \circ \sigma_2 = a_1a_2\ldots a_n \circ b_1b_2\ldots b_m$ of σ_1 and σ_2 is the string $\sigma_1\sigma_2 = a_1a_2\ldots a_nb_1b_2\ldots b_m$. If $\sigma_1 \in \mathcal{A}^*$, $\sigma_2 \in \mathcal{A}^\omega$ then $\sigma_1 \circ \sigma_2 = \sigma_1\sigma_2$ is also defined. The empty string is the identity for concatenation, that is for any string $\sigma_1 \in \mathcal{A}^*, \sigma_2 \in \mathcal{A}^\omega$, we have $\lambda\sigma_1 = \sigma_1\lambda = \sigma_1$ and $\lambda\sigma_2 = \sigma_2$.

A symbol $a \in \mathcal{A}$ *occurs* in string $\sigma \in \mathcal{A}^\infty$, if $\sigma = \sigma_1 a \sigma_2$ for some strings $\sigma_1 \in \mathcal{A}^*, \sigma_2 \in \mathcal{A}^\infty$.

Let $\sigma \in \mathcal{A}^*$, $\tau \in \mathcal{A}^\infty$ be two strings. σ is a *prefix* (initial part) of τ if there exists $\rho \in \mathcal{A}^\infty$ such that $\tau = \sigma\rho$. The prefix is *proper* if $\rho \neq \lambda$ and *nontrivial* if $\sigma \neq \lambda$.

Given $L \subseteq \mathcal{A}^\infty$, let $\mathtt{pref}(L)$ denote the set of all prefixes of all strings in L. Clearly, $L \subseteq \mathtt{pref}(L)$. In particular, $\mathtt{pref}(\{\sigma\}) = \mathtt{pref}(\sigma)$ is the set of all prefixes of the string $\sigma \in \mathcal{A}^\infty$. Note that $\mathtt{pref}(L) = \bigcup\{\mathtt{pref}(\sigma) \mid \sigma \in L\} \subseteq \mathcal{A}^*$.

Let $\mathcal{A}$ be an alphabet and σ be a finite string over an arbitrary alphabet. Then $\pi_{\mathcal{A}}(\sigma)$ denotes the (string) *projection of σ onto $\mathcal{A}$* defined as follows:

$$\pi_{\mathcal{A}}(\sigma) = \begin{cases} \lambda, & \text{if } \sigma = \lambda; \\ \pi_{\mathcal{A}}(\sigma'), & \text{if } \sigma = \sigma' a \wedge a \notin \mathcal{A}; \\ \pi_{\mathcal{A}}(\sigma')a, & \text{if } \sigma = \sigma' a \wedge a \in \mathcal{A}. \end{cases}$$

Informally, a projection onto $\mathcal{A}$ cleans strings of all symbols not in $\mathcal{A}$. $\pi_{\mathcal{A}}(\sigma) \neq \lambda$, if at least one symbol $a \in \mathcal{A}$ occurs in string σ.

Similarly, if $\Sigma \subseteq \mathcal{A}^*$, $\pi_{\mathcal{A}}(\Sigma) = \{\pi_{\mathcal{A}}(\sigma) \mid \sigma \in \Sigma\}$. $\pi_{\mathcal{A}}(\Sigma) \neq \{\lambda\}$, if in at least one string in $\sigma \in \Sigma$, at least one symbol $a \in \mathcal{A}$ occurs in σ.

V. A General Approximation Framework

In order that the vagueness can be treated in a general approximate framework, let our initial concept be the following. A pair of maps $f, g : 2^U \to 2^U$ is a *weak approximation pair on U* if

$$\forall X \in 2^U \ (f(X) \subseteq g(X)).$$

As Düntsch and Gediga noticed in [14], this constraint seems to be the weakest condition for a sensible concept of approximations of subsets in U.

The maps f, g is a *strong approximation pair on U* if each subset $X \in 2^U$ is bounded by $f(X)$ and $g(X)$ [14], i.e.,

$$\forall X \in 2^U \ (f(X) \subseteq X \subseteq g(X)).$$

In [26], a new hypothesis about approximation was drawn up recently. According to this assumption, the notion of "approximation" may be mathematically modelled by the notion of Galois connections. From now on, we call it the *approximation hypothesis*.

Let $(P, \leq_P)$ and $(Q, \leq_Q)$ be two posets.

Definition 1. A pair (f, g) of maps $f : P \to Q$, $g : Q \to P$ is a *(regular) Galois connection* or an *adjunction* between P and Q if

$$\forall p \in P \forall q \in Q \ (f(p) \leq_Q q \Leftrightarrow p \leq_P g(q)).$$

f is called the *lower adjoint* and g the *upper adjoint* of the Galois connection.

We also write (P, f, g, Q) for a whole Galois connection. If $P = Q$ it is said (P, f, g, P) is a Galois connection on P.

Remark 2. Here we adopted the definition of Galois connection in which the maps are monotone. It is also called monotone or covariant form. For more details, see, e.g., [11], [12], [15], [17].

VI. Fundamentals of Rough Set Theory

The basic concepts and properties of rough set theory can be found, e.g, in [28], [19]. Here we cite only a few of them which will be important in what follows. We partly restate these well-known facts on the language of approximations.

Definition 3. A pair (U, ε), where U is a finite universe of discourse and ε is an equivalence relation on U, is called *Pawlak's approximation space*.

A subset $X \subseteq U$ is *ε-definable*, if it is a union of ε-elementary sets, otherwise X is *ε-undefinable*. By definition, the empty set is considered to be an ε-definable set.

Let $\mathfrak{D}_{U/\varepsilon}$ denote the family of ε-definable subsets of U.

In Pawlak's approximation spaces, the lower and upper approximations of X can be defined in two equivalent forms, namely, in a *point-free* manner—based on the ε-elementary sets, and in a *point-wise* manner—based on the elements.

Definition 4. Let a Pawlak's approximation space (U, ε), a subset $X \in 2^U$ be given. The *lower ε-approximation* of X is

$$\begin{aligned} \underline{\varepsilon}(X) &= \bigcup\{Y \mid Y \in U/\varepsilon, Y \subseteq X\} \\ &= \{x \in U \mid [x]_\varepsilon \subseteq X\}, \end{aligned}$$

and the *upper ε-approximation* of X is

$$\begin{aligned} \overline{\varepsilon}(X) &= \bigcup\{Y \mid Y \in U/\varepsilon, Y \cap X \neq \emptyset\} \\ &= \{x \in U \mid [x]_\varepsilon \cap X \neq \emptyset\}. \end{aligned}$$

The set $B_\varepsilon(X) = \overline{\varepsilon}(X) \setminus \underline{\varepsilon}(X)$ is the *ε-boundary* of X. X is *ε-crisp*, if $B_\varepsilon(X) = \emptyset$, otherwise X is *ε-rough*.

Based on binary relations on U, lower and upper ε-approximations can be generalized via their *point-wise* definitions [19].

Definition 5. Let ϵ be an arbitrary binary relation on U and $X \in 2^U$. The *lower ϵ-approximation* of X is

$$\underline{\epsilon}(X) = \{x \in U \mid [x]_\epsilon \subseteq X\},$$

and the *upper ϵ-approximation* of X is

$$\overline{\epsilon}(X) = \{x \in U \mid [x]_\epsilon \cap X \neq \emptyset\}.$$

If ϵ^{-1} denotes the inverse relation of ϵ, in the same manner one can also define lower and upper ϵ^{-1}-approximations.

Theorem 6 ([19], Proposition 134)**.** *Let ϵ be an arbitrary binary relation on U. Then the pairs $(\overline{\epsilon}, \underline{\epsilon^{-1}})$ and $(\overline{\epsilon^{-1}}, \underline{\epsilon})$ are Galois connections on $(2^U, \subseteq)$.*

Some other properties of lower and upper ϵ-approximations are expressed by some properties of binary relations, and vice versa.

Theorem 7. *Let ϵ be an arbitrary binary relation on U.*

1) *The pair $(\underline{\epsilon}, \overline{\epsilon})$ is a weak approximation pair if and only if ϵ is connected.*
2) *The pair $(\underline{\epsilon}, \overline{\epsilon})$ is a strong approximation pair if and only if ϵ is reflexive.*
3) *The pair $(\overline{\epsilon}, \underline{\epsilon})$ is a Galois connection on $(2^U, \subseteq)$ if and only if ϵ is symmetric.*

Proof: In [19]. *1.* Proposition 136., *2.* Proposition 137., *3.* Proposition 138. ■

It can be shown that even if the relation ϵ is symmetric, it is not sufficient that the lower and upper ϵ-approximations defined in a *point-free* manner form a Galois connection [10].

VII. Fundamentals of Partial Approximative Set Theory

In practice there are attributes which do not characterize all members of an observed collection of objects. A very simple example, when one investigates an infinite set via a finite family of its finite subsets. For instance, a number theorist studies regularities of natural numbers using computers.

Throughout this section let U be any non-empty set.

Definition 8. Let $\mathfrak{B} \subseteq 2^U$ be a non-empty family of non-empty subsets of U called the *base system*. Its elements are the *$\mathfrak{B}$-sets*.

A family of sets $\mathfrak{D} \subseteq 2^U$ is *$\mathfrak{B}$-definable* if its elements are $\mathfrak{B}$-sets, otherwise $\mathfrak{D}$ is *$\mathfrak{B}$-undefinable*. A non-empty subset $X \in 2^U$ is *$\mathfrak{B}$-definable* if there exists a $\mathfrak{B}$-definable family of sets $\mathfrak{D}$ such that $X = \bigcup \mathfrak{D}$, otherwise X is *$\mathfrak{B}$-undefinable*. The empty set is considered to be a $\mathfrak{B}$-definable set.

Let $\mathfrak{D}_{\mathfrak{B}}$ denote the family of $\mathfrak{B}$-definable sets of U.

Definition 9. Let $\mathfrak{B} \subseteq 2^U$ be a base system and X be any subset of U. The *weak lower $\mathfrak{B}$-approximation* of X is

$$\mathfrak{C}^\flat_{\mathfrak{B}}(X) = \bigcup\{Y \mid Y \in \mathfrak{B}, Y \subseteq X\},$$

and the *weak upper $\mathfrak{B}$-approximation* of X is

$$\mathfrak{C}^\sharp_{\mathfrak{B}}(X) = \bigcup\{Y \mid Y \in \mathfrak{B}, Y \cap X \neq \emptyset\}.$$

Notice that $\mathfrak{C}^\flat_{\mathfrak{B}}$ and $\mathfrak{C}^\sharp_{\mathfrak{B}}$ are straightforward *point-free* generalizations of lower and upper ε-approximations.

Theorem 10 ([10], Theorem 4.5)**.** *Let the fixed base system $\mathfrak{B} \subseteq 2^U$ and maps $\mathfrak{C}^\flat_{\mathfrak{B}}$ and $\mathfrak{C}^\sharp_{\mathfrak{B}}$ be given.*

1) $\forall X \in 2^U (\mathfrak{C}^\flat_{\mathfrak{B}}(X) \subseteq \mathfrak{C}^\sharp_{\mathfrak{B}}(X))$.
2) $\forall X \in 2^U (\mathfrak{C}^\flat_{\mathfrak{B}}(X) \subseteq X)$*—that is, $\mathfrak{C}^\flat_{\mathfrak{B}}$ is contractive.*
3) $\forall X \in 2^U (X \subseteq \mathfrak{C}^\sharp_{\mathfrak{B}}(X))$ *if and only if $\bigcup \mathfrak{B} = U$—that is, $\mathfrak{C}^\sharp_{\mathfrak{B}}$ is extensive if and only if $\mathfrak{B}$ covers the universe.*

In other words, the pair of maps $\mathfrak{C}^\flat_{\mathfrak{B}}, \mathfrak{C}^\sharp_{\mathfrak{B}} : 2^U \to 2^U$ is a weak approximation pair on U, and it is a strong one if and only if the base system $\mathfrak{B}$ covers the universe.

Remark 11. If $\bigcup \mathfrak{B} \neq U$, then $\forall X \subseteq U \setminus \bigcup \mathfrak{B}\ \forall B \in \mathfrak{B}(X \cap B = \emptyset)$. Consequently, for all these subsets $\mathfrak{C}^\sharp_{\mathfrak{B}}(X) = \bigcup \emptyset = \emptyset$, i.e., the empty set is the weak upper $\mathfrak{B}$-approximation of certain non-empty subsets of U. This uncommon case may be interpreted so that our knowledge about the universe encoded in the base system $\mathfrak{B}$ is incomplete. This case may be excluded by a partial map called strong upper $\mathfrak{B}$-approximation. For more details, see [9].

Definition 12. Let the fixed base system $\mathfrak{B} \subseteq 2^U$ and maps $\mathfrak{C}^\flat_{\mathfrak{B}}$ and $\mathfrak{C}^\sharp_{\mathfrak{B}}$ be given. The quadruple $(U, \mathfrak{B}, \mathfrak{C}^\flat_{\mathfrak{B}}, \mathfrak{C}^\sharp_{\mathfrak{B}})$ is called a *weak $\mathfrak{B}$-approximation space*.

Theorem 13 ([10], Corollary 4.10)**.** *Let the weak $\mathfrak{B}$-approximation space $(U, \mathfrak{B}, \mathfrak{C}^\flat_{\mathfrak{B}}, \mathfrak{C}^\sharp_{\mathfrak{B}})$ be given.*

The pair of maps $(\mathfrak{C}^\sharp_{\mathfrak{B}}, \mathfrak{C}^\flat_{\mathfrak{B}})$ forms a Galois connection on $(2^U, \subseteq)$ if and only if the base system $\mathfrak{B}$ is a partition of the universe U.

VIII. The Security Model

An execution sequence consists of linearly ordered *observable* atomic actions. The manner in which execution sequences are represented is irrelevant, they may be finite sequences of primitive events, higher-level system steps, program states, state/action pairs, etc., or a mixture of all these [4], [30].

A. Types of Atomic Actions

Let $A_i = \{a_1, a_2, \ldots, a_{i_m}\}$ be a finite set of externally observable atomic actions of the i^{th} components of the distributed software system called the i^{th} *required component action set* (alphabet) ($i = 1 \ldots, n$). The required component action sets are not necessary pairwise disjoint, and the common atomic actions in different alphabets are undistinguishable. An *execution trace* (string) $\sigma \in A_i^\infty$ is a finite or infinite sequence of not necessarily different atomic actions.

Let A_{unsafe} be a finite set of insecure actions, called the *unsafe action set*, which may happen during the running time of the observed system.

$\bigcup A_i = \bigcup_{i=1}^n A_i = A_1 \cup A_2 \cup \ldots \cup A_n$ has to be augmented by a number of additional atomic actions which may or may not influence the safety of the system. Their set is called the *doubtful action set* and denoted by $A_{doubtful}$. For instance, usual interactions between end users and peripheral devices probably do not influence the safety of the system. But, too frequent interactions between them may indicate an unsafe behavior.

Note that the required component actions sets A_i are component specific, while the unsafe and doubtful action sets are not.

Let $\mathcal{A} = \bigcup A_i \cup A_{doubtful} \cup A_{unsafe}$, called the *(system) action set.* Let $\mathcal{A}_i = A_i \cup A_{doubtful} \cup A_{unsafe}$ denote the finite action set correspond to the i^{th} component called the i^{th} *component action set* ($i = 1, 2, \ldots, n$).

B. Anticipated Behaviors of Applications

We model the users' anticipated behaviors of a software component by a set of acceptable (feasible) finite linearly ordered sequences of the expected 'milestones' from A_i, in informal cases, or finite linearly ordered sequences of the required component actions corresponding to a given precedence dependency on A_i, in formal cases.

In latter case, let us suppose that the actions in a required component action set A_i have to be performed with respect to the ordering constraints called 'precedence' dependencies. Two actions are precedentially ordered if one has to precede the other specifying the precedential ordering such that starting a certain action depends on other actions being completed beforehand. For a simple example, one must enter into an application before quitting it. In symbols, $A_i = \{\text{'}enter\_into\_application\text{'}, \ldots, \text{'}quit\_application\text{'}\}$ and '$enter\_into\_application$' $\leq$ '$quit\_application$'. Of course, there may be many other precedences that must be obeyed.

We can represent these precedences by a set consisting of the pairs of type ('$before\_action$', '$after\_action$'). This situation is usually modelled as a *scheduling problem* which is a common source of partial orders. That is, the precedence dependency relation is reflexive, transitive, and antisymmetric, and renders the required action set A_i to a poset $(A_i, \leq)$. It is assumed that the precedence dependencies is configurable in this way and it is captured by the system architect in a precedential model.

In formal cases, let $\overrightarrow{A_i}$ denote the set of all topological sorts of the poset $(A_i, \leq)$. By the Szpilrajn's Theorem [33], $\#\overrightarrow{A_i} \geq 1$. An element of $\overrightarrow{A_i}$ can be represented as a finite execution $a_{i_1} a_{i_2} \ldots a_{i_m}$ of all elements of A_i in such a way that for all $i_k < i_l$, either $a_{i_k} \leq a_{i_l}$ or a_{i_k} and a_{i_l} are incomparable in $\leq$. This means that a topological sort in $\overrightarrow{A_i}$ is consistent with the precedence dependencies defined on A_i.

Similarly, in informal cases, let $\overrightarrow{A_i}$ denote simply the set of all acceptable (feasible) finite linearly ordered sequences of the expected 'milestones' from A_i.

Note that, $\overrightarrow{A_i} \subseteq A_i^*$, in both cases.

C. Modelling Software Systems and their Components

A distributed software system is modelled by a non-empty set of *infinite* execution traces over the system action set $\mathcal{A}$.

Definition 14. Let $\Sigma \subseteq \mathcal{A}^\omega$ be a non-empty set of infinite executions over the action set $\mathcal{A}$. Then, by a *distributed software system* we mean an $(\mathcal{A}, \Sigma)$ pair.

Similarly, a software component or application is a non-empty set of *infinite* execution traces over the i^{th} component action set $\mathcal{A}_i$.

Definition 15. Let $\Sigma_i \subseteq \mathcal{A}_i^\omega$ be a non-empty set of infinite executions over the action set $\mathcal{A}_i$. Then, by a *software component* or an *application* we mean an $(\mathcal{A}_i, \Sigma_i)$ pair ($i = 1, 2, \ldots, n$).

If a software system or its a component execution terminates, i.e., it is representable by finite execution trace, we represent it as an infinite execution trace by infinitely stuttering the empty action λ. The empty action λ represents the fact that the software system or its any application has not started yet, or their running has already finished.

D. Modelling Observations

An observation of a distributed software system is modelled by a non-empty set of *finite* execution traces over the system actions set $\mathcal{A}$.

Definition 16. Let $\Sigma^{obs} \subseteq \mathcal{A}^*$ be a non-empty finite set of finite execution traces over the system action set $\mathcal{A}$.

Then, by a *system observation* we mean an $(\mathcal{A}, \Sigma^{obs})$ pair.

Observations on components can be analogously defined over $\mathcal{A}_i$ ($i = 1, \ldots, n$).

Definition 17. Let $\Sigma_i^{obs} \subseteq \mathcal{A}_i^*$ be a non-empty finite set of finite executions traces over the component action set $\mathcal{A}_i$.

Then, by a *component observation* or an *application observation* we mean an $(\mathcal{A}_i, \Sigma_i^{obs})$ pair ($i = 1, 2, \ldots, n$).

In particular, Σ^{obs} and Σ_i^{obs} may consists of exactly one execution trace.

E. Modelling Security

According to the expected behavior of the system, an application is *acceptable* if it fully meets the requirements of the precedential model (prescription).

The component which contains at least one unsafe action is *unacceptable* (proscription). However, the transition from the ‘acceptable’ decision to the ‘unacceptable’ decision is a *vagueness* problem.

For the i^{th} component ($i = 1, \ldots, n$) we define

$$\begin{aligned}\mathfrak{S}_i &= \mathtt{pref}(\overrightarrow{A_i}) \\ &= \{\mathtt{pref}(\sigma_{i_j}) \mid \sigma_{i_j} \in \overrightarrow{A_i},\, i_j = 1, \ldots, \#\overrightarrow{A_i}\},\end{aligned}$$

where $\mathtt{pref}(\sigma_{i_j})$ is the set of all prefixes of either a topological sort σ_{i_j} of the poset $(A_i, \leq)$ in formal cases or a linearly ordered sequence of the expected ‘milestones’ in informal cases.

Let $\mathfrak{S} = \bigcup_{i=1}^{n} \mathfrak{S}_i$. Clearly, $\mathfrak{S} \subseteq 2^{A^*} \subseteq 2^{\mathcal{A}^*}$.

The sets in $\mathfrak{S} \subseteq 2^{\mathcal{A}^*}$ are not necessarily pairwise disjoint, and, in general, $\bigcup \mathfrak{S}$ does not cover $\mathcal{A}^*$. In other words, $\mathfrak{S}$ *is a base system over the universe* $\mathcal{A}^*$ *by the terminology of the partial approximative set theory.*

F. The Vagueness of Acceptability

Let an observation set of the i^{th} application Σ_i^{obs} be given.

If Σ_i^{obs} includes at least one finite execution trace over $\mathcal{A}_i$ in which at least one unsafe action occurs, i.e.,

$$\pi_{A_{unsafe}}(\Sigma_i^{obs}) \neq \{\lambda\},$$

the observed action set Σ_i^{obs} is *unacceptable*.

Let us assume, that the observed action set does not include unsafe action, i.e., $\pi_{A_{unsafe}}(\Sigma_i^{obs}) = \{\lambda\}$. By based on only this observation set Σ_i^{obs}, can the observed application be considered acceptable or not? This problem, as we also mentioned above, is a vagueness problem.

In order to answer this question, let us form the lower and upper approximations of $\mathtt{pref}(\Sigma_i^{obs})$ with respect to the base system $\mathfrak{S}$.

The lower $\mathfrak{S}$-approximation of $\mathtt{pref}(\Sigma_i^{obs})$ is

$$\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs})) = \bigcup\{S \in \mathfrak{S} \mid S \subseteq \mathtt{pref}(\Sigma_i^{obs})\},$$

and the upper $\mathfrak{S}$-approximation of $\mathtt{pref}(\Sigma_i^{obs})$ is

$$\mathfrak{C}^{\sharp}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs})) = \bigcup\{S \in \mathfrak{S} \mid S \cap \mathtt{pref}(\Sigma_i^{obs}) \neq \emptyset\}.$$

By means of lower and upper $\mathfrak{S}$-approximation, the set $\mathtt{pref}(\Sigma_i^{obs})$ of all prefixes of observed execution traces may be approximated, consequently, *the safety of the observed action set* Σ_i^{obs} *can be estimated to a certain degree, by the information encoded in* $\mathfrak{S}$.

$\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ and $\mathfrak{C}^{\sharp}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ can be interpreted as a security evaluation of the system working at the moment of the end of an observation time interval.

The execution traces in $\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ can be classified with certainty as members of $\mathtt{pref}(\Sigma_i^{obs})$. Formally, all elements of $\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ suit an element in $\mathtt{pref}(\overrightarrow{A_i})$, or, in other words, a prefix of an execution trace in $\overrightarrow{A_i}$. Its elements can be interpreted as certainty safe execution traces of the observation set Σ_i^{obs} with respect to $\mathfrak{S}$, i.e., they fully correspond to the users’ expectations.

$\mathtt{pref}(\Sigma_i^{obs}) \setminus \mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ may include, e.g., action sequences that miss some required actions or contain required actions in wrong order. It may also include right ordered action sequences which, however, contain doubtful actions between two required actions.

The execution traces in $\mathfrak{C}^{\sharp}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ are not guaranteed that all of them are members of $\mathtt{pref}(\Sigma_i^{obs})$. It may happen, e.g., that an execution sequence for a while suits a prefix of an execution trace in $\overrightarrow{A_i}$, but the next action is not a required one, it may be missing or it is a doubtful one.

By the partial feature of the base system $\mathfrak{S}$, it may take place that $\mathtt{pref}(\Sigma_i^{obs}) \nsubseteq \mathfrak{C}^{\sharp}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$. It may emphasize that our knowledge about the system encoded in the base system $\mathfrak{S}$ is not enough to approximate $\mathtt{pref}(\Sigma_i^{obs})$.

The situation $\mathtt{pref}(\Sigma_i^{obs}) \subseteq \mathfrak{C}^{\sharp}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs}))$ can be interpreted so that all observed execution traces for a while suit a prefix of an execution trace in $\overrightarrow{A_i}$, but some of them has a wrong continuation or the next action is a doubtful one.

Of course, $\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs})) \subseteq \mathtt{pref}(\Sigma_i^{obs})$. If $\mathfrak{C}^{\flat}_{\mathfrak{S}}(\mathtt{pref}(\Sigma_i^{obs})) = \mathtt{pref}(\Sigma_i^{obs})$, it means that all elements of the observation set Σ_i^{obs} can be viewed as safe execution sequences with respect to the users’ expectations.

IX. Conclusions and Future Work

We have shown a framework in which many questions corresponding to security features of distributed software systems can be represented uniformly.

The presented model is a theoretical outline. The next most important task is to work out a partial approximative information system model analogous to Pawlak’s one [28]. This will enable to set up models which can be applied to solving practical problems. Such a model could be a base on which expert systems for enforcement of security policies can be built up.

Theorem 13 shows that the pair of weak lower and upper $\mathfrak{B}$-approximations forms a Galois connection only in a very special case. This restriction can be partly exceeded by using the notion of partial Galois connection [24].

Abstract— **The objective of this research was to present and demonstrate the major aspects and underlying constructs of social engineering. An in-depth literature review was carried out resulting in the construction of a conceptual model of social engineering attacks. A case study was undertaken to understand the phenomenon with New Zealand-based IT practitioners to contribute insightful opinions. On this basis an improved model of social engineering-based attacks was formulated.**

I. Introduction

IN THE context of information security, social engineering describes a method of launching attacks against information and information systems. Both organizations and individuals have suffered enormous loss from these attacks. However, social engineering as a security threat is constantly overlooked because awareness of this phenomenon is currently low and there is a lack of a conceptual model to represent this form of attack.

The objective of this research was to present and demonstrate the major aspects and underlying constructs of social engineering and identify the relations between them. An in--depth literature review was carried out resulting in the construction of a conceptual model of the social engineering attacks.

A case study was undertaken to understand the phenomenon and a total of twenty-five New Zealand-based IT practitioners participated in this research to contribute insightful opinions.

Analysis of the collected opinions allowed us to present an improved model of social engineering-based attacks.

The paper starts with the formulation of the research objective and hypotheses followed by a presentation of a literature-based model of these attacks. Analysis of the New Zealand-based researchers' opinions is then presented. The paper terminates at the formulation of an improved model of social engineering based attacks.

II. Research objective, working hypotheses and methodology

The overall research objective of this study was defined as:

Exploring the significant entities and relations within social engineering-based attacks

To properly address this research objective, we formulated the following specific research questions:

RQ1*:What are existing security vulnerabilities which can be exploited by social engineering based-attacks?*

RQ2*:What are the methods of social engineering-based attacks?*

RQ3*:What are the consequences of a successful social engineering attack?*

RQ4*:What can be done to mitigate Social Engineering-based attacks?*

RQ5*:What is New Zealand's perspective of social engineering-based attacks?*

An exploratory case study approach was chosen to conduct the research investigation.

III. Proposed Model

Based on analysis and discussion of the conducted literature review, several key entities of social engineering attacks have been identified: People, Security Awareness, Psychological Weaknesses, Technology, Defenses, and Attack Methods.

As shown in Table 1, hacking and social engineering are the most common attack methods adopted across most fields. Traditional hacking and malicious code attacks are technical-based, targeting system or application vulnerabilities. However, the effectiveness of technical-based attacks has decreased as technological security solutions are gradually being adopted by more and more people and organizations [1]. Hence, this has encouraged technical hackers to choose the alternative – social engineering, targeting the existing vulnerabilities of both people and technology [2]. As a result, it is considered as the biggest security threat faced by both organizations and individuals today.

Social engineering is a diverse and complex technique for gaining unauthorized access to confidential proprietary and personal information [3]. It is primarily known as non-technical (human-based) attack, including impersonation, dumpster diving, shoulder surfing, and reverse social engineering; however, it could also be technology-based, including pop up applications, email attachment, online scams, and vishing. The literature review also indicates that the trend of technology-based attack is increasing with the emerging Internet technologies, such as online services and social networks [4], [5], [6] and [7].

IV. Consequences

The impact of social engineering attacks can be significant to both individuals and organizations [3]. The phase of the attack decides the type of information that may be valuable to social engineers. For instance, at the information gathering stage, information such as miscellaneous trivia within an organization; internal documents such as phone directories and organizational charts can be very useful. From an individual perspective, it will be personal information, such as date of birth, address and so on. Loss of CIA is the lesser damage and seen as the

Table I.
Summary of Security Threats and Attack Methods

Threat Initiator	Motivation	Attack Action	Method
Hacktivism (hacker, cracker, Phreaker, script kiddies)	• Ego, fame • Destruction of system or information	• DoS / DDoS • System intrusion • Website defacement • DNS attack	• Hacking • **Social engineering**
Computer Criminal	• Theft of data • Monetary gain • Privacy compromise • Illegal information disclosure • Unauthorized data alteration	• Cyber stalking • Fraudulent act (man-in-the-middle, spoofing)	• Hacking • **Social engineering**
Insider (disgruntled, poorly trained, dishonest, malicious, negligent, former employee)	• Revenge • Monetary gain • Intelligence	• Unauthorized access • Computer abuse • Fraud • Theft of proprietary information (both logical and physical) • Bribery • System sabotage	• Malicious code (logic bomb, Trojan, malcode inserted as part of the software development process) • **Social engineering**
Industrial Espionage	• Competitive advantage	• Unauthorized access • Information theft • System Penetration	• Hacking • **Social engineering**

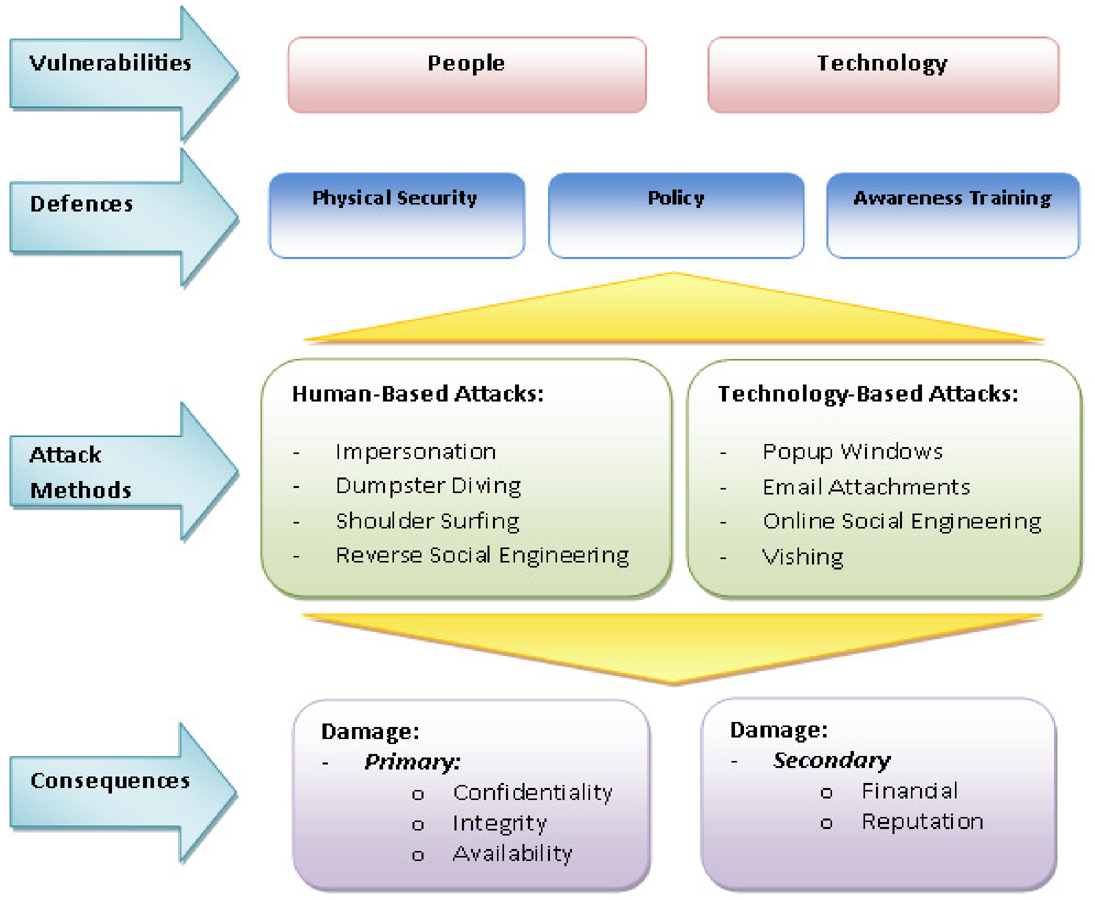

Fig. 1 The Conceptual Model of the Major Aspects of Social Engineering-Based Attacks

TABLE 2
SIX ENTITIES USED FOR DATA ANALYSIS

Entities	Description
People	Vulnerabilities in people that can be exploited by social engineering-based attacks.
Technology	Vulnerabilities in technology that can be exploited by social engineering-based attacks.
Security Strategy	Vulnerabilities in security strategy that can be exploited by social engineering-based attacks.
Defenses	Possible defenses to mitigate the risk of social engineering-based attacks.
Attack Methods	Types of the common social engineering-based attack methods.
Consequences	The damage of social engineering-based attacks to both organizations and individuals.

primary result of a successful social engineering attack. The information gathered is later used in the subsequent stage - attack phase. Again depending of the purpose of the attack, the level of damage varies. This is considered as the secondary damage of successful attacks.

The secondary damage is twofold. From a commercial perspective, firstly, social engineering attacks may cause significant financial losses, for instance, loss of business secrets to the competitor as a result of an insider attack, or loss of important equipments as a result of physical attack. Secondly, public disclosure of sensitive customer information stolen from a financial institution will damage the organization's image, followed by subsequent financial loss. From an individual's perspective, social engineering is a threat to people's personal life and finance, for instance, bogus advertisement and phishing attacks are the typical examples. The direct consequence to these attacks is identity theft which will finally lead to financial damage.

The above major entities form the basis of the social engineering-based attacks model presented in Figure 1.

V. Data Analysis & Finding

To verify the proposed model a total of 25 interviews were conducted, and the participants (from 17 organizations) were of various IT related backgrounds and experiences. The organizations the participants work for are across industries, including financial institution, security advisory services, government department, IT advisory, IT outsourcing, multi discipline computer firms, multi discipline consulting firms, and education. Among these organizations, there were seven local organizations and ten international organizations. The participants' job functions can be largely divided into seven categories: IT advisor, IT architect specialist, IT consultant, security specialist, IT solution designer, database management, and IT educator.

The entities used for the interview were derived from the conceptual model proposed in Fig.1 and summarized in Table 2. Major findings are presented next while the detailed answers are in [8].

VI. The Refined Model

Based on previous discussion and analysis of the information gathered during the interview phase, the revised model was developed shown in Fig 2. In the "Vulnerabilities" section, Security Strategy is added as a new entity which emerged from the analysis of the twenty-five conducted interviews. Security Strategy is in place to eliminate existing risks; however, the result from the interview analysis suggests that immature security strategy can be exploited indirectly by social engineering-based attacks. Therefore, Security Strategy is also considered as a vulnerable entity in information security. In the "Defenses" section, Technical Controls, Security-Enhanced Products, and Education entities were added.

These are the additional defence approaches which were believed to improve the mitigation of social engineering risks. In the "Attack Methods" section, Questionnaires are added as a new information gathering method.

Answering the research questions presented at the beginning of the paper:
RQ1: *What are existing security vulnerabilities which can be exploited by social engineering based-attacks?*

This research question was answered by findings from both the literature review and data analysis. The literature review identified two major components in information security that can be directly exploited by social engineering, including people and technology. In agreement with the literature review, the interview analysis suggested that security process should also be considered as a component which is vulnerable to such attacks.

Both the literature review and data analysis have suggested that people are the weakest link in security control systems. In addition, lack of security awareness and psychological weaknesses of people are the main reasons that social engineering-based attacks succeed. According to the literature review, people lack understanding of the current security issues - especially social engineering. This is supported by **64%** of the interview participants. Secondly, in agreement with the identified psychological weaknesses from the literature review, **40%** of the participants commented that appearance is a significant factor that can influence people's perceived trustworthiness.

The findings have suggested that there are three major issues associated with technology. First, the literature review has revealed that a lot of technology products have flaws in the security design. These flaws are used by an attacker to generate technology based scams which preys on people's fear of security. Data analysis shows that **16%** of the participants agreed to this. Secondly, in line with the literature review, **12%** of the participants pointed out that most security technologies are incapable of detecting and preventing social engineering as social engineering bypasses technical controls via manipulating people who are managing them. Additionally, **12%** of the participants stated that there is an increasing trend of malicious misuse of advancing technology products, such as Google Applications. It was also noted that online social networking services are often used as information gathering tools by the social engineers.

