# Proceedings of the Federated Conference on Computer Science and Information Systems

September 18–21, 2011. Szczecin, Poland

2011

**D**EAR Reader, it is our pleasure to present to you Proceedings of the 2011 Federated Conference on Computer Science and Information Systems (FedCSIS), which took place in Szczecin, Poland, on September 18–21, 2011.

FedCSIS was organized by the Polish Information Processing Society (Mazowsze and West Pomerania Chapters) in technical cooperation with: IEEE Region 8, Computer Society Chapter Poland, Gdańsk Computer Society Chapter, Poland, Gesellschaft für Informatik, Asociación de Técnicos de Informática, Naukowe Towarzystwo Informatyki Ekonomicznej. Furthermore, the 6th International Symposium Advances in Artificial Intelligence and Applications (AAIA'11) was organized in technical cooperation with: World Federation of Soft Computing, European Neural Networks Society, Poland Chapter of the IEEE Computational Intelligence Society (CIS), Polish Neural Networks Society; while the Workshop on Computer Aspects of Numerical Algorithms (CANA'11) was organized in-cooperation with the Society for Industrial Applied Mathematics.

FedCSIS consisted of the following events (and Proceedings are organized into sections that correspond to each of them):

- 6th International Symposium Advances in Artificial Intelligence and Applications (AAIA'11),
  - International Workshop on Artificial Intelligence in Medical Applications (AIMA'2011)
  - 1st International Workshop on Advances in Semantic Information Retrieval (ASIR'11),
  - Workshop on Computational Optimization (WCO'2011),
- International Workshop on Advances in Business ICT (ABICT'11),
- Advances in Healthcare Information Technologies (HIT 2011)
  - 1st International Workshop on Interoperable Healthcare Systems (IHS'2011)—Challenges, Technologies, and Trends,
  - International Workshop on Ubiquitous Home Healthcare (UHH),
- Computer Aspects of Numerical Algorithms (CANA'11),

- 3rd International Symposium on Services Science,
- Joint Agent-oriented Workshops in Synergy (JAWS 2011)
  - Workshop on Agent Based Computing: from Model to Implementation—VIII (ABC:MI),
  - 5th International Workshop on Multi-Agent Systems and Simulation (MAS&S),
- International Symposium on Multimedia Applications and Processing (MMAAP 2011),
- Risks Awareness and Management through Smart Solutions (RAMSS 2011),
- 3rd Workshop on Advances in Programming Languages (WAPL'11),
- 3rd Workshop on Software Services: Semantic-based Software Services (WoSS'11),

Each of these events had its own Organizing and Program Committee (listed in these Proceedings). We would like to express our warmest gratitude to members of all of them for their hard work in attracting and later refereeing 250 submissions.

FedCSIS was organized under the auspices of Prof. Barbara Kudrycka, Minister of Science and Higher Education and Prof. Michał Kleiber, President of Polish Academy of Sciences. It was sponsored by Ministry of Science and Higher Education and Intel.

***Maria Ganzha**, Conference Co-Chair, Systems Research Institute Polish Academy of Sciences, Warsaw, Poland, and Gdańsk University, Gdańsk, Poland.*

***Leszek Maciaszek**, Conference Co-Chair, Wrocław University of Economics, Wrocław, Poland and Macquarie University, Sydney, Australia.*

***Marcin Paprzycki**, Systems Research Institute Polish Academy of Sciences, Warsaw and Management Academy, Warsaw, Poland.*

# Proceedings of the Federated Conference on Computer Science and Information Systems

September 18–21, 2011. Szczecin, Poland

## TABLE OF CONTENTS

---

### 6<sup>TH</sup> INTERNATIONAL SYMPOSIUM "ADVANCES IN ARTIFICIAL INTELLIGENCE AND APPLICATIONS":

---

<b>Call For Papers</b>	<b>1</b>
<b>A Web Statistics based Conflation Approach to Improve Arabic Text Retrieval</b>	<b>3</b>
<i>Farag Ahmed, Andreas Nürnberger</i>	
<b>Improving the predictiveness of ICU medical scales by the method of pairwise comparisons</b>	<b>11</b>
<i>Mohammed Alqarni, Yassen Arabi, Tamar Kakiashvili, Mohammed Khedr, Waldemar W. Koczkodaj, J. Leszek, A. Przelaskowski, K. Rutkowski</i>	
<b>A rough k-means fragile watermarking approach for image authentication</b>	<b>19</b>
<i>Lamiaa M. El Bakrawy, Neveen I. Ghali, Aboul ella Hassanien, Tai-hoon Kim</i>	
<b>Sparse PCA for gearbox diagnostics</b>	<b>25</b>
<i>Anna Bartkowiak, Radosław Zimroz</i>	
<b>CWJess: Implementation of an Expert System Shell for Computing with Words</b>	<b>33</b>
<i>Elham S. Khorasani, Shahram Rahimi, Patel Purvag, Daniel Houle</i>	
<b>Visual Exploration of Cash Flow Chains</b>	<b>41</b>
<i>Jerzy Korczak, Walter Łuszczuk</i>	
<b>Logical Inference in Query Answering Systems Based on Domain Ontologies</b>	<b>47</b>
<i>Juliusz Kulikowski</i>	
<b>Competitive and self-contained gene set analysis methods applied for class prediction</b>	<b>55</b>
<i>Henryk Maciejewski</i>	
<b>Knowledge patterns for conversion of sentences in natural language into RDF graph language</b>	<b>63</b>
<i>Rostislav Miarka, Martin Žáček</i>	
<b>Graph Mining Approach to Suspicious Transaction Detection</b>	<b>69</b>
<i>Krzysztof Michalak, Jerzy Korczak</i>	
<b>Growing Hierarchical Self-Organizing Map for searching documents using visual content</b>	<b>77</b>
<i>Paweł Myszkowski, Bartłomiej Buczek</i>	
<b>Automatic Image Annotation by Image Fragment Matching</b>	<b>83</b>
<i>Mariusz Paradowski, Andrzej Śluzek</i>	
<b>How to predict future in a world of antibody-antigen chromosomes</b>	<b>91</b>
<i>Zbigniew Pliszka, Olgierd Unold</i>	
<b>The Fuzzy Genetic Strategy for Multiobjective Optimization</b>	<b>97</b>
<i>Krzysztof Pytel</i>	

<b>New property for rule interestingness measures</b>	<b>103</b>
<i>Izabela Szczęch, Salvatore Greco, Roman Słowinski</i>	
<b>The Add-Value of Cases on WUM Plans Recommendation</b>	<b>109</b>
<i>Cristina Wanzeller, Orlando Belo</i>	
<b>Problem of website structure discovery and quality valuation</b>	<b>117</b>
<i>Dmitrij Žatuchin</i>	

---

**INTERNATIONAL WORKSHOP ON ARTIFICIAL INTELLIGENCE IN MEDICAL APPLICATIONS:**

---

<b>Call For Papers</b>	<b>123</b>
<b>Identification of Patient Deterioration in Vital-Sign Data using One-Class Support Vector Machines</b>	<b>125</b>
<i>Lei Clifton, David Clifton, Peter Watkinson, Lionel Tarassenko</i>	
<b>Data Mining Research Trends in Computerized Patient Records</b>	<b>133</b>
<i>Payam Homayounfar, Mieczysław Owoc</i>	
<b>A Bezier Curve Approximation of the Speech Signal in the Classification Process of Laryngopathies</b>	<b>141</b>
<i>Krzysztof Pancierz, Jarosław Szkola, Jan Warchol</i>	
<b>Validation of Data Categorization Using Extensions of Information Systems: Experiments on Melanocytic Skin Lesion Data</b>	<b>147</b>
<i>Krzysztof Pancierz, Grzegorz Owsiany, Łukasz Piątek</i>	
<b>Interval based attribute evaluation algorithm</b>	<b>153</b>
<i>Mostafa Salama, Nashwa El-Bendary, Aboul Ella Hassanien, Kenneth Revett, Aly A. Fahmy</i>	
<b>Medical Image Segmentation Using Information Extracted from Deformation</b>	<b>157</b>
<i>Kai Xiao, Neven Ghali, Aboul Ella Hassanien</i>	
<b>Discovering similarities for the treatments of liver specific parasites</b>	<b>165</b>
<i>Pinar Yildirim, Kagan Ceken, Osman Saka</i>	
<b>Reliability Analysis of Healthcare System</b>	<b>169</b>
<i>Elena Zaitseva, Vitaly Levashenko, Miroslav Rusin</i>	

---

**1<sup>ST</sup> INTERNATIONAL WORKSHOP ON ADVANCES IN SEMANTIC INFORMATION RETRIEVAL:**

---

<b>Call For Papers</b>	<b>177</b>
<b>Fuzzy Cognitive Maps Theory for the Political Domain</b>	<b>179</b>
<i>Sameera Alshayji, Nahla Elzant Elkadhi, Zidong Wang</i>	
<b>Building a Model of Disease Symptoms Using Text Processing and Learning from Examples</b>	<b>187</b>
<i>Marek Jaszuk, Grazyna Szostek, Andrzej Walczak, Leszek Puzio</i>	
<b>Query Expansion: Term Selection using the Semantic Relatedness Measure</b>	<b>195</b>
<i>Vitaly Klyuev, Yannis Haralambous</i>	
<b>LTIMEX: Representing the Local Semantics of Temporal Expressions</b>	<b>201</b>
<i>Paweł Mazur, Robert Dale</i>	
<b>Dependency-Based Rules for Grammar Checking with LanguageTool</b>	<b>209</b>
<i>Maxim Mozgovoy</i>	
<b>Preserving pieces of information in a given order in HRR and GA<sub>c</sub></b>	<b>213</b>
<i>Agnieszka Patyk-Łońska</i>	
<b>Some tests on geometric analogues of Holographic Reduced Representations and Binary Spatter Codes</b>	<b>221</b>
<i>Agnieszka Patyk-Łońska, Marek Czachor, Diederik Aerts</i>	

---

**WORKSHOP ON COMPUTATIONAL OPTIMIZATION:**

---

<b>Call For Papers</b>	<b>229</b>
<b>Task Scheduling with Restricted Preemptions</b> <i>Tomasz Baranski</i>	<b>231</b>
<b>A Branch-and-Cut-and-Price Algorithm for a Fingerprint-Template Compression Application</b> <i>Andreas Chwatal, Corinna Thöni, Karin Oberlechner, Günther Raidl</i>	<b>239</b>
<b>Improved asymptotic analysis for SUMT methods</b> <i>Jean-Pierre Dussault</i>	<b>247</b>
<b>Numerical Assessment of Finite Difference Time Domain (FDTD) and Complex-Envelope Alternating-Direction-Implicit Finite-Difference-Time-Domain (CE-ADI-FDTD) Methods</b> <i>Gebriel Gannat</i>	<b>255</b>
<b>Performing Conjoint Analysis within a Logic-based Framework</b> <i>Adrian Giurca, Ingo Schmitt, Daniel Baier</i>	<b>261</b>
<b>Extending the definition of beta-consistent biclustering for feature selection</b> <i>Antonio Mucherino</i>	<b>269</b>

---

**INTERNATIONAL WORKSHOP ON ADVANCES IN BUSINESS ICT:**

---

<b>Call For Papers</b>	<b>275</b>
<b>Formal Verification of Business Processes Represented as Role Activity Diagrams</b> <i>Amelia Badica, Costin Badica</i>	<b>277</b>
<b>Virtualization as an approach in the development of IT system implementation process</b> <i>Iwona Chomiak-Orsa, Wiesława Gryncewicz, Maja Leszczyńska</i>	<b>281</b>
<b>An architecture of a Web recommender system using social network user profiles for e-commerce</b> <i>Damian Fijałkowski, Radostaw Zatoka</i>	<b>287</b>
<b>Geospatial presentation of purchase transactions data</b> <i>Maciej Grzenda, Krzysztof Kaczmarek, Mateusz Kobos, Marcin Luckner</i>	<b>291</b>
<b>Explaining MCDM acceptance: a conceptual model of influencing factors</b> <i>Martina Maida, Konradin Maier, Nikolaus Obwegeser, Volker Stix</i>	<b>297</b>
<b>A Context-Aware Mobile Accessible Electric Vehicle Management System</b> <i>Nils Masuch, Marco Luetzenberger, Sebastian Ahrndt, Axel Hessler</i>	<b>305</b>
<b>NotX Service Oriented Multi-platform Notification System</b> <i>Filip Nguyen, Jaroslav Škrabálek</i>	<b>313</b>
<b>Commonality in Various Design Science Methodologies</b> <i>Lukasz Ostrowski, Markus Helfert</i>	<b>317</b>
<b>A Hybrid Algorithm for Detecting Changes in Diagnostic Signals Received From Technical Devices</b> <i>Tomasz Petech-Pilichowski</i>	<b>321</b>
<b>Adapting Scrum for Third Party Services and Network Organizations</b> <i>Lukasz D. Sienkiewicz, Leszek A. Maciaszek</i>	<b>329</b>
<b>Extending the Descartes Specification Language Towards Process Modeling</b> <i>Joseph Urban, Vinitha Hannah Subburaj, Lavanya Ramamoorthy</i>	<b>337</b>
<b>Influence of search engines on customer decision process</b> <i>Marek Zgódko</i>	<b>341</b>

---

**ADVANCES IN HEALTHCARE INFORMATION TECHNOLOGIES:**

---

<b>1<sup>ST</sup> INTERNATIONAL WORKSHOP ON INTEROPERABLE HEALTHCARE SYSTEMS—CHALLENGES, TECHNOLOGIES, AND TRENDS:</b>	
<b>Call For Papers</b>	<b>345</b>
<b>The Intersection of Clinical Decision Support and Electronic Health Record: A Literature Review</b>	<b>347</b>
<i>Hajar Kashfi</i>	
<b>EMeH: Extensible Mobile Platform for Healthcare</b>	<b>355</b>
<i>Jacek Kobusiński, Maciej Matecki, Krzysztof Stefaniak, Tomasz Biały</i>	
<b>Semantic Interoperability for Infectious Disease Reporting System</b>	<b>363</b>
<i>Murugavell Pandiyan, Osama Elhassan, Zakaria Maamar, Pallikonda Rajasekar</i>	
<b>INTERNATIONAL WORKSHOP ON UBIQUITOUS HOME HEALTHCARE:</b>	
<b>Call For Papers</b>	<b>369</b>
<b>The role of a mobile device in a home monitoring healthcare system</b>	<b>371</b>
<i>Marcin Bajorek, Jędrzej Nowak</i>	
<b>MuSA: a multisensor wearable device for AAL</b>	<b>375</b>
<i>Valentina Bianchi, Ferdinando Grossi, Ilaria De Munari, Paolo Ciampolini</i>	
<b>Intelligent bathroom</b>	<b>381</b>
<i>Adam Bujnowski, Adam Wtorek, Arkadiusz Paliński</i>	
<b>Low-coherence method of hematocrit measurement</b>	<b>387</b>
<i>Małgorzata Jędrzejewska-Szczerska, Marcin Gnyba, Michał Kruczkowski</i>	
<b>Multimodal platform for continuous monitoring of elderly and disabled at home</b>	<b>393</b>
<i>Mariusz Kaczmarek, Jacek Ruminski, Adam Bujnowski</i>	
<b>Design of a wearable sensor network for home monitoring of human behavior</b>	<b>401</b>
<i>Eliasz Kańtoch, Joanna Jaworek, Piotr Augustyniak</i>	
<b>Measuring Pulse Rate with a Webcam—a Non-contact Method for Evaluating Cardiac Activity</b>	<b>405</b>
<i>Magdalena Lewandowska, Jacek Ruminski, Tomasz Kocejko, Jędrzej Nowak</i>	
<b>Pulse pressure velocity measurement—a wearable sensor</b>	<b>411</b>
<i>Mateusz Moderhak, Mariusz Moderhak, Jerzy Wtorek, Bart Truyen</i>	
<b>Analysis of Correlation between Heart Rate and Blood Pressure</b>	<b>417</b>
<i>Artur Polinski, Jacek Kot, Anna Meresta</i>	
<hr/> <b>COMPUTER ASPECTS OF NUMERICAL ALGORITHMS:</b> <hr/>	
<b>Call For Papers</b>	<b>421</b>
<b>The incomplete factorization preconditioners applied to the GMRES(m) method for solving Markov chains</b>	<b>423</b>
<i>Beata Bylina, Jarosław Bylina</i>	
<b>Cache-Aware Matrix Multiplication on Multicore Systems for IPM-based LP Solvers</b>	<b>431</b>
<i>Mujahed Eleyat, Lasse Natvig, Jorn Amundsen</i>	
<b>Object Oriented Model of Generalized Matrix Multiplication</b>	<b>439</b>
<i>Maria Ganzha, Stanislav Sedukhin, Marcin Paprzycki</i>	
<b>Parallel alternating directions algorithm for 3D Stokes equation</b>	<b>443</b>
<i>Ivan Lirkov, Marcin Paprzycki, Maria Ganzha, Paweł Gepner</i>	
<b>GPGPU calculations of gas thermodynamic quantities</b>	<b>451</b>
<i>Igor Mračka, Peter Somora, Tibor Žáčik</i>	

<b>The influence of a matrix condition number on iterative methods' convergence</b>	<b>459</b>
<i>Anna Pызara, Beata Bylina, Jarosław Bylina</i>	
<b>Solving Linear Recurrences on Hybrid GPU Accelerated Manycore Systems</b>	<b>465</b>
<i>Przemysław Stpiczynski</i>	
<b>A multipoint shooting feasible-SQP method for optimal control of state-constrained parabolic DAE systems</b>	<b>471</b>
<i>Krystyn Styczeń, Wojciech Rafajłowicz</i>	
<b>A modified multipoint shooting feasible-SQP method for optimal control of DAE systems</b>	<b>477</b>
<i>Krystyn Styczeń, Paweł Drąg</i>	
<b>On the implementation of stream ciphers based on a new family of algebraic graphs</b>	<b>485</b>
<i>Vasyl Ustimenko, Stanisław Kotorowicz, Urszula Romanczuk</i>	
<b>Implementation of Movie-based Matrix Algorithms on OpenMP Platform</b>	<b>491</b>
<i>Dmitry Vazhenin, Alexander Vazhenin</i>	

---

### 3<sup>RD</sup> INTERNATIONAL SYMPOSIUM ON SERVICES SCIENCE:

---

<b>Call For Papers</b>	<b>495</b>
<b>Learning to Innovate in Distributed Mobile Application Development: Learning Episodes from Tehran and London</b>	<b>497</b>
<i>Neek Alyani, Sara Shirzad</i>	
<b>Configuring services regarding service environment and productivity indicators</b>	<b>505</b>
<i>Michael Becker, Stephan Klingner, Martin Bottcher</i>	
<b>Service quality description—a business perspective</b>	<b>513</b>
<i>Marija Bjekovic, Sylvain Kubicki</i>	
<b>Towards an Interdisciplinary View on Service Science—The Case of the Financial Services Industry</b>	<b>521</b>
<i>Michael Fischbach, Thomas Puschmann, Rainer Alt</i>	
<b>Services Composition Model for Home-Automation peer-to-peer Pervasive Computing</b>	<b>529</b>
<i>Juan A. Holgado-Terriza, Sandra Rodríguez-Valenzuela</i>	
<b>Violation of Service Availability Targets in Service Level Agreements</b>	<b>537</b>
<i>Maurizio Naldi, Loretta Mastroeni</i>	
<b>Orchestration of Service Design and Service Transition</b>	<b>541</b>
<i>Bernd Pfitzinger, Thomas Jestadt</i>	
<b>Service Innovation Capability: Proposing a New Framework</b>	<b>545</b>
<i>Jens Pöppelbuß, Ralf Plattfaut, Kevin Ortbach, Andrea Malsbender, Matthias Voigt, Björn Niehaves, Jörg Becker</i>	
<b>A Framework for Comparing Cloud-Environments</b>	<b>553</b>
<i>Rainer Schmidt</i>	

---

### JOINT AGENT-ORIENTED WORKSHOPS IN SYNERGY:

---

<b>Call For Papers</b>	<b>557</b>
<b>WORKSHOP ON AGENT BASED COMPUTING: FROM MODEL TO IMPLEMENTATION—VIII:</b>	
<b>Call For Papers</b>	<b>559</b>
<b>A methodology for developing component-based agent systems focusing on component quality</b>	<b>561</b>
<i>George Eleftherakis, Petros Kefalas, Evangelos Kehris</i>	

<b>Monitoring Building Indoors through Clustered Embedded Agents</b>	<b>569</b>
<i>Giancarlo Fortino, Antonio Guerrieri</i>	
<b>Multiagent Distributed Grid Scheduler</b>	<b>577</b>
<i>Victor Korneev, Dmitry Semenov, Andrey Kiselev, Boris Shabanov, Pavel Telegin</i>	
<b>Tuning Computer Gaming Agents using Q-Learning</b>	<b>581</b>
<i>Purvag Patel, Norman Carver, Shahram Rahimi</i>	
<b>Developing intelligent bots for the Diplomacy game</b>	<b>589</b>
<i>Sylwia Polberg, Marcin Paprzycki, Maria Ganzha</i>	
<b>Computing Equilibria for Constraint-based Negotiation Games with Interdependent Issues</b>	<b>597</b>
<i>Mihnea Scafes, Costin Badica</i>	
<b>Agent-Oriented Knowledge Elicitation for Modeling the Winning of "Hearts and Minds"</b>	<b>605</b>
<i>Inna Shvartsman, Kuldar Taveter</i>	
<b>5<sup>TH</sup> INTERNATIONAL WORKSHOP ON MULTI-AGENT SYSTEMS AND SIMULATION:</b>	
<b>Call For Papers</b>	<b>609</b>
<b>Multi Agent Simulation for Decision Making in Warehouse Management</b>	<b>611</b>
<i>Massimo Cossentino, Carmelo Lodato, Lopes Salvatore, Patrizia Ribino</i>	
<b>A Multi-Agent Architecture for Simulating and Managing Microgrids</b>	<b>619</b>
<i>Massimo Cossentino, Carmelo Lodato, Salvatore Lopes, Marcello Pucci, Gianpaolo Vitale, Maurizio Cirrincione</i>	
<b>Agent.GUI: A Multi-agent Based Simulation Framework</b>	<b>623</b>
<i>Christian Derksen, Cherif Branki, Rainer Unland</i>	
<b>Minority Game: the Battle of Adaptation, Intelligence, Cooperation and Power</b>	<b>631</b>
<i>Akihiro Eguchi, Hung Nguyen</i>	
<b>Towards a Generic Testing Framework for Agent-Based Simulation Models</b>	<b>635</b>
<i>Onder Gurcan, Oguz Dikenelli, Carole Bernon</i>	
<b>Modeling Agent Behavior Through Online Evolutionary and Reinforcement Learning</b>	<b>643</b>
<i>Robert Junges, Franziska Klügl</i>	
<b>Visualizing Agent-Based Simulation Dynamics in a CAVE—Issues and Architectures</b>	<b>651</b>
<i>Athanasia Louloudi, Franziska Klügl</i>	
<b>SimConnector: An Approach to Testing Disaster-Alerting Systems Using Agent Based Simulation Models</b>	<b>659</b>
<i>Muaz Niazi, Qasim Siddique, Amir Hussain</i>	
<b>A Chemical Inspired Simulation Framework for Pervasive Services Ecosystems</b>	<b>667</b>
<i>Danilo Pianini, Sara Montagna, Mirko Viroli</i>	
<b>BioMASS: a Biological Multi-Agent Simulation System</b>	<b>675</b>
<i>Candelaria Sansores, Flavio Reyes, Hector Gomez, Juan Pavon, Luis Calderon</i>	
<hr/>	
<b>INTERNATIONAL SYMPOSIUM ON MULTIMEDIA APPLICATIONS AND PROCESSING:</b>	
<hr/>	
<b>Call For Papers</b>	<b>683</b>
<b>Robust Digital Watermarking System for Still Images</b>	<b>685</b>
<i>Sergey Anfinogenov, Valery Korzhik, Guillermo Morales-Luna</i>	
<b>Estimating Topographic Heights with the StickGrip Haptic Device</b>	<b>691</b>
<i>Tatiana V. Evreinova, Grigori Evreinov, Roope Raisamo</i>	

<b>Image Indexing by Spatial Relationships between Salient Objects</b>	<b>699</b>
<i>Eugen Ganea, Marius Brezovan</i>	
<b>From icons perception to mobile interaction</b>	<b>705</b>
<i>Chrysoula Gatsou, Anastasios Politis, Dimitrios Zevgolis</i>	
<b>Automatic Speech Recognition for Polish in a Computer Game Interface</b>	<b>711</b>
<i>Artur Janicki, Dariusz Wawer</i>	
<b>Classification of Learners Using Linear Regression</b>	<b>717</b>
<i>Cristian Mihaescu</i>	
<b>Data Centered Collaboration in a Mobile Environment</b>	<b>723</b>
<i>Maciej Panka, Piotr Bala</i>	
<b>Computerized Three-Dimensional Craniofacial Reconstruction from Skulls Based on Landmarks</b>	<b>729</b>
<i>Leticia Carnero Pascual, Carmen Lastres Redondo, Belen Rios Sanchez, David Garrido Garrido, Asuncion Santamaria Galdon</i>	
<b>DCFMS: A Chunk-Based Distributed File System for Supporting Multimedia Communication</b>	<b>737</b>
<i>Cosmin Marian Poteras, Constantin Petrisor, Mihai Mocanu, Cristian Marian Mihaescu</i>	
<b>Automatic classification of gestures: a context-dependent approach</b>	<b>743</b>
<i>Mario Refice, Michelina Savino, Michele Caccia, Michele Adduci</i>	
<b>Concurrency control for a Multimedia Database System</b>	<b>751</b>
<i>Cosmin Stoica Spahiu</i>	
<b>Automated annotation system for natural images</b>	<b>755</b>
<i>Liana Stanescu</i>	
<b>Fuzzy UML and Petri Nets Modeling Investigations on the Pollution Impact on the Air Quality in the Vicinity of the Black Sea Constanta Romanian Resort</b>	<b>763</b>
<i>Elena-Roxana Tudoroiu, Adina Astilean, Tiberiu Letia, Gabriela Neacsu, Zoltan Maroszy, Nicolae Tudoroiu</i>	
<b>Pass-Image Authentication Method Tolerant to Video-Recording Attacks</b>	<b>767</b>
<i>Hirakawa Yutaka, Hiroyuki Take, Kazuo Ohzeki</i>	
<hr/>	
<b>RISKS AWARENESS AND MANAGEMENT THROUGH SMART SOLUTIONS:</b>	
<hr/>	
<b>Call For Papers</b>	<b>775</b>
<b>Enhancing DNS Security using Dynamic Firewalling with Network Agents</b>	<b>777</b>
<i>Joao Afonso, Pedro Veiga</i>	
<b>Enhanced CakES representing Safety Analysis results of Embedded Systems</b>	<b>783</b>
<i>Yasmin I. Al-Zokari, Daniel Schneider, Dirk Zeckzer, Liliana Guzman, Yarden Livnat, Hans Hagen</i>	
<b>Integrated management of risk information</b>	<b>791</b>
<i>José Barateiro, José Borbinha</i>	
<hr/>	
<b>3<sup>RD</sup> WORKSHOP ON ADVANCES IN PROGRAMMING LANGUAGES:</b>	
<hr/>	
<b>Call For Papers</b>	<b>799</b>
<b>Implementation of a Domain-Specific Language EasyTime using LISA Compiler Generator</b>	<b>801</b>
<i>Iztok Jr. Fister, Marjan Mernik, Iztok Fister, Dejan Hrnčič</i>	
<b>Using Aspect-Oriented State Machines for Resolving Feature Interactions</b>	<b>809</b>
<i>Tom Dinkelaker, Mohammed Erradi</i>	
<b>Domain-Specific Modeling in Document Engineering</b>	<b>817</b>
<i>Verislav Djukic, Ivan Luković, Aleksandar Popovic</i>	

<b>A MOF based Meta-Model of IIS* Case PIM Concepts</b>	<b>825</b>
<i>Milan Čeliković, Ivan Luković, Slavica Aleksić, Vladimir Ivančević</i>	
<b>Memory Safety and Race Freedom in Concurrent Programming Languages with Linear Capabilities</b>	<b>833</b>
<i>Niki Vazou, Michalis Papakyriakou, Nikolaos Papaspyrou</i>	
<b>Decomposition of SBQL Queries for Optimal Result Caching</b>	<b>841</b>
<i>Piotr Cybula, Kazimierz Subieta</i>	
<b>Automated Conversion of ST Control Programs to Why for Verification Purposes</b>	<b>849</b>
<i>Jan Sadolewski</i>	
<b>Implementing Attribute Grammars Using Conventional Compiler Construction Tools</b>	<b>855</b>
<i>Daniel Rodriguez Cerezo, Antonio Sarasa Cabezuelo, Jose Luis Sierra Rodriguez</i>	
<b>The embedded left LR parser</b>	<b>863</b>
<i>Bostjan Slivnik</i>	
<b>Nonlinear Tree Pattern Pushdown Automata</b>	<b>871</b>
<i>Jan Travnicek, Jan Janoušek, Borivoj Melichar</i>	
<b>A Type and Effect System for Implementing Functional Arrays with Destructive Updates</b>	<b>879</b>
<i>Georgios Korfiatis, Michalis Papakyriakou, Nikolaos Papaspyrou</i>	
<b>Checking the Conformance of Grammar Refinements with Respect to Initial Context-Free Grammars</b>	<b>887</b>
<i>Bryan Temprado Battad, Antonio Sarasa Cabezuelo, Jose Luis Sierra Rodriguez</i>	
<b>Identification of Patterns through Haskell Programs Analysis</b>	<b>891</b>
<i>Jan Kollar, Sergej Chodarev, Emilia Pietrikova, Lubomir Wassermann</i>	
<b>Computer Language Notation Specification through Program Examples</b>	<b>895</b>
<i>Miroslav Sabo, Jaroslav Porubán, Dominik Lakatoš, Michaela Kreutzová</i>	
<b>Tree Indexing by Pushdown Automata and Repeats of Subtrees</b>	<b>899</b>
<i>Tomas Flouri, Jan Janoušek, Borivoj Melichar, Costas Iliopoulos, Solon Pissis</i>	
<b>Subtree Oracle Pushdown Automata for Ranked and Unranked Ordered Trees</b>	<b>903</b>
<i>Martin Plicka, Jan Janoušek, Borivoj Melichar</i>	
<b>Semi-Automatic Component Upgrade with RefactoringNG</b>	<b>907</b>
<i>Zdeněk Troníček</i>	
<b>Extension of Iterator Traits in the C++ Standard Template Library</b>	<b>911</b>
<i>Norbert Pataki, Zoltán Porkoláb</i>	
<hr/>	
<b>3<sup>RD</sup> WORKSHOP ON SOFTWARE SERVICES: SEMANTIC-BASED SOFTWARE SERVICES:</b>	
<hr/>	
<b>Call For Papers</b>	<b>915</b>
<b>Search-Based Testing, the Underlying Engine of Future Internet Testing</b>	<b>917</b>
<i>Arthur Baars, Kiran Lakhota, Tanja E. J. Vos, Joachim Wegener</i>	
<b>Testing and Remote Maintenance of Real Future Internet Scenarios, Towards FITTEST and FastFix Advanced Software Engineering</b>	<b>925</b>
<i>Alessandra Bagnato, Anna Esparcia Alcazar, Tanja E. J. Vos, Beatriz Marin, José Oliver Murillo, Salvador I. Folgado, Auxiliadora Carlos Alberola</i>	
<b>A Neural Model for Ontology Matching</b>	<b>933</b>
<i>Emil Stefan Chifu, Ioan Alfred Letia</i>	
<b>An Adaptive Virtual Machine Replication Algorithm for Highly-Available Services</b>	<b>941</b>
<i>Adrian Coleșa, Mihai Bica</i>	

<b>Service Modelling for Internet of Things</b>	<b>949</b>
<i>Suparna De, Payam Barnaghi, Martin Bauer, Stefan Meissner</i>	
<b>Self-Healing Approach in the FastFix Project</b>	<b>957</b>
<i>Benoit Gaudin, Mike Hinchey</i>	
<b>Autonomic Execution of Computational Workflows</b>	<b>965</b>
<i>Tomasz Haupt, Nitin Sukhija, Igor Zhuk</i>	
<b>An Analysis of mOSAIC ontology for Cloud Resources annotation</b>	<b>973</b>
<i>Francesco Moscato, Rocco Aversa, Beniamino Martino, Teodor-Florin Fortis, Victor Munteanu</i>	
<b>Multi-Agent Architecture for Solving Nonlinear Equations Systems in Semantic Services Environment</b>	<b>981</b>
<i>Victor Ion Munteanu, Cristina Mindruta, Viorel Negru, Calin Sandru</i>	
<b>Cloud-based Assistive Technology Services</b>	<b>985</b>
<i>Ane Murua, Igor González, Elena Gómez-Martínez</i>	
<b>Semantic P2P Search engine</b>	<b>991</b>
<i>Ilya Rudomilov, Ivan Jelinek</i>	
<b>Hybrid Immune-inspired Method for Selecting the Optimal or a Near-Optimal Service Composition</b>	<b>997</b>
<i>Ioan Salomie, Monica Vlad, Viorica Rozina Chifu, Cristina Bianca Pop</i>	
<b>Dynamic Consolidation Methodology for Optimizing the Energy Consumption in Large Virtualized Service Centers</b>	<b>1005</b>
<i>Cioara Tudor, Ionut Anghel, Ioan Salomie, Daniel Moldovan, Georgiana Copil, Pierluigi Plebani</i>	

# 6<sup>th</sup> International Symposium Advances in Artificial Intelligence and Applications

CELEBRATING 65TH BIRTHDAY OF PROFESSOR BOHDAN MACUKOW

THE AAIA'11 will bring researchers, developers, practitioners, and users to present their latest research, results, and ideas in all areas of artificial intelligence. We hope that theory and successful applications presented at the AAIA'10 will be of interest to researchers and practitioners who want to know about both theoretical advances and latest applied developments in Artificial Intelligence. As such AAIA'11 will provide a forum for the exchange of ideas between theoreticians and practitioners to address the important issues.

Papers related to theories, methodologies, and applications in science and technology in this theme are especially solicited. Topics covering industrial issues/applications and academic research are included, but not limited to:

- Knowledge management
- Decision Support System
- Approximate Reasoning
- Fuzzy modeling and control
- Data Mining
- Web Mining
- Machine learning
- Combining multiple knowledge sources in an integrated intelligent system
- Neural Networks
- Evolutionary Computation
- Nature Inspired Methods
- Natural Language processing
- Image processing and understanding (interpretation)
- Applications in Bioinformatics
- Hybrid Intelligent Systems
- Granular Computing
- Architectures of intelligent systems
- Robotics
- Real-world applications of Intelligent Systems

## PROGRAM COMMITTEE

**Janos Abonyi**, University of Pannonia, Hungary

**Ajith Abraham**, Machine Intelligence Research Labs, USA

**Hans Jorgen Andersen**, Aalborg University, Denmark

**Jaroslav Arabas**, Warsaw University of Technology, Poland

**Mohammad Azzeh**, Applied Science Private University, Jordan

**Valentina Emilia Balas**, Aurel Vlaicu University of Arad, Romania

**Anna Bartkowiak**, Wrocław University, Poland

**Roberto Basili**, University of Roma, Italy

**Bernhard Beckert**, University of Koblenz-Landau, Germany

**Francesco Bergadano**, University of Torino, Italy

**Jerzy Blaszczynski**, Poznan University of Technology, Poland

**Sheryl Brahnam**, Missouri State University, USA

**Minhua Eunice Ma**, The Glasgow School of Art, UK

**Min Cai**, Oklahoma State University

**Giovanna Castellano**, University of Bari, Italy

**Ryszard Choras**, Institute of Telecommunications, Poland

**Alfredo Cuzzocrea**, University of Calabria, Italy

**Jeremiah Da Deng**, University of Otago, New Zealand

**Krzysztof Dembczyński**, Poznan University of Technology, Poland

**Włodzisław Duch**, Nicolaus Copernicus University, Poland

**Krzysztof Goczyla**, Gdańsk University of Technology, Poland

**Zdzisław Hippe**, University of Information Technology and Management in Rzeszów, Poland

**Elżbieta Hudyma**, Wrocław University of Technology, Poland

**Lim-Joo Hwee**, Nanyang Technological University, Singapore

**Giancarlo Iannizzotto**, University of Messina, Italy

**Jerzy W. Jaromczyk**, University of Kentucky, USA

**Piotr Jędrzejowicz**, Gdynia Maritime University, Poland

**Jerzy Józefczyk**, Wrocław University of Technology, Poland

**Janusz Kacprzyk**, Polish Academy of Sciences, Poland

**Radosław Katarzyniak**, Wrocław University of Technology, Poland

**Przemysław Kazienko**, Wrocław University of Technology, Poland

**Etienne Kerre**, University of Gent, Belgium

**Jacek Kluska**, Rzeszów University of Technology, Poland

**Waldemar Koczkodaj**, Laurentian University, Canada

**Mieczysław M. Kokar**, Northeastern University, USA

**Yiannis Kompatsiaris**, Informatics and Telematics Institute, Greece

**Józef Korbicz**, University of Zielona Góra, Poland

**Adam Krzyzak**, Concordia University, Canada

**Juliusz Lech Kulikowski**, Polish Academy of Sciences, Poland

**Rory Lewis**, University of Colorado at Colorado Springs, USA

**Penousal Machado**, University of Coimbra, Portugal

**Jacek Mandziuk**, Warsaw University of Technology, Poland

**Victor Marek**, University of Kentucky, USA

**Radek Matousek**, Brno University of Technology, Czech Republic

**Zbigniew Michalewicz**, University of Adelaide, Australia

**Łukasz Mirosław**, Wrocław University of Technology, Poland

**Pawel Myszkowski**, Wrocław University of Technology, Poland

**Ngoc-Thanh Nguyen**, Wrocław University of Technology, Poland

**Marek Ogiela**, AGH University of Science and Technology, Poland

**Mariusz Paradowski**, Wrocław University of Technology, Poland

**Witold Pedrycz**, University of Alberta, Canada

**Marco Porta**, University of Pavia, Italy

**Tapani Raiko**, Aalto University, Finland

**Sheela Ramanna**, University of Winnipeg, Canada

**Zbigniew Ras**, University of North Carolina, USA

**Jan Rauch**, University of Economics, Prague, Czech Republic

**Izabela Rejer**, West Pomeranian University of Technology, Poland

**Paolo Rosso**, Universidad Politécnica Valencia, Spain

**Khalid Saeed**, AGH University of Science and Technology, Poland

**Abdel-Badeeh Salem**, Ain Shams University, Egypt

**Jerzy Sas**, Wrocław University of Technology, Poland

**Mika Sato-Ilic**, University of Tsukuba, Japan

**Christelle Scharff**, Pace University, USA

**Lothar Schmitt**, University of Aizu, Japan

**Abstract**—We present a language independent approach for conflation that does not depend on predefined rules or prior knowledge of the target language. The proposed unsupervised method is based on an enhancement of the pure  $n$ -gram model that is used to group related words based on a revised string-similarity measure. In order to detect and eliminate terms that are created by this process, but that are most likely not relevant for the query (“noisy terms”), an approach based on mutual information scores computed based on web statistical co-occurrences data is proposed. Furthermore, an evaluation of this approach is presented.

## I. INTRODUCTION

ARABIC is a Semitic language that is based on the Arabic alphabet containing 28 letters. Its basic feature is that most of its words are built up from, and can be analyzed down to common roots. The exceptions to this rule are common nouns and particles. Arabic is a highly inflectional language with 85% of words derived from trilateral roots. Nouns and verbs are derived from a closed set of around 10,000 roots [1]. Arabic has three genders, feminine, masculine, and neuter; and three numbers, singular, dual, and plural.

The specific characteristics of Arabic morphology make the Arabic language particularly difficult for developing natural language processing methods for Information Retrieval (IR). Arabic is different from English and other Indo-European languages with respect to a number of important aspects: words are written from right to left; it is mainly a consonantal language in its written forms, i.e., it excludes vowels; its two main parts of speech are the verb and the noun in that word order, and these consist, for the main part, of trilateral roots (three consonants forming the basis of noun forms that are derived from them); it is a morphologically complex language, in that it provides flexibility in word formation: as briefly mentioned above, complex rules govern the creation of morphological variations, making it possible to form hundreds of words from one root [2]. Furthermore, the letter shapes are changeable in form, depending on the location of the letter at the beginning, middle or at the end of the word.

One of the main problems we face when indexing and retrieving unstructured text is the variations in word forms. These variations result from the morphological variants, for example in English, verb forms like walk, walked, walking. In the Arabic language, the variations are even more abundant

and a word can sometimes be represented by more than 100 different forms. These variation in word forms results from the fact that Arabic nouns and verbs are heavily prefixed. The definite article *al* “the” is always attached to nouns, and many conjunctions and prepositions are also attached as prefixes to nouns and verbs, hindering the retrieval of morphological variants of words. In Table I some word form variations for the word “student” is presented in order to clarify this issue. The absence of these word form variations in the user query causes a loss of vast amounts of retrieved information. One way to tackle such problems are conflation methods. Conflation is a general term for all processes of merging together nonidentical words that refer to the same principal concept, i.e., merging words that belong to the same meaning class. The primary goal of conflation is to allow matching of different variants of the same word. In natural language processing, conflation is the process of merging or lumping together nonidentical words that refer to the same principal concept. In the context of information retrieval (IR), conflation has a more restricted meaning and usually refers to the process of grouping together morphological variants of the same or related words [3]. Since the variants have similar semantics, it is possible to consider them as equivalent for the purpose of the retrieval tasks. Applying conflation approaches in morphologically complex languages, such as Arabic, improves the retrieval effectiveness and frees the users from taking into account all variants of the same word. Therefore, conflation approaches can be quite beneficial in many fields such as information retrieval and word-processing systems. In order to solve or at least alleviate some of the problems raised by a high inflectional morphology, the stem of the word need to be detected. There are two, widely used, stemming approaches: First, approaches that are language dependent and designed to handle morphological variants. In stemming, morphological variants are reduced to common basic form called root, and second, string-similarity approaches i.e ( $n$ -gram), which are (usually) language independent and designed to handle all types of word variants. In this paper, the proposed approach is based on the enhancement of the  $n$ -gram pure approach therefore we will focus in describing the  $n$ -gram approach in more detail with respect to the Arabic language.

TABLE I  
WORD FORM VARIATIONS FOR طالب *ālb* (STUDENT).

Feminine	Masculine	English
طالبة <i>ālbh</i>	طالب <i>ālb</i>	student
الطالبة <i>ālālbh</i>	الطالب <i>ālālb</i>	the student
طالبتان <i>ālbīān</i>	طالبان <i>ālbān</i>	(two) students(dual)
بِطالبة <i>biālbh</i>	بِطالب <i>biālb</i>	by student
بِطالبة <i>bālbh</i>	بِطالب <i>bālb</i>	by the student
وطالبة <i>wālbh</i>	وطالب <i>wālb</i>	and student
والطالبة <i>wālālbh</i>	والطالب <i>wālālb</i>	and the student
إِطالبة <i>īālbh</i>	إِطالب <i>īālb</i>	to the, for a student
إِطالبة <i>īālbhā</i>	إِطالبة <i>īālbh</i>	his student
إِطالبة <i>īālbhā'</i>	إِطالبة <i>īālbhā</i>	her student
إِطالبة <i>īālbāh</i>	إِطالبة <i>īālbh</i>	his students
إِطالبة <i>īālbāhā'</i>	إِطالبة <i>īālbhā</i>	her students

## II. CONFLATION TECHNIQUES

Conflation algorithms can be categorized into four main classes: affix removal, table lookup, successor variety, and  $n$ -gram [4]. Affix-removal algorithms reduce a word to its morphological root or a stable stem by stripping off suffixes and prefixes in order to determine the stem. They are the most popular group of conflation algorithms, mainly due to the work of [5] and [6]. In the table-lookup approach, all desired stems for a particular surface-form word are stored in a table. Therefore, this approach can be implemented in a computationally efficient manner, since no word transformation is needed. However, one of the main drawbacks is that due to its manual creation usually not all words and word forms can be covered and thus table-lookup approaches are in most cases domain-dependent. The successor-variety approach was first introduced by Hafer and Weiss (1974) [7]. In successor variety, a lexical text is segmented into stems and affixes. The method uses statistical properties-successor and predecessor variety counts-of a corpus, in order to identify the root [8]. The idea is to count the number of different letters encountered after (or before, respectively), a part of a word and to compare it to the counts before and after that position. Morpheme boundaries are then likely to occur at sudden peaks or increases of that value [9].

In the following, we describe two main approaches (Stemmer and  $n$ -gram) which are used to solve or at least alleviate some of the problems raised by a high inflectional morphology.

### A. Stemmer Approaches

In information retrieval systems stemming is used to reduce variant word forms to common roots and thereby improve the ability of the system to match query and document vocabulary [10]. Although stemming has been studied mainly for English, stemming approaches have also been developed for several other languages .e.g., Latin [11], Indonesian [12], Swedish [13], Dutch [14], German [15] and Arabic [16]. There are three main types of approaches for stemming, dictionary-based, rule-based, and statistical-based (mainly  $n$ -gram based) approaches [17].

*Dictionary-based approaches* provide very good results at the cost of high development efforts for the dictionary. The dictionary contains all known words with their inflection forms. The main weakness for this approach is the missing words in the dictionary which would not be recognized by the system for stemming. Another weakness is the inability of this method to stem inert names and foreign words. Also the need to process a large dictionary during runtime can result in high requirements for storage space and processing time. The closest Arabic equivalent for this kind of stemmer is the *root-based stemmer* for Arabic [18] which is based on extracting the root of a given Arabic surface word by stripping off all attached prefix and/or suffix then attempt to extract the root of it. Several morphological analyzers were developed based on this concept [19], [18]. The weaknesses of this stemmer is that the construction of the corresponding dictionaries or rules is a tedious and labor-intensive task due to the result of the morphology complexity of Arabic language. Another problem is that only some small linguistic resources are available for Arabic language. The second type are the *rule-based approaches*. They are based on set of predefined conditions rules. The most well known stemmer of this type is Porter stemmer [5]. The main weakness for this stemmer is that building the rules for the arbitrary language is time consuming. Furthermore, there is a need for experts with linguistic knowledge in that particular language. The Arabic equivalent for this is the *Light stemmer* [16]. Unlike English, both prefixes and suffixes need to be removed for effective stemming. it is based on stripping off prefix and suffix from the word, it uses predefined list of prefix and suffix, it is simply stripping off prefix and/or suffix without any further processing in the rest of the stemmed word [20], [16]. The weakness of this stemmer is that the stripping off prefixes or suffix in Arabic is a not an easy task. Removing them can lead to unexpected results, as many words start with one letter or more which can mistakenly assumed to be prefix or suffix.

## III. $n$ -GRAM

The main idea of  $n$ -gram-based approaches, which groups together words that contain identical character substrings of length  $n$ , called  $n$ -grams, is that the character structure of the word can be used to find semantically similar words and word variants.  $n$ -gram, as a conflation technique, differs from stemmers in that they do not require language knowledge, predefined rules, or a vocabulary database. Furthermore,  $n$ -gram approaches take into account misspelled and transliterated words <sup>1</sup>. For example, Table II shows 15 different spellings for the name Condoleezza; four of them were found in the same news web site ( 'CNN-Arabic') <sup>2</sup>.

### A. $n$ -gram and Arabic Text

Over the last years, several studies, which explore the use of  $n$ -grams for processing Arabic text, have been performed.

<sup>1</sup>Transliteration is the process of converting one orthography from one language into another.

Mayfield et al. (2001) have found that  $n$ -grams work well in many languages. Furthermore, they investigated the use of character  $n$ -grams for Arabic retrieval in TREC-2001 and found that  $n$ -grams of length 4 were most effective [21]. Darwish and Oard examined multiple tokenization strategies for retrieval of scanned Arabic documents. They found that  $n$ -grams of size  $n = 3$  or  $n = 4$  are well suited to Arabic document retrieval [22]. Mustafa (2004) assessed the overall performance of two  $n$ -gram techniques that he called conventional and hybrid. In his results, Mustafa pointed out that the hybrid approach outperforms the conventional approach [23]. However, all of the previous studies rely on studying the use of  $n$ -gram on the Arabic text based on the following aspects: The effectiveness of  $n$ -gram size and assessing the performance of existing  $n$ -gram approaches. None of the prior studies attempt to modify the pure  $n$ -gram model, so that it also considers language characteristics, while computing the similarity score, in order to improve its performance. Ghaoui et al. (2005) investigated a new morphological class based language model. They used the Morphological rules to derive the different words in a class from their stem. Furthermore, a linear interpolation between the  $n$ -gram model and the morphological model has been evaluated. In their experiments they pointed out that morphological class-based model yields poor performance compared to a classical trigram [24]. The performance of the  $n$ -gram in Arabic text has been studied by many researchers. For example, Abu-Salem (2004) found that all of the proposed  $n$ -gram methods outperform the Word, Stem, and Root index methods [25]. We would like to emphasize again, that none of the prior studies attempted to modify the pure  $n$ -gram model, such that it also considers language characteristics while computing the similarity score, in order to improve its performance. All of the previous studies considered only to investigate the performance on Arabic text based on the effectiveness of  $n$ -gram size using existing  $n$ -

gram approaches. Due to the mentioned insufficiencies of the existing approaches, we propose a "revised"  $n$ -gram algorithm that makes it possible to handle one-character infixes, prefixes, and suffixes, which are frequent in Arabic. The proposed method obtained superior results on a large newspaper corpus.

### B. Computing Similarity Scores Based on $n$ -grams

The  $n$ -gram model can be used to compute the similarity between two strings by counting the number of similar  $n$ -grams they share. The more similar  $n$ -grams between two strings exist, the more similar they are. Based on this idea the similarity coefficient can be derived. The similarity coefficient  $\delta$  is defined by the following equation:

$$\delta = \frac{|\alpha \cap \beta|}{|\alpha \cup \beta|} \quad (1)$$

where  $\alpha$  and  $\beta$  are the  $n$ -gram sets for two words  $a$  and  $b$  to be compared.  $\alpha \cap \beta$  denotes the number of similar  $n$ -grams in  $\alpha$  and  $\beta$ , and  $\alpha \cup \beta$  denotes the number of unique  $n$ -grams in the union of  $\alpha$  and  $\beta$ .

## IV. THE PROPOSED APPROACH

We successfully used our revised  $n$ -gram approach for the conflation task in [26]. However, the revised  $n$ -gram approach in some cases expanded the user query with terms not relevant for the query ("noisy terms"). Here in this paper, we propose an approach, based on computed mutual information scores, based on web statistical co-occurrences data, in order to detect and eliminate such noisy terms.

In the following, we describe first in Section IV-A our algorithm based on the enhancement of the  $n$ -gram model, in order to expand the user query with relevant terms; then in Section IV-B, the approach to eliminate any potentially generated noisy terms based on mutual information scores computed on corpora or web based co-occurrence statistics is presented. The  $n$ -gram based approach assumes two strings are alike based only on a string similarity comparison: the more  $n$ -grams existing between two strings, the more similar they are. However, there are many words that are have a very similar text pattern but a quite different meaning. Therefore, we improved our  $n$ -gram approach by eliminating such noisy terms that could have been generated. This is done by computing the cohesion score between all revised  $n$ -gram generated expanded terms using the mutual information ( $MI$ ) measure. The term/terms that have a lower  $MI$  score than the  $MI$  score mean for all expanded terms can be considered as noisy term/terms and thus will be eliminated.

### A. Revised $n$ -gram Approach

Arabic nouns and verbs are heavily prefixed and suffixed as described in the first section. As a result, it is possible to have words with different lengths that share the same principal concept. Furthermore, the pure  $n$ -gram based approach to compute the similarity coefficient as described above (see Eq. (1)) does not consider the order of the  $n$ -grams in the target word [27]. This increases the probability that the matching

score between two strings will be higher even though they do not share the same concept. Therefore, we revised the computation of the similarity between words to take these two aspects into account. For simplicity, we describe our algorithm for  $n = 2$  (bigrams). However, the approach can be applied for trigrams and  $n$ -grams with  $n > 3$  as well. We define bigrams of words by their respective position in the word  $w_{i,i+(n-1)}$  where  $i$  defines the position of the first letter and  $i + (n - 1)$  the position of the last letter of the considered  $n$ -gram. Thus, the last possible position of an  $n$ -gram, in a word, is defined by  $j = |w| - n + 1$  where  $|w|$  defines the length of the word. In order to deal with the first and second aspect mentioned above, we define a window of  $n$ -grams of the target candidate words that should be compared, i.e., while in Eq. (1) all  $n$ -grams are compared with each other, we only compare  $n$ -grams that are in close proximity to the position of the  $n$ -gram in the word to be compared when computing the similarity score.

Overall, the computation of the similarity score  $S$  for a given  $n$ -gram size  $n$  and a given odd-numbered window size  $m$  can be defined as follows. Assuming that  $u$  is the longer word (if  $v$  is longer than  $u$  then  $u$  and  $v$  can be simply exchanged):

$$S_{n,m}(u, v) = \frac{\sum_{i=2}^{|u|-n+1} \sum_{j=\frac{m-1}{2}}^{\frac{m-1}{2}} g(u_{i,i+(n-1)}, v_{i+j,i+j+(n-1)})}{N} \quad (2)$$

$$\text{where } g(a, b) = \begin{cases} 1 & \text{if } a = b \\ 0 & \text{otherwise.} \end{cases} \quad \text{and}$$

$$u_{i,j} = \begin{cases} \text{substring}(u, i, j) & \text{if } i \leq j \\ \text{""} & \text{otherwise.} \end{cases}$$

Here,  $u$  and  $v$  are the words to be compared, the nested sum counts the number of  $n$ -grams in  $v$  that are similar to  $n$ -grams in a window the size of  $m$  around the same position in word  $v$ .  $N$  is computed similarly as in Eq. (1).

### B. Mutual Information (MI)

Given a query, the set of possible expanded terms using the revised  $n$ -gram will be generated; the coherence between the expanded terms is computed based on mutual information (MI). Giving a source of data, Mutual Information (MI) is a measure to calculate the correlation between terms in specific space (corpus or web). MI based approaches have been used often in word sense disambiguation task e.g., [28], [29]. Here in this paper mutual information approach is used to detect the noise term/terms based on its correlation with other terms in web.

Given a query term  $q_i = \{t_1, t_2, \dots, t_n\}$  and a set of its revised  $n$ -gram model generated expanded terms  $\{ext_{i,1}, ext_{i,2}, \dots, ext_{i,m_i}\}$ , where  $m_i$  defines the number of extended terms for  $t_i$  and  $1 \leq i \leq n$ . Given the set of  $\frac{n(n-1)}{S}$  combinations, where  $S$  is the size of each combinations set, then the set of combinations between all expanded terms is defined as  $Com_i = \{\{ext_{i,j}, ext_{i,k}\} | 1 \leq j < n, j < k \leq n\}$ . The mutual information of each combination set can be

computed based on the following equation:

$$MI(q_{t_1}, q_{t_2}) = \log_2 \frac{p(q_{t_1}, q_{t_2})}{p(q_{t_1})p(q_{t_2})} \quad (3)$$

where  $p(q_{t_i}, q_{t_j})$  being the joint probability of both expanded terms in the combination sets to occur in web. The probability is estimated by the relative frequency of the expanded terms in a given corpus, here the web, i.e., it is estimated by how many times  $q_{t_i}, q_{t_j}$  occur together in a (web) document.

### C. A Walk Through Example

To illustrate the improvement of the revised  $n$ -gram algorithm using the statistical co-occurrences data obtained from web, let us consider the following example.

The user submit the query صحيفة *shyfh* (Newspaper), the system using the revised  $n$ -gram model with similarity threshold of 60% expanded the user query with the following terms: (بصحيفة *bshyfh* "by Newspaper", وصحيفة *wshyfh* "and Newspaper", الصحيفة *alshyfh* "for the Newspaper", نحيفة *nhyfh* ("slim" Feminine) and الصحيفة *alshyfh* "for a Newspaper". The algorithm starts by generating all possible combinations between the expanded terms where  $Com_i = \{\{ext_{i,j}, ext_{i,k}\} | 1 \leq j < 5, j < k \leq 5\}$ . After generating all possible combinations between the expansion terms, the mutual information score for each expansion term combination will be calculated based on Eq. (3). Table III illustrates possible expanded term combinations and their mutual information score. As shown in Table III, one of the expanded term combinations included the expanded term نحيفة *nhyfh* "slim". It has the lowest mutual scores (23.793, 23.790, 23.165 and 21.314).

As shown in Table IV, the same expanded term has the lowest MI average score (23.015), which is below the MI score mean (25.456), and thus will be classified by the proposed approach as a noisy term and will be eliminated. In contrast, all other expanded terms have an average mutual score, which is above the MI score mean and thus should be correct expanded terms for the user's query.

## V. EVALUATION

In our evaluation, we compared our Revised  $n$ -gram and (revised  $n$ -gram + MI) approaches with the pure  $n$ -gram and edit distance approaches. We used  $n = 2$  (bigrams) to enable retrieval of short words, as well as other word lengths. In order, to gain a certain degree of accuracy, we obtained the

TABLE III  
EXPANDED TERM COMBINATIONS AND THEIR *MI* SCORES.

Expanded Terms Combinations	<i>MI</i> Score
(صحيفة و صحيفه , الصحيفة الصحيفه ) "and Newspaper, for the Newspaper"	28.651
(الصحيفة الصحيفه , الصحيفة الصحيفه ) "for the Newspaper, for a Newspaper"	28.075
(بصحيفة الصحيفه , الصحيفة الصحيفه ) "by Newspaper, for a Newspaper"	27.054
(صحيفة و صحيفه , الصحيفة الصحيفه ) "and Newspaper, for a Newspaper"	27.047

(صحيفة نحيفة ) "slim"	23.015

statistical co-occurrence data needed for the *MI* algorithm, from the web, using the yahoo search engine <sup>3</sup>.

#### A. Data Selection

In order to create the lists of expanded terms for each test query, we crawled the Web for articles published on one popular Arabic news Web site (CNN-Arabic)<sup>4</sup> in the period from January 2002 to March 2007. We obtained 5,792 Arabic documents, all of which are abstracts of articles on politics, sports, art, economy, and information science (size 60 MB). The approaches were evaluated against 500 queries that were formulated randomly, ensuring that the length of the query terms vary and short as well as long query terms are included. In order to construct the random queries, the algorithm requires the availability of a lexicon of terms that were extracted from the test data.

#### B. Comparison of Conflation Approaches and Web Experiment

To evaluate the proposed approaches, we used Precision and Recall. Precision and Recall are measures used to evaluate the performance of information retrieval (IR) approaches. Precision is the number of relevant documents retrieved divided by the total number of documents retrieved. Recall is the number of relevant documents retrieved divided by the total number of existing relevant documents in the data collection that should have been retrieved.

As table VI shows, in the first experiment, we calculated the average precision (based on the randomly selected 500 queries) for the pure trigram, edit distance, revised bigram and

(revised bigram + *MI*) for the similarity thresholds of 60, 65, 70, 75, 80, 85, 90, and 95% (Table VI shows the precision average). The trigram approaches (pure and revised) achieved higher precision than the revised bigram approach but in the same time it achieved lower recall than the revised bigram as it will be shown next in this section. The revised bigram precision was improved by 3.3% using mutual information approach based on statistical data obtained from web.

For the second experiment, we estimated the average recall and F-measure for a sample of 30 queries out of 500. The query terms were selected in the same way as described in Section V-A. For all queries, the number of relevant documents were obtained manually, by selecting all possible word variations (due to this huge manually work we could only provide this data for 30 queries). We obtained the precision, recall and F-Measure using five conflation approaches pure-trigram, pure-bigram, edit distance, revised-bigram and (revised-bigram + *MI*). As shown in Table V the revised bigram approach gained a higher F-measure of up to 84% compared to the pure trigram, pure bigram, and edit-distance approaches. These results show that the revised *n*-gram has gained an overall higher degree of retrieval performance than the pure *n*-gram and edit-distance approaches. As Table V shows, the revised bigram and pure trigram approaches have very similar precision, but the pure trigram approach missed many relevant documents and therefore has a lower average recall than the revised bigram approach.

The pure bigram approach has similar recall compared to the revised bigram approach. The pure bigram approach has lower precision since it does not take into account the order of the *n*-grams and therefore it is possible that many irrelevant

<sup>4</sup>http://arabic.cnn.com/

Fig. 1. Average recall for pure trigram, edit distance, pure bigram, revised bigram and (revised bigram +  $MI$ ) approaches (sorted by recall value).

documents will be retrieved. The approach using edit distance has lower precision. This is due to the fact that this method does not take into account the relationship between characters in the compared words as the  $n$ -gram approaches do. Figure 1 illustrates that the revised bigram approach gained a higher average recall than the pure trigram, edit distance and pure bigram approaches, since it took into account different word lengths and similarity enhancement.

For the third experiment, we performed the web experiments using the mutual information approach to improve the precision of revised bigram approach. This was done by eliminating the bigram generated noisy expanded terms as discussed in Section IV-B, Table V and Figure 1 shows that the mutual information approach using statistical co-occurrence data obtained from the web succeeded in eliminating 25 irrelevant expanded terms generated by the revised bigram approach. The failed cases were counted when the algorithm failed to eliminate the noisy terms or when the algorithm eliminate a corrected expanded term/terms along with the noisy one.

For example, we consider the query  $افريقيا$   $afryqyā$  "Africa", the algorithm succeeded in eliminating the noisy term  $فريقي$   $fryqy$  "my team" or "two teams" but at the same time, it eliminated a relevant term  $بافريقيا$   $bāfryqyā$  "by Africa". One interpretation for this lack, is that the word  $فريقي$   $fryqy$  "my team" or "two teams" with average  $MI$  score's (27.999) frequently appeared in the context of African sport and thus it increases the  $MI$  score mean (28.437) in that the average

$MI$  scores for the relevant word  $بافريقيا$   $bāfryqyā$  "by Africa" (27.708) is below the  $MI$  score mean.

TABLE VI  
AVERAGE PRECISION FOR ALL APPROACHES.

Techniques	Precision %
Revised bigram	91.3
Revised-bigram + $MI$	94.6
Pure bigram	79.4
Revised trigram	98.7
Pure trigram	95.7
Edit distance	87.3

## VI. CONCLUSION

We presented a language-independent conflation approach, i.e., an approach that does not depend on any predefined rules or previous knowledge of linguistic information about the target language. Furthermore, we evaluated our approach successfully on the Arabic language, which is one of most inflected languages in the world. In order to deal with  $n$ -gram noisy expanded terms, a mutual information approach applied to statistical co-occurrences data obtained from web was developed, in that the terms that have less cohesion score with other will be assumed as noisy terms and thus will be eliminated. The eliminations of the  $n$ -gram noisy generated terms improved the precision of the revised  $n$ -gram with 4%. The failed cases by the algorithm can be interrelated by the lack of the training data or by the very generic term usage where terms can appear in different contexts.

**Abstract**—This study demonstrates how to improve the predictability of one of the commonly used ICUs severity of illness scales, namely APACHE II, by using the consistency-driven pairwise comparisons (CDPC) method. From a conceptual view, there is little doubt that all items have exactly equal importance or contribution to predicting mortality risk of patients admitted to ICUs. Computing new weights for all individual items is a considerable step forward since it is based on reasonable to assume that not all individual items have equal contribution in predicting mortality risk. The received predictability improvement is 1.6% (from 70.9% to 72.5%) and the standard error decreased from 0.046 to 0.045. This must be taken as an indication of the right way to go.

**Index Terms**—medical scales, illness severity, expert system, consistency-driven pairwise comparisons, inconsistency analysis.

## I. INTRODUCTION

**E**VER growing medical care costs motivate us to conduct more research toward the improvement of the severity of illness scales. The challenge is to leave the severity of illness scales unchanged as they are based on well established medical knowledge. Under this assumption, we are left with only one solution: weight for individual scale items must be computed instead of being arbitrarily set.

Severity of illness scales have wide application in medicine but psychiatry and intensive care settings are two top specializations where the use of severity of illness scales seems to be of great use, although for different reasons. In psychiatry, the use of tests, such as blood or X-rays, is limited and psychiatrists often rely on asking questions or observations. On the other hand, patients in the intensive care medicine must be rapidly evaluated based on many factors upon arrival and it can be at least in part done by nurses. Systems for predicting hospital mortality, such as the Acute Physiology and Chronic Health Evaluation (APACHE) II, are attractive options for this purpose because they rely on data collected within 24 hours after admission to the intensive care unit (ICU). It is mainly used to predict hospital mortality and reflect the severity of illness.

The corresponding author: wkoczkodaj@cs.laurentian.ca  
 Alphabetical order implies the equal contribution.

Acute Physiology and Chronic Health Evaluation, APACHE II, was introduced in [7] by Knaus in 1985 for predicting the hospital mortality in ICU patients. It has been designed based on data collected in 5,815 intensive care admissions from 13 hospitals. APACHE II measures severity of illness by a numeric score which can be converted into predicted mortality by using a logistic regression formula developed and validated on populations of ICU patients (for details, see [2], [3]).

## II. ICU SCALES

Medical scales (sometimes called medical measures) are scales used to describe or assess medical conditions. Amongst them, ICU scales are of considerable importance. An intensive care unit (ICU) also called intensive therapy unit, critical care unit (CCU), or intensive treatment unit (ITU) is a specialized department in a hospital for providing intensive-care medicine. Some hospitals also have designated intensive care areas for certain specialties of medicine, depending on the needs and resources of the hospital. For example, stroke is usually treated this way. Glasgow Coma Scale (GCS) was first introduced in 1974 by Teasdale G, Jennett B. in [17]. It aims to provide an understandable and clear way of observing change in the level of consciousness of patients having head injuries. In essence, the GCS was developed to standardize the reporting of neurologic findings and to provide an objective measure of the level of function of comatose patients [6]. Currently, GCS is one of the most used scales to assist the conditions of Trauma patients. It has only three items (elements):

- 1) Best eye response (E)
- 2) Best verbal response (V)
- 3) Best motor response (M)

There are four grades eye responses (E) starting with the most severe: 1 = "No eye opening" to 4 = Eyes opening spontaneously. For verbal response (V), the grads range from 1 = "Makes no sounds" to 5 = "Oriented, converses normally". Motor response (M) starts with 1 = "Makes no movements" and ends with 6 = "Obeys commands". Generally, brain injury is classified as:

- Severe, with  $GCS \leq 8$

TABLE I  
REVISED TRAUMA SCORE

Glasgow Coma Scale (GCS)	Systolic Blood Pressure (SBP)	Respiratory Rate (RR)	Coded Value
13-15	>89	10-29	4
9-12	76-89	>29	3
6-8	50-75	6-9	2
4-5	1-49	1-5	1
3	0	0	0

- Moderate, GCS 9 - 12
- Minor, GCS  $\geq$  13.

GCS is a part of several ICU scales, including APACHE II.

The Revised Trauma Score is a concatenation of: Glasgow Coma Scale, systolic blood pressure, and respiratory rate. Based on [4], TABLE II demonstrate the Revised Trauma Score. The RTS ranges from 0 to 12. A patient with an RTS = 12 is categorized as DELAYED (e.g., walking wounded), 11 is URGENT (intervention is required but the patient can wait a short time), and 10-3 is IMMEDIATE (immediate intervention is necessary). The last possible category is MORGUE, which is given to mortally injured people having RTS score from 0 to 3.

Needless to say that with the method presented in this study, the predictability can be improved for all these scales. However, the deep throat for our research is data gathering. It is not only costly and time consuming but it is easy to envision that the data collection may often interfere with the rescuing efforts so the emergency physician intuition may surpass it.

### III. DATA GATHERING AND ANALYSIS

Raw data, received from the Intensive Care Unit (ICU) of King Abdulaziz Medical City in Riyadh, Saudi Arabia in paper form, were entered into MS Excel to ease processing by other systems (e.g., SPSS). Excel provides a good tool for building forms for such a task using Visual Basic for Application (VBA) environment. Several forms were designed and then used to enter raw data. During the data entry process, 22 records from the received 165 records had to be removed. That was because three patients were re-admitted to the ICU, three patients had length of stay less than 24 hours, one patient had incomplete data, and all others had one or more missing value either it was not measured or was not available. According to [7], the first 3 group (re-admitted patients, patients with less than 24 hours stay, patients with incomplete data) are excluded from APACHE scoring. Moreover, in statistical analysis, all patients with one or more missing values were removed.

While considerable efforts have been taken to ensure high standards throughout all stages of collection and processing, the resulting data may not be sterile as they are clinical. Despite this effort, it should be clear that accidental errors are inevitable. Data was looked at from the medical point of view for mistakes and errors. We stress the use of the clinical data in our analysis as opposed to trial data.

Trial data tend to be more sterile than clinical data but as such, less valuable. They have the tendency of generating

TABLE II  
APACHE II SIMPLIFIED SPECIFICATION WITH GIVEN WEIGHTS

No	Item	Description	Range	weight
1	Temp	Temperature	0-4	1.67%
2	MAP	Mean Arterial Pressure	0-4	1.67%
3	HR	Heart Rate	0-4	1.67%
4	RR	Respiratory Rate	0-4	1.67%
5	OXY	Oxygenation	0-4	1.67%
6	$\rho$ H	$\rho$ H (Arterial)	0-4	1.67%
7	SS	Sodium (Serum)	0-4	2%
8	PS	Potassium (Serum)	0-4	2%
9	CS	Creatinine (Serum)	0-4	2%
10	He	Hematocrit	0-4	2%
11	WBC	White Blood Count	0-4	2%
12	GCS	15-GCS	0-15	20%
13	Age	Age	0-6	20%
14	CHP	Chronic Health Points	0, 2, 5	40%

better results since experiments are designed to prove a certain hypothesis.

### IV. PAIRWISE COMPARISONS LOGICAL MODEL

Based on existing data, we hypothesize that assuming identical weights for all scale items is not realistic for computing the predictability. Therefore, we grouped scale items according to their cohesiveness trying to have as loosely coupled groups as possible. It is done by the domain (medical) experts as following: First, a conceptual model must be designed by grouping criteria together. A rule of thumb proposed by Saaty in [14] is that no group should have more than seven criteria. To solve the problem of one group having a large number of criteria, split the group into subgroups with an acceptable number of criteria. Evidently, GCS, age and chronic conditions of patients have been kept in separation in the spirit of what was previously mentioned in the *Data collection and analysis* section. The remaining items have been grouped as shown in Fig. 1.

In a simplified model for APACHE II, we compared only the upper level observing that 11 items in the physiological group account for maximum 44 points while Chronic Health Point (CHP) is 2 or 5. It has created an immediate problem for relating groups at this level since our system allows us to define the ratio from 1 to 5 (and the inverse values). It is not a deficiency since the introduction of more groups is a solution. However, it requires more time so we decided to “cut the corners” and entered the compromised relative pairwise comparisons in Fig. 2.

The challenge posed to the pairwise comparisons method comes from the lack of consistency in assessments which arise in the real world [11]. With the development of the software, The Concluser, the consistency analysis has become relatively easy despite its complicated look. During the analysis process, the most inconsistent combinations of criteria are highlighted in the pairwise comparisons matrix in Fig. 3.

On Fig. 3, the maximum inconsistency is shown 0.67 and evidently bigger than the assumed heuristic  $\frac{1}{3}$  (as explained in the Appendix) hence the relative importance had to be

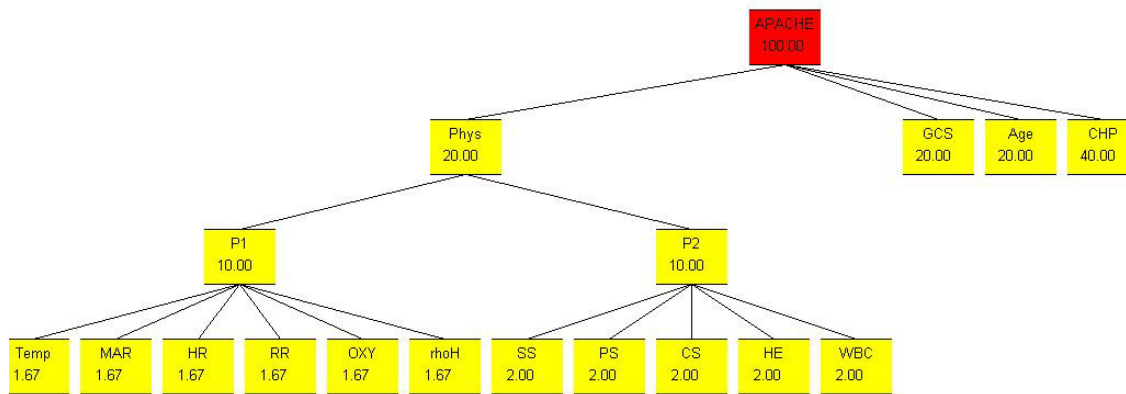

Fig. 1. The conceptual model of Apache II

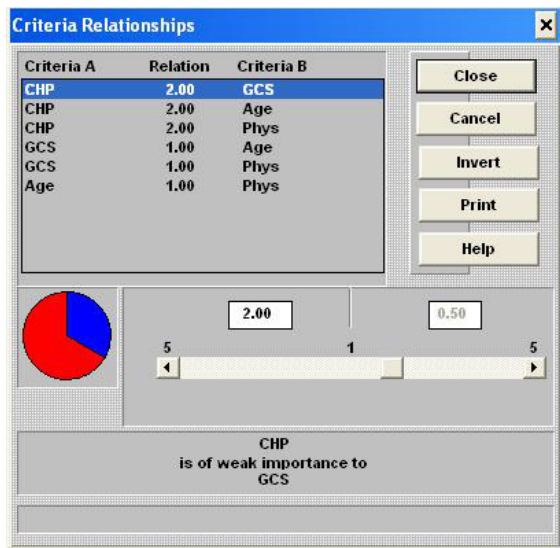

Fig. 2. The relative importance of the APACHE II scale items for level 1

reconsidered by experts based on their professional judgement and medical knowledge.

When an acceptable consistency level is reached (in our case, it has happened to be 0.00) as shown in fig 4, the weights [40%, 20%, 20%, 20%] are computed as normalized geometric means of rows and illustrated by Fig. 5. It needs to be stressed that for inconsistent pairwise matrix only approximated solution, in terms of weights, exists but it is sufficient since the reconstructed matrix from computed weights does not vary dramatically from the inconsistent pairwise comparisons matrix.

By the method of pairwise comparisons, the weight of 2.5 for CHP to Physio, GCS, and Age was optimal for the collected data. By dividing the original ratios of CHP to Physio, CHP to GCS, and CHP to Age over 2.5, we get the values in the upper row in Fig. 4. By the inconsistency analysis, we reduced values in the second row of matrix in Fig. 4 from 3 to 1.

The comorbidity component of APACHE II is represented

Fig. 3. The initial inconsistency analysis

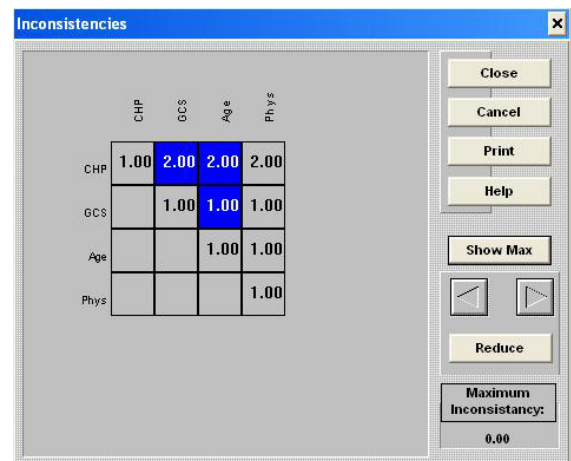

Fig. 4. The inconsistency analysis after the improvement

by Chronic Health Points (CHP). CHP are added for patients with a history of severe organ system deficiency or for patients who have immuno-compromised as follows:

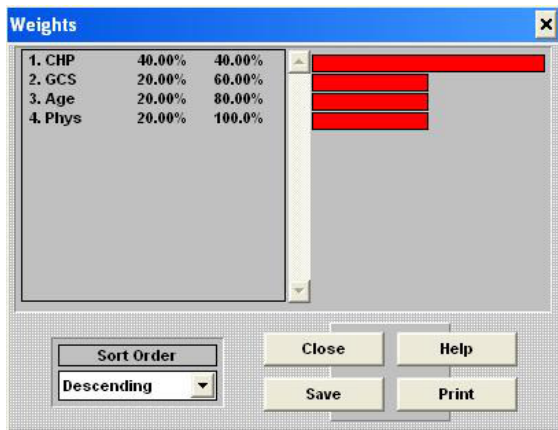

Fig. 5. The final weights computed for the APACHE II scale

- for nonoperative or emergency postoperative patients (5 points),
- for selective postoperative patients (2 points).

Immuno-compromised state must have been evident prior to the hospital admission and conform to the set medical criteria of liver, respiratory or renal system which are beyond the scope of this presentation. It was pointed out in [13] that: "The Chronic Health Points component of APACHE II had no significant discriminating ability (ROC area = 0.57, SE = 0.05)." However, we have provided evidence that the importance of CHP is greater than it has been originally assumed in [7] and should be changed from 2 and 5 to 5 and 12.5 respectively. To verify that these values are giving a better prediction of mortality, we applied ROC analysis by using SPSS. For CHP set to be 2.5, and 5, AUC (Area Under the Curve) was computed for the original data as 70.9% with the standard error of 0.046. While for the weight of 5 and 7.5 for CHP, AUC has increased to 72.5% with a better standard error of 0.045. The received predictability improvement is 1.6% and the standard error by 0.1%. Two ROCs are illustrated by Fig. 6.

In our humble opinion, the higher contribution of chronic conditions (CHP) can be explained by the simple observation that patients with chronic conditions are already receiving more medical attention than the rest of the population. When they are brought to ICU, usually it is for a serious enough reason that increases chance for their mortality.

## V. CONCLUSIONS

In this data analytic study, we tested the impact of applying the pairwise comparisons method to intensive care scales such as APACHE II. As far as we are aware, this is the first study to examine APACHE II's effectiveness while improving the predictability of a clinical assessment using a well-established method. Our results, although seemingly modest, have been consistent with improved psychometric properties of the questionnaire examined, as evidenced by the superior AUC classifier percentage after weights were added.

It is a progress report and a part of the MSc degree thesis of the first author. The presented hypothesis of changing the

weight for just one APACHE II scale item (Chronic Health Points) has been statistically proven and published in [9], [10], [1].

However, this is the first time of validation on the presented clinical data and every attempt will be made to use other clinical data in the future. We have proven the hypothesis that the proposed values in [7] in 1985 for Chronic Health Points should be changed from 2 and 5 to 5 and 7.5 respectively for elective post-operative patients and non-operative or emergency post-operative patients. This hypothesis is of considerable importance for health care planners. We hope that a more labor intensive analysis for the second level of the model would further improve the accuracy of the predictions of the presented scale. Similarly, adding the 50 principal diagnosis categories leading to ICU admission is a bit time consuming but will be incorporated in our approach for approximation of the mortality.

APPENDIX

Using pairwise comparisons is a powerful method for synthesizing measurements and subjective assessments. From the mathematical point of view, the pairwise comparisons method generates a matrix (say  $A$ ) of ratio values ( $a_{ij}$ ) of the  $i$ th entity compared with the  $j$ th entity according to a given criterion. Entities/criteria can be both quantitative or qualitative allowing this method to deal with complex decisions. Comparing two entities in pairs to assess which of them is preferred, or has a greater amount of some property is irreducible since having one entity compared with itself has very little or practical meaning. However, subjective assessments often involve inconsistency, which is usually undesirable. The assessment can be refined via analysis of inconsistency, leading to reduction of the latter.

Making one comparison at a time is simpler than simultaneously assessing *all* items of a scale according to their contribution to the overall score. However, we need a method of synthesizing these partial assessments. The pairwise comparisons method, used since 1785, serves exactly this purpose, with the inconsistency analysis allowing us to localize the most questionable partial assessments and revise them if necessary.

From the mathematical point of view, the pairwise comparisons method creates a matrix (say  $A$ ) of values ( $a_{ij}$ ) of the  $i$ th entity compared with the  $j$ th entity:

$$A = \begin{bmatrix} 1 & a_{12} & \cdots & a_{1n} \\ \frac{1}{a_{12}} & 1 & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{1}{a_{1n}} & \frac{1}{a_{2n}} & \cdots & 1 \end{bmatrix}$$

A scale  $[\frac{1}{c}, c]$  is used for ‘ $i$  to  $j$ ’ comparisons where  $c > 1$  is a not-too-large real number (5 to 9 is used in most practical applications). It is usually assumed that all the values  $a_{ii}$  on the main diagonal are 1 (the case of ‘ $i$  compared with  $i$ ’, that is with itself) and that matrix  $A$  is *reciprocal* :  $a_{ij} = \frac{1}{a_{ji}}$  since ‘ $i$  to  $j$ ’ is (or at least, is expected to be) the reciprocal of ‘ $j$  to  $i$ ’. (In other words, for  $x, y \neq 0$ ,  $\frac{x}{y} = \frac{1}{\frac{y}{x}}$ .) However, in practice even the reciprocity condition is not always guaranteed. For example, in blind wine testing we may conclude that *wine  $i$*  is better than *wine  $j$*  if it is served in unmarked glasses.

Since 1996, a *distance-based* adjective has been used by other researchers for the new inconsistency defined in 1993 in [8]. The distance-based adjective reflects the nature of the *inconsistency indicator*, which is defined, in essence, as a function of a distance from the nearest consistent *triad* in matrix  $A$ . Unlike the eigenvalue-based inconsistency, introduced in [14]), which is of a *global* indicator, and as such a non-identifying, the distance-based inconsistency identifies the most inconsistent triad (or triads). It is the maximum over all triads  $\{a_{ik}, a_{kj}, a_{ij}\}$  of elements of  $A$  (say, with all indices  $i, j, k$  distinct) of their inconsistency indicators, which in turn are defined as  $ii := \min(|1 - \frac{a_{ij}}{a_{ik}a_{kj}}|, |1 - \frac{a_{ik}a_{kj}}{a_{ij}}|)$ .

The inconsistency indicator of  $A$  equals zero if and only if  $A$  is fully consistent as it was (in all likelihood shown for the first time in [14]. Consistent matrices correspond to the ideal situation in which we know all exact values of all properties (or at least it seems to be a reasonable assumption to make). However, a realistic situation which is complex enough, nearly always involves inconsistency and we need to deal with it. In fact, when we are able to locate it, our comparisons can be reconsidered to reduce the inconsistency in the next round.

Certainly, inconsistency is undesirable in a system. On the other hand, although this may sound strange, it is not easy (we suspect, impossible) to construct a non-trivial *fully* inconsistent system: an “ideal” system where everything contradicts everything else. This question (or a family of questions, which we suggest only vaguely here) seems quite important as such impossibility would imply that *every* scenario of answers to pairwise comparison queries (even deliberately false) would necessarily create “apparent” consistencies.

In practical applications, a high value of the inconsistency indicator is a “red flag,” or a sign of potential problems. A distance-based inconsistency reduction algorithm focuses, at each step, on an inconsistent triad and “corrects” it by replacing it with a consistent (or, more generally, less inconsistent) triad. It resembles “whac-a-mole,” a popular arcade game. One difference is that instead of one mole, we have three array elements as explained above. After “hitting the mole” (which generally results in some other “moles” coming out), the next triad is selected according to some rule (which may be for example the greedy algorithm), and

the process is repeated. Numerous practical implementations (e.g., a hazard rating system for abandoned mines in Northern Ontario) have shown that the inconsistency converges relatively fast. However, the need for rigorously *proving* the convergence (that is, showing that whacked moles *always* have the tendency of coming out less and less eagerly) was evident.

The distance-based inconsistency locates the most inconsistent triad or triads. This allows the user to reconsider the assessments included in the most inconsistent triad.

$$\begin{array}{c|cccc} & \mathbf{A} & \mathbf{B} & \mathbf{C} & \mathbf{D} \\ \hline \mathbf{A} & 1 & \boxed{1} & \boxed{5} & 4 \\ \mathbf{B} & 1 & 1 & \boxed{2} & 2\frac{1}{2} \\ \mathbf{C} & \frac{1}{5} & \frac{1}{2} & 1 & \frac{1}{2} \\ \mathbf{D} & \frac{1}{4} & \frac{2}{5} & 2 & 1 \end{array} \quad (1)$$

Changing the value 1 in the above triad to 2.5 makes this triad fully consistent since  $2.5 \cdot 2 = 5$ . Unfortunately, this is not the end of our problems since there is another triad  $[2, 2\frac{1}{2}, \frac{1}{2}]$  that is inconsistent and “boxed” below:

$$\begin{array}{c|cccc} & \mathbf{A} & \mathbf{B} & \mathbf{C} & \mathbf{D} \\ \hline \mathbf{A} & 1 & 2\frac{1}{2} & 5 & 4 \\ \mathbf{B} & \frac{2}{5} & 1 & \boxed{2} & \boxed{2\frac{1}{2}} \\ \mathbf{C} & \frac{1}{5} & \frac{1}{2} & 1 & \boxed{\frac{1}{2}} \\ \mathbf{D} & \frac{1}{4} & \frac{2}{5} & 2 & 1 \end{array} \quad (2)$$

Assume that we have good reason (coming from the knowledge domain; not from mathematics), to change the value of  $2\frac{1}{2}$  to 1. It is an arbitrary decision since 2 could have been changed to 5 or  $\frac{1}{2}$  to  $1\frac{1}{4}$ , also making this triad consistent. Only the domain knowledge can determine the change of the value (or values) in a triad. However, changing 2 may not be wise since it belongs to a consistent triad altered in the previous step. In our case, the only reason why we have chosen to change  $2\frac{1}{2}$  to 1 was to illustrate how the inconsistency procedure works and the reader may be disappointed to find that there is yet another triad “boxed” below which is inconsistent:

$$\begin{array}{c|cccc} & \mathbf{A} & \mathbf{B} & \mathbf{C} & \mathbf{D} \\ \hline \mathbf{A} & 1 & \boxed{2\frac{1}{2}} & 5 & \boxed{4} \\ \mathbf{B} & \frac{2}{5} & 1 & 2 & \boxed{1} \\ \mathbf{C} & \frac{1}{5} & \frac{1}{2} & 1 & \frac{1}{2} \\ \mathbf{D} & \frac{1}{4} & 1 & 2 & 1 \end{array} \quad (3)$$

Finally, we change 4 to  $2\frac{1}{2}$  making the entire table fully consistent.

$$\begin{array}{c|cccc} & \mathbf{A} & \mathbf{B} & \mathbf{C} & \mathbf{D} \\ \hline \mathbf{A} & 1 & 2\frac{1}{2} & 5 & 2\frac{1}{2} \\ \mathbf{B} & \frac{2}{5} & 1 & 2 & 1 \\ \mathbf{C} & \frac{1}{5} & \frac{1}{2} & 1 & \frac{1}{2} \\ \mathbf{D} & \frac{1}{4} & 1 & 2 & 1 \end{array} \quad (4)$$

In practice, inconsistent assessments are unavoidable when at least three factors are independently compared against each other. The corrections for real data are done on the basis of

professional experience, the case-based knowledge, and by the careful examination of all criteria involved (not necessarily in the current triad).

An acceptable threshold of inconsistency, for most practical applications, turns out to be  $\frac{1}{3}$ . This is so because one value in a triad is not more than two grades off the scale from the remaining two values. This heuristic was introduced in [8] and it seems more mathematically sound than 10% proposed in [14].

There is no need to continue decreasing the inconsistency indefinitely to zero, as only a high value of it is harmful. In fact, a zero or a small inconsistency value may indicate that artificial data were entered hastily without reconsideration of former assessments, which is an unacceptable practice.

For the improved matrix, the normalized vector of weights is:

$$w = [0.5, 0.2, 0.1, 0.2]$$

It is identical for both the geometric means method, and the eigenvector method, since the eigenvector of a consistent pairwise comparisons matrix is always equal to the geometric means. For the original input matrix, which is inconsistent, the solutions are,

for the eigenvector method:

$$w = [0.441, 0.317, 0.101, 0.140]$$

and for geometric means method (computed as  $\sqrt[4]{\prod_{j=1}^N a_{ij}}$ ):

$$w = [0.445, 0.315, 0.100, 0.141]$$

The difference between both solutions is negligible. However, both solutions for the inconsistent matrix vary drastically from the solution for the consistent matrix.

It is important to note the difference between inaccuracy and inconsistency. For example, in a triad  $[2, 5, 3]$ , a rash approach may lead us to believe that  $A/C$  should indeed be 6 since it is  $2 \cdot 3$ , but we do not have any reason to reject the estimation of  $B/C$  as 2.5 or  $A/B$  as  $5/3$ . This is what inconsistency is about. It is not inaccuracy, but when used wisely, it may help to decrease inaccuracy.

The reader will notice that while the three-step inconsistency-reduction procedure performed above does not offend the common sense, it is rather *ad hoc*, hence not fully satisfactory. This remark applies both to the choices of triads to be corrected, and to the choices of the particular members of each such triad that is being modified. The algorithm analyzed in [12] (and, by extension, the present note) is more canonical with respect to the second point. In general, it replaces the triad  $\{a_{ik}, a_{kj}, a_{ij}\}$  by  $\{a_{ik}/r, a_{kj}/r, ra_{ij}\}$ , where  $r := \sqrt[3]{a_{ik}a_{kj}/a_{ij}}$ . This corresponds to subtracting from the matrix  $(\log a_{uv})$  its orthogonal projection onto the direction of the skew-symmetric matrix  $B = (b_{uv})$  defined by the requirement that  $a_{ik} = 1 = a_{kj}$ ,  $a_{ij} = -1$  and that all other super-diagonal entries are 0; the corresponding subspace in the context of Theorem is  $U = \{X : X \text{ is an } n \times n \text{ skew-symmetric matrix such that } \text{tr}BX = 0\}$ . In particular, for the first triad  $[1, 2, 5]$

considered above, we have  $r = 2/5$  and the corrected triad is  $[\sqrt[3]{5/2}, 2\sqrt[3]{5/2}, 5\sqrt[3]{2/5}] \approx [1.36, 2.71, 3.68]$ .

Monte Carlo studies have shown that approximations of highly inconsistent pairwise comparisons matrices yields high errors. Finding consistent approximations of such matrices makes little practical sense. From mathematical logic, we know that *only* falsehood can generate both truth or falsehood. However, the old adage that *one bad apple spoils the barrel* seems to be more applicable here: even a little bit of falsehood may contribute to massive errors and misjudgments. An approximation of a pairwise comparisons matrix is meaningful only if the initial inconsistency is acceptable (that is, located, brought under control and/or reduced to a certain predefined minimum; in our analogy, *always remove overripe fruit promptly if it is possible to find it*).

The new results and applications of pairwise comparisons show the importance of the consistency-driven approach. The

inconsistency concept still remains enigmatic and more research needs to be done. In particular, inconsistency in a general system needs to be defined and this study is a step forward. The idea of improving inaccuracy by controlling inconsistency cannot be wrong and a new approach to it is presented in [18]. Knowing what we do not know is essential to managing the knowledge and improving it. On the other hand, it is hard to change our knowledge if we choose not to know what we know or even should know.

The method of pairwise comparisons was used by a research team, lead by W.W. Koczkodaj, to develop AMIS (Abandoned Mines Hazard Rating System) for the government of Ontario (The Ministry of Northern Ontario and Mines). The system ranked an abandoned mine, located in Northern Ontario, as one of the most dangerous from a public safety point of view. Its eventual collapse convinced the government that its research founding was well spent.

# A Rough K-means Fragile Watermarking Approach for Image Authentication

**Abstract**—In the past few years, various fragile watermarking systems have been proposed for image authentication and tamper detection. In this paper, we propose a rough k-means (RKM) fragile watermarking approach with a block-wise dependency mechanism which can detect any alterations made to the protected image. Initially, the input image is divided into blocks with equal size in order to improve image tamper localization precision. By combining image local properties with human visual system, authentication data are acquired. By computing the class membership degree of each image block property, data are generated by applying rough k-means clustering to create the relationship between all image blocks and cluster all of them. The embed watermark is carried by least significant bits (LSBs) of each pixel within each block. The effectiveness of the proposed approach is demonstrated through a series simulations and experiments. Experimental results show that the proposed approach can embed watermark without causing noticeable visual artifacts, and does not only achieve superior tamper detection in images accurately, it also recovers tampered regions effectively. In addition, the results show that the proposed approach can effectively thwart different attacks, such as the cut-and paste attack and collage attack, while sustaining superior tamper detection and localization accuracy. Furthermore, the results show that the proposed approach can embed watermark without causing noticeable visual artifacts.

## I. INTRODUCTION

**D**UE TO significant improvements in computer and Internet technology, a large amount of digital data is easily accessible to every one these days. This digital data, such as images, are commonly transmitted via the Internet. On the other hand, a variety of powerful image processing tools have also made digital image manipulations much easier. The ease and extent of such manipulations emphasize the need for image authentication techniques in applications where verification of integrity and authenticity of the image content is essential. Therefore, various authentication approaches have recently been proposed for verifying the integrity and authenticity of the image content [1], [2], [4].

The authentication approaches can be branched into two categories: digital signature-based approaches and digital watermark-based approaches. A digital signature can be either an encrypted or a signed hash value of image contents or

image features. The drawback of signature based approaches is that they cannot locate the regions where the image has been modified although they can detect if an image has been modified or not, also the transmission of a digital signature for each image requires additional bandwidth or storage that may not always be available [3], [11], [12]. Digital watermark-based approaches embed the authentication data directly into the original multimedia which provides an obvious solution to the preciously mentioned problems. Moreover, the digital watermark is capable of isolating manipulated image areas which is known as the tamper localization [5], [13]. So many researchers have proposed watermarking based approaches for image authentication [4], [5], [14].

The authentication digital watermark-based approaches can be classified as either fragile watermarking or semi-fragile watermarking. A fragile watermarking can detect any possible modification of the pixel values. On the other hand, semi-fragile watermarking can distinguish content-preserving operations from malicious manipulations, e.g., addition or removal of a significant element of the image [3], [15]. Various approaches for fragile watermarking [16][18] and semi-fragile watermarking [19], [20] have been proposed. since tamper detection and localization are well defined in fragile watermarking approaches, the work presented in this paper concentrates on the latter.

The remainder of this paper is ordered as follows. Brief introduction of rough sets and rough k-means clustering are introduced in Section (II). The details of the proposed approach is presented in Section (III). Section (IV) shows the experimental results. Conclusions are discussed in Section (V).

## II. PRELIMINARIES

### A. Rough sets

Due to space limitations we provide only a brief explanation of the basic framework of rough set theory, along with some of the key definitions. A more comprehensive review can be found in sources such as [10].

Rough sets theory proposed by Pawlak [9] is a new intelligent mathematical tool. It is based on the concept of

Fig. 1. Rough: boundary region

approximation spaces and models of the sets and concepts [7,8,9,11]. In rough sets theory, feature values of sample objects are collected in what are known as information tables. Rows of a such a table correspond to objects and columns correspond to object features.

Let  $\mathcal{O}, \mathcal{F}$  denote a set of sample objects and a set of functions representing object features, respectively. Assume that  $B \subseteq \mathcal{F}, x \in \mathcal{O}$ . Further, let  $[x]_B$  denote:  $[x]_B = \{y : x \sim_B y\}$ .

Rough sets theory defines three regions based on the equivalent classes induced by the feature values: lower approximation  $\underline{BX}$ , upper approximation  $\overline{BX}$  and boundary  $BND_B(X)$ . A lower approximation of a set  $X$  contains all equivalence classes  $[x]_B$  that are proper subsets of  $X$ , and upper approximation  $\overline{BX}$  contains all equivalence classes  $[x]_B$  that have objects in common with  $X$ , while the boundary  $BND_B(X)$  is the set  $\overline{BX} \setminus \underline{BX}$ , i.e., the set of all objects in  $\overline{BX}$  that are not contained in  $\underline{BX}$ . The approximation definition is clearly depicted in Fig. 1.

### B. Adaptation of K-means to rough set theory

K-means clustering is used for other segmentation than medical images [6], [10]. The name K-means originates from the means of the  $k$  clusters that are created from  $n$  objects. Let us assume that the objects are represented by  $m$ -dimensional vectors. The objective is to assign these  $n$  objects to  $k$  clusters. Each of the clusters is also represented by an  $m$ -dimensional vector, which is the centroid or mean vector for that cluster. The process begins by randomly choosing  $k$  objects as the centroids of the  $k$  clusters. The objects are assigned to one of the  $k$  clusters based on the minimum value of the distance  $d(v, x)$  between the object vector  $v = (v_1, \dots, v_j, \dots, v_m)$  and the cluster vector  $x = (x_1, \dots, x_j, \dots, x_m)$ . After the assignment of all the objects to various clusters, the new centroid vectors of the clusters are calculated as:

$$x_j = \frac{\sum_{v \in x} v_j}{|x|} \quad (1)$$

Where  $1 \leq j \leq m$ ,  $|x|$  is the size of cluster  $x$ . Incorporating rough sets into K-means clustering requires the addition of the concept of lower and upper bounds [7,8]. Calculation of the centroids of clusters from conventional K-means needs to

be modified to include the effects of lower as well as upper bounds. The modified centroid calculations for rough sets are given in Algorithm(1).

**Algorithm 1** The modified centroid calculations for rough sets

---

```

if  $\underline{BX} \neq \emptyset$  and  $\overline{BX} - \underline{BX} = \emptyset$  then
  Compute  $x_j = \frac{\sum_{v \in \underline{BX}} v_j}{|\underline{BX}|}$ 
end if
if  $\underline{BX} = \emptyset$  and  $\overline{BX} - \underline{BX} \neq \emptyset$  then
  Compute  $x_j = \frac{\sum_{v \in (\overline{BX} - \underline{BX})} v_j}{|\overline{BX} - \underline{BX}|}$ 
else
  Compute  $x_j = w_{lower} \times \frac{\sum_{v \in \underline{BX}} v_j}{|\underline{BX}|} + w_{upper} \times \frac{\sum_{v \in (\overline{BX} - \underline{BX})} v_j}{|\overline{BX} - \underline{BX}|}$ 
end if

```

---

Where  $1 \leq j \leq m$ . The parameters  $w_{lower}$  and  $w_{upper}$  correspond to the relative importance of lower and upper bounds, and  $w_{lower} + w_{upper} = 1$ . If the upper bound of each cluster were equal to its lower bound, the clusters would be conventional clusters. Therefore, the boundary region  $(\overline{BX} - \underline{BX})$  will be empty, and the second term in the equation will be ignored. Thus, the equation on Algorithm (1) will reduce to conventional centroid calculations.

The next step in the modification of the K-means algorithm for rough sets is to design criteria to determine whether an object belongs to the upper or lower bound of a cluster given as follows:

For each object vector,  $v$ , let  $d(v, x_j)$  be the distance between itself and the centroid of cluster  $x_j$ . Let  $d(v, x_i) = \min_{1 \leq j \leq K} d(v, x_j)$ . The ratio  $d(v, x_i)/d(v, x_j)$ ,  $1 \leq i, j \leq k$ , are used to determine the membership of  $v$ . Let  $T = \{j : d(v, x_i)/d(v, x_j) \leq \text{threshold } \epsilon \text{ and } i \neq j\}$ .

- 1) If  $T \neq \emptyset, v \in \overline{BX}_i$  and  $v \in \overline{BX}_j, \forall j \in T$ . Furthermore,  $v$  is not part of any lower bound. The above criterion guarantees that property (3) is satisfied.
- 2) Otherwise, if  $T = \emptyset, v \in \underline{BX}_i$ . In addition, by property (2),  $v \in \overline{BX}_i$ . It should be emphasized that the approximation space  $A$  is not defined based on any predefined relation on the set of objects. The upper and lower bounds are constructed based on the criteria described above.

## III. THE PROPOSED FRAGILE WATERMARKING APPROACH FOR IMAGE AUTHENTICATION

In this section, we explain the proposed watermarking approach. The system contains two procedures: watermark embedding procedure and tamper detection procedure. Details of the proposed system are described as follows.

### A. Watermark embedding

Let us consider,  $I$  is the host image of size  $M \times M$ , where  $M$  is assumed to be an even number. The original image is divided into non-overlapping  $2 \times 2$  blocks  $B_j (1 \leq j \leq \frac{M}{2} \times \frac{M}{2})$  which are arranged by the order from left to right and then top to bottom.

To generate the watermark, the two LSBs of all the pixels within each block of the host image are first set to zero. Each block  $B_j$  can be regarded as a 4-dimensional vector,  $B_j = (B_{j1}, B_{j2}, B_{j3}, B_{j4})$ . Then the RKM clustering is applied to classify all the blocks into  $k$  clusters. After performing the RKM clustering, for each block,  $B_j$ , let  $d(B_j, x_c)$  be the distance between itself and the centroid of cluster  $x_c$ ,  $1 \leq c \leq k$ . Let  $d(B_j, x_i) = \min_{1 \leq c \leq k} d(B_j, x_c)$ ,  $d(B_j, x_m) = \max_{1 \leq c \leq k} d(B_j, x_c)$ ,  $1 \leq i, m \leq k$ . Then we compute feature sequence  $F = \{f_1, f_2, \dots, f_{\frac{M}{2} \times \frac{M}{2}}\}$  by

$$f_j = \frac{d(B_j, x_i)}{d(B_j, x_m) - d(B_j, x_i)} \quad (2)$$

When  $f_j < 0.1$  then  $f_j = 0$  otherwise  $f_j = 1$

Assume that  $R = \{r_1, r_2, \dots, r_{\frac{M}{2} \times \frac{M}{2}}\}$  is a random sequence created by using a pseudorandom number generator (PRNG) seeded with a secret key SK, where  $r_j \in [0, 255]$ . For each block  $B_j$ , its corresponding authentication data  $a_j$  is constructed by the following Equation:

$$a_j = f_j \oplus r_j \quad (3)$$

where the symbol  $\oplus$  denotes the XOR operation. Each resultant 8-bit authentication data is embedded into the 8 LSBs of the corresponding image block, and the watermarked image  $I'$  is thus obtained. Finally, the set of cluster centers  $x$  acquired after performing the RKM clustering on image  $I$ , and the secret key SK should be kept securely by the image owner for further tamper detection.

### B. Tamper detection

The possibly distorted image  $I''$ , as in the authentication data embedding procedure, is first divided into non-overlapping  $2 \times 2$  blocks  $B_j''$  ( $1 \leq j \leq \frac{M}{2} \times \frac{M}{2}$ ). By verifying the watermark embedded in each image block, we can determine whether an image block has been tampered with.

To perform tamper detection, the embedded watermark sequence,  $A = \{a_1, a_2, \dots, a_{\frac{M}{2} \times \frac{M}{2}}\}$  is extracted from all the blocks of image  $I''$ , and then the two LSBs of all the pixels within each block are set to zero. Employing the set of cluster centers  $x$  kept by the image owner, to all blocks a feature sequence  $F'' = \{f_1'', f_2'', \dots, f_{\frac{M}{2} \times \frac{M}{2}}''\}$  can be derived by

$$f_j'' = \frac{d(B_j'', x_i)}{d(B_j'', x_m) - d(B_j'', x_i)} \quad (4)$$

When  $f_j'' < .1$  then  $f_j'' = 0$  otherwise  $f_j'' = 1$ . Let  $R = \{r_1, r_2, \dots, r_{\frac{M}{2} \times \frac{M}{2}}\}$  be a random sequence created by using the PRNG seeded with the secret key SK kept by the image owner, where  $r_j \in [0, 255]$ . The authentication data sequence  $A'' = \{a_1'', a_2'', \dots, a_{\frac{M}{2} \times \frac{M}{2}}''\}$  corresponds to image  $I''$  can be computed by applying  $f_j''$  and  $R$  to Eq. (3). Finally, the legitimacy of each block  $B_j''$  can be recognized by comparing  $a_j''$  with  $a_j$ . If they are the same,  $B_j''$  is a legitimate block; otherwise,  $B_j''$  is regarded as a tampered block.

## IV. EXPERIMENTAL RESULTS

Various experiments are carried out in this section to demonstrate the validity of the proposed fragile watermarking approach. We set the number of clusters  $k = 3$ ,  $w_{lower} = 0.75$ ,  $w_{upper} = 0.25$  and threshold  $\epsilon = 0.05$ . For quantitative evaluation, peak signal-to-noise ratio (PSNR) was used to measure the image quality of the watermarked image  $I'$  in comparison with the original image  $I$  which is given by the following form:

$$PSNR = 10 \times \log_{10} \frac{255^2}{MSE} (dB) \quad (5)$$

$$MSE = \frac{1}{M \times M} \sum_{i=1}^M \sum_{j=1}^M (I_{i,j} - I'_{i,j})^2, \quad (6)$$

where  $I_{i,j}$  denotes the pixel value of the original image,  $I'_{i,j}$  denotes the pixel value of the watermarked image,  $M \times M$  is the image size. Also, the true positive (TP) and false positive (FP) rates were used to measure the accuracy of tamper detection and localization, where the TP rate is the proportion of actual tampered pixels that were correctly reported as tampered pixels and the FP rate is the proportion of actual non-tampered pixels that were erroneously reported as tampered pixels.

### A. Performance evaluation

1) *Performance under cut-and-paste attack*: In this experiment, to simulate the cut-and-paste attack, the content of a watermarked image was modified by cutting regions from the same or another watermarked image and pasting them together to form a new image.

We used two 8-bit grayscale images, Pool image of size  $256 \times 256$  and field image of size  $320 \times 240$ . They were used to simulate the cut-and-paste attack. Figs. 2a and 3a show the original images and their corresponding watermarked images are shown in Figs. 2b and 3b, respectively. The simulations and their respective results are described in the following:

- The watermarked Pool image was tampered by copying one black ball and one white ball from the watermarked image and pasting them into the same image. The tampered image is shown in Fig. 2c. Fig. 2d shows the ground truth of tampered regions. The tamper detection result is shown in Fig. 2e.
- The modification made to the watermarked Field image, was done by cutting a white goat and a black cattle from other watermarked images and paste them in Fig. 3b. The tampered image is shown in Fig. 3c, and the ground truth of tampered regions is shown in Fig. 3d. Fig. 3e shows the tamper detection result.

Fig. 2 (a) Original pool image; (b) watermarked pool image; (c) tampered pool image; (d) ground truth image; (e) tamper detection result.

Fig.3. (a) Original field image; (b) watermarked field image; (c) tampered field image; (d) ground truth image; (e) tamper detection result.

2) *Performance under collage attack*: To evaluate the performance under collage attack, a counterfeit image is formed by combining the portions of multiple watermarked images, while preserving their relative spatial location within the target image. Sofa and Doll images given in Figs. 4a, 4b respectively are used to evaluate the performance under the collage attack. The size of both images are  $320 \times 240$  pixels. Figs. 4c and 4d show the corresponding watermarked images. The collage image, as shown in Fig. 4e, was created by copying the three dolls from Fig. 4d and pasting them in Fig. 4c. The ground truth of tampered regions and the tamper detection result are shown in Figs. 4f, 4g respectively.

TABLE I  
COMPARISON RESULTS OF PSNR OF WATERMARKED IMAGES.

### B. Performance comparisons and analysis

The two fragile watermarking approaches proposed by Li and Yuan in [15] and Chen and Wang in [3] were provided in this study for performance comparisons.

Table (I) shows the comparison results of image quality, the value of PSNR of watermarked images in the proposed method is greater than the value of PSNR of watermarked images in Li and Yuan's approach and Chen and Wang's approach. It means that the watermarked image of our proposed method have better image quality.

The comparison results of tamper detection are listed in Table (II). The results demonstrate that the proposed approach outperforms the other two approaches in both TP and FP rates. Furthermore, the results show that the proposed approach can completely resist collage attack, as all the blocks which have been modified by collage attack can be correctly identified by our approach.

TABLE II  
COMPARISON RESULTS OF TAMPER DETECTION.

Image	Li and Yuan's approach		Chen and Wang's approach		Proposed approach	
	TP (%)	FP (%)	TP (%)	FP (%)	TP (%)	FP (%)
Pool	74.30	0.91	99.71	0.32	99.72	0.004
Field	74.89	1.33	99.66	0.48	99.71	0.02
Sofa	13.34	2.43	99.30	0.81	98.77	0.11

## V. CONCLUSIONS

In this paper, the proposed fragile watermarking algorithm is presented. It can detect and locate any modification of the embedded image if it is tampered. Realizing that the basic requirement of thwarting counterfeiting attacks is to break blockwise independency, the proposed approach used the RKM clustering technique to create the relationship between image blocks. A series of experiments were conducted to illustrate the validity of the proposed approach.

Experimental results showed that the proposed approach not only can embed authentication data with acceptable visual quality, but also can effectively thwart diverse attacks, such as the cut-and-paste attack and collage attack, while sustaining superior localization accuracy. Furthermore, the results demonstrated that the proposed approach, compared with Li and Yuan's approach which exploited nondeterministic dependence information to resist counterfeiting attacks and Chen and Wang's [5], [11] approach which applied the fuzzy c-means clustering technique to cluster all the image blocks, provided more accurate tamper detection and localization accuracy.

**Abstract**—The paper presents our experience in using sparse principal components (PCs) (Zou, Hastie and Tibshirani, 2006) for visualization of gearbox diagnostic data recorded for two bucket wheel excavators, one in bad and the other in good state. The analyzed data had 15 basic variables. Our result is that two sparse PCs, based on 4 basic variables, yield similar display as classical pair of first two PCs using all fifteen basic variables. Visualization of the data in Kohonen’s SOMs confirms the conjecture that smaller number of variables reproduces quite well the overall structure of the data. Specificities of the applied sparse PCA method are discussed.