From the data analysis, security strategy emerged to be a significant entity that is vulnerable to social engineering-based attacks. The literature review has suggested that social engineering depends on uncertainty, for example, people are unsure about the requestor's identify, or people are

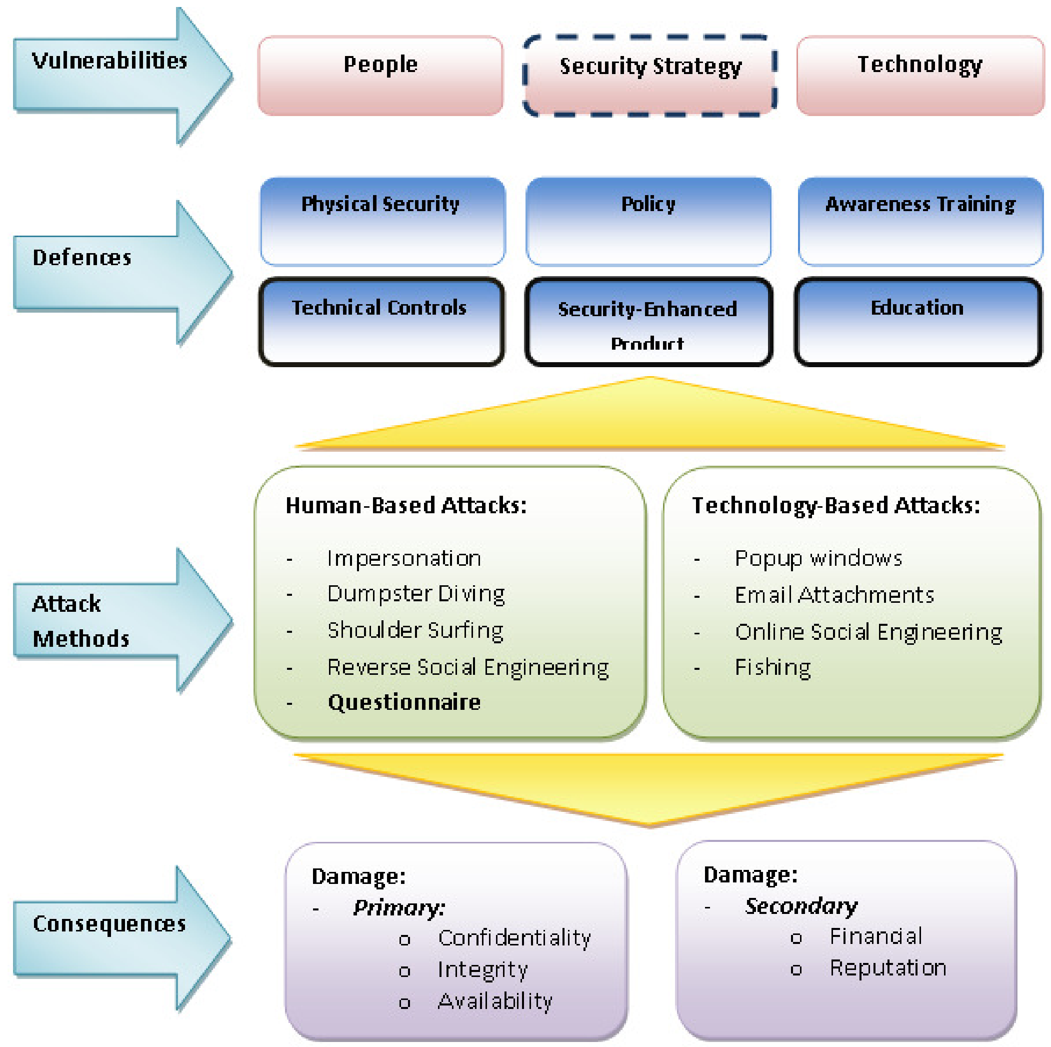

Fig 2. The Revised Conceptual Model of the Major Aspects of Social Engineering-Based Attacks

unsure about if it is the right thing to grant access to the requestor, etc. This is the main reason for putting in place a well-thought-out security strategy. However, **40%** of the interviewed participants emphasized that in general security strategies of organizations in New Zealand had poor security strategies because they overlooked people issues. Four types of threats from ineffective security strategies resulted from the data analysis - human behavior, system types of threats from ineffective security strategies resulted from the data analysis - human behavior, system implementation, physical environment, and governance issues. As the interview participants pointed out, a prospective social engineer may launch attacks against any of these vulnerabilities and conduct successful attacks.

RQ2: *What are the methods of social engineering-based attacks?*

Social engineering is often referred to as the people side of hacking which relies on influencing, deceiving, and psychological manipulation with or without the use of technology. It is diverse and complex and the form of the attack varies based on the attack motivation. Today, social engineering-based attacks can be basically classified into two categories, including human-based and technology-based.

Human-based social engineering is purely based on deception and can be conducted either in person or over the telephone. The methods include impersonation, dumpster diving, shoulder surfing, reverse social engineering, and questionnaire. Also, compared to an in person attack, by telephone is the most widespread mode as voice can be disguised. This mode is also easier for the social engineers to cover their tracks.

Technology-based social engineering is closer to traditional hacking technique. The purpose is to trick users into believing that they are interacting with authentic computer systems through the use of software or application. The attack methods include popup windows, email attachments, online social engineering, fishing, and rogue security software.

RQ3: *What are the damages after the attacks have been launched successfully?*

TABLE 6
ANALYSIS OF PARTICIPANTS' SOCIAL ENGINEERING-BASED ATTACK EXAMPLES

Attack Method	**Case #**	**Description**	**Damage**
Dumpster Diving	**Case 1**	The attacker went through waste to discover useful information such as credit card number simply because the merchant didn't pay attention to their waste management.	The victim lost their confidential information and money.
In Person	**Case2**	The pen-tester pretended to be someone who worked on the management floor and made the cleaner believe him. The cleaner had full access to the building, yet, their security awareness is very low. They are not trained to respond to unusual request.	It is only a penetration testing for the company, therefore nothing was lost.
	Case3	The attacker impersonated a cleaner to plant the key logger to steal sensitive information.	There was no significant damage because that bank has adopted appropriate security controls.
	Case4	People got access to the building and stole company property during office hours simply because the office staffs don't challenge strangers and abnormal behaviours.	Company equipment got stolen; this is considered as a financial loss.
	Case5	Similar to the previous pen-test case, the pen-tester was able to bypass security controls and gain access to company resources because the internal staffs, such as the reception was convinced that the pen-tester was part of the company.	It was a penetration testing; therefore there was no real damage.
Online Social Engineering	**Case6**	The attacker built trust with the victims and sent them photos with an embedded Trojan. The victims accepted the photos because their level of security awareness is very low.	The victim lost their confidential information and money.
	Case7	The attacker set up a fake website with full merchant facilities and security certificate to sell bogus Olympic tickets. It was never a business to begin with, yet, the bank and VeriSign didn't validate at all.	A large number of people paid for the ticket that would never get delivered, over 50 million dollars was scammed.
	Case8	The attacker took advantage of the online dating services and tricked a number of female victims. He first chatted with them through email and gradually built trust with them. He then sent them photos with an embedded key logger to steal their bank account details.	Victims lost money.
Telephone	**Case9**	The attacker tricked people over the phone into revealing biometric authentication (voice) pass phrase to use it later at the authentication point.	People's pass phrase got stolen and used for later attacks.
	Case10	The pen-tester pretended to be a customer who knows about the services. He was able to get sensitive information out of the helpdesk by bypassing the normal identify checks. On the other hand, it also showed that there was a lack of training and security awareness in that company.	If it was a real attack, the company may end up losing business confidentiality.
	Case11	A practical test to see how the bank handled abnormal situations. The initiator pretended to be helpless and prey on the customer services' sympathy.	The tester successfully changed the other party's passwords twice. In a real attack, the likely result is money loss.
	Case12	The attacker called the helpdesk and impersonated one of the contractors trying to gain access to the company network. Fortunately, the helpdesk found out and successfully prevented the potential attack.	Nothing happened because the helpdesk was doing their job properly.

The damages of a successful social engineering attack are twofold, primary and secondary. Similar to traditional hacking, social engineers spend most of their time in preparation via information gathering. To do so, the social engineer needs to gain authorized access to resources which leads to a breach of CIA. This is considered as the primary damage if the attack is successful. The information gathered is then used in the subsequent attack phase - the secondary damage.

Secondary damage can be largely divided into two parts, reputation damage and financial damage. The typical social engineering attack targets organizations with sensitive information, such as customer database. Loss and improper disclosure of information will seriously damage the organizations' reputation as well as finances. Moreover, finances may be rebuilt, but people's confidence and positive reputation can take years to rebuild.

RQ4: *What can be done to mitigate Social Engineering-based attacks?*

Social engineering represents a wide range of threats. To effectively defend against social engineering-based attacks, it is necessary to have a multifaceted approach. Firstly, on the very basic level, physical security must be properly implemented because a lot of the attacks are through gaining physical access. Therefore, access control must be in place to allow the authenticated people to have access while keeping the rest out. Ideally, organizations should apply different access control mechanisms based on the security classification. Secondly, proper technical controls can help to reduce social engineering risks, such as multifactor authentication can effectively prevent unauthorized access, especially for online financial identify theft. Thirdly, security policy is the key and most important element of a good defence against social engineering because it can take out uncertainty which is what social engineering depends on. The policy should include all the business components which are necessary to protect. Ultimately, security policy should be supplemented by education and training. People's vulnerability to social engineering can be described in terms of their awareness to these types of attacks. Therefore, people must be educated and trained constantly to be social engineering resistant.

RQ5: *What is New Zealand's perspective of social engineering-based attacks?*

In general, New Zealand shares a similar trend with other countries in terms of technology adoption and security risks. However, with regards to awareness of security issues and the implementation of countermeasures, New Zealand is a behind others.

First, according to **64%** of the interviewed participants, the majority of businesses and people in New Zealand do not have sufficient understanding of existing security issues. **32%** of them particularly mentioned the social engineering phenomenon is overlooked. The findings show that apart from people's careers, environmental factors (economical scale, legislation, and breach disclosure) also affect people's security awareness. In particular, **28%** of the interview participants mentioned it is mainly because there have not been major security disasters in New Zealand. **8%** of the interviewed participants pointed out that the other reason is the large number of security breaches, especially internal breaches in New Zealand that are underreported due to insufficient law enforcement. In addition, **44%** of the interviewed participants commented that people in New Zealand generally have a higher level of social trust which implies that they are more vulnerable to social engineering-based attacks.

Secondly, with regards to security strategy, **40%** of the interview participants commented that the organizations in New Zealand in general do not have a well-defined security strategy because they overlook people issues. **16%** of them pointed out being a small country; the majority of businesses in New Zealand have less than twenty people which have difficulties implementing segregation of duties. **20%** of the interviewed participants mentioned that the lack of legislations, standards, and compliances in New Zealand also have impact on immature strategies within the organizations. Furthermore, **40%** of the participants commented that immature strategies expose four categories of vulnerabilities which can be exploited by prospective social engineers.

Thirdly, the social engineering-based attack examples given by the participants show the diversity and complexity of this form of attack. As they stressed, there is a need for multifaceted defence approach to mitigate the risks associated with social engineering. In agreement with the approaches identified in the literature, the participants suggested that education, appropriate technical controls, and security-enhanced products should also be adopted.

VII. Research Contribution, Limitations and Future Research

This study makes three contributions:

Firstly, it provides insights regarding the social engineering phenomenon from both theoretical and practical perspective and developing a conceptual model to demonstrate the findings.

Secondly, it enhances understanding of social engineering in terms of the impact of this form of attack to businesses and individuals, through illustration of real New Zealand examples from the research participants.

Thirdly, it provides a multifaceted defence approach towards mitigating the risks associated with social engineering.

The research limitations are twofold. The first limitation is the selection of the interview participants. The participants of this research were the IT practitioners in New Zealand who either had a security background or had an interest in security issues. As a result, there is a lack of understanding from the non-IT perspective as people's perception of the problem might be different. This can be justified as the purpose of this research is to collect insightful opinions about major issues regarding social engineering-based attacks in New Zealand. Therefore, it was not the researchers' interest to investigate the research topic from a non-IT perspective. Secondly, this study constructed a conceptual model for social engineering-based attacks based on the findings from the literature review and interview analysis with twenty-five New Zealand-based IT experts. However, the model and the underlying theory require further validations.

Opportunities for future research on the basis of this research are in three areas. First, as mentioned in the previous section, one area would be to validate the constructed concept of social engineering-based attacks by assessing the underlying theory of each identified entity. In addition to this, a more sophisticated model can be built using this conceptual model. Secondly, this research has provided detailed analysis of how to conduct social engineering attacks. The analysis can be used as the basic guideline to design an educational software application that educates people on how to act in different attack situations. Lastly, as part of this research, a multi-faceted countermeasure against social engineering-based attacks was illustrated. Each of the proposed defense approach can be seen as a future research direction.

***Abstract*—The incentive of the mobile applications presented in this paper is the extensive spread of the mobile phone culture during the past decade. The first application is CalorieMeter, a calorie intake monitoring application. Cheer Up, the second application is based on self-help scientific methodologies for diagnosing possibilities of different kinds of depressions. Designs of both applications are based on the ideology of Mobile Phone Template applications. It supports easy transformation of a given application into other application domains and allows us gain natural language and regional languages independence, hence the global nature of our approach. Our applications have been developed for and tested on low- medium range of mobile phones.**

I. Introduction

MOBILE phone applications developed for the improvement of health of individuals capitalize the ubiquitous nature of mobile phones. Our first application, CalorieMeter concentrates on the improvement of the physical well-beingof an individual. The goal of this application is to motivate an individual to monitor his food and calorie intake so that he is able to meet his calorie needs without exceeding his permissible calorie amount for a particular day. The number of calories available for consumption per day is calculated using the Harris-Benedict equation [1]. We have created an intuitive and graphical interface to persuade users to use CalorieMeter regularly. This application as it is presented here targets English-literate users but its food choices can be conveniently adapted to any language and culture. The English texts in the language dependent screens (for example, user's profile) can be readily translated to any language we want to adapt the application to. The English texts can then be easily replaced by translations. All this is possible because the application design follows Template Ideology as defined in [2]. A template application is an application which can easily be modified from one domain to another.

The second application, Cheer Up is designed to help an individual to check the state of his mental health. Its goal is to help the user to become aware of his depressed state, if he is in one and to get a confirmation of his good mental status otherwise. We have created an appealing and enticing interface so the user can understand the flow of the application without any outside explanations. We believe that the intimacy and privacy of mobile phones will make people use the application and consequently help them overcome the stigma attached to depression. Eventually, they would seek a professional help, when needed. The application mainly targets teenagers who are regular cell phone users, might be depressed but otherwise would not seek help. We also show that application design follows Template Ideology.

A. Paper Organization

In section II, we present the physical health aid application, CalorieMeter. In section III, we present the mental health application, Cheer Up. For each application, we have described the application functionality, technical details, challenges and lessons learnt. In Section IV we show the working of the applications followed by the Template Ideology [2]. Section V is a conclusion of the paper.

II. CalorieMeter

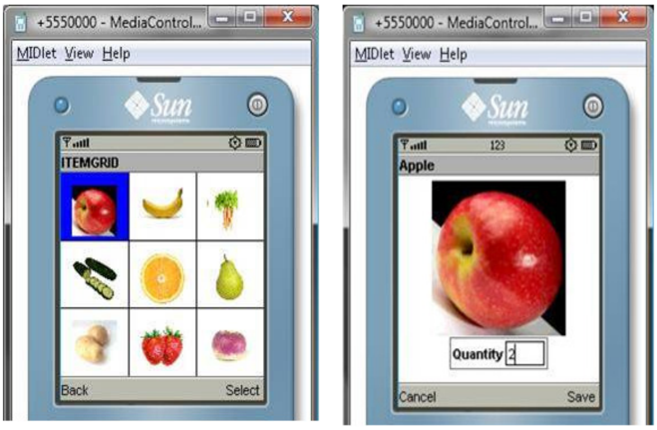
CalorieMeter helps the user monitor his food and calorie intake. In this application, the user sets his profile, enters food consumed, and the application monitors and reports his caloric intake and balance. The application also suggests food items the user could consume while still remaining within the permitted calorie intake.

Four major factors motivated us to develop CalorieMeter. The first factor is the rising obesity throughout the world. WHO [5] projects that by 2015, approximately 2.3 billion adults will be overweight and more than 700 million will be obese. The second factor is the lack of awareness of the calorific value of food items amongst individuals. Another factor is the lack of awareness of the calorie needs of an individual and need of consumption of a balanced diet.

A. Application Functionality

On using the application for the first time, the user is prompted to set a profile. The *Profile* screen consists of a form like interface with fields for name, sex, birth date, height and weight. On saving the profile, the *Home* screen appears. The *Home* screen has four options: *Profile, Food Categories, Calorie Balance* and *What To Eat???*. All the options navigate to their respective screens.

On the *Food Categories* screen, the user selects the food category and a food item grid of the corresponding food category appears. The three food categories are *Fruits and Vegetables*, *Meats and Grains* and *Deserts and Soda*. Each category is represented as a 3X3 grid of food items. The background color of the selected food item in the grid changes dynamically according to the time of the day along with the audio pronunciation (Fig. 1(a)). On selecting the food item the user is navigated to the *Food Item Details*



Quantity 2

Fig 1. (a) Food Items Grid , (b) Food Item Details

screen (Fig. 1(b)). Quantity can be entered on the *Food Item Details* screen [for grains, 1 implies 100 grams]. On choosing *Save*, the calories for the food item are added to the already consumed calories of that particular day.

The *Calorie Balance* screen helps the user approximate his share of daily permitted calories consumed (as calculated for user profile by our algorithm) and left to be consumed through a pie chart. The red color fraction of the pie signifies calories consumed and the green portion of the pie signifies the calories available for the day (Fig. 2(a)).

The What To Eat??? button on the *Home* screen navigates the user to the *What To Eat???* Screen (Fig. 2(b)). This screen suggests intelligent and healthy food item suggestions to the user. The suggestions are displayed in the form of a grid. Any food item consumed from this grid assures that the user does not exceed the permitted calorie intake for that day.

The application also has additional alert messages displayed on the screen on occasions when the user does not eat or exceeds the calorie limit.

B. *Key Features*

CalorieMeter has attractive grid navigation with integrated audio support. The user can use the up, down, left and right buttons to navigate and select food items from the cells of the 3X3 grid. The name of the selected food item is pronounced in English, but that can be changed due to the template design to any other language. The application can also serve as language teaching tool in a case when user language is different than the language used in the application. Another feature is the dynamic resizing of images in the grid. Hence we store only one copy of the image. The application also implements an intelligent algorithm for suggestions of healthy food items that can be consumed to remain within the calorie limit.

C. *Technical Details*

CalorieMeter incorporates 27 .png images with 120X120 size and 27 .wav files in the application and supports low end mobile phones (CLDC, MIDP 1.0). It has been developed using J2SDK, Eclipse IDE, J2ME Wireless Toolkit and Eclipse ME, Eclipse plug-in to develop J2ME code.

We reuse our custom grid implementation code which is populated dynamically based on the food category chosen. Our custom method dynamically re-sizes the images to fit the grid irrespective of the mobile phone screen size. The widths and heights of the images initially 120X120 are divided by an integer factor which is incremented on iteration till the re-sized image fits perfectly in the grid. We also implemented a string tokenizer to parse the .txt files containing data about the food items. We used RecordStores to emulate RDBMS by creating separate RecordStores to store information related to User Profile, Food Categories, Food Items and Food Consumption. Since J2ME does not have a built in date type, we accept the birth date of the user and store it as month, date and year.

What To Eat??? screen considers calories consumed for the day and permissible calorific value for the day and outputs a grid of food items which can be consumed without exceeding the permissible calorie limit. The weight-age assigned to each category is the motivation factor as the output has more healthy options than unhealthy ones.

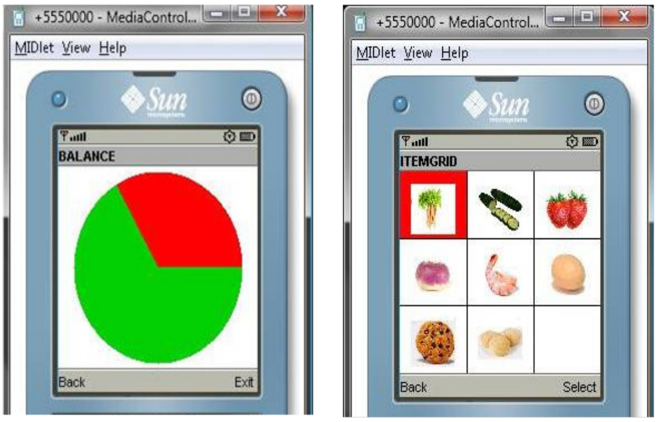


Fig 2. (a) Calorie Balance screen (b) What To Eat??? Screen

D. *Challenges and Lessons Learned*

The success of the application depended on the image size and clarity for easy comprehension by the user. Also, inclusion of packaged food items, platters and combos as food choices could increase the versatility of the application. This can be easily added during the customization. CalorieMeter can be also customized by adding/replacing picture set of food items according to the age groups and the regions, counties of users. Our application does not consider the frequencies of consumption of food items or the physical activities of the individual, but the template design allows and supports extensions.

E. *Related Work and Comparison*

This section describes a short comparison between prototypes of health applications deployed on technology platforms with consideration to type of architecture, motivational strategy employed and target audience. The applications we compare are PmEB [11], BALANCE [9], Heart Angel [10], FotoFit [7], and Wellness Diary [12]. PmEB [11] requires an internet enabled mobile phone whereas HeartAn-

gel [10] requires a Bluetooth enabled cell phone. All of them are standalone applications whereas PmEB [11] has client-server architecture. All the applications except PmEB [11] and Wellness Diary [12] require an external hardware device. For example Heart Angel [10] requires a heart rate monitoring hardware device. The motivational strategy in PmEB [11] and Wellness Diary [12] is control, in BALANCE [9] is challenge, in FotoFit [7] is competition and in HeartAngel [10] is encouragement. BALANCE [9], Heart Angel [10], Wellness Diary [12] target fitness enthusiasts, PmEB [11] targets obese mobile phone users and FotoFit [7] was developed for college students.

III. Cheer Up

Cheer Up is designed to evaluate the mental health of individuals by discovering if they are in a depressed state, categorize this state and send a warning to the user. It is an attempt to make Cognitive Behavioral Therapy (referred as CBT hereafter) [14] more accessible and personalized. We hope it would appeal to young people and make them aware that they might need to seek professional help.

A. *Motivation*

Depression is the single biggest cause of suicides in the world [22]. Most cases of depression go unnoticed, unreported and are aggravated due to lack of self-awareness, easily accessible psychiatric help or stigma associated with visiting a psychiatrist. The portable and personalized nature of mobile phones along with its ubiquitous nature might help to breach the gap between people who need professional help and those who eventually reach for it [15].

B. *Requirements Elicitation*

The foundation of Beck's cognitive theory of depression is a stress-diathesis model [13]. Persons may be vulnerable to depression because they have dysfunctional beliefs. These beliefs may remain latent for years, prior to and between depression pangs, but they can become primed by environmental stressors. The Cognitive Behavioral Therapy [13] aims at knowing how we think about ourselves and our surroundings and our emotional reactions to events occurring around us. By changing our thought process, we can change our emotional reactions which in turn can prove helpful in treating depression.

To feed our diagnosis algorithm with quantifiable associations between images & depression types, we conducted a survey of around 100 people in the age group of 20 – 30 (Fig. 3(a)). They were asked to rate the images on the scale of 1 to 5 where 5 indicated maximum association of the image with the type of depression. The entered weights were aggregated and the mean values were used to derive the probability of associations.

Based on the survey results we tabulate the mapping of each image to various types of depressions. This is stored in the configuration file and is used in the diagnosis algorithm.

C. *Application Functionality*

The *Home* screen consists of three options. The first option is *Diagnose* which is the key part of the application where user takes a self-diagnosis by responding, with numbers, to an adaptive display of images (Fig. 3(b)). The users' responses are used to predict their cause and degree of depression. These values are stored as user's profile in the record store until the user takes a new diagnosis. The user's predicted depression type and level is also used to assign a personalized set of therapy tasks like art therapy, cope, mood logs etc. The second option *To-Do* suggests ways to figure the type of depression discovered.

The *Help* button displays instructions on how to use the application. The *Diagnose* button starts a slide-show of images which evaluate the type of depression in the user. For each image, the user selects a number from 0-9 where a higher number indicates that the user can relate to the image to a higher extent (Fig. 2(b-c)). Once the slide-show is over, the results are displayed. Once the user completes the diagnosis, the user's profile is stored in the phone. On clicking on the *To-Do* button, the application launches a therapy task customized for the user based on the depression diagnosis. Scientific research proves the efficacy of art therapy in healing depression [23]. The tasks are usually timed and self-evaluated. Depending on the task image these may try to divert the user's mind, make him busy in a soothing hobby, or try to make him learn to cope with him causes of depression.

D. *Technical Details*

Extensibility was one of the primary goals in our design as we wanted to develop our application as a frame work for a generic family of applications that plays an interactive and adaptive sequence of images to gather up user responses and analyze them. This was made possible through an efficient object oriented design. The Diagnosis Algorithm multiplied the score entered by the user by the weights of various depression types. These weights were calculated as a result of the survey conducted by taking the weighted mean of the percentage of user responses. The sum of all results calculated to get the final result was then mapped to the various types of depressions.

We believe that the algorithm will be more accurate if the data obtained from the survey was actually obtained from real controlled clinical trials of patients suffering from depression. Our application is a proof of concept of a diagnostic tool. Our application can serve as a template for a real application. The diagnostic mobile based tool should be developed in collaboration with medical specialists and we plan to do so.

E. Related Work

There have been some innovative attempts at diagnosing and healing depression using computing technologies. They can be categorized into three major forms Internet Based CBT [19], Computer Based CBT [20], Mobile Based [16], [17], [18], and [21].

Mobile based depression therapy is a very new area and there are only few applications we came across. A disadvantage of these applications is that they require high end mobile phones and rely heavily on the use of the Internet.

In [16] the mobile phone acts as a patient terminal, mobile phone providers connect the patient to the Internet where the IIS web server stores the information. The patient receives an email with a link to interview page. The user selects a number which gives information about the degree of particular symptom.

In [17] the data is stored and can be accessed online through a mobile phone. This existing system contains a real-time advice function. Real time advice function implements an algorithm that is performed over the user responses to analyze the kind of depression he is in and provides encouraging or warning messages in order to boost his morale and take actions to perform better.

In [18] a mobile phone program monitors adolescents' mood, stress and coping behaviors with some specific aims. [21] presents a mobile application developed in Murdoch Children's Research Institute. This application is used to track young users' experiences of moods and stress levels. The authors have developed a real-time, youth-friendly mobile phone program based on momentary sampling (MS) with interactive monitoring programs that can be run on java-enabled MIDP 2.0 mobile phones. MS data may be recorded by calling participants on mobile phones and using automated interactive voice response systems or researcher-lead interviews.

IV. Template Ideology

CalorieMeter can be transformed into an application of another domain with minimal knowledge of programming in J2ME. Three types of changes are possible in the transformation. Firstly the user can change the set of food items displayed in our application. Secondly the weight-age of each category can be changed. Thirdly the categories can be changed. The only constraint is that the number of categories should remain three. However the user would have to clean and build the code and redeploy it as the .jar and .jad file would get modified.

A.CalorieMeter

For example the CalorieMeter might be transformed for use of university students in the USA. In this circumstance, the picture set should consist of fruit and vegetable salads, pizzas, burgers, soda available in the cafeteria. The steps to transform the application are as explained below in the following sentences. To change the set of images, the .png files in the pictures folder of the application source code should be replaced by the picture files of new food items. The size of image should be 120X120. To change the set of audio files, the .wav files should be replaced by the audio files of new food items. The average size of our .wav files was 90kb. Standard notations have been followed in the text files which have the information about the object items to be present in the grid. The following should be followed as standard in the text files. '#' is used as separator between each field on the same line. '?' is used as the end of line at the end of each description. Each text file is one single line. '?$' is used as end of file. For example Categorydefaultentries.txt is in the form of 1#Fruit#Fruit.png#50? Where category id is 1, category name is fruit, icon is fruit.png, weight is 50, weightage is 2, # is a separator between fields and ? is for end of line.

B.Cheer Up

To ensure consistent display of Cheer Up across different mobile phone devices, all images adapt to phone screen size. Data regarding depression types, diagnostic images, and therapy tasks can be added via the configuration files of the application. The application can used as a framework to design and develop applications which evaluate user responses and provide homework tasks in an adaptive manner. All text comes from text files which can be easily changed and translated.

V. Conclusion

In this paper we presented two mobile applications inspired by the globally pervasive nature of mobile phones. Our first application, CalorieMeter helped the user keep track of his calorie intake on a daily basis thereby helping him to maintain a check on the calorie intake in a healthy fashion. Our second application, Cheer Up is an initiative to help depressed individuals become aware of their condition and henceforth curb the stigma attached with seeking external medical help. Mobile phones prove to be an ideal platform for health applications as they are affordable, personalized and interactive. Template Ideology renders our applications independent of regional, language, age, educational and social barriers.

***Abstract*—This thesis is intended to examine factors that affect customer satisfaction in the domestic mobile communication terminal market as to expectations before purchase and actual satisfaction after purchase. Also, how the factors that affect customer satisfaction about mobile phones influence the customer base was theoretically and positively examined. The mobile communication terminal industry, which has been the driving force behind the development of Korea as a great power in the information and communication industry, has a great influence on the global market as well as the domestic economy. Nevertheless, research efforts on the existing mobile communication market havebeen focused on the mobile communication service market rather than the mobile communication terminal market. In addition, research on customer satisfaction about mobile communication terminals, which has been done by a few scholars in the related fields, has been limited to prices and brands. That is, the traditional research efforts on customer satisfaction about mobile communication terminal products have been focused on the influences of prices and brands on the purchase of products rather than on the evaluation of the unique quality attribute of each product.Therefore, this thesis is intended to examine factors expected to enhance customer satisfaction about products and expand the customer base other than the external factors including the prices andbrand images of mobile phones so that customer-oriented mobiles phones can be developed and manufactured.**

Keywords-component: Mobile Communication Industry, Customer Satisfaction, Mobile Communication Terminal

I. Introduction

KOREA succeeded in developing the world's first commercial CDMA system in the year 1995 and started to provide commercial services in the year 1996. Ever since then, the domestic mobile communication industry has marked an unprecedented growth on a consistent basis. As of November, 2006, the number of subscribers to the domestic mobile communication services is over 40 million, which comes to one mobile phone per person as to the economic activity ratio per population, a high supply rate of mobile communication services (the Ministry of Information and Communication, 2006). 5). The rapid supply of mobile phones, which have become a necessity in modern life, and the development of communication service technology have led Korea to become a great power in the world's communication industry where communication services are available in the most convenient manner. Services activated by the development of CDMA equipment have made the domestic mobile communication market rapidly grow and develop, having a huge influence on the global and domestic economies. The birth of Korea as a great power in information technology has resulted in an unprecedented growth within a short span of time and helped Korea take the lead in the export of information technology worth 100 billion dollars. Also, information technology, now a representative industry of Korea at the peak of the "Korea Brand Premium", is being admired by a number of nations in the world. Nevertheless, research efforts on the existing mobile communication market have been focused on the mobile communication service market rather than the mobile communication terminal market. As stated above, the mobile communication market is a combination of the service industry where services are provided through a network of mobile communication and the manufacture industry where systems and terminals are produced and supplied. Thus, research on the mobile communication market must be accompanied by the analysis of the mobile communication terminal market. Moreover, the quality evaluation of tangible terminals intended to use intangible services must be done besides the quality evaluation of mobile communication services. In general, the mobile phone industry is a production-led industry where the manufacturer's ideas stimulate the user's desires to purchase the supplied products. Also, new technology developed by mobile phone manufacturers has consistently educated consumers. Accordingly, customer satisfaction is formed on the basis of the nature of products suggested by manufacturers, and it is our tendency to understand the level of customer satisfaction as unmatched loyalty to the corresponding products. In addition, research on customer satisfaction about mobile communication terminals, which has been done by a few scholars in the related fields, has been limited to prices and brands. That is, the traditional research efforts on customer satisfaction about mobile communication terminal products have been focused on the influences of prices and brands on the purchase of products rather than on the evaluation of the unique quality attribute of each product. This research is designed to analyze factors that affect customer satisfaction in the mobile communication terminal market. Furthermore, the influences of expectations before purchase and actual satisfaction after purchase on customer loyalty will be analyzed so that factors expected to enhance customer satisfaction about products and improve customer loyalty as a result can be suggested and customer-oriented mobile phones can be manufactured with priority given to the unique quality attribute of each product.

II. Theoretical Backgrounds

A. *Customer Satisfaction*

(1) Quality Attributes of Mobile Communication Terminal Products

The previous studies evaluated the quality of tangible materials as having a long life and a number of functions. However, the concept of quality is now being reinterpreted with the focused placed on "meeting the needs of customers". Parasuraman, Zeithaml and Berry (1985, 1988) claim that quality perceived by customers is determined by the comparison between customers' expectations for the level of quality to be met by manufacturers and their actual perception of quality supplied by manufacturers. Such studies mainly use "Servqual"as a means to evaluate customer service quality. The 10 categories of corporeality, credibility, response, capability, courtesy, reliability, accessibility, communication, and customer understanding are expounded within the limit of corporeality, credibility, reactivity, assurance, and response. The quality evaluation of corporeal materials like mobile communication terminals mainly uses the attribute clue (Zeithaml, 1988), and the criteria for the attribute clue vary according to the nature of corporeal materials. SERVQUAL is customized in accordance with the criteria used by service providers, and the attributes like "polite and tidy-looking staff" and "accurate customer record maintenance" are very much different from the quality evaluation of corporeal materials.Thus, this research selected 8 attribute clues from 22 attribute clues of SERVQUAL closely associated with the unique attributes of mobile communication terminals through interviews with experts in mobile communication.

Table I. Quality Attributes of Mobile Communication Terminal Products

Corporeality	Shape and Size of Terminals / Design of Terminals
Performanc e	Various Functions of Terminals / Up-to-date Functions of Terminals
Convenience	Convenience of Character Input / Convenience of Subsidiary Functions of Terminals
Durability (Credibility)	Life of Terminals / Breakdown Frequency of Terminals

(2) Customer Satisfaction

Customer satisfaction wasperceived differently by a number of scholars in their previous studies, and it has been also evaluated in different manners. Research efforts on customer satisfaction can be roughly categorized into two perspectives. Yi (1990) divided customer satisfaction into resultant satisfaction obtained from consumer experience and interim satisfaction in the middle of the evaluation process. Oliver (1980) defined customer satisfaction as the function of expectations met and perceptions of discrepancies, suggesting a discrepancy paradigm. Westbrook & Reilly (1983) referred to customer satisfaction as a psychological response caused by experiences associated with the purchase of products or services. Churchill and Surprenant (1982) defined customer satisfaction as a conceptual, practical meaning and regarded the conceptual implication of customer satisfaction as the comparison between expected results of purchase, use, and consumption and price and compensation. In addition, Churchill and Surprenant regarded the practical implication of customer satisfaction as the sum of satisfaction about various attributes of products or services. In addition, they claimed that the quality of products and services increases when it exceeds the demands, needs, and expectations of customers in that customer satisfaction relies on the perceptions and expectations of customers. On the basis of such studies, this research is intended to analyze customer satisfaction about mobile communication terminal products as to expected satisfaction in the middle of evaluation before purchase and actual satisfaction coming from purchase experiences. The previously mentioned quality attributes of mobile communication terminal products will be measuredas a major factor that determines customer satisfaction based on the level of customer perception (Bitner, 1990; Zeithamal and Bitner, 1996).

(3) Customer Loyalty

Customer loyalty has been studied with a wide scope by a number of scholars. The existing studies on customer loyalty can be roughly categorized into behavioral, attitudinal, and integrated approaches (Oh, 1995). The behavioral approach examines the continuity of customer purchase history and deals with customer loyalty in association with the rate, frequency, and probability of purchase (Jeuland, 1979; Raj, 1982). The attitudinal approach interprets customer loyalty as psychological immersion, preference, and favorable attitude toward particular products or services (Jacoby and Chestnut, 1978; Oh, 1995; Oliva et al., 1992). Combining these two approaches, the integrated approach uses customer behaviors and attitudes to conceptualize customer loyalty and is used as a valuable means to understand customer loyalty in various industrial fields (Dick and Basu, 1994). Customer loyalty is sometimes manipulated as behaviors and attitudes, and the attitudinal criteria include recommendations of brands, resistance against superior competitive alternatives, intention to buy again, and intention to pay for the premium (Anderson & Sullivan, 1993; Boulding et al., 1993; Cronin & Taylor, 1992; Narayandas, 1996; Zeithaml et al., 1996). Based on such studies, this thesis defines customer loyalty as the sum of 7 behavioral patterns and uses them as a means of measurement: superiority as to mobile phone brand images, favorable attitudes toward mobile phone brands, pride in using mobile phones, resistance against superior competitive alternatives, recommendations of products being used, intention to buy again, and intention to pay for the premium.