## I. INTRODUCTION

NOWADAYS we are witnessing a growing interest in the predictive assessment of industrial machinery. Machines work everywhere and are critical in maintenance of environmental and life conditions of humans. Machines use gearboxes, which in turn are substantial for functioning of the devices. Bad functioning is connected with huge economic losses; therefore early detection of malfunctioning is crucial both from economic and vital aspect. Although there are many general rules how to assess the problem, the working devices are quite different and different approaches are needed. What concerns machinery faults, vibration analysis has become almost the universal method to assess the state of a machine. See [1], [2], [3], [4], [5], [8], [6], [7] for methods of fault analysis used in this domain. Further references may be found in [10].

We will be concerned with diagnosis of gearboxes, used in bucket wheel excavators, working in surface mining. These are huge and expensive machines. In the following we will analyze vibration sounds obtained from two machines: one in bad state (machine A), and one in good state (machine B). We will show that, on the basis of vibration signals, it is possible to assess, what is the state of the machine: good or bad. This will be done by two combined methods: using self-organizing maps (SOMs) and sparse principal components (sPCs). Next section describes how the data were acquired; it contains also some statistical characterization of the recorded data. A preliminary approach to dimensionality reduction - by using Kohonen’s self-organizing maps (SOMs) is shown in Section 3. The principles of constructing classical and sparse PCs are presented in Section 4. Results of applying sparse

PCA to the recorded data, and discussion on the results may be found in Section 5. An overall discussion on the applied methods and their validity is presented in Section 6.

## II. THE DATA

### A. Collection of the data

Data were recorded in an experiment carried out during a research conducted in the Vibro-Acoustics Science Laboratory of Wrocław University of Technology [9]. Two complex multistage gearboxes used in two bucket wheel drive units – working in surface mining – were investigated. The Bruel&Kjaer Pulse system was used in the experiment. The vibration signals were measured in two auxiliary channels (tachometer signal and electric current signal) and four vibration channels. The signal duration was 60s and the sampling frequency 16384 Hz. After data acquisition, the speed profile and the vibration signal data were processed. This was done by (a) signal segmentation (according to digging process cyclicity), and (b) feature extraction.

The recorded vibration signal is shown in the top exhibit of Fig. 1. The exhibit contains two graphs depicting *speed [RPM]* and *acc [m/sec<sup>2</sup>]* (acceleration) viewed as function of *time [sec]*. To achieve stationarity, the recorded signal was cut into segments (two cuts are also shown in the top exhibit of Fig. 1).

Next, each of the obtained segments was subjected to spectral analysis using Matlab function `psd`. This yielded for each segment a power spectrum. Two such power spectra are shown in Fig. 1, bottom exhibit. One may notice some periodicity in appearing of the peaks of the spectrum: all they appear at equally spaced values of mesh frequency (expressed in Hz). This can be explained, taking into account the architecture of the gearbox and its way of working (to learn more, see [9], [8], where also a preliminary analysis of the data may be found).

As result of this stage of data recording and preprocessing, two sets of data vectors were obtained, each with 15 components. Each data vector corresponds to the recorded variables `pp1`,  $\dots$ , `pp15` obtained from the spectral analysis carried out for one segment of the vibration recording. The bad data yielded  $n_A = 1232$ , and the good data  $n_B = 951$  segments. The obtained two sets of data vectors constitute two matrices named A and B. These matrices, of size  $[n_A \times 15]$  and  $[n_B \times 15]$ , are the basis of our further analysis.

\* This work was partially supported by (Polish) State Committee for Scientific Research in 2009 - 2012 as research project by R. Zimroz

Fig. 1. Data acquisition. Top exhibit: Recorded vibration signals shown as dependence of speed [RPM] and acceleration [m/s<sup>2</sup>] from time [s]. Bottom: Two samples of power spectra, obtained from the Matlab PSD procedure, the amplitude of the spectra is depicted as function of frequency [Hz].

The number of spectral components extracted from a spectrum depends on many factors (design of machine, its condition, external load, signal-to-noise ratio etc). In literature usually 5-6 components were used.

Generally, the obtained variables  $pp1, \dots, pp15$  are expected to indicate whether the device is in bad or good state; in our case they are expected to be associated with state of particular element of the working device, i.e. the planetary stage. It seems that so far this problem (how many power spectra take for the analysis) has not been investigated in a systematic way.

What concerns the damages of the gearbox A, it was found that all the rolling bearings had exceeded the allowable radial backlash and most of the gears had scuffs and micro cracks on their teeth [8].

### B. Preliminary analysis of the data: simple statistics and visualization

Firstly, univariate characteristics such as means, medians and boxplots were calculated. This was done both for raw and normalized data. Each data matrix ( $\mathbf{X}$ ) has been firstly centered to have the mean of each column equal zero, and next normalized so to have the length of each column equal to 1 (this was the way used by [18] and [19] in their sparse PCA). In consequence, every column of  $\mathbf{X}$  has variance equal to  $1/n$ . The boxplots obtained for both raw and normalized data matrices are shown in Fig. 2.

Looking at the boxplots constructed from raw data of sets A and B, one may notice that their distributions differ (in absolute value) considerably in these two sets. For example, in set A, the most characteristic are very large values in variable 5 and 7; while in set B the largest values are exhibited by variable 2 (contains exceedingly large part of outliers) and variable 4.

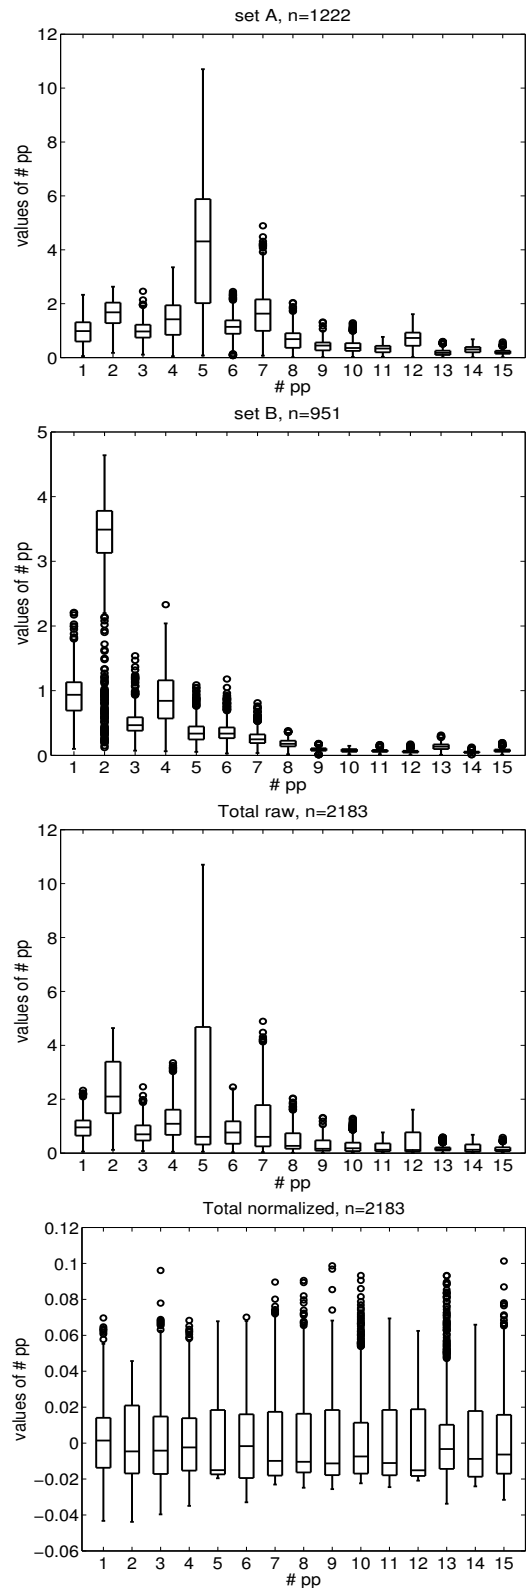

Fig. 2. The top two boxplots depict groups A (bad) and B (good) with raw data, i.e. non-standardized. The bottom two exhibits depict set C containing the sets A and B merged into one common group. Two boxplots are shown for the set C: firstly for raw data, next for normalized data.

On the other hand, looking at the variables no. 9–15, which have very small amplitudes, but differentiated distributions, it is difficult to say something definite about their abilities of differentiation between groups A and groups B.

The medians calculated for all the 15 variables are shown in Fig. 3.

There are two plots constructed for raw and standardized data of both groups. The bottom plot, exhibiting medians for normalized data, is especially interesting. One may notice that:

- (i) variable no. 1 has practically the same value in both groups, therefore it is hard to expect that this variable will contribute to the differentiation between groups A and B; the same can be said about variable no. 13
- (ii) variable no. 2 has inverted value as compared to remaining variables; why does it happen? needs further exploring
- (iii) remaining variables No.s 3 – 12, 14 – 15 exhibit approximately the same difference between their medians, thus any one of them is a candidate for a good discriminator.

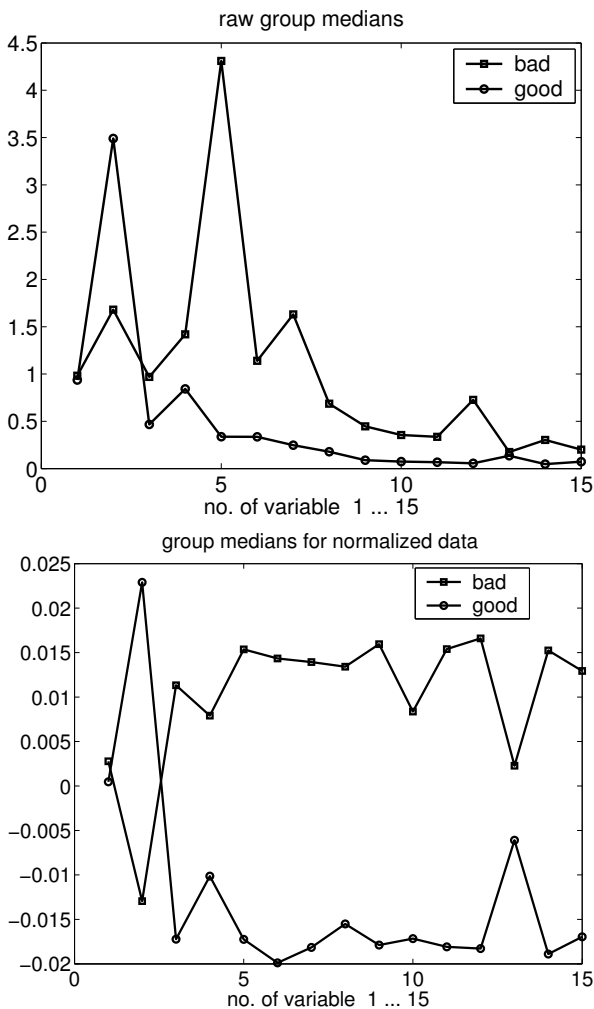

Fig. 3. **Medians** for the raw (top) and normalized (bottom) groups A and B of the recorded data.

### III. MULTIVARIATE DATA VISUALIZATION USING KOHONEN’S SELF-ORGANIZING MAPS

To visualize the considered 15-dimensional data, we use two methods: Canonical discriminant analysis and Kohonen’s self-organizing maps.

Canonical discriminant analysis is a supervised method, it needs as input two data matrices, A and B, containing the two groups of data. The question to answer is: Do the variables pp1 - pp15 have some discriminative power with respect to the bad and good state of the machine? The problem was considered in [10] by using all the 15 variables pp2–pp15 and considering so called Fisher’s LDA criterion. The method yields one canonical discriminant variate which - combined with another one without discriminative power - permits to construct a scatterplot, in which one may see the location of data points belonging to the two considered groups A and B. It happens that these two sets are separated nearly perfectly: only 5 data points are misclassified [10].

Kohonen’s self-organizing maps (the SOM method) are constructed in an unsupervised way. The algorithm obtains as input only one set of data points and tries to depict their mutual neighborhoods in a predefined map. Maps obtained for set C of our data, when considering all 15 variables, and a reduced set of 7 variables, are shown in Fig. 4. First row of maps is based on 15, and the second row on 7 variables.

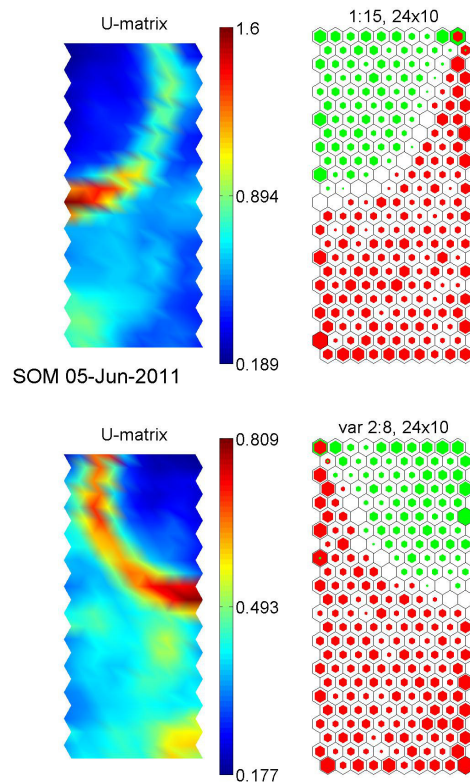

Fig. 4. Kohonen’s self-organizing maps visualizing groups A and B when taking (top) all 15 variables, and (bottom) only variables 2–8. Notice the topological similarity between the two rows of maps.

For construction of the maps we have used the Matlab SOM Toolbox [11]. The architecture of the map is hexagonal; the map is composed from  $24 \times 10$  hexagons. The data were standardized statistically, that is to have zero mean and unit variance for each column.

The maps displayed in Fig. 4 are based on  $24 \times 10$  nodes, which subdivide the total area of the map into 240 sub-areas having the shape of hexagons organized in a grid having 24 rows and 10 columns. To each hexagon a *prototype* vector called by Kohonen a *codebook* vector is found during training of the map. Each codebook represents a certain number ( $n_{kl}$ ,  $k = 1, \dots, 24$ ;  $l = 1, \dots, 10$ ) of input vectors located nearby in the data space. We may find which ones of the data vectors are represented by the given codebook. We may also split each count  $n_{kl}$  into the sum  $n_{kl}^A + n_{kl}^B$ , which shows how many of data points localized at the node  $\langle k, l \rangle$  belong to group A and how many to group B. Having the counts  $n_{kl}^A$  and  $n_{kl}^B$ , we may insert into each hexagon constituting the map two others with size proportional to the counts  $n_{kl}^A$  and  $n_{kl}^B$ , each inserted hexagon painted with different color. The respective maps constructed that way are shown in the right exhibits of Fig. 4. One may notice that data coming from group A and group B are differentiated quite nice.

In the upper map only two nodes (no. 217 and 218) have mixed group content, i.e. represent data vectors belonging either to A or to B.

In the bottom map, the topological locations are inverted with respect to the y-axis (this happens quite often, both maps are topologically equivalent). In this map only two hexagons (no. 1 and 2) have mixed group content, the others are perfectly disjoint. Apart from this, both maps show a decided separation of hexagons containing either bad (group A, color red) or good (group B, color green) data.

We have constructed also another kind of maps, showing directly - by color - the distances of neighboring prototype vectors in the data space. These maps are shown in left exhibits of Fig. 4. The distances are indicated by colors as shown by the adjacent colorbars. One may notice that the two groups are separated quite distinctly by an empty space; also: group A is more homogenous than group B.

The quality of the maps is measured by two indices:  $q$  - *quantization error* and  $t$  - *topographic error* (see [11] for definitions). The respective errors amount:

when using all variables:	$q = 1.075,$	$t = 0.041$
when using variables 2-8:	$q = 0.586,$	$t = 0.040$

The quantization error  $q$  is measuring an average Euclidean distance of data points (located in one node) to their prototype, that is, to their codebook vector. It is obvious, that with more components (variables taken for analysis) this distance is larger. The topographic error  $t$  reflects the fidelity of the topographic representation in the map compared to the true topology in the data space. Surprisingly or not, this error is practically the same for the maps based on 15 and 7 variables.

The above considerations have shown, that the number of considered variables can be reduced, without losing the

essential information about the topological location of the data points. A principled way for finding relevant variables is presented in next section.

#### IV. ORDINARY AND SPARSE PRINCIPAL COMPONENTS

##### A. The classical PCA

Principal component analysis (PCA) is one of the most common and widespread methods for multivariate linear data analysis. It serves for investigating data structure, data mining, data smoothing and approximation, also for exploring data dimensionality. The method permits to build new features, called principal components (PCs), which may serve for visualization of the data [12].

Let  $\mathbf{X}$  of size  $n \times d$  denote the observed data matrix. For simplicity of presentation, assume that  $n > d$ , and that  $\mathbf{X}$  is of full rank. It is advised to standardize or normalize the matrix  $\mathbf{X}$ . Following [18], [19], we assume that the data matrix is column wise centered and has columns of unit length. This means that all columns have means = 0 and variances equal  $1/n$ . The PCA starts from computing the eigenvalues ( $\lambda$ ) and eigenvectors ( $\mathbf{v}$ ) of the cross-product matrix  $\mathbf{S} = \mathbf{X}^T \mathbf{X}$  satisfying the matrix equation  $(\mathbf{S} - \lambda \mathbf{I})\mathbf{v} = \mathbf{0}$ . This results in  $d$  eigenvalues

$$\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_d \quad (1)$$

and associated with them  $d$  eigenvectors

$$\mathbf{v}_j = (v_{1j}, \dots, v_{dj})^T, \quad j = 1, \dots, d. \quad (2)$$

The eigenvectors constitute the loading matrix  $\mathbf{V} = [\mathbf{v}_1, \dots, \mathbf{v}_d]$ . The two fundamental PCA paradigms are:

##### 1) Feature construction:

$$\mathbf{Z}_{n \times K}^{(K)} = \mathbf{X} * [\mathbf{v}_1, \dots, \mathbf{v}_K], \quad 1 \leq K \leq d. \quad (3)$$

The new features identified as columns of  $\mathbf{Z}^{(K)}$  are called **Principal Components** (PCs).

##### 2) Data reconstruction:

$$\hat{\mathbf{X}}_{n \times d}^{(K)} = \mathbf{Z}^{(K)} * ([\mathbf{v}_1, \dots, \mathbf{v}_K]^T). \quad (4)$$

Taking  $K = d$ , the full original data matrix  $\mathbf{X}_{n \times d}$  is reconstructed. For  $K < d$  the best linear approximation of  $\mathbf{X}_{n \times d}$  by a rank- $K$  matrix  $\hat{\mathbf{X}}_{n \times d}^{(K)}$  is obtained - it is best in the meaning of the L2 norm.

The constructed PCs have the major advantage that they are uncorrelated, which permits to analyze each of them separately, without referring to the others.

Principal components can be also computed via SVD:

$$\mathbf{X} = \mathbf{U} \mathbf{D} \mathbf{V}^T$$

where  $\mathbf{Z} = \mathbf{U} \mathbf{D}$  contains the PCs, and  $\mathbf{V}$  the loadings.

##### Applications.

Concerned our domain of interest, that is machine condition monitoring and fault detection: the authors [13] considered some statistical characteristics of vibration signals recorded from an internal-combustion engine sound analysis and an automobile gearbox vibration analysis; after performing a

reduction of dimensionality of the data by PCA they obtained indices suitable for machine condition monitoring. PCA proved also to be very useful in vibration-based damage detection in an aircraft wing and in implementing a procedure for automatic detection and identification of ball bearing faults of some rotating machinery [14], [15].

A detailed analysis of the considered data (sets A, B, C described in Section 2) is shown in [10]. Among others it was found that the first three PCs calculated from set C explain 86 % of total variance of the data. Displaying a scatterplot of the first two PCs (i.e. PC1 and PC2) the points-projections of sets A and B are practically separated and it is possible to draw a linear line separating the two sets with only 5 misclassified data points (out of total  $n_A = 1232$  and  $n_B = 951$  data points).

### B. Sparse PCA

*The idea of sparse PCA:* To construct a PC, one needs all the variables contained in the data set. Is this necessary? It would be desirable to reduce the number of explicitly used variables. This idea was floating for some time among the data analysts and some proposals were offered (see [12], [19], [18]). A reasonable approach with a fast implementation algorithm was proposed in [18]. The authors proposed a regression approach. The idea starts from the observation that each PC is a linear combination of all  $d$  variables. Thus, for known values of a given PC (given as vector  $\mathbf{z}$ , being a column of the matrix  $\mathbf{Z}$  defined in formula 3), and for known values of the matrix  $\mathbf{X}$ , we are able to recover the coefficients of that combination by applying a regression method. If we want a sparse PC (which means that it is based only on few original variables), we should apply here a sparse regression method. The authors of [18] proposed for this purpose the *sparse elastic net regression* [17], [19].

*The computational algorithm proposed by Zou, Hastie et Tibshirani:* The sparse PCs are computed in an iterative way. The computations are for fixed  $K$  ( $1 \leq K \leq d$ ) chosen by the user. The starting point of the reasoning is the observation that the eigenvectors  $\mathbf{v}_j$ ,  $j = 1, 2, \dots, K$  constituting the matrix  $\mathbf{V} = [\mathbf{v}_1, \dots, \mathbf{v}_K]$  appear in PCA in two roles: when constructing the features (formula 3)

$$\mathbf{Z}^{(K)} = \mathbf{X}\mathbf{V}^{(K)}, \quad (5)$$

or reconstructing the original data matrix (formula 4).

$$\hat{\mathbf{X}}^{(K)} = \mathbf{Z}^{(K)} * (\mathbf{V}^{(K)})^T. \quad (6)$$

Let  $\mathbf{B}$  denote the matrix  $\mathbf{V}^{(K)}$  used in construction of  $\mathbf{Z}^{(K)}$  (formula 5), and  $\mathbf{A}$  the matrix  $\mathbf{V}^{(K)}$  used in reconstruction of  $\hat{\mathbf{X}}$  (formula 6). To obtain sparse PCs, the authors [18] propose to estimate the loading matrix  $\mathbf{V}^{(K)}$  in an alternating way, working in two stages:

*Stage 1.* Given  $\mathbf{A}$ , compute  $\mathbf{B}$ ; and

*Stage 2.* Given  $\mathbf{B}$ , compute  $\mathbf{A}$ .

The initial estimate of  $\mathbf{A}$  may be obtained, e.g. by ordinary PCA.

*Stage 1. Given  $\mathbf{A}$ , compute  $\mathbf{B}$ .* Having  $\mathbf{A}$ , we may perform for each  $j = 1, \dots, K$  the following evaluations:

- compute the values (scores) of the  $j^{\text{th}}$  feature  $Z_j$  appearing in the  $j^{\text{th}}$  column of  $\mathbf{Z}^{(K)}$  as:

$$\mathbf{z}_j^* = \mathbf{X} * \mathbf{a}_j,$$

- notice that the values (scores) of the  $j^{\text{th}}$  feature  $Z_j$  may be also computed as

$$\mathbf{z}_j = \mathbf{X} * \mathbf{b}_j, \quad (7)$$

- notice, that at this moment we know  $\mathbf{z}_j^*$ , and so we may substitute in equation (7):  $\mathbf{z}_j = \mathbf{z}_j^*$ , obtaining

$$\mathbf{z}_j^* = \mathbf{X} * \mathbf{b}_j, \quad (8)$$

- since equation (8) may be viewed as a linear regression problem in unknown regression coefficients vector  $\mathbf{b}_j$ , obtain an estimate of  $\mathbf{b}_j$  by applying a sparse regression algorithm (e.g. `larsen` [17]).

In such way it is enforced that only few columns of  $\mathbf{X}$  will appear in the regression equation, because only few elements of the vector  $\mathbf{b}$  will have non-zero elements. The degree of sparseness of the regression depends on the algorithm. The `larsen` algorithm permits the user to declare, how many original variables (columns of  $\mathbf{X}$ ) should be retained.

Performing the estimation of sparse regression coefficients vectors  $\mathbf{b}_j$  for  $j = 1, \dots, K$  we obtain  $K$  successive vectors composing estimates of the sought matrix  $\hat{\mathbf{B}} = [\hat{\mathbf{b}}_1, \dots, \hat{\mathbf{b}}_K]$  – which was desired at this stage of the calculations.

Now we pass to stage 2.

*Stage 2. Given  $\mathbf{B}$ , compute  $\mathbf{A}$ .*

If  $\mathbf{B}$  is fixed, then the problem is to find such a matrix  $\mathbf{A}$ , that minimizes the quadratic form

$$\|\mathbf{X} - (\mathbf{X}\mathbf{B})\mathbf{A}^T\|^2$$

subject to the restriction that  $\mathbf{A}^T\mathbf{A} = \mathbf{I}_{K \times K}$ .

It is shown in [18] that this is obtained by a reduced rank form of the *Procrustes rotation* by computing the SVD of  $(\mathbf{X}^T\mathbf{X})\mathbf{B}$ :

$$(\mathbf{X}^T\mathbf{X})\mathbf{B} = \mathbf{U}\mathbf{D}\mathbf{V}^T$$

and substituting  $\hat{\mathbf{A}} = \mathbf{U}\mathbf{V}^T$ .

Stages 1 and 2 are repeated alternately until a final criterion of convergence is met. The convergence might be achieved if the maximal difference computed for the respective elements  $B_{ik}$  ( $i = 1, \dots, d$ ,  $k = 1, \dots, K$ ) is smaller than an assumed small number  $\epsilon$  (say,  $\epsilon = 1 * e^{-6}$ )

$$|B_{ik}^{old} - B_{ik}^{new}| < \epsilon,$$

where  $\mathbf{B}^{old}$  and  $\mathbf{B}^{new}$  denote the matrices of loadings obtained in two successive iterations. This condition might be combined with another condition that the total number of iterations carried out so far is smaller than a declared maximal number of iterations.

AV	0.12	0.03	0.01	$\Sigma$ 15.54%

## V. SPARSE PCA – RESULTS FOR THE GEARBOX DATA

For calculations we have used the Matlab software implemented by Karl Skoglund and available at <http://www2.imm.dtu.dk/~ksjo/kas/software/index.html> [19]. The software works extremely fast, and being in the form of M-files, can be quite easily adopted to the wishes of its user. Sparse principal components are calculated by the function `sPCA`. The most important parameters to be declared by the user are:  $K$ , the number of desired sparse principal components,  $\lambda$ , parameter for the function `larsen` performing the elastic net regression (see description of stage 2 of the algorithm presented in Section 4), `stop`, a parameter specifying some stopping criteria, containing also the option how many non-zero components to retain in each loading vector (eq. 2) of the retained PCs. The algorithm relies heavily on the function `larsen` realizing the algorithm for elastic net regression [18], [19], being an extension of the least angle regression [16], [17].

Assuming  $K=3$  (compute 3 sparse principal components),  $stop=2$  (each PC uses only 2 original variables) and  $\lambda=1$  ( $\lambda$  is a parameter needed by the function `larsen` called in Stage 1 of the algorithm) we got for our data the (constructed) feature matrix  $\mathbf{Z}_{n \times 3}$  containing in its columns three sparse principal components:  $\langle PC1, PC2, PC3 \rangle$ . They are depicted in Fig. 5.

The displays look much similar to those obtained by ordinary PCA (shown in [10]).

Similar displays (not shown here) were obtained when using  $\lambda=10$  and  $\lambda=100$ . Details of the results, for the same values of  $K$  ( $=3$ ),  $stop$  ( $=2$ ) but different values of  $\lambda$  are shown in Table 1.

When analyzing the results, one should consider:

- (i) Which original variables were chosen by the applied `sPCA` algorithm to constitute the sparse principal components?
- (ii) How much of total variance is explained by the constructed sparse PCs?

Before discussing the results, we should emphasize that the applied method yields sparse PCs that have different properties than the classic ones. This happens because the classical PCs are set with the criterion of extracting the maximum amount of total variance of the data, while in construction of sparse PCs this principle is *de facto* not used. To say it plainly, the

Fig. 5. Sparse principal components PC1, PC2 and PC3. Legend: a red '+' denotes 'bad' data point (set A); a green hexagon denotes 'good' data point (set B). Top: scatterplot of  $\langle PC1, PC2 \rangle$ . Middle: Zoom of the overlapping parts of the 'bad' and 'good' data clouds, the bad points, i.e. red pluses, are additionally circled. Bottom: 3D display of  $\langle PC1, PC2, PC3 \rangle$ .

columns of  $\mathbf{B}$  (used for construction of  $\mathbf{Z}$ ) are based on other principle: the sparse regression. This makes that the variances of the sparse PCs need not decrease with the no. of the PC; also that the variances of the sparse PCs do not need to sum to the total variance, given as  $trace$  of  $\mathbf{S} = \mathbf{X}^T \mathbf{X}$ . To make them act similarly like the classical PCs, after convergence of the 2-stage algorithm the following actions are undertaken :

- $\alpha$ ) normalization of the loadings appearing in  $\mathbf{B}$ , to have unit Euclidean length.
- $\beta$ ) ordering of the columns of the  $\mathbf{Z}$  matrix according to their decreasing variance, and next orthogonalizing them – to have adjusted increments (AV) of explained variance.

Now let us look at Table 1. We find that

- Considering point (i) formulated above: The variables

chosen for two pairs of the sparse PCs are the same for  $\lambda=1$  and  $\lambda=2$ , but one pair of chosen variables differs.

- Considering point (ii) formulated above: An inversion happened in finding the PCs with the largest variances. In the experiment using 3 different values of  $\lambda$ , the sparse PC explaining the maximum variance was found as the third (for  $\lambda=1$ ) or the second (for  $\lambda=10$  and  $\lambda=100$ ).

- Generally, the total percentage of explained variance called AV (adjusted variance) is low, however that the graphically displayed information of the data is practically the same as that obtained from first three classical PCs, which reconstruct together 86.05% of total variance. This leads to the conclusion that the sparse PCA is able to recover the proper information on the topological structure of the data. This is interesting and needs further elaboration. Probably this is due to the specificity of our data. It was noticed already in Section 2 that there are several variables which repeat the same information. The classical PCA is able to notice them at once and account all their information into the first PCs. The sparse PCA algorithm deals only with part of the variables and constructs dependent PCs. However, despite this, the sparse PC algorithm is able to recover the proper information on the topological structure of the analyzed gearbox data.

## VI. DISCUSSION AND CONCLUDING REMARKS

The necessity and usefulness of producing sparse PCs was considered since long as part of so called *factor analysis* seeking to group the analyzed variables into some subgroups which appear jointly indicating for a hidden, non-measurable variable which manifests itself through the observed and measurable phenomena [12] (e.g. 'intelligence' is such a hidden variable). One very popular method consisted of performing rotations of the loading matrix obtained from PCA (e.g., the varimax rotation). Other method acted by determining simple thresholds of elements of the loading matrix; e.g. elements smaller than 70% of the maximum from all elements were simply set to zero.

The sparse algorithm proposed in [18] is mathematically very sophisticated. It can be implemented to work effectively and fast when using Matlab [19]. The algorithm is relatively new and not very much in use. We have applied this algorithm with the aim of reducing the number of variables needed when making a diagnosis of gearbox functioning. It seems that we were successful and the set of used variables can be reduced. However, we have noticed that the results of analysis depend from few initial parameters needed by the spca algorithm. For the moment the parameters are found by a kind of cross-validation. The results may also depend on the structure of the data. Therefore, before advising the algorithm for an automated procedure, some further research on work of the algorithm is needed.

SCotLASS is another interesting method, developed about the same time [20]. It seems to be easier in determining the input parameters for a sparse PCA, however the numerical optimization of the applied criterion is more complex.

SCoTLASS has elucidated a difficult problem connected with structure of Yeast DNA [21], which could not be identified previously.

# CWJess: Implementation of an Expert System Shell for Computing with Words

Elham S. Khorasani, Shahram Rahimi, Purvag Patel, Daniel Houle  
Department of Computer Science  
Southern Illinois University Carbondale  
Carbondale, IL, USA

**Abstract**—Computing with Words (CW) is an emerging paradigm in knowledge representation and information processing. It provides a mathematical model to represent the meaning of imprecise words and phrases in natural language, and to perform reasoning on perceptual knowledge. This paper describes a preliminary extension to Jess, CWJess, which allows reasoning in the framework of Computing with Words (CW). The resulting inference shell significantly enhances the expressiveness and reasoning power of fuzzy expert systems and provides a Java API which allows users to express various types of fuzzy concepts, including: fuzzy graphs, fuzzy relations, fuzzy arithmetic expression, and fuzzy quantified propositions. CWJess is fully integrated with jess and utilizes jess Rete network to perform a chain of reasoning on fuzzy propositions

**Index Terms**—Computing with Words; fuzzy Logic; Expert systems; knowledge representation

## I. INTRODUCTION

HUMAN mind has a limited capability for processing a huge amount of detailed information in his environment; thus, to compensate, the brain groups together the information it perceives by its similarity, proximity, or functionality and assigns to each group a name or a “word” in natural language. This classification of information allows human to perform complex tasks and make intelligent decisions in an inherently vague and imprecise environment without any measurements or computation. Inspired by this human capability, Zadeh introduced the machinery of CW as a tool to formulate human reasoning with perceptions drawn from natural language and argued that the addition of CW theory to the existing tools gives rise to the theories with enhanced capabilities to deal with real-world problems and makes it possible to design systems with higher level of machine intelligence [1][2]. To do this, CW offers two principal components, (1) a language for representing the meaning of words taken from natural language, this language is called the Generalized Constraint Language (GCL), and (2) a set of deduction rules for computing and reasoning with words instead of numbers. CW is rooted in fuzzy logic; however, it offers a much more general methodology for fusion of natural language propositions and computation with fuzzy variables. CW inference rules are drawn from various fuzzy domains, such as fuzzy logic, fuzzy arithmetic,

fuzzy probability, and fuzzy syllogism. This paper reports a preliminary work on the implementation of a CW inference system on top of JESS expert system shell (CWJess). The CW reasoning is fully integrated with JESS facts and inference engine and allows knowledge to be specified in terms of GCL assertions.

The current fuzzy logic expert system shells, such as: fuzzyclips [3], fuzzyjess [4], FLOPS [5], and Frill [6] are much devoted to implementing Mamdani inference system and have left out reasoning with other fuzzy concepts such as: fuzzy relations, fuzzy arithmetic, fuzzy quantifiers, and fuzzy probabilities. This paper presents a roadmap to implement a CW expert system shell capable of representing and reasoning with such concepts. The resulting CWJess expert system shell would allow users to express their knowledge in form of fuzzy quantified propositions, discrete fuzzy relations, and fuzzy arithmetic expressions as well as fuzzy if-then rules and enables them to perform advanced fuzzy reasoning.

## II. PRELIMINARY: COMPUTING WITH WORDS

This section provides a very brief introduction to computing with words, the generalized constraint language, and CW inference rules. More detailed information can be found in Zadeh’s paper [7].

The core of CW is to represent the meaning of a proposition in form of a generalized constraint (GC). The idea is that a majority of the propositions and phrases used in natural language can be viewed as imposing a constraint on the values of some linguistic variables such as: time, price, taste, age, relation, size, appearance, and etc. For example the sentence: “most Indian foods are spicy” constrains the two variables: (1) the taste of Indian food, and (2) the portion of the Indian foods that are spicy. In general, a GC is in form of:

$$X \text{ is } r \text{ R}$$

Where X is a linguistic (or constrained) variable whose values are constrained by the linguistic term R, and the small r shows the semantic modality of this constraint, i.e., how X is related to R. Various modalities are introduced in the literature of CW, among them are:

- possibility ( $r=blank$ ): where  $R$  is a fuzzy set which denotes the possibility distribution of  $X$  [8], e.g., “ $X$  is large”.
- fuzzy graph ( $r=fg$ ): where  $X$  is a function of another variable, say  $Y$ , and  $R$  is a fuzzy estimation (or granulation) of that function. This modality corresponds to a collection of fuzzy if-then rules that share the same variables in their premises and consequences. e.g., “ $X=f(y)$  isfg (small  $\times$  large + medium  $\times$  medium + large  $\times$  small)”, which is equivalent to three fuzzy rules: *if  $Y$  is small then  $X$  is large, if  $Y$  is medium then  $X$  is medium and if  $Y$  is large then  $X$  is small.*
- probability ( $r=p$ ): where  $X$  is a random variable and  $R$  is the probability distribution of  $X$ , e.g., “( $X$  is large) isp likely”.
- usuality ( $r=u$ ): where  $X$  is a random variable and  $R$  is the usual (or typical) value of  $X$ , e.g., “ $X$  isu big”

A collection of GCs together with a set of logical connectives (such as: and, or, implication, and negation) and a set of inference rules form the generalized constraint language (GCL). The inference rules regulates the propagation of GCs. Table 1 lists instances of inference rules introduced for GCL. As shown in this table, each rule has a symbolic part and a computational part. The symbolic part shows the general abstract form of the GCs that appear in the premises and conclusion of a rule, while the computational part calculates the fuzzy value of the consequent of the rule based on its premises.

TABLE I. INSTANCES OF CW INFERENCE RULES

Inference rule	Symbolic part	Computational part
Conjunction Rule	$x$ is $A$ $y$ is $B$ $(x, y)$ is $C$	$\mu_C(u, v) = \mu_A(u) * \mu_B(v)$
Extension Principle	$X$ is $A$ $f(X)$ is $B$	$\mu_B(z) = \sup_u (\mu_A(u))$ subject to : $z = f(u)$
Compositional Rule of Inference	$X$ is $A$ $(Y, X)$ is $B$ $Y$ is $C$	$\mu_C(v) = \sup_u (\mu_A(u_i) * \mu_B(v, u))$
Fuzzy graph Interpolation	$\sum_i$ if $X$ is $A_i$ then $Y$ is $B_i$ $X$ is $A$ $Y$ is $B$	$\mu_B(v) = \sup_i (m_i * B_i)$ $m_i = \sup_u (\mu_A(u) * \mu_{A_i}(u))$ $i = 1 \dots n$
Fuzzy Syllogism	$Q_1 A$ 's are $B$ 's $Q_2(B)$ 's are $C$ 's $Q_3 A$ 's are $(C)$ 's	$\mu_{Q_3}(z) = \sup(\mu_{Q_1}(w_1) * \mu_{Q_2}(w_2))$ subject to : $z = w_1 * w_2$ $w_1, w_2$ , and $z$ are the universes of discourse of $Q_1, Q_2$ , and $Q_3$ , respectively

### III. INCORPPRATING CW REASONING IN JESS

Figure 1 shows a schematic view of CWJess Inference System.

Figure 1. The schematic view of CWJess Inference System

CWJess consists of two components: the Java API and the CWJess library. The Java API is the core element which implements CW concepts, such as linguistic variables, various types of generalized constraints, and *the computational part* of CW inference rules. The CWJess library consists of a list of production rules which define the *symbolic part* of CW inference rules. When a user adds a GCL assertion to the fact base, Jess Rete algorithm checks the symbolic part of CW inference rules in CWJess library to find a production rule whose premises match with the facts and place the consequents of such rules into the agenda. When a CW inference rule is fired, its consequent calls the java method which performs the computational part of the rule and asserts the result back to the fact base.

#### A. GC Assersions in CWJess Fact Base

The CWJess fact base consists of a set of GC assertions. A GC assertion may have one of the following forms:

- (1) a simple generalized constraint,
- (2) a fuzzy graph,
- (3) a quantified generalized constraint
- (4) an arithmetic generalized constraint.

Different forms of generalized constraints are implemented as java classes in the java API. The GC facts are then created as jess shadow facts connected to the corresponding java object.

A simple generalized constraint consists of four elements:

- An atomic or composite linguistic variable, such as: “age”, “size”, “weight”, “price”, “distance”, etc.
- A list of objects of linguistic variables, for example object “Mary” for the linguistic variable “Age”, or object “McDonald’s”, for the linguistic variables “service-quality”.
- A semantic modality. The semantic modality may be: “possibistic”, “probabilistic” “verisitic”. The semantic modality is by default possibilistic. At this point, we have only implemented the possibilistic semantic modality. The implementation of probabilistic and veristic modalities and their combination with possibilistic modality requires the availability of more complex theories and will be considered as future work of this study.

- A linguistic value associated with the linguistic variable and constraint its values.

For example, the generalized constraint: *service-quality(McDonald's) is good* consists of the linguistic variable: *service quality*, object: *McDonald's*, semantic modality: *possibilistic*, and linguistic value: *good*.

Two types of linguistic variables are considered: *atomic* and *composite*. The atomic linguistic variable consists of a name (e.g., oil-price), a unit (e.g., \$ per gallon), a range of values (e.g. 1.0-5.0), and a set of linguistic terms (e.g., “cheap”, “mid-price”, and “expensive”). The linguistic terms are defined using a term name and a membership function that is a fuzzy set over the range of values for the linguistic variable. The membership functions may be defined to have a standard shape, such as : triangular, trapezoid, Gaussian, Pi shape, S shape, Z shape, crisp interval, or it may be a piecewise linear, or a discrete function specified by a set of singletons. Figure 2 shows three linguistic terms with different type of membership function for the linguistic variable: “oil-price”.

Figure 2. Examples of membership functions for the linguistic variable: oil\_price

A composite linguistic variable is a fuzzy relation between two or more linguistic variables. To reduce the complexity of computation, the membership function of composite linguistic variable is assumed to be discrete. The inclusion of continuous fuzzy relation requires complex non-linear computation, and will be considered as the future developments of CWJESS. Figure 3 shows the membership function for the linguistic term “petite” of the composite linguistic variable, “size”, where “size” is a fuzzy relation of two atomic linguistic variables: “height” and “weight”.

Figure 3. The membership function for the linguistic term: “petite” of the composite linguistic variable “size”.

A linguistic value in a generalized constraint may be modified by a fuzzy modifier. The modifiers implemented in

CWJESS are: *not*, *more-or-less*, *a-little-more*, *slightly-more*, *somewhat*, *very*, *extremely*, *indeed*, and their combinations.

A Fuzzy graph is a collection of fuzzy if...then rules in which all the premises and the conclusion share the same linguistic variables. The general form of a fuzzy graph in CWJESS is as follows:

$$\sum_{i=1..n} \text{if } (GC_{i1} \wedge GC_{i2} \dots \wedge GC_{in}) \text{ then } GC_{ik}$$

Where  $GC_{i1}, GC_{i2}, \dots, GC_{in}$  denote the generalized constraints in the premise of the rule, and  $GC_{ik}$  is the generalized constraint in the consequent of the rule. For example:

*if age(x) is young  $\wedge$  health(x) is good then insurance(x) is very low*  
*if age(x) is middle-age  $\wedge$  health(x) is good then insurance(x) is average*  
*if age(x) is old  $\wedge$  health(x) is moderate then insurance(x) is relatively high*  
*if age(x) is old  $\wedge$  health(x) is poor then insurance(x) is very high*

Although fuzzy graph may seem as the conjunction of a set of fuzzy if-then rules (or fuzzy implications), it has a very different meaning. From the mathematical point of view, a fuzzy graph expresses a functional dependency between two or more linguistic variables and provides a fuzzy description of such function when the point to point data is not available. Hence, fuzzy graph has a completely different semantics than the fuzzy implication and must be treated differently by the inference engine.

A quantified generalized constraint (QGC) consists of a fuzzy quantifier and a generalized constraint with an anonymous object (variable) which is bounded by the quantifier. For example: “most<sub>x</sub> price(x) is expensive” is a quantified generalized constraint in which  $x$  is an anonymous object bounded by the quantifier “most”. Fuzzy quantifiers are defined as fuzzy sets and are assigned a membership function:  $\mu : [0,1] \rightarrow [0,1]$ . In this version of CWJESS we limited ourselves to monotone increasing quantifiers, such as : “most”, “many”, “several”, “a few”, etc., for applying Zadeh’s syllogism reasoning [9].

We have implemented two types of QGC: unary and binary. A unary QGC puts constraint on the proportion of objects that satisfy a single generalized constraint, e.g., “most<sub>x</sub> (age(x) is young)” whereas a binary QGC imposes a constraint on the proportion of number of objects that satisfy one. For example: “most<sub>x</sub> ( age(x) is young, health(x) is good)” is a binary QGC which states that the number of “x” s who are young and healthy over the number of “x”s who are young, is most.

An arithmetic generalized constraint (AGC) is a generalized constraint which has an arithmetic fuzzy expression as its linguistic value. The arithmetic expression may consist of linguistic terms or other linguistic variables. For example: “gas-price(Europe) is gas-price(US) + approximately \$4 per gallon”, which states that the gas price in Europe is approximately \$4 more per gallon than in the United States.

**B. Implementation of CW Inference Rules**

The computational part of all CW rules is implemented in the java API as the following java methods. The result of the each method is a normalized fuzzy set.

- **Conjunction method:** The conjunction method takes a number of linguistic terms associated with a linguistic variable, and computes their minimum intersection. (The minimum operation can be easily replaced with a t-norm [10])
- **Disjunction method:** The disjunction method takes a number of terms associated with a linguistic variable and computes their maximum union. The maximum operation can be replaced with a t-conorm.
- **Compositional method:** The compositional method takes two linguistic terms: one associated with a composite linguistic variable and the other one associated with an atomic linguistic variable, which occurs in the composite linguistic variable, and calculates their max-min composition. As an example let us assume that the composite linguistic variable size of a woman consists of the atomic linguistic variables, height and weight, i.e.,

$$size(x) = (height(x), weight(x))$$

let's also assume that the membership function for the term "petite" associated with size, and the term "about 5.2" associated with the height are given. The compositional method calculates the membership function of the weight of a petite woman who is about 5.2 tall, as shown in the following figure.

Figure 4. Compositional rule of inference. Composition of the fuzzy relation "petite" with the fuzzy set "about 5.2". the

- **Fuzzy graph Interpolation method:** This method corresponds to Mamdani method of inference. It takes a fuzzy graph as well as a set of linguistic terms associated with the linguistic variables in the premises of a fuzzy graph and computes the corresponding fuzzy set for the linguistic variable in the conclusion. Unlike Mamdani inference method, where the input is a singleton, the fuzzy interpolation method accepts a linguistic term (fuzzy set) as input and, for each rule, computes the match score as the degree of similarity between the input fuzzy set and the ones in the premise of the rule. For instance, consider the fuzzy graph mentioned as an example in the previous subsection, and let us assume that the input it: "age is about 55" and "health is "excellent", then the fuzzy graph interpolation

method would calculate the fuzzy set for the linguistic variable "insurance" as illustrated in figure 5.

Figure 5. Example of fuzzy graph interpolation rule. The gray areas in the first and second column show the membership functions of "about 55", and "excellent" for the linguistic variables "age" and "health", respectively.

- **Fuzzy Extension method:** The fuzzy extension method, takes an arithmetic expression on a number of linguistic terms associated with a linguistic variable, and returns the fuzzy set resulted from performing the arithmetic operations. The linguistic terms appear in the arithmetic expressions are required to have a normal convex fuzzy set.

The implementation of the extension principle is not trivial and involves nonlinear optimization. Thus approximation methods are usually used to obtain the membership function of the resulting fuzzy set. A common practice is to discretize the membership interval [0,1] into a finite number of values and, for each value, take the  $\alpha$ -cut of all the operands. The arithmetic operations then may be performed on the resulting intervals, using the interval arithmetic, in order to come up with the  $\alpha$ -cut of the output fuzzy set. Finally, these  $\alpha$ -cuts are put together to obtain the output of the arithmetic operations. This approach can be efficiently implemented and provides a good approximation to the exact solution of the extension principle [11]. Figure 6 demonstrates the  $\alpha$ -cut method for computing the result of the arithmetic expression: "around3 + approximately4 \* about-half", for the linguistic variable "oil\_price".

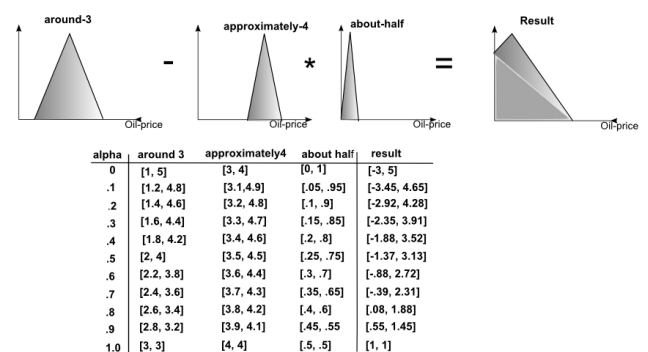

Figure 6. An example of alpha-cut implementation of the extension principle. The table shows the  $\alpha$ -cuts of the operands and the output of the arithmetic expression

- **Fuzzy Syllogism:** The fuzzy syllogism method takes two monotone increasing fuzzy quantifiers, and calls the extension method to calculate and return their multiplication.

The symbolic parts of the above rules are implemented as production rules in the CWJESS library. For example, the symbolic part of the conjunction rule may be defined as follows:

```
;; The conjunction rule
(defrule conjunction
  (declare (salience 100))
  ?c1<-(GC (linguistic_var ?x ) (object ?a)
    (linguistic_value ?w))
  ?c2<-(GC (linguistic_var ?x) (object ?a)
    (linguistic_value ?z&:(<> ?z ?w)))
=>
  (assert (GC (linguistic_var ?x) (object ?a)
    (value (CWRULES.conjunction ?w ?z))))
  (retract ?c1 ?c2))
```

This rule states that if there are two different generalized constraints in the fact base sharing the same linguistic variable and the same object, they are combined to one generalized constraint whose value is the conjunction of the linguistic values of the premises. GC is a template automatically created from the generalized constraint class in the java API. GCWRULES is a java class which implements the computational parts of CW rules as described earlier.

As another example, consider the compositional rule of inference, the symbolic part of this rule is defined in CWJESS library as follows:

```
;; The compositional rule of inference.
(defrule composition
  (GC (linguistic_var ?u &:(instanceof ?u
    COMPOSITE_LINGUISTIC_VARIABLE))
    (object ?o) (linguistic_value ?w))
  (GC (linguistic_var ?x &:(instanceof ?x
    ATOMIC_LINGUISTIC_VARIABLE))
    (object ?o) (linguistic_value ?z))
  (test (occurs ?x ?u )
    =>
  (assert (GC (linguistic_var (CWRULES.composedVar ?u
    ?x)) (object ?o) (linguistic_value
    (CWRULES.composedValue ?w ?z ))))
```

This rule states that if there are two generalized constraints in the fact base, one with a composite linguistic variable ?u, and another one with an atomic linguistic variable ?x, and ?x occurs in ?u, then assert a new generalized constraint which is the composition of the two generalized constraints in the premises. The methods composedVar, and composedValue are static methods defined in CWRULES and return, respectively, the linguistic variable and the fuzzy set resulted from the composition.

The symbolic parts of the fuzzy graph interpolation rule, fuzzy syllogism, and fuzzy extension principle, are defined in a similar way but are excluded from the paper due to their complexity and length.

#### IV. AN EXAMPLE

To demonstrate the CWJESS we present a simple example.

Suppose that we would like to encode the following information in a CWJESS fact base:

- *The average chance that a woman is diagnosed by breast cancer depends directly on her age. The younger a woman is, the lower is her risk of developing a breast cancer.*
- *Many obese women have higher risk of developing a breast cancer and a Mammogram is strongly recommended for most women at high risk of breast cancer.*
- *Mary has a son who is about 15. She gave birth to her son when she was in her 20's. Also She is few years younger than Ann who is in her mid-50.*

The dependency between the age and the risk of breast cancer should be represented as a fuzzy graph. To create a fuzzy graph, the related linguistic variables and their associated terms must be first defined. In the following Jess code, "trap-mf", "tri-mf", "z-mf", "p-impf", "s-mf", and "interval-mf" denote trapezoid, triangular, z shape, pi shape, s shape, and the crisp interval membership functions, respectively.

```
;; Defining the linguistic variables and terms that
;; appear in the fuzzy graph
(bind ?age (new ATOMIC_LINGUISTIC_VARIABLE "age"
  "year" 0 120 ))
(?age addTerm "young" "(0,1) (25,1) (50,0)" )
(?age addTerm "middle-age" "trap-mf" "30 40 50 60")
(?age addTerm "old" "(40, 0) (65 1) (120,1)" )

(bind ?riskbc (new ATOMIC_LINGUISTIC_VARIABLE
  "risk-breast-cancer" "percentage" 0 100)
  (?riskbc addTerm "low" "z-mf" "5 10" )
  (?riskbc addTerm "average" "pi-mf" "5 10 15 20")
  (?riskbc addTerm "high" "s-mf" "15 30"))
```

Now the fuzzy graph may be created to show the dependency between the linguistic variables: ?age and ?riskbc, and fuzzy rules may be created and added to the fuzzy graph. A fuzzy rule consists of a list of generalized constraints that makes its premises and its conclusion. The parameter "?x" denotes an anonymous object which may be instantiated by the object of a matching generalized constraint in the fact base. The fuzzy graph is added as a shadow fact [12] to the working memory.

```
;; Creating the fuzzygraph
(bind ?fg (new FUZZY_GRAPH)

;;Defining the fuzzy rule: "if age(x) is young then
;;riskbc(x) is low"
(bind ?gc1 (new GENERALIZED_CONSTRAINT ?age "?x"
  "young")
  (bind ?gc2 (new GENERALIZED_CONSTRAINT ?riskbc
    "?x" "low"))
  (bind ?rule1 (new FUZZY_RULE ?gc1 ?gc2))

;;Defining the fuzzy rule: "if age(x) is middle-age
;;then riskbc(x) is average"
(bind ?gc3 (new GENERALIZED_CONSTRAINT ?age "?x"
  "middle-age")
  (bind ?gc4 (new GENERALIZED_CONSTRAINT ?riskbc
    "?x" "average"))
  (bind ?rule2 (new FUZZY_RULE ?gc3 ?gc4))

;;Defining the fuzzy rule: "if age(x) is old then
;;riskbc(x) is high"
(bind ?gc5 (new GENERALIZED_CONSTRAINT ?age "?x"
```

```

"old"))
(bind ?gc6 (new GENERALIZED_CONSTRAINT ?riskbc
  "?x" "high"))
(bind ?rule3 (new FUZZY_RULE ?gc3 ?gc4))
(?fg addRule ?rule3)

;;Adding the rules to the fuzzy graph
(?fg addRule ?rule1)
(?fg addRule ?rule2)

;; adding the fuzzy graph to the working memory
(add ?fg)

```

The statement with fuzzy quantifiers may be represented as a binary quantified generalized constraint. In the following parameter “?x” is a variable bounded by the quantifier.

```

;; creating the generalized constraints that appear
;; in the quantified statements
(bind ?weight (new ATOMIC_LINGUISTIC_VARIABLE
  "weight" "Kilogram" 40 250))
(?weight addTerm "obese" "s-mf" "85 100")
(bind ?gc1 (new GENERALIZED_CONSTRAINT ?weight "?x"
  "obese" ) )
(bind ?gc2 (new GENERALIZED_CONSTRAINT ?riskbc "?x"
  "high"))
(bind ?recom (new ATOMIC_LINGUISTIC_VARIABLE
  "mammogram-recommendation" "percentage" 0 1))
(?recom addTerm "strongly-recommended" "s-mf"
  ".85 1")
(bind ?gc3 (new GENERALIZED_CONSTRAINT ?recom "?x"
  "strongly-recommended" ))

;; Creating the quantified generalized constraints
(bind ?qgc1 (new QUANTIFIED_GENERALIZED_CONSTRAINT
  "many" "?x" ?gc1 ?gc2))
(bind ?qgc2 (new QUANTIFIED_GENERALIZED_CONSTRAINT
  "most" "?x" ?gc2 ?gc3))
;; Adding the quantified generalized constraints to
;; the working memory
(add ?qgc1)
(add ?qgc2)

```

Given that the age of mother is equal to the age of her son plus the age that she gave birth to him, we have two pieces of information regarding Mary’s age which we can be encoded as the following arithmetic generalized constraints.

```

;; Defining the linguistic terms that appear in the
;; arithmetic generalized constraints
(?age addTerm "in-20's" "Interval-mf" "20 30" )
(?age addTerm "about 15" "tri-mf" "13 15 17" )
(?age addTerm "few-years" "trap-mf" " 2 3 5 7")

;; Defining the arithmetic generalized constraints
;; and adding them to the working memory
(bind ?agc1 (new ARITHMETIC_GENERALIZED_CONSTRAINT
  ?age "Mary" "in-20's + about 15" ))
(bind ?agc2 (new ARITHMETIC_GENERALIZED_CONSTRAINT
  ?age "Mary" "?age(Ann) - few-years"))

;; Adding the arithmetic generalized constraints to
;; the working memory
(add ?agc1)
(add ?agc2)

```

And finally, the information regarding Ann’s age can be defined as a simple generalized constraint:

```

(?age addTerm "mid-50" "tri-mf" "50 55 60")
(bind ?gc8 (new GENERALIZED_CONSTRAINT ?age "Ann"

```

```

  "mid-50"))
(add ?gc8)

```

Once the above Jess program is run, the pair of simple and arithmetic facts: ?gc8 and ?agc2 fire the extension principle rule. The extension principle rule replaces “?age(Ann)” with “mid-50” in the arithmetic expression “?age(Ann) – few years” to achieve a fuzzy value for Mary’s Age. The extension principle rule is also fired for the arithmetic fact ?agc1 to calculate the value “in-20’s + about-15”. At this point the fact base would consist of two generalized constraints regarding Mary’s age with different fuzzy values which leads to firing the conjunction rule to combine the constraints to obtain one fuzzy value for Mary’s age.

Now the resulting fact regarding Mary’s age together with the fuzzy graph fact ?fg activate the fuzzygraph interpolation rule, which in turn calculates the value of ?riskbc (Mary) and adds it as a simple generalized constraint to the fact base.

The fuzzy graph interpolation rule is also fired by the pair of facts: ?fg and ?gc8 to calculate the value of ?riskbc(Ann).

Furthermore, the pair of quantified facts: ?qgc1 and ?qgc2 activate the fuzzy syllogism rule which calculates the proportion of obese women for whom the Mammogram is highly recommended. The result of this calculation is asserted to the fact base as a quantified generalized constraint.

In order to show the output of a jess program to the user, the CWJess library includes a jess function: “print-GC”. This function allows users to query the fact base to find the value of a given linguistic variable. For example in the above program if the user wishes to know Mary’s age, or her risk of developing a breast cancer, she can add the following lines to the jess program:

```

;; Querying the fact-base
(print-GC ?age "Mary")
(print-GC ?riskbc "Mary")

```

The output is the two normalized fuzzy sets in figures 7 and 8, deduced by using the extension principle, the conjunction, and the fuzzy graph interpolation rules.

Figure 8. The value of the linguistic variable: "riskbc(Mary)"

## V. SUMMARY AND FUTURE WORK

The paper reports a preliminary work on the implementation of an expert system shell on top of Jess to perform CW reasoning. The resulting shell, CWJess, is a powerful tool which allows users to express fuzzy facts in form of generalized constraints of various types. It provides java classes which enable users to define atomic or composite linguistic variables, linguistic terms, fuzzy quantified statements, fuzzy rules, fuzzy arithmetic expressions, and fuzzy graphs. The CW inference rules, implemented in CWJess, along with Jess Rete algorithm render an inference engine which is able to perform forward reasoning over a set of generalized constraints.

We are working on making the CWJess tool available for download via [www.purvag.com/cwjess](http://www.purvag.com/cwjess). We will provide a complete set of instructions to help users to express their knowledge in terms of GCL. Nevertheless, to facilitate easier translation of linguistic knowledge, we are planning to develop a human readable intermediate language to hide the complexity of underlying GCL.

Several other developments to CWjess can be proposed to make it more expressive and to enhance its reasoning power, among which are:

- Developing necessary classes and methods to allow users to assert generalized constraints with probabilistic

modality, such as: "(age(Mary) is young) isp likely" and perform reasoning on such generalized constraints.

- Implementing the compositional rule of inference for fuzzy relations with a continuous membership function.

**Abstract**—The paper proposes a new method for interactive visual exploration of the chains of financial transactions, assisting an analyst in the detection of money laundering operations. The method mainly concerns searching, displaying and annotating selected groups of transactions from a database. We show how one can programmatically and interactively reduce the volume of the chains surveyed and limit the analysis to the most suspicious transactions. In order to improve readability of the transaction graph, an evolution-based algorithm has been designed to optimize its visual representation. The system is verified on the real-life database of financial transactions. The experiments conducted have shown that allowing visual exploration, one can accelerate the search process and enrich the data analysis.

### I. INTRODUCTION

**M**ONEY laundering denotes the financial operations aimed at putting into circulation money from illegal sources, mainly from criminal activities. Detection of the transactions involved in the process of money laundering is extremely difficult and complex. This follows on the one side from the large amount of data that must be examined and, on the other from the difficulty of distinguishing the ordinary transactions from suspicious ones. Many systems of recording and monitoring transactions, type AML (Anti-Money Laundering), use predetermined rules to detect suspicious transactions [1]; [6]; [10]; [11]. However, despite the commitment of huge resources, the effectiveness of current solutions is very low. In general, the percentage of verified transactions as indicated by the system of suspicious transactions, measured by the index of TPR (True Positive Rate), is very small. For example, one of the largest financial institutions in the Balkans, after the purchase and implementation of software - some of the newest and most expensive software against money laundering - scored TPR equal to 0.02%. This result may seem daunting, but, as practice shows, the majority of institutions start with this level of accuracy and, after years of fine-tuning the system

and finding new patterns, TPR may reach about 5% [4] Government bodies involved in the issuance of regulations recommend to developers that the system should reach TPR ranged from 4% to 7% [4]; [6].

In this paper, we propose an interactive method for visual data mining, assisting an analyst in the detection of illegal transactions. Support consists mainly of visualization and annotation of some of the operations in a graph showing the money flow chains between accounts.

In real-world applications, the number of accounts and transactions is huge; therefore even a partial graph visualization poses problems of feasibility, readability and interpretation of financial operations. In order to assist the analyst to interactive interrogation of the database, we have introduced the functionality of defining SQL queries and graphical operations on the graph of transactions resulting in a significant reduction in the search space. We have also provided a number of editing and graph visualization features, including heuristics to visualize sequences of transactions, graphical aggregation of transactions corresponding to the same account, and the transaction graph optimization by evolutionary algorithm.

The fundamental characteristic which determines the ease of interpretation and pattern matching operations is the representation of the transactions. Typically in financial information systems, transactions are represented in a tabular form as shown in fig. 1, a report of program cash flow chains between accounts taken from the SART system (System for Analysis and Registration of Transactions, developed by TETA SA company) [12]. We see that the presentation of a large number of transactions is barely legible. The report contains information on only a few dozen transactions and yet these are difficult to display on a computer screen. An additional difficulty in visualizing the chain of transactions using the tables and data sheets is heterogeneity. For example, an account can have several incoming and dozens or even hundreds of outbound transactions. In such cases the transactions recorded in the traditional table are hardly legible and are cumbersome to handle because the analyst must often "scroll" the report.

The paper is organized as follows. The next section will show how one can interactively reduce the volume of the

This work has been performed in the framework of a research project on methods of mining anti-money laundering data, conducted by the Center for Intelligent Information Technology in Management of Wrocław University of Economics, Poland.

analyzed chains, namely how one can view in place of all the data only the most important transactions.

Fig. 1. Tabular representation of chains of transactions

Then we show a simple, intuitive way in which one can find more detailed information. We will present a solution that optimizes the visual representation of transaction chains enabling easier analysis of graphic schemes, accelerating the search process, and enriching the functionality of the system. For example, by marking the selected transactions as suspicious, one can try to learn the system to recognize patterns of money laundering operations.

More details about the database structures in AML systems may be found in [7], [8], [9].

## II. REPRESENTATION OF TRANSACTION CHAINS

The main concern while designing a visualization algorithm of sequential operations is the complexity of the resulting graph. In the project, the main measure of assessment of the graph readability was the number of intersections of edges connecting vertices of the graph: the fewer the edges, the better the resulting graph. If the graph contains  $n$  accounts there could occur approximately  $n^2/2$  edges between them [13]. Let us note that in practice some of the edges can be repeated. It follows that the complexity of such a graph is  $O(n^2)$  [2], [3]. Fig.2 presents an example of a graphical representation of the transaction chains. The bold edges indicate that there are many transactions between linked accounts. Red color means that the edge, or at least one of multiple edges, represents a suspicious transaction.

To effectively minimize the number of cuts generated in the initial graph, the whole transformation process was divided into two stages. In the first the simple heuristics have been applied such as the aggregation of multiple edges, the clustering of accounts by type, the linking accounts with the same neighbor in the graph, and the displacement at the bottom of the graph the accounts that are related to transactions with one another account. The graph thus prepared leads to the second stage of the optimization process, which aims to reduce the number of edge intersections and thus improves the readability of the graph.

Fig. 2 Graph of transaction chains obtained by application

Let us now proceed to describe the evolutionary algorithm that minimizes the number of intersections of edges in the graph. The task of the algorithm is to find such repartition of vertices on the plane that the number of intersections of edges of the graph is as small as possible (see the specification of Algorithm 1).

*Algorithm 1. Minimization of the number of edge intersections*

```

C = 5000; // number of iterations without changes to
stop evolution
MutSrcPr = 0.45; // probability of source account mutation
MutInterPr = 0.1; // probability of intermediate account mutation
MutDstPr = 0.45; // probability of target account mutation
Fmin = infinity; // minimal number of intersections
F = infinity; // minimal number of intersections of individual in
one trial
FTemp = infinity; // number of intersections in currently mutated
individuals
IBest = NULL; // the best individual
ITemp = NULL; // temporary individual, similar for all trials
I = NULL; // evolved individual in the trial
Imut = NULL; // mutated individual in a given iteration
N = 3; // number of tested individuals
M = 3; // number of mutations of a given individual
FOR i = 1 TO N DO // number of tested individuals

BEGIN
ITemp = initiated new graph of transactions();
FOR j = 1 TO M DO // number of mutation of an individual
I = ITemp;
DO
Imut = I;
IF RAND() < MutSrcPr THEN Perform Imut mutation of source
accounts;
IF RAND() < MutInterPr THEN Perform Imut mutation of
interm. accounts;
IF RAND() < MutDstPr THEN Perform Imut mutation of target
accounts;
FTemp = compute a number of intersections in Imut;
IF FTemp > F THEN
BEGIN
F = FTemp;
I = Imut;
END
WHILE (F doesn't change in C last iterations)
IF F < Fmin THEN

```

```
BEGIN
  Fmin = F;
  lBest = l;
END
END
END
```

To explain the algorithm let us start by describing the process of evolution. The outer loop FOR algorithm indicates how many individuals will be considered in the initial population. Since the algorithm does not use crossover operator, the evolution of population is equivalent to the evolution of each of the individuals separately. The inner loop FOR controls the number of mutation attempts on the same individual. The algorithm may fall into a local minimum of the objective function, therefore repeating the evolution several times from the same starting point greatly reduces these cases.

The main part of the evolutionary algorithm is the most nested DO-WHILE loop. Mutations are performed until the number of iterations reaches *C* or the solution is not improving. We have proposed three types of mutation: displacement of source, intermediate and target nodes. Displacement of the source nodes changes the headings of two randomly selected groups of vertices (there may be a group containing one vertex). Here we use the heuristics that when the order of accounts in the group does not change, it is therefore permissible to move only the entire group. A similar mutation relates to the target accounts. Mutation of intermediate nodes is drawing the new position in the permitted area between the source and target accounts.

The second important feature concerns the user interaction related to the definition of the scope of data investigation. This is done in two ways. The first solution is the ability to filter transactions that are selected from a database by SQL query. The second way is a direct manipulation on the displayed graph of chains of transactions. For large databases, sequential viewing and analysis of all transactions would be very time-consuming or even impossible. To partially overcome these difficulties, the two phase commit was implemented, namely a display of the transactions characteristics that meet the search criteria; and acceptance by the analyst to draw the graph.

In the example in fig.3 the analyst launched a simple query searching for the transactions with the amount of more than 190 thousand zł. From the computing, *Characteristics*, we see that there are 809 such transactions involving 401 source, intermediate, and target accounts, and the area calculated for visualization is 4004 x 4004 pixels. This form lets the analyst select whether to view the graph, or modify the query to reduce or extend the set of transactions. The graph is displayed after optimization using an evolutionary algorithm

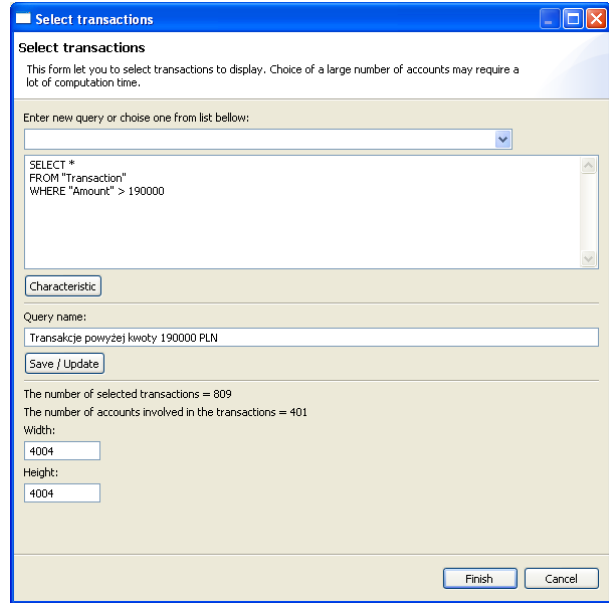

Fig. 3 Two-phase commit - the appearance of the window after query execution

In some cases the analyst may optionally re-arrange the graph manually. An example of the moving operation of the account ID 5169 is shown in fig.4.

Fig.4. Moving a node: A - selection, B - dragging, C - a new position

Another operation is to remove vertices of the graph. This may happen when, after SQL filtering, the graph contains either too many accounts or accounts which have proved during the analysis to be uninteresting. To obtain a more readable graph, the analyst may then remove them manually. Let us note that the accounts are not removed physically from the database, but only from the currently displayed diagram. The steps of account deletion are shown in fig. 5.

An important operation is the interactive marking of transactions as suspicious. With this functionality, an analyst or pattern recognition program may mark the transaction as suspicious [cf. TABLE I]. Information about the suspicious transaction is stored in a database and can be used in subsequent studies.

In the system many other useful features have been designed, such as memorizing a query filtering transactions, zooming graph, *Undo* and *Redo* functions, and saving a trace

Fig.5. Remove a node: A - the initial situation, B – selection from the menu, *Delete*, C - after removal of the top figure

operations log. A detailed description of these functions along with examples is given in [9].

### III. DESCRIPTION OF EXPERIMENTS

This section contains descriptions of two experiments, namely: 1) advanced retrieval of database transactions, and 2) optimization of the graph using an evolutionary algorithm. In the experiments, the real-life data obtained from one of the Polish banks are stored in a relational database PostgreSQL 8.3.

The experimental database consists of three tables: *Transaction*, *Query* and *Trace*. The first one contains the input data in the form of transaction descriptions (TABLE I). *TransId* column is a unique key serving to identify unambiguously the transaction. The next two columns contain information about the accounts involved in the transaction: *SrcAcctId* is the identifier of the account from which money is transferred, and *DstAccl* indicates a debited account. In this example, identifiers are represented by small integers, but in real applications, the account identifier may be the IBAN or NRB. The *Date* and *Amount* columns contain the date of execution and the transfer amount, expressed in PLN. The *Suspected* column indicates whether the transaction is suspicious in terms of money laundering, and may be modified by the system.

TABLE I. EXAMPLE OF TRANSACTION DESCRIPTIONS

TransId	SrcAccl	DstAccl	Date	Amount	Suspected
677	21561	22924	01-02	73 095,67	
678	21561	22924	01-02	88 142,15	
2888	24756	16579	01-02	67 684,03	
730	558	22971	01-02	66 495,43	
1821	19202	23934	01-02	57 669,16	
1823	18677	22839	01-02	80 000,00	
1933	2135	24037	01-02	180 000,00	
1925	21561	24032	01-02	74 657,08	
1926	21561	24033	01-02	76 910,61	
1927	21561	24033	01-02	109 671,77	
1928	21561	24032	01-02	134 746,56	

Other tables are *Query* and *Trace*. The first of these tables holds query requests through which data about the transactions are loaded. The second, the *Trace* table, stores the user actions on the displayed graph of chains of

transactions. Data for application can be obtained from any bank's financial system which offers the functionality of transaction registration and thus at least partially satisfies the requirements of the legislature. If the data have a different structure than that shown in TABLE I, any tool of the class ETL (Extract, Transform, Load) can be used for importing data.

The system runs on PC computers, currently on the two leading operating systems, Windows and UNIX, using the popular database management system Postgres. To meet the requirement to run on different systems, the system was implemented using Java environment and a library Eclipse RCP GEF for graphics editing. Eclipse RCP (called the Eclipse Rich Client Platform) is a library which gives rise to the creation of rich graphical interfaces. To implement the system a so-called fat client architecture (called thick client) has been used. The program is executed directly on the user's computer called the client, and the data is stored on the server side.

#### *Experiment 1. Advanced database retrieval – queries*

In this experiment, we assume the role of the banking analyst who analyzes the context of transactions to detect money laundering operations.

Suppose that an analyst is interested in transactions having the most frequent accounts, that is, accounts which participate in the largest number of transactions during a specified period. For example, assume that the concerns are related to transactions in January 2011, involving a top 10 the most frequent accounts in the database. This task can be written in the form of the following SQL query:

```

SELECT *
FROM "Transaction"
WHERE ("Date" BETWEEN '2011-01-01' AND '2011-01-31')
AND ("SrcAccl" IN
(
SELECT "AccountId"
FROM
(
SELECT "SrcAccl" AS "AccountId" FROM "Transaction"
UNION ALL
SELECT "DstAccl" AS "AccountId" FROM "Transaction"
)
GROUP BY "AccountId"
ORDER BY COUNT(*) DESC
LIMIT 10
)
OR "DstAccl" IN
(
SELECT "Accl"
FROM
(
SELECT "SrcAccl" AS "AccountId" FROM "Transaction"
UNION ALL
SELECT "DstAccl" AS "AccountId" FROM "Transaction"
)
GROUP BY "AccountId"
ORDER BY COUNT(*) DESC
LIMIT 10
)
)

```

Following the query definition, the system shows the characteristics of the resulting graph (Fig. 6), where the number of accounts in the graph is 140 and the number of

transactions 306. The analyst can visualize the transactions chains because the volume seems feasible to display. This experiment also illustrates an advantage over traditional reports. Data having 140 accounts and 306 transactions could be displayed on one page. However, this visualization does not show all relevant data, such as account numbers, amounts and dates of transactions; but the analyst can easily identify the main streams of cash flow. If necessary, by using the graph zooming, or by clicking on particular objects, he can very quickly get more information. The resulting graph is the subject of further research.

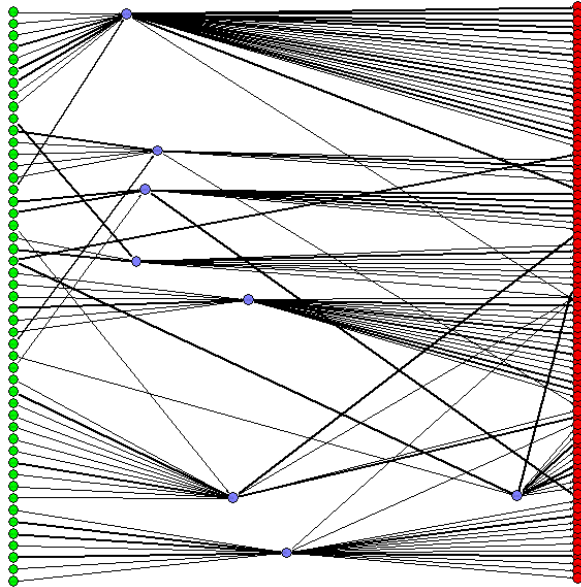

Fig.6. Graph showing the selected transactions by the query

This experiment shows how the analyst can apply his previous experience in searching money laundering transactions and the possibilities of visual exploration of cash flow chains. The program interface is in fact very simple, but just to define a SQL query may require some skills and experience in using this language. The solution to this question could be collaboration of the analyst with an SQL programmer who may predefine the specified queries or templates allowing the formulation of queries by QBE. However, the great advantage is the richness of language features that allow us to define any transaction filtering operation.

*Experiment 2. Genetic optimization of graph of transactions*

In this experiment, we are going to assess the quality of an evolutionary algorithm used to plot the graph [5]. The goal is to answer the question whether the parameters - the population size and number of mutations ( $N$  and  $M$ ) - significantly affect the result obtained. In other words, we are interested whether with limited computing power it is more profitable to run a lot more shorter evolutions or fewer but longer ones.

Computing of the number of intersections in the graph has the complexity  $O(m^2)$ , where  $m$  is the number of edges

in the graph [3], [13]. Thus, the computational complexity of the algorithm is  $O(m^2 * N * M * C')$ , where the parameter  $C'$  is dependent on the parameter  $C$ . From the definition of the parameter  $C$ , the estimation of  $C'$  is very difficult, since it is not known how many times one can carry out the innermost loop of the algorithm.

The algorithm has been tested on the previous database with 140 accounts and 306 transactions. In the experiment, the parameter  $C = 100$ , mutation probability of the source and destination nodes are 50%, and 90% of intermediate vertices. TABLE II shows the number of intersections obtained in each of the nine trials.

TABLE II. RESULTS OF GRAPH OPTIMIZATION

Number of individuals	Number of mutation trials	Number of intersections
1	1	277
	2	426
	3	258
2	1	229
	2	304
	3	373
3	1	506
	2	353
	3	334

The best result is the 229 intersections, and this is less than half the size of the worst. The standard deviation of the results is 87.0. The experimental data showed that the number of iterations ( $C$ ) and population size ( $N$ ) affected the value of the evaluation function. Fig. 7 shows the decreasing value of the objective function for individual evolution. After conducting many experiments we can conclude that it is better to run several times short mutations of many individuals rather than focus on a few individuals and increase the number of iterations.

Fig.7. Curves of evaluation functions

#### IV. CONCLUSIONS

This study presents the visual exploration of cash flow chains, which has not previously been addressed in existing systems. The greatest difficulty in designing and implementing the system was to find a way to reduce the size of the transaction chains graph. This process has been divided into two stages. First, the heuristics have been applied to deploy accounts by type, then grouping accounts with the same neighbor in the graph, and placing at the bottom of the graph accounts that are related with only one other account. In order to reduce the visual complexity of the multiple edges, the edges were aggregated into a single edge (displayed in bold).

The graph visualization was optimized by an evolutionary algorithm whose task was to find an organization of vertices and edges with minimal number of intersections. Experiments have shown that the number of intersections in the graph has been reduced significantly, which improved its readability.

It is noteworthy that the system offers other interesting features such as logging user operations performed on the graph. The register of user actions can be used to work further on machine learning that would try to imitate the work of the analyst.

The proposed solution can be easily adapted into existing systems of transactions analysis and contribute to the development of new methods for exploration of complex data structures.

**Abstract**—This paper describes a proposal of using ontological models as a basis of Query Answering Systems design. It is assumed that the models are presented in the form of relations described on some classes of items (ontological concepts) specified by taxonomic trees. There are analyzed the sufficient and necessary conditions for getting the replies to the queries as solution of relational equations based on the data provided by ontological databases. Simple examples illustrate basic concepts of practical realization of the Query Answering Systems based on domain ontologies.

**Index Terms**—query answering systems, domain ontologies, relations, relational equations,

## I. INTRODUCTION

DOMAIN ontology is a tool of formal representation of knowledge concerning an application area that in a decision problem should be taken into consideration. The application area knowledge can in general in many different forms be represented. Despite the traditional, descriptive form, rather unsuitable to computer implementation purposes, various types of knowledge can be presented by propositional logic terms [1] graphs (including their specific forms like trees [2], Petri nets [3], PERT networks [4], Bayesian networks [5], etc.), Horn clauses [6], semantic networks [7], Minsky frames [8], etc., less or more useful in a given decision problem. Generally speaking, a domain knowledge consists of verified data concerning the domain, its general nature, components, structure, properties of the components and satisfied by them relations. The above-mentioned formal tools to presentation of various aspects of the domain knowledge can be used. Otherwise speaking, they make possible construction of formal models of selected aspects of the application domain under consideration. The model should specify the concepts used to the application domain characterization and the existing among them physical, logical, organizational, etc. relationships. This leads to a domain ontology described by a quadruple [9]:

$$O = [C, R, A, Top] \quad (1)$$

where:  $C$  – a non-empty set of concepts,  
 $R$  – a set of relations among the concepts,  
 $A$  – a set of axioms,  
 $Top$  – a highest-level concept in  $C$ .

Among the relations a taxonomy of concepts headed by  $Top$  is mandatory, other relations are established according to the application problem needs.

This is illustrated by the following example.

Example 1.

A problem consists in calculation of a voltage drop on an electric resistor. This is well known that the solution is given by the Ohm law:

$$U = I \cdot r \quad (2)$$

where  $U$  denotes the voltage drop [V],  $I$  – current intensity [A],  $r$  – resistor resistance [ $\Omega$ ]. However, the problem can also be described by a domain ontology formalism. The domain ontology is then given by (1) where:

$C = \{\text{electric current flow, physical entities, measurable parameters, resistor, electric current, electric tension, electric resistance } r, \text{ current intensity } I, \text{ voltage drop } U\}$ ;

$R = \{\text{a taxonomy } T \text{ of concepts (see below), relationships between the concepts, formula (2)}\}$ ;

$A = \{\text{axioms concerning real functions}\}$ ;

$Top = \text{electric current flow}$ .

The taxonomy  $T$  of concepts can be presented in the form of a tree (Fig.1.):

Fig. 1. A taxonomic tree of concepts constituting a domain ontology *electric current flow*.

The domain ontology should also contain a relation not following directly from the taxonomic tree, assigning *measurable parameters* to the *physical entities*. The relation  $D$  (described by) is given by a set of ordered pairs:

$$D = \{[\text{resistor, electric resistance } r], [\text{electric current, current intensity } I], [\text{electric tension, voltage drop } U]\}.$$

So-presented domain ontology contains full information necessary to solve the above-formulated task. At a first glance it may see that the ontological description of the given application domain is too much complicated; this is because in practice, in a simplified reality description most of the ontology components by default are assumed. Nevertheless, solutions of a large class of simple physical, engineering, economical, management etc. tasks consciously or unconsciously on the corresponding domain ontologies are based. On the other hand, domain ontologies presented by (1) in many other cases are insufficient. For example, description of an enterprise (a domain) should consist of components concerning its organizational structure, personal staff, administrative procedures, services, etc. The relationships between the staff members and the administrative procedures, the services and the organizational sections etc. play a substantial role in the enterprise functioning description, however, they do not follow directly from the domain ontology presented in the above-given form. This problem has also been remarked in [9] where an attempt to construct a taxonomy for the *blood* concept led to the necessity of *blood* characterization as a *fluid* and as a biological *tissue*. Each aspect of a composite real object like an enterprise, blood circulatory system, large educational project, etc. constitutes a specific sub-domain which by its proper ontology should be described. A formal description of such object should thus rather by several sub-domain ontologies than by a single, general domain ontology be presented. It also seems clear that a multi-aspect description of a composed object would be difficult when a single, unified taxonomic tree of concepts is used. E.g., in a domain representing a certain city, an entity *City Hall* of the corresponding taxonomic tree, as having several aspects, should be included into the sub-trees *Architectural monuments*, *Municipal offices*, *City communication sites*, etc. However, this destroys the structure of a single taxonomy tree where each concept by only one node should be represented. On the other hand, if the original concept *City Hall* is split into three separate concepts, say: *City Hall<sup>1</sup>*, *City Hall<sup>2</sup>*, *City Hall<sup>3</sup>* then it arises a problem, how in the taxonomic tree some pairs, triples, etc. of nodes should be to the same physical object assigned. Entering into consideration a concept of *multi-model domain ontologies* removes the above-mentioned difficulty. In such case, the domain ontology should also contain a set  $Q$  of higher-level relations (*super-relations*) among the relations constituting the ontological models. The concept of *ontological models* defined as sub-domain ontologies used to formal description of various aspects of a higher-level application domain has been introduced in [11]. The more general, multi-aspect domain ontology definition takes thus the form:

$$O = \{OM_1, OM_2, \dots, OM_i; Q; A\} \quad (3)$$

where:

$OM_i$  – ontological models of the sub- domains;

$Q$  – a family of *super-relations* over the models;

$A$  – an extended algebra of relations and super-relations.

This concept is convergent with a represented by other Authors [12], [13] general tendency to base domain ontologies on strong mathematical backgrounds. In the below-presented case mathematical set theory and extended relations algebra is used as a basic tool for domain ontologies formal description. Domain ontology given in the form (3) provides a basic information that makes possible reasoning about objects belonging to the given domain and relations among them not directly specified by the ontological models.

However, also this concept has some drawbacks caused by the dependencies between the component ontological models leading to a problem of effective logical reasoning based on the statements drawn from several different ontological models. The problem has been partially analyzed in a context of using domain ontologies to computer-aided image understanding [14]. In the present paper a problem of logical inference in computer query answering systems (QAS) based on domain ontologies is more largely presented. In particular, the concepts of *relational equations* and of *reversed relations* using to logical inference improvement is below presented. Basic concepts of the extended algebra of relations and super-relations have been presented in the papers [14]-[16] and here only roughly are described. The paper is organized as follows: In Sec. II selected basic concepts used in the paper are shortly presented. Sec. III presents the idea of the relationships among the ontological models description by super-relations. Sec IV contains a proposal of using reversed relations to improve the effectiveness of reasoning based on the statements drawn from the domain ontology. Conclusions are given in Sec. V.

## II. BASIC CONCEPTS

### A. Ontologies

Generally speaking, ontology is a philosophical concept while domain ontology in computer science is a notion related to a formal description of a selected, less or more complicated, part of reality. Domain ontology is also not a mathematical notion, but it in mathematical terms can be described. However, a certain duality of terms used in domain ontologies occurs and needs to be explained. In particular, concepts in ontological sense are equivalent to classes or to sets in a mathematical sense. A taxonomy of concepts  $T$  in ontology is represented by a rooted tree in the graph theory sense while the highest-level concept  $Top$  is the root of the tree. The leafs (lowest-level nodes) of a tree are in ontological sense interpreted as instances of the closest higher-level ontological concepts, usually representing some basic, individual objects of the described reality. Relations in the mathematical sense (see below) may denote not only simple set theory relations but also any algebraic or functional, discrete or continuous, deterministic or fuzzy relations. Entities described by ontological models are objects if considered in the application domain context while from ontological models point of view are instances satisfying the corresponding relations. The family  $Q$  of super-relations

tions (see below) in (3) in ontological sense can be interpreted as a domain knowledge structure.

### B. Relations and super-relations

For description of a relation  $r$  between the elements of a finite family of sets  $S_1, S_2, \dots, S_K$  they should be linearly ordered in a logical sense and then the family can be denoted by  $[S_k]$ ,  $k = 1, 2, \dots, K$  or, shortly, by  $[S_k]_1^K$ . However, the logical order is not obviously identical to the physical one assuming that the a permutations transforming the logical order into the physical one (and vice versa) are defined. For the sake of simplicity, below, any logical order of a linearly ordered set will be assumed to be identical to the one of its presentation in the text. This is substantial for correct understanding of the operations of the extended algebra of relations.

A Cartesian product of a family of sets  $[S_k]_1^K$  will be denoted by  $C$ . If  $|S_k|$  denotes a cardinal number of elements of  $S_k$  then  $|C| = |S_1| \cdot |S_2| \cdot \dots \cdot |S_K|$ . The relation is called *finite* if  $|C|$  is finite. Any subset

$$\rho \subseteq C \quad (4)$$

is called a *relation* described on  $[S_k]_1^K$ . The number  $K$  is called a *length* of the relation while the maximum among the cardinal numbers  $|S_1|, |S_2|, \dots, |S_K|$  is called an *extent* of the relation. The relation is called an *empty relation* if it is an empty set; in such case it is denoted by  $\theta$ . The relation  $\rho$  is called a *trivial relation* if  $\rho \equiv C$ . For a given relation  $\rho$  any subset  $\rho', \rho' \subseteq \rho$ , is called a *sub-relation* of  $\rho$  while  $\rho$  is called an *over-relation* of  $\rho'$ . For a given relation  $\rho$  described on  $[S_k]_1^K$  any  $K$ -tuple  $s = [s_1, s_2, \dots, s_K]$  belonging to  $\rho$  is called an *instance* of the relation. For a given sub-family of  $n$  sets  $[S_p, S_q, \dots, S_t] \subseteq [S_k]_1^K$  (preserving its original logical order), and their Cartesian product denoted by  $C^*$ , the corresponding elements of the instances  $s$  of  $\rho$  determine linearly ordered  $n$ -tuples ( $n \leq K$ ) belonging to  $C^*$ . The set  $\rho^*$  constitutes a relation called a *partial relation* of  $\rho$  created by its projection on  $[S_p, S_q, \dots, S_t]$ ; in such case it is said that  $\rho$  is an *extension* of  $\rho^*$ .

In computer realization, due to the necessity of numerical data quantization, all relations are approximated by the finite ones. In a finite relation of finite length a coefficient:

$$d = \frac{|\rho|}{|C|} \quad (5)$$

is called a *density* of the relation.

Due to the fact that relations are described as subsets of Cartesian products the general set algebraic notions to the relations can be applied. In particular, if a countable linearly ordered family of sets  $F$  is taken into consideration and  $2^F$  denotes a class of all its sub-families (including a null

sub-family  $\emptyset$  and  $2^F$  itself) then it can be taken into consideration a family  $\Omega$  of all possible relations described on the linearly ordered sub-families of  $2^F$ . In  $\Omega$  the ordinary set algebra can be interpreted as an *extended algebra of relations* described on the sub-families of  $2^F$  [15]. The so-defined *extended algebra of relations* is a Boolean algebra with  $\theta$  as its null-element and  $\Omega$  as its unity element. The result of an algebraic operation (sum, intersection, difference) performed on any two relations  $\rho', \rho''$  described, respectively, on the families of sets  $F', F''$  is by a definition a relation described on  $F' \cup F''$  (this is not so in a “traditional” algebra of relations defined on the families of all relations described on a fixed family of sets). The extended algebra of relations admits algebraic operations on finite algebraic compositions of other relations.

In a family  $[S_k]_1^K$  of sets on which a relation is described some sets may be defined as relations described on lower-level sub-families of sets. This leads to the concept of *super-relations* as relations whose instances contain variables being instances of some lower-level relations. The structure of a super-relation may be presented by a multi-level bracket-expression, like e.g.:

$$\rho \subseteq S_1 \times [S_2 \times [S_3 \times S_4]] \times S_5 \times S_6$$

representing a three-level super-relation. It should be remarked that the above-given super-relation is not identical to  $\rho^* \subseteq S_1 \times S_2 \times S_3 \times S_4 \times S_5 \times S_6$ , because a Cartesian product of sets is neither a symmetrical nor associative operation. Dates [year, month, day] or addresses [country, city, street, house, flat] are typical examples of compact variables used in super-relations. In algebraic operations performed on super-relations the contents of the pairs of corresponding (the same level) brackets should be considered as a compact (single) variables. Therefore, the extent of the above-presented relation is equal 4 (not 6).

### C. Semantic interpretation

The relations described on the concepts of a domain ontology can usually be semantically interpreted. For example, if a domain ontology *Teaching plan* contains the concepts *Teacher, Subject, Group, Day, Time, Room* then the relation  $\rho'$  described on [Teacher, Subject, Group] can be semantically interpreted as “teacher’s obligations” while  $\rho''$  described on [Group, Subject, Day, Time, Room] as “groups’ time-schedule”, etc. Similarly, if there is given an instance of  $\rho'$ :

$$s = [Smith, physics I, A3]$$

where :  $Smith \in Teacher, physics I \in Subject, A3 \in Group$ , then a semantic interpretation of  $s$  may be:

“Smith is a teacher of physics I in the group A3”.

The semantic interpretation of the relation instance can thus be given by an affirmative statement presented in any of stylistic forms admissible in a given natural language. Any given ontological model  $OM$  specifying its concepts

and based on them relations defines thus a *semantic area*  $\Sigma$  as a set of semantic interpretations that can be assigned to the instances of any formally admissible instances of the relations. However, the semantic area may in general contain not only relations' instances corresponding to some real situations but also the ones that only theoretically are admissible, that are suggested, supposed, suspected, etc. In this sense, the semantic area does not describe the reality but rather a space of conceptual models in which a description of the actual reality is possible.

Let  $s = [s_1, s_2, \dots, s_k]$  be an instance of the relation  $\rho$  described on  $[S_k]_1^K$ . We can replace a selected value  $s_k$  by  $x$  as a symbol of unknown variable and put:

$$[s_1, s_2, \dots, s_{k-1}, x, s_{k+1}, \dots, s_k] \in \rho \quad (6)$$

This expression is *true* only for certain  $x \in S_k$ . Therefore, (6) is a *relational equation* and any  $x$  making it *true* is its solution. The values  $s_1, s_2, \dots, s_{k-1}, s_{k+1}, \dots, s_k$  can be considered as fixed *equation parameters*. The relational equation (6) can semantically be interpreted as a question: "What is (are) an  $x$  such that for given  $s_1, s_2, \dots, s_{k-1}, s_{k+1}, \dots, s_k$  the relation  $\rho$  is satisfied?". Similar questions can be formulated with respect to any other variable or subsets of variables.

Example 2

On the basis of the (above-mentioned) relation:

$$\rho' \subseteq \text{Teacher} \times \text{Subject} \times \text{Group}$$

and its instance  $s = [\text{Smith}, \text{physics I}, \text{A3}]$  the following relational equations can be formulated:

- i.  $[x, \text{physics I}, \text{A3}] \in \rho'$ ,
- ii.  $[\text{Smith}, y, \text{A3}] \in \rho'$ ,
- iii.  $[\text{Smith}, \text{physics I}, z] \in \rho'$ .

In the equations two parameters are fixed (e.g. *physics I* and *A3* in eq. i). Similarly, some multi-variable equations, like e.g.:

$$\text{iv. } [x, \text{physics I}, z] \in \rho',$$

(containing a single parameter *physics I*) can be formulated. The following queries correspond to the above-given relational equations:

- i. "Who is the teacher of physics I in the group A3?";
- ii. "What is the subject Mr Smith teaches the group A3?";
- iii. "What is the group Mr Smith teaches physics I?";
- iv. "What group and by whom is taught physics I?";

(the queries, if necessary, can be stylistically reformulated). Therefore, a given relation  $\rho$  generates a set of *schemes of*

*queries* that potentially on the basis of domain knowledge contained in the relation can be replied. A relational equation may represent a given query if the following conditions are satisfied:

- a) Each item which in the query is asked for in the relational equation is represented by a variable;
- b) each parameter of the query occurs and takes the same value as a parameter of the relational equation;
- c) semantic interpretation of the relational equation is in accordance with this suggested by the query.

The conditions *a)*, *b)* can be formally proven. However, the condition *c)* is not easy to be proven if the semantic accordance is not by default assumed and no relations' entries suggest their semantic meaning. Moreover, some queries can not be replied on the basis of a given relation if it does not admit formulation of a relational equation satisfying the above-given conditions. E.g., a query:

"What day Mr Smith teaches the group A3 physics I?"

can not be replied on the basis of  $\rho'$  which does not contain a variable *Day* being an item of the query. However, such queries can be replied if the ontological model contains additional relations satisfying the necessary conditions. For example, suppose that from the above-mentioned relation  $\rho'$  the following instances can be drawn:

$$\begin{aligned} s' &= [\text{A3 Mathematics II}, \text{Tuesday}, 11^{00}-11^{45}, 120], \\ s'' &= [\text{A3, Mathematics II}, \text{Wednesday}, 12^{00}-12^{45}, 122], \\ s''' &= [\text{A3, Physics I}, \text{Friday}, 11^{00}-11^{45}, 122]. \end{aligned}$$

Then, we can take into consideration an extended intersection of the relations  $\tau = \rho' \sqcap \rho''$  and on the basis of the above-given instances the following instances will be obtained:

$$t = [\text{Smith}, \text{physics I}, \text{A3}, \text{Friday}, 11^{00}-11^{45}, 122].$$

One can try to express the above-given query in the form of a set of relational equations:

$$[\text{Smith}, \text{physics I}, \text{A3}, x, *, *] \in \tau$$

where  $*$  denotes any value of the parameters *Time* and *Room* which in the question have not been specified. Therefore, the relation  $\tau$  can be reduced by taking into consideration a partial relation  $\tau^*$  defined as a projection of  $\tau$  on  $[\text{Teacher}, \text{Subject}, \text{Group}, \text{Day}]$ . This leads to the relational equation

$$[\text{Smith}, \text{physics I}, \text{A3}, x] \in \tau^*$$

whose solution is *Friday*.

III. LOGICAL INFERENCE BASED ON A DOMAIN ONTOLOGY

It has been shown that a domain ontology provides domain knowledge presented in the form of concepts and based on them relations and also it determines the set of admissible structures of queries about the given application domain that can be logically answered. In the case of a single ontological model the set of admissible questions is the larger the larger is the number of relations and are their lengths.

The *sufficient* conditions for answering by a QAS a query concerning the given application domain are:

- 1) Existence of a corresponding domain ontology;
- 2) Expression of the query in the terms semantically equivalent to some concepts of the given ontology;
- 3) Presentation of the query by a semantically equivalent form of a relational equation based on a non-empty relation belonging to an ontological model and satisfying the conditions *a)*, *b)*, *c)* (formulated in Sec. II).

Let us remark that if  $\rho$  is a relation in the given ontological model then any its sub-relation as well as any partial relation can also be considered as a relation of this ontological model. Hence, the sufficient condition 3) means that a relational equation can be based on a relation directly belonging to the ontological model or on any its sub-relation or partial relation. And still, the situations in which the above-described sufficient conditions are fully satisfied are rather exceptional. In a more general case, a relation that directly can be used to presentation of a given query in the form of a relational equation can not be found. In such case it is necessary to look for the suitable *algebraic combinations* of the relations satisfying the below-formulated *necessary* conditions:

- a) the algebraic combination of relations contains as its entries the variables and parameters of the query;
- b) the algebraic combination of relations is not empty by definition;
- c) the algebraic combination of relations admits semantic interpretation being in accordance with this suggested by the query.

Like in Sec. II, the conditions a) , b) can be formally proven by the below-described procedure while c) is assumed to be satisfied in the below-considered cases.

Let  $\rho^1, \rho^2, \dots, \rho^M$  be all relations that in a given ontology have been described. Each relation  $\rho^m$ ,  $m = 1, 2, \dots, M$ , is described on a sub-family of sets (ontological concepts)  $S^m$ .

The sum

$$S = S^1 \cup S^2 \cup \dots \cup S^M \tag{7}$$

contains all concepts on which the relations are based.

A general structure of the domain ontology then can be described by a *hyper-graph* [17]  $H$  whose nodes are given by  $S$  and the subfamilies  $S^m$ ,  $m = 1, 2, \dots, M$ , represent its hy-

Fig. 2. A hyper-graph consisting of 10 nodes and 4 hyper-edges.

per-edges. Two hyper-edges are *adjacent* if their intersection  $S^u \cap S^v$  is non-empty.

Example of a hyper-graph is shown in Fig. 2. It consists of 10 nodes ( $S^1, \dots, S^{10}$ ) and 4 hyper-edges ( $\rho^1, \dots, \rho^4$ ) denoted by circles in the corresponding rows. In the context of ontology's structure interpretation, each hyper-edge represents a relation described on the sets (ontological concepts) represented by the nodes. So, for example,  $\rho^1$  is a relation described on the sets  $S^2, S^5$  and  $S^9$ . The pairs of hyper-edges  $(\rho^1, \rho^2)$  and  $(\rho^2, \rho^3)$  are adjacent while  $(\rho^1, \rho^3)$  is not. Similarly,  $\rho^4$  is not adjacent to any other hyper-edge. A subset of hyper-edges such that any pair of them can be connected by a sequence of pair-wise adjacent hyper-edges of the subset is called a *weak component* of the hyper-graph. The hyper-graph in Fig. 2 consists thus of two weak components:  $(\rho^1, \rho^2, \rho^3)$  and  $(\rho^4)$ .

Let us denote by  $Q$  a family of concepts that are used as unknown data or fixed parameters of a query ordered to the QAS. For proving the necessary conditions a)-b) for replying the query on the basis of a domain ontology whose structure is described by the hyper-graph  $H$  it is necessary:

1. to select in  $H$  the minimum sub-family of nodes such that  $Q \subseteq \{S^i\}^*$ ;
2. to find in  $H$  all minimal subsets  $R^h$  of hyper-edges such that the sum  $I^h$  of nodes belonging to  $R^h$  satisfies the condition:

$$Q \subseteq I^h \subseteq \{S^i\}^*; \tag{8}$$

3. taking into account that each hyper-edge in  $R^h$  represents a relation of the domain ontology described by  $H$ , construct an extended intersection of all represented by  $R^h$  relations;
4. if  $Q \subset I^h$  then replace the intersections by partial relations defined as projections of the intersections on  $Q$ , denote such relations by  $r^\alpha$ ;

5. from any relation  $r^\alpha$  select its instances whose components corresponding to the query parameters take values equal to those of the query, collect all such instances as a sub-relation of  $r^\alpha$ ,  $\chi^\alpha \subseteq r^\alpha$ ;

6. each  $\chi^\alpha$  being not an empty relation can be used as a basis for a relational equation representing the given query;

7. solution of the relational equation based on  $\chi^\alpha$  is given as its projection on the set (node of  $H$ ) belonging to  $Q$  and denoting the unknown data of the query.

The above-described procedure may provide more than one solution of the problem presented by the query. This may happen not only because  $\chi^\alpha$  may contain several instances satisfying the condition 7 but also because in the step 2 more than one subset  $R^h$  can be found. In such case elimination of formal solutions not satisfying the necessary semantic condition c) is possible and recommended.

### Example 3

Let us assume that a query has a form:

“What is the value of  $S^2$  assuming that the values of  $S^4$  and  $S^7$  are given?”

Let the corresponding domain ontology is represented by the hyper-graph  $H$  shown in Fig. 2. For replying the question the set  $Q = \{S^2, S^4, S^7\}$  will be taken into consideration. No hyper-edge of  $H$  directly covers  $Q$ . However, it is covered by the sub-set of hyper-edges  $R = \{\rho^1, \rho^2\}$  for which we obtain

$$\Gamma = \{S^1, S^2, S^4, S^5, S^7, S^9\} \supset Q.$$

It will be thus taken into consideration an extended intersection of the relations:

$$r = \rho^1 \sqcap \rho^2$$

described on the family of sets  $\Gamma$ . However, this relation is redundant and for replying the query it is sufficient to take into account its projection  $\chi$  on the sub-family  $Q$ . Then the steps 6 and 7 should be performed by taking into account the instances of  $\chi$ .

In the above-described procedure of query answering the following basic steps can be discriminated:

- i. reformulation of the query for its formal processing;
- ii. proving formal possibility to reply the query on the basis of the given domain ontology (steps 1, 2);
- iii. finding formal solutions of the query problem (steps 3 – 7).

Therefore, a block-scheme of a QAS based on a domain ontology can be presented as shown in Fig. 3.

## IV. CONCLUSIONS

A practical role of QAS in numerous application areas is permanently increasing. However, it arises the problem of application domain knowledge representation in a form suitable to computer processing. The proposal of using for this purpose ontological models based on the extended algebra of relations seems to be one of several possible ones. It seems to be relatively easy to be realized by computer system assuming that the ontological models for the application domains being of interest are designed and available. However, this approach needs practical solution of several technical problems among which proving semantic accordance between the queries expressed in natural language with the ontological models and effective searching of rela-

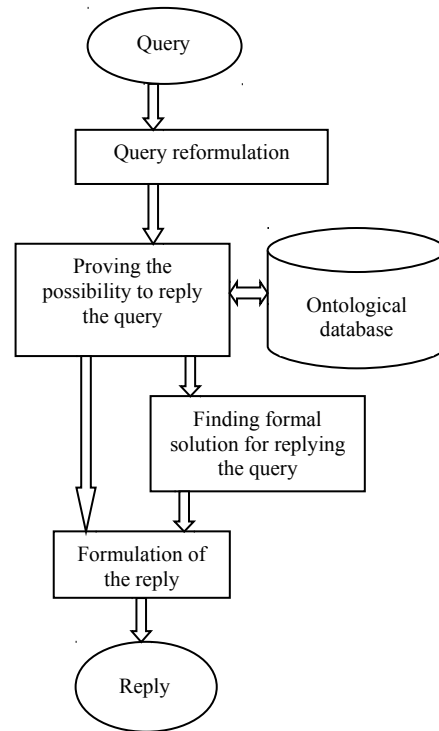

Fig. 3. Block-scheme of a Query-Answering System based on domain ontology.

tions' instances in ontological databases should be mentioned as the most important ones.

**Abstract**—This paper compares two methodologically different approaches to gene set analysis applied for selection of features for sample classification based on microarray studies. We analyze competitive and self-contained methods in terms of predictive performance of features generated from most differentially expressed gene sets (pathways) identified with these approaches. We also observe stability of features returned. We use the features to train several classifiers (e.g., SVM, random forest, nearest shrunken centroids, etc.) We generally observe smaller classification errors and better stability of features produced by the self-contained algorithm. This comparative study is based on the leukemia data set published in [3].

## I. INTRODUCTION

**B**UILDING diagnostic or prognostic classifiers based on profiles of gene expression from microarray or similar massive throughput experiments seems one of the most challenging tasks in bioinformatics. The problem of class prediction can be regarded as ill-formulated as the number of samples (e.g., patients) in a typical microarray study does not exceed a few hundred with the number of features (gene expression values) recorded for a sample usually exceeding 20 thousand. Many different approaches to class prediction based on massive throughput data were proposed (e.g., [7], [10], [13], [14]). One of the most challenging problems is related to feature selection based on high dimensional data. Standard approaches start with identification of sets of differentially expressed genes to be used as features for class prediction. These methods focus on features with individual strong predictive power, however they treat the features as unrelated and they do not take into account potential (biological) relationships among features. This explains why most feature selection methods produce very unstable features, i.e. small changes in training data result in different feature sets, [25], [15], [16]. This further explains why classifiers built from microarray studies are very sensitive to the selection of parameters (such as the number of features, etc.), and generally demonstrate unstable estimates of prediction error.

In our previous work [17], we proposed an enhanced procedure of feature selection based on domain knowledge about potential relationships among features (genes). Such knowledge of groups of functionally related genes is available in databases e.g., KEGG, Gene Ontology or Biocarta, and is

now being actively developed. The method proposed in [17] derives features for class prediction from the most strongly activated pathways. In [17] we compare this approach to the standard method and empirically show that although individually weaker, the new features seem more stable and bring improved performance.

In [17] the global test algorithm, developed in [11], was applied to identify activated pathways to be used as features for class prediction. Recently different approaches to gene set analysis were proposed, e.g., [8], [23], [11], [4], [25]. They can be broadly categorized as *competitive* or *self-contained*, and they fundamentally differ methodologically, [12]. It is not clear whether these two approaches produce similar feature sets in terms of their predictive performance and in terms of stability. The purpose of this work is to investigate this issue. We compare predictive performance of features generated with a selected competitive method (Gene set analysis (GSA) algorithm) and a selected self-contained method (global test). We also analyze whether the feature sets differ in terms of stability.

The organization of the paper is as follows. First, competitive and self-contained methods of gene set analysis are described in detail. Then an algorithm of sample classification based on activation of gene sets is presented. The algorithm is later used to evaluate predictive performance and stability of feature sets returned by the two gene set analysis methods. Finally, results of a comparative study are elaborated based on a real microarray assay.

## II. GENE SET ANALYSIS METHODS

Many different approaches to gene set analysis have been recently proposed. An overview of the most important methods is available in [25], and the statistical issues related to these different methods were analyzed by Goeman and Buehlmann in [12]. The earliest developed and probably simplest methods compare the list of genes in the set of interest with the list of differentially expressed genes. An example of such methods is the over-representation analysis (ORA) proposed in [6], which compares these two lists of genes by means of contingency tables. The chi-square test is used in order to verify the null hypothesis that the differentially expressed genes are not over-represented in the gene set of interest. Rejection of the null hypothesis indicates that the gene set is differentially expressed

This work was sponsored by the grant MNiSzW N516 510239

(or *activated*). An extension of the ORA method is the Gene Set Enrichment Analysis (GSEA), proposed in [20], [23], which does not require that genes are potentially arbitrarily declared as differentially expressed by using a fixed threshold. The method ranks the genes by some measure of differential expression and then tests the null hypothesis that the members of the gene set of interest are uniformly distributed along the ranking list. The null is tested against the alternative that the gene set appears at the top or bottom of the ranking list, ie. can be regarded as activated. GSEA uses a modified Kolmogorov-Smirnov statistic to test the null hypothesis. Another method, based on GSEA is the Get Set Analysis (GSA) algorithm developed in [8]. It uses a maxmean statistic in place of the Kolmogorov-Smirnov test which leads to slightly better power.

In the methodological paper [12], these and similar approaches were named as *competitive* methods. These methods test whether a gene set is differentially expressed (or associated with the target) by comparing expression of genes in the set with expression of genes not in the set. A fundamentally different approach is realized by *self-contained* methods [12], which directly analyze association of genes in the set of interest with the target and do not take the remaining genes into account. Examples of self-contained methods are the Global Test [11], Global Ancova, [18], PLAGE, [24] or SAM-GS proposed in [4].

In this work we use gene set analysis methods to identify pathways which will be used to generate features for classification of samples. We identify the most differentially expressed (or activated) pathways and then use genes in these pathways as features for class prediction. In this study, we use one self-contained approach (global test) and one competitive method (GSA algorithm) and experimentally compare these methods in terms of (a) predictive power of features returned, and (b) stability of features in the presence of small modifications of data. The gene set analysis methods used in the study are now explained in detail.

#### A. Competitive methods – GSA algorithm

The competitive methods compare differential expression of genes in the gene set of interest  $G$  with expression of genes not in  $G$ . More specifically, they aim to verify the null hypothesis:

$H_0$  : The genes in  $G$  are at most as often differentially expressed as the genes not in  $G$ .

The GSEA method and its more powerful version GSA test the specific null hypothesis that the genes in the set  $G$  are uniformly distributed over the list of all genes ranked by some measure of differential expression.