III. Positive Analysis

A. *Research Model and Hypothesis*

On the basis of the results of the previous studies, this thesis categorizes customer satisfaction into expected satisfaction in the middle of evaluation before purchase and actual satisfaction comingfrom purchase experiences and illustrates the relationship with customer loyalty as shown in Figure 1.To emphasize use Emphasis and Strong styles. For code fragments use Code style, for URLs standard Hyperlink style, for file names – File Name style.

Satisfaction about products is divided into expected satisfaction in the course of evaluation before purchase and actu-

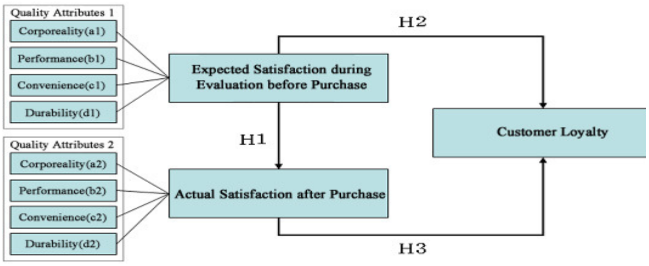

Fig. 1 Research Model

al satisfaction coming from purchase experiences (Yi, 1990), and customer satisfaction about products relies on customer expectations, increasing when such expectations exceed the quality of products (Churchill& Surprenant, 1982). In addition, Oliver (1980) defined customer satisfaction as the function of expectations met and perceptions of discrepancies, suggesting a discrepancy paradigm. Based on such studies, hypotheses 1 and 2 were established as follows:H1. The level of expected satisfaction in the course of evaluation before the purchase of mobile communication terminals is expected to have a positive influence on the level of actual satisfaction coming from purchase experiences. H2. The level of expected satisfaction in the course of evaluation before the purchase of mobile communication terminals will have a positive influence on the level of customer loyalty. According to the studies done by Westbrook & Reilly (1983), customer satisfaction is defined as a psychological response resulted from experiences associated with the purchase of products or services, and such attitudes are related to customer loyalty including psychological immersion, preference, and favorable attitude toward the corresponding products (Jacoby and Chestnut, 1978; Oh, 1995; Oliva et al., 1992). Hypothesis 3 was then established based on the results of such studies.H3. The level of actual satisfaction obtained from the purchase of mobile communication terminals is expected to have a positive influence on the level of customer loyalty. On the basis of the 3 hypotheses stated above, this thesis will analyze the relationship between variables through the SEM (Structural Equation Model) with the focus placed on factors like the level of expected satisfaction in the course of evaluation before purchase, the level of customer satisfaction obtained from purchase experiences, and the interrelated influence on and causal relationship between various levels of customer loyalty.

B. *Makeup of Measured Items*

The manipulative definition of variables used to test the hypotheses established in this thesis is based on the suggestions made by the previous studies. This research selected 8 attribute clues from22 attribute clues of SERVQUAL closely associated with the unique attributes of mobile communication terminals through interviews with experts in mobile communication. The 4 factors that affect the level of customer satisfaction in the course of evaluation before purchase consist of 8 items: corporeality (2 items), performance (2 items), convenience (2 items), and durability (2 items). In addition, the 4 factors that affect the level of customer satisfaction after purchase consist of 8 items: corporeality (2 items), performance (2 items), convenience (2 items), and durability (2 items), making the total of 8 factors and 16 items. Also, the factors that affect customer loyalty were measured as 7 items. Expected satisfaction in the course of evaluation before purchase, actual satisfaction obtained from purchase experiences, and customer loyalty were measured by the Likert 7-score criteria, with score 1 being "Not at all" and score 5 being "Very much".

C. *Data Collection and Analysis*

1,000 male and female consumers ranging from 10's to 60's across the nation including small and medium-sized cities who own mobile communication terminals were interviewed in person, and samples were assigned and extracted in consideration of gender, age, region, and the occupancy ratio in the domestic mobile communication service market. SPSS was used to statistically process the questionnaire results, and an analysis was made as follows: First, the demographic density of respondents was analyzed based on the collected data so that the representativeness of the population could be checked. Second, credibility was checked with the Cronbach's alpha value by using SPSS in order to check whether the actual concept measured corresponds to the abstract concept to be measured in the measurement model (measurement variable) of this research, and then the research model was analyzed by using Amos 4.0 of the covariance structure analysis in order to examine the determinant factors that affect customer loyalty.

D. *Results of the Analysis*

(1) Characteristics of the Sample Data

(A) Distribution of Gender and Age

Among the 1,000 respondents who own mobile communication terminals, there were 472 men (47.2%) and 528 women (52.8%) while there were 155 people in the 10's (15.5%), 328 people in the 20's (32.8%), 291 people in the 30's (29.1%), 193 people in the 40's (19.3%), 30 people in the 50's (3%), and 3 people in the 60's (0.3%).

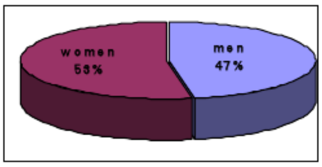

Fig. 2 Research Model

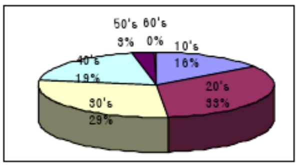

Fig. 3 Research Model

TABLE 2
DISTRIBUTION OF GENDER AND AGE

	10's	20's	30's	40's	50's	60's	Total (ratio)
Number of Men	71	153	142	95	9	2	472 (47.2%)
Number of Women	84	175	149	98	21	1	528 (52.8%)
Number of Samples (ratio)	155 (15.5%)	328 (32.8%)	291 (29.1%)	193 (19.3%)	30 (3%)	3 (0.3%)	1,000 (100%)

(B) Distribution of Terminal Manufacturers

As for the terminal manufactures that are currently selling mobile communication terminals in the domestic market, those whose names start with S, L, ST, P, M, and K were targeted, and 453 respondents turned out to own terminals manufactured by company S (45.3%), 179 by company L (17.9%), 107 by company ST (10.7%), 109 by company P (10.9%), 77 by company K (7.7%), 65 by company M (6.5%), and 10 by other manufacturers (1%).

Table 3
Distribution of Mobile Phone Manufacturers

	S	L	ST	P	K	M	Others	Total
Number of Samples (%)	453 (45.3)	179 (17.9)	107 (10.7)	109 (10.9)	77 (7.7)	65 (6.5)	10 (1)	1000 (100)
Population Ratio	46.87	20.5	16.38	6.92	4.66	2.66	2.00	100%

(C) Distribution of Mobile Communication Service Providers

The mobile communication service providers in the domestic market include SK Telecom, KTF, and LG Telecom, and 507 respondents turned out to have made a contract with SK Telecom (50.7%), 328 with KTF (32.8%), and 165 with LG Telecom (16.5%) in consideration of the occupancy ratio of each provider in the domestic market.

Table 4 Distribution of Mobile Communication Service Providers

Category	SK Telecom	KTF	LG Telecom	Total
Number of Samples (%)	507 (50.7)	328 (32.8)	165 (16.5)	1,000 (100)
Population (ratio)	52%	32%	16%	100%

(2) Analysis of Credibility

As means to test the credibility of variables, the split-half method and the internal consistency analysis are used to compute the credibility coefficient as to measured items. The most widely used method is the internal consistency analysis in that it tests credibility in consideration of the average relationship between items within each measurement device in case a number of items are used to measure the identical concept. In particular, in case a measurement variable consists of a number of items, the method using the Cronbach's alpha tests whether the component items are formed to measure the identical concept, enhancing credibility by excluding the items that hamper credibility from the measurement device. In this research credibility was tested by the Cronbach's alpha, and the results are shown in Table 5.

Table 5
Credibility Coefficients

Name of Variables		Number of Items	Cronbach' Alpha
Expected Satisfaction during Evaluation before Purchase	Corporeality	2	.7679
	Performance	2	.7457
	Convenience	2	.6877
	Durability	2	.6279
Actual Satisfaction after Purchase	Corporeality	2	.8928
	Performance	2	.7228
	Convenience	2	.7457
	Durability	2	.6993

The standards for credibility vary among a number of scholars, but in general, if the Cronbach's alpha coefficient exceeds 0.6, no one doubts the level of credibility, and if the Cronbach's alpha coefficient is over 0.8, the level of credibility is said to be significantly high. Most of the Cronbach's alpha coefficients for the measurement variables used in this research exceed 0.6, making all variables credible.

(3) Testing Hypotheses

The method used to analyze the relationship between a number of variables using the correlation matrix or the covariance matrix in a synthetic manner is referred to as the "multivariate analysis", and the covariance structure model is a model that integrates various methods of the multivariate analysis. That is, the multiple regression analysis is possible if there are more than 2 independent variables and only 1 dependent variable whereas the multivariate analysis is a proper method to analyze the causal relationship between variables if there are more than 2 dependent variables. LISREL has been widely used up until now for the covariance analysis, but it has several drawbacks including the complexity in entering data or processing statements. To complement such drawbacks, therefore, Amos was used to analyze the structural equation model in that the interface works well on the Windows platform and the SPSS or Excel worksheet data are easily retrieved. The causal relationship between variables is obtained by the causal coefficient (estimation) or the correlation coefficient of each path, and the level of significance needs to be evaluated. As a means of evaluation, the Wald test is often used where the hypothesis that the path coefficient is zero or there is no causal relationship is tested. This is based on the fact that the estimation divided by the standard error becomes the t distribution. If the number of samples is significantly large, the distribution is regarded normal, so if the estimation divided by the standard error is over 1.96, the hypothesis is accepted at 5% of the significance level and it can be said that there is a causal relationship. In Amos this is output as the critical ratio. The structural equation model analyzed in this thesis to test the hypotheses is shown in Figure 6.

.Fig. 4
Covariance Structural Model

Research Hypothesis		Estimate	S.E	C.R	P	Acceptance
H1	Expected Satisfaction during Evaluation before Purchase → Actual Satisfaction after Purchase	0.737	0.070	10.545	0.000	Accepted
H2	Expected Satisfaction during Evaluation before Purchase → Customer Loyalty	0.411	0.100	4.125	0.000	Accepted
H3	Actual Satisfaction after Purchase → Customer Loyalty	0.915	0.115	7.987	0.000	Accepted

The results of the covariance structural analysis between variables are shown in Table 6. * Accepted if the critical ratio is over 1.96 and the level of significance (P) is below 0.05, C.R. = Estimate / S.E.As a result of the covariance structural analysis as shown in Table 6, the hypotheses proposed in this research (H1, H2, and H3) were all accepted.

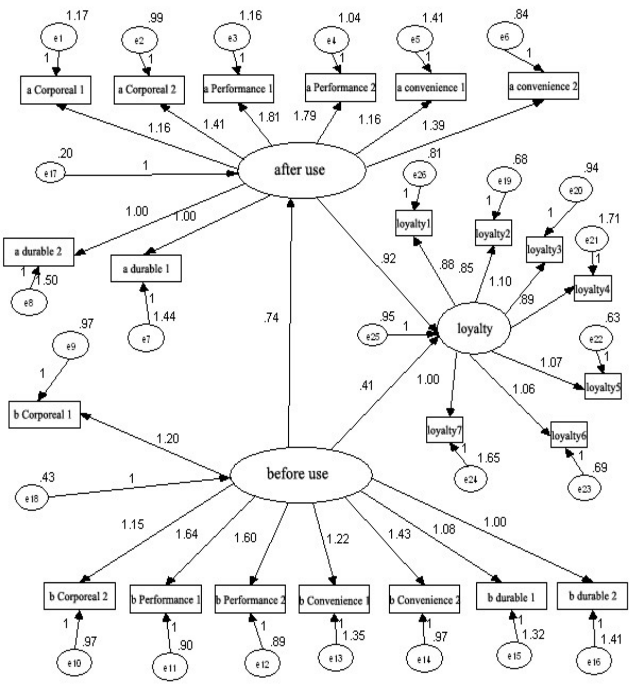

Table 6 Results of the Covariance Structural Analysis

First, hypothesis 1 states that the level of expected satisfaction in the course of evaluation before the purchase of mobile communication terminals is expected to have a positive influence on the level of actual satisfactionobtained from purchase experiences. As a result of the analysis, the level of expected satisfaction in the course of evaluation before the purchase of mobile communication terminals turned out to have 0.737 of the estimation and 10.545 of the critical ratio, which are similar to those of actual satisfaction obtained from purchase experiences. Accordingly, hypothesis 1 is eligible for acceptance. Second, hypothesis 2 states that the level of expected satisfaction in the course of evaluation before the purchase of mobile communication terminals is expected to have a positive influence on the level of customer loyalty. As a result of the analysis, the level of expected satisfaction in the course of evaluation before purchase turned out to have 0.411 of the estimation and 4.125 of the critical ratio, which are similar to those of customer loyalty. Accordingly, hypothesis 2 is eligible for acceptance. H3. The level of actual satisfaction obtained from the purchase of mobile communication terminals is expected to have a positive influence on the level of customer loyalty. As a result of the analysis, the level of actual satisfaction obtained from purchase experiences turned out to have 0.915 of the estimation and 7.985 of the critical ratio, which are similar to those of customer loyalty. Accordingly, hypothesis 3 is eligible for acceptance

IV. Conclusion

This research was intended to positively analyze factors that affect customer satisfaction about products in the mobile communication terminal market as to the influences of expected satisfaction and actual satisfaction before and after purchase on customer loyalty. As a means to measure the relationship between related variables, Amos 4.0 was implemented to test the structural equation model hypothesized in this research. Hypotheses 1, 2, and 3 were all accepted while each of the measurementvariables describing the level of expected satisfaction before the purchase of products, the level of actual satisfaction after the purchase of products, and the level of customer loyalty was also over 1 with a high level of credibility. The results of this research point out many important aspects of product designs, sales, and consistent customer services managed by the R&D department and the marketing department at a mobile communication terminal manufacturer. First, for hypothesis 1 the influence of expected satisfaction before the purchase of mobile communication terminals on actual satisfaction after the purchase of products turned out to be 0.737, which has an extremely high level of significance. This implies that when customers planning to buy mobile phones have a high expectation for the shape, design, performance, convenience, and durability, actual satisfaction about such quality elements after the purchase of products also increases. Thus, mobile phone manufacturers must pour their efforts into the elevation of customer satisfaction about the unique quality attributes of mobile communication terminals at the stages of product design and production. In addition, accurate information on the basic attributes of mobile phones must be provided in that the level of customer satisfaction may drop rapidly in case the actual functions and performance of mobile phones differ from those publicly advertised. Second, as for the influence of expected satisfaction before the purchase of mobile communication terminals on customer loyalty, the estimation is 0.411, which has a fairly high level of significance. As customers have a certain level of expectation for the quality of products through the preliminary product information provided by mobile phone manufacturers, strategic methods must be established so that the information on the unique features of products can be provided to customers through advertisements. As the mobile communication terminal technology rapidly develops, new attributes start to take their forms while convergence products that combine the existing attributes also appear. Wibro, developed locally first in the world and ready for commercialization, is now breaking the boundary between wired and wireless communication by combining the highly efficient transmission capability of wired communication and the mobility of wireless communication. Moreover, the terrestrial DMB service expected to lead the era when communication and broadcasting are combined was commercially provided in the domestic market, first in the world, drawing attention from all around the world. According to such convergence trends for mobile communication terminals, customers acquire information on new products with attributes different from those of the existing products through a variety of channels. Furthermore, as suggested by this research, customer expectations for the quality of products whose information is obtained before purchase through various channels were analyzed to have a direct influence on customer loyalty. Therefore, mobile phone manufacturers must enhance the level of customer satisfaction by providing information on the unique quality attributes of products ultimately to improve the level of customer loyalty. Third, as for the influence of actual satisfaction after the purchase of mobile communication terminals on the level of customer loyalty, the estimation turned out to be 0.915, which has a fairly high level of significance, and this helps conclude that mobile phone manufactures need to pour their efforts into the enhancement of product quality in that customer satisfaction after purchase is directly proportional to customer loyalty and that customer loyalty may stimulate the intention to buy again. As suggested by the positive analysis, mobile phone manufacturers must strive to develop and manufacture mobile communication terminals with enhanced designs, performance, convenience, and durability. Mobile phone manufacturers have recently focused on the R&D and designs of mobile communication terminals. Nokia, with the No. 1 occupancy rate in the global market, have been making utmost efforts to manufacture products ranging from monoblock to cramshell and slide devices under the motto, "To satisfy the customer and the operator". Ever since the year 1993, Samsung Electronics, one of the domestic manufacturers, has hired more than 1,000 designers for the Design Management Center, differentiating a group of products, establishing a consistent identity, and developing a design first.. In this research the uniquequality attributes of mobile phones were analyzed besides prices and brand images regarded, in general, as important factors that affect customer satisfaction. Prices and brand images are the most influential attributes applicable to almost all purchase circumstances. However, the two factors were excluded from this research in that such external factors had a possibility to cause conflict in the analysis of the unique quality attributes of products. Nevertheless, in the future research the previous studies need to be carefully reexamined while the balance of such factors is considered for a broader understanding and diverse research attempts. On the basis of the results of this research as well as the following research efforts as to customer satisfaction about mobile communication terminals, customer expectations for the quality of products must be met while actual satisfaction is achieved through the use of products. Also, manufacturers must pay close attention at all manufacturing stages to improve customer loyalty and maintain the competitive power of the domestic mobile communication terminal industry in the global market.

Workshop on Ad-Hoc Wireless Networks

The extent to which wireless networking has succeeded as a practicable approach to telecommunication depends on the class of applications and the underlying technology. On one end of the "success spectrum" we have cellular telephony with its avalanche of existing and forthcoming services. On the other end, there are various (so far mostly hypothetical) applications and embodiments of ad-hoc networking, usually connotated with wireless sensing, which, despite enormous attention of the academic community, find it difficult to materialize in the real world. Our workshop will focus on practical aspects of wireless telecommunication, with stress on mobility, survivability, resilience, quality of service, and security. Its leitmotif will be an identification of the problems hampering progress in the "practically challenged" areas of wireless networking. Case studies, especially ones illustrating unorthodox solutions adopted in the context of specific practical applications are particularly encouraged. The non-exclusive list of topics includes:

- performance studies and comparisons
- network protocols
- cross-layered protocol design
- design and programming methodologies for network protocols and applications
- wireless sensor networks
- virtual execution platforms
- simulation and modeling methodologies
- security and reliability in wireless networks
- traffic patterns, including multimedia traffic
- multimodal networks
- satellite networks
- high-altitude platform networks

***Abstract*—This article deals with the control of mobile embedded devices via wireless transceiver. The only way how to control the mobile devices such as robots, is to use a wireless data transfer. The possible wireless transceiver solution using the nRF24L01 transceiver by Nordic Semiconductor, which works in license-free worldwide 2.4 GHz ISM frequency band, is presented. Overview of this chip is included at the beginning of this article. The main part of this article deals with the design of a communication protocol. Then some optimizations of this protocol to improve its performance and determinism are discussed. In the last part, the results of measurement of some data transfer characteristics are presented.**

I. TIntroduction

HE wireless data transfer has been a very popular topic in recent years. It replaces the wire or optical connection in some applications. However, this article is focused on applications where a wire is impossible to use. The wireless connection is the only possibility in applications such as the control of the mobile embedded devices [1], e. g. robots. We can distinguish the two basic types of communication. In the first configuration of the wireless network, one stationary device is controlling one or more mobile devices. In the second configuration, all the devices are mobile.

This article discusses possible approaches of the control of the mobile embedded devices by the one stationary control system. This is intended to be used in the real-time application where a group of five robots is controlled by the stationary control system.

II. Design of Wireless Transceiver

The designed wireless transceiver is based on the nRF24L01 transceiver [3] which ensures the data transmission over the air. The nRF24L01 provides SPI (Serial Peripheral Interface) for connection with a target device. SPI is appropriate for the connection of the nRF24L01 with a microcontroller of the mobile device which has this interface also (this is the case of the mobile robots). However, it is not the suitable interface for the connection of control computer. So that SPI has to be converted to another more suitable interface for the connection of the nRF24L01 with a personal computer. USB (Universal Serial Bus) was chosen because each modern personal computer has available at least a few unused USB ports. The conversion from SPI to USB is done in two steps. At first, SPI is converted to UART. The conversion is made by the Freescale MC9S12D64 microcontroller which controls the nRF24L01 also. Any other microcontroller with the same or higher performance can be used. Then UART is converted to USB by the FTDI FT232RL converter. The block diagram of the wireless transceiver is shown in Fig. 1.

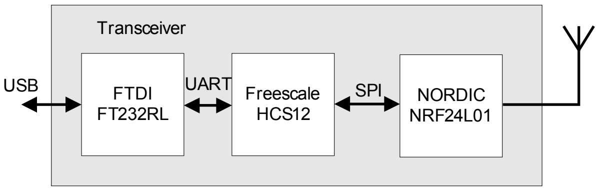

Fig. 1 Block diagram of wireless transceiver

I. Nordic nRF24L01

The nRF24L01 is a single chip 2.4GHz transceiver with an embedded baseband protocol engine (version with integrated MCU based on i8051 is also available), designed for ultra low power wireless applications. The nRF24L01 is designed for operation in the worldwide 2.4 GHz ISM frequency band. The air data rate is configurable to either 1 Mbps or 2 Mbps. The radio front end uses GFSK modulation. The chip has user configurable parameters like frequency channel, output power and air data rate.

1) Enhanced Shock-Burst™

The nRF24L01 provides Enhanced Shock-Burst™ mode beside manual operation mode. This mode allows 1 to 32 bytes dynamic payload length, automatic packet handling, auto packet transaction handling, data pipe MultiCeiver for 1:6 star networks.

2) MultiCeiver™

MultiCeiver™ is a feature used in receive mode that contains a set of 6 parallel data pipes with unique addresses. A data pipe is a logical channel in the physical RF channel. The nRF24L01 configured as primary receiver can receive data addressed to six different data pipes in one frequency channel. Each data pipe has its own unique address and can be configured for individual behavior. All data pipe address-

This work was supported by the GAČR project 102/08/1429 "Safety and security of networked embedded system applications" and by the internal project SP/2010165 "Development and using new methods for design and realization of embedded systems"

es are searched for simultaneously. The length of the messages can vary among data pipes [3].

II. Freescale MC9S12D64

The MC9S12D64 microcontroller [4] is a 16-bit device composed of standard on-chip peripherals including a 16-bit central processing unit, 64 Kbytes of Flash EEPROM for user program, 4 Kbytes of RAM for application data, 1 Kbyte of EEPROM as persistent data storage, two UARTs, one SPI, 29 discrete digital I/O channels, and so on. The inclusion of a PLL circuit allows power consumption and performance to be adjusted to suit operational requirements.

III. FTDI FT232RL

The FT232R is a single chip USB to asynchronous serial data transfer interface. UART interface supports 7 or 8 data bits, 1 or 2 stop bits and odd, even, mark, space, or no parity. Data transfer rates from 300 baud up to 3 Mbaud at TTL levels are supported. The entire USB protocol is handled on the chip, so that no USB specific firmware programming is required. The FT232RL supports bus powered, self powered, and high power bus powered USB configurations. For complete specification of the FTDI FT232RL please refer to [5].

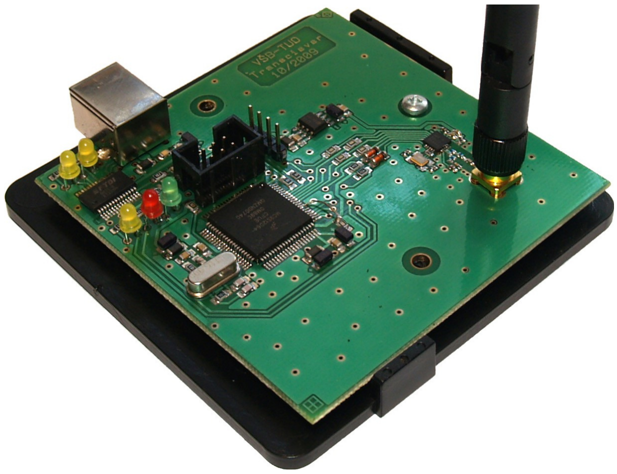

Fig. 2 Realized transceiver

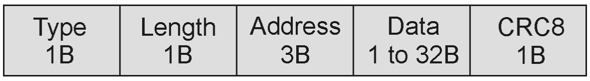
III. Communication Protocol

For systems where the real-time requirement should be met a deterministic access method should be used for channels which are not dedicated for the only two communicating devices [2]. The master-slave access method is appropriate for the robot control application because the prevailing data transfer direction is from the stationary device to the mobile devices. So the stationary device is the master and the mobile devices are the slaves.

We can distinguish the three types of messages which are sent from the personal computer to the wireless transceiver and then to the remote device:

1. Data for the mobile device.
2. Request for the mobile device status data.
3. Service messages to the wireless transceiver (these data are not sent over the air).

The data for mobile device are sent from the computer via the USB serial port to the microcontroller. This data are encapsulated by some extra information such as the type of the message, its length, CRC, etc. The structure of the message is shown in Fig. 3.



Type 1B	Length 1B	Address 3B	Data 1 to 32B	CRC8 1B

Fig. 3 Message structure

The data that are received and successfully checked by the microcontroller are unpacked (the header and footer are removed) and then they are sent directly to the nRF24L01. The nRF24L01 adds the destination address and CRC to the message and after that it sends this message over the air. A device that receives a correct message with its address sends the received message to the connected microcontroller on its request. The nRF24L01 is configured to send data with the 3 bytes address (the shortest possible option) and to secure the data by CRC16.

I. Protocol optimization

In the robot control application, two data pipes with different addresses can be used to distinguish the unicast and broadcast messages. The first data pipe is used for the unicast messages and the second data pipe is used for the broadcast messages. The unicast address is unique for each device in the net. The broadcast address is the same for all devices in the net.

The broadcast messages can be used only for the control messages where a response is not expected. The use of the broadcast messages instead of the unicast messages eliminates the delivery time delay and improves the determinism of the transmission time. The determinism is improved because all robots receive the message in the exactly same time. The improvement was tested and the results are presented in the next paragraph of this article.

The particular structure of the broadcast message is in Fig. 5. This message is inserted to the data part of the message shown in Fig. 3. The broadcast message contains data for up to 6 mobile robots. The data for each robot are identified by its address. The left and right wheel revolutions are the typical data for the robots. The command for each robot is the same hence it appears only once in the message. The counter is increased for the every new message. For better reliability of transmission, each message can be sent twice or more times without increasing of this counter so the remote device can recognize if the message has been sent before.

IV. Testing of wireless transceivers

Two wireless transceivers developed according to the previous design were tested. Two similar transceivers with the same configuration of the wireless part and the same antenna with gain 2 dBi were used for testing. The first wireless

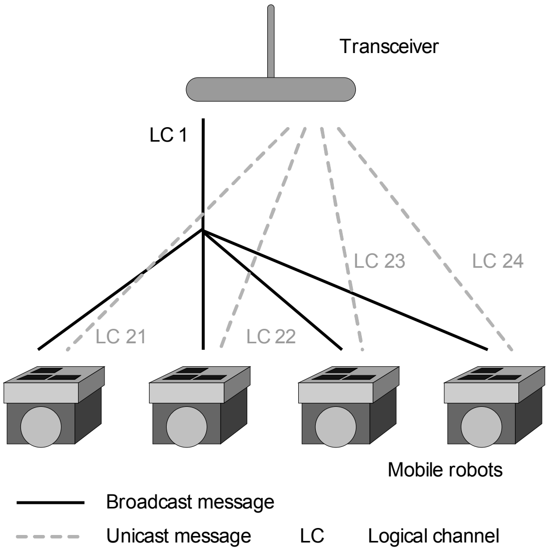


Fig. 4 Unicast and broadcast configuration

Counter 1B	Command 1B	1 to 6 times	
		Address 1B	Data 4B

Fig. 5 Structure of broadcast message

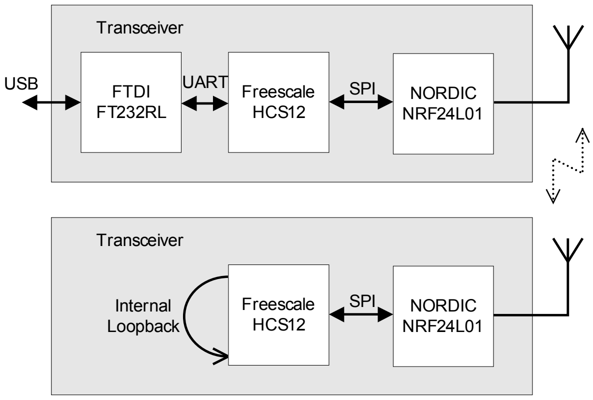

Fig. 6 Configuration of the experiment

transceiver had implemented the internal loopback on wireless interface while the second sent the data received from the wireless interface to USB and vice versa. The test configuration is shown in Fig. 6.

I. Delivery time

The first of all, the message delivery times via wireless interface were tested. For this measurement, the oscilloscope was used because very short delivery times were expected. The microcontroller, which is on wireless transceiver, sets (for 3 milliseconds) one of its outputs on the data sent event and the other output on the data received event. These events were measured by oscilloscope. The measurement was performed for various packet lengths and for the both air data rates supported by the nRF24L01. The results are in Table 1.

Table I.
Comparison of 1 Mbps and 2 Mbps

number of bytes	1 Mbps	2 Mbps
5	224 µs	202 µs
10	289 µs	220 µs
15	325 µs	239 µs
20	367 µs	259 µs
25	406 µs	277 µs
30	448 µs	297 µs

Notice that the delivery times for 2 Mbps are not a half of the delivery times for 1 Mbps. This is caused by the constant time that is necessary to set up the nRF24L01 to the transmit mode. This setup takes 150 microseconds according to the performed test. It is possible to send more than one message after setting the nRF24L01 to the transmit mode but the nRF24L01 must not be in the transmit mode for more than 4 milliseconds [3].

One byte at 1 Mbps is transmitted in 8 microseconds. At 2 Mbps, this time is a half. According to the test, there is 7 bytes overhead on the wireless interface. This overhead includes 3 bytes of address, 2 bytes of CRC, and 2 extra bytes (probably preamble).

1) Unicast vs. broadcast messages delivery time

From the results in Table 1, we can calculate the difference in the delivery time DT between the unicast and broadcast messages. For this calculation, we use equation (1), where the setup_time is 150 us, the overhead_length is 7 and the byte_time is 8 us for 1 Mbps and 4 us for 2 Mbps.

When we use the unicast messages we have to send five messages with 5 bytes payload. This takes 630 us at 1 Mbps and 390 us at 2 Mbps. When we use the broadcast messages we have to send one message with 32 bytes. This takes 462 us at 1 Mbps and 306 us at 2 Mbps.

$$DT = setup_{time} + msgs_{cnt} \cdot \text{¿}$$
$$\text{¿¿}(overhead_{length} + paylod_{length}) \cdot byte_{time} \quad (1)$$

The calculated unicast delivery times are only theoretical because all messages must be sent together after one setup of the nRF24L01 to the transmit mode. In reality, each message is send separately and this takes 1.2 ms at 1 Mbps and 1.0 ms at 2 Mbps.

The theoretical difference between the unicast messages and the broadcast messages is not significant but the practical difference is considerable. The real delivery time is three times greater for the unicast messages than for the broadcast messages.

II. Lost messages

The lost of the messages was tested by sending one message per second from the PC during 10 minutes to the wireless transceiver that sent this message to the second wireless

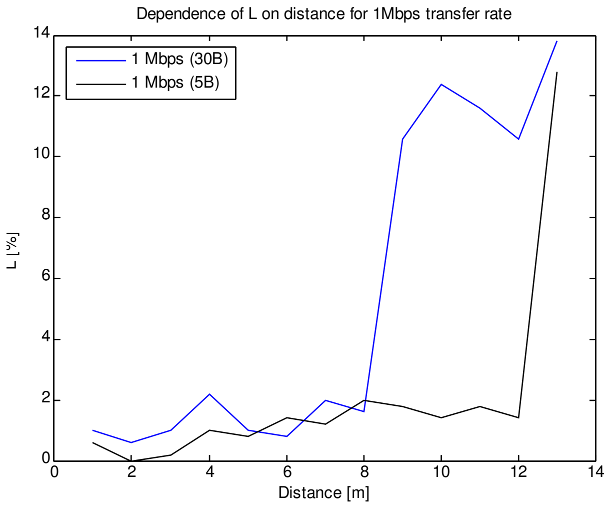

Fig. 7 Message lost ratio (1 Mbps)

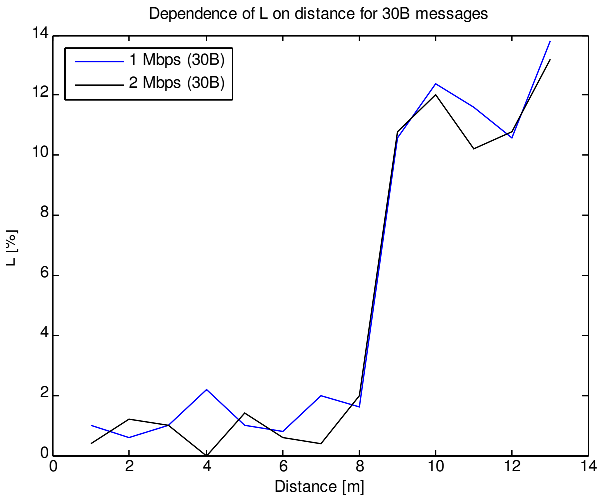

Fig. 8 Message lost ratio (30B messages)

transceiver with internal loopback. The second wireless transceiver only sent the received message back so sender should receive the sent message back. The message lost ratio L is given by equation (2).

$$L=1-\frac{received_{messages}}{sent_{messages}} \tag{2}$$

The lost of the messages was tested for both air data rates supported by the nRF24L01, for two lengths of message, and for various wireless transceiver distances. The dependence of the lost messages ratio on distance for 1 Mbps air data rate and for 5 and 30 bytes messages is shown in Fig. 7. And the dependence on distance for 30B messages for 1 and 2 Mbps air data rate is shown in Fig. 8. We can see that the dependence of L on the distance becomes significant for a distance over 8 meters for 30 bytes messages and for a distance over 12 meters of 5 bytes messages, respectively. The air data rate does not significantly affect the lost ratio.

V. Conclusion

The described wireless transceivers were constructed from components and then they were tested. According to the tests, the new design of the wireless system for the control of mobile embedded devices is suitable. Using the communication protocol optimization, the significant improvement has been done. The same information can be sent (using the broadcast messages and air data rate 2 Mbps) in one third time in comparison to the previous solution (using the unicast messages and air data rate 1 Mbps). Each of the controlled robots receives its piece of information in the same time as its team-mates. Furthermore, the use of the broadcast messages allows sending the same message more times so the information delivery probability can be increased. All of these optimizations help to control the mobile embedded devices more accurately which was the objective of our work.

Efficient Coloring of Wireless Ad Hoc Networks With Diminished Transmitter Power.

Krzysztof Krzywdziński
Faculty of Mathematics and Computer Science
Adam Mickiewicz University, 60–769 Poznań, Poland
Email: kkrzywd@amu.edu.pl

***Abstract*—In our work we present a new approach to the problem of channel assignment in Wireless Ad Hoc Network. We introduce a new algorithm which works in distributed model of computations on Unit Disc Graphs modeling the Wireless Ad Hoc Network. The algorithm first modifies the transmitting power of the devices constituting the network (radii of the vertices of the Unit Disc Graph) and then it assigns the frequencies in the network adjusted to our demands. We assume that initially all the devices have the same transmission range and we are able to reduce the transmission range of some of them in order to decrease the number of necessary frequencies. We are able to diminish the number of communication links without loosing connectivity of the network, i.e. reduce the number of possible interference threats without risk of loosing possibility to exchange information. In addition, the diminution of communication range reduce the power consumption of the transmitting devices.**

***Index Terms*—Diminished Transmitter Power, Distributed Algorithm, Wireless Ad Hoc Networks, Coloring**

I. Introduction

THE WIRELESS Ad Hoc Network consists of the devices having computational ability placed on the given area (for example wireless cellphone network formed by the cellphones). We consider the problem of channel assignment in the Wireless Ad Hoc Network. In the proper channel assignment each vertex transmits information using one channel and without interference. An interference may occur due to two possible collisions. The primary one have place when a vertex simultaneously transmits and receives signals over the same channel. The secondary one occurs when a vertex simultaneously receives more than one signals over the same channel. Thus, to prevent the primary collision, two vertices may be assigned the same channel if neither of them is within the transmission range of the other. Similarly, to prevent the secondary collision, two vertices can be assigned the same channel if no other vertex is located in the intersection of their transmission ranges. The crucial problem concerning Wireless Ad Hoc Networks is finding the appropriate channel assignment. This problem is equivalent to determining optimal proper coloring of the square of graph representing the network.

In the standard model of the Ad Hoc Network each device of the network is placed in some point of the given area and all the devices have the same transmitting power. Therefore a widely used model for such a network is the Unit Disc Graph (UDG) model. The Unit Disc Graph is a graph in which the set of vertices is a set of vertices on the plane and two vertices are connected by an edge if and only if they are at the distance at most one in Euclidian norm. The optimal coloring (which bound from below minimum number of channels in channel assignment) of any Unit Disk Graph uses at least $\omega(G)$ colors, where $\omega(G)$ is the size of the largest clique. Moreover the chromatic number of UDG G $(\chi(G))$ is between $\omega(G)$ and $3\omega(G)$ (see [1]). Obviously, for dense graphs, the number $\omega(G)$ may be large, thus the number of channels necessary to ensure appropriate communication is large as well. The algorithms, working in various models, finding proper colorings of the Disk Graphs may be found in [3], [5], [6] and [11].

Surely, the absorbing issue is how to change the characteristics of the Wireless Ad Hoc Network which is represented by the graph with a large chromatic number in order to assure good communication using small number of frequencies. An effective approach to minimize the number of assigned channels is to diminish power of the transmitters installed in the devices (make the radius of transmission smaller). This concept has already appeared to be beneficial in total energy reducing problem (see [4],[9],[8],[10],[14],[17],[18],[19]) and interference reduction (see [2],[7],[12]). Diminishing power of transmitters enables to save energy of the batteries in devices, since during the transmission the full power of the transmitters is not used. Moreover such procedure reduce number of edges in the corresponding Unit Disc Graph and, since the graph is sparser, decrease the chromatic number. However diminishing transmission power may have disadvantageous impact on the connectivity of the network. Due to reduction of the number of active links the network may be partitioned (i.e. the corresponding graph would become disconnected) and some messages may never be delivered. Therefore our goal is to create an efficient algorithm which diminish powers of transmitters keeping strong connectivity of the graph and significantly reducing the chromatic number of the graph. To the best of our knowledge, in our algorithm the concept of diminishing transmitting power for solving the problem of channel assignment is used for the first time. Moreover this is fast distributed topology control algorithm which combine ideas of coloring and reducing total energy.

Our work is organized as follows: in Section II we introduce the model of computation in which the algorithm works. In Section III we sketch the main results of our work. In

978-83-60810-27-9/09/$25.00 © 2010 IEEE

Section IV we present the main algorithm and show that it works properly. In the last section we show that the number of colors used by our algorithm is the best possible.

II. Model

The presented algorithm will work in distributed synchronous model of computations on Unit Disc Graphs with possible reduction of radii length. The Unit Disc Graphs (UDG) is a wiely used Wireless Ad Hoc Networks. The set of vertices of UDG is a set of vertices on the plane and any vertex v is connected by an edge with the vertex w if and only if the vertex w is contained in the disk of radius 1 with a center in v. In our model we make also additional assumption that every vertex can diminish its radius. We introduce a function $f : V(G) \to (0, 1]$ assigning to each vertex its reduced radius. The value $f(v)$ will be interpreted as the power of the transmitter v. Given the Unit Disc Graph G and the function $f : V(G) \to (0, 1]$ we define the directed Disc Graph $G\langle f\rangle$ as follows: $V(G\langle f\rangle) = V(G)$ and in $G\langle f\rangle$ there is an edge pointing from v to w if and only if w is contained in the circle of radius $f(v)$ and a center in v (i.e. $vw \in E(G\langle f\rangle) \Leftrightarrow \|v, w\| \leq f(v)$). The existence of the edge vw in $G\langle f\rangle$ is interpreted as the fact that vertex v can send information to w (w is in the communication range of v).

We make also additional assumption that all the devices constituting the network are equipped with the Global Positioning System (GPS), or know their position on the plane by other sources. We also assume that the network is synchronized and in one round a vertex can send, receive messages from its neighbors and can perform some local computations. Neither the amount of local computations nor the size of messages sent is restricted in any way. Concluding, the algorithm will work in a synchronous, message-passing model of computations introduced in [13], called LOCAL model, in which we additionally know the position on the plane of each element of the network.

III. Previous Work and Our Result

The presented algorithm DiminishPower works in the model introduced in Section II and finds a function f and channel assignment such that the network represented by $G\langle f\rangle$ is connected and in the network the number of necessary frequencies and energy consumption is significantly diminished comparing to the network with initial characteristics.

In order to formalize our arguments we give two additional definitions. We say that the directed graph $G\langle f\rangle$ is *strongly connected* if for all $v, w \in V(G\langle f\rangle)$ there exists a directed path form v to w. Strong connectivity of $G\langle f\rangle$ will imply the possible communication between any two devices constituting the network represented by $G\langle f\rangle$. The second definition concerns the amount of energy consumed by the network. By *total energy cost* we will mean the value $TE(G\langle f\rangle) = \sum_{v\in V(G\langle f\rangle)} f(v)^2$. The concept of saving energy in wireless networks was introduced in [15], [20]. Our definition of total energy cost includes the value f in second power since in the real two dimensional space the area of transmission is of order square of the power of the transmitter.

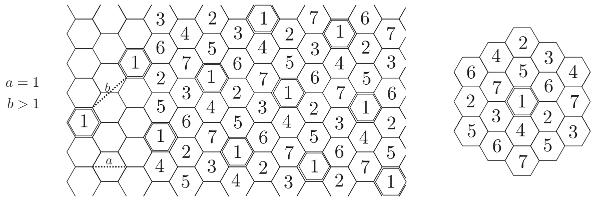

Fig. 1. Division of the plane into 7 classes of hexagons.

The idea of the algorithm DiminishPower is to divide the plane into 7 classes of hexagons with diameter 1 as in Figure 1. To each class we will attribute a different palette of colors. The subgraph of UDG G induced by the vertices contained in one hexagon form a clique. We will use that property of the division and in each hexagon we will run independently the procedure OnClique, which will locally color the vertices of the hexagon with colors from the palette attributed to that hexagon and assign the value of the function f to each vertex v from the given hexagon. The function will be such that the subgraph of $G\langle f\rangle$ induced by the vertices from a hexagon will be strongly connected and the coloring constructed by the procedure will be proper coloring of that subgraph. Finally we will join local colorings and obtain the proper colloring of $G\langle f\rangle$.

We will prove that for a given connected Unit Disc Graph G the algorithm DiminishPower finds in constant number of synchronous rounds in LOCAL model (see Theorem 8) a function $f : V(G) \to (0, 1]$ such that:

1) $G\langle f\rangle$ is strongly connected (see Theorem 5);
2) $G\langle f\rangle$ has proper coloring with $O(\log(\chi(G)))$ colors (see Theorem 6);
3) total energy cost of the wireless network represented by $G\langle f\rangle$ is of range

$$TE(G\langle f\rangle) = O\left(|MIS(G)| \log \frac{|V(G)|}{|MIS(G)|}\right)$$

(see Theorem IV) , where $|MIS(G)|$ is the size of the maximum independent set in G.

Moreover there exists a channel assignment with the above properties (see Remark 9). Another important property of the construction is possibility of defining an effective routing protocol in $G\langle f\rangle$ (see Remark 10).

In comparison M. Fussen, R. Wattenhofer and A. Zollinger in [7] present the Algorithm NCC which finds strongly connected $G_{ncc}\langle f\rangle$, i.e. the graph which has property 1. However the maximum degree in $G_{ncc}\langle f\rangle$ is $O(\log(|V(G)|))$ (in $G\langle f\rangle$ it is $O(\log(\omega(G)))$). In their approach they do not solve problems of coloring, channel assignment and do not compute total energy. The Algorithm NCC strictly base on one predefined global sink and its distributed implementation takes $O(diameter(G))$ synchronous rounds (our algorithm takes $O(1)$ time). Also the graph constructed by the Algorithm NCC do not allow to define fast routing protocol (see Remark 10).

Moreover vertices in one hop distance in G can be at distance of $O(diameter(G)\log(|V(G)|))$ hops in $G_{ncc}\langle f\rangle$ (in $G\langle f\rangle$ they are at most $O(\log(\omega(G)))$ hops away).

IV. Main algorithm

First we present the procedure OnClique, which will be implemented independently on each subgraph induced by the vertices contained in a hexagon. We assume that the input graph K is a clique, therefore information about all the vertices may be send to one vertex of the clique and all the computations may be performed by that vertex. In the algorithm and later on we will call a pair of vertices vw a *double directed edge* if in the directed graph there are edges pointing from v to w and pointing from w to v.

```
OnClique
Input: Unit Disc Graph $K$ which is a clique and palette $P(K)$ of colors.
Output: Disc Graph $K\langle f\rangle$ and its coloring.
 (1) Let $i := 1$, $M_i = V(K)$, $f \equiv 1$ and $K\langle f\rangle[M_i]$ be the graph induced by the set of vertices $M_i$.
 (2) For all $v \in M_i$ set $f(v) := \min_{w\in M_i, w\neq v}\|v,w\|$.
 (3) Color graph $K\langle f\rangle[M_i]$ using new 5 colors from palette $P(K)$.
 (4) Let $N$ be a subgraph of $K\langle f\rangle[M_i]$ induced by all double directed edges.
 (5) $i := i+1$.
 (6) Set $M_i$ to be the set of leaders of the connected components of $N$.
 (7) If $|M_i| \geq 2$ then go to step (2).
 (8) If $M_i = \{v\}$ then $f(v) := 1$ and color $v$ with a new color from $P(K)$.
 (9) Return $K\langle f\rangle[V(K)]$ with coloring.
```

It should be mentioned that it is possible to implement the step (3) of the procedure, since the graph $K\langle f\rangle[M_i]$ is planar (see the proof of Lemma 3).

In addition the graph N is always well defined (i.e. has at least one vertex) and, as a consequence, for all i the set M_i contains at least one element. It is necessary for correctness of the algorithm. It is enough to notice that for all M_i such that $|M_i| \geq 2$ and f defined as in (2) the graph $K\langle f\rangle[M_i]$ has at least one double directed edge. From definition of f in $K\langle f\rangle[M_i]$ each vertex has out–degree at least one, therefore in $K\langle f\rangle[M_i]$ there is at least one cycle (the last vertex from the longest path has an out–neighbour on that path). Moreover, from definition of f each cycle in $K\langle f\rangle[M_i]$ consists of double directed edge. More precisely if $v_1,\ldots,v_t,v_1$ is a cycle, then: $f(v_1) = \min_{w\in M_i, w\neq v_1}\|v_1,w\| = \|v_1,v_2\| \geq f(v_2) = \|v_2,v_3\| \geq \ldots \geq f(v_t) = \|v_t,v_1\| \geq f(v_1)$ thus all the inequalities above are equalities and all the edges of the cycle are double directed.

Lemma 1. *Let $V(K) = M_1 \supseteq M_2 \supseteq M_3 \supseteq \ldots \supseteq M_k$ be the sequence of all the subsets of $V(K)$ constructed by the algorithm* OnClique. *Then $|M_i| \geq 2\left|M_{(i+1)}\right|$, $k \leq \log_2(|V(K)|)$ and $|M_k| = 1$.*

Proof: Since N is a subgraph of $K\langle f\rangle[M_i]$ induced by some edges, each connected component of N contains at least two vertices. M_{i+1} contains exactly one vertex from each component of N. Therefore $|M_i| \geq 2\left|M_{(i+1)}\right|$ for all $1 \leq i \leq k$. Consequently we have $k \leq \log_2(|V(K)|)$. $|M_k| = 1$ since for all i the set M_i contains at least one element. ■

Lemma 2. *The graph $K\langle f\rangle$ constructed by the algorithm* OnClique *is strongly connected.*

Proof: Let $V(K) = M_1 \supseteq M_2 \supseteq M_3 \supseteq \ldots \supseteq M_k = \{m\}$ be the sequence of all the subsets of $V(K)$ constructed by the algorithm OnClique. Let $w = w_1$ be any vertex from $V(K)$. We only need to prove that in $K\langle f\rangle[V(K)]$ after the last iteration there is a directed path from w to m. This combined with the fact that in $K\langle f\rangle$ there are directed edges pointing from m to all other vertices (since $f(m) = 1$) implies strong connectivity.

In the first iteration in (2) we set $f(v) := \min_{w\in K, w\neq v}\|v,w\|$ for all $v \in V(K) = M_1$. By definition of $f(v)$ every vertex v in $K\langle f\rangle[M_1]$ have out-degree at least 1. Notice that this implies that there exists a directed path from $w = w_1$ to a vertex w_1' which is incident to a double directed edge. We just have to take w_1' – the last vertex of the longest directed path with origin in w_1 and notice that w_1' have to have a neighbour on that path. Thus w_1' is contained in directed cycle and, as mentioned before, cycles in $K\langle f\rangle[M_1]$ consist of double directed edges or are a double directed edges. If w_2 is the leader of the connected component of N (defined as in (4) during the first iteration) containing w_1', then there exists a directed path from w_1 to $w_2 \in M_2$.

Using the same reasoning but replacing M_1 by M_i ($i > 1$) and the first iteration by the i-th one, we can prove that there exists a directed path from $w_i \in M_i$ to $w_{i+1} \in M_{i+1}$ in $K\langle f\rangle[M_i]$ defined in the i-th iteration. Since $f(v)$ in the next iterations may only grow, therefore the above–considered directed paths from $w = w_1$ to w_2, from w_2 to w_3, …, from w_{k-1} to $w_k = m$ are also directed paths in the final graph $K\langle f\rangle[V(K)]$. ■

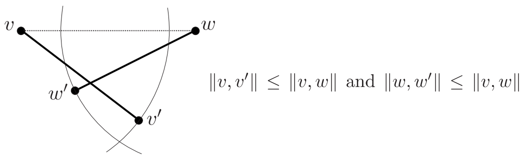

Fig. 2. $\|v,w'\| < \|v,v'\|$

Lemma 3. *The algorithm* OnClique *finds a coloring of the graph $K\langle f\rangle$ using at most $5\log_2(|V(K)|)$ colors from the palette.*

Proof: First observe that in the i-th iteration of the algorithm the graph $K\langle f\rangle[M_i]$ is plane. Otherwise there would exist two directed edges vv' and ww' which would cross each other. So by definition of f we know that $\|v,v'\| \leq \|v,w\| \,\&\, \|v,v'\| \leq \|v,w'\|$ and $\|w,w'\| \leq \|w,v\| \,\&\, \|w,w'\| \leq \|w,v'\|$. However if we suppose that $\|v,v'\| \leq \|v,w\|$ and $\|w,w'\| \leq \|v,w\|$ then w' would lie inside the circle with a center in v and the radius of length $\|v,v'\|$ (see Figure 2). So $\|v,w'\| < \|v,v'\|$, a contradiction.

It is possible to color any planar graph using 5 colors in polynomial time. In each iteration we use at most 5 new colors and if in iteration we enlarge the value of $f(v)$ then in the same iteration the color of v is changed and a new color have not been used in previous iterations. Therefore the output coloring is a proper coloring of $K\langle f\rangle$. By Lemma 1 we know that there are at most $\log_2(|V(K)|)$ iterations, thus the coloring use at most $5\log_2(|V(K)|)$ colors. ■

Lemma 4. *The graph $K\langle f\rangle$ constructed by the algorithm* OnClique *has total energy cost $TE(K\langle f\rangle) \leq 16\log_2(|V(K)|)$*

Proof: Let $V(K) = M_1 \supseteq M_2 \supseteq M_3 \supseteq \ldots \supseteq M_k$ be the sequence of the subsets of $V(K)$ constructed by the algorithm OnClique. Let $1 \leq i \leq k$ and $\{v_1, v_2, \ldots, v_{|M_i|}\} = M_i$. During the i-th iteration we set $f(v) := \min_{w\in M_i, w\neq v} \|v,w\|$ for all $v \in M_i$, therefore $f(v_t) \leq \|v_t,v_l\|$ and $f(v_l) \leq \|v_t,v_l\|$ for all $1 \leq k \neq l \leq |M_i|$. This implies $f(v_t)/2 + f(v_l)/2 \leq \|v_t,v_l\|$ for all $1 \leq k \neq l \leq |M_i|$. So, if we denote by $c(v,r)$ the disk with the center in v and the radius of length r, then all the disks $c(v_1, f(v_1)/2)$, $c(v_2, f(v_2)/2)$, …, $c(v_{|M_i|}, f\left(v_{|M_i|}\right)/2)$ are pairwise disjoint. Moreover K is a clique, thus v_1 is connected by an edge with all other vertices of K. Therefore, since K is UDG, all of the vertices from K are contained in $c(v_1, 1)$. This implies that all the disks $c(v_1, f(v_1)/2)$, $c(v_2, f(v_2)/2)$, …, $c(v_{|M_i|}, f\left(v_{|M_i|}\right)/2)$ lie inside $c(v_1, 2)$. Therefore

$$\pi 2^2 \geq \sum_{j=1,2,\ldots|M_i|} \pi \left(\frac{f(v_j)}{2}\right)^2.$$

So $TE(M_i) \leq 16$.

We use the same reasoning for all iterations and for all $v \in V(K)$ the value $f(v)$ from the outcome graph is set in one of those iterations, therefore we have $TE(K\langle f\rangle) \leq \sum_{j=0,1,\ldots,k} TE(M_i) \leq \sum_{j=0,1,\ldots,k} 16 = 16\log_2(|V(K)|)$. By Theorem 1 the number of iterations $k \leq \log_2(|V(K)|)$. ■

Now we are ready to introduce the main algorithm. In the algorithm, for all $i = 1, 2, \ldots 7$, we will define C_i to be the set of all connected components of the subgraph of the input UDG G induced by the vertices contained in the haxagons of the i-th class (see Figure 1). Obviously each of those connected components is a clique induced by the vertices from one hexagon of the i-th class.

```
DiminishPower
Input: Connected Unit Disc Graph $G$
Output: Disc Graph $G\langle f\rangle$ with proper coloring.
(1) Divide the set of vertices of $G$ into 7 classes as in Figure 1.
(2) For each $K \in C_i$ define palette of colors $P(K)$ as follows $P(K) = \{x \in \mathbb{N} : x = i \pmod 7\}$.
(3) Let $\mathcal{C} := C_1 \cup C_2 \cup \ldots \cup C_7$ For each $K \in \mathcal{C}$ parallel do:
    (a) Run algorithm OnClique on graph $K$ and color it using palette $P(K)$.
    (b) Define $\mathcal{K}' := \{K' \in \mathcal{C} : K' \neq K$ and $\exists_{k\in V(K), k'\in V(K')} kk' \in E(G)\}$. Denote the graphs from $\mathcal{K}'$ by $K'_1, K'_2, \ldots, K'_{|\mathcal{K}'|}$.
    (c) For $j = 0, 1, \ldots |\mathcal{K}'|$ do:
        (c1) Select one vertex $w_j \in V(K)$ such that $\exists_{w'_j \in V(K'_j)} w_j w'_j \in E(G)$.
        (c2) Color $w_j$ taking first free color from the palette $P(K)$
        (c3) Set $f(w_j) = 1$.
```

The following theorems show that the algorithm has the properties claimed in Section III.

Theorem 5. *Given the connected Unit Disk Graph G as an input, the algorithm* DiminishPower *finds the graph $G\langle f\rangle$ which is strongly connected.*

Proof: Let $K, K' \in \mathcal{C}$. By Lemma 2 and the fact that during the algorithm DiminishPower in step 3(c) we only may enlarge the radius of some vertices from $V(K)$ and $V(K')$, thus in the output graph $G\langle f\rangle$ the subgraphs induced on vertices from $V(K)$ and $V(K')$ are strongly connected. Moreover, if in G there were edges between $V(K)$ and $V(K')$, then after step 3(c3) in $G\langle f\rangle$ there is at least one edge pointing from $V(K)$ to $V(K')$ and at least one edge pointing from $V(K')$ to $V(K)$. Therefore, if G was connected, then $G\langle f\rangle$ is strongly connected. ■

Theorem 6. *Given Unit Disc Graph G algorithm* DiminishPower *finds a proper coloring for graph $G\langle f\rangle$ which use $O(\log(\chi(G)))$ colors.*

Proof: By Lemma 3 we know that in step (a) of the algorithm DiminishPower for each $K \in \mathcal{C}$ we use at most $5\log_2(|V(K)|)$ colors from palette $P(K)$. Moreover $|\mathcal{K}'| \leq 18$ (see Figure 1), therefore for any graph $K \in \mathcal{C}$ in step 3(c2) we use at most 18 colors from palette. Since there are 7 types of palettes and $|V(K)| \leq \omega(G)$ (K is a clique), during the whole algorithm at most $\max_{K\in\mathcal{C}} 7\left(5\log_2(|V(K)|) + 18\right) = O\left(\log(\omega(G))\right)$ colors are used. The result follows from the fact that $\omega(G) \leq \chi(G) \leq 3\omega(G)$ (see [1]).

By Lemma 3 the coloring constructed by the procedure OnClique is a proper coloring of the output graph of the procedure. Moreover in step 3(c), if we change the radius of the vertex, then we color that vertex with a new color, which have not been used before in K. Therefore, for any $K \in \mathcal{C}$, the coloring constructed by the algorithm DiminishPower is a proper coloring of the subgraph of $G\langle f\rangle$ induced by the vertices from $V(K)$. To conclude that this coloring is also a proper coloring of $G\langle f\rangle$ we only have to notice that in the communication range of the vertices from K exept other vertices from K there are only vertices from neighboring hexagons (see Figure 1). Those vertices are from different type then K, therefore their colors are from different palettes. ■

Theorem 7. *Given as an input a connected Unit Disc Graph G the algorithm* DiminishPower *finds graph $G\langle f\rangle$ such that the total energy cost of $G\langle f\rangle$ equals*

$$TE(G\langle f\rangle) = O\left(|MIS(G)|\log\left(\frac{|V(G)|}{|MIS(G)|}\right)\right),$$

where $|MIS(G)|$ is the size of the maximum independent set in G.

Proof: For each $K \in \mathcal{C}$, by Lemma 4 and the fact that in step 3(c) we enlarge the radius of at most 18 vertices we have that for the function f constructed by the algorithm DiminishPower

$$TE\left(G\langle f\rangle[V(K)]\right) \leq 16(\log_2(|V(K)|) + 18.$$

Therefore

$$\begin{aligned}TE(G\langle f\rangle) &= \sum_{K\in\mathcal{C}} [16(\log_2(|V(K)|) + 18] \\ &= 16\log_2\left(\prod_{K\in\mathcal{C}} |V(K)|\right) + 18|\mathcal{C}|.\end{aligned}$$

Now notice that $|MIS(G)| \leq |\mathcal{C}| \leq 7|MIS(G)|$, since in each $K \in \mathcal{C}$ there is at most one vertex from $MIS(G)$ and we can construct an independent set by choosing one vertex from each hexagon from one class. Moreover for any positive numbers a_i and a natural number n we have: $((a_1+a_2+\ldots+a_n)/n)^n \geq a_1a_2\ldots a_n$, therefore:

$$\begin{aligned}TE(G\langle f\rangle) &\leq 16\log_2\left(\frac{|V(G)|}{|\mathcal{C}|}\right)^{|\mathcal{C}|} + 18|\mathcal{C}| \\ &\leq 16\cdot 7|MIS(G)|\log_2\left(\frac{|V(G)|}{|MIS(G)|}\right) + 18|\mathcal{C}|\end{aligned}$$

■

Theorem 8. *The algorithm* DiminishPower *can be implemented in $LOCAL$ model in constant number of synchronous rounds.*

Proof: Since we assume that each vertex knows its position on the plane, step (1) (dividing into 7 classes) and step (2) (defining palettes of colors) of the algorithm DiminishPower can be easily implemented in one synchronous round. In addition each $K \in \mathcal{C}$ is a clique, thus information about the whole graph K may be send to a leader of K, which run the algorithm OnClique. From the properties of the $LOCAL$ model the leader can execute the algorithm OnClique in one synchronous round. Therefore OnClique can be implemented in four synchronous rounds: first we select a leader, next we send to him all information about the graph, then the leader run the algorithm OnClique and finally the leader send to the vertices of K the output of the algorithm). Finally $|\mathcal{K}'| \leq 18$, therefore the step (c) consists of at most 18 iterations. ■

As we claimed in Section I channel assignment problem is equivalent to coloring of the square of the graph. To obtain a proper channel assignment we will modify two steps in algorithm DiminishPower.

- In step (1) of the algorithm DiminishPower divide the set of vertices of G into 12 (instead of 7) hexagons (see Figure 1 in [16]).
- In step (3) of the algorithm OnClique we color square of the graph $K\langle f\rangle[M_i]$ with 37 colors from palette $P(K)$ (instead of 5) using greedy algorithm.

Remark 9. *The algorithm* DiminishPower *with above modifications constructs in constant number of synchonous rounds a graph $G\langle f\rangle$ with a proper channel assignment. Moreover it uses $O(\log(\chi(G)))$ channels and have properties claimed in Theorems IV and 5.*

Proof:

Firstly, in the partition into 12 classes any two vertices in the different hexagons of the same class are at least two hops away. So there is no channel collision between channels of vertices from different hexagons.

Secondly, in the i-th iteration of the algorithm OnClique the graph $K\langle f\rangle[M_i]$ has maximum degree bounded by 6. It follows from this observation that the maximal angle between edges in the graph $K\langle f\rangle[M_i]$ is $\frac{\pi}{3}$. Suppose that there would be two directed edges $wv, w'v \in E(K\langle f\rangle[M_i])$ such that angle $\angle(wvw') < \frac{\pi}{3}$ and $\|w,v\| \geq \|w',v\|$ then $\|w,w'\| < \|w,v\|$ and we arrive at the contradiction with a fact that $wv \in K\langle f\rangle[M_i]$. Therefore square of the graph $K\langle f\rangle[M_i]$ have degree bounded by 36. Thus using standard greedy algorithm it is simple to color square of $K\langle f\rangle[M_i]$ graph using 37 colors in polynomial time.

Concluding in channel assignment constructed by the modified algorithm DiminishPower we use at most $12\,(37\log_2(|\omega(G)|) + 18)$ channels. ■

Remark 10. *If we have a routing protocol in Unit Disc Graph G then we can easily define the routing protocol in $G\langle f\rangle$. Namely, if the routing protocol use the edge vw then we can use the directed path from v to w constructed as in the proof of Theorem 5. More precisely as w'_i we may take the first vertex from any path with origin in w_i, which is incident to a double directed edge in $G\langle f\rangle[M_i]$ defined as in the i-th iteration.*

V. Lower Bound

The chromatic number (and analogously channel assignment) of the graph constructed by the algorithm DiminishPower is best up to a constant factor. Namely there exists a connected Unit Disc Graph graph G such that for any function $f : V(G) \to (0,1]$ such that $G\langle f\rangle$ is strongly connected we have $\chi(G\langle f\rangle) = \Omega\left(\log\left(\chi(G)\right)\right)$. Our lower bound on chromatic number (and also channel assignment) is based on the idea of Theorem (4.1) [7] where authors shown a lower bound for maximum interference of $G_{ncc}\langle f\rangle$.

The construction of the example will be inspired by the construction of the Cantor Set. More precisely the set A_i will be the set of the end points of the segments of the i-th step of the construction of the Cantor Set. Formally $A_1 = \{0,1\}$, $A_2 = \left\{0,\frac{1}{3},\frac{2}{3},1\right\}$, $A_3 = \left\{0,\frac{1}{9},\frac{2}{9},\frac{1}{3},\frac{2}{3},\frac{7}{9},\frac{8}{9},1\right\}$ etc. as on Figure 3.

Let G be Unit Disc Graph with the vertex set A_k. Obviously G is a clique and have exactly 2^k vertices.

Theorem 11. *Let G be the Unit Disc Graph with the vertex set A_k and $f : V(G) \to (0, 1]$ be any function. If $G\langle f\rangle$ is strongly connected then $\chi(G\langle f\rangle) = \Omega(\log(\chi(G)))$.*

Proof: First define $G\{x_1, x_2\}$ to be the set of vertices of the graph G with x-coordinate between x_1 and x_2. Since $G\langle f\rangle$ is connected then there exists at least one directed edge e_1 from $v_1 \in G\langle f\rangle\{\frac{2}{3}, 1\}$ to $w_1 \in G\langle f\rangle\{0, \frac{1}{3}\}$. Without loosing generality suppose that $v_1 \in G\langle f\rangle\{\frac{2}{3}, \frac{7}{9}\}$ have color 1 (see Figure 3). Observe now that since $f(v_1) \geq \frac{1}{3}$ then all other vertices from $G\langle f\rangle\{\frac{2}{3}, 1\}$ cannot have color 1. Analogously there exists at least one directed edge e_2 from $v_2 \in G\langle f\rangle\{\frac{8}{9}, 1\}$ to $w_2 \in G\langle f\rangle\{\frac{2}{3}, \frac{7}{9}\}$. Without loosing generality suppose that $v_2 \in G\langle f\rangle\{\frac{26}{27}, 1\}$ and have color 2 (see Figure 3). Observe now that since $f(v_2) \geq \frac{1}{9}$ then all others vertices from $G\langle f\rangle\{\frac{8}{9}, 1\}$ cannot have color 2. If we continue the reasoning, then in the k-th step we notice that we must use at least k colors to color $G\langle f\rangle$. Since G is a clique, $\chi(G) = V(G) = 2^k$, so $\chi(G\langle f\rangle) \geq \log_2(\chi(G))$. ■

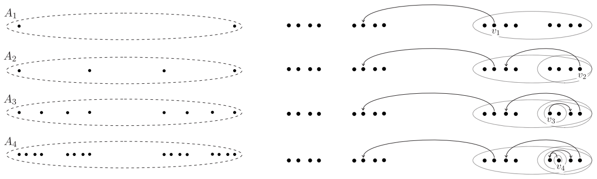

Fig. 3.

VI. Conclusion

In this paper we have studied the problem of channel assignment in Wireless Ad Hoc Network represented by unit disk graphs. We have diminished the number of communication links without loosing connectivity of the network. In addition we have shown, how the diminution of communication range reduces power consumption of transmitting devices. We also show that the number of colors used by our algorithm is the best possible.

Email: kkrzywd@amu.edu.pl

Abstract—**This paper studies the minimum latency broadcast schedule (MLBS) problem in ad hoc networks represented by unit disk graphs. In our approach we use an algorithm, which does not need BFS tree. We introduce a construction, which does not depend on a source, can be found in constant number of synchronous rounds, uses only short messages and produces broadcast schedule with latency at most 258 times optimum. The advantage of our construction over known algorithms is its ability to adapt fast to the changes in the network, such as adding, moving or deleting vertices (even during the broadcasting).**

We also study the minimum-latency gossiping (all-to-all broadcast) problem in unit disk graphs. Our algorithm is the best result for gossiping in unit disk graph in unbounded-size messages model.

Since our construction of broadcast scheduling does not depend on the source, it may be also used to solve other problems concerning broadcasting in unit disk graphs, such as single source multiple message broadcasting and multi channel broadcast scheduling.

I. Introduction

DUE TO a wide range of applications, such as military surveillance, emergency disaster relief or environmental monitoring, solving problems considering the communication in wireless ad hoc networks (such as sensor networks or cell phone networks) became an important issue. Generally the wireless ad hoc network is modeled by an undirected connected graph G, where the set of vertices $V(G)$ represents the set of computational units constituting the network (for example sensors, cellphones) and $E(G)$ contains unordered pairs of distinct vertices, such that $(v,w) \in E(G)$ if and only if the transmissions of the computational unit represented by the vertex v can directly reach the computational unit represented by the vertex w and vice versa (the reachability of transmissions is assumed to be a symmetric relation). For simplicity in the following considerations frequently we will say vertex v instead of the computational unit represented by the vertex v. Also if $(v,w) \in E(G)$ we will say that the vertices v and w are neighbours in G.

Usually it is assumed that communication in the wireless ad hoc network is synchronous and consists of a sequence of communication steps. Moreover in a wireless ad hoc network, a message transmitted by a vertex is always sent to all of its neighbours. In each step, a vertex v either transmits or listens. If v transmits, then the transmitted message reaches each of its neighbours by the end of the step. However, a vertex w adjacent to v successfully receives this message if and only if in this step w is listening and v is the only transmitting vertex among the neighbours of w. If vertex w is a neigbour of more than one transmitting vertex, then due to the interference, w does not receive any message in this step.

The classical problem of the information dissemination in wireless networks is the broadcasting problem. In the broadcasting problem the aim is to disseminate a particular message from a distinguished source vertex to all other vertices in the network. Due to the interference threat the brute force algorithm may not be the effective tool to solve this problem. The classical approach is to construct the broadcast schedule in order to minimize the adverse influence of interferences. The broadcast schedule of latency l is the sequence of subsets $(U_1, U_2 \dots U_l)$ of $V(G)$ satisfying

(1) $U_1 = \{s\}$;
(2) $U_i \subseteq \bigcup_{j=1}^{i-1} Inf(U_j)$ for each $2 \leq i \leq l$;
(3) $V(G) \setminus \{s\} \subseteq \bigcup_{j=1}^{l} Inf(U_j)$,

where for any $U \subseteq V$, $Inf(U)$ is the set of vertices in $V(G) \setminus U$ each of which has exactly one neighbour in U. By the definition we have that, given the broadcast schedule $(U_1, U_2 \dots U_l)$, we may disseminate information from s into the whole network in l synchronous rounds. Namely, in order to do so, in the i-th round the information should be transmitted only by vertices from U_i.

In this paper we consider the problem of minimum latency broadcast schedule (MLBS), i.e., the problem of minimization of the time needed to complete the task of dissemination of the information from a single source. Therefore we seek a fast algorithm which constructs the broadcast schedule with the minimum latency.

For general graphs the best approximation algorithms construct the broadcast schedules with latency: $O(R\Delta)$ [14], $O(R\log^2(n/R))$ [13], $O(R\log n + \log^2 n)$ [4], $R + O(\sqrt{R}\log^2 n)$ [18], $O(R + \log^6 n)$ [15], $R + O(\log^3 n)$ [17], $R + O(\log^3 n / \log\log n)$[6] and $O(R + \log^2 n)$ [16].

Here by R we mean the radius of the graph (the maximum distance between the source s and the vertices from $V(G)$) and $n = |V(G)|$.

The MLBS problem in unit disk graphs has been considered in [8], [5],[7],[20] and [11].

In [8] Gąsieniec, Kowalski, Lingas and Wahlen show that $R + \Omega(\log(n-R))$ rounds are required to accomplish broadcasting in UDG. In [5] Dessmark and Pelc presented a broadcast schedule of latency at most $2400R$. In [7] Gandhi, Parthasarathy and Mishra claim the NP-hardness of MLBS in unit disk graphs and construct broadcast schedule of latency at most $648R$. In [20] Scott, Huang, Wan, Jia and Du improve latency to $51R$, $24R$, and $R+O(\sqrt{R}\log^{1.5} R)$. In [11] Huang, Wan, Jia, Du and Shang propose three different algorithms which produce broadcast schedules with latency at most $24R+23$, $16R+15$ and $R+O(\log R)$. However implementation of these algorithms in distributed model depend on the source and is based on BFS algorithm, therefore using these algorithms $\Omega(R)$ rounds to build the broadcast structure are needed. This is not efficient enough in many applications.

Here we present HexagonsBroadcasting, which is the first distributed algorithm solving MLBS problem without using BFS tree. In fact HexagonsBroadcasting needs only $O(1)$ synchronous rounds to prepare the vertices for the transmission. Our algorithm has latency $258R$. The structure constructed by HexagonsBroadcasting does not depend on the source, therefore the additional advantage of our algorithm is that the source can be easily changed or even chosen randomly. Previous algorithms do not take into account possible changes in network during propagation of information. If a vertex is delete, they fail to deliver a message to a part of graph, despite the fact that graph might be still connected. In our algorithm bad impact of the movement, addition or deletion of the vertex in the network during the broadcasting may be rapidly diminished (Subsection III-A).

Finally the HexagonsBroadcasting approach can be applied to solve real problems such as gossiping, multiple messages and multi channel broadcast schedule.

Our paper is organized as follows. In Section II we present basic definitions and facts. In Section III we introduce the auxiliary algorithms SelectBroadcastNodes and BroadcastSets and the main algorithm HexagonsBroadcasting. In Section IV we present the algorithm GossipingInUDG and in Section V other two important generalizations of MLBS are presented.

II. Preliminaries

The natural theoretical model for wireless ad hoc network is a unit disk graph (UDG). By definition, the set of vertices of UDG is a set of points on the plane and two vertices of UDG, v and w, are connected by an edge if and only if they are at the distance at most one in Euclidean norm ($\|v, w\| \leq 1$). UDG vertices represent computational units and edges represent communication links between them.

Our algorithms will work on unit disk graphs, in distributed, synchronous, message-passing model of computations. We assume that local clocks of computational units (vertices of UDG) can be synchronized i.e., we assume that we perform computations in rounds (model LOCAL defined in [19]). In each round a computational unit represented by a vertex of UDG can send, receive messages from its neighbours, and can perform some local computations. Moreover we assume that every computational unit is either equipped with the Global Positioning System (GPS), or knows own position on the plane by other sources.