In order to test the hypothesis, the GSA algorithm uses the maxmean statistic [25]:

$$M = \max \left\{ \left| \frac{\sum_{i=1}^m I(t_i > 0) t_i}{m} \right|, \left| \frac{\sum_{i=1}^m I(t_i < 0) t_i}{m} \right| \right\} \quad (1)$$

where  $m$  is the number of genes in  $G$  and  $t_i$  is the measure of differential expression of the  $i$ -th gene in  $G$ .

Significance of the  $M$  statistic is evaluated using the permutation test (permutation involves both genes and class labels). In the algorithm proposed in the next section we will use the permutation based p-values to select the top differentially expressed pathways whose member genes will be used as features for class prediction.

#### B. Self-contained methods – global test

The global test method aims to verify the null hypothesis of no association of the set  $G$  with the target, namely:

$H_0$  : No genes in a set  $G$  are associated with the target (ie. no genes in  $G$  are differentially expressed).

In order to test the hypothesis, global test uses generalized linear models to express the relationship between expression of genes in the set  $G$  and the target, such that

$$g(E(Y_i|\beta)) = \alpha + \sum_{j=1}^m x_{ij}\beta_j \quad (2)$$

where  $g$  is link function in generalized linear models (e.g., the logit function for binary target),  $x_i$  denotes vector of expression of  $m$  genes in the gene set  $G$  for sample  $i$ , with class label  $Y_i$ , and  $\beta_j$  is the coefficient for gene  $j$ .

The assumption that no genes in  $G$  are associated with the target is equivalent to testing the null hypothesis:

$$H_0 : \beta_1 = \beta_2 = \dots = \beta_m = 0 \quad (3)$$

Global test assumes that the coefficients  $\beta_1 \dots \beta_m$  are iid with mean 0 which simplifies the hypothesis and makes the test feasible given small number of samples relative to the number of genes in  $G$ . In the algorithm presented in the next section we will use pathways with the smallest global test p-value as features for class prediction.

### III. ALGORITHM OF CLASS PREDICTION

In [17] we proposed an algorithm for class prediction based on activation of pathways and compared it with the commonly used approach where top most differentially expressed unrelated genes are used as features. Here we will use a slightly modified version of this algorithm, with two different methods of feature selection: GSA-based and global test (GT)-based. The estimates of the expected prediction error (EPE) returned by the algorithm will be used as a measure of quality of features produced by these competing gene set analysis methods.

Using the same notation as in [17], we denote results of a microarray study as a matrix  $X_{n,p}$  with  $p$  features (gene expressions) measured for  $n$  samples, with class designation for a sample  $i$  given in  $Y_i$ ,  $i = 1, 2, \dots, n$  (which represent e.g., tumor and control samples). Also let PWDB be the set of  $d$  subsets (denoted  $PW_i$ ,  $i = 1, 2, \dots, d$ ); these represent a priori domain knowledge of groups of related features (e.g., genes in a signaling pathway or genes with a common GO term, etc). The purpose of the algorithm proposed in [17] is

to (a) build the sample classifier given  $X$ ,  $Y$  and PWDB, and (b) estimate the expected prediction error for new samples. Since the number of samples  $n$  is small relative to the number of features  $p$  (the  $p \gg n$  problem), the  $EPE$  has to be estimated by data reuse techniques. We use *internal* cross validation (CV) where the data are repeatedly split into training and test partitions, with the  $EPE$  calculated as the average misclassification rate over all the test partitions. *Internal* cross validation places the feature selection step within subsequent iterations of cross validation, which is mandatory to obtain a reliable measure of classifier performance, as argued e.g. in [19]. (Note that the commonly used and computationally cheaper *external* cross validation realizes the feature selection step once, prior to the CV loop, and based on the complete training data.)

It should be noted that by using internal cross validation we can simultaneously observe *stability* of features generated under slight modifications of the training data. Namely, with the leave-one-out (LOO) internal cross validation scheme the data used for feature selection differs by one sample in consecutive iterations of CV. Hence by observing how the features change during CV steps we will be able to compare the GSA and GT-based procedures in terms of stability of features generated. This is the main justification of our choice to use the LOO cross validation loop in the algorithm proposed. It should be noted that LOO cross validation (realizing low bias but high variance of the estimate of prediction error) is often used in similar studies, e.g., [9], [21], [22].

It should be noted that poor stability of features produced by standard methods (ie. by selecting most differentially expressed unrelated genes) may account for unstable behavior of classifiers built from microarray data [16].

The class prediction algorithm can be summarized in the following steps.

- 1) Leave out sample  $i$ ,  $i = 1, 2, \dots, n$  for model testing, ie., remove row  $i$  from  $X$  and element  $i$  from vector  $Y$  and denote the remaining matrix and vector as  $X^i$  and  $Y^i$ .
- 2) Using the training data  $(X^i, Y^i)$  calculate the p-value with the GT or GSA for each of the PWs in PWDB. Order the PWs by increasing p-value:  $PW_{(1)}, PW_{(2)}, \dots, PW_{(d)}$ .
- 3) Remove columns from  $X^i$  related to features not present in  $PW_{(1)} \cup \dots \cup PW_{(k)}$ , denote this matrix as  $X_{tr}^i$ .
- 4) Using the training data  $(X_{tr}^i, Y^i)$  fit a predictive model  $f$  and classify the sample  $Y_i$  as  $\hat{Y}_i = f(Y_i)$ .
- 5) In the list of counters  $c(PW_j), j = 1, \dots, d$ , corresponding to the  $d$  elements of PWDB, increment the counters  $c(PW_{(j)}), j = 1, \dots, k$ , which correspond to the PWs selected in the current step.
- 6) Repeat steps 1 through 5 for  $i = 1, 2, \dots, n$ .
- 7) Calculate the expected misclassification rate as  $EPE = \frac{1}{n} \sum_{i=1}^n I(\hat{Y}_i \neq Y_i)$ .

In the following section, we will compare performance of several classifiers based on GSA or GT features in terms of the  $EPE$ . For the purposes of this numerical example, the following classifiers were used:

Fig. 1. Number of misclassifications as a function of the number of PWs selected. SVM classifier. Solid line - GSA method, dashed line - global test.

- support vector machine (SVM),
- logistic regression with L2 (Ridge) penalty,
- nearest neighbors,
- nearest shrunken centroid algorithm,
- random forests.

The cost parameter of the SVM classifier as well as the lambda (shrinkage) parameter of the logistic regression were tuned using a simple grid search.

We will also compare the methods in terms of stability of features selected for varying number of gene sets used as features:  $k \in \{1, 3, 5, 10, 20, 30\}$ . Note that the counters in step 5 of the algorithm are maintained to facilitate stability analysis.

#### IV. COMPARATIVE STUDY

The numerical study is based on a subset of the acute leukemia microarray data, published by S. Chiaretti [3]. The dataset includes  $n = 79$  samples with  $p = 12625$  gene expressions; 37 samples represent patients with leukemia and 42 samples represent the control group (the samples are labeled in the original data as ‘BCR/ABL’ and ‘NEG’, respectively). In this example we use the KEGG signaling pathway databases as the collection of gene sets PWDB. The task is to classify patients as leukemia or control based on a profile of most activated pathways.

The overall performance of the different classifiers for varying number of most activated pathways used as features is summarized in Figs. 1 through 5. In the figures the  $EPE$  obtained for the global test and GSA feature selection is compared (note that the  $EPE$  is shown as the the number of misclassified items in 79 iterations of cross validation rather than the ratio).

Fig. 2. Number of misclassifications as a function of the number of PWs selected. Logistic regression. Solid line - GSA method, dashed line - global test.

Fig. 4. Number of misclassifications as a function of the number of PWs selected. Nearest shrunken centroid algorithm. Solid line - GSA method, dashed line - global test.

Fig. 3. Number of misclassifications as a function of the number of PWs selected. KNN classifier. Solid line - GSA method, dashed line - global test.

Fig. 5. Number of misclassifications as a function of the number of PWs selected. Random forest algorithm. Solid line - GSA method, dashed line - global test.

We observe that the overall best result was realized by the random forest classifier with  $k = 3$  top PWs selected by the GT algorithm. The winning classifier realized 9 misclassifications, i.e.  $EPE = 11\%$ . This result is better than the best result obtained with the standard feature selection method where the top ranking unrelated genes are selected as features [17]. We also observe that for all the five classifiers the smallest number of misclassifications along  $k \in \{1, 3, 5, 10, 20, 30\}$  is always realized for features selected by the global test (dashed line

Fig. 6. Features selected in consecutive iterations of CV with corresponding frequency, 1 PW.

Fig. 8. Features selected in consecutive iterations of CV with corresponding frequency, 5 PWs.

Fig. 7. Features selected in consecutive iterations of CV with corresponding frequency, 3 PWs.

Fig. 9. Features selected in consecutive iterations of CV with corresponding frequency, 10 PWs.

in Figs. 1–5), rather than the GSA method (solid line). The smallest number of misclassifications observed for consecutive classifiers are:

- SVM: 13,
- logistic regression: 11,
- nearest neighbors: 13,
- nearest shrunken centroid algorithm: 13,
- random forests: 9.

It can be observed that with growing number of features (for  $k > 3$ ), performance of models generally deteriorates,

however this effect is strong only for the nearest neighbors classifier (Fig. 3), as the other models internally realize feature selection and therefore are more immune to overfitting.

Another important characteristic of the competing methods is stability of features observed when data changes slightly. Analysis of stability of features is doable using the table of counters  $c(PW_j)$ ,  $j = 1, \dots, d$  maintained in step 5 of the algorithm. The counters record how often (in all 79 iterations of cross validation) a given pathway was selected as a feature. High values of the counters indicate that the feature selection

Fig. 10. Features selected in consecutive iterations of CV with corresponding frequency, 20 PWs.

method tends to produce the same features even if data is (slightly) different. On the other hand, if a change of just one sample in the training data leads to many different features, this should be regarded as a drawback of feature selection used.

To analyze stability of features, we first present values of the counters  $c$  for varying value of  $k$  (ie. the number of pathways selected as features) – Figs. 6–10. Fig. 6 shows that the global test kept selecting the same PW (PW with index = 184) over all iterations of CV, while GSA selected 6 different features in 79 iterations, with the feature with index = 86 selected most frequently. (It should be noted that pathways in Figs. 6–10 are denoted by indices to the table of KEGG pathways, as given e.g. in the Bioconductor hgu95av2.db package. For instance, the pathway index=184 corresponds to the KEGG pathway ID 05130.)

For  $k = 3$  (Fig. 7) global test always selects 2 features (184 and 130) and 77 out to 79 times also feature 214. The GSA selects 10 different features (with the winner PW=86 selected 75 times). Similar observations hold for Figs. 8–10.

Although in the method proposed we do not check if  $p$ -values of the selected PWs are significant (as we rely on feature selection capabilities of the classifier used next), we observe in this study that all the top  $k$  PWs selected in step 3 are significant under multiple testing adjustment for  $k$  up to 20 (Holm-adjusted  $p$ -values below 0.05). It should be also noted that since the number of items in PWDB is much smaller than the number of genes (e.g., KEGG database includes ca. 200 pathways, as compared with ca.  $10^4$  genes on a typical microarray), multiple testing correction in the proposed method will be much less conservative than in standard gene selection procedures.

TABLE I  
NUMBER OF DIFFERENT PWs SELECTED AS FEATURES ( $NF$ ) AND MEAN FREQUENCY OF PW SELECTION IN THE CV PROCEDURE AS A FUNCTION OF THE NUMBER OF TOP PWs ( $k$  IN STEP 3 OF THE ALGORITHM)

No of top PWs ( $k$ )	GSA		GT	
	NF	mean freq (%)	NF	mean freq (%)
1	6	16.7	1	100.0
3	10	30.0	4	75.0
5	17	29.4	8	62.5
10	29	34.5	15	66.7
20	43	46.5	29	69.0
30	55	54.5	37	81.1

Analysis of stability can be summarized by using two measures calculated from the tables of counters  $c$  (see step 5 of algorithm):

$$NF = \sum_{i=1}^d I(c(PW_i) > 0) \quad (4)$$

which gives the overall number of different features selected in  $n = 79$  rounds of cross validation, and

$$mean\ freq = \frac{1}{n\ NF} \sum_{i=1}^d c(PW_i) = \frac{k}{NF} \quad (5)$$

which shows mean frequency of selection of features in the set of  $NF$  different features in  $n$  rounds of cross validation. It should be noted that for fixed value of  $k$  the second measure does not provide any more information than  $NF$ , however this measure is convenient to highlight the difference between the methods. Results for  $k \in \{1, 3, 5, 10, 20, 30\}$  are given in Tab. 1, with the mean frequency expressed as percentage. As already observed in Fig. 6, global test always selected one feature ( $NF = 1$ , hence the frequency of its selection is 100%, ie. 79 times in 79 rounds of CV); the GSA selects 6 features, each with mean frequency equal ca. 17% (which translates into 13 times a feature is selected in 79 rounds of CV). For growing  $k = 1, 3, 5$  we observe decreasing mean frequency, which suggests that a growing number of weaker features start getting included, which leads to less consistent feature selection when data changes. It is interesting to notice that for  $k > 5$  the mean frequency again increases, however explanation of this effect requires further investigation.

The final conclusion from stability analysis is clear: the sets of features selected by global test seem more stable as compared to GSA-based features. This characteristic of the global test may account for better predictive performance of these features.

## V. CONCLUSIONS

In this work two methods of gene set analysis were empirically compared in terms of predictive performance of classifiers built using most activated pathways as features. The methods realize different approaches to pathway analysis: global test is a self-contained algorithm and the GSA is a competitive method. The comparative study brings several

interesting observations. First, the self-contained method outperforms the competitive approach in terms of classification error. Second, features selected by the self-contained method appear more stable if data is modified. This is a remarkable characteristic of this feature selection procedure, as due to high dimensionality and small number of samples used for microarray class prediction, standard methods of feature selection demonstrate poor stability. Finally, the methods do select different features (pathways) for prediction (although some overlapping is observed). Based on these results a number of interesting questions and directions for further research can be raised. First, it seems interesting to investigate characteristics of the features returned by the self-contained and competitive methods: whether the activation of pathways is due to weaker effect observed consistently over a large number of member genes, or on the contrary - the method favors stronger local effect in the set of member genes. Next, a hybrid method is worth considering which would combine the strong points of these two approaches. Further research is also necessary into how features can be generated in a more sophisticated way out of the set of most activated pathways. Also, the proposed method requires more comprehensive validation based on further microarray datasets as well as simulated data. Although the purpose of this work was to compare different approaches to gene set analysis in terms of quality of feature selection, another interesting direction for further research involves comparison of these prior biological knowledge based methods with regularized learning techniques such as ridge regression, lasso or elastic net.

**Abstract**— This paper describes the knowledge patterns for the conversion of sentences in natural language into RDF graph language. While creating knowledge base in RDF graph language from sentences expressed in natural language, one must convert words from sentences to nodes and arcs in RDF graphs. For this conversion, it is important to know which members of a sentence represent particular words. In this paper, knowledge patterns are proposed as a tool for conversion of sentences. In order to capture knowledge patterns one can use extended RDF graph language. For the representation of knowledge patterns, further extension of this language is proposed. The paper contains four examples of knowledge patterns and their use.

## I. WORD ORDER IN NATURAL LANGUAGE

**I**N NATURAL language, people use sentences to express various statements, questions, orders etc. Each natural language is defined by its vocabulary and its grammar. Individual words are marked as vocabulary; they are words one can use in a given language. Typically, words are divided into word classes (nouns, pronouns, verbs, adverbs etc.), which determine their meaning. The grammar of a language determines the construction of sentences, which means the way of ordering particular words in sentences. Constituents of sentences (members) are basic building blocks of constructions of sentences. The basic members are subject and predicate. Other members, which extend information included in a sentence, are object, attribute and adverbial complement. The word classes of particular words are not important. It is important which member these words represent. A word-order in language, which determines the order of members in sentence, relates to the creation of sentences. Word order abides by some rules and one can identify two basic types of a word order – fixed word order and free word order. Fixed word order defines relatively strict rules of order of members in sentence. This word order is typical for Germanic languages such as English. On the other hand, free word order is greatly flexible, rules of ordering members are not so strict and they can be modified to the context of the sentence. Free word order is typical for languages which enable declension and inflexion. Among

these languages are Slavonic languages such as the Czech language [6], [8].

The essential members are subject and predicate, which form bare sentences. For the marking of these members the letter S is used for subject and the letter V for predicate (verb). Except of these essential members, other, elaborative members can be used: object, attribute and adverbial complement. To mark an object the letter O is used. According to the combination of subject, verb and object we can differentiate six basic word orders in sentence: SVO (subject verb object), SOV (subject object verb), VSO (verb subject object), VOS (verb object subject), OSV (object subject verb) and OVS (object verb subject). English language uses word order SVO [6], [8].

## II. CONCEPTS AND THEIR RELATIONS

The typical approach for the creation of formal ontologies is presently the concept-oriented approach. A concept is a set of objects sharing some particular features. One of the methods for searching concepts is formal concept analysis [7], which has a formal context as its input and a conceptual graph as its output. Problems of the sentence creation can be depicted as a formal context R, which is represented by a table called the data matrix, where columns are particular properties and rows are objects (types of sentences – declarative sentence, question etc.). If the table cell contains “X”, an object on the appropriate row has the property in the appropriate columns. If the cell contains “O”, objects can have the appropriate property. The data matrix for English grammar is displayed in table I; next tables describe objects and properties.

Figure 1 shows a conceptual graph based on the data matrix in table I. Each node represents one concept and it has a label consisting of two rows. Objects in this concept are in the first row, properties in this concept are in the second row. The top concept of this graph contains all objects, which share the property f (verb) – each sentence must contain a verb. The bottom concept of this graph contains all properties and no object at all, because there are no types of sentences that contain all the properties from the data matrix. Each concept, except the top concept, has its superconcepts; they are concepts connected with particular concept and are positioned above it. Each concept, except the bottom concept, has its subconcepts; they are concepts

TABLE I.  
FORMAL CONTEXT R

R	a	b	c	d	e	f	g	h	i	j

2		X				X	X	O	O	O
3		X		X		X	X	O	O	O
4	X	X		X		X	X	X	X	X
5	X	X		X		X	X	O	O	O
6		X		X		X	X	O	O	O
7					X	X	X	O	O	O
8				X		X		O	O	O
9				X		X	X	O	O	O
10		X				X	X	X	X	X
11		X	X			X	X	X	X	X
12		X	X	X		X	X	X	O	O

TABLE II.  
OBJECTS AND ATTRIBUTES IN FORMAL CONTEXT R

	objects
1	Basic construction of sentence
2	Affirmative declarative sentence
3	Negative declarative sentence
4	General interrogative sentence
5	Factual interrogative sentence
6	Declaratory interrogative sentence
7	Interrogative sentence for subject
8	Imperative – 2 <sup>nd</sup> person
9	Imperative 1 <sup>st</sup> and 3 <sup>rd</sup> person
10	Adverbial complements
11	Adverb of frequency
12	Adverb of frequency with complex predicate

	attributes
a	Wh – Interrogative pronoun or interrogative verb
b	S – Subject
c	AF – Adverb of frequency
d	AV – Auxiliary verb
e	S (Wh) – Interrogative pronoun
f	V – Verb
g	O – Object
h	M – Adverbial complement of Manner
i	P – Adverbial complement of Place
j	T – Adverbial complement of Time

connected with particular concept and are positioned below it. For example, the concept containing objects 1, 4, 10, 11, 12 and properties b, f, g, h has two superconcepts (first with objects 1, 2, 3, 4, 5, 6, 10, 11, 12 and with properties b, f; second with objects 1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 12 and with properties f, g) and two subconcepts (first with objects 1, 4, 10, 11 and with properties b, f, g, h, i, j; second with objects 11, 12 and properties b, c, f, g, h). Further, concepts containing optional properties (h, i, j) are connected with its superconcepts and subconcepts by a dashed line. In the conceptual graph shown on figure 1, we can see how the concepts are connected.

With the help of knowledge patterns the representation of natural language sentences in extended RDF graph language [2] will be further described. This representation is useful while building an ontology or knowledge base. The representation of some types of sentences does not make sense, e.g. an imperative or interrogative sentence. In the rest of this paper the representation of affirmative declarative sentences and negative declarative sentences will be described. A basic construction of a sentence is the special case of affirmative declarative sentences.

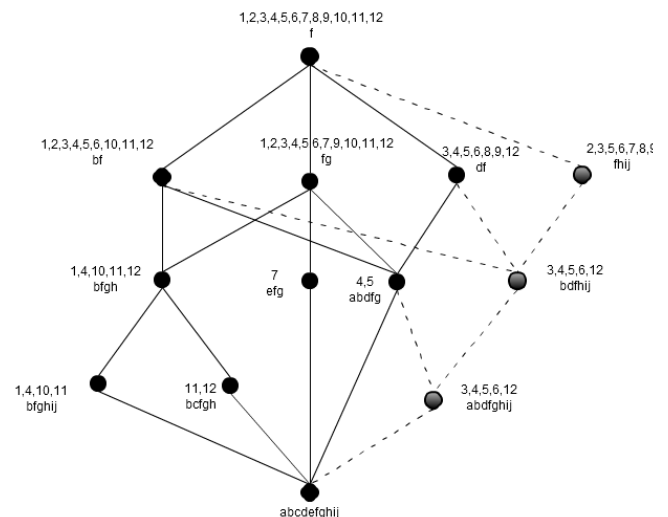

Fig. 1. Conceptual graph of formal context R

### III. KNOWLEDGE PATTERNS

The term 'knowledge pattern' was first used in [1]. While building ontologies or knowledge bases, one can see that some structures of modelled knowledge are the same. These same structures of knowledge can be captured as knowledge patterns. Knowledge patterns are general structures (patterns) of knowledge, which are not a part of the target knowledge base. They can be included into a target knowledge base by renaming their non-logical symbols. This renaming is called morphism. The morphism is an important part of using knowledge patterns.

Presently, there is no direction for capturing knowledge patterns. We propose to model knowledge patterns in RDF graph models [4], [5]. This model is simple to understand, even for amateur users. The RDF graph model is a set of RDF triples. The RDF triple consists of subject, predicate and object. Subject and object are nodes of the graph; predicate is a directed-arc from subject to object. Each more complex statement must be decomposed into individual RDF triples. In this paper, the idea of knowledge patterns for conversion of sentences in English language into RDF graph language will be introduced. For modelling of knowledge patterns extended RDF graph model introduced in [2] will be used.

RDF(S), enriched with possibility of quantification and reasoning (analogous to associative networks [9]), is an

accessible tool on conceptual level even for users that do not know OWL or other formal languages based on logic which are suitable for formalization of knowledge patterns. A transcription from RDF to OWL is then quite simple.

#### A. Representation of knowledge patterns in RDF graph language

Solid lines are used to display nodes and arcs in classical RDF graphs. To distinguish the knowledge patterns from the classical statements in RDF graph we will use dashed lines. Figure 2 shows a classical RDF triple (above) and RDF triple representing knowledge pattern (below).

Fig. 2. RDF triples in classical RDF graph and as knowledge pattern

Apart from knowledge patterns, morphisms will be introduced for some sentences. Morphisms for mentioned knowledge patterns will be displayed as classical RDF triples. Subject of triples for morphisms will represent the term from a modelled domain, the predicate will be “isa” (Is-

daily	<a href="http://en.wiktionary.org/wiki/daily">http://en.wiktionary.org/wiki/daily</a>

A relation – relation of specialization) and the object will symbolize the general term from the knowledge pattern.

URI references are used to identify nodes and arcs in RDF graph. RDF graphs with full URI references would be too confusing to the users, therefore shortcuts usage for each node and arc are essential. These shortcuts are shown in table III.

1) *Affirmative declarative sentence*

The first described type of sentence is an affirmative declarative sentence. This sentence can have two forms. The first form is a sentence without an adverbial complement, second is one which includes it. In the first case, the sentence is in the form subject – predicate – object. This sentence forms RDF triple. The knowledge pattern for this type of sentence is shown in figure 3. This knowledge pattern will be marked as KPS1.

Fig. 3. KPS1

Particular members play the same role, in the RDF triple as in the sentence. Subject plays the role of subject etc. For instance, we convert the sentence “David likes chocolate.” into RDF graph language. The morphism for particular members is shown in the next figure.

Fig. 4. KPS1 – morphism

While using the knowledge pattern KPS1 in a target knowledge base, the labels of nodes and arcs are renamed using morphism in figure 4. The resulting RDF graph (in this case, it is one RDF triple) is shown in figure 5.

Fig. 5. KPS1 – result

The second form of affirmative declarative sentence contains an adverbial complement, which extends the meaning of the verb in this sentence. It can be an adverbial complement of manner, place or time. The sentence can contain one, two or all three types of adverbial complement. In terms of RDF triples, it means that adverbial complements extend the whole RDF triple containing the appropriate verb. In order to represent the whole RDF triple the RDF data model offers the predefined resource `rdf:statement` and

to represent parts of this statement it offers the predefined properties `rdf:subject`, `rdf:predicate` and `rdf:object` (full URIs for predefined resource and properties are in table III). When capturing an affirmative declarative sentence with adverbial complements as the knowledge pattern, the RDF container `rdf:Bag` is used (full URI is in table III). The knowledge pattern of an affirmative declarative sentence with adverbial complements is shown in figure 6 and will be marked as KPS2.

Fig. 6. KPS2

Furthermore, it is important to note that 'subject' and `rdf:subject` in KPS2 are not the same thing. The node with the 'subject' label represents the member of the sentence subject, while the arrow with label `rdf:subject` represents the predefined property from the RDF data model. Similarly, it stands both for the pair predicate – `rdf:predicate` and for the pair object – `rdf:object`.

While using pattern KPS2, the morphism contains only renaming the following symbols: subject, predicate, object, manner, place and time. The remaining symbols do not change. Let us consider the sentence “David plays the piano loudly at home daily.”. The morphism for this sentence is shown on figure 7.

Fig. 7. KPS2 – morphism

After applying this morphism to the knowledge pattern, the symbols are renamed and the target knowledge base will contain the resulting RDF graph (figure 8).

Fig. 8. KPS2 – result

2) *Negative declarative sentence*

The second described type of sentence is a negative declarative sentence. As well as an affirmative declarative sentence, this type of sentence can have two forms; the first form contains only subject, predicate and object, the second form contains an adverbial complement as well.

Extended RDF graph language [2] allows user to express negation of a statement. Negation is expressed by the help of special symbol called falsum (notation  $\otimes$ ), which is false in all interpretations. Falsum is always bound to predicate.

The knowledge pattern for a negative declarative sentence without adverbial complements (KPS3) is shown in figure 9. The pattern is very similar to pattern KPS1, the only difference is that the arrow representing predicate is marked by falsum.

Fig. 9. KPS3

For simplicity, let us consider the knowledge base contains negation of a sentence, stated as an example in KPS1, i. e. the sentence “David does not like chocolate.”. The morphism for this sentence (figure 10) is very similar to the morphism for affirmative sentences. To denote that the predicate is in its negative form, the falsum is inside the node representing the predicate.

Fig. 10. KPS3 – morphism

After renaming the symbols, the resulting RDF graph contains one RDF triple (figure 11).

Fig. 11. KPS3 – result

The second form of negative declarative sentences contains adverbial complements. It can be an adverbial complement of manner, place, time or more adverbial complements together. The knowledge pattern for this type of sentence will be marked as KPS4 and is very similar to KPS2. The only difference is, again, in using falsum for marking the predicate in the negative form. Falsum is inside the node representing the predicate. KPS4 is shown on figure 12.

Fig. 12. KPS4

While using this knowledge pattern in a concrete knowledge base, let us consider, again for simplicity, the negation of sentence shown while using of KPS2, i. e. sentence “David does not play the piano loudly at home daily.”. The morphism for this sentence is shown in figure 13.

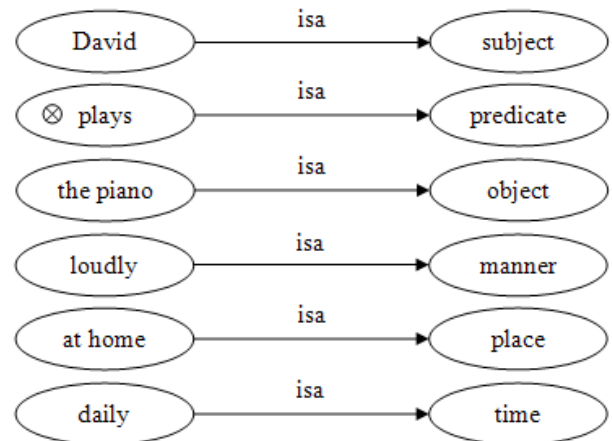

Fig. 13. KPS4 – morphism

The resulting RDF graph (figure 14) was created by renaming the symbols listed in the morphism.

Fig. 14. KPS4 – result

#### IV. CONCLUSION AND FUTURE WORK

While creating a knowledge base from sentences expressed in natural language, it is important to determine members of particular words in a sentence. The member of a sentence determines the position of a word in the RDF graph. In this paper, it was proposed that the help of knowledge patterns would be a way of converting natural language sentences into RDF graph language. Knowledge patterns are general structures of knowledge, which are not part of the target knowledge base or ontology. An essential part of the use of the knowledge patterns is the specification of renaming non-logical symbols. This part is called morphism. This paper introduced a way of capturing knowledge patterns in extended RDF graph language. A dashed line was used for the representation of knowledge patterns in RDF graphs (in

contrast to solid line in classical RDF graphs). Several examples of knowledge patterns and their use are part of this paper.

Future work will be focused on discovering other knowledge patterns and the representation of these knowledge patterns in the RDF/XML languages.

# Graph Mining Approach to Suspicious Transaction Detection

Krzysztof Michalak, Jerzy Korczak

Institute of Business Informatics

Email: {krzysztof.michalak, jerzy.korczak}@ue.wroc.pl

**Abstract**—Suspicious transaction detection is used to report banking transactions that may be connected with criminal activities. Obviously, perpetrators of criminal acts strive to make the transactions as innocent-looking as possible. Because activities such as money laundering may involve complex organizational schemes, machine learning techniques based on individual transactions analysis may perform poorly when applied to suspicious transaction detection.

In this paper, we propose a new machine learning method for mining transaction graphs. The method proposed in this paper builds a model of subgraphs that may contain suspicious transactions. The model used in our method is parametrized using fuzzy numbers which represent parameters of transactions and of the transaction subgraphs to be detected. Because money laundering may involve transferring money through a variable number of accounts the model representing transaction subgraphs is also parametrized with respect to some structural features. In contrast to some other graph mining methods in which graph isomorphisms are used to match data to the model, in our method we perform a fuzzy matching of graph structures.

## I. INTRODUCTION

**F**INANCIAL institutions such as banks are legally obliged to monitor activities of their customers and to report events that may indicate involvement in a criminal act. In the case of bank transactions monitoring, one of the goals is to detect money laundering activities i.e. activities aimed at concealing the origin of illegally-obtained money.

There are several difficulties in money laundering detection. People involved in money laundering obviously try to conceal the real purpose of money transfers used in this process. Therefore, one can expect that individual transactions will not clearly stand out from amongst other bank transfers. The probability of a fraud depends not only on parameters of individual bank transfer but also on relations with other transfers and the entities that send them.

The volume and value of transactions reported as suspicious are very high. For example, the value of transactions reported to the anti-money laundering watchdog by Russian financial institutions in the first nine months of 2010 was 120 trillion roubles (2.44 trillion pounds, 3.8 trillion dollars) [9]. 5.6 million filings were made by banks, insurance companies and financial service companies in this period.

In the area of fraud detection it is typical that events to be detected are in considerable minority compared to the overall amount of data. For example, in 2010 there were

593,819 fraudulent credit card transactions detected in Australia worth in total \$145,854,208 [7]. In the same year over 1.4 billion credit card transactions were made for a total amount of more than 195 billion dollars (values calculated using statistics from [8]). The same sources report 241,063 fraudulent credit card transactions totalling \$85,215,615 in 2006 and a total number of over 1.1 billion transactions worth in total over 155 billion dollars. In the above-cited cases fraudulent transactions constitute only 0.02 – 0.04% of all transactions which means that data manifest extreme class imbalance. This in itself creates a significant challenge for many machine learning methods.

Typically, the money laundering process is divided into three stages: placement, layering and integration [5]. Each of the stages involves various schemes of money transferring between bank accounts. These schemes can be identified as subgraphs in the transaction graph. Figure 1 shows two simple examples of subgraphs which represent transferring money via a number of intermediaries.

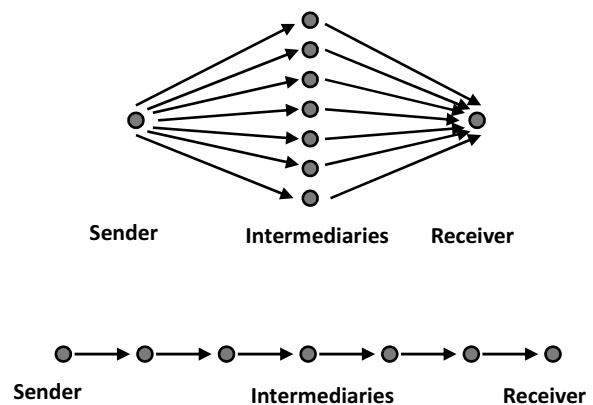

Fig. 1. Examples of subgraphs which may indicate money-laundering activities

In the first case a larger amount is split to smaller transfers in order to decrease the probability that individual transactions will be reported as suspicious. The second case serves the purpose of obscuring the connection between the sender and the receiver. The entire money laundering operation may involve many such schemes, so identification of a suspicious subgraph may help in uncovering much larger network of ille-

gal transactions. Money laundering operations are intertwined with many other transactions, including legal ones. Figure 2 shows a small subgraph of transactions (in which vertices are shaded in gray) that may raise suspicion because funds are transferred from one account to another via many independent transaction chains. It is clear that accounts participating in what may turn out to be illegal transaction structuring may as well be engaged in other, probably harmless activities.

Fig. 2. Suspicious transaction graph connected with other, possibly legal activities. Vertex labels are account identifiers, edge labels contain number of transactions between the two accounts and the total amount transferred.

## II. PROPOSED METHOD

Money laundering is hard to detect because the occurrences are very infrequent in the graph of all transactions and individual bank transfers involved in a money laundering scheme are structured so that they appear as legitimate. These obstacles are especially hard to overcome if the detection process is based only on features of individual transactions. Therefore, graph mining methods seem to be interesting, because they can detect complex dependencies between transactions. It is also possible to take into account properties and relations of entities involved in sending and receiving the transfers.

We present a method for graph structure learning using a model which can be trained on a previously annotated graph of transactions and then can be matched against a graph of unannotated transactions in order to select a number of transactions for a more thorough checking by human expert. This is in agreement with the mode of operation of financial watchdog institutions which employ experts to scrutinize suspicious transactions. Because of a huge number of transactions the work of an expert can be made significantly more efficient if a computer system is able to suggest a limited number of transactions to be checked for indications of possible money laundering. The results of the expert's work may in turn be used to train the system again.

The work presented in this paper is a part of a larger research project carried out at our Institute aimed at developing various money laundering detection methods. One of the research topics in this project is money laundering detection in data warehouses [3], [4]. Suspicious transactions discovered in data warehouses can be used as training data for the method described in this paper.

As described in the introduction, organizational schemes involved in money laundering may vary to a great extent with respect to the number of transactions used to conceal the nature of the activity. Therefore, we propose a model which can

adapt to training data with respect not only to transaction and account parameters but also with respect to the graph structure.

Proposed model represents subgraphs similar in structure to the graph presented in Figure 3.

Fig. 3. General structure of a detected subgraph

In order to model such subgraphs, hierarchical three-level patterns are generated. Some of the parameters of the model are polygonal fuzzy numbers [1]. They are denoted using the hat ( $\hat{\cdot}$ ) symbol. In the proposed method we use simplified polygonal fuzzy numbers which use only 6 real numbers  $x_1$ ,  $x_2$ ,  $x_3$ ,  $x_4$ ,  $m_2$  and  $m_3$ . Membership function  $\mu_{\hat{x}}$  of such fuzzy number  $\hat{x}$  is presented in Figure 4 and is calculated as follows:

$$\mu_{\hat{x}}(x) = \begin{cases} 0 & \text{for } x \leq x_1, \\ m_2 \cdot \frac{x-x_1}{x_2-x_1} & \text{for } x \in (x_1, x_2], \\ m_2 + (m_3 - m_2) \cdot \frac{x-x_2}{x_3-x_2} & \text{for } x \in (x_2, x_3], \\ m_3 \cdot \frac{x_4-x}{x_4-x_3} & \text{for } x \in (x_3, x_4), \\ 0 & \text{for } x > x_4. \end{cases} \quad (1)$$

where:

$\hat{x} = \langle x_1, x_2, x_3, x_4, m_2, m_3 \rangle$  - polygonal fuzzy number.

Fig. 4. Polygonal fuzzy number with components  $x_1$ ,  $x_2$ ,  $x_3$ ,  $x_4$ ,  $m_2$  and  $m_3$

The lowest level of the model is a *TR* pattern that describes a single transaction:

$$TR = \langle \hat{a}, r(\cdot), s(\cdot) \rangle, \quad (2)$$

where:

$\hat{a}$ —polygonal fuzzy number representing transaction amount,

$s(\cdot)$ —function assigning weights to classes to which entities sending transfers belong,

$r(\cdot)$ —function assigning weights to classes to which entities receiving transfers belong.

The middle level is a *SER* pattern that describes transaction chains in which transactions are connected in series:

$$SER = \langle \hat{m}, \hat{\delta} \rangle, \quad (3)$$

where:

$\hat{m}$ —polygonal fuzzy number representing the number of transactions in a chain,

$\hat{\delta}$ —polygonal fuzzy number representing the ratio of amount transferred in the last transaction to the amount transferred in the first transaction.

The top level is a *PAR* pattern that describes parallel transaction chains (which are described by the *SER* pattern)

$$PAR = \langle \hat{n}, \hat{\Delta}, \tau \rangle, \quad (4)$$

where:

$\hat{n}$ —polygonal fuzzy number representing the number of transactions in a chain,

$\hat{\Delta}$ —polygonal fuzzy number representing the ratio of the sum of amounts received by the receiving account to the sum of amounts sent from the sending account.

$\tau$ —acceptance threshold used for deciding which transaction subgraphs match the pattern.

A complete pattern contains one set of parameters for each of the three levels.

Using such patterns, transaction subgraphs are evaluated in the following manner. First, weights are assigned to individual transfers using parameters of the *TR* pattern. A transfer  $T$  of amount  $a$  sent by an entity belonging to a class  $c_s$  to an entity belonging to a class  $c_r$  is assigned a weight  $w_{TR}$  which is calculated as:

$$w_{TR}(T) = \mu_{\hat{a}}(a) \cdot s(c_s) \cdot r(c_r), \quad (5)$$

where:

$TR = \langle \hat{a}, s(\cdot), r(\cdot) \rangle$  - pattern to which the transaction is matched,

$\mu_{\hat{a}}(\cdot)$ —membership function of the fuzzy number  $\hat{a}$ .

Transaction chains are evaluated using parameters of the *SER* pattern. A transaction chain  $L$  of length  $m$  in which the ratio of amount transferred in the last transaction to the amount transferred in the first transaction equals  $\delta$  is assigned a weight  $w_{SER}$  which is calculated as:

$$w_{SER}(L) = \frac{\sum_{T \in L} w_{TR}(T)}{m} \cdot \mu_{\hat{m}}(m) \cdot \mu_{\hat{\delta}}(\delta), \quad (6)$$

where:

$SER = \langle \hat{n}, \hat{\delta} \rangle$  - pattern to which the transaction chain is matched,

$TR$ —pattern used to match individual transactions,

$T$ —transaction which belongs to the transaction chain  $L$ ,

$\mu_{\hat{m}}(\cdot)$ —membership function of the fuzzy number  $\hat{m}$ ,

$\mu_{\hat{\delta}}(\cdot)$ —membership function of the fuzzy number  $\hat{\delta}$ .

Subgraphs consisting of parallel paths are evaluated using parameters of the *PAR* pattern. A subgraph  $P$  containing  $n$  parallel paths in which the ratio of the sum of amounts received by the receiving account to the sum of amounts sent from the sending account equals  $\Delta$  is assigned a weight  $w_{PAR}$  which is calculated as:

$$w_{PAR}(P) = \frac{\sum_{L \in P} w_{SER}(L)}{n} \cdot \mu_{\hat{n}}(n) \cdot \mu_{\hat{\Delta}}(\Delta), \quad (7)$$

where:

$PAR = \langle \hat{n}, \hat{\Delta}, \tau \rangle$  - pattern to which the transaction subgraph is matched,

$SER$  - pattern used to match transaction chains,

$L$  - transaction chain which belongs to the subgraph  $P$ ,

$\mu_{\hat{n}}(\cdot)$  - membership function of the fuzzy number  $\hat{n}$ ,

$\mu_{\hat{\Delta}}(\cdot)$  - membership function of the fuzzy number  $\hat{\Delta}$ .

The entire *PAT* pattern includes all the parameters required to match graph elements at each of three levels:

$$PAT = \langle TR, SER, PAR \rangle, \quad (8)$$

$$PAT = \langle \hat{a}, r(\cdot), s(\cdot), \hat{m}, \hat{\delta}, \hat{n}, \hat{\Delta}, \tau \rangle. \quad (9)$$

Fuzzy parameters  $\hat{a}$ ,  $\hat{m}$ ,  $\hat{\delta}$ ,  $\hat{n}$  and  $\hat{\Delta}$  can be described by 6 real numbers each. Functions  $r(\cdot)$  and  $s(\cdot)$  have discrete domains and thus are adequately represented by discrete sets of weights. The entire *PAT* pattern is thus described by  $31 + 2k$  real numbers, where  $k$  is the number of entity classes.

Model parameters ( $31 + 2k$  real numbers describing a *PAT* pattern) have to be adjusted based on a training data set containing transactions annotated by an expert. For optimization of parameters of *PAT* patterns we propose to use a genetic algorithm with the following properties.

**Specimen**—a set of  $31 + 2k$  real numbers interpreted as *PAT* pattern parameters,

**Mutation**—each of the  $31 + 2k$  real numbers in each of the specimens is mutated with equal probability  $P_{mut}$ .

Mutation of the numbers that represent fuzzy number components  $x_1$ ,  $x_2$ ,  $x_3$  and  $x_4$  is controlled by additional parameters  $\Delta_x$ ,  $m_x$  and  $M_x$  defined separately for each fuzzy parameter of the model (i.e.  $\hat{a}$ ,  $\hat{m}$ ,  $\hat{\delta}$ ,  $\hat{n}$  and  $\hat{\Delta}$ ). First, a random value  $d$  is drawn with uniform probability from the range  $[-\frac{\Delta_x}{2}, \frac{\Delta_x}{2}]$ . Then, value of the component  $x_i$  is modified by adding  $d$ . As this modification may disrupt the order of fuzzy number components  $x_1$ ,  $x_2$ ,  $x_3$  and  $x_4$  and may also lead to violation of constraints  $m_x \leq x_1$  and  $x_4 \leq M_x$  a check (and possibly also a correction) must be performed. This correction is performed as follows:

- if  $x_1 < m_x$  then  $x_1 \leftarrow m_x$
- for  $i = 1, 2, 3$  : if  $x_{i+1} \leq x_i$  then  $x_{i+1} \leftarrow x_i + 0.001$
- if  $x_4 > M_x$  then  $x_4 \leftarrow M_x$
- for  $i = 3, 2, 1$  : if  $x_i \geq x_{i+1}$  then  $x_i \leftarrow x_{i+1} - 0.001$

Mutation of the numbers that represent fuzzy number parameters  $m_2$  and  $m_3$ , weights assigned to entity classes and the value of acceptance threshold  $\tau$  is performed by adding a value drawn with uniform probability from the range  $[-0.005, 0.005]$  and ensuring that the result is in the range  $[0, 1]$ .

**Selection**—a standard roulette-wheel selection procedure [6] is used.

**Crossover**—a standard single-point crossover operator [2] is used. Probability of a crossover being performed on any two specimens is controlled by the parameter  $P_{cross}$ .

**Evaluation function**—the evaluation function for a given specimen  $S$  is calculated in the following way:

- from the specimen  $S$  a pattern  $PAT(S) = \langle TR(S), SER(S), PAR(S) \rangle$  is constructed using  $31 + 2k$  real numbers as parameters,
- a set  $\mathcal{P}$  is constructed containing those subgraphs  $G$  that match the pattern  $PAT(S)$  and have a weight  $w_{PAR(S)}(G) > \tau$ ,
- for each subgraph  $G \in \mathcal{P}$  a total number of transactions  $t_n(G)$  in this subgraph and a sum of weights of transactions  $t_w(G)$  in this subgraph are calculated. Weights of transactions are based on annotations made by the expert. For example, transactions annotated as "illegal" may have a weight 1.0, transactions annotated as "legal" a weight 0.0 and transactions annotated as "not classified" a weight 0.1.
- evaluation of the specimen is calculated as:

$$F(S) = \frac{\sum_{G \in \mathcal{P}} w_{PAR(S)}(G) \cdot t_w(G)}{\sum_{G \in \mathcal{P}} t_n(G)}. \quad (10)$$

The specimen (or specimens) achieving the highest values of evaluation function  $F$  may be used to identify suspicious transactions in previously unseen data.

### III. EXPERIMENTS

For experiments training and testing data sets containing transactions annotated by an expert are required. Because such data sets are hard to obtain due to confidentiality of banking data, the experiments performed so far were based on artificially-generated data. In order to build a data set containing transactions similar to those encountered in real-life we used a model which represents transactions in a "mini-economy" during a period of one year. In this model, three classes of economic entities are defined: companies, individual persons and offices (tax offices and social security offices). Economic entity classes are characterized by probability distributions which are used to generate parameters for instances belonging to each class.

Companies are characterized by the following probability distributions:

- distribution of the number of employees:  $N(m_E, \sigma_E)$ ,
- distribution of salary:  $N(m_S, \sigma_S)$ ,
- distribution of the number of goods sold per year:  $N(m_G, \sigma_G)$ ,

- distribution of prices of goods:  $N(m_P, \sigma_P)$ .

A predefined number of companies  $n_c$  is generated. For each company a number of employees  $n_E$  is drawn from the Gaussian distribution  $N(m_E, \sigma_E)$ . Then,  $n_E$  persons are added to the model. For each of the 12 months in a year a salary  $a_s$  is drawn from the Gaussian distribution  $N(m_S, \sigma_S)$  and a transaction representing the payment (with the amount  $a_s$ ) is generated.

Next, buying of goods is simulated. For each company a number of goods sold during the simulated year  $n_G$  is drawn from the Gaussian distribution  $N(m_G, \sigma_G)$ . For each good a price  $a_p$  is drawn from the Gaussian distribution  $N(m_P, \sigma_P)$ . A buyer is selected at random from all employees of all companies and a new transaction (with the amount  $a_p$  - a payment for the good) is added.

Generation of offices is controlled by the parameters  $n_T$  - the number of tax offices and  $n_F$ —the number of social security offices. Offices are also characterized by two probability distributions:

- distribution of tax rate:  $N(m_T, \sigma_T)$ ,
- distribution of social security fee rate:  $N(m_F, \sigma_F)$ .

One tax office and one social security office are assigned at random to each company. The sum of payments  $C_p$  received by the company for goods sold in each month is calculated and a tax rate  $\alpha_T$  is drawn from the Gaussian distribution  $N(m_T, \sigma_T)$ . Tax amount  $a_T$  is calculated as  $a_T = C_p \cdot \alpha_T / 100$  and a transaction sent by the company to the tax office account is generated. Social security fee  $a_F$  is calculated as  $a_F = C_s \cdot \alpha_F / 100$  based on the sum of salaries in each month  $C_s$  and a social security fee rate  $\alpha_F$  which is drawn from the Gaussian distribution  $N(m_F, \sigma_F)$ .

The steps described above produce a set of transactions representing the usual activities observed in economy. To this set of transactions  $n_{ML}$  money laundering schemes are added. Each of these schemes consists of a sender, a number  $n_B$  of intermediaries and a receiver. Transfers are sent from the sender to one intermediary and then to the receiver. Each parallel path goes through one intermediary only, so  $n_B$  parallel paths are created. The generation of the money laundering schemes is characterized by the following probability distributions:

- distribution of the amount sent from the sender to one intermediary:  $N(m_Q, \sigma_Q)$ ,
- distribution of the number of intermediaries (equal to the number of parallel paths):  $N(m_B, \sigma_B)$ ,
- distribution of the fraction of the amount received by the intermediary that is forwarded to the receiver:  $N(m_\Delta, \sigma_\Delta)$ .

Generated transactions are annotated in the following manner:

- legal—tax and social security fee transactions,
- illegal—transactions belonging to the generated money laundering schemes,
- unknown—all the remaining transactions (salaries and payments for goods).

Using data generation method described above, we have generated four data sets:  $SMALL_A$ ,  $SMALL_B$ ,  $LARGE_A$ ,  $LARGE_B$ . All data sets were generated using the same parameters for offices:  $n_T = 5$ ,  $n_F = 5$ ,  $m_T = 15$ ,  $\sigma_T = 1.5$ ,  $m_F = 20$ ,  $\sigma_F = 2.0$ . Also, parameters of money laundering were the same:  $m_Q = 5000$ ,  $\sigma_Q = 1000$ ,  $m_B = 40$ ,  $\sigma_B = 10$ ,  $m_\Delta = 1.0$ ,  $\sigma_\Delta = 0.1$ . These data sets contain three classes of companies that can be briefly characterized as large (L), medium (M) and small (S). The  $SMALL$  and  $LARGE$  data sets differ in the number of companies in each class. Parameters controlling generation of companies for data sets  $SMALL_A$  and  $SMALL_B$  and for data sets  $LARGE_A$  and  $LARGE_B$  are summarized in Tables I and II respectively.

TABLE I

PARAMETERS CONTROLLING GENERATION OF COMPANIES FOR DATA SETS  $SMALL_A$  AND  $SMALL_B$

Parameter	Company class		
	large	medium	small
$n_C$	2	4	25
$m_E$	5 000	500	50
$\sigma_E$	1 000	100	20
$m_S$	6 000	5 000	4 000
$\sigma_S$	1 500	1 200	1 000
$m_G$	100 000	1 000	100
$\sigma_G$	30 000	300	30
$m_P$	50	500	500
$\sigma_P$	10	100	100

TABLE II

PARAMETERS CONTROLLING GENERATION OF COMPANIES FOR DATA SETS  $LARGE_A$  AND  $LARGE_B$

Parameter	Company class		
	large	medium	small
$n_C$	2	8	100
$m_E$	5 000	500	50
$\sigma_E$	1 000	100	20
$m_S$	6 000	5 000	4 000
$\sigma_S$	1 500	1 200	1 000
$m_G$	1 000 000	10 000	1 000
$\sigma_G$	300 000	3 000	300
$m_P$	50	500	500
$\sigma_P$	10	100	100

The number of accounts and transactions of each type in each of the data sets is summarized in Table III.

In the experiments, one of data sets in a  $LARGE/SMALL$  pair was used for training and the other one for testing. A population of  $N_{pop} = 20$  specimens was trained for  $N_{gen} = 20$  generations of genetic algorithm. Crossover and mutation probabilities were set to  $P_{cross} = 0.1$  and  $P_{mut} = 0.01$  respectively. Parameters controlling mutation of  $x_i$  components of fuzzy numbers are summarized in Table IV.

Specimen evaluation requires that transaction annotations are converted to numerical weights. In the experiments a weight 1.0 was assigned to “illegal” transactions,

TABLE III

THE NUMBER OF ACCOUNTS AND TRANSACTIONS OF EACH TYPE IN EACH OF THE DATA SETS

Object type	Number of objects			
	$SMALL_A$	$SMALL_B$	$LARGE_A$	$LARGE_B$
Accounts	11 238	11 401	19 261	21 270
companies	31	31	110	110
offices	10	10	10	10
personal	11 197	11 360	19 261	21 150
Transactions	294 972	383 463	2 854 965	2 625 671
legal	744	744	2 640	2 640
unknown	289 336	377 207	2 848 435	2 619 049
illegal	4 892	5 512	3 890	3 982
annot. ratio	0.0191	0.0166	0.0023	0.0025

TABLE IV

PARAMETERS CONTROLLING MUTATION OF  $x_i$  COMPONENTS OF FUZZY NUMBERS

Fuzzy number	Parameter		
	$\Delta_x$	$m_x$	$M_x$
$\hat{a}$	200	range not limited	
$\hat{m}$	$x_i$ not mutated, fixed at 0, 1, 2 and 3, only $m_2$ and $m_3$ are mutated		
$\hat{\delta}$	0.1	0.5	1.5
$\hat{n}$	2	3	100
$\hat{\Delta}$	0.1	0.5	1.5

a weight 0.0 to transactions annotated as “legal” and a weight 0.1 to transactions annotated as “not classified.”

Tests were performed in 10 independent iterations for each pair of  $SMALL$  and  $LARGE$  data sets. In each iteration, after the training has been completed, the best specimen (with the highest value of the evaluation function) was selected from the population and it was used for selecting suspicious transaction subgraphs from the testing data set. Only one, the best specimen, was used, because we wanted to limit the number of transactions marked as suspicious. In the real-life environment, transactions marked as suspicious are reviewed by human expert which obviously imposes limitations on the number of transactions that can be processed. The number of transactions that were actually legal, illegal and of unknown status (according to annotations) was used to measure the quality of the detection. Results are summarized in Tables V-VIII.

During the experiments execution time of test iterations was recorded. Measured values are summarized in Table IX.

A meaningful comparison of execution times is only possible for tests performed on the same machine. Therefore, only three tests that were performed on the same computer are included in the table. For comparison, the number of accounts and the number of transactions in each data set are also presented in the table.

TABLE V

THE NUMBER OF "LEGAL", "NOT CLASSIFIED" AND "ILLEGAL" TRANSACTIONS MARKED AS SUSPICIOUS IN THE EXPERIMENT WITH TRAINING DATA SET *SMALL<sub>A</sub>*, TEST DATA SET *SMALL<sub>B</sub>* AND EACH ITERATION PERFORMED INDEPENDENTLY. PERCENTAGE OF "NOT CLASSIFIED" TRANSACTIONS AMONG TRANSACTIONS MARKED AS SUSPICIOUS: 15.98%

Iteration	Number of transactions		
	<i>legal</i>	<i>unknown</i>	<i>illegal</i>
1	0	0	26
2	0	9	9
3	0	8	8

#### IV. CONCLUSION

In this paper we presented a graph mining method intended for detection of suspicious transactions. Contrary to data mining methods based solely on transaction features the method proposed in this paper takes into consideration those dependencies between individual transfers that may be indicative of illegal activities. We expect this feature to be a significant advantage, because single transactions are often tailored by criminals in order to be as innocent-looking as possible.