In the algorithm HexagonsBroadcasting we will use a partition of UDG based on grid tiling of the plane into hexagons of side equal $1/2$ (see Figure 1). Since each vertex of UDG knows its position on the plane, it also knows the hexagon of the grid to which it belongs. We define spanning subgraph G' of G where $V(G') = V(G)$ and $vw \in E(G')$ if and only if v and w lie in the same hexagon. We define $Hex(G)$ to be the set of all connected components of its spanning subgraph G' (notice that each hexagon lies inside a circle of radius $\frac{1}{2}$ so each $K \in Hex(G)$ is a clique).

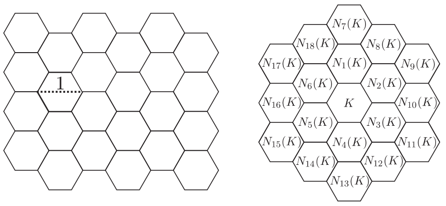

Fig. 1. Division into hexagons and numeration of the 18 neighbouring hexagons of the hexagon.

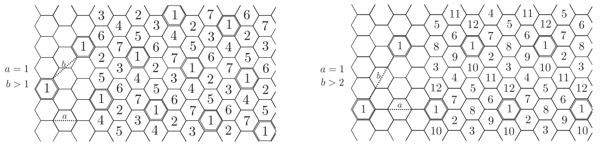
Let $K \in Hex(G)$ be any clique. Obviously K may have communication links only with vertices belonging to its 18 neighbouring hexagons (see Figure 1). We denote them by $N_1(K), N_2(K), \ldots, N_{18}(K)$ as on Figure 1 (the index of the clique depends on its position in the hexagon grid). Notice that, for example, $N_2(N_5(K)) = K$ and $N_{11}(N_{17}(K)) = K$. Therefore for any $k \in \{1, \ldots, 18\}$ we define a value $\bar{k}$ to be the number such that $N_{\bar{k}}(N_k(K)) = K$ (for example $\bar{5} = 2$, $\bar{1}7 = 11$). In addition we set

$$N(K) = \\ \{K' \in Hex(G) : K' \neq K, \exists_{v \in K, v' \in K'} vv' \in E(G)\}.$$

For comparison, by $N(v)$ we denote the set of neighbours of the vertex v.



$f^{(7)} : Hex(G) \to \mathbb{N}$ $f^{(12)} : Hex(G) \to \mathbb{N}$

Fig. 2. Concept of $f^{(7)}$ and $f^{(12)}$ functions.

Finally we define two functions $f^{(7)} : Hex(G) \to \{1, \ldots, 7\}$ and $f^{(12)} : Hex(G) \to \{1, \ldots, 12\}$ (see Figure 2). Notice that in the labeling with the numbers $\{1, \ldots, 7\}$ any two vertices from different hexagons with the same label are at distance greater than 1. Similarly in the labeling with the numbers $\{1, \ldots, 12\}$ any two vertices from different hexagons with the same label are at distance geater than 2. This implies two simple facts.

Fact 1. *Any two vertices from different cliques $K_1, K_2 \in Hex(G)$ such that $f^{(7)}(K_1) = f^{(7)}(K_2)$ are not connected by an edge in G.*

Fact 2. *Any two vertices from different cliques $K_1, K_2 \in Hex(G)$ such that $f^{(12)}(K_1) = f^{(12)}(K_2)$ do not have a common neighbour in G.*

III. Main Algorithm

The main algorithm selects a small number of vertices, which we call broadcast vertices. In fact the algorithm assigns to each vertex two sets $F_{out}(\cdot)$ and $F_{in}(\cdot)$ and *broadcast* vertices are those for which $F_{out}(\cdot)$ and $F_{in}(\cdot)$ are nonempty. The first function F_{out} is used when $K \in Hex(G)$ sends information to cliques from the neighbouring hexagons. The second one F_{in} is used in dissemination of the message inside the clique. The auxiliary algorithm SelectBroadcastNodes selects broadcast vertices.

```
SelectBroadcastNodes
Input: Unit disk graph $G$
Output: Functions $F_{in} : V(G) \to \mathcal{P}(\{1,\dots,18\})$, $F_{out} : V(G) \to \mathcal{P}(\{1,\dots,12\})$, where $\mathcal{P}(A)$ denotes the set of all subsets of $A$.
1) For every $v \in V(G)$ set $F_{in}(v) \equiv \emptyset$ and $F_{out}(v) \equiv \emptyset$.
2) For $i = 1$ to 7 do : For $k = 1$ to 18 do
   For every $K \in Hex(G)$ such that $f^{(7)}(K) = i$ and $f^{(7)}(N_k(K)) > f^{(7)}(K)$ parallel do
     a) Let $V_k(K) = \{v \in V(N_k(K)) : N(v) \cap K \neq \emptyset\}$
     b) If $V_k(K) \neq \emptyset$ then
        i) Select a vertex $v_k \in V_k(K)$ and set
              $F_{in}(v_k) := F_{in}(v_k) \cup \{\bar{k}\};$
              $F_{out}(v_k) := F_{out}(v_k) \cup \{f^{(12)}(K)\}.$
        ii) Select a vertex $w \in N(v_k) \cap K$ and set
              $F_{in}(w) := F_{in}(w) \cup \{k\};$
              $F_{out}(w) := F_{out}(w) \cup \{f^{(12)}(N_k(K))\}.$
     c) We call $v_k$ and $w$ coupled broadcast vertices.
```

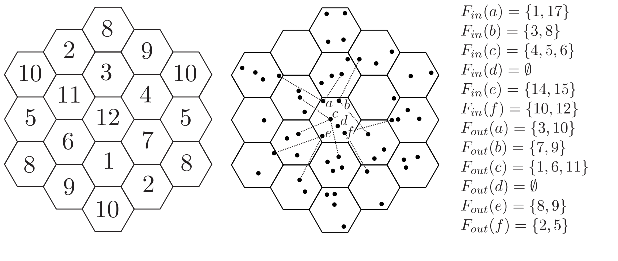


Fig. 3. Vertices from one hexagon with respective sets $F_{in}(\cdot)$ and $F_{out}(\cdot)$ and vertices from neighbouring hexagons coupled with them.

Notice that the algorithm SelectBroadcastNodes assigns exactly one pair of coupled broadcast vertices connected by an edge to each pair of the cliques $\{K, K'\}$ connected by at least one edge.

Basing on functions $F_{in} : V(G) \to \mathcal{P}(\{1,\dots,18\})$, $F_{out} : V(G) \to \mathcal{P}(\{1,\dots,12\})$ we construct sets $U_{out}(\cdot,\cdot)$ and $U_{in}(\cdot,\cdot)$ containing broadcast vertices, which will be used to construct the broadcast schedule.

The vertices in $U_{out}(i,k)$ send information from hexagons K with $f^{(12)} = i$ to hexagons K' with $f^{(12)}(K') = k$ and the vertices $U_{in}(i,1),\dots,U_{in}(i,18)$ are used in propagating information inside hexagons K with $f^{(7)} = i$.

```
BroadcastSets
Input: Unit disk graph $G$, Functions $F_{in} : V(G) \to \mathcal{P}(\{1,\dots,18\})$, $F_{out} : V(G) \to \mathcal{P}(\{1,\dots,12\})$
Output: Sets $U_{out}(i,k)$ and $U_{in}(i,k)$
1) Let $K_v$ denote clique $K \in Hex(G)$ such that $v \in K$.
2) For $i = 1$ to 12 : For $k = 1$ to 12 do
      $U_{out}(i,k) :=$
          $\Big\{v \in V : k \in F_{out}(v)$ and $f^{(12)}(K_v) = i\Big\}$
3) For $i = 1$ to 7 : For $k = 1$ to 18 do
      $U_{in}(i,k) :=$
          $\Big\{v \in V : k \in F_{in}(v)$ and $f^{(7)}(K_v) = i\Big\}$
```

Note that for all $1 \le t \le 12$ the set $U_{out}(t,t)$ is empty. Hence the number of construced nonempty sets is at most $11 \times 12 + 7 \times 18 = 258$ and in the main algorithm sets $U_{out}(t,t)$ may be omitted.

Lemma 1. *Let $1 \le i \le 12$, $1 \le k \le 12$ and $A \subseteq U_{out}(i,k)$. If $B \subseteq V(G)$ is the set of all vertices coupled with vertices from A and contained in cliques on which the value of $f^{(12)}$ equals k, then $B \subseteq Inf(A)$.*

Proof: Set $1 \le i \le 12$, $1 \le k \le 12$. Let $v_1 \dots v_t \in K$ be vertices from $U_{out}(i,k)$. For each vertex v_j the set $F_{out}(v_j)$ contains k if and only if v_j is coupled with at least one vertex from a neighbouring clique K' such that $f^{(12)}(K') = k$. Denote by W the set of vertices coupled with vertices from $\{v_1 \dots v_t\}$. Each vertex from W is contained in distinct clique (since to each pair of cliques at most one coupled pair of broadcast vertices is attributed). Combining Fact 2 with observation that on those distinct cliques the value of the function $f^{(12)}$ is k we have that no pair of vertices from the set W has a common neighbour in G, in particular no common neigbour in $\{v_1 \dots v_t\}$. Therefore, if $v_1 \dots v_t$ send information simultaneously into the network, then the vertices coupled with them (i.e vertices from W) receive it without interference. Now consider the vertices k_1, k_2 from $U_{out}(i,k)$ contained in two cliques K_1, K_2 (recall that, by the definition of U_{out}, $f^{(12)}(K_1) = f^{(12)}(K_2) = i$). By the Fact 2 vertices k_1 and k_2 do not have a common neighbour. Concluding, if vertices from the set $U_{out}(i,k)$ send information into the network, then the vertices coupled with them must get it without interference. ■

Lemma 2. *Let $1 \le i \le 7$, $1 \le k \le 18$. Suppose that vertices from the set $A \subseteq U_{in}(i,k)$ send information into the network* *simultaneously. Then for every $K \in Hex(G)$ such that $K \cap A \neq \emptyset$ we have that $K \subseteq Inf(A)$.*

Proof: Set $1 \leq i \leq 7$, $1 \leq k \leq 18$. Note that, for each broadcast vertex v, the set $F_{in}(v)$ contains k if and only if v is coupled with a vertex w from $N_k(K)$. So the set $V(K \cap U_{in}(i,k))$ has at most one element. Moreover any two distinct verices $v, v' \in U_{in}(i,k)$ are contained in cliques on which the function $f^{(7)}$ has value i. Therefore, from Fact 1 if any vertices from $U_{in}(i,k)$ sends simultaneously information into the network, then the vertices from cliques in which those vertices are contained, receive information without interference. ■

Now we are ready to introduce the main algorithm of propagating the information from the source $s \in V(G)$.

```
HEXAGONSBROADCASTING
Input: Unit disk graph $G$ and a vertex $s \in V(G)$
Output: Dissemiantion of the information from the source vertex $s$ to $V(G)$.
1) Run SELECTBROADCASTNODES algorithm on a graph $G$.
2) Run BROADCASTSETS algorithm on $G$.
3) Vertex $s$ transmits information to all his neighbours.
4) For $t = 1$ to $R$ do
    a) For $i = 1$ to 12; For $k = 1$ to 12; $k \neq i$ do
        - vertices from $U_{out}(i,k)$ which have received information transmit it in parallel
    b) For $i = 1$ to 7 : For $k = 1$ to 18 do
        - vertices from $U_{in}(i,k)$ which have received information transmit it in parallel
```

Such approach to the problem enables us to construct a broadcast schedule in constant number of rounds, since the algorithm SELECTBROADCASTNODES obviously takes constant number of synchronous rounds and also building sets U_{out} and U_{in} takes constant time.

Theorem 3. *Let R be the radius of unit disk graph G. Latency of the broadcast schedule $U_1, U_2, U_3, \ldots$ used by the algorithm* HEXAGONSBROADCASTING *is at most $258R + 1$.*

Proof: Let $U_1, U_2, U_3, \ldots$ be broadcast schedule used by HEXAGONSBROADCASTING algorithm and $K \in Hex(G)$ be such that $s \in K$. In the first step the vertex s sends information to all the vertices from K (i.e. $K \subseteq Inf(U_1)$). Then, by Lemma 1, in the next $11 \times 12 = 132$ steps broadcast vertices contained in K send information to all vertices coupled with them in cliques from $N(K)$. By Lemma 2, in the next 7×18 steps broadcast vertices propagate information inside the cliques from $N(K)$. Therefore, surely, $\bigcup_{l=1}^{258+1} Inf(U_l)$ contains all vertices from K and all vertices from cliques $N(K)$. Therefore all neighbours of vertex s in G receive information in the first $258 + 1$ steps. Now, we may repeat the reasoning replacing the broadcast vertices from clique K by broadcast vertices contained in cliques from $N(K)$. Therefore in the next 258 steps all vertices at distance 2 from s will receive the message (i.e. all vertices at distance two from s are contained in $\bigcup_{l=1}^{2\times 258+1} Inf(U_l)$). So by the same reasoning we get that all vertices at distance at most R from s are contained in $\bigcup_{l=1}^{258R+1} Inf(U_l)$. ■

A. Modification of the network during the broadcasting

The presented algorithm can be adjusted to construct the broadcast scheduling in the dynamic network in which appearance or deletion of vertices is possible. More precisely, we assume that at any time one of the following events may happen:

1) A vertex v, such that $G \cup \{v\}$ is connected, can be added.
2) A vertex $v \in V(G) \setminus \{s\}$, such that $G \setminus \{v\}$ is connected, can be deleted.
3) A vertex $v \in V(G)$ can change position on the plane (can be moved), if after this operation G is still connected.

Let s be a source and a be some constant. The following broadcasting algorithm broadcast information in the dynamic network.

```
DYNAMICBROADCASTING
1) Run HEXAGONSBROADCASTING and break step 4 of HEXAGONSBROADCASTING after $a$ iterations.
2) Go to step 1.
```

Since procedures SELECTBROADCASTNODES and BROADCASTSETS takes one round then using those algorithms it is possible to refresh rapidly the broadcast structure using the algorithm DYNAMICBROADCASTING. Therefore the algorithm DYNAMICBROADCASTING is an efficient tool to propagate information in dynamic network. If in some round the modifications (add, delete and move events) stop, then in the next $258R + (1/a)R + O(a)$ rounds all vertices receive information from the source. In reality the information will reach all the vertices even faster and it is possible, that the information will reach all vertices even if the modifications happen all the time.

In all known distributed algorithms (which are based on BFS tree) building the broadcast structure takes $O(R)$ time. Thus the analogous modification of those algorithm will not give comparable results. Namely, even if in some synchronous round the modifications (add, delete and move events) stop, then it would take at least $O(R^2/a + a)$ time to propagate the information from the source.

IV. GOSSIPING

In the gossiping problem each vertex in the network is initially given a message and the objective is to design a minimum-latency schedule such that each vertex distributes its message to all other vertices. We assume that during distribution of the messages interferences may occur.

There are two important models of the problem regarding whether or not we can combine two or more messages as a single message: unit-size and unbounded-size models. In unit-size trivial lower bound for latency is $V(G) + D - 1$ (D is a diameter of the graph G) and in unbounded-size model lower bound is $\Delta(G) + D - 1$ ($\Delta(G)$ is a maximum degree of a graph G).

For general graphs gossiping problem in unbounded-size model was investigated in: [1], [2], [3], [9], [10]. The known algorithms construct broadcast schedules which are approximations of the optimal one with approximation factor larger than any constant. For unit disk graphs in [7] the authors present constant approximation for gossiping. Although in the paper the exact ratio of approximation was not given it may be estimated to be at least $1944(D+|V(G)|)$. The best known algorithm for unit-size messages gossiping in unit disk graph is given in [12]. The authors present algorithm for gossiping with latency $27(|V(G)|+D-1)$. We should add that all known algorithms are based on the BFS tree therefore the time to build gossiping schedule is $\Omega(D)$.

We present here the algorithm for gossiping in unit disk graph in unbounded-size messages model which have latency $7\Delta + 258D$. The algorithm GOSSIPINGINUDG builds gossiping structure in constant time thus it can be adapted to become insensitive to adding, deleting or moving vertices (see Subsection III-A).

```
GOSSIPINGINUDG
1) Set function $F_{out}$ and $F_{in}$ using algorithm SELECT-BROADCASTNODES.
2) For each $K \in Hex(G)$ and vertices $v_1, v_2, v_3 \ldots = V(K)$ define $c(v_i) = 7i + f^{(7)}(K)$ for all $1 \leq i \leq |V(K)|$.
3) Let $v$ be a broadcast vertex. Define
       $c_2(v) = \max\{c(w) : \exists_u u \in N(v) \text{ and } w \in N(u)\}$
   (maximal value of the function $c$ in 2-neighbourhood of $v$).
4) Set all broadcast vertices (vertices which have $F_{out} \neq \emptyset$ and $F_{in} \neq \emptyset$ ) as inactive.
5) Parallel do:
   a) Each inactive vertex $v$ send his initial message in $c(v)$-th synchronous round.
   b) Every broadcast vertex $v'$ is activated in $c_2(v') + 1$ synchronous round and then sends all combined messages in rounds defined by point 4 of HEXAGONSBROADCASTING.
```

Theorem 4. *The algorithm* GOSSIPINGINUDG *delivers all messages to all vertices in* $7\Delta + 258D$ *synchronous rounds.*

Proof: Let $v \in V(K)$ and $v' \in V(K')$ be two distinct vertices such that $c(v) = c(v')$. From definition of the function c we have $f^{(7)}(K) = f^{(7)}(K')$ and $K \neq K'$. Therefore it follows from Fact 1 that in Step 5a no vertex from K will receive the initial message from v' while all vertices from K will receive the initial message from v. In step 5b broadcast vertices send messages after all vertices from their 2-neighbourhood (vertices at distance 2) have sent the initial message. Therefore there is no interference produced by broadcast vertices and the vertices sending the initial messages.

We use at most 7Δ synchronous rounds to send initial messages in Step 5a (there are 7 classes of hexagons and vertices from each hexagon form a clique) The number of rounds needed to complete 5b equals to the lattency of the schedule constructed by HEXAGONSBROADCASTING. Namely after the vertices from 2-neighbourhood have sent their initial message, all broadcast vertices send information according to HEXAGONSBROADCASTING. Properties of this broadcasting follow from Theorem 3. Therefore 5b takes at most $258D$ synchronous rounds.

Concluding the algorithm GOSSIPINGINUDG have latency at most $7\Delta + 258D$. ■

V. GENERALIZATIONS OF MLBS

A. Single Source Multiple Messages

Ghandi et al. in [7] introduce the problem of the single sources multiple messages broadcasting. They assume that the source may send multiple messages in different intervals of time and define latency as number of synchronous rounds in which all messages are received by all vertices. Let M be the number of the messages to be sent. In [7] latency is at least $194(M-1) + 7128(R-2)$.

We present algorithm which is a modification of the HEXAGONSBROADCASTING algorithm and construct Single Source Multiple Messages Broadcasting schedule of latency $518M+258R$. We only have to use the following modification of the points 3 and 4 of the algorithm HEXAGONSBROADCASTING.

```
3. Repeat $M + \lceil R/2 \rceil$ times
(a) If $s$ contains a new message, then send it
(b) Repeat two times
    – For $i = 1$ to 12; For $k = 1$ to 12; $k \neq i$ do
        - vertices from $U_{out}(i,k)$, which have received information and have not sent it before, send the information
    – For $i = 1$ to 7 : For $k = 1$ to 18 do
        - vertices from $U_{in}(i,k)$, which have received information and have not sent it before, send the information
```

Theorem 5. *If in the modified algorithm* HEXAGONSBROADCASTING *the source sends messages every* 259 *synchronous rounds then every vertex in network receive all the messages in at most* $518M + 258R$ *rounds, where* M *is the number of messages.*

Proof: Divide the broadcast schedule used by HEXAGONSBROADCASTING (omitting the first round) into intervals of 258 rounds. Notice that, if the broadcast vertex receive information in the t-th interval, then in the $t+1$-th interval the information is sent to all its neighbours. Therefore this vertex may send a new information in the $t+2$-th interval. The lack of bad impact of the interference follows from the proof of Theorem 3. Thus the gap of two intervals plus one round (to give time for s to send the message) is enough to broadcast several messages. ■

B. Multi Channel Broadcast Scheduling

In some applications the vertices can use n different channels and if two neighbours of the vertex v send information using different channels then vertex v receives it without interference. This is idea of multi channel broadcast scheduling. To the best of our knowledge this problem is considered for the first time.

Notice that in the previous considerations, if for any pair of indices $(i_1, k_1) \neq (i_2, k_2)$, vertices from sets $U_{out}(i_1, k_1)$ and $U_{out}(i_2, k_2)$ use different channels, then they may send information simultaneously in all the above mentioned algorithms without interference. The same thing concerns the sets $U_{in}(i_1, k_1)$ and $U_{in}(i_2, k_2)$ $((i_1, k_1) \neq (i_2, k_2))$. Therefore, if we use 132 channels ($11 \times 12 \leq 132$, $7 \times 18 \leq 132$) and attribute to each set of type U_{out} different channel and the same thing with the sets U_{in}, then we may rewrite all the presented algorithms and reduce significantly the time needed to disseminate information. If we define the latency in the analogous manner as in the classical definition, then for example the multi channel broadcast schedule used in the algorithm HEXAGONSBROADCASTING has latency $2R$.

VI. CONCLUSION

In this paper we have studied the MLBS problem in ad hoc networks which are represented by unit disk graphs. We have introduced a construction which produces broadcast schedule with latency at most 258 times optimum. The advantage of our construction over known algorithms is its ability to adapt fast to the changes in the network. We have also studied the minimum-latency gossiping, single source multiple message broadcasting and multi channel broadcast scheduling problem in unit disk graphs.

Workshop on Computational Optimization

Many real world problems arising in engineering, economics, medicine and other domains can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints which ask for adequate computational methods.

The aim of this workshop is to stimulate the communication between researchers working on different fields of optimization and practitioners who need reliable and efficient computational optimization methods.

We invite original contributions related to both theoretical and practical aspects of optimization methods.

The list of topics includes, but is not limited to:

- unconstrained and constrained optimization
- combinatorial optimization
- global optimization
- multiobjective and multimodal optimization
- dynamic and noisy optimization
- large scale optimization
- parallel and distributed approaches in optimization
- random search algorithms, simulated annealing, tabu search and other derivative free optimization methods
- interval methods
- nature inspired optimization methods (evolutionary algorithms, ant colony optimization, particle swarm optimization, immune artificial systems etc)
- hybrid optimization algorithms involving natural computing techniques and other global and local optimization methods
- memetic algorithms
- optimization methods for learning processes and data mining
- computational optimization methods in statistics, econometrics, finance, physics, medicine, biology, engineering etc.

***Abstract*—Ant Colony Optimization (ACO) is a stochastic search method that mimics the social behavior of real ants colonies, which manage to establish the shortest route to feeding sources and back. Such algorithms have been developed to arrive at near-optimal solutions to large-scale optimization problems, for which traditional mathematical techniques may fail. On this paper semi-random start is applied. A new kind of estimation of start nodes of the ants is made and several start strategies are prepared and combined. The idea of semi-random start is better management of the ants. This new technique is tested on Multiple Knapsack Problem (MKP). Benchmark comparison among the strategies is presented in terms of quality of the results. Based on this comparison analysis, the performance of the algorithm is discussed. The study presents ideas that should be beneficial to both practitioners and researchers involved in solving optimization problems.**

I. Introduction

Many combinatorial optimization problems are fundamentally hard. This is the most typical scenario when it comes to realistic and relevant problems in industry and science. Examples of optimization problems are Traveling Salesman Problem [10], Vehicle Routing [12], Minimum Spanning Tree [8], Multiple Knapsack Problem [5], etc. They are NP-hard problems and in order to obtain solution close to the optimality in reasonable time, metaheuristic methods are used. One of them is Ant Colony Optimization (ACO) [3].

ACO algorithms have been inspired by the real ants behavior. In the nature, ants usually wander randomly, and upon finding food return to their nest while laying down pheromone trails. If other ants find such a path, they are likely not to keep traveling at random, but to instead follow the trail, returning and reinforcing it if they eventually find food. However, as time passes, the pheromone starts to evaporate. The more time it takes for an ant to travel down the path and back again, the more time the pheromone has to evaporate and the path to become less prominent. A shorter path, in comparison will be visited by more ants and thus the pheromone density remains high for a longer time.

ACO is implemented as a team of intelligent agents which simulate the ants behavior, walking around the graph representing the problem to solve using mechanisms of cooperation and adaptation. ACO algorithm requires to define the following [1], [4]:

- The problem needs to be represented appropriately, which would allow the ants to incrementally update the solutions through the use of a probabilistic transition rules, based on the amount of pheromone in the trail and other problem specific knowledge. It is also important to enforce a strategy to construct only valid solutions corresponding to the problem definition.
- A problem-dependent heuristic function, that measures the quality of components that can be added to the current partial solution.
- A rule set for pheromone updating, which specifies how to modify the pheromone value.
- A probabilistic transition rule based on the value of the heuristic function and the pheromone value, that is used to iteratively construct a solution.

The structure of the ACO algorithm is shown by the pseudocode below (Figure 1). The transition probability $p_{i,j}$, to choose the node j when the current node is i, is based on the heuristic information $\eta_{i,j}$ and the pheromone trail level $\tau_{i,j}$ of the move, where $i, j = 1, \ldots, n$.

$$p_{i,j} = \frac{\tau_{i,j}^a \eta_{i,j}^b}{\sum_{k \in allowed} \tau_{i,k}^a \eta_{i,k}^b}, \tag{1}$$

The higher the value of the pheromone and the heuristic information, the more profitable it is to select this move and resume the search. In the beginning, the initial pheromone level is set to a small positive constant value τ_0; later, the ants update this value after completing the construction stage. ACO algorithms adopt different criteria to update the pheromone level.

The pheromone trail update rule is given by:

$$\tau_{i,j} \leftarrow \rho \tau_{i,j} + \Delta \tau_{i,j}, \tag{2}$$

where ρ models evaporation in the nature and $\Delta \tau_{i,j}$ is new added pheromone which is proportional to the quality of the solution.

Our novelty is to use estimations of start nodes with respect to the quality of the solution and thus to better manage the search process. On the basis of the estimations we offer several start strategies and their combinations. Like a benchmark problem is used Multiple Knapsack Problem (MKP) because a

lot of real world problems can be represented by it and MKP arises like a subproblem in many optimization problems.

The rest of the paper is organized as follows: in section 2 several start strategies are proposed. In section 3 the MKP is introduced. In section 4 the strategies are applied on MKP and the achieved results are compared and strategies are classified. At the end some conclusions and directions for future work are done.

II. Start Strategies

The known ACO algorithms create a solution starting from random node. But for some problems, especially subset problems, it is important from which node the search process starts. For example if an ant starts from node which does not belong to the optimal solution, probability to construct it is zero. Therefore we offer several start strategies.

Let the graph of the problem has m nodes. We divide the set of nodes on N subsets. There are different ways for dividing. Normally, the nodes of the graph are randomly enumerated. An example for creating of the nodes subsets, without loss of generality, is: the node number one is in the first subset, the node number two is in the second subset, etc. the node number N is in the $N-th$ subset, the node number $N+1$ is in the first subset, etc. Thus the number of the nodes in the subsets are almost equal. We introduce estimations $D_j(i)$ and $E_j(i)$ of the node subsets, where $i \geq 2$ is the number of the current iteration. $D_j(i)$ shows how good is the j^{th} subset and $E_j(i)$ shows how bad is the j^{th} subset. $D_j(i)$ and $E_j(i)$ are weight coefficients of $j-th$ node subset $(1 \leq j \leq N)$, which we calculate by the following formulas:

$$D_j(i) = \phi.D_j(i-1) + (1-\phi).F_j(i), \tag{3}$$

$$E_j(i) = \phi.E_j(i-1) + (1-\phi).G_j(i), \tag{4}$$

where $i \geq 1$ is the current process iteration and for each j $(1 \leq j \leq N)$:

$$F_j(i) = \begin{cases} \frac{f_{j,A}}{n_j} & \text{if } n_j \neq 0 \\ F_j(i-1) & \text{otherwise} \end{cases}, \tag{5}$$

$$G_j(i) = \begin{cases} \frac{g_{j,B}}{n_j} & \text{if } n_j \neq 0 \\ G_j(i-1) & \text{otherwise} \end{cases}, \tag{6}$$

$f_{j,A}$ is the number of the solutions among the best $A\%$, $g_{j,B}$ is the number of the solutions among the worst $B\%$, where $A + B \leq 100$, $i \geq 2$ and

$$\sum_{j=1}^{N} n_j = n, \tag{7}$$

where n_j $(1 \leq j \leq N)$ is the number of solutions obtained by ants starting from nodes subset j, n is the number of ants. Initial values of the weight coefficients are: $D_j(1) = 1$ and $E_j(1) = 0$. The parameter ϕ, $0 \leq \phi \leq 1$, shows the weight of the information from the previous iterations and from the last iteration. When $\phi = 0$ only the information from the last iteration is taken in to account. If $\phi = 0.5$ the influence of the previous iterations versus the last is equal. When $\phi = 1$ only the information from the previous iterations is taken in to account. When $\phi = 0.25$ the weight of the information from the previous iterations is three times less than this one of the last iteration. When $\phi = 0.75$ the weight of the previous iterations is three times higher than this one of the last iteration. The balance between the weights of the previous iterations and the last is important. At the beginning when the current best solution is far from the optimal one, some of the node subsets can be estimated as good. Therefore, if the value of the parameter ϕ is too high the estimation can be distorted. If the weight of the last iteration is too high then information for good and bad solutions from previous iterations is ignored, which can distort estimation too.

We try to use the experience of the ants from previous iteration to choose the better starting node. Other authors use this experience only by the pheromone, when the ants construct the solutions [4]. Let us fix threshold E for $E_j(i)$ and D for $D_j(i)$, than we construct several strategies to choose start node for every ant, the threshold E increases every iteration with $1/i$ where i is the number of the current iteration:

1 If $E_j(i)/D_j(i) > E$ then the subset j is forbidden for current iteration and we choose the starting node randomly from $\{j \ |j$ is not forbidden$\}$;

2 If $E_j(i)/D_j(i) > E$ then the subset j is forbidden for current simulation and we choose the starting node randomly from $\{j \ |j$ is not forbidden$\}$;

3 If $E_j(i)/D_j(i) > E$ then the subset j is forbidden for K_1 consecutive iterations and we choose the starting node randomly from $\{j \ |j$ is not forbidden$\}$;

4 Let $r_1 \in [0.5, 1)$ is a random number. Let $r_2 \in [0, 1]$ is a random number. If $r_2 > r_1$ we randomly choose node from subset $\{j \ |D_j(i) > D\}$, otherwise we randomly chose a node from the not forbidden subsets, r_1 is chosen and fixed at the beginning.

5 Let $r_1 \in [0.5, 1)$ is a random number. Let $r_2 \in [0, 1]$ is a random number. If $r_2 > r_1$ we randomly choose node

from subset $\{j \mid D_j(i) > D\}$, otherwise we randomly chose a node from the not forbidden subsets, r_1 is chosen at the beginning and increase with r_3 every iteration.

Where $0 \leq K_1 \leq$"number of iterations" is a parameter. If $K_1 = 0$, than strategy 3 is equal to the random choose of the start node. If $K_1 = 1$, than strategy 3 is equal to the strategy 1. If $K_1 =$"maximal number of iterations", than strategy 3 is equal to the strategy 2.

We can use more than one strategy for choosing the start node, but there are strategies which can not be combined. We distribute the strategies into two sets: $St1 = \{strategy1,\ strategy2,\ strategy3\}$ and $St2 = \{strategy5,\ strategy6\}$. The strategies from same set can not be used at once. Thus we can use strategy from one set or combine it with strategies from the other set. Exemplary combinations are $(strategy1)$, $(strategy2;\ strategy5)$, $(strategy3;\ strategy6)$. When we combine strategies from $St1$ and $St2$, first we apply the strategy from $St1$ and according it some of the regions (node subsets) become forbidden, and after that we choose the starting node from not forbidden subsets according the strategy from $St2$

III. Multiple Knapsack Problem

We test the ideas for controlled start on MKP. MKP is a real world problem and is a representative of the class of subset problems. The MKP has numerous applications in theory as well as in practice. It also arises as a subproblem in several algorithms for more complex problems and these algorithms will benefit from any improvement in the field of MKP. The following major applications can be mentioned: problems in cargo loading, cutting stock, bin-packing, budget control and financial management. Sinha and Zoltner [9] proposed to use the MKP in fault tolerance problem and in [2] is designed a public cryptography scheme whose security realize on the difficulty of solving the MKP. Martello and Toth [7] mention that two-processor scheduling problems may be solved as a MKP. Other applications are industrial management, naval, aerospace, computational complexity theory.

The MKP can be thought as a resource allocation problem, where there are m resources (the knapsacks) and n objects and every object j has a profit p_j. Each resource has its own budget c_j (knapsack capacity) and consumption r_{ij} of resource i by object j. The aim is maximizing the sum of the profits, while working with a limited budget.

The MKP can be formulated as follows:

$$\max \textstyle\sum_{j=1}^{n} p_j x_j$$

$$\text{subject to} \textstyle\sum_{j=1}^{n} r_{ij} x_j \leq c_i \quad i = 1, \dots, m \tag{8}$$

$$x_j \in \{0, 1\} \quad j = 1, \dots, n$$

x_j is 1 if the object j is chosen and 0 otherwise.

There are m constraints in this problem, so MKP is also called m-dimensional knapsack problem. Let $I = \{1, \dots, m\}$ and $J = \{1, \dots, n\}$, with $c_i \geq 0$ for all $i \in I$. A well-stated MKP assumes that $p_j > 0$ and $r_{ij} \leq c_i \leq \sum_{j=1}^{n} r_{ij}$ for all $i \in I$ and $j \in J$. Note that the $[r_{ij}]_{m \times n}$ matrix and $[c_i]_m$ vector are both non-negative.

In the MKP one is not interested in solutions giving a particular order. Therefore a partial solution is represented by $S = \{i_1, i_2, \dots, i_j\}$ and the most recent elements incorporated to S, i_j need not be involved in the process for selecting the next element. Moreover, solutions for ordering problems have a fixed length as one search for a permutation of a known number of elements. Solutions for MKP, however, do not have a fixed length. The graph of the problem is defined as follows: the nodes correspond to the items, the arcs fully connect nodes. Fully connected graph means that after the object i one can chooses the object j for every i and j if there are enough resources and object j is not chosen yet.

IV. Computational Results

The computational experience of the ACO algorithm is shown using 10 MKP instances from "OR-Library" available within WWW access at **http://people.brunel.ac.uk/mastjjb/jeb/orlib/**, with 100 objects and 10 constraints. To provide a fair comparison for the above implemented ACO algorithm, a predefined number of iterations, $k = 100$, is fixed for all the runs. Thus we can observe which strategy reaches good solutions faster. If the value of k (number of iterations) is too high, the achieved results will be very close to the optimal solution and will be difficult to appreciate different strategies. We apply strategies on MMAS [11], because it is one of the best ACO approach. The developed technique has been coded in C++ language and implemented on a Pentium 4 (2.8 Ghz). The parameters are fixed as follows: $\rho = 0.5$, $a = 1$, $b = 1$, number of used ants is 20, $A = 30$, $B = 30$, $D = 1.5$, $E = 0.5$, $K_1 = 5$, $r_3 = 0.01$. The values of ACO parameters (ρ, a, b) are from [6] and experimentally is found that they are best for MKP. The tests are run with 1, 2, 4, 5 and 10 nodes within the nodes subsets and values for ϕ are 0, 0.25, 0.5 and 0.75. For every experiment, the results are obtained by performing 30 independent runs, then averaging the fitness values. The computational time which takes start strategies is negligible with respect to the computational time which takes solution construction.

Tests with all possible combinations of strategies and with random start (12 combinations at all), four value for ϕ and five kind of node subsets are run and every test 30 times. Thus the all runs are 72 000. One can observe that sometimes all nodes subsets become forbidden and the algorithm stops before performing all iterations (strategies 1, 2, 3 and combinations with them). So if all nodes subsets become forbidden the algorithm performs several iterations without any strategy with random start till some of the subsets become not forbidden. Then the algorithm continue to apply the chosen strategy.

The problem which arises is how to compare the achieved solutions by different strategies and different node-devisions. Therefore the difference (interval) d between the worst and best average result for every problem is divided to 10. If the

TABLE I
ESTIMATON OF STRATEGIES AND NODES DEVISIONS FOR $\phi = 0$

number nodes	10	5	4	2	1
random	32	32	32	32	32
strat. 1	84	84	87	83	83
strat. 2	33	31	36	53	74

strat. 2-5	33	36	35	63	82
strat. 3-4	69	89	88	87	**90**
strat. 3-5	69	89	88	87	**90**

average result for some strategy, node devision and ϕ is in the first interval with borders the worst average result and worst average plus $d/10$ it is appreciated with 1. If it is in the second interval with borders the worst average plus $d/10$ and worst average plus $2d/10$ it is appreciated with 2 and so on. If it is in the 10th interval with borders the best average minus $d/10$ and the best average result, it is appreciated with 10. Thus for a test problem the achieved results for every strategy, every nodes devision and every ϕ is appreciated from 1 to 10. After that is summed the rate of all test problems for every strategy, every nodes devision and ϕ. So the rate of the strategies/node-devision/ϕ becomes between 10 and 100, because the benchmark problems are 10. It is mode of result classification.

On Table I is shown the rate of the strategies/node-devision when parameter $\phi = 0$, which means that only the achieved results from the last iteration are taken in to account in the node-subsets estimation, in bold is the best rate. We observe that the rate of the ACO algorithm with start strategies outperforms the traditional ACO with completely random start. Comparing the strategies, the worst rate has strategy 3 and their combinations with strategies 4 and 5. In strategy 3 the nodes-subsets with high value of estimation $E_j(i)$ become forbidden for current simulation. So if at the beginning iterations of the algorithm from some node-subset start only bad solutions it will be forbidden, but it is possible from this node subset to start good solutions too. The best rate have the combinations of strategies 1 and 3 with strategies 4 and 5. It means that it is better the node subsets which are appreciated like bad to be forbidden for a fixed number of iterations and it is better to forbid some node-subsets and to stimulate ants to start from other which looks to be good, than to apply only one strategy (forbidden or stimulated). The worst rate with respect of node devision is when there are 10 nodes in the node-subsets. When there

are to many nodes in the node subset then it is possible from this subset to start good and bad solutions and it is difficult to appreciate it. The best rate with respect to the node devision is when in the node subsets is only one node.

On Tables II, III and IV are shown the rate of the strategies/node-devision when parameter $\phi = 0.25, 0.5$ and 0.75. We can make similar to the $\phi = 0$ conclusions. For all values of the parameter ϕ the best rate according node devision is when there is only one node in node-subsets. So we put in Table V the rate of the start strategies when the node subsets consist one node, with bold is the best rate.

On Table V we observe that the worst rate according value of the parameter ϕ is when we take in to account only the achieved solutions from the last iteration ($\phi = 0$). The rate

strat. 3-5	90	**97**	96	**97**

of strategies when $\phi = 0.5$ is slightly better than rate when $\phi = 0.25$ and $\phi = 0.75$. So we can conclude that the balance between information from previous iterations and from last iteration is very important. According to the strategies, the worst rate is when is applied traditional ACO with random start and with strategy 2 when the subsets stay forbidden for current simulation. The best rate are combinations of strategy 3 with strategies 4 and 5. So for better performance of the ACO algorithm is advisable to forbid bad regions for several iterations and to stimulate ants to start construction of the solutions from good regions.

V. CONCLUSION

In this paper we address the modeling of the process of ant colony optimization method by using estimations, combining five start strategies. So, the start node of each ant depends of the goodness of the respective region. We focus on parameter settings which manage the starting procedure. We investigate on influence of the parameter ϕ to algorithm performance. The best solutions are achieved when ”bad” regions are forbidden for several iterations and the probability the ants to start from ”good” regions is higher. In future we will apply our modification of ACO algorithm on various classes of problems. We will investigate the influence of the estimations and start strategies on the achieved results.

***Abstract*—We study a probabilistic optimization model for MIN SPANNING TREE, where any vertex v_i of the input-graph $G(V,E)$ has some presence probability p_i in the final instance $G' \subset G$ that will effectively be optimized. Supposing that when this "real" instance G' becomes known, a decision maker might have no time to perform computation from scratch, we assume that a spanning tree T, called *anticipatory* or *a priori* spanning tree, has already been computed in G and, also, that a decision maker can run a quick algorithm, called *modification strategy*, that modifies the anticipatory tree T in order to fit G'. The goal is to compute an anticipatory spanning tree of G such that, its modification for any $G' \subseteq G$ is optimal for G'. This is what we call PROBABILISTIC MIN SPANNING TREE problem. In this paper we study complexity and approximation of PROBABILISTIC MIN SPANNING TREE in complete graphs as well as of two natural subproblems of it, namely, the PROBABILISTIC METRIC MIN SPANNING TREE and the PROBABILISTIC MIN SPANNING TREE 1,2 that deal with metric complete graphs and complete graphs with edge-weights either 1, or 2, respectively.**

I. Introduction

The basic problematic of probabilistic combinatorial optimization (in graphs) is the following. We are given a graph $G(V,E)$ on which we have to solve some optimization problem Π. But, for some reasons depending on the reality modeled by G, Π is only going to be solved for some subgraph G' of G (determined by the vertices that will finally be present) rather than for the whole of G. The measure of how likely it is that a vertex $v_i \in V$ will belong to G' (i.e., will be present for the final optimization) is expressed by a probability p_i associated with v_i. How we can proceed in order to solve Π under this kind of uncertainty?

A first very natural idea that comes to mind is that one waits until G' is specified (i.e., it is present and ready for optimization) and, at this time, one solves Π in G'. This is what is called *reoptimization*.

But what if there remains very little time for such a computation? In this case, another way to proceed is the following. One solves Π in the whole of G in order to get a feasible solution (denoted by S), called *a priori* or *anticipatory solution*, which will serve her/him as a kind of benchmark for the solution on the effectively present subgraph G'. One has also to be provided with an algorithm that modifies S in order to fit G'. This algorithm is called *modification strategy* (let us denote it by $\mathtt{M}$). The objective now becomes to compute an anticipatory solution that, when modified by $\mathtt{M}$, remains "good" for any subgraph of G (if this subgraph is the one where Π will be finally solved).

This amounts to computing a solution that optimizes a kind of expectation of the value of the modification of S over all the possible subgraphs of G, i.e., the sum of the products of the probability that G' is the finally present graph multiplied by the value of the modification of S in order to fit G' over any subgraph G' of G. This expectation, depending on both the instance of the deterministic problem Π, the vertex-probabilities, and the modification strategy adopted, will be called the *functional*. Obviously, the presence-probability of G' is the probability that all of its vertices are present and the other vertices outside G' are absent.

Seen in this way, the probabilistic version PROBABILISTIC Π of a (deterministic) combinatorial optimization problem Π becomes another equally deterministic problem Π', the solutions of which have the same feasibility constraints as those of Π but with a different objective function where vertex-probabilities intervene.

In this sense, probabilistic combinatorial optimization is very close to what in the last couple of years has been called "one stage optimisation under independent decision models", an area very popular in the stochastic optimization community.

What are the main mathematical problems dealing with probabilistic consideration of a problem Π in the sense discussed above? One can identify at least five interesting mathematical and computational problems dealing with probabilistic combinatorial optimization:

1) write the functional down in an analytical closed form;
2) if such an expression of the functional is possible, prove that its value is polynomially computable (this amounts to proving that the modified problem Π' belongs to **NP**);
3) determine the complexity of the computation of the optimal *a priori* solution, i.e., of the solution optimizing the functional (in other words, determine the computational complexity of Π');
4) if Π' is **NP**-hard, study polynomial approximation issues;
5) always, under the hypothesis of the **NP**-hardness of Π', determine its complexity in the special cases where Π is polynomial, and in the case of **NP**-hardness, study approximation issues.

Let us note that, although curious, point 2 in the above list is neither trivial nor senseless. Simply consider that the summation for the functional includes, in a graph of order n, 2^n terms (one for each subgraph of G). So, polynomiality of the computation of the functional is, in general, not immediate.

Several optimization frameworks have been introduced by the operations research community for handling data uncertainty, the most well developed being *Stochastic programming* (see [1], [2] for basics) and *Robust discrete optimization* (see, for example, [3]).

The framework of *Probabilistic combinatorial optimization* where our work lies at, was introduced by [4], [5]. In [6], [5], [7], [8], [9], [4], [10], [11], [12], restricted versions of routing and network-design probabilistic minimization problems (in complete graphs) have been studied under the robustness model dealt here (called *a priori optimization*). In [13], the analysis of the probabilistic minimum travelling salesman problem, originally performed in [5], [4], has been revisited and refined.

Several other combinatorial problems have been recently treated in the probabilistic combinatorial optimization framework, including minimum coloring ([14], [15]), maximum independent set and minimum vertex cover ([16], [17]), longest path ([18]), Steiner tree problems ([19], [20]). Note also that probabilistic minimum spanning tree has also studied by [8] but under a very different probabilistic model.

We apply in this paper the probabilistic combinatorial optimization setting just described in the minimum spanning tree problem.

Given an edge-weighted graph $G(V, E)$, with positive edge weights $d : E \rightarrow \mathbb{Q}^+$, the minimum spanning tree problem (MIN SPANNING TREE) consists of determining a minimum total edge-weight tree spanning V.

MIN SPANNING TREE is a celebrated problem, very frequently modeling several kinds of networks in transports, communications, energy, logistics, etc. MIN SPANNING TREE has been actively studied under several optimization models like on-line computation, dynamic optimization, etc. Its study always motivates numerous researchers in theoretical computer science and in operational research.

In what follows, we first design a modification strategy and derive an analytic expression of the expected value (called *functional* in what follows) of a spanning tree of G, under this modification strategy.

We next show that the problem of *a priori optimization*, i.e., the problem of determining an anticipatory solution minimizing the functional, is **NP**-hard in general complete graphs (Section II).

Subsequently, we study complexity of the PROBABILISTIC MIN SPANNING TREE problem when dealing with particular cases of vertex-probabilities values and/or edge weights and particular cases of anticipatory solutions (Section IV).

We next derive polynomial-time approximation results for metric graphs and for graphs where edge-weights are either 1 or 2 (Section V). Because of the limits to the paper's size, some of the results are given without their proofs.

II. THE MODIFICATION STRATEGY, THE FUNCTIONAL ASSOCIATED WITH, AND THE COMPLEXITY OF PROBABILISTIC MIN SPANNING TREE

Consider a complete[1] weighted graph $G(V, E)$ on n vertices, with edge weights given by a function $d : E \rightarrow \mathbb{Q}^+$. Set $V = \{v_1, v_2, \ldots, v_n\}$. Each vertex $v_i \in V$, is associated with a presence probability $p_i \in \mathbb{Q}^+$ measuring, as already mentioned, how likely is that v_i will be present in the instance where PROBABILISTIC MIN SPANNING TREE will really be solved. We assume that subgraph $G'(V', E')$ of G materializes as the outcome of n independent Bernoulli trials, one per vertex $v_i \in V$: $v_i \in V'$ with probability p_i. Then, $E' = \{(u, v) \in E : u \in V' \text{ and } v \in V'\}$. Let us note that it seems to be natural that, for a fixed modification strategy M, given an anticipatory spanning tree T, some basic properties of its structure must be preserved in any tree T' built when M adjusts T to $G'(V', E')$, for any $V' \subseteq V$. Such a basic property is, for instance, the relation "predecessor-successor" in T. In order that this relation is preserved in any T', we assume that there exists a vertex, denoted by v_1 with $p_1 = 1$.

To motivate this assumption, consider a pacifist version of an application in [5]. Let G be a graph of order n and let its vertices represent researchers of a research network. The weight of an edge linking researcher i to researcher j quantifies the "inefficiency" risk incurred when i and j have to accomplish a common task. We wish to determine an organizational structure of this network where all the researchers implied accomplish some tasks and where the total "inefficiency" risk is minimized.

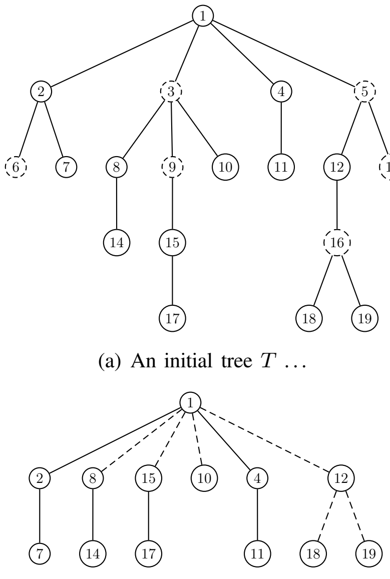
This can be modeled as a minimum spanning tree T^* of G. Let us now suppose that the project at hand involves several tasks where only a subset of researchers are implied, the project manager (the omnipresent vertex v_1) being involved to all of them. The probability associated with a researcher $v_i \neq v_1$, is the probability that v_i participates to an arbitrary task undertaken by the research network. Each such task will be represented by some subgraph G' of G and its "inefficiency" risk is the cost of a minimum spanning tree of G'. The modification strategy that is to be adopted for such a model must allow us to keep the same structure from a task to another one in order that the "inefficiency" risk remains as low as possible. Other applications from distributed systems also justify similar assumptions.

Formally, let $G(V, E)$ be a complete graph with $|V| = n$ and $(p_i)_{i=1,\ldots,n}$ a vertex-probability system with $p_1 = 1$ (in other words, vertex v_1 is assumed to be always present). Consider a tree T spanning V and number vertices in T in a left-to-right breadth-first-search (bfs) way. Consider a subgraph $G'(V', E') = G[V']$ of G induced by a set $V' \subseteq V$. The modification strategy (adjusting T to a spanning tree T' of G' and denoted by LEV in what follows) that will be analyzed in the sequel works as follows:

[1] The assumption that the input-graph is complete is made in order to ensure connectivity of the tree T' for any subgraph $G' \subseteq G$; in any case if the real-world problem at hand implies non-complete graphs, one can complete them by "appropriately heavy" edges.

1) remove the vertices of $V \backslash V'$ and the edges of E incident to these vertices; let $F(V') = \{T_1, T_2, \dots, T_k\}$ be the so-obtained forest and assume that $v_1 \in V(T_1)$ and that, for $i, j = 2 \dots, k$, $i < j$ if the index of the root of T_i is smaller than that of the root of T_j;
2) for $i = 2, \dots, k$ add as father of the root of T_i its largest-index ancestor that is still present in $V(T)$.

Note that, given two vertices v_j and v_l with $j < l$ (in the bfs numbering of T), if v_j is not an ancestor of v_l in T, then edge (v_j, v_l) will never belong to any T' modification of T for any $V' \subseteq V$.



(a) An initial tree T ...

(b) ...and its modification by LEV

Fig. 1. An anticipatory spanning tree T and its adjustment.

Figure 1(b) gives an example of how strategy LEV works starting from an initial tree T shown in Figure 1(a) and assuming that vertices 3, 5, 6, 9, 13 and 16 are absent from V'.

The functional $E(G,T)$ associated with LEV is defined by:

$$E(G,T) = \sum_{V' \subseteq V} \Pr\left[V'\right] m\left(G', T'\right)$$

where $\Pr[V'] = \prod_{v_i \in V'} p_i \prod_{v_i \in V \backslash V'} (1 - p_i)$ is the distribution describing probability of occurrence of a specific subset $V' \subseteq V$, i.e., of the graph $G[V']$ and $m(G', T')$ is the value of the tree T' spanning V' produced by application of LEV on the anticipatory tree T.

Notice that, since there exist $2^{|V|}$ distinct sets V', any of them inducing a distinct subgraph $G[V']$ of G, both polynomial computation of $E(G,T)$ and tight combinatorial characterization of the optimal anticipatory solution are not always obvious or easy to perform.

Our goal is to study the following problem: *find an algorithm for taking a priori decisions, i.e., that determines a spanning tree T^*, that optimizes $E(G,T)$"*; this is PROBABILISTIC MIN SPANNING TREE.

In what follows, we show that this problem is **NP**-hard in general complete graphs with $p_1 = 1$. We then study approximation of this problem in metric graphs as well as in a particular subclass of them where edge-weights are either 1 or 2. The approximation ratio is defined as $E(G,T)/E(G,T^*)$.

The following result holds for the functional $E(G,T)$ associated with an anticipatory spanning tree T and the modification strategy LEV.

Proposition 1: Consider a complete graph $G(V,E)$, provided with a vertex-probability system $(p_i)_{i=1,\dots,n}$ with $p_1 = 1$, any edge (v_i, v_j) of which has weight d_{ij} and a spanning tree T of G. Then, the expectation associated with LEV can be expressed by:

$$\begin{aligned} E(G,T) = & \\ & \sum_{(v_i,v_j)\in T} p_i p_j d_{ij} \\ & + \sum_{v_i \in V} \sum_{\substack{v_j \in D(v_i) \\ (v_i,v_j) \notin T}} p_i p_j \times \prod_{v_k \in \mu[v_i,v_j]} \left(1 - p_k\right) d_{ij} \quad (1) \end{aligned}$$

where $D(v_i)$ denotes the set of successors of v_i in T and $\mu[v_i, v_j]$ denotes the set of vertices in the (unique) path of T from v_i to v_j not including neither of them. Expression (1) can be computed in polynomial time. Consequently, PROBABILISTIC MIN SPANNING TREE $\in$ **NPO**, the class of the optimization problems the decision versions of which are in **NP**.

Proof: Following LEV, if $(v_i, v_j) \in T$, then this edge will be in T' iff $v_i, v_j \in V'$; on the other hand, if $(v_i, v_j) \notin T$, then edge (v_i, v_j) will be added in T' iff $v_i, v_j \in V'$ and $v_j \in D(v_i)$ and every vertex in $\mu[v_i, v_j]$ is not in V'. From these observations we derive:

$$\begin{aligned} E(G,T) = & \\ & \sum_{V' \subseteq V} \Pr\left[V'\right] m\left(G', T'\right) \\ = & \sum_{V' \subseteq V} \Pr\left[V'\right] \sum_{(v_i,v_j)\in T'} d_{ij} \\ = & \sum_{V' \subseteq V} \Pr\left[V'\right] \sum_{(v_i,v_j)\in T' \cap T} d_{ij} \\ & + \sum_{V' \subseteq V} \Pr\left[V'\right] \sum_{(v_i,v_j)\in T' \cap (E \backslash T)} d_{ij} \\ = & \sum_{(v_i,v_j)\in T} \sum_{V' \subseteq V} \Pr\left[V'\right] \mathbf{1}_{\{(v_i,v_j)\in T'\}} d_{ij} \\ & + \sum_{(v_i,v_j)\in (E \backslash T)} \sum_{V' \subseteq V} \Pr\left[V'\right] \mathbf{1}_{\{(v_i,v_j)\in T'\}} d_{ij} \\ = & \sum_{(v_i,v_j)\in T} p_i p_j d_{ij} \\ & + \sum_{v_i \in V} \sum_{\substack{v_j \in D(v_i) \\ (v_i,v_j) \notin T}} p_i p_j \prod_{v_k \in \mu[v_i,v_j]} \left(1 - p_k\right) d_{ij} \end{aligned}$$

Clearly, (1) can be computed in polynomial time, since the ranges of the indices implied are polynomial. ■

As already mentioned, PROBABILISTIC MIN SPANNING TREE consists of determining an anticipatory spanning tree T^* of G minimizing $E(G,T)$.

Unfortunately, Proposition 1 does not derive a compact combinatorial characterization for the optimal anticipatory solution of PROBABILISTIC MIN SPANNING TREE.

In particular, the form of the functional does not imply solution, for instance, of some well-defined weighted version of the (deterministic) MIN SPANNING TREE. This is due to the second term of the expression for $E(G,T)$ in (1). There, the "costs" assigned to the edges depend on the structure of the anticipatory solution chosen and of the present subgraph of G.

The decision version of PROBABILISTIC MIN SPANNING TREE, denoted by PROBABILISTIC MIN SPANNING TREE(K) can be stated as follows: "given an edge-weighted complete graph $G(V,E)$, provided with a vertex-probability system $(p_i)_{i=1,\dots,n}$ with $p_1 = 1$ and a constant K, does there exist a tree T such that $E(G,T) \leqslant K$?", where $E(G,T)$ is given by (1).

Dealing with PROBABILISTIC MIN SPANNING TREE(K), by a technical reduction from 3 EXACT COVER, the following proposition holds.

Proposition 2: PROBABILISTIC MIN SPANNING TREE(K) is **NP**-complete.

Sketch of proof: PROBABILISTIC MIN SPANNING TREE $\in$ **NP**. In order to show completeness, we reduce 3 EXACT COVER to PROBABILISTIC MIN SPANNING TREE. 3 EXACT COVER that is defined as follows: "given a ground set X of size $3q$ and a collection $\mathcal{E}$ of $3q$ subsets of X each of size 3, does there exist a subcollection $\mathcal{E}' = \{S_1,\dots,S_q\}$ of $\mathcal{E}$ such that $\bigcup_{i=1}^{q} S_i = X$?" (obviously, $\mathcal{E}'$ is a partition of X). 3 EXACT COVER is **NP**-complete ([21]).

Consider an arbitrary instance $I(X,\mathcal{E})$ of 3 EXACT COVER; we construct the following instance for PROBABILISTIC MIN SPANNING TREE:

- the vertex-set V is a set of $6q+2$ vertices built by associating a vertex x_i with an element $x_i \in X$, a vertex y_j with a set $S_j \in \mathcal{E}$ and by adding a vertex r (playing the role of the omnipresent root) and a vertex s (representing the solution); for some positive fixed constant $p < 1/2$, vertices x_i are provided with probability p, vertices y_j with probability $1-p$ and vertices r and s with probability 1;
- edge-weights are defined as follows:
  - for every $S_j = \{x_{i_1}, x_{i_2}, x_{i_3}\}$, $j = 1,\dots,3q$, $d_{i_1 j} = d_{i_2 j} = d_{i_3 j} = 1$;
  - edges linking s to vertices y_j have weight $M > 0$ and those linking s to vertices of x_i have weight $M/p + 2$;
  - edges linking r to vertices y_j as well as edge (r,s) have all weight 0, while edges linking r to vertices x_i have weight $M/p^2 + 1$;
  - all the other edges have arbitrarily large weight $B \gg M/p^2 + 1$;
- $K = q(M(1+2p) + 3p(p+1))$.

It is easy to see that this reduction is polynomial. It is illustrated in Figure 2 where, for readability, some edges, in particular those of weight B are omitted.

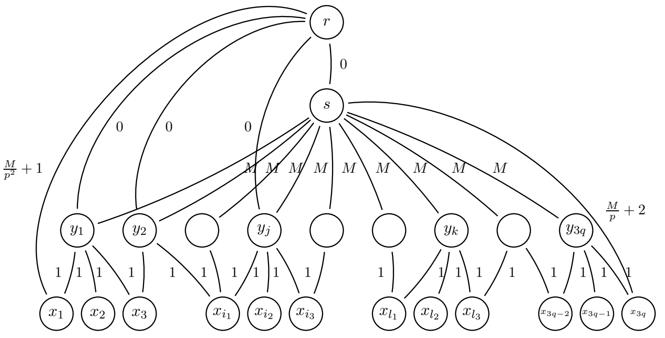


Fig. 2. An example for the reduction from 3 EXACT COVER to PROBABILISTIC MIN SPANNING TREE.

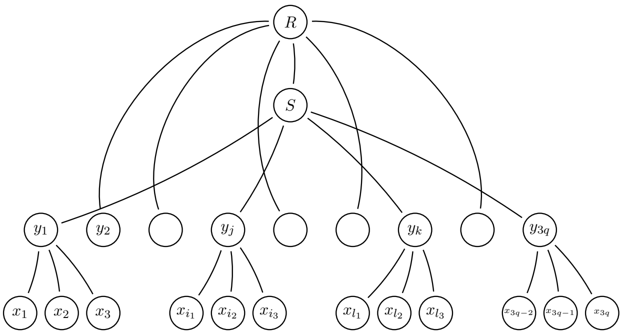

Fig. 3. The shape of T^*.

One can prove that if 3 EXACT COVER admits a solution $\mathcal{E}^*$, then G has a minimum spanning tree T^* the shape of which is as in Figure 3 and whose value is:

$$\begin{aligned} E(G,T^*) &= \\ &\quad 0 + 2q \times 0 + q[(1-p)M + 3p(1-p) \times 1 + \\ &\quad 3p(1-(1-p)) \times (M/p+2)] \\ &= q[M - pM + 3p - 3p^2 + 3pM + 6p^2] \\ &= q[M(1+2p) + 3p(p+1)] \;=\; K \end{aligned}$$

This can be done by inspection of all the possible solutions for MIN SPANNING TREE in G. ■

III. REOPTIMIZATION AND MIN SPANNING TREE

As mentioned in Section I, a complementary framework to the one of the a priori optimization, is the *reoptimization* consisting of solving ex nihilo and optimally the portion of the instance presented for optimization. Reoptimization is introduced in [4]. Let $\mathrm{opt}(G')$ refer to the weight of the optimum spanning tree on G' for every subgraph $G'(V',E')$ of G. The expected minimum weight over the distribution of subgraphs of G, i.e., the functional of reoptimization is defined by $E^*(G) = \sum_{V' \subseteq V} \Pr[V']\,\mathrm{opt}(G')$.

Obviously, denoting by T^* the optimal anticipatory solution of PROBABILISTIC MIN SPANNING TREE: $E^*(G) \leqslant E(G,T^*)$. Denote also by $\operatorname{opt}(G)$ the value of an optimal solution T^* for (deterministic) MIN SPANNING TREE. By elementary but technical combinatorial arguments, the following result holds.

Proposition 3: Consider a complete edge-weighted graph G defined on a set V of n vertices $V = \{v_1, \ldots, v_n\}$ associated with a system of vertex probabilities $p_1 = 1$, $p_i = p$, $i = 2, \ldots, n$. Then, $E^*(G) \geqslant p \operatorname{opt}(G)$.

Sketch of proof: Since vertex v_1 (assumed to be the root of every tree solution of MIN SPANNING TREE in every subgraph of G) is always present, setting $G' = G[V']$, $E^*(G)$ can be written as:

$$E^*(G) = \sum_{k=2}^{n} p^{k-1}(1-p)^{n-k} \times \sum_{\substack{V' \subseteq V \\ |V'|=k}} \operatorname{opt}(G')$$

Set $D_k = \sum_{V' \subseteq V, |V'|=k} \operatorname{opt}(G')$. Then:

$$E^*(G) = \sum_{k=2}^{n} p^{k-1}(1-p)^{n-k} D_k$$

By somewhat technical combinatorial arguments it can be proved that

$$D_k \geqslant \binom{n-2}{k-2} \operatorname{opt}(G)$$

and putting it together with the expression for $E^*(G)$ derives the claim. ■

Combining inequality $E^*(G) \leqslant E(G,T^*)$ and Proposition 3, the following holds: $E(G,T^*) \geqslant p \operatorname{opt}(G)$. Equality is attained for $p = 1$.

IV. PARTICULAR CASES

We study in this section some particular but natural cases carrying over assumptions either on the values of vertex-probabilities and/or edge-weights, or on the form of the anticipatory solution.

Revisit functional's expression (1). For a vertex v_i, denote by $f(v_i)$ its father in T, by $p_{f(i)}$ the presence probability of $f(v_i)$ and by $A(v_i)$ the set of its ancestors in T. Then, (1) can be rewritten as:

$$\begin{aligned} E(G,T) = & \\ & \sum_{v_i \in V \setminus \{v_1\}} p_i p_{f(i)} d_{if(v_i)} + \\ & \sum_{v_i \in V \setminus \{v_1\}} \sum_{v_j \in A(v_i) \setminus \{f(v_i)\}} p_i p_j \prod_{v_k \in \mu[v_i,v_j]} (1-p_k)\, d_{ij} \\ = & \sum_{v_i \in V \setminus \{v_1\}} C_i \end{aligned} \tag{2}$$

where:

$$\begin{aligned} C_i \quad = \quad & p_i p_{f(i)} d_{if(v_i)} + \\ & \sum_{v_j \in A(v_i) \setminus \{f(v_i)\}} p_i p_j \prod_{v_k \in \mu[v_i,v_j]} (1-p_k) d_{ij} \end{aligned}$$

and can be seen as the contribution of vertex v_i in $E(G,T)$.

Based upon (2) and the expression for C_i, the following result holds.

Proposition 4: If edge-weights are all identical, then:

$$E(G,T) = d \times \sum_{j=2}^{n} p_j$$

In this case all the anticipatory solutions have the same value.

Let us give an illustration of Proposition 4. It can easily be shown that, if $d_{ij} = d$, $(v_i, v_j) \in E$, then $C_i = d \times p_i$, $v_i \in V$. In order to give some intuition about it let us consider the anticipatory tree of Figure 4, assume that edge weights in the input-graph are identical and equal to d and take, say, vertex 7. The contribution of it in (1) is:

$$\begin{aligned} C_7 = & \\ & d \times p_7 \left[p_5 + p_4 (1-p_5) + p_2 (1-p_5)(1-p_4) + \right. \\ & \left. (1-p_5)(1-p_4)(1-p_2)\right] \\ = \quad & d \times p_7 \end{aligned} \tag{3}$$

The same holds for the contribution of any other vertex in the tree.

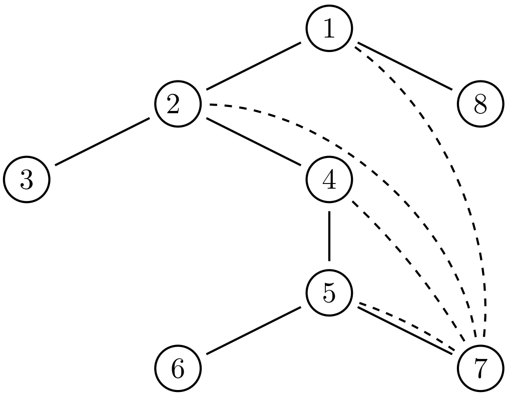

Fig. 4. About a reinterpretation of functional's expression (1).

Indeed, consider some vertex $v_i \in V$ and assume, for simplicity, that vertices in the path of T from v_1 to v_i are numbered from 1 to i. By writing down C_i and by some algebra as previously in (3) we derive $C_i = d \times p_i$. Hence, (2) becomes:

$$E(G,T) = d \times \sum_{j=2}^{n} p_j$$

Corollary 1: If $p_1 = 1$, $p_i = p$, $i = 2, \ldots, n$ and $d_{ij} = d$, $(v_i, v_j) \in E$, $i \neq j$, then, for any tree T spanning V, $E(G,T) = dp(n-1)$.

The above can be directly generalized for deriving a general upper bound for $E(G,T)$ and for every anticipatory solution T. Set $D = \max\{d_{ij} : (v_i, v_j) \in E\}$.

Corollary 2: If $D = \max\{d_{ij} : (v_i, v_j) \in E\}$ then, for any anticipatory solution T of PROBABILISTIC MIN SPANNING TREE, $E(G,T) \leqslant D \times \sum_{j=2}^{n} p_j$.

Let us now address the following question: "can an optimal solution for MIN SPANNING TREE remain an optimal solution for PROBABILISTIC MIN SPANNING TREE and if yes under which conditions?". In what follows we deal with two particular structures of trees, the star and the path.

Consider the star rooted at (the omnipresent) vertex v_1. The following result holds.

Proposition 5: Let T be a star rooted at v_1. If T is an optimal solution for MIN SPANNING TREE then it is also an optimal anticipatory solution for PROBABILISTIC MIN SPANNING TREE.

Proof: Recall that by (2), $E(G,T) = \sum_{v_i \in V \setminus \{v_1\}} C_i$ where C_i is given by:

$$\begin{aligned} C_i = {} & \\ & p_i p_{f(i)} d_{if(v_i)} + \\ & \sum_{v_j \in A(v_i) \setminus \{f(v_i)\}} p_i p_j \prod_{v_k \in \mu[v_i, v_j]} (1 - p_k)\, d_{ij} \end{aligned}$$

Observe now that, if the vertices of T are numbered in a dfs order (starting from the root) and if the set $A(v_i)$ of the ancestors of a vertex v_i in T is exactly the set $A(v_i) = \{v_1, v_2, \ldots, v_{i-1}\}$, then C_i can be written as:

$$C_i = \sum_{j=1}^{i-1} p_i p_j d_{ij} \prod_{l=j+1}^{i-1} (1 - p_l) \tag{4}$$

Since the star T is a minimum spanning tree, it holds that, for any vertex i, $d_{1i} \leqslant d_{ij}$, for every $j \neq 1, i$. Hence:

$$C_i \geqslant p_i \times d_{1i} \times \sum_{j=1}^{i-1} p_j \prod_{l=j+1}^{i-1} (1 - p_l)$$

If we denote by C_i^T the contribution of vertex v_i in the functional $E(T)$ of the star T, then, for every i, $C_i^T = p_i \times d_{1i}$. So, in order to complete the proof of the proposition, we have to show that, for any $v_i \in V$, $C_i^T \leqslant C_i$, where C_i refers to every other spanning tree of G. For this, it suffices to prove that:

$$\sum_{j=1}^{i-1} p_j \prod_{l=j+1}^{i-1} (1 - p_l) \geqslant 1 \tag{5}$$

We show (5) by induction on i. For $i = 2$, the lefthand side of (5) is equal to $p_1 = 1$, so the inequality claimed is true. Suppose it true for $i = n$, i.e.:

$$\sum_{j=1}^{n-1} p_j \prod_{l=j+1}^{n-1} (1 - p_l) \geqslant 1 \tag{6}$$

Then, at range $n + 1$ it holds:

$$\begin{aligned} & \sum_{j=1}^{n} p_j \prod_{l=j+1}^{n} (1 - p_l) = \\ & \quad \sum_{j=1}^{n-1} p_j \prod_{l=j+1}^{n} (1 - p_l) + p_n \\ = & \quad \sum_{j=1}^{n-1} p_j \prod_{l=j+1}^{n-1} (1 - p_l) \times (1 - p_n) + p_n \\ = & \quad (1 - p_n) \times \sum_{j=1}^{n-1} p_j \prod_{l=j+1}^{n-1} (1 - p_l) + p_n \\ \overset{(6)}{\geqslant} & \quad (1 - p_n) + p_n \quad = \quad 1 \end{aligned}$$

as claimed. ■

Unfortunately, in the case where optimal solution for MIN SPANNING TREE is a path, optimality of such a solution for PROBABILISTIC MIN SPANNING TREE cannot be derived as previously in the case of stars.

Indeed, consider a complete graph G, the adjacency matrix of which is given in Table I and its vertex-probability system is $(1, p \ldots, p)$, with $p < (K-2)/(K-1)$ and $K \geqslant n$.

TABLE I
THE ADJACENCY MATRIX OF A GRAPH G WHERE OPTIMAL SOLUTIONS FOR MIN SPANNING TREE AND PROBABILISTIC MIN SPANNING TREE DO NOT COINCIDE.

	v_1	v_2	v_3	$\cdots$	v_{n-2}	v_{n-1}	v_n
v_1	0	1	2	$\cdots$	2	2	2
v_2	1	0	1	$\cdots$	2	2	2
v_3	2	1	0	$\cdots$	2	2	2
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\cdots$	$\vdots$	$\vdots$	$\vdots$
v_{n-2}	2	2	2	$\cdots$	2	1	K
v_{n-1}	2	2	2	$\cdots$	1	0	1
v_n	2	2	2	$\cdots$	K	1	0

Optimal MIN SPANNING TREE-solution in G is unique and is the path $P = (1, 2, \ldots, n-1)$ with value $n - 1$. The functional $E(G, P)$ of path P is:

$$E(G,P) = (2n-3)p + (K-n)p^2 - (K-2)p^3$$

On the other hand, the unique optimal anticipatory solution for PROBABILISTIC MIN SPANNING TREE is the tree T^* of Figure 5 with functional's value:

$$E(G,T^*) = (2n-3)p + (2-n)p^2 + p^3 < E(G,P)$$

when $p < (K-2)/(K-1)$.

V. APPROXIMATION OF PROBABILISTIC METRIC MIN SPANNING TREE

In this section, we study PROBABILISTIC METRIC MIN SPANNING TREE problem, that is PROBABILISTIC MIN SPANNING TREE in metric complete graphs, i.e., in complete graphs whose edge-weights satisfy the triangular property that can

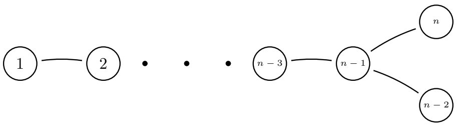

Fig. 5. The optimal solution of the graph of Table I.

be expressed as follows: if (v_i, v_j, v_k) is a K_3 in G, then $d_{ab} \leqslant d_{ac} + d_{bc}$, for any permutation (a, b, c) of $\{i, j, k\}$.

Note that, as it can be seen from the proof of Proposition 2, it does not apply in the case of metric graphs. Indeed, the complexity status of PROBABILISTIC METRIC MIN SPANNING TREE remains open, even if we feel that this variant is also **NP**-complete. In what follows we give approximation results for the general case of PROBABILISTIC METRIC MIN SPANNING TREE as well as for a natural subcase, namely PROBABILISTIC MIN SPANNING TREE 1,2, where edge weights are either 1, or 2.

We denote by $\hat{T}$ and T^* a tree computed by Kruskal's algorithm (i.e., a minimum spanning tree of G) and an optimal anticipatory solution for PROBABILISTIC METRIC MIN SPANNING TREE, respectively, and we assume that they are represented as sets of edges.