Results of the experiments suggest that the method proposed in the paper has several advantageous properties:

- in the experiments the proposed method managed to avoid marking as suspicious of any transactions that were annotated as "legal". Although it is not clear at this point to what extent this quality will persist in the case of other data sets, this is a desirable behaviour for a suspicious transaction detection method;

- more than 2/3 of transactions marked as suspicious were actually involved in money laundering schemes;
- as shown in Table IX computation time doubled with the similar—twofold increase in the number of accounts. The difference in transaction number between the same two data sets was about 10 times. This is beneficial, because the volume of transactions in historic record increases more rapidly than the number of bank customers;

The fact that the proposed method did not mark any legal transactions as suspicious is promising. It is easy to understand that reporting transactions which are considered legal by human experts most probably means raising a false alarm. A much harder question is, how large percentage of transactions that are unannotated by human expert (or annotated as "not classified") should be marked as suspicious by the algorithm. In the case of artificial data used in this paper it is obvious that all "not classified" transactions were,

TABLE IX

EXECUTION TIME (IN SECONDS) OF TEST ITERATIONS. ALL TESTS PRESENTED IN THE TABLE WERE PERFORMED ON THE SAME MACHINE.

Training data set	<i>SMALL<sub>B</sub></i>	<i>LARGE<sub>A</sub></i>	<i>LARGE<sub>B</sub></i>

Average time	1 165	2 099	2 192

in fact, legal. Therefore, the percentage of "not classified" transactions among transactions marked as suspicious can be interpreted as a false positive ratio. In real-life scenario, however, some of the "not classified" transactions contained in the training data set will actually be illegal (i.e. involved in a money laundering schemes) because it is never possible to identify all illegal activities. Nevertheless, statistically, most of the "not classified" transactions are legal. It is thus hard to decide at this point, to what extent the learning model should be trained to avoid reporting transactions similar to "not classified" examples from the training set.

Further work may concern improving the precision of the detection (in order to avoid too many legal transactions being submitted to human experts for evaluation) but also improving the completeness of the results (ensuring that as many illegal transactions as possible are marked as suspicious). Also, improvement in computational speed may be important, especially because computation time may be a factor limiting the possibility of searching for more complex subgraph patterns.

In order to achieve the above mentioned goals further work may be conducted in some of the following directions:

- training a population of positive and negative patterns. Currently, specimens represent only such patterns that identify suspicious subgraphs. Learning patterns that represent legal transaction subgraphs may help in reducing the false positive ratio;
- using decision rules designed by experts to improve detection quality. Apart from knowledge extracted from annotated graphs, rules, for example excluding tax transfers from suspicion, may help in reducing the search space that must be processed;
- interacting with human expert, for example using the number of transactions confirmed by the expert to be

illegal as a criterion in model training. Another possibility is to allow the expert who uses the system to adjust some parameters by hand. For example, parameters controlling fuzzy number mutation ( $\Delta_x$ ,  $m_x$  and  $M_x$ ) may be tuned in order to ensure that the model obtained during training satisfies certain constraints;

- using Genetic Multi-Objective Optimization (GMOO) in order to balance conflicting requirements (maximizing the number of detected frauds, but at the same time limiting the number of transactions suggested for review by human expert);
- implementing computationally-intensive parts of the algorithm (for example, evaluation function calculation) using CUDA architecture in order to take advantage of massive parallelism available on modern GPUs;
- allowing more complex subgraph patterns to be used. One of the possible approaches can be to implement evolving graph structure (not only evolutionary optimization of subgraph model parameters);
- alternative methods for searching for matching subgraphs. Currently all matching subgraphs are evaluated at each level of the hierarchical pattern. Using non-deterministic methods may be hard to avoid, especially if more complex subgraph patterns will be used.

Another important aspect of further research is to obtain real-life data from financial institutions and test the proposed method on such data.

**Abstract**—This paper presents document search model based on its visual content. There is used hierarchical clustering algorithm - GHSOM. Description of proposed model is given as learning and searching phase. Also some experiments are described on benchmark image sets (e.g. ICPR, MIRFlickr) and created document set. Paper presents some experiments connected with document measures and their influence on searching results. Also in this paper some first results are given and directions of further research are given.

## I. INTRODUCTION

THE document search task is connected to large dataset of documents which can be used in many applications e.g. in libraries to find a relevant document similar to one given in a query. Such task can be solved as classification task of data mining domain in knowledge discovery database process. However, classification needs labeling of all documents and this is nearly impossible because of time/cost constraints connected to labeling by human. Thus our work concerns on clustering task in unsupervised learning mode, where structure of data is not given or we barely know anything about it. Also, we decided to use a special type of clustering – hierarchical clustering to build a hierarchy of documents. It gives us a very useful advantage in navigation of document search space to find similar documents navigating between included images that can be connected and further in searching for similar documents basing of its visual aspects. However, our task is specific, where the document is analyzed only in the visual context. So basically our model bases only on visual content of document, not text. The visual content of document, in this stage of research, means only included images, figures, tables and schemas. Our work is alternative to semantic text based document analyses and indeed our approach results would be linked to such method in the complex system.

There are many methods that bases on hierarchical clustering of data for previously artificially created hierarchy by human. There are also some methods, like Growing Hierarchical Self-Organizing Map (*GHSOM*) which creates hierarchy from scratch.

Description of methods and architectures based on similar images search or image category search, clustering or clusterisation can be found in work [13]. Another survey [5] presents various approaches to document layout description, document/images features selection, classification and application. Models are hidden markov model, neural network, k-Nearest Neighbor or rule based approaches.

This work presents our first research results for quality of documents search using *GHSOM*. The 2nd section shows ideas of organizing data as a map and *GHSOM* as extension of *SOM*. Section 3rd presents proposed approach, architecture and connected processes. Some experiments are included in section 4th, it also shows results of our first research. Last section concludes and describes directions of further research.

## II. GROWING HIERARCHICAL SELF-ORGANIZING MAP

Organizing data was firstly proposed in 1982 by Kohonen to explain the spatial organization of the brain's functions. The data is presented as neural network with the aid of adaptation of weights vectors becomes organized [10]. The Self-Organizing Map (*SOM*) is a computational, unsupervised tool to the visualization and analysis of high-dimensional data. There are plenty applications where *SOM* is used, especially in text mining [10].

A useful way to organize data presents Mäkelä [3]. His method can be described as Hierarchical Self-Organizing Map (*HSOM*) which relays on series of *SOMs* which are placed in layers where the number of *SOMs* in each structure layer depends on number of *SOMs* in previous layers (the upper one). In this model number of structure layers in *HSOM* and dimension of maps are defined *a priori*.

In the learning process (which always starts from top layers to the bottom layer) units weight vectors in *SOMs* of each layer are adapted. The adapt of weight in next layer is only possible when given layer is finished. Final effect of this process is hierarchical clustering of data set. This approach has some advantages:

- smaller number of connections between input and units in *HSOM* layers [3],

This work is partially financed from the Ministry of Science and Higher Education Republic of Poland resources in 2010-2013 years as a research SYNAT project (System Nauki i Techniki) in INFINITI-PASSIM.

- much shorter processing time which comes from the point above and from hierarchical structure of learning process [3].

In *HSOM* there are some necessities:

- definition of maps sizes and number of layers which depends on data set,
- choosing of learning parameters for each layer in *HSOM*.

There is another *SOM* extension that reduces some above disadvantages. Growing Self-Organizing Map (*GSOM*) is another variant of *SOM* [1] to solve the map size issue. The model consists of number of units which in learning process grows. The learning process begins with minimal number of units and grows (by adding new units) on the boundary based on a heuristic. To control the growth of the *GSOM* there is special value called Spread Factor (*SF*) [1] - a factor that controls the size of growth. At the beginning of learning process all units are boundary units which means that each unit has the freedom to grow in its own direction. If the unit is chosen to grow it grows in all its free neighboring positions.

However in *HSOM* still exists a problem of *a priori* given architecture. Another approach, Growing Hierarchical Self-Organizing Map (*GHSOM*) solves it.

The architecture of *GHSOM* allows to grow in both a hierarchical and in a horizontal direction [2]. This provides a convenient structure of clustering for large data sets which can be simple navigate through all layers from the top to the bottom.

The learning process begins with a virtual map which consists of one vector initialized as average of all input data [15]. Also for this unit, error (distance) between its weight vector and all data is calculated - this error is global stop parameter in *GHSOM* learning process. Then next layer map (usually initialized by 2x2 [8]) is created below the virtual layer (this newly created *SOM* indeed is a child for unit in virtual layer). From now on, each map grows in size to represent a collection of data at a specified level of detail. The main difference between growing in *GHSOM* from *GSOM* is that the whole row or column of units is added to currently learning *SOM* layer. The algorithm can be shortly described as:

1. For present *SOM* start learning process and finish it after  $\lambda$ -iterations.

2. For each unit count error (distance) between its weight vector  $m_i$  and input patterns  $x(t)$  mapped onto this unit in the *SOM* learning process (this error is called quantization error  $qe$ ).

3. If the sum of quantization errors is greater or equal than certain fraction of quantization error of parent unit:

$$\sum qe_i \geq \tau_1 * qe_{parent_{unit}}$$

3a. If yes - select unit with biggest error and find neighbor to this unit which is most dissimilar. Go to step 4.

3b. else - stop.

4. Between these two units put row/columnn.

5. Reset learning parameter and neighbor function for next *SOM* learning process.  
Go to step 1.

When the growth process of layer is finished the units of this map are examined for hierarchical expansion [11]. Basically, units with large quantization error will add a new *SOM* for the next layer in the *GHSOM* structure according to  $\tau_1$  value. More specifically, when quantization error of unit in examined map is greater than fraction  $\tau_2$  of global stop parameter, then a new *SOM* (usually initialized by 2x2) is added to structure. The learning process and unit insertion now continue with the newly established *SOMs*. The difference in learning process of new layer is that fraction of data set is used for training corresponding to units mapped into parent unit [2].

The whole learning process of the *GHSOM* is terminated when no more units are required for further expansion. This learning process does not necessarily lead to a balanced hierarchy (the hierarchy with equal depth in each branch) [15]. To summarize, the growth process of the *GHSOM* is guided by two parameters  $\tau_1$  and  $\tau_2$ . The parameter  $\tau_1$  controls the growth process in layer (certain fraction in algorithm for expanding in layer for *GHSOM*) and the parameter  $\tau_2$  controls hierarchical growth of *GHSOM*.

The clustering of images is needed because, when today's search engine is asked about images usually as an answer comes images which were named by the asked phrase. It would be better if the answer come on the base of what image contains. The content of images can be described by a vector of features - vector of numbers. *GHSOM*, in simply way, bases on vectors of real numbers so images can be successfully used as a data set. In this work the idea was to create a *GHSOM* structure which will hierarchically organize images in groups of similar images. The visual aspects of such clustering (visualization of images in cluster) can be analyzed by human or by some quality measures and ratings.

### III. PROPOSED *GHSOM* BASED MODEL

Model base on *GHSOM* for searching similar documents in database includes mainly 3 modules: document preprocessing (for visual element extraction and description), *GH-SOM* structure and document of indexed documents. The schema of proposed model is given on Fig.1.

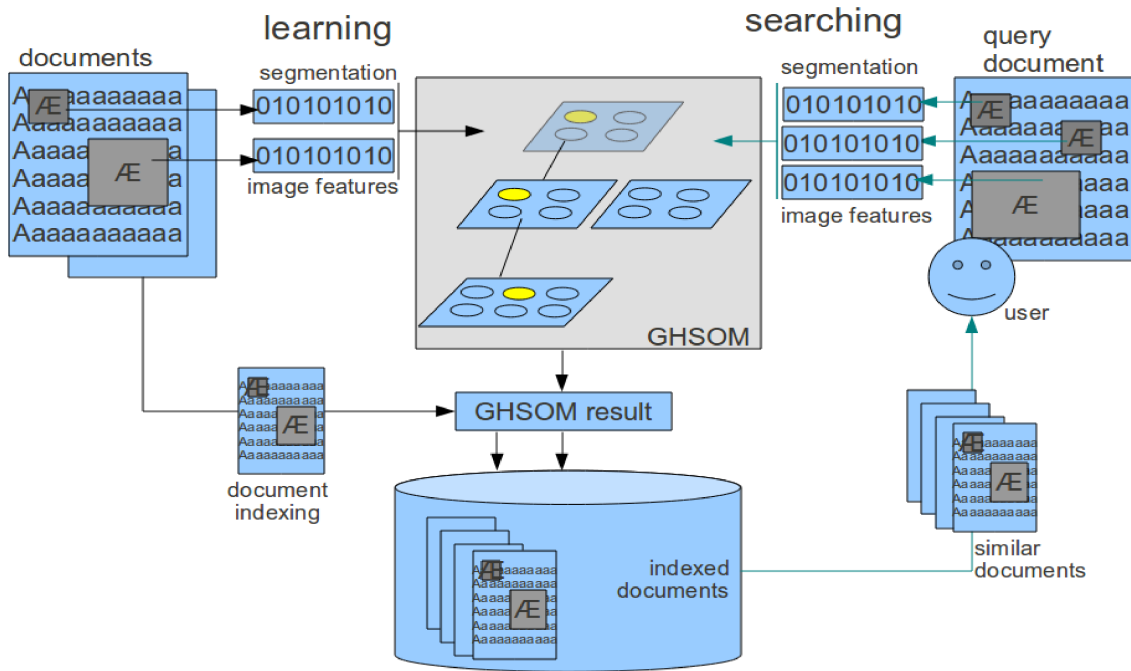

Fig. 1 Proposed document searching model

### A. Learning phase

The first stage of such process is preprocessing. Each document is analyzed by getting its visual content: figures, tables, schemas and others. Each visual element is divided in 25 segments (5x5 grid); for each segment image features are calculated (e.g. feature connected to image color, structure or shapes). Each visual element is represented as a sequence of vectors (=segments) and set of visual elements gives the whole representation of document.

Next stage of learning phase uses the hierarchical clustering in *GHSOM* model to organize space of set of documents. Each visual element is presented to *GHSOM* to build hierarchical cluster that would be used in search phase.

In the next step *GHSOM* learning procedure runs and gives hierarchical clustering structure for document indexing. The document is indexed and then registered into base of all indexed documents as vector of output *nodes* from *GHSOM* structure. The length of vector equals to the total number of *node* units, and each node unit has the own identifier and place in output document vector  $\Phi(\text{document}_i)$ . If its activated value is not zero, e.g. if in *i*-th document the 2nd node has been activated once and 6th has been activated twice output document vector is:

$$\Phi(\text{document}_i) := \langle 0,0,1,0,0,0,2,0 \rangle.$$

Such representation is intuitive and allows to use document similarity or metrics in simple way (very crucial aspect in searching phase). On the end of learning proces each already indexed document is registered in database, that works the special role in searching phase.

### B. Searching phase

The already learned *GHSOM* can be used for searching similar documents in database of all indexed documents. We assume that the best way of searching is the document query

*document<sub>query</sub>*. The query document has to be converted by preprocessing procedure (finding visual elements, its segmentation and features calculations) and it allows to present to *GHSOM* structure the document representation. Already calculated the output of activated *GHSOM* units gives  $\Phi(\text{document}_{\text{query}})$  and it becomes the base of similar documents searching in database. According to used document measure (we experimented mainly with euclidean and cosine measures) it returns the sequence of *n* most similar documents in database.

### C. Model parameters discussion

The proposed model parametrization is not a complex problem. The more difficult issue is selection of visual images features. In this stage of research we used only color RGB based features, but we plan to extend this representation by adding extra features connected to shape and texture. The *GHSOM* algorithm uses only two basic values for steering learning process  $\tau_1$  and  $\tau_2$ . Another parameter is connected with database and searching process, where document measure must be given. We experimented with euclidean and canonical cosine measures of documents representation and it gives very promising results.

## IV. EXPERIMENTS AND FIRST RESULTS

We developed proposed model as programistic platform written in Java for experiments. Our experiments are divided into separate tasks: similar image search and similar document search. The motivation of the first task is connected with series of experiments to basic *GHSOM* model quality verification. Results of second types of experiments give information about effectiveness of the whole model.

### A. Similar image searching

The experiments of image hierarchical clustering using GHSOM were based on benchmark images dataset: ICPR<sup>1</sup>, IAPR TC12<sup>2</sup> and MIRFlickr<sup>3</sup>. These datasets consist of labeled images that make possible not only image clusterisation but also verification of image distribution in GHSOM hierarchical structure. Our research was concerned on:

- external measure of *GHSOM*: image query to model and verification according to connected with image and *GHSOM* unit keywords,
- internal measure of *GHSOM* as the set of image clusters – we used Davies Bouldin Index (*DBI*) and Dunn Index (*DI*)

Our experiments, detailed in description [4], show that *GHSOM* is a useful tool of image hierarchical clustering. Although we used only RGB color image features, results are very successful. The example of proper *GHSOM* clustering image distribution is presented in Fig. 2.

Fig. 2 Example of GHSOM images clustering – 'buildings' in benchmark ICPR benchmark image dataset

The *GHSOM* application to similar images searching task gives also some hints about further research. There are some badly created cluster and badly classified images (but the percent of them are respectively small). In the future, visual aspects of images in hierarchical clusters created by *GHSOM* can be researched. As well, in this work not only classical Euclidean distance was used (but also L1 and Tchybyszew's measure) but another experiments with different measures for distance should be applied.

<sup>1</sup>ICPR dataset: <http://www.cs.washington.edu/research/>

<sup>2</sup>IAPR TC12 dataset: <http://www.imageclef.org/photodata/>

<sup>3</sup>MIRFlickr dataset: <http://www.flickr.com/>

### B. Similar documents searching

The main task of GHSOM in proposed model is similar document searching. We created a dataset 1kPDF that consist of 1000 PDF documents. Each document is in polish language and has at least one visual element. Documents are not labeled but only grouped into 100 or 200 domain groups: sport, motorization, general, architecture and art. Each group is created by other person to make the whole document set more independent. Thus documents in various domains can be alike.

We developed on experiments to examine the search quality of model using given document measure. 25 selected randomly from various groups: 4 documents are connected with architecture, 8 motorization documents, 8 general, 4 sport and 1 concerns art. Search results for cosine document measure for these 25 documents are presented in Table I. The 'general' domain also has high effectiveness (33%). It means that these documents are more relevant in 10 answer documents.

The worst result is observed in art (5%) and sport (2,7%) documents. For art document query situation seems to be problematic in interpretation as there is chosen only one doc-

TABLE I.  
RESULTS OF FIRST EXPERIMENTS – COSINE DOCUMENT MEASURE

Q \ A	architect	motor.	general	sport	art
architect.	<b>25,00%</b>	33,75%	32,50%	6,25%	2,50%
motor.	31,87%	<b>26,87%</b>	35,00%	2,50%	3,75%
general	35,00%	25,64%	<b>33,12%</b>	1,25%	5,00%
sport	22,97%	27,02%	36,48%	<b>2,70%</b>	10,80%
art	45,00%	30,00%	15,00%	5,00%	<b>5,00%</b>

ument connected with art domain and result cannot be representative. Also, not clear situation occurs for sport, where only 5% of relevant answers were given. However, selected documents connected to sport are very specific – they are short and often consist of one image. Search result returns on first place similar documents (in sport domain) but some answered documents are connected to others domains.

The same set of 25 documents was used to examine Euclidean document measure (see Table II). Such measure seems to be more effective in search similar documents. The

TABLE II.  
RESULTS OF FIRST EXPERIMENTS – EUCLIDEAN DOCUMENT MEASURE

Q \ A	architect	motor.	general	sport	art
architect	<b>21,25%</b>	40,00%	18,75%	6,25%	13,75%
motor.	5,62%	<b>63,12%</b>	11,25%	7,50%	12,50%
general	9,37%	45,62%	<b>21,25%</b>	8,12%	15,62%
sport	0,00%	66,25%	7,50%	<b>11,20%</b>	15,00%
art	0,00%	35,00%	20,00%	10,00%	<b>35,00%</b>

best result was for 'motor' domain – 63%, the worst for sport group (11,2% valid, and 66% answer is motorcycle).

The example query for 'motor' document is presented on Table III, where 9 first most similar documents of 20 are relevant to questioned document, which makes answer very accurate.

TABLE III.  
EXAMPLE RESULTS OF 'MOTORYZACJA/620' DOCUMENT QUERY DOCUMENT  
USING EUCLIDEAN DOCUMENT MEASURE

<b>motoryzacja/656; 17.34935</b>	
<b>motoryzacja/628; 17.52141</b>	
<b>motoryzacja/1293; 17.7200</b>	...
<b>motoryzacja/613; 18.41195</b>	sztuka/1376; 20.09975124
<b>motoryzacja/1269; 18.4661</b>	arch-bud/529; 20.12461179
<b>motoryzacja/1290; 19.39071</b>	<b>motoryzacja/627; 20.17424</b>
<b>motoryzacja/1288; 19.51922</b>	<b>motoryzacja/1291; 20.1990</b>
<b>motoryzacja/645; 19.748417</b>	arch-bud/572; 20.2731349
<b>motoryzacja/665; 19.899748</b>	arch-bud/569; 20.29778313
arch-bud/552; 20.02498439	ogolne/1085; 20.3224014
ogolne/1115; 20.07485989	ogolne/1060; 20.3469899
...	ogolne/1058; 20.37154878

Our experiments show that model gives very promising results, however it difficult to say which measure is better. Also, results are better than it seems because groups of documents are alike and some documents can be labeled as member of two groups e.g. 'architecture' documents can be included to 'art' group too.

## V. SUMMARY AND FURTHER RESEARCH

This paper presents results of our first experiments with *GHSOM* based document searching model. Our approaches use hierarchical clustering of image content of collected documents to search for similar document. Paper presents results of experiments connected to different document measure (Euclidean and classic Cosine one). Thus there is no the best document measure and in conclusion is that there is strong need of extra experiments series. The important factor of future research is the image feature selection. In this stage only *rbg* based features were selected while there are useful features like texture and shape.

Presented series of experiments are initiative and extra experiments are planned for document collections of 10 000 documents (results given in paper bases of 1000 document collection). The larger collection may give the experiments more precision and generalization, which also allows to do various experiments.

**Abstract**—Automatic image annotation problem is one of the most important sub-problems of computer vision. It is strongly related to and goes beyond image recognition. The key goal of annotation is to assign a set of words from a given dictionary to a previously unseen image. In this paper, we address two key problems related to image annotation. The first one is low precision of generated answers, the second one is automatic localization of image fragments related to annotations. The proposed method utilizes image fragment matching to precisely localize near-duplicate visual content of images.

## I. INTRODUCTION

**A**UTOMATIC image annotation (AIA) is an extension of image recognition. The input for an AIA method is an image. The output is a set of words (also referred as classes), from a given dictionary, which describe the input image in a best possible way. However, in the AIA problem additional assumptions are made [1], comparing to the classic recognition problem [2]. The major assumption is the lack of relations between the words and their visual representation (feature vectors) within a single image. Each word within the image description is represented by all feature vectors, which can be generated from the visual content of the image. Instead of a one to one relations (like in a classic recognition), there are many to many relations.

Most of the available image annotation methods outputs a set of words, without any information on the localization of the detected words. Precise localization of image fragments related to detected words is a challenging task. The earliest approaches to AIA assumed image segmentation. Each segment has been related with one or more words, e.g. [3], [4]. Such approach fails in most cases, because image segmentation usually do not covers true boundaries of objects represented by the dictionary. More recent research shows that image segmentation used for the purpose of annotation do not have to recreate true object boundaries, e.g. [5]. Rectangular blocks [5], [8] or various setups of fixed regions [6] became very popular and effective. Obtained quality results are usually better than those with classic segmentation, but word localization is practically impossible. There are attempts to handle AIA with word localization without image segmentation, e.g. [7]. A very dense grid of rectangles is utilized. In general, all mentioned approaches give some rough, very imprecise information on the localization of word representations on the image.

Another problem is a low precision of practically all available image annotation approaches. Even the state-of-the-art methods (e.g. [8]) tested on relatively simple image databases fail to reach precision above 90%. There are many sources of this problem, however one of the most prominent is the mentioned lack of relations between words and image fragments. Construction of high quality recognition models is not possible, due to very high noise in the training data. Only a small fragment of positive training data is correct [7].

Recent research in AIA (e.g. [8]) shows that distance based methods, strongly related to image retrieval, give very promising results. Key-point based, near-duplicate retrieval is particularly interesting. Key-points such as *SIFT* [9] are used to model local photometric properties of images. These fragments are matched together to establish candidate relations between images. Global geometric [10], [11] or topological [12] constraints provide necessary information to verify the correctness of candidates.

The paper presents a new automatic image annotation method, strongly related to key-point based image retrieval. It solves mentioned problems for a specific sub-domain of images and words. Generated annotations reach high precision. The method it is able to precisely locate words on the image, without such information in the training set. The proposed approach has limited applicability, it is only able to annotate words with near-duplicate visual representation.

## II. PROPOSED APPROACH

The proposed method is called *Automatic Image Annotation by Matching* (AIAM). Let us formalize important concepts at the beginning. We follow with a general description and all the necessary details.

### A. Formal definitions

Let us give the formal definitions of important concepts. First, we focus on automatic image annotation. Later on, near-duplicate fragment detection is described.

a) *Automatic image annotation*: The dictionary  $\mathcal{W} = \{w_1, w_2, \dots, w_k\}$  is a set of words  $w_x : x = \{1, \dots, k\}$ , where  $k$  is the size of the dictionary. Words are strings, they do not have any related semantics. The training set  $\mathcal{I}$  consists of  $n$  pairs: images  $I_x$  and their annotations  $W_x \subseteq \mathcal{W}$ , where  $x = \{1, \dots, n\}$ :

$$\mathcal{I} = \{(I_1, W_1), (I_2, W_2), \dots, (I_n, W_n)\}. \quad (1)$$

Input image  $J$  is an image to be described in an automatic manner. Automatic image annotation method  $\mathcal{A}$  describes image  $J$  using words from the dictionary  $\mathcal{W}$ , based on the data from the training set  $\mathcal{I}$ . Output of the method is an annotation  $\mathcal{A}(J) = W_J \subseteq \mathcal{W}$  of the input image  $J$ .

b) *Near-duplicate image fragments*: Near-duplicate image fragment matching method  $\mathcal{M}$  accepts a pair of images  $(X, Y)$  as an input. If these two images contain near-duplicate image fragments, they are marked using outlines (convex hulls). Each pair of outlines represent a single near-duplicate image fragment. The output is a set of  $m$  outline pairs. Both the number of outline pairs ( $m$ ) and the outlines are detected fully automatically by the matching method  $\mathcal{M}(X, Y)$ :

$$\mathcal{M}(X, Y) = \{(f_X^1, f_Y^1), (f_X^2, f_Y^2), \dots, (f_X^m, f_Y^m)\}. \quad (2)$$

### B. Outline of the method

The proposed automatic image annotator utilizes near-duplicate fragment matching method as a key component. Matching of near-duplicates has to be performed with possible highest quality. Out of several available approaches to image fragment matching, a method proposed by the authors is chosen [13]. The method utilizes low level image features (*SIFT* [9]) and affine geometry. A six dimensional probability density function of available affine transformations is constructed. The density function is modelled using a non-parametric approach (sparse histogram built using hash-table), which allows simultaneous matching of unknown number of image fragments.

The largest advantage of this matching method is high precision. There are only a few *false positive* errors. *False negatives* are much frequent ones, but lack of detection is a problem of much less grade. Additionally, the applied method generates highly precise outlines of detected near-duplicates.

In the first step of the method input image  $J$  is matched with all images  $I_x : x = \{1, \dots, n\}$  from the training set  $\mathcal{I}$ . Output of a single matching is a set of outlines representing near-duplicates. Exemplary near-duplicates for a selected input image  $J$  are shown in Fig. 1.

Generated set of near-duplicates may not be directly used to propagate words from image annotations. There are no relations between image fragments and words. Presence of near-duplicates is only a prerequisite to word propagation. First, it has to be determined which words are to be propagated. Second, matching may be erroneous, thus it has to be verified.

1) *Propagation of words*: For each image  $I_x$  from the training set  $\mathcal{I}$  we have to automatically determine additional information required for word propagation. A set of images  $S_x^w \subset \mathcal{I}$  is called a *supporting set* for word  $w \in W_x$  and image  $I_x$ . Supporting set  $S_x^w$  contains images having exactly one common word ( $w$ ) with annotation  $W_x$  of image  $I_x$ . Formally, supporting set  $S_x^w$  for image  $I_x$  and word  $w \in W_x$  is defined as:

Fig. 1. Examples of matched near-duplicates for input image  $J$  and various images from the training set  $\mathcal{I}$ .

$$S_x^w = \bigcup_{\substack{1 \leq y \leq n \\ y \neq x}} \{I_y\} : (W_y \cap W_x = \{w\}). \quad (3)$$

Supporting set  $S_x^w$  for a given image  $I_x$  and word  $w \in W_x$  allows to:

- propagate word  $w$  from the annotation  $W_x$  with higher precision,
- relate word  $w$  with matched image fragments generated by  $\mathcal{M}(J, I_x)$ ,
- verify the correctness of image fragments matching  $\mathcal{M}(J, I_x)$ .

In case the fragment matching of two images ( $J$  and  $I_x$ ) is not empty ( $\mathcal{M}(J, I_x) \neq \emptyset$ ), propagation is performed for all words that annotate image  $I_x$ . Input image  $J$  is matched with all images from the supporting sets ( $\mathcal{M}(J, s) : s \in S_x^w$ ). If a word  $w \in W_x$  has supporting matches ( $\mathcal{M}(J, s) \neq \emptyset$ ), it is verified if matching outlines intersect each other. To get the most credible answer (we assume that matching precision is high, but recall may be low), the largest intersection is selected:

$$(f_J^1, f_{I_x}^1), (g_J^1, g_s^1) = \operatorname{argmax}_{\substack{(f_J, f_{I_x}) \in \mathcal{M}(J, I_x) \\ (g_J, g_s) \in \mathcal{M}(J, s)}} |f_J \cap g_J|. \quad (4)$$

Near-duplicate fragments generated by method  $\mathcal{M}$  are considered as valid, if and only if the intersection of outlines is large enough, i.e. it meets the following criterion (*first intersection test*):

$$\left( \frac{|f_J^1 \cap g_J^1|}{|f_J^1|} > t \right) \cap \left( \frac{|f_J^1 \cap g_J^1|}{|g_J^1|} > t \right), \quad (5)$$

where:  $t \in (0, 1)$  is the method parameter. This concept is presented in Fig. 2.

Fig. 2. Basic propagation of words with the usage of supporting sets. There are two different near-duplicate sets on image  $J$ , the first one comes from  $\mathcal{M}(J, I_x)$ , the second one from  $\mathcal{M}(J, s)$ . Outline intersections on image  $J$  have to match as close as possible.

Basic propagation of words with the proposed intersection tests eliminates a large number of *false positives*. However, some of them are still accepted as correct matches.

2) *Extended propagation of words*: Let us now propose another variant of word propagation. To get even higher precision of annotations, we introduce an extended propagation method. It is also based on the image fragment matching and the sets of supporting images  $S_x^w$ . It encapsulates the *first intersection test* used in basic propagation (eq. 5).

The extended propagation also utilizes a triple of images:  $J$ ,  $I_x$  and a supporting image  $s$ . As already mentioned, the basic propagation may not be sufficient to prevent *false positives*. Given the results of matching  $\mathcal{M}(I_x, s)$ , it is possible to define two additional tests of propagation correctness. They allow for even better rejection of incorrect matches. In case  $\mathcal{M}(I_x, s) \neq \emptyset$ , largest intersections of outlines within images  $I_x$  and  $s$  are found. The first one is done on image  $I_x$ :

$$(f_J^2, f_{I_x}^2), (h_{I_x}^2, h_s^2) = \operatorname{argmax}_{\substack{(f_J, f_{I_x}) \in \mathcal{M}(J, I_x) \\ (h_{I_x}, h_s) \in \mathcal{M}(I_x, s)}} |f_{I_x} \cap h_{I_x}|, \quad (6)$$

The second one is done on image  $s$  (from the supporting set  $S_x^w$ ):

$$(g_J^3, g_s^3), (h_{I_x}^3, h_s^3) = \operatorname{argmax}_{\substack{(g_J, g_s) \in \mathcal{M}(J, s) \\ (h_{I_x}, h_s) \in \mathcal{M}(I_x, s)}} |g_s \cap h_s|. \quad (7)$$

Having the largest intersections of outlines, we propose two additional tests to validate the correctness of  $\mathcal{M}(J, I_x)$  matching. For each test a threshold  $t \in (0, 1)$  is given (the same as in basic propagation, see eq. 5). The first test examines the intersection of outlines in image  $I_x$ :

$$\left( \frac{|f_{I_x}^2 \cap h_{I_x}^2|}{|f_{I_x}^2|} > t \right) \cap \left( \frac{|f_{I_x}^2 \cap h_{I_x}^2|}{|h_{I_x}^2|} > t \right), \quad (8)$$

The second test examines the intersection of outlines in image  $s$ :

$$\left( \frac{|g_s^3 \cap h_s^3|}{|g_s^3|} > t \right) \cap \left( \frac{|g_s^3 \cap h_s^3|}{|h_s^3|} > t \right). \quad (9)$$

The idea is presented in Fig. 3.

Fig. 3. Extended word propagation routine. Three outline intersection tests are performed. The first one is done on image  $J$  (matches  $\mathcal{M}(J, I_x)$  and  $\mathcal{M}(J, s)$ ), the second one is done on image  $I_x$  (matches  $\mathcal{M}(J, I_x)$  and  $\mathcal{M}(I_x, s)$ ) and the last one on image  $s$  (matches  $\mathcal{M}(J, s)$  and  $\mathcal{M}(I_x, s)$ ).

Experimental results presented in the later part of the paper shown that the extended propagation routine is fully sufficient. Less precise matching routines may require additional tests to reject false matches. In case such tests are necessary, they may be constructed using the same idea, as the above.

### C. Localization of annotated objects

One of our goals is to precisely localize fragments of images to which generated annotation should be related. It is possible due to the application of image fragment matching routine. Presented word propagation mechanism automatically relates words with some image fragments.

The input image  $J$  is automatically annotated with word  $w \in \mathcal{W}$ . The word could be propagated from any image  $I_x \in \mathcal{I}$  annotated by this word ( $w \in W_x$ ). To maximize recall we should propagate outlines from all matched images. However, such solution is not a precise and valid one.

Let us assume that three (or more) images from the training set contain a visual representation of word  $w$  on a near-duplicate background. Image fragment matching method  $\mathcal{M}$  works on a purely visual manner, and thus does not know anything about visual representation of word  $w$  or any neighboring background. The main near-duplicate match  $\mathcal{M}(J, I_x)$  and the supporting matches  $\mathcal{M}(J, s)$  and  $\mathcal{M}(I_x, s)$  are going to generate outlines containing both the proper image fragment

representing word  $w$  and the neighboring background. Intersection tests (see eqs. 5, 8 and 9) are also going to accept both the object and the background.

However, the intersection tests accept only near-duplicates of a similar relative fragment size (up to a threshold). If  $\mathcal{M}(J, I_x)$  returns both the objects of interest and the background, only a small subset (images containing both the object and the background) of supporting set will support this match. Thus it is worth rejecting near-duplicate matches  $\mathcal{M}(J, I_x)$  supported by small subsets of their supporting sets. We propose to select a single image  $I_x$ , for which the matched subset of the supporting set is the largest. In other words, to get the most credible match  $I_x$ , it is expected that the match is supported by as many other matches as possible.

#### D. The dictionary and the training set

The proposed automatic image annotation approach does have three noticeable flaws. They are related to the training set and the dictionary. We are going to describe them in detail.

First, the method annotates words that have near-duplicate visual representation. The proposed annotator utilizes highly precise, key-point based, image fragment matching method. The matching method is only able to detect near-duplicates, all other types of visual similarity are not taken into account. Words such as *sky*, *cloud*, etc. are not going to be detected (recall will be near zero or zero). The proposed method is applicable to words representing mainly *rigid bodies*, similar in shape and appearance. Surprisingly, most of automatic image annotation methods usually fail to correctly annotate such words. They focus on the mentioned holistic concepts, which can be easily generalized. This method does the opposite, it does not generalize. It annotates words with complex, but highly repeatable appearance.

Second, effective annotation of a word requires a sufficient representation in the training set. Propagation of a word requires an existence of the supporting set (see II-B1). The larger the supporting set is, the easier it is to propagate annotations. Used near-duplicate detection method has very high precision, but lower recall. It rarely makes *false positive* errors, but often causes *false negatives*. False negatives may be eliminated by providing a larger set of examples, e.g. captured under various lighting conditions, relative position to camera, etc. To propagate a word, it is sufficient to have only three correct matches. Larger word representations make finding such triples much easier.

Third, background repetition in the training set should be minimized. Near-duplicate detection is purely visual, i.e. it does not differentiate between objects of interest and background. If the same background goes together with object of interest in most images, it is also considered a valid part of image. Generated annotations are going to be correct. However, localization of these annotations on the image will not depict the true and expected boundaries. We consider this flaw the most prominent one, because it may require manual modification of the training set.

### III. EXPERIMENTAL VERIFICATION

The goal of experimental verification is to check the expected properties of the proposed method. According to the initial assumptions, the main expectation is a high precision of generated annotations. Additionally, annotated objects have to be precisely localized.

Presented experimental verification consists of four parts:

- presentation of exemplary results of the method,
- setup of method parameters,
- analysis of annotation quality,
- analysis of object localization quality.

The image set consists of 100 images, together with annotations and outlines for each annotated word<sup>1</sup>. Single images contain multiple objects of interest, thus the set is well suited for AIA. The dictionary is constructed from all available annotations. All performed tests are done using *leave one out* experimental protocol. Typical, state-of-the-art automatic image annotation methods fail to get high precision results.

#### A. Exemplary results

According to the definition of automatic image annotation, we have a database of annotated images. Annotations are related with entire images, there are no relations between words and image fragments. Exemplary elements from the training set are presented in Fig. 4.

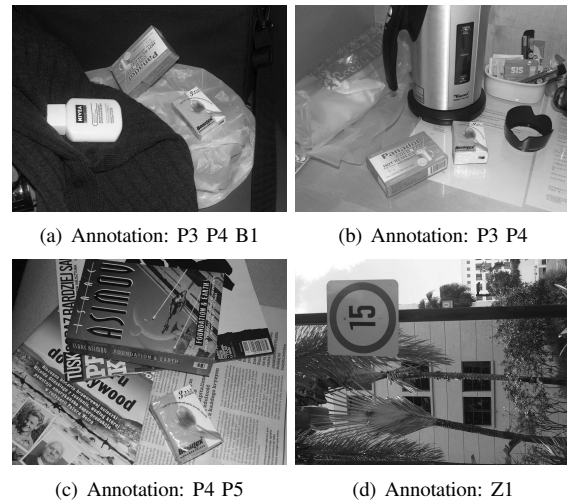

Fig. 4. Exemplary described images from the training set. According to the definition of automatic image annotation problem, annotations are related with entire images, instead of image fragments.

Fig. 5 presents exemplary results generated by the proposed method. The method generates image annotations and outlines of image fragments representing single words. Annotation outlines are generated by the near-duplicate image fragment detection method. They are a combination of at least two (usually much more) near-duplicate outlines. Of course, the more precise the near-duplicate outlines are, the better are the final results.

<sup>1</sup><http://www.ii.pwr.wroc.pl/~visible>

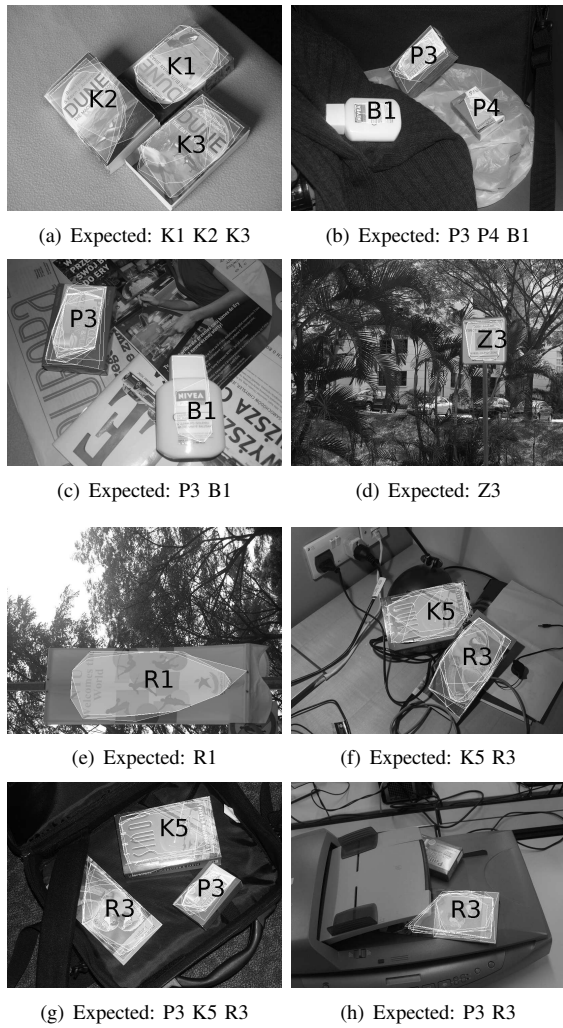

Fig. 5. Generated annotations together with localization of found words. Expected words are shown below the images. It should be noted, that the training set does not contain any information on words localization. It is determined by the proposed method fully automatically.

The automatic image annotator uses geometric approach to image fragment matching. The geometric approach tends to generate outlines smaller than the true boundaries of objects. Due to usage of key-points (*SIFT*) as the elementary visual data, it is very difficult to recreate affine transformations on object boundaries. Simply, there are not enough key-points on the boundaries (usually there are very few). Key-points outside the true boundaries may not be taken into consideration, because they do not generate valid affine transformations. Mentioned behaviour may be observed in Fig. 5.

### B. Setup of method parameters

The second part of experimental verification addresses the parameter setup. Two standard annotation quality measures are used: *recall* and *precision*. Unlike in automatic image annotation, these quality measures may be calculated in two different manners. The first one is the classic approach, based

TABLE I  
QUALITY OF RESULTS FOR VARIOUS SETUP OF METHOD PARAMETERS. EXTENDED PROPAGATION PROVIDES HIGHER PRECISION COMPARING TO BASIC PROPAGATION.

<i>thres. t</i>	<i>prec. [obj.]</i>	<i>recall [obj.]</i>	<i>prec. [area]</i>	<i>recall [area]</i>
Basic propagation				
0.00	0.92	0.81	0.86	0.43
0.25	0.95	0.80	0.89	0.43
0.33	0.96	0.80	0.89	0.43
0.50	0.96	0.80	0.90	0.43
0.66	0.96	0.80	0.89	0.43
0.75	0.96	0.78	0.89	0.43
Extended propagation				
0.00	0.99	0.69	0.95	0.40
0.25	1.00	0.68	0.96	0.38
0.33	1.00	0.67	0.95	0.39
0.50	1.00	0.66	0.96	0.40
0.66	1.00	0.62	0.96	0.37
0.75	1.00	0.58	0.97	0.36

on the presence or absence of words in annotations. The second one is based on the quality of generated outlines. Outline pixels on the image may be considered as false positives, false negatives and true positives (true negatives are irrelevant) and used in complex measures: *recall* and *precision*.

Two variants of the proposed method are taken into consideration: basic propagation (see Sec. II-B1) and extended propagation (see Sec. II-B2). Results achieved for the basic propagation reach precision near 95% and recall near 80%. However, the key goal is to get as high precision as possible. Given the extended propagation, precision is equal to 100%. Recall is lowered to 68% because higher requirements of the propagation routine. Summary of the method quality is presented in Tab. I.

Cutoff threshold  $t$  is the second parameter of the method. The threshold is used in the supporting set acceptance tests (eqs. 5, 8 and 9). The larger the threshold, the more similar size of the detected fragments is required. According to the performed tests,  $t = 0.25$  is sufficient. However, given the need of background matches rejection (see Sec. II-D), suggested threshold value is higher and equal to  $t = 0.50$ .

### C. Quality of generated annotations

The third part of the experimental verification is the analysis of annotation quality. Table II contains detailed results calculated for each word from the dictionary.

Taking into account the initial requirements, the most interesting column is the *false positives* one. No *false positives* are found during our experiments with the extended propagation. Proposed extended propagation routine with three built-in validation tests is sufficient to eliminate *false positive* matches. The quality of generated outlines plays the key role. Better outlines cause larger outline intersections with smaller relative size changes. Better intersections are a better confirmation of near-duplicate matches, and a better confirmation of generated annotations.

The second interesting observation is related to *false negatives*. Words with the lowest recall (mostly 0) are the least

TABLE II

QUALITY OF GENERATED ANNOTATIONS. ONLY THE PRESENCE OF WORDS IS TAKEN INTO ACCOUNT. LOCALIZATION OF WORDS IS NOT TAKEN INTO ACCOUNT.

class	TP	FP	FN	prec.	recall

Z6	0	0	2	–	0.00
Z7	0	0	2	–	0.00
all	103	0	53	1.00	0.66

frequent ones in the training set. This confirms the second mentioned flaw of the proposed annotator (see Sec. II-D). In case of more frequent words, recall grows up. A sufficiently large number of diversified training examples makes near-duplicate matching possible.

#### D. Quality of annotated words localization

The last part of the presented experimental verification is assessment of object localization quality. The assessment requires additional information, *not available* in the training set, i.e. outlines of all annotated objects. This allows to verify the quality of localization up to single pixels.

The quality measurement is performed using *precision* and *recall* based on outline intersections. Detailed results are shown in Tab. III. Precision of results is slightly lower than 100%. It is directly related to the image fragment matching method: outlines of generated fragments are in sometimes larger than the true boundaries of objects. Annotation outline is a sum of several matching outlines, i.e. it contains all false positives of these outlines. One of possible solutions is to use intersection of all outlines, however this causes a very large drop of recall.

#### IV. SUMMARY

A new method of automatic image annotation is presented. The method is called *Automatic Image Annotation by Matching* (AIAM). To annotate a previously unseen image, word

propagation is used. Words are propagated between images sharing near-duplicate visual content. Near-duplicates are detected using low level key-points (*SIFT*) and global affine geometry.

Two routines of near-duplicate image matching verification are proposed: basic and extended one. Triples of images sharing common visual content are found. Each accepted triple is a sufficient premise to propagate a single word from the training set image into the final annotation.

For a sub-domain of images (with the presence of near-duplicates) the method is able to get very high precision (up to 100%). Recall achieved for the test image set reaches 68%. Another interesting feature of the proposed annotator, is the ability to localize fragments of image representing annotated words. The major feature and the limitation of the proposed approach is the limitation to near-duplicates. Words with very similar visual appearance may be used in the dictionary. All other words will be automatically discarded, because near-duplicate matches will not be found.

Further research will cover two main areas. The first one is the speed-up of matching routines, while keeping high quality of outlines (partially done already). The second one will focus on increase of recall, within the near-duplicate detection framework. Once there two goal are reached, we expect to get a much more viable annotator.

# How to predict future in a world of antibody-antigen chromosomes

Zbigniew Pliszka and Olgierd Unold, *Member, IEEE*

**Abstract**—The paper deals with a representation of the antibody-antigen chromosomes. The proposed new binary decoding allows us to prove the dependence between subsequent generations of chromosomes, using quick and simple operations on chromosomes indices, instead of processing the binary strings. Some formal properties of the immune system were expressed based on this representation. A consistency theoretical proof for epistatic properties as well as exploration possibilities of a crossover operator was given.

**Index Terms**—Genetic algorithm, Crossover, Binary coding, Hadamard representation, Artificial Immune System.

## I. INTRODUCTION

**A**RTIFICIAL Immune Systems (AISs) constitute currently a significant trend in the studies on biologically inspired calculations [2], [14]. Much work on AIS has concentrated on simple extraction of biological metaphors and direct application. There is very limited work on the more theoretical aspects of AIS, especially on the formal proofs of AIS algorithms [13]. A complete proof for a specific multiobjective clonal selection algorithm using Markov chains has been given in [15]. In [1] Markov chain model of the B-cell algorithm has been developed to show a convergence proof, and also a mathematical model of the mutation operator.

Work in theoretical immunology has developed various representations for the interactions between antibody and antigen, and affinity metrics for modeling these such interactions. These antibody-antigen binding models were proposed for describing antibody cross-reactivity [5].

In this paper we attempt to model binary space, which includes both antigens and antibodies, and try to theoretically predict their further development based on knowledge of the first (initial) population. Antibody-antigen chromosomes are represented as binary, fixed-length chromosomes, using an alternative to zero-one decoding technique, called Hadamard representation.

In addition to above mentioned aim, the present paper seeks to address potential capabilities of a crossover operator. There is much criticism of the role of the crossover in evolutionary algorithm (EA) literature. Several authors [11], [3], [4] have pointed out that the crossover causes the premature convergence of the EA, i.e. the EA loses population diversity before some goal is met. Some of them argue that for problems of nontrivial size and difficulty, the contribution of crossover

search is marginal [8]. Spears [10] claims that mutation is more powerful than crossover in terms of exploration, although the two operators can be treated as two forms of a searching operator. Experiments conducted by Schaffer and Eshelman [12] have been indicated that population of chromosomes manipulated by crossover contains epistatic interaction.

A consistency theoretical proof for epistatic properties as well as exploration possibilities of a crossover operator is given in this paper.

This paper extends the results of our previous study [9] by (1) using different notation that leads to a shift of the indices, (2) defining a crossover operator in  $H^n$  space, (3) introducing new property of the immune system called *Expansive system with global range*, (4) proving formal properties of a crossover operator (**Theorem 1**), (5) and supporting the states of AIS by redefined examples. In addition, some remarks on **Schema Theorem** used in Hadamard space are made.

This paper is organized as follows. Section 2 describes binary representation used in the research, next Section 3 gives some formal properties of populations in AIS. Section 4 formulates a concept of an ancestral population. Finally Section 5 concludes the paper with future works.

## II. BINARY REPRESENTATION

### A. Hadamard model

In the study [9] the search space  $\{0, 1\}^n$  was replaced by  $\{-1, 1\}^n$  (so called a Hadamard representation [6]). Thanks to use a new binary model the requirement of orthogonal columns pairs is omitted. Subject of this study is the following set:

$$H^n = \{(h_{s,n}, h_{s,n-1}, \dots, h_{s,2}, h_{s,1}) : \forall s \in \{0, 1, \dots, 2^n - 1\} \\ \forall i \in \{1, 2, \dots, n\} \quad h_{s,i} \in \{-1, 1\}\} \quad (1)$$

Its elements represent all possible binary chromosomes of equal length  $n$ , where  $n$  is a natural number higher than 1. The proposed representation has one, apparently insignificant property, which distinguishes it from the binary representation: a square of each coordinates is equaled 1. This fact draws two subsequent conclusions: the sum of the squares of coordinate of each element of the  $H^n$  space is constant and equals this space dimension, and there is no element with zero coordinates. The collection of these simple facts allows for the formulation of rules for phenotypes (indices) and development of automate methods of moving frame  $H^n$ , as well as determination of the distance (level of differentiation) between the elements of this space.

Z. Pliszka is with Wroclaw Public Library, Sztabowa 95, 53-310 Wroclaw, Poland.

O. Unold is with Institute of Computer Engineering, Control and Robotics, Wroclaw University of Technology, Wyb. Wyspianskiego 27, 50-370 Wroclaw, Poland, e-mail: olgierd.unold@pwr.wroc.pl.

At the beginning, we determined the order of the indexing of points in  $H^n$  and their four representations, which we will use alternating (see Table I).

TABLE I  
INDEXING AND REPRESENTATION OF POINTS IN  $H^n$  SPACE.

Element's symbol	Decimal representation	Binary representation	Hadamard representation
$r_0$	0	(0,0,...,0,0,0)	( 1, 1,..., 1, 1, 1)
$r_1$	1	(0,0,...,0,0,1)	( 1, 1,..., 1, 1,-1)
$r_2$	2	(0,0,...,0,1,0)	( 1, 1,..., 1,-1, 1)
$r_3$	3	(0,0,...,0,1,1)	( 1, 1,..., 1,-1, -1)
$\vdots$	$\vdots$	$\vdots$	$\vdots$
$r_{2^n-3}$	$2^n-3$	(1,1,...,1, 0, 1)	(-1,-1,...,-1, 1,-1)
$r_{2^n-2}$	$2^n-2$	(1,1,...,1, 1, 0)	(-1,-1,...,-1,-1, 1)
$r_{2^n-1}$	$2^n-1$	(1,1,...,1, 1, 1)	(-1,-1,...,-1,-1,-1)

The number of points included in  $H^n$  is equal to  $|H^n| = 2^n$ . For each element in the binary representation there are numerous functions transforming the elements of this representation to the elements of the Hadamard representation and inversely (see [9]).

Index  $s$  of the element  $r_s$  having a binary representation  $(b_{s,n}, \dots, b_{s,1})$  and the Hadamard representation  $(h_{s,n}, \dots, h_{s,1})$ , and equal to the value of the decimal representation, can be calculated from one of the formulas:

$$ID(r_s) = s = \sum_{t=1}^n 2^{t-1} b_{s,t} = \sum_{t=1}^n 2^{t-2} (1 - h_{s,t}) \quad (2)$$

In cases of doubt, we will use the function symbol  $ID(r_s)$ , otherwise the sign of the index  $s$  will be used.

### B. The distance in $H^n$

The distance of two points  $r_t = (h_{t,n}, h_{t,n-1}, \dots, h_{t,2}, h_{t,1})$  and  $r_k = (h_{k,n}, h_{k,n-1}, \dots, h_{k,2}, h_{k,1})$  in  $H^n$  space is measured according to the following equation:

$$\forall r_t, r_k \in H^n \quad w(r_t, r_k) = n - \frac{1}{4} \sum_{i=1}^n (h_{t,i} + h_{k,i})^2 \quad (3)$$

The distance defined in that way will always be a nonnegative integer, which will tell us on how many coordinates in Hadamard representation the values differ (exactly as in the binary representation) (see Table I). In addition,  $H^n$  space with the  $w$  distance determined in this way is metric and has many interesting properties (proved in [9]). For example, there is an algorithmic method for construction a table of distances between any elements from the  $H^n$  space (without calculating the distance between elements). Bearing in mind that the space  $H^n$  contains  $2^n$  elements, and the space  $H^{n+1}$  contains  $2^{n+1} = 2 \cdot 2^n$ , the distance table  $W_{n+1}$  of dimension  $2^{n+1} \times 2^{n+1}$  is to be obtained from the table  $W_n$  of dimension  $2^n \times 2^n$  according to the following formula:

$$\langle W_n \rangle \mapsto \left\langle \begin{array}{cc} W_n & \langle W_{n+1} \rangle \\ \langle W_{n+1} \rangle^T & W_n \end{array} \right\rangle,$$

where +1 means addition to each element of the table a value of 1, and  $W_n^T$  the transpose of a matrix  $W_n$ . The number situated on the cross of the  $k$ -row with the  $t$ -column corresponds to  $w(r_k, r_t)$  distance. Exceptionally, for the purposes of this algorithm, we assume that  $W_0 = \langle 0 \rangle$ , because, as already mentioned, the spaces  $H^n$  where  $n > 1$  are considered in this study. The distance table for  $n = 4$  is presented in Table II.