Observe also that, by the metric property the weight of any edge of G is smaller than the weight of any spanning tree of G and a fortiori than the weight $m(G, \hat{T}) = \text{opt}(G)$ of $\hat{T}$. Indeed, let (v_i, v_j) be any edge of G, T be some spanning tree of G and $P(v_i, v_j)$ be the unique path from v_i to v_j in T.

According to the metric hypothesis:

$$d_{ij} \leqslant w\left(P(v_i, v_j)\right) \leqslant m(G, T)$$

where $w(P(v_i, v_j))$ is the weight of the path $P(v_i, v_j)$. In what follows, given a set Q of (weighted) edges, we denote by $w(Q)$ its total weight.

We first handle the general metric case. For any $V_i \subseteq V$, we set $G_i(V_i, E_i) = G[V_i]$. Let T_i^* and $\hat{T}_i$ be the spanning trees on G_i resulting from the application of strategy LEV on T^* and $\hat{T}$, respectively. Set:

$$\begin{aligned} r\left(G_i\right) &= \frac{m\left(G_i, \hat{T}_i\right)}{m\left(G_i, T_i^*\right)} \\ E(r) &= \sum_{V_i \subseteq V} \Pr\left[V_i\right] r\left(G_i\right) \end{aligned}$$

Quantity $E(r)$ is indeed the average approximation ratio of a minimum spanning tree for PROBABILISTIC METRIC MIN SPANNING TREE. In the following proposition an upper bound is given for $E(r)$.

Proposition 6: $E(r) \leqslant (n+2)/4$.

Proof: Fix an induced subgraph G_i of G and let $\hat{T} \cap \hat{T}_i = S$. Edges of S are part of an optimal spanning tree on G and thus, they are also part of an optimal spanning tree of G_i. Indeed, revisiting the proof of optimality of Kruskal's Algorithm, one can see that a tree T is a minimum spanning tree on G, iff all the edges of T are of minimum weight in at least one cut of G. Applying this to PROBABILISTIC MIN SPANNING TREE, any edge e belonging to S is of minimum weight in at least one cut of G; thus, e is also of minimum weight in one cut in any subgraph G_i (provided that e appears in G_i) and, therefore, it belongs to a minimum spanning tree in all the subgraphs of G where it is present.

Discussion just above leads to:

$$w(S) \leqslant m\left(G_i, T_i^*\right) \tag{7}$$

The edge-set $\hat{T}_i \setminus S$ is the set of the edges used by LEV to reconnect the S. As observed in the beginning of Section V, the weight of each edge of $\hat{T}_i \setminus S$ is smaller than, or equal to, $m(G_i, T_i^*)$, so:

$$w\left(\hat{T}_i \setminus S\right) \leqslant \left|\hat{T}_i \setminus S\right| m\left(G_i, T_i^*\right) \tag{8}$$

Combining (7) and (8), we get:

$$r_i = \frac{m\left(G_i, \hat{T}_i\right)}{m\left(G_i, T_i^*\right)} \leqslant 1 + \left|\hat{T}_i \setminus S\right| \tag{9}$$

The quantity $|\hat{T}_i \setminus S|$ is, as mentioned above, the number of edges inserted by strategy LEV to reconnect S, but it also represents the number of vertices present in G_i, but whose fathers in $\hat{T}$ (assumed rooted at v_1) are absent from G_i. For each vertex of $\hat{T}$ except for those directly connected to the root v_1, the probability to be present in G_i but not its father is $p(1-p)$. Obviously, for the vertices directly connected to the root, this probability is 0. In order to count the number of edges in $\hat{T}_i \setminus S$, one can consider a set of $n-1-X$ Bernoulli trials (where X is the number of vertices directly connected to v_1 in $\hat{T}$), with a probability of success $p(1-p)$, each success adding an edge to $\hat{T}_i \setminus S$. In this way, $|\hat{T}_i \setminus S|$ is a random variable following a binomial law, so one can directly compute its expectation:

$$\begin{aligned} \left|\hat{T}_i \setminus S\right| &\sim B\left(n-1-X, p(1-p)\right) \\ E\left(\left|\hat{T}_i \setminus S\right|\right) &= (n-1-X)p(1-p) \end{aligned} \tag{10}$$

Summing (9) for each G_i, we derive:

$$E\left(\frac{m\left(G_i, \hat{T}_i\right)}{m\left(G_i, T_i^*\right)}\right) \leqslant 1 + E\left(\left|\hat{T}_i \setminus S\right|\right)$$

and combining it with (10), we can easily get:

$$\begin{aligned} E\left(\frac{m\left(G_i, \hat{T}_i\right)}{m\left(G_i, T_i^*\right)}\right) &\leqslant 1 + (n-1-X)p(1-p) \\ &\overset{X \geqslant 1}{\leqslant} \frac{n}{4} + \frac{1}{2} = \frac{n+2}{4} \end{aligned}$$

as claimed. ■

We now study the approximation of PROBABILISTIC METRIC MIN SPANNING TREE. The following result can be proved.

Proposition 7: The PROBABILISTIC METRIC MIN SPANNING TREE problem is approximable in polynomial time within ratio bounded above by:

$$\min\left\{1+(n-2)(1-p), \frac{2}{p}\right\}$$

To conclude the paper, let us focus on a particular but natural and well-studied class of metric complete graphs where edge weights are either 1 or 2. It is easy to see that any such graph is metric. The following result, that will be subsequently improved, holds for PROBABILISTIC MIN SPANNING TREE $1{,}2$.

Proposition 8: A minimum spanning tree of G is a $(2-p)$-approximation for PROBABILISTIC MIN SPANNING TREE $1{,}2$.

In what follows we refine the result above. For this, we consider an execution of Kruskal's algorithm that starts by introducing in the tree all the edges of weight 1 incident to the vertex v_1. Let us denote by $\tilde{T}$ the spanning tree so constructed; notice that $\tilde{T}$ is a minimum spanning tree for G.

Proposition 9: $\tilde{T}$ approximates T^* within ratio:

$$\frac{1+(2-p)(n-2)}{n-1+\frac{(1-p)^2-(1-p)^n}{p}}$$

One can see that when p is fixed (i.e., independent on n), the approximation ratio achieved is strictly better than 2. On the other hand, when $p \sim 1/n$ then, since:

$$\lim_{n\rightarrow+\infty}\frac{(1-p)^n}{p}=\frac{n}{e}$$

the ratio claimed in Proposition 9 tends to 1.225, for large values of n.

If $p \sim 1/n^k$, $k > 1$, then for large values of n, this ratio tends to 1. Finally, if $p \sim 1/n^k$, $k < 1$, then (always for large values of n) the ratio is asymptotically equal to 2.

VI. CONCLUSION

In this paper we have treated the PROBABILISTIC MIN SPANNING TREE problem under the framework of probabilistic combinatorial optimization. We have proposed a fast modification strategy (LEV) for reconstructing a second-stage tree and shown that problem of optimizing the expectation of the second-stage cost by selecting an appropriate first-stage (anticipatory) solution is in **NPO** under the proposed modification strategy and we have shown that the general case of PROBABILISTIC MIN SPANNING TREE is **NP**-hard.

We have also given approximation results for the probabilistic problem associated with the LEV strategy. We also have studied particular cases of anticipatory solutions.

Finally we have given approximation results for PROBABILISTIC METRIC MIN SPANNING TREE and PROBABILISTIC MIN SPANNING TREE $1{,}2$.

There are several open questions subject for further research. To our opinion, the major among them are the complexities of PROBABILISTIC METRIC MIN SPANNING TREE and PROBABILISTIC MIN SPANNING TREE $1{,}2$ (we conjecture that they are both **NP**-hard) and the improvement of their approximation ratios.

Abstract—**The portfolio optimization problem is modeled as a mean-risk bicriteria optimization problem where the expected return is maximized and some (scalar) risk measure is minimized. In the original Markowitz model the risk is measured by the variance while several polyhedral risk measures have been introduced leading to Linear Programming (LP) computable portfolio optimization models in the case of discrete random variables represented by their realizations under specified scenarios. Among them, the second order quantile risk measures, recently, become popular in finance and banking. The simplest such measure, now commonly called the Conditional Value at Risk (CVaR) or Tail VaR, represents the mean shortfall at a specified confidence level. Recently, the second order quantile risk measures have been introduced and become popular in finance and banking. The corresponding portfolio optimization models can be solved with general purpose LP solvers. However, in the case of more advanced simulation models employed for scenario generation one may get several thousands of scenarios. This may lead to the LP model with huge number of variables and constraints thus decreasing the computational efficiency of the model since the number of constraints (matrix rows) is usually proportional to the number of scenarios. while the number of variables (matrix columns) is proportional to the total of the number of scenarios and the number of instruments. We show that the computational efficiency can be then dramatically improved with an alternative model taking advantages of the LP duality. In the introduced models the number of structural constraints (matrix rows) is proportional to the number of instruments thus not affecting seriously the simplex method efficiency by the number of scenarios.**

I. Introduction

FOLLOWING Markowitz [13], the portfolio selection problem is modeled as a mean-risk bicriteria optimization problem where the expected return is maximized and some (scalar) risk measure is minimized. In the original Markowitz model the risk is measured by the variance but several polyhedral risk measures have been introduced leading to Linear Programming (LP) computable portfolio optimization models in the case of discrete random variables represented by their realizations under specified scenarios. The simplest LP computable risk measures are dispersion measures similar to the variance. Konno and Yamazaki [6] presented the portfolio selection model with the mean absolute deviation (MAD) while Young [33] introduced the Minimax model. Yitzhaki [32] introduced the mean-risk model using Gini's mean (absolute) difference as the risk measure. The Gini's mean difference turn out to be a special aggregation technique of the multiple criteria LP model [18] based on the pointwise comparison of the absolute Lorenz curves. The latter leads the quantile shortfall risk measures directly related to the dual theory of choice under risk [26], [28], [31] which are more commonly used and accepted. Recently, the second order quantile risk measures have been introduced in different ways by many authors [2], [4], [16], [17], [27]. The measure, usually called the Conditional Value at Risk (CVaR) or Tail VaR, represents the mean shortfall at a specified confidence level. The CVaR measures maximization is consistent with the second degree stochastic dominance [19]. Several empirical analyses confirm its applicability to various financial optimization problems [1], [11].

This paper is focused on computational efficiency of the portfolio optimization models based on the CVaR or the Minimax measures. We assume that the instruments returns are represented by their realizations under T scenarios. The basic LP model for the CVaR portfolio optimization contains then T auxiliary variables as well as T corresponding linear inequalities. Actually, the number of structural constraints in the LP model (matrix rows) is proportional to the number of scenarios T, while the number of variables (matrix columns) is proportional to the total of the number of scenarios and the number of instruments $T+n$. Hence, its dimensionality is proportional to the number of scenarios T. It does not cause any computational difficulties for a few hundreds of scenarios as in computational analysis based on historical data. However, in the case of more advanced simulation models employed for scenario generation one may get several thousands of scenarios [25]. This may lead to the LP model with huge number of auxiliary variables and constraints thus decreasing the computational efficiency of the model. Actually, in the case of fifty thousand scenarios and one hundred instruments the model may require more than an hour computation time with the state-of-art LP solver (CPLEX code). To overcome this difficulty some alternative solution approaches are searched trying to reformulate the optimization problems as two-stage recourse problems [8] or to employ nondifferential optimization techniques [9]. We show that the computational efficiency can be then dramatically improved with an alternative model formulation taking advantages of the LP duality. In the introduced model the number of structural constraints is proportional to the number of instruments n

978-83-60810-27-9/09/$25.00 © 2010 IEEE

while only the number of variables is proportional to the number of scenarios T thus not affecting so seriously the simplex method efficiency. Indeed, the computation time is then below a minute.

The paper is organized as follows. In the next section we introduce briefly basics of the mean-risk portfolio optimization with the LP computable risk measures. In Section 3 we develop and test computationally efficient optimization models taking advantages of the LP duality.

II. Portfolio Optimization and Risk Measures

The portfolio optimization problem considered in this paper follows the original Markowitz' formulation and is based on a single period model of investment. At the beginning of a period, an investor allocates the capital among various securities, thus assigning a nonnegative weight (share of the capital) to each security. Let $J = \{1, 2, \ldots, n\}$ denote a set of securities considered for an investment. For each security $j \in J$, its rate of return is represented by a random variable R_j with a given mean $\mu_j = \mathbf{E}\{R_j\}$. Further, let $\mathbf{x} = (x_j)_{j=1,2,\ldots,n}$ denote a vector of decision variables x_j expressing the weights defining a portfolio. The weights must satisfy a set of constraints to represent a portfolio. The simplest way of defining a feasible set Q is by a requirement that the weights must sum to one and they are nonnegative (short sales are not allowed), i.e.

$$Q = \{\mathbf{x} \;:\; \sum_{j=1}^{n} x_j = 1, \quad x_j \geq 0 \quad \text{for } j = 1, \ldots, n\} \tag{1}$$

Hereafter, we perform detailed analysis for the set Q given with constraints (1). Nevertheless, the presented results can easily be adapted to a general LP feasible set given as a system of linear equations and inequalities, thus allowing one to include short sales, upper bounds on single shares or portfolio structure restrictions which may be faced by a real-life investor.

Each portfolio $\mathbf{x}$ defines a corresponding random variable $R_{\mathbf{x}} = \sum_{j=1}^{n} R_j x_j$ that represents the portfolio rate of return while the expected value can be computed as $\mu(\mathbf{x}) = \sum_{j=1}^{n} \mu_j x_j$. We consider T scenarios with probabilities p_t (where $t = 1, \ldots, T$). We assume that for each random variable R_j its realization r_{jt} under the scenario t is known. Typically, the realizations are derived from historical data treating T historical periods as equally probable scenarios ($p_t = 1/T$). Although the models we analyze do not take advantages of this simplification. The realizations of the portfolio return $R_{\mathbf{x}}$ are given as $y_t = \sum_{j=1}^{n} r_{jt} x_j$.

The portfolio optimization problem is modeled as a mean-risk bicriteria optimization problem where the mean $\mu(\mathbf{x})$ is maximized and the risk measure $\varrho(\mathbf{x})$ is minimized. In the original Markowitz model, the standard deviation was used as the risk measure. Several other risk measures have been later considered thus creating the entire family of mean-risk models (c.f., [10], [11]). These risk measures, similar to the standard deviation, are not affected by any shift of the outcome scale and are equal to 0 in the case of a risk-free portfolio while taking positive values for any risky portfolio. Unfortunately, such risk measures are not consistent with the stochastic dominance order [15] or other axiomatic models of risk-averse preferences [29] and coherent risk measurement [2].

In stochastic dominance, uncertain returns (modeled as random variables) are compared by pointwise comparison of some performance functions constructed from their distribution functions. The first performance function $F_{\mathbf{x}}^{(1)}$ is defined as the right-continuous cumulative distribution function: $F_{\mathbf{x}}^{(1)}(\eta) = F_{\mathbf{x}}(\eta) = \mathbf{P}\{R_{\mathbf{x}} \leq \eta\}$ and it defines the first degree stochastic dominance (FSD). The second function is derived from the first as $F_{\mathbf{x}}^{(2)}(\eta) = \int_{-\infty}^{\eta} F_{\mathbf{x}}(\xi)\, d\xi$ and it defines the second degree stochastic dominance (SSD). We say that portfolio $\mathbf{x}'$ dominates $\mathbf{x}''$ under the SSD ($R_{\mathbf{x}'} \succ_{SSD} R_{\mathbf{x}''}$), if $F_{\mathbf{x}'}^{(2)}(\eta) \leq F_{\mathbf{x}''}^{(2)}(\eta)$ for all η, with at least one strict inequality. A feasible portfolio $\mathbf{x}^0 \in Q$ is called SSD efficient if there is no $\mathbf{x} \in Q$ such that $R_{\mathbf{x}} \succ_{SSD} R_{\mathbf{x}^0}$. Stochastic dominance relates the notion of risk to a possible failure of achieving some targets. As shown by Ogryczak and Ruszczyński [19], function $F_{\mathbf{x}}^{(2)}$, used to define the SSD relation, can also be presented as follows: $F_{\mathbf{x}}^{(2)}(\eta) = \mathbf{E}\{\max\{\eta - R_{\mathbf{x}}, 0\}\}$ and thereby its values are LP computable for returns represented by their realizations y_t.

An alternative characterization of the SSD relation can be achieved with the so-called Absolute Lorenz Curves (ALC) [16], [30] which represent the second quantile functions defined as $F_{\mathbf{x}}^{(-2)}(0) = 0$ and

$$F_{\mathbf{x}}^{(-2)}(p) = \int_{0}^{p} F_{\mathbf{x}}^{(-1)}(\alpha) d\alpha \tag{2}$$

where $F_{\mathbf{x}}^{(-1)}(p) = \inf\ \{\eta : F_{\mathbf{x}}(\eta) \geq p\}$ is the left-continuous inverse of the cumulative distribution function $F_{\mathbf{x}}$. The pointwise comparison of ALCs is equivalent to the SSD relation [20] in the sense that $R_{\mathbf{x}'} \succeq_{SSD} R_{\mathbf{x}''}$ if and only if $F_{\mathbf{x}'}^{(-2)}(\beta) \geq F_{\mathbf{x}''}^{(-2)}(\beta)$ for all $0 < \beta \leq 1$. Moreover,

$$\begin{aligned} F_{\mathbf{x}}^{(-2)}(\beta) &= \max_{\eta \in R} \left[\beta\eta - F_{\mathbf{x}}^{(2)}(\eta)\right] \\ &= \max_{\eta \in R} \left[\beta\eta - \mathbf{E}\{\max\{\eta - R_{\mathbf{x}}, 0\}\}\right] \end{aligned} \tag{3}$$

where η is a real variable taking the value of β-quantile $Q_\beta(\mathbf{x})$ at the optimum. For a discrete random variable represented by its realizations y_t problem (3) becomes an LP.

For any real tolerance level $0 < \beta \leq 1$, the normalized value of the ALC defined as

$$M_\beta(\mathbf{x}) = F_{\mathbf{x}}^{(-2)}(\beta)/\beta \tag{4}$$

is called the *Conditional Value-at-Risk (CVaR)* or Tail VaR or Average VaR. The CVaR measure is an increasing function of the tolerance level β, with $M_1(\mathbf{x}) = \mu(\mathbf{x})$. For any $0 < \beta < 1$, the CVaR measure is SSD consistent [20] and coherent [24]. Opposite to deviation type risk measures, for coherent measures larger values are preferred and therefore the measures are sometimes called safety measures [11]. Due to (3), for a discrete random variable represented by its realizations y_t the CVaR measures are LP computable. It is important to notice that although the quantile risk measures (VaR and CVaR) were introduced in banking as extreme risk measures for very small tolerance levels (like $\beta = 0.05$), for the portfolio optimization good results have been provided by rather larger tolerance levels [11]. For β approaching 0, the CVaR measure tends to the Minimax measure $M(\mathbf{x}) = \min_{t=1,\ldots,T} y_t = \min_{t=1,\ldots,T} \sum_{j=1}^n r_{jt}x_j$ introduced to portfolio optimization by Young [33].

The commonly accepted approach to implementation of the Markowitz-type mean-risk model is based on the use of a specified lower bound μ_0 on expected returns while optimizing the risk measure. This bounding approach provides a clear understanding of investor preferences and a clear definition of optimal solution portfolio to be sought. For coherent and SSD consistent risk measures we consider the approach results in the following maximization problem:

$$\max\{\ \varrho(\mathbf{x}) :\quad \mu(\mathbf{x}) \geq \mu_0, \quad \mathbf{x} \in Q\} \tag{5}$$

where $\varrho(\mathbf{x}) = M_\beta(\mathbf{x})$ or $\varrho(\mathbf{x}) = M(\mathbf{x})$ respectively

We demonstrate that such portfolio optimization models can be effectively solved for large numbers of scenarios while taking advantages of appropriate dual LP formulations.

III. Computational LP Models

Let us consider portfolio optimization problem with security returns given by discrete random variables with realization r_{jt} thus leading to LP portfolio optimization model (5) for the risk measures we consider.

Following (3) and (4), the CVaR portfolio optimization model can be formulated as the following LP problem:

$$\begin{array}{ll} \max & \eta - \dfrac{1}{\beta}\sum_{t=1}^T p_t d_t \\ \text{s.t.} & \sum_{j=1}^n \mu_j x_j \geq \mu_0 \\ & \sum_{j=1}^n x_j = 1 \\ & x_j \geq 0,\ j = 1,\ldots,n \\ & d_t - \eta + \sum_{j=1}^n r_{jt}x_j \geq 0,\ d_t \geq 0,\ t = 1,\ldots,T \end{array} \tag{6}$$

where η is unbounded variable. Except from the core portfolio constraints (1) and the expected return bound, the model (6) contains T nonnegative variables d_t plus single η variable and T corresponding linear inequalities. Hence, its dimensionality is proportional to the number of scenarios T. Exactly, the LP model (6) contains $T + n + 1$ variables and $T + 2$ constraints. It does not cause any computational difficulties for a few hundreds of scenarios as in several computational analysis based on historical data [12]. However, in the case of more advanced simulation models employed for scenario generation one may get several thousands of scenarios. This may lead to the LP model (6) with huge number of variables and constraints thus decreasing the computational efficiency of the model. If the core portfolio constraints contain only linear relations, like (1), then the computational efficiency can easily be achieved by taking advantages of an alternative LP formulation.

Note that, due to the finite distribution of returns, the CVaR measure is well defined by the following optimization

$$\begin{aligned} M_\beta(\mathbf{x}) \quad = \quad & \min_{u_t}\{\sum_{t=1}^T(\sum_{j=1}^n r_{jt}x_j)u_t : \sum_{t=1}^T u_t = 1, \\ & 0 \leq u_t \leq \frac{p_t}{\beta}\ t = 1,\ldots,T\} \end{aligned} \tag{7}$$

that implements directly the ALC formula (2). The entire CVaR portfolio optimization problem may be respectively expressed as

$$\max_{\mathbf{x}\in Q} M_\beta(\mathbf{x}) = \max_{\mathbf{x}\in Q}\min_{\mathbf{u}\in U}\sum_{t=1}^T(\sum_{j=1}^n r_{jt}x_j)u_t \tag{8}$$

where

$$\begin{aligned} U \quad = \quad & \{(u_1,\ldots,u_T) : \sum_{t=1}^T u_t = 1, \\ & 0 \leq u_t \leq \frac{p_t}{\beta} \quad t = 1,\ldots,T\}. \end{aligned}$$

The inner optimization problem represents (7). It is an LP for a given vector $\mathbf{x}$. However, within the entire portfolio optimization problem (8) the objective function $\sum_{t=1}^T(\sum_{j=1}^n r_{jt}x_j)u_t$ becomes nonlinear for $\mathbf{x}$ being a vector of variables. This difficulty can be overcome by an equivalent dual LP formulation of problem (7). Indeed, introducing dual variable η corresponding to the equation $\sum_{t=1}^T u_t = 1$ and variables d_t corresponding to upper bounds on u_t one gets the LP dual

$$\begin{aligned} M_\beta(\mathbf{x}) \quad = \quad & \max_{q,d_t}\ \{\eta - \frac{1}{\beta}\sum_{t=1}^T p_t d_t : \\ & \sum_{j=1}^n r_{jt}x_j \geq \eta - d_t,\ d_t \geq 0\ \forall\ t\}. \end{aligned} \tag{9}$$

This leads us to the standard LP model (6) for the CVaR portfolio optimization.

An alternative CVaR optimization model can be built by taking advantages of the minimax theorem. Since both sets Q and U are convex polyhedra, formula (8) can be rewritten into a dual form

$$\begin{aligned} & \max_{\mathbf{x}\in Q}\min_{\mathbf{u}\in U}\sum_{t=1}^T(\sum_{j=1}^n r_{jt}x_j)u_t \\ & = \min_{\mathbf{u}\in U}\max_{\mathbf{x}\in Q}\sum_{t=1}^T(\sum_{j=1}^n r_{jt}x_j)u_t \\ & = \min_{\mathbf{u}\in U} D(\mathbf{u}) \end{aligned} \tag{10}$$

with the inner optimization problem

$$\begin{aligned} D(\mathbf{u}) &= \max_{x_j} && \{\sum_{t=1}^{T} u_t \sum_{j=1}^{n} r_{jt} x_j : \\ &&& \sum_{j=1}^{n} \mu_j x_j \geq \mu_0,\ \sum_{j=1}^{n} x_j = 1, \\ &&& x_j \geq 0,\ j = 1, \ldots, n\} \\ &= \max_{x_j} && \{\sum_{j=1}^{n} (\sum_{t=1}^{T} r_{jt} u_t) x_j : \\ &&& \sum_{j=1}^{n} \mu_j x_j \geq \mu_0,\ \sum_{j=1}^{n} x_j = 1, \\ &&& x_j \geq 0,\ j = 1, \ldots, n\}. \end{aligned} \tag{11}$$

Again, we may take advantages of the LP dual to the inner problem. Indeed, introducing dual variable q corresponding to the equation $\sum_{j=1}^{n} x_j = 1$ and variable u_0 corresponding to the inequality $\sum_{j=1}^{n} \mu_j x_j \geq \mu_0$ we get the LP dual

$$\begin{aligned} D(\mathbf{u}) = \min_{q, u_0} \quad & \{q - \mu_0 u_0 : \\ & q - \mu_j u_0 - \sum_{t=1}^{T} r_{jt} u_t \geq 0 \quad j = 1, \ldots, n\}. \end{aligned}$$

Hence, an alternative model for the CVaR portfolio optimization (10) can be expressed as the following LP:

$$\begin{aligned} \min \quad & q - \mu_0 u_0 \\ \text{s.t.} \quad & q - \mu_j u_0 - \sum_{t=1}^{T} r_{jt} u_t \geq 0,\ j = 1, \ldots, n \\ & \sum_{t=1}^{T} u_t = 1 \\ & 0 \leq u_t \leq \frac{p_t}{\beta},\ t = 1, \ldots, T \end{aligned} \tag{12}$$

LP model (12) contains $T + 1$ variables u_t, but the T constraints corresponding to variables d_t from (6) take the form of simple upper bounds on u_t (for $t = 1, \ldots, T$) thus not affecting the problem complexity. The number of constraints in (12) is proportional to the total of portfolio size n, thus it is independent from the number of scenarios. Exactly, there are $T + 1$ variables and $n + 1$ constraints. This guarantees a high computational efficiency of the model even for very large number of scenarios. Similarly, other portfolio structure requirements are modeled with rather small number of constraints thus generating small number of additional variables in the model. Actually, the model (12) is the LP dual to the model (6), thus similar to that introduced in [23]. Obviously, the optimal portfolio shares x_j are not directly represented within the solution vector of problem (12) but they are easily available as the dual variables (shadow prices) for inequalities $q - \mu_j u_0 - \sum_{t=1}^{T} r_{jt} u_t \geq 0$.

The Minimax portfolio optimization model can be written as the following LP problem:

$$\begin{aligned} \max \quad & \eta \\ \text{s.t.} \quad & \sum_{j=1}^{n} \mu_j x_j \geq \mu_0, \\ & \sum_{j=1}^{n} x_j = 1 \\ & x_j \geq 0,\ j = 1, \ldots, n \\ & -\eta + \sum_{j=1}^{n} r_{jt} x_j \geq 0,\ t = 1, \ldots, T \end{aligned} \tag{13}$$

which is simpler than the standard CVaR optimization model (6). Except from the portfolio weights x_j, the model contains only one additional variable η. Nevertheless, it still contains T linear inequalities in addition to the core constraints. Hence, its dimensionality is $(T + 2) \times (n + 1)$.

The Minimax portfolio optimization model representing a limiting case of the CVaR model for β tending to 0. Actually, for any $\beta \leq \min_{t=1,\ldots,T} p_t$ we gets $M_\beta(\mathbf{x}) = M(\mathbf{x})$ thus allowing to represent the Minimax portfolio optimization by the CVaR optimization model (6) and to take advantages of its dual form (12). Due to $\beta \leq p_t$ for all $t = 1, \ldots, T$, the upper bounds on variables u_t becomes redundant and we get the following dual form of the Minimax portfolio optimization:

$$\begin{aligned} \min \quad & q - \mu_0 u_0 \\ \text{s.t.} \quad & q - \mu_j u_0 - \sum_{t=1}^{T} r_{jt} u_t \geq 0,\ j = 1, \ldots, n \\ & \sum_{t=1}^{T} u_t = 1 \\ & u_t \ \geq 0,\ t = 1, \ldots, T \end{aligned} \tag{14}$$

The model dimensionality is only $(n + 1) \times (T + 2)$ thus guaranteeing a high computational efficiency even for very large number of scenarios.

The Mean Absolute Deviation (MAD) risk measure is directly given by the value of the second order cdf $F_{\mathbf{x}}^{(2)}$ at the mean $\bar{\delta}(\mathbf{x}) = \mathbf{E}\{\max\{\mu(\mathbf{x}) - R_{\mathbf{x}}, 0\}\} = F_{\mathbf{x}}^{(2)}(\mu(\mathbf{x}))$ [19]. Therefore, its leads to an LP portfolio optimization model very similar to that for the CVaR optimization (6). Indeed, we get:

$$\begin{aligned} \max \quad & -\sum_{t=1}^{T} p_t d_t \\ \text{s.t.} \quad & \sum_{j=1}^{n} \mu_j x_j \geq \mu_0, \quad \sum_{j=1}^{n} x_j = 1 \\ & d_t \geq \sum_{j=1}^{n} (\mu_j - r_{jt}) x_j,\ d_t \geq 0,\ t = 1, \ldots, T \\ & x_j \geq 0,\ j = 1, \ldots, n \end{aligned} \tag{15}$$

with $T + n$ variables and $T + 2$ constraints. The LP dual model

TABLE I
COMPUTATIONAL TIMES (IN SECONDS) FOR THE STANDARD MEAN-RISK MODELS

Scenarios	Securities	CVaR (6)						Minimax	MAD
(T)	(n)	$\beta = 0.05$	$\beta = 0.1$	$\beta = 0.2$	$\beta = 0.3$	$\beta = 0.4$	$\beta = 0.5$	(13)	(15)
5 000	76	2.5	2.6	3.7	5.2	6.7	7.6	0.5	19.0
7 000	76	4.1	4.4	6.9	9.3	11.8	14.8	0.9	9.3
10 000	76	6.5	8.3	13.9	18.4	24.2	29.8	1.3	18.4
50 000	50	3275.4	4876.6	–	–	–	–	7.8	–
50 000	100	–	–	–	–	–	–	24.1	–

TABLE II
COMPUTATIONAL TIMES (IN SECONDS) FOR THE DUAL MEAN-RISK MODELS

Scenarios	Securities	CVaR (12)						Minimax	MAD
(T)	(n)	$\beta = 0.05$	$\beta = 0.1$	$\beta = 0.2$	$\beta = 0.3$	$\beta = 0.4$	$\beta = 0.5$	(14)	(16)
5 000	76	0.9	0.9	1.1	1.3	1.4	1.6	0.5	2.1
7 000	76	1.2	1.4	1.8	2.0	2.2	2.3	0.7	3.1
10 000	76	2.0	2.3	2.9	3.4	3.9	4.0	1.0	10.8
50 000	50	14.9	19.4	24.0	26.8	28.2	27.9	3.9	25.8
50 000	100	40.0	54.6	68.7	77.7	78.2	78.8	8.2	76.7

takes then the form:

$$\begin{array}{ll} \min & q - \mu_0 u_0 \\ \text{s.t.} & q \geq \mu_j u_0 - \sum_{t=1}^{T} (\mu_j - r_{jt}) u_t, \ j = 1, \ldots, n \\ & 0 \leq u_t \ \leq p_t, \ t = 1, \ldots, T \end{array} \tag{16}$$

with dimensionality $n \times (T + 2)$. Hence, there is again guaranteed the high computational efficiency even for very large number of scenarios.

We have run two groups of computational tests. The medium scale tests of 5 000, 7 000 and 10 000 scenarios and 76 securities were generated following the FTSE 100 related data [5]. The large scale tests instances developed by Lim et al. [9] were generated from a multivariate normal distribution for 50 or 100 securities with the number of scenarios 50 000 just providing an adequate approximation to the underlying unknown continuous price distribution. When applying the lower bound on the required expected return, its value μ_0 was defined as the expected return of the portfolio with equal weights (market value). All computations were performed on a PC with the Pentium 4 2.6GHz processor and 3GB RAM employing the simplex code of the CPLEX 9.1 package.

In Tables I and II there are presented computation times for all the above primal and dual models. All results are presented as the averages of 10 different test instances of the same size. For the medium scale test problems the solution times of the dual CVaR models (12) ranging from 0.9 to 4.0 seconds are not much shorter than those for the primal models ranging from 2.5 to 29.8 seconds, respectively. However, an attempt to solve the primal CVaR model (6) of the large scale test problems was successful only for $\beta = 0.05$ and $\beta = 0.1$ and the times were dramatically longer than those for the dual model. For other values of β the timeout of 6000 seconds occurred (marked with '–'). For 100 securities the primal model was not solvable within the given time limit, while the dual models could be successfully solved in 40.0 to 78.8 seconds.

The Minimax models are computationally very easy. Running the computational tests we were able to solve the medium scale test instances of the dual model (14) in times below 1 second and the large scale test instances in up to 8.2 seconds on average. In fact, even the primal model could be solved in reasonable time between 0.5 and 24 seconds, for medium and large scale test instances, respectively.

The MAD models are computationally similar to the CVaR models. Indeed, only medium scale test instances of the primal model (15) could be solved within the given time limit. Much shorter computing times could be achieved for the dual MAD model (16) – not more than 10.8 seconds for the medium scale and 76.7 seconds for the large scale test instances.

To see how the value of the required expected return affects the solution times we have performed additional tests for the reformulated CVaR (with $\beta = 0.1$) and Minimax models with increased value μ_0. The increased value was set in the middle between the expected return of the market value and the maximum possible return for single security portfolio. The computational times are generally comparable with those for the market value constraints. Actually, for the medium scale problems (10 000 scenarios) the CVaR optimization time has remained unchanged (2.3 seconds) while the Minimax optimization time has only raised from 1.0 to 1.1 seconds and for the MAD model optimization it has raised from 10.8 to 13.9. For the large scale problems (50 000 scenarios) we have noticed even a drop in computation times for the CVaR model (reduction from 54.6 to 49.9 seconds) and similar reduction (from 76.7 to 55.4 seconds) has occured for the MAD model optimization while the Minimax optimization time has increased from 8.2 to 10.5 seconds.

IV. GINI'S MEAN DIFFERENCE AND RELATED MODELS

Yitzhaki [32] introduced the portfolio optimization model using Gini's mean difference (GMD) as risk measure. The GMD is given as $\Gamma(\mathbf{x}) = \frac{1}{2} \int \int |\eta - \xi| dF_{\mathbf{x}}(\eta) dF_{\mathbf{x}}(\xi)$ although several alternative formulae exist. For a discrete random variable represented by its realizations y_t, the measure

$$\Gamma(\mathbf{x}) = \sum_{t'=1}^{T} \sum_{t'' \neq t'-1} \max\{y_{t'} - y_{t''}, 0\} p_{t'} p_{t''}$$

is LP computable (when minimized) leading to the following portfolio optimization model:

$$\begin{array}{ll} \max & -\sum_{t=1}^{T} \sum_{t' \neq t} p_t p_{t'} d_{tt'} \\ \text{s.t.} & \sum_{j=1}^{n} \mu_j x_j \geq \mu_0, \quad \sum_{j=1}^{n} x_j = 1 \\ & d_{tt'} \geq \sum_{j=1}^{n} r_{jt} x_j - \sum_{j=1}^{n} r_{jt'} x_j \\ & d_{tt'} \geq 0, \ t \neq t' = 1, \dots, T \\ & x_j \geq 0, \ j = 1, \dots, n \end{array} \tag{17}$$

which contains $T(T-1)$ nonnegative variables $d_{tt'}$ and $T(T-1)$ inequalities to define them. This generates a huge LP problem even for the historical data case where the number of scenarios is 100 or 200. Krzemienowski and Ogryczak [7] have shown with the earlier experiments that the CPU time of 7 seconds on average for $T = 52$ has increased to above 30 sec. with $T = 104$ and even more than 180 sec. for $T = 156$. However, similar to the CVaR models, variables $d_{tt'}$ are associated with the singleton coefficient columns. Hence, while solving the dual instead of the original primal, the corresponding dual constraints take the form of simple upper bounds (SUB) which are handled implicitly outside the LP matrix. For the simplest form of the feasible set (1) the dual GMD model takes the following form:

$$\begin{array}{l} \min q - \mu_0 u_0 \\ q \geq \mu_j u_0 + \sum_{t=1}^{T} \sum_{t' \neq t} (r_{jt} - r_{jt'}) u_{tt'}, \ j = 1, \dots, n \\ 0 \leq u_{tt'} \ \leq p_t p_{t'}, \ t, t' = 1, \dots, T; t \neq t' \end{array} \tag{18}$$

where original portfolio variables x_j are dual prices to the inequalities. The dual model contains $T(T-1)$ variables $u_{tt'}$ but the number of constraints (excluding the SUB structure) $n+1$ is proportional to the number of securities. The above dual formulation can be further simplified by introducing variables:

$$\bar{u}_{tt'} = u_{tt'} - u_{t't}, \quad t, t' = 1, \dots, T; t < t' \tag{19}$$

which allows us to reduce the number of variables to $T(T-1)/2$ by replacing (18) with the following:

$$\begin{array}{l} \min q - \mu_0 u_0 \\ q \geq \mu_j u_0 + \sum_{t=1}^{T} \sum_{t' > t} (r_{jt} - r_{jt'}) \bar{u}_{tt'}, \ j = 1, \dots, n \\ -p_t p_{t'} \leq \bar{u}_{tt'} \ \leq p_t p_{t'}, \ t < t' = 1, \dots, T \end{array} \tag{20}$$

Such a dual approach may dramatically improve the LP model efficiency in the case of larger number of scenarios. Actually, as shown with the earlier experiments of [7], the above dual formulations let us to reduce the optimization time below 10 seconds for $T = 104$ and $T = 156$. Nevertheless, the case of really large number of scenarios still may cause computational difficulties, due to huge number of variables ($T(T-1)/2$). This may require some column generation techniques [3] or nondifferentiable optimization algorithms [9].

As shown by Yitzhaki [32] for the SSD consistency of the GMD model one needs to maximize the complementary measure

$$\mu_\Gamma(\mathbf{x}) = \mu(\mathbf{x}) - \Gamma(\mathbf{x}) = \mathbf{E}\{R_\mathbf{x} \wedge R_\mathbf{x}\} \tag{21}$$

where the cumulative distribution function of $R_\mathbf{x} \wedge R_\mathbf{x}$ for any $\eta \in \mathbf{R}$ is given as $F_\mathbf{x}(\eta)(2 - F_\mathbf{x}(\eta))$. Hence, (21) is the expectation of the minimum of two independent identically distributed random variables (i.i.d.r.v.) $R_\mathbf{x}$ thus representing the *mean worse return*. This provides us with another LP model although it is not more compact than that of (17) and its dual (18). Alternatively, the GMD may be expressed with integral of the absolute Lorenz curve as

$$\begin{aligned} \Gamma(\mathbf{x}) &= 2 \int_0^1 (\alpha \mu(\mathbf{x}) - F_\mathbf{x}^{(-2)}(\alpha)) d\alpha \\ &= 2 \int_0^1 \alpha (\mu(\mathbf{x}) - M_\alpha(\mathbf{x})) d\alpha \end{aligned}$$

and respectively

$$\mu_\Gamma(\mathbf{x}) = 2 \int_0^1 F_\mathbf{x}^{(-2)}(\alpha) d\alpha = 2 \int_0^1 \alpha M_\alpha(\mathbf{x}) d\alpha \tag{22}$$

thus combining all the CVaR measures. In order to enrich the modeling capabilities, one may treat differently some more or less extreme events. In order to model downside risk aversion, instead of the Gini's mean difference, the *tail Gini's* measure introduced by Ogryczak and Ruszczyński [21], [20] can be used:

$$\begin{aligned} \mu_{\Gamma_\beta}(\mathbf{x}) &= \mu(\mathbf{x}) - \frac{2}{\beta^2} \int_0^\beta (\mu(\mathbf{x})\alpha - F_\mathbf{x}^{(-2)}(\alpha)) d\alpha \\ &= \frac{2}{\beta^2} \int_0^\beta F_\mathbf{x}^{(-2)}(\alpha) d\alpha \end{aligned} \tag{23}$$

In the simplest case of equally probable T scenarios with $p_t = 1/T$ (historical data for T periods), the tail Gini's measure for $\beta = K/T$ may be expressed as the weighted combination of CVaRs $M_{\beta_k}(\mathbf{x})$ with tolerance levels $\beta_k = k/T$ for $k = 1, 2, \dots, K$ and properly defined weights [21]. In a general case, we may resort to an approximation based on some reasonably chosen grid β_k, $k = 1, \dots, m$ and weights w_k expressing the corresponding trapezoidal approximation of the integral in the formula (23). Exactly, for any $0 < \beta \leq 1$, while using the grid of m tolerance levels $0 < \beta_1 < \dots < \beta_k < \dots < \beta_m = \beta$ one may define weights:

$$\begin{aligned} w_k &= \frac{(\beta_{k+1} - \beta_{k-1})\beta_k}{\beta^2}, \ k = 1, \dots, m-1 \\ w_m &= \frac{\beta - \beta_{m-1}}{\beta} \end{aligned} \tag{24}$$

where $\beta_0 = 0$. This leads us to the Weighted CVaR (WCVaR) measure [12] defined as

$$\begin{aligned} M_{\mathbf{w}}^{(m)}(\mathbf{x}) &= \sum_{k=1}^{m} w_k M_{\beta_k}(\mathbf{x}) \\ \sum_{k=1}^{m} w_k &= 1, \quad w_k > 0,\ k = 1,\dots,m \end{aligned} \tag{25}$$

We emphasize that despite being only an approximation to (23), any WCVaR measure itself is a well defined LP computable measure with guaranteed SSD consistency and coherency, as a combination of the CVaR measures. Hence, it needs not to be built on a very dense grid to provide proper modeling of risk averse preferences. While analyzed on the real-life data from the Milan Stock Exchange the weighted CVaR models have usually performed better than the GMD itself, the Minimax or the extremal CVaR models [12].

Here we analyze only computational efficiency of the LP models representing the WCVaR portfolio optimization. For returns represented by their realizations we get the following LP optimization problem:

$$\begin{aligned} \max\quad & \sum_{k=1}^{m} w_k \eta_k - \sum_{k=1}^{m} \frac{w_k}{\beta_k} \sum_{t=1}^{T} p_t d_{tk} \\ \text{s.t.}\quad & \sum_{j=1}^{n} \mu_j x_j \geq \mu_0, \quad \sum_{j=1}^{n} x_j = 1 \\ & x_j \geq 0,\ j = 1,\dots,n \\ & d_{tk} \geq \eta_k - \sum_{j=1}^{n} r_{jt} x_j \\ & d_{tk} \geq 0,\ t = 1,\dots,T; k = 1,\dots,m \end{aligned} \tag{26}$$

where η_k (for $k = 1,\dots,m$) are unbounded variables taking the values of the corresponding β_k-quantiles (in the optimal solution). The problem dimensionality is proportional to the number of scenarios T and to the number of tolerance levels m. Exactly, the LP model contains $m \times T + n$ variables and $m \times T + 2$ constraints. The LP problem structure is similar to that of reperesenting the so-called WOWA optimization in fuzzy approaches [22]. It does not cause any computational difficulties for a few hundreds scenarios and a few tolerance levels, as in a simple computational analysis based on historical data [12]. However, in the case of more advanced simulation models employed for scenario generation one may get several thousands scenarios. This may lead to the LP model (26) with huge number of variables and constraints thus decreasing the computational efficiency of the model. If the core portfolio constraints contain only linear relations, like (1), then the computational efficiency can easily be achieved by taking advantages of the LP dual to model (26). The LP dual model takes the following form:

$$\begin{aligned} \min\quad & q - \mu_0 u_0 \\ \text{s.t.}\quad & q - \mu_j u_0 - \sum_{t=1}^{T} r_{jt} \sum_{k=1}^{m} u_{tk} \geq 0,\ j = 1,\dots,n \\ & \sum_{t=1}^{T} u_{tk} = w_k \\ & 0 \leq u_{tk} \leq \frac{p_t w_k}{\beta_k},\ t = 1,\dots,T; k = 1,\dots,m \end{aligned} \tag{27}$$

that contains $m \times T$ variables u_{tk}, but the $m \times T$ constraints corresponding to variables d_{tk} from (26) take the form of simple upper bounds on u_{tk} thus not affecting the problem complexity. Hence, again the number of constraints in (27) is proportional to the total of portfolio size n and the number of tolerance levels m, thus it is independent from the number of scenarios. Exactly, there are $m \times T + 2$ variables and $m + n$ constraints thus guaranteeing a high computational efficiency of for very large number of scenarios.

TABLE III
COMPUTATIONAL TIMES (IN SECONDS) FOR THE DUAL WCVAR MODELS

Scenarios	Securities	Model (27)	
(T)	(n)	$m = 3$	$m = 5$
5 000	76	6.2	13.8
7 000	76	10.0	22.8
10 000	76	16.2	37.7
50 000	50	121.8	281.0
50 000	100	335.3	731.7

We have tested computational efficiency of the dual model (27) using the same randomly generated test instances as for testing of the CVaR and other basic models in Section III. Table III presents average computation times of the dual models for $m = 3$ with tolerance levels $\beta_1 = 0.1$, $\beta_2 = 0.25$, $\beta_3 = 0.5$ and weights $w_1 = 0.1$, $w_2 = 0.4$ and $w_3 = 0.5$, thus representing the parameters leading to good results on real life data [12], as well as for $m = 5$ with uniformly distributed tolerance levels $\beta_1 = 0.1$, $\beta_2 = 0.2$, $\beta_3 = 0.3$, $\beta_4 = 0.4$, $\beta_5 = 0.5$ and weights (24).

V. CONCLUDING REMARKS

The classical Markowitz model uses the variance as the risk measure, thus resulting in a quadratic optimization problem. There were introduced several alternative risk measures which are computationally attractive as (for discrete random variables) they result in solving linear programming (LP) problems. The LP solvability is very important for applications to real-life financial decisions where the constructed portfolios have to meet numerous side constraints and take into account transaction costs. A gamut of LP computable risk measures has been presented in the portfolio optimization literature although most of them are related to the absolute Lorenz curve and thereby the CVaR measures. We have shown that all the risk measures used in the LP solvable portfolio optimization models can be derived from the SSD shortfall criteria. This allows us to guarantee their SSD consistency for any distribution of outcomes.

The corresponding portfolio optimization models can be solved with general purpose LP solvers. However, in the case of more advanced simulation models employed for scenario generation one may get several thousands of scenarios. This may lead to the LP model with huge number of variables and constraints thus decreasing the computational efficiency of the models. For the CVaR model, the number of constraints (matrix rows) is proportional to the number of scenarios. while the number of variables (matrix columns) is proportional to the total of the number of scenarios and the number of instruments. We have shown that the computational efficiency can be then dramatically improved with an alternative model taking advantages of the LP duality. In the introduced model the number of structural constraints (matrix rows) is proportional to the number of instruments thus not affecting seriously the simplex method efficiency by the number of scenarios. In particular, for the case of 50 000 scenarios, it has resulted in computation times below 30 seconds for 50 securities or below a minute for 100 instruments. Similar computational times have also been achieved for the reformulated Minimax model.

Similar reformulation can be developed for other LP computable portfolio optimization models as many of them are related to the Absolute Lorenz Curve [18], [10]. In particular, this applies to the classical LP portfolio optimization models based on the mean absolute deviation as well as to the Gini's mean difference. The standard LP models for the Gini's mean difference [32] and its downside version [7] require T^2 auxiliary constraints which makes them hard already for medium numbers of scenarios, like a few hundred scenarios given by historical data. The models taking advantages of the LP duality allow one to limit the number of structural constraints making it proportional to the number of scenarios T thus increasing dramatically computational performances for medium numbers of scenario although still remaining hard for very large numbers of scenarios.

Acknowledgment

The authors are indebted to Churlzu Lim from the University of North Carolina at Charlotte for providing the test data of 50 000 scenarios portfolio selection problem and to Diana Roman from CARISMA, Brunel University for providing the FTSE 100 related test data of 5 000, 7 000 and 10 000 scenarios we have used in our computational studies.

***Abstract*—The constrained optimization with differential evolution (DE) is addressed. A novel variant of competitive differential evolution with a hybridized search of feasibility region is proposed, where opposition-based optimization and adaptive controlled random search are combined. Various variants of the algorithm are experimentally compared on the benchmark set developed for the special session of IEEE Congress of Evolutionary Computation (CEC) 2010. The results of the enhanced competitive DE show effective search of feasible solutions, in difficult problems significantly better than the competitive DE variant presented at CEC 2010.**

I. Introduction

DIFFERENTIAL evolution (DE) was proposed by Storn and Price [1] as a global optimizer for continuous optimization problems with a real-value objective function, where only the search space (domain) S is specified by lower (a_j) and upper (b_j) limits of each component j, $S = \prod_{j=1}^{D}[a_j, b_j]$, $a_j < b_j$, $j = 1, 2, \ldots, D$, D is the dimension of the domain. The global minimum point $\boldsymbol{x}^* = \arg\min_{\boldsymbol{x} \in S} f(\boldsymbol{x})$ is the solution of the problem.

DE has been studied intensively in recent years and many new variants of DE have been proposed. The research has mostly focused on proper settings of control parameters and their adaptation during the search process. However, variants of DE for solving discrete or constrained problems have also appeared, for overview see e.g. [2].

The paper is organized as follows. In Section II, the constrained optimization problem is defined and sevral stochastic algorithms for its solution are mentioned. The DE algorithm is described in Section III, the description is focused on important features of the competitive DE used in this study. Techniques of enhanced search of the feasibility region are summarized and all algorithms tested in this study are described in Section IV. Section V involves specification of experiments and the results of comparison of the feasibility rates obtained by all the competitive DE variants in the tests as well as detailed results of the best performing algorithm. Concluding remarks are made in Section VI.

II. Constrained Optimization

We consider the optimization problem in the following format [3]:

$$\textit{Minimize: } f(\boldsymbol{x}),\ \boldsymbol{x} = (x_1, x_2, \ldots, x_D) \textit{ and } \boldsymbol{x} \in S \qquad (1)$$

$$\textit{subject to: } \begin{array}{ll} g_i(\boldsymbol{x}) \leq 0, & i = 1, \ldots, p \\ h_j(\boldsymbol{x}) = 0, & j = p+1, \ldots, m. \end{array}$$

A solution is regarded feasible if $g_i(\boldsymbol{x}) \leq 0,\ \textit{for}\ i = 1, \ldots, p$, and $|h_j(\boldsymbol{x})| - \varepsilon \leq 0,\ \textit{for}\ j = p+1, \ldots, m$. Mean violation $\bar{v}$ of any point $\boldsymbol{x}$ in population defined according to [3] can be evaluated

$$\bar{v} = \frac{\sum_{i=1}^{p} G_i(\boldsymbol{x}) + \sum_{j=p+1}^{m} H_j(\boldsymbol{x})}{m},$$

where

$$G_i(\boldsymbol{x}) = \begin{cases} g_i(\boldsymbol{x}) & \text{if} \quad g_i(\boldsymbol{x}) > 0 \\ 0 & \text{if} \quad g_i(\boldsymbol{x}) \leq 0 \end{cases}$$

$$H_j(\boldsymbol{x}) = \begin{cases} |h_j(\boldsymbol{x})| & \text{if} \quad |h_j(\boldsymbol{x})| - \varepsilon > 0 \\ 0 & \text{if} \quad |h_j(\boldsymbol{x})| - \varepsilon \leq 0. \end{cases}$$

Some versions of DE for constrained problems have been published recently. One of the first modifications of DE for constrained problems was published by Lampinen [4]. In [5], the authors proposed self-adaptive algorithm ε-jDE which is a modification of jDE algorithm [6] extended for constrained optimization. They presented ε level controlling. The ε level is updated according to the mean violation of individuals in the current generation until the number of generations G reaches the control generation G_C. After the number of generations exceeds G_C, the ε level is set to 0 to obtain a solution with minimum constraint violation.

An up-to-date overview of evolutionary techniques for constrained problems is presented in [7]. The authors also proposed a novel algorithm using an ensemble of constraint handling techniques (ECHT). The included techniques are superiority of feasible solution, self-adaptive penalty, ε-constraint, and stochastic ranking. In the algorithm which uses ECHT together with differential evolution (ECHT-DE) each constraint handling method has its own population and new trial points are computed separately for each constraint handling method in the current generation.

This work was supported by Czech Ministry of Education, the research project MSM 6198898701.

A simple DE algorithm for constrained problem was presented in [8]. This algorithm alternates minimization of mean violation $\bar{v}$ and $f(\boldsymbol{x})$ using one generation of the adaptive DE algorithm with 12 competing DE strategies, where various values of control parameters and two types of crossover are used. The algorithm performed well on most problems of the benchmark test set [3]. However, in a few problems the algorithm found feasible solution rarely or even never, see counts of feasible solutions in Tables II and III. This failure in search of the feasible region is a motivation for the proposal of a new algorithm with enhanced search of the feasible region.

III. Differential Evolution

Algorithm of DE works with a population of individuals (*NP* points in domain S) that are considered as candidates of solution. The population develops iteratively by using evolutionary operators of selection, mutation, and crossover. Each iteration corresponds to an evolutionary generation. Let us denote two subsequent generations P and Q. Application of evolutionary operators in the old generations P creates a new generation Q. After completing the new generation Q, the Q becomes the old generation for next iteration. The basic scheme of DE is written in a pseudo-code in Figure 1.

```
1   generate an initial generation $P$, $(\boldsymbol{x}_i,\ i = 1, 2, \dots, NP)$
2   while stopping condition not achieved
3       for $i$ := 1 to $NP$ do
4           generate a new trial vector $\boldsymbol{y}$ using $P$
5           if $\boldsymbol{y}$ better $\boldsymbol{x}_i$ then insert $\boldsymbol{y}$ into $Q$
6                                 else insert $\boldsymbol{x}_i$ into $Q$
7           endif
8       endfor
9       $P := Q$
10  endwhile
```

Fig. 1. **Algorithm 1** – Basic scheme of DE in pseudo-code

The relation "better" (line 5 in Algorithm 1) means $f(\boldsymbol{y}) < f(\boldsymbol{x}_i)$ in unconstrained problems. In constrained problems, the preference of a more feasible solution is usually applied according to the following rule: Accept a new trial point $\boldsymbol{y}$ if

$$\bar{v}_y < \bar{v}_i \text{ or } (\bar{v}_y = 0 \text{ and } \bar{v}_i = 0 \text{ and } f(\boldsymbol{y}) < f(\boldsymbol{x}_i)), \qquad (2)$$

where $\bar{v}_i$ is mean violation of the current point $\boldsymbol{x}_i$.

A new trial point $\boldsymbol{y}$ (line 4 in Algorithm 1) is generated by using mutation and crossover. There are various strategies of mutation and crossover [1], [2], [9]. The most popular mutation strategy called DE/rand/1/ generates the mutant point $\boldsymbol{u}$ by adding the weighted difference of two points,

$$\boldsymbol{u} = \boldsymbol{r}_1 + F\,(\boldsymbol{r}_2 - \boldsymbol{r}_3)\,, \quad F > 0\,, \qquad (3)$$

where $\boldsymbol{r}_1, \boldsymbol{r}_2$, and $\boldsymbol{r}_3$ are three mutually distinct points randomly taken from population P, not coinciding with the current point $\boldsymbol{x}_i$, and F is an input parameter. In the implementation of the DE algorithm in this paper is used a slightly modified mutation strategy. It was proposed by Kaelo and Ali [10]. They called it random localization and it can be denoted as DE/randrl/1/. The point $\boldsymbol{r}_1$ in (3) is the best one among $\boldsymbol{r}_1$, $\boldsymbol{r}_2$, and $\boldsymbol{r}_3$.

The elements y_j, $j = 1, 2, \dots, D$, of the trial point $\boldsymbol{y}$ are built up by the crossover of the current point $\boldsymbol{x}_i$ and the mutant point $\boldsymbol{u}$. The most frequently used kind of crossover is called *binomial*. It uses the following rule of combination of parents' elements

$$y_j = \begin{cases} u_j & \text{if} \quad U_j \le CR \quad \text{or} \quad j = l \\ x_{ij} & \text{if} \quad U_j > CR \quad \text{and} \quad j \ne l\,, \end{cases} \qquad (4)$$

where l is a randomly chosen integer from $\{1, 2, \dots, D\}$, $U_1, U_2, \dots, U_D$ are independent random variables uniformly distributed in $[0,\ 1)$, and $CR \in [0, 1]$ is an input parameter influencing the number of elements to be exchanged by the crossover. The rule given by Eq. (4) ensures that at least one element of vector $\boldsymbol{x}_i$ is changed, even if $CR = 0$. The DE variants applying binomial crossover according to (4) are denoted DE/·/·/bin in literature.

The *exponential* crossover denoted by abbreviation DE/·/·/exp was also proposed in the first version of DE by Price and Storn [1]. The exponential crossover in DE is similar to the two-point crossover in genetic algorithms. For the exponential crossover, the starting position of crossover $(k = 1)$ is randomly chosen from $\{1, \dots, D\}$, and L consecutive elements (counted in circular manner) are taken from the mutant vector $\boldsymbol{u}$. The probability of replacing the k-th element in the sequence $1, 2, \dots, L,\ \ L \le D$, decreases exponentially with increasing k.

The probability of crossover p_m can be defined as the mean relative length of overwritten elements of $\boldsymbol{x}_i$, i.e. $p_m = E(L)/D$. The relation between the p_m and control parameter *CR* was studied by Zaharie [11], [12]. For the binomial crossover, the relation between p_m and control parameter *CR* is linear,

$$p_m = CR(1 - 1/D) + 1/D, \qquad (5)$$

while for the exponential crossover the relationship is strongly non-linear,

$$p_m = \frac{1 - CR^D}{D(1 - CR)}, \quad \text{for} \quad CR < 1. \qquad (6)$$

This non-linearity should be taken into account when we set the *CR* value for a problem to be solved.

Differential evolution has a few control parameters, namely the size of population *NP*, mutation strategy, crossover type, and couple of parameters F and *CR*. However, the efficiency of differential evolution is very sensitive especially regarding the setting of F and *CR* values. The most suitable control-parameter values for a specific problem may be found by trial-and-error tuning, which requires a lot of time. There are some recommendations for setting of these parameters [1], [2], [9], [13], [14] but their applicability is not universal.

Because trial-and-error control-parameter tuning is time-consuming, several new adaptive variants of DE have been recently proposed, e.g. [6], [15]–[21].

Competitive setting of the control parameters was proposed in [22]. In this adaptive approach to the choice of proper DE strategy, we randomly choose among H different settings of control parameters (F, *CR*, mutation, and crossover) with probabilities $q_h,\ h = 1, 2, \ldots, H$.

These probabilities change according to the success rate of the settings in the preceding steps of the search process. The h-th setting is considered successful if it generates a trial point $\boldsymbol{y}$ better than its counter-partner $\boldsymbol{x}_i$ in the old generation P, see line 5 of Algorithm 1 in Figure 1. Probability q_h is evaluated as the relative frequency

$$q_h = \frac{n_h + n_0}{\sum_{j=1}^{H}(n_j + n_0)}\,, \tag{7}$$

where n_h is the current count of the h-th setting's successes, and $n_0 > 0$ is a constant. The input parameter $n_0 > 1$ prevents a dramatic change in q_h by one random successful use of the h-th parameter setting. To avoid degeneration of the search process, the current values of q_h are reset to their starting values $q_h = 1/H$ if any probability q_h decreases bellow the given limit $\delta > 0$ during the search process.

Mutation according to (3) could cause that a new trial point $\boldsymbol{y}$ moves out of the domain S. In such a case, the point $\boldsymbol{y}$ can be skipped and a new one generated. A more effective attempt is to replace the values of $y_j < a_j$ or $y_j > b_j$, either by random value in $[a_j,\, b_j]$, see [9], or by reversed value of this coordinate y_j into S over the a_j or b_j by mirroring, see [23]. The latter method is used in algorithms implemented for numerical tests.

TABLE I
VALUES OF CROSSOVER PROBABILITY AND THE CORRESPONDING VALUES OF *CR* PARAMETER FOR EXPONENTIAL CROSSOVER

	$D = 10$				$D = 30$		
i	1	2	3		1	2	3
p_{mi}	0.3250	0.5500	0.7750	p_i	0.2750	0.5167	0.7583
CR_i	0.7011	0.8571	0.9418	CR_i	0.8815	0.9488	0.9801

In several benchmark tests [24], [25], the competitive variant of DE/randrl/1/ with $H = 12$ competing settings was among the most efficient. In this variant, six various settings of (F, CR) for the binomial crossover and six settings for the exponential crossover take part in the competition. Two values of F are used for the both type of crossover, one of them $F = 0.5$ is rather small and the second one $F = 0.8$ is rather big when the recommendation in [1], [2], [9], [13], [14] are followed. Three values of *CR* for the binomial crossover are set to their minimum, middle, and maximum value, that is $\mathit{CR} = 0$, $\mathit{CR} = 0.5$, and $\mathit{CR} = 1$. All the three values are combined in tuples with two values of F, which gives six settings mentioned above. For the exponential crossover, three values of *CR* are used as well, but they are set in such a way in order to have the values of the crossover probability given by (6) equally spaced inside the interval of their possible values, $[1/D,\ 1]$. Notice, that for extremal values of the crossover probability $p_m = 1/D$ or $p_m = 1$ the both types of crossover do not differ. Both the mutation probability values and the corresponding *CR* values are dependent on the dimension of the problem. The values of mutation probability and the corresponding values of *CR* evaluated from (6) for $D = 10$ and $D = 30$ are given in Table I. Like in the case of the binomial crossover, three values of *CR* are combined with two values of F, which gives six settings of (F, CR) for the exponential crossover taking part in competition. The competitive DE variant using these 12 settings is hereafter referred as *b6e6rl*.

Thus, the *b6e6rl* algorithm modified for constrained problems has only the following control parameters:

- Size of the population, *NP* – can be intuitively set with respect to the dimension of the problem.
- Parameters n_0 and δ to control the competition – can be set to the values, $n_0 = 2$, $\delta = 1/(5 \times H)$ used in other problems.
- Stopping condition – can be formed by maximum of objective function evaluations (MaxFES) or in other way.
- Parameter ε for the tolerance of feasibility violation – the value depends on the user's request.

IV. Enhanced Search of Feasibility Region

The basic idea, how to enhance the search of the feasibility region, consists in exploitation of strategies different from DE in the search. Opposite-based optimization and adaptive controlled random search were applied for minimization of mean violation $\bar{v}$ in this study.

A. Opposition-Based Optimization

Application of opposition-based learning in stochastic optimization algorithms has appeared recently [26], [27] and it is called opposition-based optimization (OBO). Basic idea is to search for solution not only within the individuals of the population developed by evolutionary operators but also in the opposite part of the search space T. The opposite point to the point $\boldsymbol{x} \in T$, $T = \prod_{j=1}^{D}[l_j, u_j],\ l_j < u_j,\ j = 1, 2, \ldots, D$ is defined as symmetric with respect to the center of T by

$$\breve{\boldsymbol{x}} = \boldsymbol{l} + \boldsymbol{u} - \boldsymbol{x}. \tag{8}$$

The opposite population O of *NP* points to the population P according to relation (8) is generated occasionally, then the function values in the opposite points are evaluated and from the set $P \cup O$ the *NP* fittest individuals are selected to the new population. At the start of the optimization, $T = S$, which is $\boldsymbol{l} = \boldsymbol{a}$ and $\boldsymbol{u} = \boldsymbol{b}$. The search space T for the opposite points shrinks dynamically during the search process. If P is a matrix of size (*NP*, D), then $\boldsymbol{l} = \min(P)$ and $\boldsymbol{u} = \max(P)$, the functions $\min(\cdot)$ and $\max(\cdot)$ return the vectors of column minima and maxima, respectively. Thus, current dynamically shrinking search space for the opposite population can be written as

$$T = \prod_{j=1}^{D}[l_j, u_j],\ l_j < u_j,\ j = 1, 2, \ldots, D, \qquad \text{where} \quad \boldsymbol{l} = \min(P), \quad \boldsymbol{u} = \max(P). \tag{9}$$

The opposite population is generated after the initialization of the population for the first time. During the search process, the opposite population is generated in randomly selected generations if the condition of $rand(0,1) < \mathit{JR}$, where $rand(0,1)$ is a random value from uniform distribution on $[0,1)$ and *JR* (jumping rate) is an input parameter of the algorithm. The jumping rate is usually set to constant value, e.g. $\mathit{JR} = 0.3$ [26].

B. Adaptive Controlled Random Search

Another algorithm for enhanced search of the feasible solution is the adaptive controlled random search (CRS) with four competing local heuristics. This algorithm was applied successfully to the estimation of parameters in non-linear regression models [28].

Three of the competing local heuristics are based on a randomized reflection in the simplex Σ created by $D+1$ points chosen from P. A new trial point $\boldsymbol{y}$ is generated from the simplex by the relation

$$\boldsymbol{y} = \boldsymbol{g} + U\left(\boldsymbol{g} - \boldsymbol{x}_H\right), \tag{10}$$

where $\boldsymbol{x}_H = \arg\max_{\boldsymbol{x}\in\Sigma} f(\boldsymbol{x})$ and $\boldsymbol{g}$ is the centroid of remaining D points of the simplex Σ. The multiplication factor U is a random variable distributed uniformly in $[s, \alpha - s)$, $\alpha > 0$ and s being input parameters, $0 < s < \alpha/2$. All the $D + 1$ points of simplex are chosen randomly from P in two heuristics. Regarding the third heuristic, one point of the simplex is the point of P with the minimum objective function value and the remaining D points of the simplex Σ are chosen randomly from the remaining points of P. The fourth competing local heuristic is derived from differential evolution, where strategy DE/rand/1/bin is used and adaptive setting of control parameter F according to [15] is applied. The algorithm was used as described in [28] with the same setting of the parameters controlling the competition of local heuristics.

C. Enhanced Search of Feasible Individuals

The scheme of enhanced search of the feasible region is written in a pseudo-code in Figure 2. By the term "one generation" of an algorithm is meant one generation of DE (algorithm *b6e6rl*) or a run of another algorithm, where *NP* evaluations of objective function is needed. Notice that except the *b6e6rl* all the other algorithms minimize only the mean violation $\bar{v}$ as objective function. In the algorithm described in Figure 2 (hereafter denoted *CRSrOBO*) are shown all the enhanced search techniques used in this study. *CRSrOBO* appeared best performing in the experimental tests. The other algorithms tested miss one or more enhancement parts. The algorithm labeled by *CRSOBO* does not use the refreshment of population for the controlled random search, i. e. lines 4 to 6 in Figure 2 are not applied. The algorithm not using lines 4 to 6 and no opposition-based optimization (lines 10 to 12 Figure 2) is labeled *CRS*. The algorithm without enhancing the search of the feasible solutions by controlled random search (skipped lines 3 to 9 in Figure 2) is marked as *OBO*. The dynamically shrinking search space according to relation (9) is applied in all the algorithms using enhanced search by OBO, whereas the static search space S is used in refreshment of the population for CRS, because of no a priori information on allocation of the feasibility regions is assumed. One generation of OBO with static search space S is also applied immediately after the initialization of P at line 1 in Figure 2.

```
 1 generate an initial generation $P$
 2 while stopping condition not achieved
 3    if no individual feasible then
 4       if $rand(0,1) < \mathit{JR}_{\mathit{CRS}}$ then
 5          refresh $P$ using opposite population in $S$
 6       endif
 7       perform one generation of CRS
 8    endif
 9    perform one generation of b6e6rl
10    if no individual feasible & $rand(0,1) < \mathit{JR}_{\mathit{OBO}}$ then
11       perform one generation of OBO
12    endif
13    $P := Q$
14 endwhile
```

Fig. 2. **Algorithm 2** – Enhanced Search of Feasible Solutions

The mnemonic labels of the algorithms with enhanced search respect the applied techniques and the basic algorithm of competitive DE is not stressed in labels of variants because it is present in all the tested algorithms. Finally, if we omit all enhanced search (lines 3 to 8 and 10 to 12) then the rest is the algorithm *b6e6rl* described in Section III.

V. Experiments and Results

The modification of DE for the solution of constrained problems presented in [8] consists in alternating minimization of mean violation $\bar{v}$ and $f(\boldsymbol{x})$ using one generation of the *b6e6rl* algorithm. An extra minimization of mean violation could be considered as enhanced search of the feasibility region by *b6e6rl*. This variant labeled by *CEC10* hereafter is compared with the algorithms described in this study. All the variants of algorithm were implemented in Matlab.

The algorithms were tested on the benchmark set developed for the special CEC 2010 session [3]. The set consists of 18 problems at two levels of dimension. The code for test-function evaluation was loaded from the web page of the organizers [3].

Six algorithms were compared in experimental tests, namely algorithm labeled *CEC10*, simple competitive DE for constrained optimization (*b6e6rl*) and four new variants with enhanced search of the feasible solutions (*CRS*, *OBO*, *CRSOBO*, and *CRSrOBO*).

The control parameters of the algorithms were set to the same values for all the test problems, some parameters depend on the dimensionality of the test problems, the values follows:

- Size of the population, $NP = 50$ for $D = 10$, $NP = 100$ for $D = 30$.
- Parameters to control the competition, $n_0 = 2$, $\delta = 1/(5 \times H)$ for all the test problems.
- Stopping condition, MaxFES $= 2 \times 10^5$ for $D = 10$, MaxFES $= 6 \times 10^5$ for $D = 30$, as given in [3].
- Parameter for tolerance of feasibility violation, the value $\varepsilon = 0.0001$ is prescribed in [3].
- Jumping rate for OBO was set to $JR_{OBO} = 0.3$ as mostly applied in [27].
- Jumping rate of population refreshment for CRS was set to $JR_{CRS} = 0.1$ in order not to waste time by too frequent using static OBO.
- Control parameters of adaptive CRS were used the same as in [28].

No tuning of control-parameter was performed before the test experiments.

For each problem and dimension, 25 independent optimization runs were performed. From each run the function value $f(\boldsymbol{x}^*)$ found at the minimum of the mean violation $\bar{v}$ is returned together with the corresponding values of variables needed for the processing of the results presented in the tables. If there are more feasible solutions in the last generation, the minimum function value $f(\boldsymbol{x}^*)$ of the feasible solutions is returned.

Comparison of the feasibility rates obtained by all the tested variants are shown in Tables II and III, where counts of runs that found a feasible solution ($\bar{v} = 0$) of 25 runs are given. If we compare the results of the algorithms in problems 5, 6, and 9 to 12, we see a complementary effect of different enhanced techniques. Where CRS does not help, OBO is useful, and vice versa. Moreover, a synergic effect appears if more types of enhanced search are applied together. The best results were obtained by *CRSrOBO*, where the average count of the feasible solutions is almost 23 of 25 and the minimum of feasible solutions is 14, i.e. more than a half of 25.

The two-tailed Fisher's exact test was applied to the statistical comparison of the feasibility rates of the algorithms. All the algorithms were compared with respect to *CRSrOBO*. The values of the feasibility rate for which the proportion of the feasible solutions is different significantly from the corresponding proportion of *CRSrOBO* at level of 0.05 are underlined.

Detailed results of the best performing variant of enhanced competitive DE (*CRSrOBO*) in 18 test problems at two levels of the dimension are presented in Tables IV and V. The structure of the results follows the requirements given in [3]. The results obtained from 25 runs of each problem were sorted according to their values of mean violation $\bar{v}$ in an ascending way. Then the part of the feasible solutions was sorted according to their function values $f(\boldsymbol{x}^*)$ in an ascending way. The presented values of $f(\boldsymbol{x}^*)$ in columns Best, Median, and Worst refer to this order. The sorting according to the values of mean violation $\bar{v}$ can cause that the best or median of $f(\boldsymbol{x}^*)$ need not be necessarily less than the worst one in some of the problems. The values of $\bar{v}$ and c correspond to the row of Median. Three numbers in vector c indicate the number of violations more than 1, the number of violations in $(0.1,\ 1]$, and the number of violations in $(0.0001,\ 0.1]$. The mean and the standard deviation (Stdev) of $f(\boldsymbol{x}^*)$ are evaluated from all

the 25 runs. The feasibility rate in the last column of tables is defined as

$$FR = 100 \times \frac{\text{number of runs with feasible solution}}{\text{number of all runs}}.$$

In comparison with the results of *CEC10* [8], not only the feasibility rate of *CRSrOBO* is significantly better in some problems, but also the minimum function values (column Best) found by *CRSrOBO* are less than those found by *CEC10* in more than a half of problems. Thus, the novel enhanced competitive DE variant combining adaptive controlled random search with population refreshment and opposition-based optimization for the search of feasible solution proved to be a substantial improvement of the competitive DE for constrained single-objective optimization.

VI. CONCLUSION

A novel competitive DE variant with enhanced search of the feasibility region for constrained single-objective optimization was proposed. This algorithm includes adaptive controlled random search with population refreshment by applying opposite points in the search space and opposition-based optimization. These techniques are used for the search of the feasibility region (minimization of violation), whereas the competitive differential evolution is used both for minimizing the constraints' violation and the function value. The novel algorithm proved to be a substantial improvement of the competitive DE for constrained single-objective optimization presented recently [8].

In near future, we are planning to compare this algorithm with good performing algorithms available in literature [5], [7] and with the other algorithms succeeded in the competition of Congress on Evolutionary Computation 2010 at Barcelona. It is needed for a decision on applicability of the algorithm in real-world problems. A more detailed analysis of the algorithms is intended. Its results can bring a new impuls for further development of algorithms for constrained single-objective optimization with enhanced search of the feasible solutions.