In the work [9] the definition of the polar points was introduced. Two points  $r_t$  and  $r_k$  in  $H^n$  are called polar points if and only if for each coordinate these points have opposite values.

$$\forall j \in \{1, \dots, n\} \quad h_{t,j} = -h_{k,j}$$

According to the formula (3), the distance between polar points is constant and equals  $w(r_t, r_k) = n$ . Some other properties of polar points were given in [9].

### C. Crossover in $H^n$

Any two points from  $H^n$  can be provided in accordance with the definition (1) as:

$$\begin{aligned} r_t &= (r_{t,n}, r_{t,n-1}, \dots, r_{t,2}, r_{t,1}) \\ r_k &= (r_{k,n}, r_{k,n-1}, \dots, r_{k,2}, r_{k,1}) \end{aligned}$$

Assuming that  $c$  is the position of the cutting operation in a crossover counted from the right, fulfilling the inequality  $0 \leq c \leq n$ , we define the operation of the crossing-over an element  $r_t$  with an element  $r_k$  after the locus  $c$  as follows (note that crossover operator corresponds to 1-point-crossover):

$$\begin{aligned} K(\{r_t, r_k\}, c) \mapsto \\ \{ &(r_{t,n}, r_{t,n-1}, \dots, r_{t,c+1}, r_{k,c}, r_{k,c-1}, \dots, r_{k,1}), \\ &(r_{k,n}, r_{k,n-1}, \dots, r_{k,c+1}, r_{t,c}, r_{t,c-1}, \dots, r_{t,1}) \} \end{aligned}$$

The newly received elements belong to the  $H^n$  and can be symbolically represented:

$$r_s = (r_{t,n}, r_{t,n-1}, \dots, r_{t,c+1}, r_{k,c}, r_{k,c-1}, \dots, r_{k,1}) \quad (4)$$

$$r_q = (r_{k,n}, r_{k,n-1}, \dots, r_{k,c+1}, r_{t,c}, r_{t,c-1}, \dots, r_{t,1}) \quad (5)$$

Now, the operation of the crossover can be written as

$$K(\{r_t, r_k\}, c) \mapsto \{r_s, r_q\}, \quad (6)$$

where the indices  $s$  and  $q$  can be taken from the formulas ([9]):

$$s = t - (t \bmod 2^c) + (k \bmod 2^c) \quad (7)$$

$$q = k - (k \bmod 2^c) + (t \bmod 2^c) \quad (8)$$

## III. PROPERTIES OF ARTIFICIAL IMMUNE SYSTEM IN $H^n$ SPACE

This section depicts some properties of AIS, in which antibody-antigen chromosomes are represented using Hadamard encoding. Introduced properties are illustrated by the examples based on the content of Table II.

TABLE II  
THE DISTANCE TABLE BETWEEN ANY ELEMENTS IN  $H^4$ .

	$r_0$	$r_1$	$r_2$	$r_3$	$r_4$	$r_5$	$r_6$	$r_7$	$r_8$	$r_9$	$r_{10}$	$r_{11}$	$r_{12}$	$r_{13}$	$r_{14}$	$r_{15}$
$r_0$	0	1	1	2	1	2	2	3	1	2	2	3	2	3	3	4
$r_1$	1	0	2	1	2	1	3	2	2	1	3	2	3	2	4	3
$r_2$	1	2	0	1	2	3	1	2	2	3	1	2	3	4	2	3
$r_3$	2	1	1	0	3	2	2	1	3	2	2	1	4	3	3	2
$r_4$	1	2	2	3	0	1	1	2	2	3	3	4	1	2	2	3
$r_5$	2	1	3	2	1	0	2	1	3	2	4	3	2	1	3	2
$r_6$	2	3	1	2	1	2	0	1	3	4	2	3	2	3	1	2
$r_7$	3	2	2	1	2	1	1	0	4	3	3	2	3	2	2	1
$r_8$	1	2	2	3	2	3	3	4	0	1	1	2	1	2	2	3
$r_9$	2	1	3	2	3	2	4	3	1	0	2	1	2	1	3	2
$r_{10}$	2	3	1	2	3	4	2	3	1	2	0	1	2	3	1	2
$r_{11}$	3	2	2	1	4	3	3	2	2	1	1	0	3	2	2	1
$r_{12}$	2	3	3	4	1	2	2	3	1	2	2	3	0	1	1	2
$r_{13}$	3	2	4	3	2	1	3	2	2	1	3	2	1	0	2	1
$r_{14}$	3	4	2	3	2	3	1	2	2	3	1	2	1	2	0	1
$r_{15}$	4	3	3	2	3	2	2	1	3	2	2	1	2	1	1	0

### A. Radius of tolerance

A radius of tolerance  $R$  is understood as the border value enabling a mutual recognition of elements in  $H^n$  space.

Two elements  $x, y \in H^n$  recognize or do not tolerate each other if the distance between them is higher than the radius of tolerance.

$$w(x, y) > R \quad (9)$$

where  $R$  complies with the inequality:  $0 \leq R \leq n$ .

Elements  $x, y \in H^n$  complying the weak inequality

$$w(x, y) \leq R \quad (10)$$

will be described as not recognizing or tolerating each other.

#### Example 0

In the examples considered here we use the  $H^4$  space, whose distance tables are presented in Table II. Moreover, for all the demonstrated examples we assume the value of the radius of tolerance  $R = 2$ .

### B. Self-aggression

System  $B_k \subseteq H^n$  undergoes self-aggression if elements  $x, y$  occur, which recognize each other and belong to this system.

$$\exists x, y \in B_k : w(x, y) > R \quad (11)$$

#### Example 1

In  $H^4$  the systems undergoing self-aggression are for example:

$$B_8 = \{r_0, r_1, r_2, r_4, r_8, r_3, r_5, r_6\} \text{ where } w(r_1, r_6) = 3$$

$$B_4 = \{r_3, r_5, r_6, r_9\} \text{ where } w(r_6, r_9) = 4$$

System  $B_k \subseteq H^n$  is free of self-aggression if any two elements belonging to this system do not recognize themselves.

$$\forall x, y \in B_k \quad w(x, y) \leq R \quad (12)$$

#### Example 2

Free systems of self-aggression, when  $R = 2$ :

$$B_5 = \{r_0, r_1, r_2, r_4, r_8\}$$

$$B_3 = \{r_3, r_5, r_6\}$$

$$B_2 = \{r_0, r_1\}$$

Let us notice that system  $B_2$  is free of self-aggression also when  $R = 1$ .

Systems undergoing self-aggression have elements (chromosomes) dispersed in the space under consideration, systems free of self-aggression are centered around a certain element (chromosome) and we have a suspicion that this is a local extremum for many used objective functions.

### C. Dazzling distance set

A dazzling distance set of a system  $B_k \subseteq H^n$  is a set of points of  $H^n$  recognized by any point of  $B_k$ .

$$P(B_k) = \{z \in H^n : \exists x \in B_k \wedge w(x, z) > R\} \quad (13)$$

#### Example 3

For  $B_3 = \{r_3, r_5, r_6\}$  from the **Example 2** the dazzling distance set is:

$$P(B_3) = \{r_1, r_2, r_4, r_8, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}\}$$

If  $B_k$  undergoes self-aggression then some points belonging to  $B_k$  simultaneously belong to  $P(B_k)$ , which means that

$$B_k \cap P(B_k) \neq \emptyset$$

because, according to (11) there is a pair of points  $x, y \in B_k$  that  $w(x, y) > R$  and  $y \in H^n$ , what gives (13).

#### Example 4

The system  $B_4 = \{r_3, r_5, r_6, r_9\}$  from the **Example 1** is in such a state:

$$P(B_4) = \{r_1, r_2, r_4, r_6, r_7, r_8, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}\}$$

and we have:

$$B_4 \cap P(B_4) = \{r_6, r_9\} \neq \emptyset$$

Otherwise, if  $B_k$  is free of self-aggression, then  $B_k$  and  $P(B_k)$  are disjunctive sets, which can be presented as follows:

$$B_k \cap P(B_k) = \emptyset \quad (14)$$

since, according to (12), any two elements  $x, y \in B_k$  satisfy the inequality  $w(x, y) \leq R$ , which contradicts (13).

**Example 5**

$B_3$  (described in **Example 2** and **3**) is free of self-aggression, for which identity occurs:

$$B_3 \cap P(B_3) = \emptyset$$

**D. Complete system**

System  $B_k$  is complete if its dazzling distance set contains its whole completion  $\overline{B_k} = H^n \setminus B_k$ .

$$\overline{B_k} \subseteq P(B_k) \quad (15)$$

**Example 6**

The conditions of the complete system are fulfilled by  $B_7 = \{r_0, r_1, r_2, r_3, r_4\}$ , for which following identities occur:

$$P(B_7) = \{r_3, r_4, r_5, r_6, r_7, r_8, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}, r_{15}\}$$

$$\overline{B_7} = \{r_5, r_6, r_7, r_8, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}, r_{15}\},$$

Thus, a relation occurs:

$$\overline{B_7} \subseteq P(B_7)$$

The statement, that we are dealing with a complete system, gives us confidence that in many problems we control the entire space under consideration, using only a certain part of the elements (chromosomes) of that space. In many issues, the important task to deal with is to set the minimum complete systems (i.e. which contain the smallest number of elements) for a given space.

**E. Balanced system**

System  $B_k$  is balanced if at the same time it is a system free of self-aggression, and complete. System  $B_k$  satisfies the equality

$$\overline{B_k} = P(B_k)$$

The relationship  $\overline{B_k} \subseteq P(B_k)$  we have from the definition of a complete system (see (15)). Inverse relationship  $\overline{B_k} \supseteq P(B_k)$ , we get as a request from two facts:  $P(B_k) \subseteq H^n = B_k \cup \overline{B_k}$ , as well as  $B_k$  as a system free of self-aggression satisfies (14), and therefore  $\overline{B_k} \supseteq P(B_k)$ .

**Example 7**

This time let us assume that  $B_5 = \{r_0, r_1, r_2, r_4, r_8\}$  ( $B_5$  is taken from the Example 2). For such a system the following identities are fulfilled:

$$P(B_5) = \{r_3, r_5, r_6, r_7, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}, r_{15}\}$$

$$\overline{B_5} = \{r_3, r_5, r_6, r_7, r_9, r_{10}, r_{11}, r_{12}, r_{13}, r_{14}, r_{15}\}$$

and

$$\overline{B_5} = P(B_5)$$

**F. Extensive system**

We call  $B_k \subseteq H^n$  an extensive system if each crossing-over of its elements results in offspring, which also belongs to this system.

$$\forall x, y \in B_k \subseteq H^n \quad \forall c \in \{0, 1, \dots, n\} \quad K(\{x, y\}, c) \subseteq B_k$$

**Example 8**

The examples of the extensive systems are presented below:

$$B_2 = \{r_0, r_1\}$$

$$B_4 = \{r_0, r_1, r_2, r_3\}$$

$$H^4$$

$$B_1 = \{r_0\}$$

To check the extensibility of  $B_2$  and  $B_4$  systems, equations (7) and (8) can be used. It can be noticed that both the singleton system and any  $H^n$  space, as a whole, are extensive systems.

**G. Expansive system**

A system  $B_k$  is expansive if it possesses elements (not necessary different), which after a crossing-over produce elements out of the system.

$$\exists x, y \in B_k \subseteq H^n \quad \exists c \in \{0, 1, \dots, n\} : K(\{x, y\}, c) \notin B_k$$

**Example 9**

Let us assume  $B_9 = \{r_0, r_1, r_2\} \subseteq H^4$ . Assuming in equations (6) (7) and (8) fore  $c = 1, t = 1, k = 2$  we have:

$$K(\{r_1, r_2\}, 1) \mapsto \{r_0, r_3\} \notin B_9$$

due to the element  $r_3 \notin B_9$ .

**H. Expansive system with global range**

We say that the expansive system  $B_k \subseteq H^n$  is global in range, if each element from the completion of  $B_k$  can be obtained only as a result of crossing-over of its elements and offsprings.

**Example 10**

Note that the set of elements  $B_{11} = \{r_0, r_{15}\}$  is the expansive system with global range. These two elements are sufficient to be the ancestors of all space  $H^n$ . And more generally, any system consisting of two polar points, is a expansive system with global range (proof to be found below).

**Definition 1**

An *initial* or *primary population* is a set of chromosomes (elements) from the  $H^n$  space, which receives an evolutionary process (or program) input. We assume that all elements of such a set take part in the first selection process for the parent pool.

**Definition 2**

We say that the population is *ancestral*, if all its elements can be obtained from a primary population as a result of the assembling only crossing-overs.

Note that this definition does not reject the elements created by the assembly of other operations (for example, mutation

or inversion) on the initial population, but it requires the existence of the potential emergence of such elements by submitting only the crossing-overs of the initial population and its posterity. In this case, we also have the ancestral population.

#### IV. ANCESTRAL POPULATION

##### Theorem 1

The whole space  $H^n$  is the ancestral population if and only if there are the elements in the primary population  $P$ , which have the following properties:

for each position (locus), we have two elements from  $P$  having different (in terms of dual opposing) values.

##### Proof

$\Rightarrow$  (proof by contradiction)

Suppose that for the initial population  $P \subseteq H^n$  there is the locus  $l \in \{1, \dots, n\}$ , with the property that all elements from  $P$  have one value (in the case of binary representation, for example 0, and Hadamard representation 1). Then, according to formulas (4) and (5), the value of the position  $l$  will not change, regardless of the choice of parental pairs, the choice of the value  $c$  as a point of crossing-over, and the number of crossing-over operations. So we had no opportunity to receive elements with the value on position  $l$  different, than the one which have all the elements of  $P$ . And that means that we do not receive as a result of crossing-overs the elements from  $H^n$  with the opposite value (from our example is a binary value 1 or Hadamard value -1) to be set in position  $l$  in the space  $P$ . This would contradict the assumption that all space  $H^n$  is the ancestral population. Thus, the implication in this direction is true.

$\Leftarrow$

In the proof of equivalence in the other direction, we use the Restore Pattern using Crossovers (RPC) Algorithm (see Algorithm 1). Let the pattern  $W$  be an arbitrary element in space  $H^n$ . Meeting the objectives of **Theorem T1**, irrespective of the value that we are going to set to fixed, but any position (locus)  $c$  of the pattern  $W$ , we will always find a chromosome in the initial population with a value at that position of searched pattern  $W$ . This assures us that the inner loop **L1** always ends up with a variable *found* with a value of true. This, in turn, runs a block **BL1**, which carries the crossing-overs and, possibly, newly formed chromosomes attach to the pool taking part in further operations. The algorithm assumed that the offsprings replace parents. In a case when offsprings join to the current population and parents would remain in it, a block **BL1** should look like:

```

begin of BL11
  G := first_element_from(K({G,B[i]},c))
  B := B  $\cup$  K(K({G,B[i]},c),c)
  maks := maks + 2
end of BL11

```

And in a case when we want do attach to the pool the element matching the pattern, a block **BL1** should look like:

```

begin of BL12
  G := first_element_from(K({G,B[i]},c))
  B := B  $\cup$  {G}

```

---

#### Algorithm 1 RPC Algorithm

---

##### Input:

n {the length of chromosome}  
W[1,...,n]{the table containing the pattern of the chromosome}  
j {the number of chromosomes in a population}  
PB[1,...,j][1,...,n] {the table of tables containing the chromosomes of the initial population}

##### Definition:

B[1,...,j+2n][1,...,n] {the table of tables containing the chromosomes of the current population}

##### begin

B := BP {insert BP into the first n-positions of B}

maks := j

c := n

G := B[1]

##### repeat

  i := 0

  found := false

##### repeat

**begin of L1**

      i := i + 1

**if** W[c] = B[i][c] **then**

        found := true

**end if**

**end of L1**

**until** (found or (i = maks))

**if** found **then**

**begin of BL1**

      G := first\_element\_from(K({G,B[i]},c))

      B := (B  $\setminus$  K({G, B[i]},c))  $\cup$  K({G,B[i]},c)

**end of BL1**

**end if**

  c := c - 1

**until** ((not found) or (c = 0))

##### Output:

**if** found **then**

  G

**else**

  false

**end if**

**end**

---

  maks := maks + 1

**end of BL12**

The function first\_element\_from() returns, according to (6), chromosom resulting from crossing-over, having at locus  $c$  a value equals to the value of the pattern at the same position (see (4) and (5)).

Summing up, since the RPC Algorithm, meeting the objectives-led part of the Theorem, is able from the initial population—using only crossing-overs—create any element from the space  $H^n$ , so  $H^n$  is the ancestral population.

Fig. 1. Exemplary ancestral population with the primary population  $h_0$  and  $h_7$ .

### End of Proof

At the end, as a conclusion of the above **Theorem 1** let us write, without any proof, convenient Theorem in applications:

### Theorem 2

If a primary population  $P \subseteq H^n$  contains the pair of polar points, then the whole space  $H^n$  is an ancestral population.

For example, having two polar points  $h_0$  and  $h_7$  as a primary population from  $H^3$  we are able after four crossovers obtain all 8 points from the space in question, according to **Theorem 2** (see Figure 1). More crossover operations are needed when using natural selection and random points of crossing.

At this point, it seems natural to mention the **Schema Theorem** [7], one of the fundamental theorems of genetic algorithms. The **Theorem 1** shows that, if not all space  $H^n$  is the ancestral population, there must be positions (perhaps one such a position) in all chromosomes of the initial population, having the same value (locus). Thus, we should look for above-average schemes at those positions. Crossover operation is only possible to duplicate chromosomes with such a chosen scheme. Changes of this trend can only be caused by other operations (for example, mutation or inversion). Given that the vast majority of models considered, crossing is an operation with a much greater likelihood of occurrences in relation to other operations, reducing the quantity or even just reducing the growth of occurrences in the next population will be proportionately less likely.

Introduced concepts allow us to distinct and classify different populations, what is more to penetrate into the potential future directions of their evolution (states reachable, unreachable, etc.) regardless of the selected crossover algorithms, selection of parents, or the elimination of individuals. And then, we should be able to compare the genetic algorithms in terms of efficiency and optimization.

Comparing the two algorithms, we need to ensure comparability of the population, on which we conduct experiments.

It is obvious that the same algorithm, e.g. over the population of the class of expansive systems, has a chance of finding new solutions in successive generations, but over the populations form extensive class, after reviewing the current population, better solutions are no longer found.

### V. CONCLUSIONS AND FUTURE WORK

The introduced Hadamard representation allows us to prove the dependence between subsequent generations of binary chromosomes encoding antibody and antigen space. Some properties of this representation were pointed out, which allows for quick and simple operations on chromosomes indices, instead of processing the binary sequences. The main contributions of this paper are to introduce new property of the immune system called *Expansive system with global range*, and to prove for epistatic properties as well as exploration possibilities of a crossover operator. Some remarks on Schema Theorem over  $\{-1, 1\}^n$  space were also made.

Future research will show to what extent the Hadamard chromosomes are exploitable.

# The Fuzzy Genetic Strategy for Multiobjective Optimization

Krzysztof Pytel

Faculty of Physics and Applied Informatics

University of Lodz,

Lodz, Poland

Email: kpytel@uni.lodz.pl

**Abstract**—This paper presents the idea of fuzzy controlling of evolution in the genetic algorithm (GA) for multiobjective optimization. The genetic algorithm uses the Fuzzy Logic Controller (FLC), which manages the process of selection of individuals to the parents' pool and mutation of their genes. The FLC modifies the probability of selection and mutation of individuals' genes, so algorithms possess improved convergence and maintenance of suitable genetic variety of individuals. We accepted the well-known LOTZ problem as a benchmark for experiments. In the experiments we investigated the operating time and the number of fitness function calls needed to finish optimization. We compared results of the elementary algorithms and the modified algorithm with the modification of probability of selection and mutation of individuals. Some good results have been obtained during the experiments.

## I. INTRODUCTION

IN MANY practical problems, it's often expected that several indicators achieve optimal value at the same time, which is called multi-objective optimization problem [1][6][10]. These multiple objectives, often conflicting with each other, can accept the maximum or minimum in other points of the search space. The multi-objective optimization problem (MOP) can be stated as follows:

$$\begin{cases} \text{maximize } F(x) = [f_1(x)f_2(x)f_3(x)\dots f_m(x)] \\ \text{subject to: } g_j(x) \leq 0 \text{ for } j = 1, 2, \dots, k \\ x \in S \end{cases} \quad (1)$$

where

$$x = [x_1x_2x_3\dots x_n] \in \mathfrak{R}, n \in N, \quad (2)$$

is an  $n$ -dimensional vector of decision variables,

$$F(x) = [f_1(x)f_2(x)f_3(x)\dots f_m(x)], \quad (3)$$

are objective functions, and  $g_i(x)$  are constrains.

Let us choose an optimization problem, with  $m$  objectives, which are, without loss of generality, all to be maximized. The set of potential solutions can be parted to two subsets: dominated and not dominated.

Let  $x, y \in S$ ,  $x$  is said to be dominated by  $y$ , if  $f_i(y) \geq f_i(x)$  for all  $i = 1, 2, \dots, m$  and  $f_j(y) > f_j(x)$  for at least one index  $j$ . A solution  $x^* \in S$  is said to be pareto-optimal if there does not exist another solution  $x$ , such that  $x^*$  is dominated by  $x$ .  $F(x^*)$  is then called a pareto-optimal objective vector. The set of all the pareto-optimal objective vectors is called

a pareto-optimal front. A set of pareto-optimal solutions is usually found as a result of multiobjective optimization. The decision-maker can use his preferred method to choose the final solution from the pareto-optimal set.

Genetic algorithms stand for a class of stochastic optimization methods that simulate the process of natural evolution [3][5][7][9]. In a genetic algorithm, a population of strings (called chromosomes), which encode candidate solutions (called individuals) to an optimization problem, evolves toward better solutions. They usually search for approximate solutions of composite optimization problems. A characteristic feature of genetic algorithms is that in the process of the evolution they do not use the specific knowledge for given problem, except of fitness function assigned to all individuals. The specific knowledge for a given problem can set a trend for evolution and improve the efficiency of the algorithm.

The genetic algorithm consists of the following steps:

- 1) the choice of the first generation,
- 2) the estimation of an individuals' fitness,
- 3) the check of the stop condition,
- 4) the selection of individuals to the parents' pool,
- 5) the creation of a new generation with the use of operators of crossing and mutation,
- 6) the printing of the best solution.

The source code of genetic algorithm was published in [7]. We used this code as elementary genetic algorithm.

There are two parameters in elementary genetic algorithms which determine evolution: the probability of selection to the parents' pool and the probability of mutation. GA can be improved by the knowledge of experts. Experts can predict the course of the process of evolution. The experts' knowledge about evolution has a descriptive character and is often subjective, so we use the fuzzy logic controller to set a trend of evolution.

## II. ADAPTATION OF THE PROBABILITY OF SELECTION AND MUTATION

The probability of selection determines the ability of an individual to act as a parent and produce offspring. The chances of the individual for transferring its genetic material to the next generation increase with the probability of selection. Well-adapted individuals are the most wanted ones in the parents' pool. However, weak individuals should also hit for the

parents' pool in order to prevent violent loss of their genetic material and premature convergence. We suggest introduction of an additional FLC for evaluating each individual in the population. The FLC modifies the probability of selection using the following rules:

- enlarge the probability of selection for the individuals with the value of the fitness function of above the average in generations in which the average value of the fitness function grows with relation to the preceding generation,
- don't change the probability of selection for individuals with the value of the fitness function equal to the average in generations in which the average value of the fitness function does not change the relation to the preceding generation,
- diminish the probability of selection for individuals with the value of the fitness function below the average in generations in which the average value of the fitness function decreases with relation to of the preceding generation.

The FLC calculates the adaptation ratio for all individuals based on two parameters:

- the increase of the average fitness function for the whole population (determines the change of the fitness function between the current and the previous populations)

$$\Delta F_{pop} = F_{pop}^{(T)} - F_{pop}^{(T-1)} \quad (4)$$

- an individual's fitness (determine the difference between the average value of the fitness function in the population and an individual's fitness)

$$W_i = F_i^{(T)} - F_{pop}^{(T)} \quad (5)$$

where:

$F_i^{(T)}$  - the fitness function of individual  $i$  in moment  $T$ ,  
 $F_{pop}^{(T)}$  - the average fitness function of the whole population in moment  $T$ .

The FLC uses the center of gravity [9] defuzzification method. As the result from the controller we accepted:

$wps_i$  - the adaptation ratio of the probability of selection of individual  $i$ .

The modified probability of selection of individual  $i$  obeys the formula:

$$ps'(i) = ps(i) * wps_i \text{ for } i = 1, \dots, N, \quad (6)$$

where:

$ps'(i)$  - the modified probability of selection of individual  $i$ ,  
 $ps(i)$  - the probability of selection of individual  $i$ ,  
 $wps_i$  - the adaptation ratio of the probability of selection calculated by the FLC for the individual  $i$ .

The knowledge base of FLC is shown in Table 1 (fuzzy values of the adaptation ratio of probability of selection for individual  $i$ )

Values in the table are:

TABLE I  
FUZZY VALUES OF THE ADAPTATION RATIO OF PROBABILITY OF SELECTION FOR INDIVIDUAL  $i$

		$\Delta F_{pop}$			
		NS	ZERO	PS	PL
$W_i$	S	VS	S	A	A
	A	S	A	A	L
	L	S	A	L	L

Fig. 1. The membership functions of the increase of the average fitness function for the whole population

- fuzzy sets of increase fitness function for whole population  $\Delta F_{pop}$ ,
  - o NS - negative small,
  - o ZERO - closed to zero,
  - o PS - positive small,
  - o PL - positive large,
- fuzzy sets of an individual's fitness  $W_i$  and fuzzy sets of ratio  $wps_i$ ,
  - o VS - very small,
  - o S - small,
  - o A - average,
  - o L - large.

Figures 1 - 3 shows the membership functions of the increase of the average fitness function for the whole population, an individual's fitness and the adaptation ratio of the probability of selection.

The probability of mutation determines the ability of the algorithm to explore and exploit the search space. In the initial period, mutations are frequent in order to find the solution in the whole search space (exploration mode). In the final period, mutations are rarer than at the start, so the algorithm can search the earlier established areas of possible optima (exploitation mode). The mutation of the gene can cause that the new, well adapted individual will translocate the population to the area of the total optimum. We suggest introduction of an additional FLC for evaluating each individual in the population. The FLC modifies the probability of mutation using the following rules:

- enlarge the probability of mutation of individuals with the value of the fitness function of less then the average in generations in which the average value of the fitness function decreases with relation to the preceding generation,

Fig. 2. The membership functions of an individual's fitness

Fig. 3. The membership functions of the adaptation ratio of the probability of selection

- don't change the probability of mutation of individuals with the value of the fitness function equal to the average in generations in which the average value of the fitness function does not change in relation to the preceding generation,
- diminish the probability of mutation of individuals with the value of the fitness function above the average in generations in which the average value of the fitness function increases with relation to the preceding generation.

The FLC calculates the adaptation ratio for all individuals based on two parameters:

- the population's quality (defines the difference between the fitness function of the best individual discovered so far and the average fitness function of the current population)

$$\Delta F_{pop} = F_{max} - F_{pop}^{(T)} \quad (7)$$

- the individual's fitness (the same the parameter was used for the modification of the probability of selection)

$$W_i = F_i^{(T)} - F_{pop}^{(T)} \quad (8)$$

where:

$F_i^{(T)}$  - the fitness function of individual  $i$  in moment  $T$ ,  
 $F_{pop}^{(T)}$  - the average fitness function for the whole population in moment  $T$ .

The FLC uses the center of gravity defuzzification method. As the result from the controller we accepted:

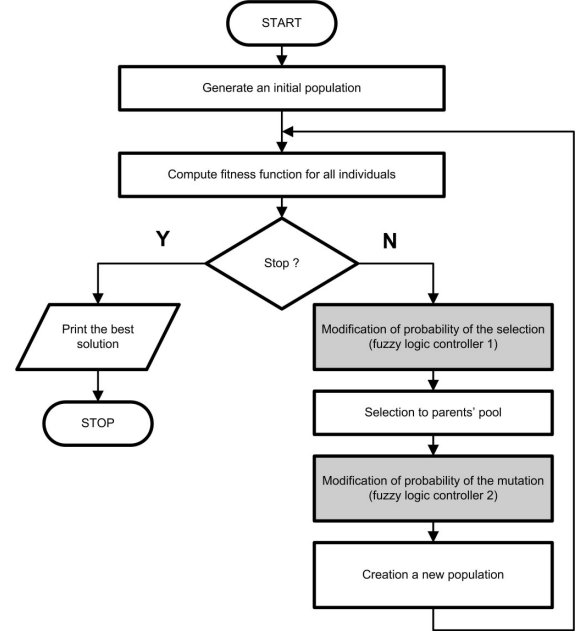

Fig. 4. The block scheme of the modified genetic algorithm

$wpm_i$  - the adaptation ratio of the probability of mutation of individual  $i$ .

The modified probability of mutation of an individual  $i$  obeys the formula:

$$pm'(i) = pm(i) * wpm_i \text{ for } i = 1, \dots, N, \quad (9)$$

where:

- $pm'(i)$  - the modified probability of mutation of individual  $i$ ,
- $pm(i)$  - the probability of mutation of individual  $i$ ,
- $wpm_i$  - the adaptation ratio of the probability of mutation calculated by the FLC for the individual  $i$ .

Figure 4 shows the block scheme of the modified genetic algorithm (the block of the fuzzy logic is noted with the grading). The construction of FLC for modification of the mutation is almost the same as FLC for modification of the selection. The construction of the fuzzy logic controller in details is considered in [8].

### III. COMPUTATIONAL EXPERIMENTS

The goal of the experiment is the verification of the idea of fuzzy controlling of evolution in the modified genetic algorithm for multiobjective optimization. The FLC estimates all individuals and modifies their probability of selection and mutation. The algorithm looks for any pareto-optimal solution. The LOTZ (Leading Ones, Trailing Zeroes) problem with the size from 50 to 100 was chosen as the test function. The LOTZ can be stated as the maximization problem of two objectives.

$$LOTZ1(x) = \sum_{i=1}^n \prod_{j=1}^i x_j, \quad (10)$$

TABLE II  
THE AVERAGE VALUES OF THE RUNNING TIME AND THE NUMBER OF FITNESS FUNCTION CALLS

		Elementary	Modification of mutation	Modification of selection	Modification of selection and mutation	SEMO	NSGA2
LOTZ50	time [s]	0,063	0,097	0,133	0,199	17,15	14,26
	number of fitness function calls	25743	15196	22985	21350	7700	10700
LOTZ60	time [s]	0,172	0,207	0,361	0,575	38,32	30,41
	number of fitness function calls	60245	31401	57052	59160	36500	27500
LOTZ70	time [s]	0,564	0,528	0,92	1,309	49,76	31,13
	number of fitness function calls	164034	75335	134509	126560	44000	28500
LOTZ80	time [s]	1,098	1,036	1,956	3,377	49,78	57,11
	number of fitness function calls	275626	137082	267112	309490	45000	49000
LOTZ100	time [s]	5,233	3,932	7,879	12,99	51,09	77,57
	number of fitness function calls	1129902	460269	984622	1125690	48000	82000

$$LOTZ2(x) = \sum_{i=1}^n \prod_{j=i}^n (1 - x_j), \quad (11)$$

$$LOTZ(x) = (LOTZ1(x), LOTZ2(x)), \quad (12)$$

where:  $x = (x_1, x_2, \dots, x_n) \in \{0, 1\}$ .

We compared algorithms with modification of selection and mutation with elementary genetic algorithm. The first population was generated randomly. All the algorithms started at the same point in the search space. The algorithms' parameters used in the experiment:

- the genes of individuals are represented by binary numbers,
- the probability of crossover = 0,8,
- the probability of mutation = 0,15,
- the number of individuals in the population = 10,
- the algorithms were stopped after finding any pareto-optimal solution.

To measure the achievements of modified algorithms, we choosed two other algorithms SEMO and NSGA2, usually used for solving LOTZ problem. SEMO is a population-based evolutionary algorithm for multiobjective optimization proposed in [4]. NSGA2 is an elitist multiobjective evolutionary algorithm proposed in [2]. We used a PISA-implementation of the algorithms written by Marco Laumanns. The SEMO and NSGA2 find a set of pareto optimal solutions, so they were stopped after finding any pareto optimal solution. For SEMO and NSGA2 we use:

- one-bit mutation,
- population size 100,
- probability of mutation 0,15
- probability of recombination 0,8.

Each algorithm was executed 10 times. In Table 2 there are average values of the running time and the number of fitness function calls obtained by the algorithms.

The graph in Figure. 5 illustrates the average running time of the algorithms.

The graph in Figure. 6 illustrates the average number of fitness function calls needed by the algorithms.

Fig. 5. The average running time of the algorithms

Fig. 6. The average number of the fitness function calls needed by the algorithms

## IV. CONCLUSION

Modified algorithms need less fitness function calls in all experiments than elementary algorithms, but it need more fitness function calls than algorithm SEMO and NSGA2. The running time of modified algorithms is noticeably shorter than the algorithm SEMO and NSGA2.

The adaptation of parameters of the algorithms demands additional computational effort. The running time of the functions of the large computational complexity in the large search space can be diminished. The FLC effectively manages evolution in genetic algorithms by modification of the probability of selection and mutation.

The algorithms looked for any pareto-optimal solution. In the future, we are going to check whether the adaptation of parameters of the algorithm can direct evolution toward the point in pareto front preferred by the decision-maker.

**Abstract**—The paper considers interestingness measures for evaluation of rules induced from data with respect to two properties: property of Bayesian confirmation and property  $Ex_1$  concerning the behavior of measures in case of entailment or refutation of the conclusion by the rule's premise. We demonstrate that property  $Ex_1$ , even though created for confirmation measures, does not fully reflect the concept of confirmation. We propose a modification of this property, called weak  $Ex_1$ , that deploys the concept of confirmation in its larger sense and allows to escape paradoxes that might appear when using measures satisfying the original  $Ex_1$  property.

### I. INTRODUCTION

DISCOVERING knowledge from data aims at finding “valid, novel and potentially useful” [5] patterns often expressed as “if... then...” rules. Typically, the number of rules generated from massive datasets is quite large, but only some of them are likely to be useful for the domain expert analyzing the data. In order to measure the relevance and utility of the discovered rules, quantitative measures, also known as interestingness or attractiveness measures, have been proposed and studied. Among the most commonly used ones there are: *support*, *confidence*, *lift*, *rule interest function*, *dependency factor*, etc. There is a rich discussion about interestingness measures for rules in data mining (see, for example, [1],[8], [12] for exhaustive reviews of the subject) as each of the measures proposed in the literature reflects different characteristics of rules. The discussion was also extended in [9], by an important issue concerning the possibility of using Bayesian confirmation measures (i.e. measures quantifying the degree to which a piece of evidence provides “support for or against” a hypothesis [7]) as interestingness measures for evaluation of rules. Moreover, the research in [13], [14], [15] shows that discovering patterns in data can be represented in terms of Bayes’ theorem. In this context, a variety of non-equivalent confirmation measures should be regarded as a useful tool able to discriminate the most interesting rules discovered by induction from data.

However, due to the plurality of ordinally non-equivalent measures and because there is no agreement which measure is the best, the choice of an interestingness measure for a particular application is non-trivial. To help to analyze measures and overcome the problem of their vast variety, some properties have been proposed. They express the user's expectations towards the behavior of measures in particular situations e.g., one could desire to use only such measures that reward the rules having a greater number of objects supporting the pattern. In general, properties group the measures according to similarities in their characteristics, thus using the measures which satisfy the desirable properties one can avoid considering unimportant rules. Different properties have been proposed and surveyed in [2], [4], [8], [9], [18].

This article concerns Bayesian confirmation measures with respect to their properties. We analyze a property denoted as  $Ex_1$ , introduced in [3], assuring that any conclusively confirmatory rule is assigned a higher value of a confirmation measure than any rule which is not conclusively confirmatory, and any conclusively disconfirmatory rule is assigned a lower value than any rule which is not conclusively disconfirmatory. We propose a modification of  $Ex_1$ , called weak  $Ex_1$ , that deploys the concept of confirmation in its larger sense and allows to escape paradoxes that might occur when using measures with  $Ex_1$  property.

The article is organized as follows. In Section 2 there are preliminaries on rules and their quantitative description. In section 3, we investigate two properties of measures, being the property of Bayesian confirmation and property  $Ex_1$ . Section 4 shows specific rankings of rules obtained using measures satisfying the property  $Ex_1$  and explains the paradox appearing in such situations. Section 5 introduces a proposition of modification of property  $Ex_1$  into weak  $Ex_1$  and shows that substituting  $Ex_1$  by weak  $Ex_1$  we escape the paradoxes. Finally, Section 6 presents conclusions.

## II. PRELIMINARIES

A rule induced from a dataset  $U$  shall be denoted by  $E \rightarrow H$  (read as “if  $E$ , then  $H$ ”). It consists of a premise (evidence)  $E$  and a conclusion (hypothesis)  $H$ .

In general, by  $\text{sup}(\gamma)$  we denote the number of objects in the dataset for which  $\gamma$  is true, e.g.,  $\text{sup}(E)$  is the number of objects in the dataset satisfying the premise, and  $\text{sup}(H, E)$  is the number of objects satisfying both the premise and the conclusion of a  $E \rightarrow H$  rule.

Moreover, the following notation shall be used throughout the paper:  $a = \text{sup}(H, E)$ ,  $b = \text{sup}(H, \neg E)$ ,  $c = \text{sup}(\neg H, E)$ ,  $d = \text{sup}(\neg H, \neg E)$ . It corresponds to a 2x2 contingency table of the premise and the conclusion.

TABLE I. CONTINGENCY TABLE OF  $E$  AND  $H$

	$H$	$\neg H$	
$E$	$a$	$c$	$a+c$
$\neg E$	$b$	$d$	$b+d$
	$a+b$	$c+d$	$ U $

Observe that  $b$  can be interpreted as the number of objects that do not satisfy the premise but satisfy the conclusion of the  $E \rightarrow H$  rule. Analogously,  $c = \text{sup}(\neg H, E)$  can be construed as the number of objects in the dataset that satisfy the premise but do not satisfy the conclusion of the  $E \rightarrow H$  rule, and  $d = \text{sup}(\neg H, \neg E)$  can be interpreted as the number of objects in the dataset that satisfy neither the premise nor the conclusion of the  $E \rightarrow H$  rule. Moreover, the following relations occur:  $a+c = \text{sup}(E)$ ,  $a+b = \text{sup}(H)$ ,  $b+d = \text{sup}(\neg E)$ ,  $c+d = \text{sup}(\neg H)$ , and the cardinality of the dataset  $U$ , denoted by  $|U|$ , is the sum of  $a$ ,  $b$ ,  $c$  and  $d$ .

Reasoning in terms of  $a$ ,  $b$ ,  $c$  and  $d$  is natural and intuitive for data mining techniques since all observations are gathered in some kind of an information table describing each object by a set of attributes. However,  $a$ ,  $b$ ,  $c$  and  $d$  can also be regarded as frequencies that can be used to estimate probabilities: e.g.,  $\text{Pr}(E) = (a+c)/|U|$  or  $\text{Pr}(H) = (a+b)/|U|$ .

## III. PROPERTIES OF INTERESTINGNESS MEASURES

The problem of choosing an appropriate interestingness measure for a certain application is non-trivial because the number and variety of measures proposed in the literature is overwhelming. To help to analyze measures, some properties have been proposed, expressing the user's expectations towards the behavior of measures in particular situations. Properties of measures group them according to similarities in their characteristics. Using the measures which satisfy the desirable properties, one can avoid considering unimportant rules.

Our analysis of properties is conducted from the view point of Bayesian confirmation theory. We propose a modification of property  $\text{Ex}_1$ , called *weak*  $\text{Ex}_1$ , that deploys the concept of confirmation in its larger sense. We

demonstrate that using property  $\text{Ex}_1$  can lead to paradoxical situations and thus, we propose to substitute  $\text{Ex}_1$  by weak  $\text{Ex}_1$ .

### A. Property of Bayesian confirmation

Bayesian confirmation theory assumes the existence of probability  $\text{Pr}$ . Given a proposition  $X$ ,  $\text{Pr}(X)$  represents the probability of  $X$ , and given  $X$  and  $Y$ ,  $\text{Pr}(X|Y)$  is the probability of  $X$  given  $Y$ , i.e.  $\text{Pr}(X|Y) = \text{Pr}(X \wedge Y)/\text{Pr}(Y)$ .

Generally speaking, a measure possessing the property of Bayesian confirmation is expected to obtain values greater than 0 when the premise of a rule confirms the conclusion of a rule, values equal to 0 when the rule's premise and conclusion are neutral to each other, and finally, values smaller than 0 when the premise disconfirms the conclusion.

Formally, an interestingness measure  $c(H, E)$  has the property of Bayesian confirmation if and only if it satisfies the following conditions (BC):

$$c(H, E) \begin{cases} > 0 & \text{if } \text{Pr}(H|E) > \text{Pr}(H), \\ = 0 & \text{if } \text{Pr}(H|E) = \text{Pr}(H), \\ < 0 & \text{if } \text{Pr}(H|E) < \text{Pr}(H). \end{cases} \quad (1)$$

The (BC) definition identifies confirmation with an increase in the probability of the conclusion  $H$  provided by the premise  $E$ , neutrality with the lack of influence of the premise  $E$  on the probability of conclusion  $H$ , and finally disconfirmation with a decrease of probability of the conclusion  $H$  imposed by the premise  $E$  [2].

It is important to note that there are many different, but logically equivalent, ways of expressing that  $E$  confirms  $H$ :

- $\text{Pr}(H|E) > \text{Pr}(H)$
- $\text{Pr}(H|E) > \text{Pr}(H|\neg E)$
- $\text{Pr}(H|E) > \text{Pr}(E|\neg H)$

Since they are equivalent (see also [7], [11]), one can also express the (BC) conditions as:

$$c(H, E) \begin{cases} > 0 & \text{if } \text{Pr}(H|E) > \text{Pr}(H|\neg E), \\ = 0 & \text{if } \text{Pr}(H|E) = \text{Pr}(H|\neg E), \\ < 0 & \text{if } \text{Pr}(H|E) < \text{Pr}(H|\neg E). \end{cases} \quad (2)$$

To avoid ambiguity, we shall denote the above formulation as (BC'). According to it  $E$  confirms  $H$  when  $E$  raises the probability of  $H$ , and  $E$  raises the probability of  $H$  if the probability of  $H$  given  $E$  is higher than the probability of  $H$  given non  $E$ .

Measures that possess the property of confirmation are referred to as *confirmation measures* or *measures of confirmation*. For a given rule  $E \rightarrow H$ , interestingness measures with the property of confirmation express the credibility of the following proposition: *H is satisfied more frequently when E is satisfied, rather than when E is not satisfied*. By using interestingness measures that possess this property one can filter out rules which are misleading and disconfirm the user, and this way, limit the set of induced rules only to those that are meaningful [17]. Let us also stress that the catalogue of confirmation measures available

in the literature is quite large and the condition (BC) (or (BC')) equivalently) does not favor one single measure as the most adequate [3], [6].

The discussion brought up in [9] about using the confirmation measures as interestingness measures for decision rules within rough set approach and, more generally, within data mining, machine learning and knowledge discovery, leads to the conclusion that the group of measures with property of Bayesian confirmation should be considered a valuable and meaningful tool for assessing the quality of rules induced from data. Using the quantitative confirmation theory for data analysis allows to benefit from the ideas of such prominent researchers as Carnap [2], Hempel [10] and Popper [16].

#### B. Property $Ex_1$

To handle the plurality of alternative confirmation measures, Crupi, Tentori and Gonzalez [3] have proposed a property (principle)  $Ex_1$  resorting to considering inductive logic as an extrapolation from classical deductive logic. On the basis of classical deductive logic they construct a function  $v$ :

$$v(H, E) = \begin{cases} \text{the same positive value, denoted as } V, & \text{if } E \models H; \\ \text{the same negative value, denoted as } -V, & \text{if } E \models \neg H; \\ 0, & \text{otherwise.} \end{cases} \quad (3)$$

For any argument  $(H, E)$  function  $v$  assigns it the same positive value  $V$  (e.g., +1) if and only if the premise  $E$  of the rule entails the conclusion  $H$  (i.e.  $E \models H$ ). The same value but of opposite sign  $-V$  (e.g., -1) is assigned if and only if the premise  $E$  refutes the conclusion  $H$  (i.e.  $E \models \neg H$ ). In all other cases (i.e. when the premise is not conclusively confirmatory nor conclusively disconfirmatory for the conclusion) function  $v$  obtains value 0.

Let us observe, that any confirmation measure obtains positive (negative) values whenever function  $v(H, E)$  is positive (negative). However, according to Crupi et al., the relationship between the logical implication or refutation of  $H$  by  $E$ , and the conditional probability of  $H$  subject to  $E$  should go further and demand fulfillment of the following principle ( $Ex_1$ ):

$$\text{if } v(H_1, E_1) > v(H_2, E_2) \text{ then } c(H_1, E_1) > c(H_2, E_2) \quad (4)$$

Property  $Ex_1$  guarantees that the measure will assign a greater value to any conclusively confirmatory rule (i.e. such that  $E \models H$ ) than to any rule which is not conclusively confirmatory. Moreover, rules that are conclusively disconfirmatory (i.e. such that  $E \models \neg H$ ) will obtain smaller values of interestingness measures than any rule which is not conclusively disconfirmatory.

Let us consider an example of drawing cards from a standard deck to review the consequences of property  $Ex_1$  in

three possible situations: conclusively confirmatory, non-conclusively confirmatory (or disconfirmatory), and conclusively disconfirmatory.

A rule  $r_1$ : *if  $x$  is a jack then  $x$  is a face-card* is conclusively confirmatory as the premise (drawing a jack) entails (i.e. confirms in 100%) the conclusion that the drawn card is a face-card. The entailment of the conclusion  $H$  by the premise  $E$  ( $E \models H$ ), implies that there cannot be any counterexamples to the rule (i.e.  $c=0$ ). Such conclusively confirmatory rules should be assigned a maximal value  $V$  of a function  $v(H, E)$ .

An inverse rule  $r_2$ : *if  $x$  is a face-card then  $x$  is a jack* should be regarded as non conclusively confirmatory. Drawing a face-card one can be lucky to get a jack, but it is not a 100% sure situation, therefore the premise does not entail the conclusion and the rule is not conclusively confirmatory. Moreover, the rule is also non conclusively disconfirmatory as the premise does not refute (i.e. disconfirm in 100%) the conclusion. For rules like  $r_2$  function  $v(H, E)$  obtains value 0, which implies that confirmation measures with property  $Ex_1$  assign to such rules smaller values than to conclusively confirmatory rules.

A conclusively disconfirmatory rule could be  $r_3$ : *if  $x$  is seven of spades then  $x$  is a face-card*. Here, the premise of drawing the seven of spades disconfirms in 100% the conclusion that the drawn card is a face-card. The refutation of the conclusion  $H$  by the premise  $E$  ( $E \models \neg H$ ), implies that there cannot be any positive examples to the rule (i.e.  $a=0$ ). Such conclusively disconfirmatory rules should be assigned a minimal value  $-V$  of a function  $v(H, E)$ .

The ordering based on function  $v$ :  $v(r_1) > v(r_2) > v(r_3)$ , implies the following relations for any confirmation measure possessing the  $Ex_1$  property:  $c(r_1) > c(r_2) > c(r_3)$ .

Concluding, measures satisfying property  $Ex_1$  have the ability to rank the rules in such a way that those in which the premise entails the conclusion (e.g., the rule: *if  $x$  is a jack then  $x$  is a face-card*) are on top of the ranking, those in which the premise refutes the conclusion (e.g., *if  $x$  is seven of spades then  $x$  is a face-card*) are on the very bottom, and rules which are neither 100% sure nor 100% false are in between. Let us also remark, that entailment is equivalent to  $\Pr(H|E)=1$ , i.e. to situations when there are no counterexamples to the rule ( $c=0$ ), and that refutation is equivalent to  $\Pr(H|E)=0$ , i.e. to situations when there are no positive examples to the rule ( $a=0$ ).

#### IV. PARADOXES OF $Ex_1$ PROPERTY

Property  $Ex_1$  was introduced to assure that rules for which the premise entails the conclusion (i.e. conclusively confirmatory rules) are assigned a higher value of a confirmation measure than any rule which is not conclusively confirmatory. Furthermore, rules for which the premise refutes the conclusion (i.e. conclusively disconfirmatory rules) are assigned a lower value than any rule which is not conclusively disconfirmatory. Ranking of rules depending on entailment and refutation seems naturally desirable, however boiling the consideration down to only two situations: when

there are no counterexamples to the rule (i.e.  $E \models H$ ,  $c=0$ ), and when there are no positive examples to the rule (i.e.  $E \models \neg H$ ,  $a=0$ ) can result in paradoxes.

Let us explain our point of view by taking into account the formulation of (BC') conditions stating that:

$E$  confirms  $H$  if the probability of  $H$  given  $E$  is higher than the probability of  $H$  not given  $E$ . We believe that it is reasonable to conclude that, *in case of confirmation*, a confirmation measure  $c(H, E)$  should express *how much it is more probable to have  $H$  when  $E$  is present rather than when  $E$  is absent*. In this context, the following example shows a paradox caused by the property of  $Ex_1$ .

Let us consider two cases in which the number of objects in  $U$  is distributed over  $a, b, c$  and  $d$  in the following manner:

Case  $\alpha$ :  $a_\alpha=10, b_\alpha=9, c_\alpha=0, d_\alpha=1$ ;

Case  $\beta$ :  $a_\beta=9, b_\beta=0, c_\beta=1, d_\beta=10$ .

In case  $\alpha$  a rule  $r_\alpha: E_\alpha \rightarrow H_\alpha$  is supported by  $a_\alpha=10$  objects from  $U$ , there are 9 objects supporting the rule's conclusion but not its premise ( $b_\alpha=9$ ), there are no counterexamples to the rule ( $c_\alpha=0$ ), and there is 1 object not supporting the rule's premise nor its conclusion ( $d_\alpha=0$ ). Analogously, in case  $\beta$  a rule  $r_\beta: E_\beta \rightarrow H_\beta$  is supported by  $a_\beta=9$  objects from  $U$ , there are no objects supporting the rule's conclusion but not its premise ( $b_\beta=0$ ), there is only 1 counterexamples to the rule ( $c_\beta=1$ ), and there are 10 object not supporting the rule's premise nor its conclusion ( $d_\beta=10$ ). The rule  $r_\alpha$  is conclusively confirmatory, as it has no counterexamples in  $U$  (i.e. the premise entails the conclusion). On the other hand, the rule  $r_\beta$  is non conclusively confirmatory because there exists in  $U$  one counterexample to that rule. Thus, in case  $\alpha$  the value of a confirmation measure should be greater than in case  $\beta$  if  $Ex_1$  holds.

Let us now also incorporate the idea that a confirmation measure  $c(H, E)$  should express how much it is more probable to have  $H$  when  $E$  is present rather than when  $E$  is absent. One can see that  $\Pr(H_\alpha|E_\alpha) = a_\alpha/(a_\alpha+c_\alpha) = 1$  and  $\Pr(H_\alpha|\neg E_\alpha) = b_\alpha/(b_\alpha+d_\alpha) = 0.9$  in case  $\alpha$ , while in case  $\beta$   $\Pr(H_\beta|E_\beta) = a_\beta/(a_\beta+c_\beta) = 0.9$  and  $\Pr(H_\beta|\neg E_\beta) = b_\beta/(b_\beta+d_\beta) = 0$ . For case  $\alpha$  and  $\beta$ , if  $Ex_1$  holds, passing from the situation when the premise is absent to the situation when the premise is present, we assign a greater value of a confirmation measure when we have a 10% increment of the probability of the conclusion (case  $\alpha$ ) rather than when the same increment is of 90% (case  $\beta$ ). A confirmation measure possessing property  $Ex_1$  favors rule  $r_\alpha$  over  $r_\beta$ , which is a paradox when we analyze how much more probable it is to have the rule's conclusion when the premise is present rather than when it is absent.

Analogously, let us interpret (BC') conditions as:  $E$  disconfirms  $H$  if the probability of  $H$  given  $E$  is smaller than the probability of  $H$  not given  $E$ . Thus, *in case of disconfirmation* a confirmation measure  $c(H, E)$  should express *how much it is less probable to have  $H$  when  $E$  is present rather than when  $E$  is absent*. In this context, the following example shows a paradox caused by the property of  $Ex_1$ .

Let us consider two cases in which the number of objects in  $U$  is distributed over  $a, b, c$  and  $d$  in the following manner:

Case  $\gamma$ :  $a_\gamma=0, b_\gamma=1, c_\gamma=10, d_\gamma=9$ ;

Case  $\delta$ :  $a_\delta=1, b_\delta=10, c_\delta=9, d_\delta=0$ .

In case  $\gamma$  a rule  $r_\gamma: E_\gamma \rightarrow H_\gamma$  is not supported by any object from  $U$  ( $a_\gamma=0$ ), there is 1 object supporting the rule's conclusion but not its premise ( $b_\gamma=1$ ), there are 10 counterexamples to the rule ( $c_\gamma=10$ ), and there are 9 objects not supporting the rule's premise nor its conclusion ( $d_\gamma=9$ ). Analogously, in case  $\delta$  a rule  $r_\delta: E_\delta \rightarrow H_\delta$  is supported by one object from  $U$  ( $a_\delta=1$ ), there are 10 objects supporting the rule's conclusion but not its premise ( $b_\delta=10$ ), there are 9 counterexamples to the rule ( $c_\delta=9$ ), and there are no object not supporting the rule's premise nor its conclusion ( $d_\delta=0$ ). The rule  $r_\gamma$  is conclusively disconfirmatory, as it has no positive examples in  $U$  (i.e. the premise refutes the conclusion). On the other hand, the rule  $r_\delta$  is non conclusively disconfirmatory because there exists in  $U$  one positive example to that rule. Thus, in case  $\gamma$  the disconfirmation should be greater than in case  $\delta$  if  $Ex_1$  holds, i.e. the value of a confirmation measure should be smaller in case  $\gamma$  than in case  $\delta$ .

From the view point of (BC') condition concerning disconfirmation, measure  $c(H, E)$  should express how much it is less probable to have  $H$  when  $E$  is present rather than when  $E$  is absent. The conditional probabilities for the two exemplary cases  $\gamma$  and  $\delta$  are:  $\Pr(H_\gamma|E_\gamma) = a_\gamma/(a_\gamma+c_\gamma) = 0$  and  $\Pr(H_\gamma|\neg E_\gamma) = b_\gamma/(b_\gamma+d_\gamma) = 0.1$ , and  $\Pr(H_\delta|E_\delta) = a_\delta/(a_\delta+c_\delta) = 0.1$  and  $\Pr(H_\delta|\neg E_\delta) = b_\delta/(b_\delta+d_\delta) = 1$ .

For case  $\gamma$  and  $\delta$ , if  $Ex_1$  holds, passing from the situation when the premise is absent to the situation when the premise is present, we should have a smaller value of confirmation measure (greater disconfirmation) when we have a 10% decrement of probability of the conclusion (case  $\gamma$ ) rather than when the same decrement is of 90% (case  $\delta$ ). A confirmation measure possessing property  $Ex_1$  treats rule  $r_\delta$  as less disconfirmatory than  $r_\gamma$ , which is a paradox when we analyze how much less probable it is to have the rule's conclusion when the premise is present rather than when it is absent.

The considerations for cases  $\alpha$ - $\delta$  show that the requirements forming  $Ex_1$  are not sufficient as using measures with this property can lead to paradoxes. Remark that in case of confirmation,  $Ex_1$  concerns situations of entailment, which is equivalent to  $\Pr(H|E)=1$ . However, confirmation should express how much it is more probable to have  $H$  when  $E$  is present rather than when  $E$  is absent. Thus, the requirement  $\Pr(H|E)=1$  is not sufficient, and property  $Ex_1$  should be modified to take into account also the value of  $\Pr(H|\neg E)$ . Analogical requirements concern the case of disconfirmation. These considerations lead to important modifications of property  $Ex_1$ , called weak  $Ex_1$ .

#### V. MODIFICATION OF $EX_1$ INTO WEAK $EX_1$ PROPERTY

Property  $Ex_1$  can be regarded as one-sided because it focuses on situations when  $E \models H$  (i.e. there are no

counterexamples to a rule and  $c=0$ ), and situations when  $E \models \neg H$  (i.e. there are no positive examples to a rule and  $a=0$ ). In our opinion, the concept of confirmation is too complex and rich to be boiled down simply to verification whether there are no counterexamples or no positive examples.

To formulate the proposition of modification of the  $Ex_1$  property, let us recall the interpretation of (BC') conditions:

- in case of confirmation, a confirmation measure  $c(H, E)$  should express how much it is more probable to have  $H$  when  $E$  is present rather than when  $E$  is absent,
- in case of disconfirmation a confirmation measure  $c(H, E)$  should express how much it is less probable to have  $H$  when  $E$  is present rather than when  $E$  is absent.

Taking into account such interpretations we can formulate a property called weak  $Ex_1$ , which generalizes the original  $Ex_1$  property:

$$\text{if } v(H_1, E_1) > v(H_2, E_2) \text{ and } v(H_1, \neg E_1) < v(H_2, \neg E_2) \quad (5) \\ \text{then } c(H_1, E_1) > c(H_2, E_2)$$

Property weak  $Ex_1$  guarantees that a confirmation measure  $c(H, E)$  cannot attain its maximal value unless the two following conditions are satisfied:

- $E \models H$
- $\neg E \models \neg H$

Let us also remark that the condition  $E \models H$  is equivalent to  $\Pr(H|E)=1$  and to  $c=\sup(-H, E)=0$ , because

$$\Pr(H|E) = \frac{\sup(H, E)}{\sup(H, E) + \sup(-H, E)} = \frac{a}{a+c} = 1 \Leftrightarrow c=0.$$

Furthermore, the condition  $\neg E \models \neg H$  can be equivalently expressed as  $\Pr(H|\neg E)=0$  or  $b=\sup(H, \neg E)=0$ , since

$$\Pr(H|\neg E) = \frac{\sup(H, \neg E)}{\sup(H, \neg E) + \sup(-H, \neg E)} = \frac{b}{b+d} = 0 \Leftrightarrow b=0.$$

Analogously, property weak  $Ex_1$  guarantees that the confirmation measure  $c(H, E)$  cannot attain its minimal value unless the two following conditions are satisfied:

- $E \not\models \neg H$
- $\neg E \models H$

Let us note that the condition  $E \not\models \neg H$  is equivalent to  $\Pr(H|\neg E)=0$  and to  $a=\sup(H, E)=0$ , as

$$\Pr(H|\neg E) = \frac{\sup(H, E)}{\sup(H, E) + \sup(-H, E)} = \frac{a}{a+c} = 0 \Leftrightarrow a=0.$$

Moreover, the condition  $\neg E \models H$  can be equivalently expressed as  $\Pr(H|\neg E)=1$  or as  $d=\sup(-H, \neg E)=0$ , because

$$\Pr(H|\neg E) = \frac{\sup(H, \neg E)}{\sup(H, \neg E) + \sup(-H, \neg E)} = \frac{b}{b+d} = 1 \Leftrightarrow d=0.$$

Using the property  $Ex_1$  can lead to unwanted situations where we favor one rule over another contrary to the increase in the confirmation or decrease of disconfirmation.

Our modification of  $Ex_1$  into weak  $Ex_1$  escapes that problem, because the condition  $c=0$  (in case of confirmation) and  $a=0$  (in case of disconfirmation) that were present in original formulation of  $Ex_1$  are now extended to  $c=b=0$  (in case of confirmation) and  $a=d=0$  (in case of disconfirmation). If we consider a confirmation measure that satisfies weak  $Ex_1$ , we do not demand that it should have a greater value in case  $\alpha$  rather than in case  $\beta$ , nor vice versa. Thus, the paradox disappears under conditions of weak  $Ex_1$  property. Moreover, if we consider a confirmation measure that satisfies weak  $Ex_1$ , we do not demand that it should have a smaller value in case  $\gamma$  rather than in case  $\delta$ , nor vice versa. Thus, the paradox disappears under conditions of weak  $Ex_1$ .

The modifications introduced to the  $Ex_1$  property are indispensable and allow to deploy the concept of confirmation in its larger sense. Therefore we postulate to substitute  $Ex_1$  by weak  $Ex_1$  property.

## VI. CONCLUSION

Analysis of rule interestingness measures with respect to their properties is an important research area. It helps to identify groups of measures that are truly meaningful. A group of measures satisfying the Bayesian confirmation property has been identified as important and useful for evaluation of patterns in form of rules [9], [13]. To handle the plurality of alternative, ordinally non-equivalent confirmation measures, property  $Ex_1$  has been proposed [3]. It relates to entailment or refutation of the rule's conclusion by its premise. The formulation of  $Ex_1$  reacts only to the absence of counterexamples or positive examples to a rule. Such approach does not reflect the deep meaning of confirmation stating that a confirmation measure should give an account of the credibility that it is more probable to have the rule's conclusion when the premise is present, rather than when the premise is absent. On the basis of such understanding of the concept of confirmation, we propose modification of  $Ex_1$  property, called weak  $Ex_1$ . It takes into account not only the value of  $\Pr(H|E)$  but also  $\Pr(H|\neg E)$ , and this way fully relates to confirmation concept.

**Abstract**—Web Usage Mining is nowadays extremely useful to a diverse and growing number of users, from all types of organizations trying hard to reach the goals of their Web sites. However, inexperienced users, in particular, face several difficulties on developing and applying this kind of mining processes. One crucial and challenging task is selecting proper mining methods to deal with clickstream data analysis problems. We have been engaged on designing, developing and implementing a case based reasoning system, specifically devoted to assist users on knowledge discovery from clickstream data. The system's main aim is to recommend the most suited mining plans, according to the nature of the problem under analysis. In this paper we present such system, giving emphasis to the retrieving of similar cases using a preliminary constructed case base.

## I. INTRODUCTION

WEB based technology is widespread, but implementing and administrating Web sites still are activities increasingly complicated and very time consuming to most of the organizations. The Web has matured and the users have diverse, rising and unusual requirements. Indeed, site usage differs very often from expectations, demanding deep decision support to orient improvements. Site promoters require objective feedback regarding site effectiveness evaluation and insights how to enhance the Web offers. Hence, knowing and understanding visitors' behaviour is strategic to achieve site goals and the maximize Web's potential.

*Web Usage Mining* (WUM) is related to the application of the general *Knowledge Discovery* (KD) processes to data related with the interaction activity between visitors and Web sites, known as clickstream or usage data. WUM is an important tool to a large diversity and increasing number of decision maker users along the organization, having very different levels of knowledge in this area. Inexperienced users face many difficulties, among them, the crucial challenge of selecting proper *Data Mining* (DM) methods to deal with clickstream data analysis problems. Conversely, skilled users hold acquired know-how that may be especially relevant to the remaining users, surrounded by the same environment and confronted to similar decision problems to solve. Ideally, this know-how should be available in order to be shared and reused across the organization, creating new forms of synergies and empowering potential analysts. Moreover, the

knowledge obtained from these experiences may be reused along diverse organizations, enlarging its application and usefulness.

Having the referred issues in mind, we decided to build a system, named *Mining Plans Selector* (MPS), especially devoted to assist users on developing and applying WUM processes. The past successful WUM exercises of the organization are the base that sustains the followed approach, based on the *Case Based Reasoning* (CBR) paradigm. CBR is a learning and problem solving approach [1], [10], [17], [18]. Instead of relying solely on general knowledge of a problem domain or making associations along the generalized relationships between problem descriptors and conclusions, CBR is able to utilize the specific knowledge of previously experienced, concrete problem situations or cases [8] [18]. A new problem is solved by finding a similarity to the formal approach of the past case and reusing it in the new problem situation. A second important difference is that CBR also is an approach to incremental and sustained learning, since a new experience is retained each time a problem has been solved, making it immediately available for future problems [1].

The MPS system behaves as a corporative tool to capture, manage and reuse the previous WUM application cases. The system's main aim is to suggest the most suited WUM plans, according to the nature of the problem under analysis. The MPS also provides support to collect and organize the knowledge gained from the experience on solving WUM problems, bringing such knowledge up to date and promoting the system's sustained incremental learning. New WUM processes are stored on a collective case base, centralizing a key resource to the MPS's capacity to solve problems in a corporative knowledge base.

Assisting decisions within KD processes is not a new initiative. There are some works that explore the CBR paradigm to undertake related purposes. For instance, the Mining Mart project [13] represents several efforts regarding the reuse of successful data pre-processing processes, appealing to a case based metadata repository. However, to help the users on establishing the mapping between the problem at hands and the stored ones, this system doesn't explore the potential meta-model neither the typical CBR methods,. The main focus of active support lies on the adaptation of the selected case to the current problem. Furthermore, this project is cen-

tered in pre-processing activities, not in DM or KD processes.

Another example is the *MetaL* project [12]. This project involved multiple research and development initiatives, some of which based on the CBR paradigm (e.g. [6], [11]). The main aim was to assist the user in the model selection step of the KD process. The project attention focused mainly on the algorithms selection issue, within regression and classification problems. Contrariwise, our work has a different perspective and scope. MPS is devoted to the WUM specific domain and considers processes development at distinct levels. MPS previews assistance on models selection, comprising diverse DM functions and processes involving transformation operations and multiple stages. Besides, the system reaches a greater level of abstraction.

In this paper we explain the motivation of our work and the followed strategy, and we present briefly the MPS system. We are testing the system more exhaustively, particularly the retrieving of solutions to similar WUM problems using a preliminary constructed case base. This case base contains WUM application examples describing and reproducing experiences available. MPS is able to capture knowledge from experience, using a semi-automatic approach, and retrieves similar WUM processes, giving a specific target dataset and analysis requirements. In section II, we present the challenge we are trying to address. We describe our approach, particularly the case base (section III) and the MPS system (section IV) main characteristics. Additionally, in section V we present some of the most relevant issues involved on the construction of the preliminary case base, and in section VI we discuss the process of retrieving similar WUM application cases and the general results of its evaluation, using the preliminary case base.

## II. MINING CLICKSTREAM DATA

Clickstream or usage data is automatically logged by Web servers, being a very rich and valuable source of visitors' behavior information. This data provides a detailed record of every single action taken by the visitor, besides the outcome of the process, typically captured on traditional off-line interactions. Moreover, clickstream data is captured implicitly without questioning users directly, providing a non-intrusive way to obtain objective feedback. Therefore, exploring WUM to extract knowledge from this and related data (e.g. users' demographic and transactions' information) has potentially enormous benefits to organizations [20]. Some important and actionable areas of WUM exploration consist of Web personalization, business intelligence, system performance improvement and site content and structure enhancement [19]. For instance, known examples of Web personalization, namely automatic recommendation, include Amazon.com's personalized recommendations and music or playlist recommenders such as Mystrand.com commercial systems [14].

Naturally, electronic commerce sites get much attention, both in professional and research arenas. Electronic commerce is considered a "killer" domain for DM since many of

the ingredients necessary for successful DM are easily satisfied, including [8] [9]:

- (i) wide records, i.e. many attributes or variables;
- (ii) many records, i.e. large volume of data;
- (iii) controlled data collection (e.g. electronic data gathering);
- (iv) results can be evaluated and return on investment measured;
- (v) action can easily be taken (e.g. change the site, offer cross-sells).

In electronic commerce the underlying goal is quite objective, typically to increase sales and profit, and may be achieved by understanding properly customer access behavior. Some businesses exist only virtually on the Web and, obviously, improving offers and even previewing needs are crucial to all organization members.

As any other KD process, WUM is an open-ended, exploratory and participant driven process, involving several actions and decisions, which usually comprise [4]: (i) picking relevant data (dataset and variables); (ii) identifying proper DM functions; (iii) choosing suitable models or algorithms and setting its parameters; (vi) transforming data to improve its quality, to better fit the methods assumptions and to answer a concrete analysis problem. Those activities and decisions are not trivial. By the contrary. Selecting proper mining methods, i.e. functions and models, and applying them to the available data are known challenges of the KD process development. Among multiple issues, they require an appropriate reformulation of the practical problem into a DM problem and a deeper technical understanding of the methods, being also influenced by many kinds of factors, often complex and subjective, such as the characteristics of the available data and the process preference or success criteria. Besides, some methods overlap in terms of the problems they can solve. Consequently, KD activities are typically accomplished repetitively, following different directions and testing several variants of each direction. Examples of variants include trying and comparing different attributes selection, data transformations and models parameter's settings. In short, KD and WUM are complex and very time consuming processes, frequently not leading to useful results for a particular goal.

As expected, the Web environment and clickstream data characteristics increase even more the general challenge. Distil the important information from the irrelevant one, deal with too much particularities and rapid changing conditions and get meaning from the data, are only a few subset of such issues. Analysts must tackle (human and not human) visitors' behavior aspects, which, in the last case (not human), skew the results and tend to be progressively more varied and difficult to distinguish. In fact, most of the previously pointed successful ingredients of the electronic commerce domain are also present in other types of Web sites or activities and viewed as truth challenges, requiring greater efficacy on WUM processes. Namely, becomes necessary to treat systematically such huge, complex and constantly growing data source, counting with hard time constraints. Decision makers across the organization demand for fast transformation of this massive data into valuable and actionable knowledge, to

orient new ways of acting and site's improvements leading to revenue. Additionally, in the specific WUM area the problem types, the kinds of mining activities, the related practical applications and the key data items are less studied and structured.

Our underlying goal is to promote a more efficient, effective, and synergetic use of the organization's resources, decreasing the effort and time required to derive useful knowledge, bringing up together multiple valuable contributions to overcome the main difficulties. The focus of our work lies on the WUM processes development challenge of selecting suitable mining methods to apply on a specific clickstream analysis problem. We gave more emphasis to the modeling phase of the WUM process, typically presuming the availability of sources containing pre-processed data, but considering also tasks of the remaining phases. Our idea is that arduous and intensive pre-processing tasks must be centralized in a previous stage, in order to make data available to all the potential analysts in more manageable forms. The primary target of our work is, precisely, the inexperienced analysts, facing problems that may be solved exploring WUM. Consequently, an implicit requirement is to support problem descriptions making use of abstractions related to the real problems to solve and, naturally, to establish direct relationships among such abstractions and the most promising DM methods and approaches.

### III. STRENGTHS AND OPPORTUNITIES OF WUM APPLICATION CASES

The most important learned lesson from 2000 KDD Cup annual competition was the crucial role played by humans in WUM processes development, even when the only interesting success criteria was accuracy or score [8]. Human insight was strategic in tasks as feature selection and construction from hundreds of available attributes and in the choice of mining methods. Indeed, most of the success obtained by experts, when dealing with WUM problems, comes from their acquired know-how. Even they cannot provide general and consistent rules to support problem solving.

Building up WUM application cases has considerable strengths, mainly realized by structuring and memorizing the knowledge acquired from the experience. Hence, we decided to document, catalogue and store WUM past experiences, in a specific oriented knowledge base that could be applied over clickstream data analysis. Examples of past successful solved problems might be the most helpful and convincing form of aid in this scope, since they may: (i) simplify the underlying complexity, providing at the same time the details of a tested and solved situation; (ii) yield context information, making possible to report the solutions along with the respective justifications and obtained discoveries; (iii) promote the mapping of the current problem, against the existent ones.

A straight reuse of WUM solutions is quite possible in this scope, since recurrent problems are common. Still, becomes necessary to enable flexible means for relating new problems and the stored ones, to help users on identifying the most plausible strategies to address the problem at hands. The

CBR paradigm brings a key opportunity to our knowledge base, providing inherently a proper way for attending this demand. CBR methods favor a flexible similarity based comparison, even if the involved features are not objective and precisely defined. CBR can cope with incomplete and subjective information and makes possible to consider only the relevant features and use specific importance levels, increasing the potential of answering the real user needs. Furthermore, CBR provides a sustained incremental learning approach, given that a new experience can be automatically integrated each time a problem is solved, becoming immediately available to apply on future problems [1]. This CBR strength is of great importance to us, due to the constant evolution of WUM and the need to incorporate knowledge about new mining algorithms, tools, types of problems, solving approaches and kinds of discoveries applications.

Defining and representing cases are also crucial issues for CBR. A case may be defined as a contextualized piece of knowledge representing an experience that teaches lessons fundamental to achieving goals [8]. In MPS, a case is a WUM process described by a set of fundamental dimensions (D, T, P, A and K) and, combining the CBR principles, structured in terms of a domain problem and the applied solution (Fig. 1). A problem is essentially defined by:

- characterizations of the available data (D), at dataset and variables level;
- categorizations of the WUM problem type (T), mainly in terms of abstractions such as main underlying activity, analysis goals and practical application areas;
- process evaluation criteria (P) (not shown in Fig. 1).

The applied solution comprises: a sequence of activities (A), including transformation and modeling stages, the involved data and the model parameter settings; prior and derived knowledge (K), concerning to facts that affected the analysis, the extracted knowledge and the relations to such facts; and general information about the WUM process (P).

We also have a context description item to organize cases in terms of a Web site's perspectives or particular sections. This item is a logic container for cases description features. The initial idea was to avoid redundancy on descriptions, since we have several datasets and common features. Though, the context provides flexibility on retaining details from different parts of one Web site. The context may be associated with some aspects of problem description, namely dataset, activity, and specific and general facts.

The most important question concerning datasets is to capture the relevant properties to the particular purpose of DM methods selection. We need a consistent characterization, in order to be able to compare dissimilar datasets. In fact, we compare the metadata, not the clickstream dataset itself. Our strategy is based on a common data characterization approach [11]. This approach has been frequently and successfully used in Meta-Learning, to select adequate learning algorithms. In general terms, we adapted this approach to clickstream data characteristics.

The cases' problem part is used to describe WUM problems and to find out previous similar cases, both defined

Fig. 1 WUM application case main elements

based on the common features (Table 1). The solution parts of the most similar cases retrieved are used to produce mining plans, forming the recommended solution to the submitted problem.

IV. MINING PLANS SELECTOR SYSTEM

The tasks involved in CBR have been described as a cyclical process, comprising the 4REs i.e. retrieve, reuse, revise and retain [1]. We adapted this widely acknowledge cycle to the activities to perform by the MPS system, devising six constituent steps. These steps form a problem solving and learning from experience strategy, oriented to the WUM so special application domain. Fig. 2 shows the adopted cycle. The original steps from [1] are presented, at italic, to distinguishing them from the added ones.

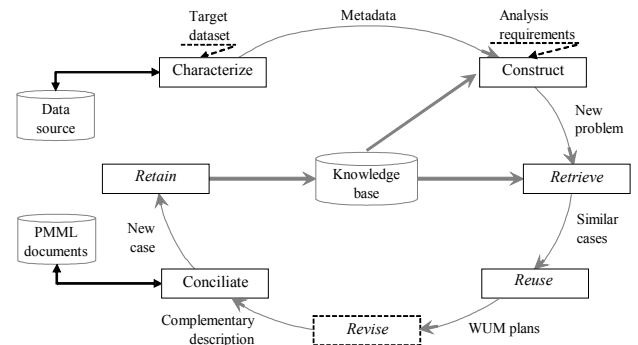

Fig. 2 Adopted CBR cycle

To solve a problem, the MPS system acts tacking as inputs the target dataset and the analysis requirements and delivers WUM plans appropriate to the current problem based on the cases kept on the knowledge base. The problem solving part of the system comprises five steps: Characterize, Construct, Retrieve, Reuse and Revise. One MPS's specific task is to characterize the target data, producing a systematic and consistent meta-representation, comprising different types of data sources. Another particular task is to construct a new WUM problem, guiding, gathering and organizing the user's explicit analysis constraints specification. The retrieve task is a typical one, being used to find out the cases most similar to the target problem. The reuse task generates WUM plans, mostly based on the mining methods and the levels of similarity of the retrieved cases, and considering also the evaluation criteria most important to the analyst. This step does not performs extensive adaptation of the solution to the current problem, namely in the wide sense intended by the original step. Nevertheless, it focus the main parts of the candidate cases that may be transferred to the target problems, by rec-

TABLE I.  
LIST OF PROBLEM DESCRIPTION FEATURES

Category	Features	Similarity measure for:		
		Single values	Set values	
<b>P</b>	Evaluation criteria	Precision, Time of reply, Interpretability, Resources requirements and Implementation simplicity	(NMDc)	
	Process date	Date	(NMD)	
<b>T</b>	Site's activity	(a set of) Activity	(SM)	(HMA)
	DM task	(a set of) Goal (a set of) Application area	(SM) (SM)	(HMA) (HMA)
<b>D</b>	Characteristics at dataset level:	-Number of lines and columns/variables -% of numeric, categorical, temporal and binary columns -Granularity (e.g. session) -Type of visitor's identification -Type of visitor's information recording -Access order and access repetition availability -Access data and hour availability	(NMD) (NMD) (E) (E) (E) (E) (E)	
	Characteristics at variable level:	(a set of) Variable: -Data type -Semantic category -Number of distinct values -Number of null values	(G) (SM) (SM) (NMD) (NMD)	(MA)

ommending mining methods instead of mere cases, preparing the reuse of the methods that constructed the solution. The revise step is accomplished outside of the system, using a KD tool.

Concerning the MPS learning perspective, the system operates accepting heterogeneous descriptions of new WUM processes and acquiring knowledge. MPS uses a semi-automated learning approach, in order to systematize and simplify such arduous activity. The steps included in learning are: *Conciliate* and *Retain*. The accepted incomings are: documents describing mining activities, generated by the KD tool in *Predictive Model Markup Language* (PMML) [15], a XML based standard to define and share statistical, and DM models across compliant applications; the process complementary description, which would be exhaustive, if the used tool does not supports the PMML standard. First, a conciliate task transforms and combines the heterogeneous descriptions items, supplied by user interaction and documents in PMML. Then the traditional retain task essentially augments the knowledge base with a new case, elaborated by integrating and structuring the incoming elements, considering the internal schema of the cases' representation.

#### V. BUILDING UP THE PRELIMINARY CASE BASE

Testing a system like MPS, specifically the problem solving point of view, requires an extensive case base. We must accept large and diverse input datasets, since clickstream data are huge and analyzed in distinct forms. More important, we need a wide set of successful and representative WUM processes, using the existent datasets. Such processes have to include different DM functions and methods and be applied to solve a comprehensive set of typical problems types.

The preliminary case base was build appealing to WUM application examples, based on real data and analyses that were available in the Internet, and some other research works. Some of these analyses reproduce WUM processes developed with such data, published together with the respective sources or in research papers. This option was made to attend the requirements previously explained, as well to overcome the issue of the discoveries success subjectivity, which in the case of simulated examples is relative and difficult to evaluate. So, we provide a greater level of success guaranty. Another advantage of this option was the greater diversity of situations.

About disadvantages, the system was not evaluated according to the previously established and idealized circumstances: pre-processed and quality data; analysis problems one of an organization. Preparing cases, in these conditions, is a more complicated and time consuming task. The analysis of each dataset is extended for longer periods, since it requires data transformation efforts and, mainly, the understanding of these data and its surrounding context. Furthermore, the case base profile changed slightly, since it concerns to more than one organization. However, first, this case base provides wide application to different kinds of organization and situations. Second, the system proved that was able to retain details from varied environments. The context

description, previously described, was very useful to deal with this new scenario.

Regarding the prepared cases main characteristics, we emphasize the diversity among the series of original data, from which the used datasets were derived. The original data vary from Web servers logs, in its rude form, to data already pre-processed, and in some cases with distinct series of data devoted for the treatment of different problems. This is precisely the situation of the 2000 KDD Cup case study [8]. One used three datasets of this source and multiple analyses based on them. In this type of situation we mainly filtered and derived new features, taking into account data quality and relevance to the problem at hands. Other datasets were pre-processed and used to generate multiple datasets, such as, for example, page view or access level clickstreams, aggregations at session level and binary matrices (e.g. sessions X accessed pages). Other known and available used examples were the *msnbc* [5] and *ECML\PKDD 2005 Discovery Challenge* [2] datasets and reported experiences, both about clickstream data analysis.

The construction of the preliminary case base provided the way to conduct experimental tests of the semi-automated learning approach of the system. This approach proved to be very useful on decreasing the efforts on processes extensive descriptions and to reduce the dependency from WUM experts. The well known datasets we mentioned are very long, being very handy to have automatic ways for capturing dataset metadata. Thus, dataset characterization was tested under demanding conditions and the respective metadata was successfully captured. Besides, usually we have processes with several stages, including each one the selection of numerous variables and the specification of several values of parameter settings. The learning approach was used, with success for all the WUM processes from which was possible to obtain PMML documents, despite the need to complement the description through explicit user interaction. We may conclude that the learning approach is effective. The problem solving part experimental results are discussed in the next section.

#### VI. RETRIEVING SIMILAR WUM PROCESSES

The retrieve step plays a vital role on problem solving. This step selects the most plausible cases to found the construction of mining plans to recommend, according to the target problem. The variants of problem description that might be submitted to the system are diverse, but may be systematized into three main types, related with the previously mentioned dimensions: oriented by the target dataset (dimension D), by other kinds of constraints (dimensions P and T) or both (dimensions D, P and T). Table 1 shows the problem description features and the measures used to assess the level of the similarity (defined on Table 2).

The similitude assessment approach devised over WUM problems comprises the modelling of the following types of measures:

- local similarity measures for simple (single-value) attributes;

- local similitude measures for structured (multiple or set value) features (namely MA and HMA measures);
- global similarity measures (G) defined through an aggregation function and a weight model.

The global similitude combines the local similarity values of several features (e.g. through a weight average function), giving an overall measure. It is applied at variable's and case's level. The local similarity measures are defined over the descriptors and depend mainly on the features domain, besides the intended semantic. Concerning simple (single-value) features, the local similitude of categorical descriptors is essentially based on exact (E) matches (e.g. for binary attributes) or is expressed in form of similarity matrices (SM), which establish each pairwise similitude level (e.g. for some symbolic descriptors). To compare numeric simple features, we adopted similarity measures mainly based on the normalized Manhattan distance.

We also need similarity measures for complex descriptors, modeled as set-value features, containing atomic values (e.g. application areas) or objects having themselves specific properties. For instance, variables have specific properties (e.g. data type) and may occur in different number for each

dataset. Indeed, these needs were the main issue faced under the similarity assessment. For instance, it appears when matching the variables from the target and each case. We have to compare two sets of variables, with inconstant and possibly distinct cardinality, where each variable has its own features. There are multiple proposals in the literature to deal with related issues (e.g. [3], [7], and [16]). Even so, we explored a number of them, for instance, the measures suggested on [7], and the comparative tests performed lead us into tailored or extended (MA and HMA) measures, better fitting our purposes, as reported in [21].

Concerning the retrieve evaluation, the general and specific tests performed so far demonstrate to the system's effectiveness. The specific tests included the comparison among distinct types of objects, such as series of variables and datasets. Regarding datasets, the system discriminates the most similar and dissimilar ones, based on the adopted features and proposed as the most relevant ones for selecting mining methods and approaches. The results conform to the intuitive notion of similarity among datasets, based on the general idea about each one. For instance, some identified trends were the following:

TABLE II.  
LIST OF MAIN USED SIMILARITY MEASURES

Description	Measure
(G) Weight average (global similarity function)	$Sim_{global}(t, c) = \frac{\sum_{f=1}^n Sim_{local}(t.f, c.f) * w_f}{\sum_{f=1}^n w_f}$
(NMD) Normalized Manhattan distance	$Sim_{Local}(t.f, c.f) = 1 - \frac{ t.f - c.f }{f_{max} - f_{min}}$
(NMDc) Normalized Manhattan distance changed	$Sim_{Local}'(t.f, c.f) = \begin{cases} 1 & c.f \geq t.f \\ 1 - \frac{ t.f - c.f }{f_{max} - f_{min}} & c.f < t.f \end{cases}$
(E) Exact (text or binary)	$Sim_{Local}(t.f, c.f) = \begin{cases} 1 & c.f = t.f \\ 0 & c.f \neq t.f \end{cases}$
(SM) Similarity matrix	
(MA) Maximums Average	$Sim_{MA}(A, B) = \frac{1}{n_A + n_B} \sum_{a \in A} \max(sim(a, b)) + \sum_{b \in B} \max(sim(a, b))$
(HMA) Half maximums Average	$Sim_{HMA}(A, B) = \frac{1}{n_A} \sum_{a \in A} \max(sim(a, b)) \quad A \subset \text{Target set}, B \subset \text{Case set}$
$t, c$ – target and case (or part of them) $t.f, c.f$ – values of each feature $f$ $Sim_{local}$ – local similarity measure $n$ – number of features $w_f$ – feature $f$ importance weighting	$f_{max}, f_{min}$ – maximum and minimum values (observed) on feature $f$ $A, B$ – two sets, such that $a \in A$ and $b \in B$ $sim(a, b)$ – similarity between each pair of elements of the two sets $n_A, n_B$ – cardinality of the sets $A$ and $B$

- When the target dataset is a binary matrix: the most similar datasets are also binary matrices; the most dissimilarity datasets are common and, frequently, datasets having access granularity.
- When the dataset has access granularity: the most similar datasets also have access granularity; the most dissimilar datasets are usually the same.
- When the target data set has session or other granularity (e.g. visitor) and is not a binary matrix: there is not a simple and strait similarity pattern (justified by the variety of attributes gathered at these levels); the most dissimilar datasets have mainly access granularity.

In terms of general tests, the remain descriptors also reflect influent factors and affect cases retrieving, contributing for establishing the bridge between analysis requirements and suited mining methods and approaches. The system relates WUM processes based on similar intentions and applications, but not necessarily coincident. Since the data characterization descriptors are in majority, within the problem description, by default their relative importance is greater and the system tends to select processes based on similar datasets. This default behaviour accords to the intended one and is considered a good result. In fact, the dataset characteristics are always a crucial (predictive) factor, since models properties and assumptions, and even other factors (e.g. goals), frequently, demand for some specific data. Furthermore, the system provides means to change the default behaviour and to improve the problem specification, namely exact filtering criteria, specific descriptors importance levels and the exclusion of irrelevant (or unknown) descriptors.

## VII. CONCLUSIONS

Rapidly changing conditions and the global competition have brought tremendous pressure into organizations way of life, demanding an effective presence on the Web and a more responsive and proactive attitude to realize its full potential. WUM is one crucial tool to bridge the gap between massive clickstream data and actionable knowledge, in order to devise Web site's opportune enhancements. However, WUM learning curve is a serious obstacle to inexperienced users, being pertinent to have a strategy showing the way how to proceed.

The proposed and developed work aims at promoting a more efficient, effective and synergetic exploration of WUM, decreasing the effort and time required to derive useful knowledge from clickstream data. To achieve this aim we designed, developed and implemented a prototype of a CBR system, specifically devoted to assist users on WUM processes, mainly on selecting proper mining methods and approaches to address analysis problems. The system also provides support to users on documenting and organizing the knowledge gained from the experience on solving new WUM problems, through a semi-automatic learning approach. The previous collected and stored WUM application cases are therefore the base that sustains the recommendation of mining plans to solve new problems.

We believe that the MPS system is a good tool for knowledge creation, sharing and reuse. The system is based on abstractions related to the real problems to solve, meaning that it could serve the particular needs of less skilled users, wishing to learn how to handle a concrete problem, being also useful to specialists interested in reusing successful solutions, instead of solving the problems from scratch. Data is always growing and is increasingly stored by organizations. DM tools are gaining more importance and KD processes are becoming more useful and widespread, although they remaining complex.

In this paper we described our system, focusing the retrieving of similar cases and its evaluation using a preliminary case base. These prepared cases reproduce WUM exercises descriptions publicly available, overcoming the need of a wide set of examples and the issue of the discoveries success subjectivity. The used datasets and the reproduced WUM processes are challenging and real applications of WUM, proving demanding conditions to test the MPS system. The cases contain some diversity of circumstances, which is beneficial to sustain the construction of a repository of this nature. The system's evaluation appealing to this preliminary case base also points to the system's effectiveness. A drawback to point out is the intentional generality of some abstractions used to categorize problems (e.g. analysis goals and application areas), which restricted their diversity. The potential of the approach has not been completely explored, since greater levels of abstraction might be achieved, enlarging the case base and developing further such categorizations.

For the future we plan to further evaluate the current implementation. This will be realized through the preparation of more cases and, particularly, within the context of a study case, based on a concrete target organization.

**Abstract**—Navigation as a part of an interface was always an important issue of a design process. Because information architecture and the navigation of current websites are very complex, especially of e-commerce websites or information portals, it is very hard to analyze or redesign a structure in a manual way. In order to solve the problem of automation of website structure analysis, there should be defined its model. Also, during the study of a subject it was found, that there is a lack of a quality estimator, which allows to valuate in a vary moments the quality of the structure. Observation of a structure quality gives possibility to analyze and decide when the structure should be changed basing on decision rules or calculated thresholds for analyzed amount of time.

The main aim of this study is to describe a model for website structure representation, derive the quality estimator, define and solve the problem of website structure discovery and quality valuation utilizing the proposed metric.

Finally, experiment with utilization of proposed methods is presented.

## I. INTRODUCTION

THE main task of the website is to provide the content and functionalities of the system. Such functionalities usually are placed to the sub-pages of the website. The main task of the navigation is to service efficiently and effectively users' requests, which are provided through these functionalities. Website usability is the measure of a success which users experience while interacting with the system. This is the extent to which users can achieve the desired objectives during their visit. Some of the website usability factors include: the compatibility of the site layout, ease of use of a search engine, adequate links that provide instant access to information, a site map which serves as a table of content for the whole site, legible fonts and appropriate use of colors to highlight and organize information or functionalities. All these factors contribute to the ease of use and make a visit on the website useful and enjoyable [1]. In 2001 Donahue [2] pointed, that difficult navigation with the limited flexibility constitutes the major problem of the usability. Therefore, a good solution for the navigation should be provided [3]. According to the National Institute of Standards and Technology [4] ease of navigation is essential for users at all lev-

*The research in this paper has been partially supported by: European Union in the scope of the European Regional Development Fund program no. POIG.01.03.01-00-008/08 and European Social Fund – fellowship “Młoda Kadra”.*

els of proficiency in using computers in order to navigate and obtain the desired information on the websites. It can be stated, that the number of planned functionalities at the design stage influences on the final number of pages and links [5]. Also it may be stated, that the increase of the quality of the interface is possible by increasing the quality of the structure of the navigation.

Users may come to the website in many ways: through the main page, as a result of the reference link from other websites, from the search results or an advertisement. Moreover, users have different goals and their objectives are very diverse. Navigation should support those differences through a variety of solutions: a hierarchical, task-oriented, chronological, alphabetical, and based on the popularity of information architecture [1]. It is required in order to avoid situation, that user will be trapped inside one page or reach the orphaned page [6]. On the static website or dynamic one with a limited number of links the navigation structure has a large impact on the quality of delivered content. Therefore, evaluation and improvement of the website structure becomes a key issue what repeatedly was underlined by researchers and experts of Human-Computer Interaction field of studies [7], [8], [9], [10], [11], [12], [13], [14], [15].

## II. WEBSITE STRUCTURE DISCOVERY

For the problem of quality valuation of the website structure there are some estimators in the literature of subject. Unfortunately, none of them treat the structure as a network and take into account such information as connections between pages, popularity of single pages, their position or utilization of edges connecting these pages among the website. Few proposed [16], [17] treat the website as a tree and in order to estimate aptitude of a structure they utilize knowledge such as click number into a page and distance from a root item. What is important is that distance from a root items is treated like in height in tree structures, what is not true for the website.

The motivation for solving the problem of a structure discovery with maximum data utilization and the problem of a structure quality measurement comes from a need to increase the efficiency of the interface redesign process. It can be reached by including into the process an automatic analysis of usage data and generating recommendations to change

existing website structures into modified ones – adapted to users' needs.

#### A. Model of a website structure

The mere idea of using graphs to model the structure of the website is widely used by practitioners and researchers. First, Perkowitz [18] used to describe links on a single webpage with the graph structures. In Garofalakis' studies [19] model of a website was described as a tree, because of optimization simplification. Yen et al. [20] defined the environment consisting of three layers of evaluation and expansion of website projects using graphs for modeling. In 2008 Yang defined the conceptual model for the structure [21] thus using ontological paradigm. Another way to model the website is to use Markov chains [22]. Also there can be found works inspired by PageRank algorithm [23], where web mining is used in order to optimize website structure [24].

The proposed model of a structure is understood as a set of unique pages which may be reached with an internal linking through navigation elements (Fig. 1b). The structure is mapped by a set of nodes and connections (Fig. 1a,c). The first node in a structure is called a root node, which is accessible through the default domain or IP address in a browser and returns the main page of a website. A navigation element may occur on one or many pages, but each time it may consist of a different set of pages and links. Connections between pages may be directed or undirected (Fig. 1c).

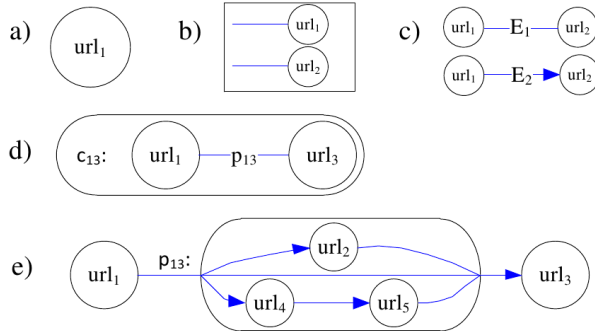

Fig. 1. Elements of website structure: a) a subsite, b) a navigation element, c) connection between two sites, d) path, e) connection.

Such defined website  $l$  is modeled as a graph structure in equation (1) of  $N$  nodes (pages) and  $M$  edges (links), where  $URL_l$  is a finite set of pages (1) which are in one domain in the range of  $l$  website and  $E_l$  (1) is a finite set of links which does not contain loops or reverse connections, where  $e_{li}$  is an edge from  $url_{lm}$  to  $url_{ln}$  to .

$$G_l = (URL_l, E_l, P_l, C_l), \quad URL_l = \{url_{li} \mid i \in [1, N]\} \quad (1)$$

$$E_l = \{e_{li} \mid e(m, n), m \neq n, m, n \in [1, N], i \in [1, M]\}$$

Basic elements of a structure model paths  $P$  (Fig. 1d) and connections  $C$  (Fig. 1e).

Path is a set of edges, which are the passage from one node to another. Paths are directed – if between nodes there is one

edge, or transitive – if on a path there is more than one intermediary node. Set of paths  $P_l$  is defined in (2).

$$P_l = \{p_{lij}, i, j \in [1, N] \mid \{e_{li} < e_{lj} \mid \exists p_{liz} \wedge \exists p_{lzz}, z \in [1, N]\}\} \quad (2)$$

A connection between two nodes exists if it is possible to pass from one node to another. The set  $C_l$  contains all connections in a graph, see equation (3).

$$C_l = \{c_{lij}, i, j \in [1, N] \mid \forall c_{lij} \exists p_{lij} \rightarrow url_{li} < url_{lj}\} \quad (3)$$

The length of from to is an average length of all paths between nodes (4).

$$D(c_{lij}) = \overline{p_{lij}} \quad (4)$$

Nodes and edges have additional characteristics and indicators, which will be used in a proposal of formulation of a quality estimator.

#### B. Node characteristics and indicators

Every node in the structure has a distance from the root node, which is calculated according to the distance function in equation (5). For the root node the distance equals 1. Pages are usually visited by users in such way, that nodes on lower levels are rarely visited. The form of equation was derived as a result of analysis of statistics gathered by Google Analytics of approximately 500 000 different users visiting 12 websites from different categories and left by them paths of visits.

$$d(url_{li}) = pow(\min|P(url_{l1}, url_{li})| + 1, \frac{1}{\sqrt{2}}) \quad (5)$$

Another characteristic for a node is *input-output* defined in equation (6), which is the sum of number of nodes, which edges point to the processed node and number of outgoing edges from the processed node (Fig. 2a).

$$io(url_{li}) = |\{e_{lj} \mid \exists e(i, n) \vee \exists e(m, i); i \in [1, N], j \in [1, M]\}| \quad (6)$$

Node indicators determine the characteristics based on usage data. These are:

- $OccU(url_{li}, [t, t + \tau_k])$  – specifies the number of edges used in all paths of all users of the website during the interval of time  $[t, t + \tau_k]$ ;
- $PopU(url_{li}, [t, t + \tau_k])$  – popularity of a node relatively to the entire structure of the website at the interval of time  $[t, t + \tau_k]$ , defined as equation (7);

$$PopU(url_{li}, [t, t + \tau_k]) = \frac{OccU_k(url_{li})}{N_l} \quad (7)$$

- $Acc(url_{li})$  – availability of a node in the structure defined in (8), is an ease for  $url_{li}$  to be visited by users and depends on the distance from the root and  $io$  characteristic;

$$Acc(url_{li}) = \frac{io(url_{li})}{d(url_{li})} \quad (8)$$

#### C. Edge characteristics and indicators

Characteristics for edges are:

- $Out(e_{ij})$  – specifies the number of all edges that come from the same node as the beginning of the edge. This indicator is illustrated in Fig. 2b and is defined as (9);

$$out(e_{ij}) = |\{e_{ij} | parent(e_{ij}) = url_{lm} \wedge parent(e_{ij}) = url_{lm}\}| \quad (9)$$

- $Reach(e_{ij})$  characteristic defined as (10) returns the number of nodes that can be achieved through following the edge (Fig. 2c). If a node, which indicates an edge, is a leaf, then the value of the characteristic equals 0.

$$reach(e_{ij}) = |\{url_{lj} | e_{ij} \in p_{lxj}; x, j \in [1, N]\}| \quad (10)$$

Indicators are defined as follow:

- $OccE(e_{ij}, [t, t+\tau_k])$  – specifies the number of occurrences of edges in all paths in the interval of time  $[t, t+\tau_k]$ ;
- The indicator  $r$  in (11) is an information about traffic between two nodes;

$$r(m, n) = \sum_{i=1}^{|p_{lij}|} OccE(e_{ij}, [t, t+\tau_k]), e_{ij} \in p_{lij} \quad (11)$$

- $PopE(e_{ij}, [t, t+\tau_k])$  is the edge's popularity (12) – a number of occurrence of an edge in all paths obtained from usage data in the interval of time  $[t, t+\tau_k]$ ;

$$PopE(e_{ij}, [t, t+\tau_k]) = \frac{OccE(e_{ij}, [t, t+\tau_k])}{|P_l|} \quad (12)$$

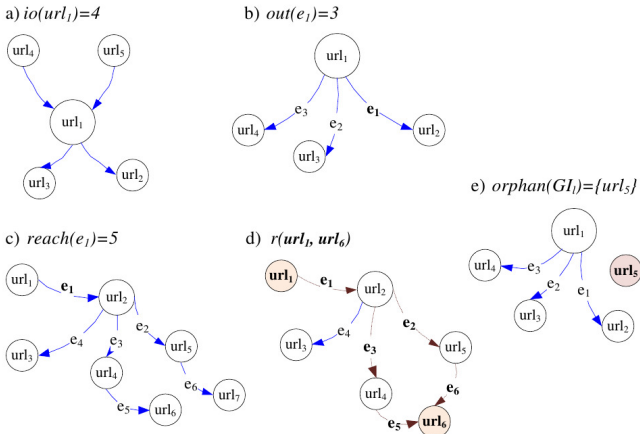

Fig. 2. Illustration of some characteristics of a model in a website structure.

#### D. Problem of a website structure discovery

Structure discovery is a required procedure for quality valuation task.

**For given:** URL address of the  $l$  website; usage data collected for the website  $l$ ; time  $k$ ;

**Determine:** website structure based on navigation patterns modeled as a graph  $GI_k$ .

There are several limitations: orphan pages (Fig. 1e) must be excluded; all internal content resources are excluded (i.e. mp3, avi, flv, swf etc. files), non-significant nodes in folders (e.g. /css, /media, /js, /admin) are filtered; limited response time for server; threshold of usage for every node (i.e. less than 1.5%) are ignored.

The proposed solution combines two approaches found in the literature:

- The structure discovered on the basis of usage. Such approach includes such nodes and edges, which are present in navigation patterns.
- The website crawled with a robot.

The structure is fully discovered after the results of two approaches are merged. It will effect with the structure containing detail information of both the navigation and the usage of nodes and edges. The solution of this task consists of three subtasks:

- The scanning task of structure;
- The process of exclusion of orphan nodes;
- The task of sampling and applying data obtained from statistics module.

An algorithm for website discovery is proposed (Fig.3). The scanning task is solved by using the method of multithreaded searching by a limited number of crawlers. It is assumed that the tested website has a system for monitoring the usage data. Such an external system through a connector does exchange data with the website.

Orphan nodes in the structure of the website are frequently the result of a human error. These are not nodes intently hidden from the user in the navigation, because such a node is discovered during obtaining the usage data.

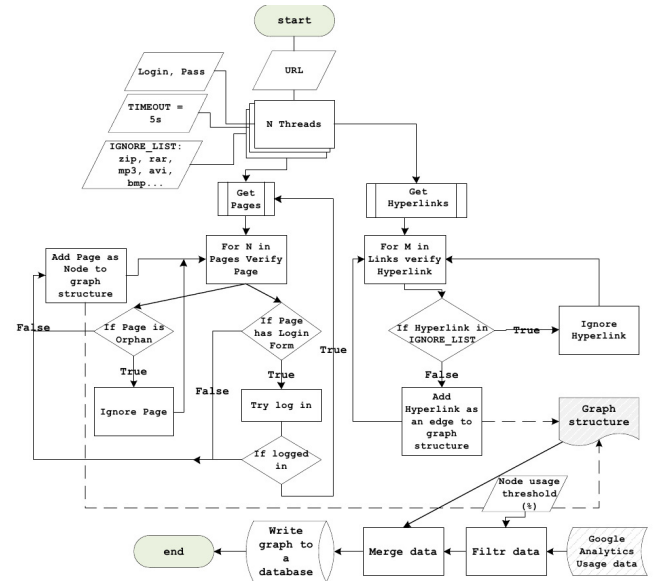

Fig. 3. An algorithm for discovering the website structure.

The node may contain links to external websites, but there is no reference to it from the navigation. Orphan exclusion is done in order to reduce the number of nodes that adversely affect the value of the quality estimator of the structure. Finding orphan nodes may help to understand which pages have not been connected with the others. This task is solved by using a recursive analysis of all the pages that contain at least one working internal link in order to detect all isolated nodes.

Fig. 4. A conference website [icss.pwr.wroc.pl](http://icss.pwr.wroc.pl), 13 nodes and 124 edges. a) Graph structure before MST processing; b) after processing with MST algorithm.

### E. Examples of discovered website structures

Using the proposed method of website representation it is possible to map simple structure with no connections between nodes. Such structure is constructed as a tree (Fig.4b, Fig.6). Because most of websites are graphs, in order to simplify the structure for analysis in terms of distribution of information in the nodes of the graph, a Minimum Spanning Tree (MST) algorithm is applied.

Fig. 5. Student's portal [edukacja.pwr.wroc.pl](http://edukacja.pwr.wroc.pl), 41 nodes, 142 edges with applied usage data discovered between 2010-08-01 and 2011-05-05.

Structures of e-commerce websites are very complex, manual modification of the structure is done by an information architect and it takes long time to process it manually. Such a structure can be optimized using only the recommendations or intuitive knowledge. Application of MST is used to solve this problem. Developed method of structure discovery is regulated with a filtering parameter which allows filtering nodes to address name or percent of usage. It is reasonable to set usage data parameter to a high value ( $>2\%$ ) for complex structures.

The spectrum of possible application of described method is shown on figures (Fig.4ab, Fig.5, Fig.6, Fig.7).

### III. PROBLEM OF QUALITY VALUATION OF WEBSITE STRUCTURE

The problem is: for given graph  $GI_t$  and history usage data in the interval of time  $[t, t+k]$  determine the quality of the website structure. Note that for various periods of time  $\tau$  the value of the quality estimator will be different. Assuming that the location of each node and the way of connections

Fig. 6. E-commerce website structure with 638 nodes with usage data discovered between 2009-05-05 and 2011-05-05.

Fig. 7. Hair beauty website structure with 30 nodes and 177 edges and usage data discovered between 2010-10-01 and 2011-06-01.

between them designates how users operate the website, the quality estimator should be dependent on the characteristics of the nodes and edges. Therefore there are defined quality criteria: number of node usage; number of edge usage; node position in the structure; the importance of a node; the importance of an edge.

Usage data results with information whether the originally designed structure is suitable for users or not. The quality measure should include popularity of nodes and edges. Therefore indicators of nodes and edges as defined in Section 2.B and 2.C are applied to develop the components of an estimator. Therefore, the node influence on the structure is defined as (13) and an indicator of the connectivity degree of an edge is defined as (14).

$$ImpU_k(url_{li}) = PopU_k(url_{li}) \cdot Acc(url_{li}) \quad (13)$$

$$CD_k(e_{li}) = PopE_k(e_{li}) \cdot \frac{reach(e_{li})/(N-1)}{out(e_{li})} \quad (14)$$

The quality estimator of the whole structure will be the sum of all values  $ImpU$  of the nodes proportional to the sum of edges values of  $CD$  and will be called Graph Energy and defined as (15).

$$En_k(GI) = \sum_{n=1}^N ImpU_k(url_{ln}) \cdot \sum_{m=1}^M CD_k(e_{lm}) \quad (15)$$

For the bare structure of the website it will be equal to 0 until the usage data will be applied. As the number of users during observed interval of time  $\tau_k$  may vary and thus generate different traffic within nodes and edges, characteristics of the graph in time  $\tau_{k+1}$  should be normalized proportionally to the value in  $\tau_k$  period.

#### A. Complexity of a website structure discovery algorithm

The initial method in order to discover all connections within graph has a complexity of  $O(N!)$  and is a NP-hard, therefore the proposed method of website discovery explores only the paths which are actually used by users in selected interval of time. Computational complexity of method consists of the execution of subtasks:

- Scanning task (Fig. 3) is of  $O(k(N+M))$ , where  $k$  is the maximum depth of the graph.
- Usage data extraction is of  $O(N+M)$  complexity, because of need to obtain data of every node and every edge.
- Calculation of the graph characteristics:  $io$  has  $O(N)$ ,  $out$  is of  $O(M)$  complexity,  $reach$  has  $O(M)$ ,  $d$  is of  $O(M+N \cdot \log N)$ .

The total complexity of the quality estimation after simplification is  $O(N \log N + M)$ . The crucial for this method is number of nodes in the structure.

#### B. Experiments

To test proposed methods different websites were analyzed and monitored. In Fig.8 there are two of them – the conference website ([www.icss.pwr.wroc.pl](http://www.icss.pwr.wroc.pl)) and the website of hair beauty salon ([www.salonczare.pl](http://www.salonczare.pl)). For both, the structure was scanned (Fig. 4a, Fig.7), then usage data was recorded and merged with the graph discovered by the crawler. The sampling of the Graph Energy was done daily (Fig.8), so the tendency could be better observed. There are two lines on Fig.8 – blue stands for the equation (15), and orange is a modified equation (15) with changed operation between  $ImpU$  and  $CD$  to the sum. Orange is less resistant for small changes, and blue is appropriate for long-term observations.

For the conference website, there were periods, where energy of the graph was lower or higher than average, and they are considered as potential points of change in the website structure, especially concerning the schedule of conference. Intuitively it is understood that the conference's structure should change in different periods of time i.e. paper submission, accommodation page before the conference start. As

the graph energy is higher, the structure of the website is utilized better by users and they may reach goals more efficiently. Observation of changes in the quality of the structure contributes to detection of the moments in which there are derogations from certain value  $En(\tau_k)$ . For the hair beauty website the lower line shows the  $En(\tau_k)$  (Fig.8b) and is inside lower and higher limit all the time with only twice short alarms detected. For the high and low limit Shewhart control chart [25] was utilized and for observing tendencies and making the decision of structure change Nine Nelson Rules [26] were applied.

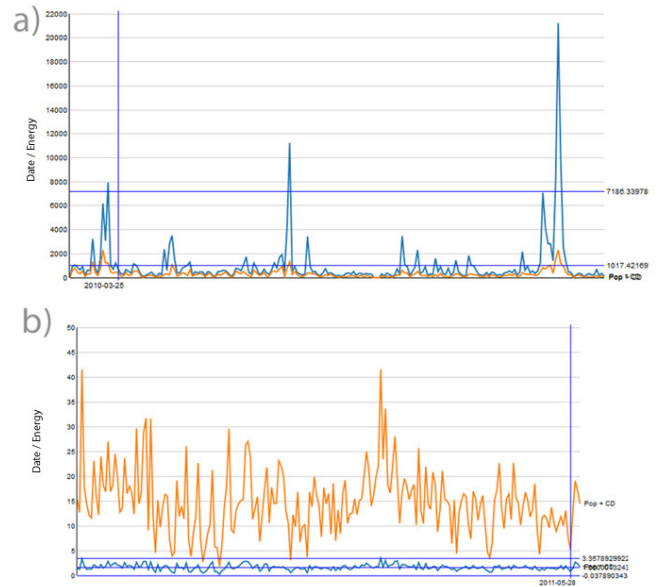

Fig. 8. Graph energy diagram of:

a) a conference website, b) a hair beauty salon website.

In order to compare results of two websites from the same categories (i.e. two beauty salons) the normalization of edge's and node's indicators should be done. More data on experiment and framework can be found in [27].

#### IV. SUMMARY

The main aim of this study was to state and propose a solution for structure discovering problem and quality valuation problem. A website structure quality estimator gives the ability to evaluate a website's navigation conformity to the way of how real users do use the website after its release to the general public. Besides consistency and repeatability, automation provides increased cost benefits to the developer. It improves the website redesign process and saves time.

In the future research there will be concerned following tasks. First, the problem of website structure optimization will be stated and the usage of quality metric based on Graph Energy will be proposed. Second, the problem of usage change detection will be stated and algorithms for it will be proposed. Third, the experimental framework will be upgraded with the new methods. Forth, the solution for discovering groups of users and recommending adapted structures to them individually will be proposed. The solution of all

discussed tasks will be an important step forward in studies on automated analysis, optimization problem and synthesis of website structures.

# International Workshop on Artificial Intelligence in Medical Applications

**T**HE WORKSHOP on Artificial Intelligence in Medical Applications – AIMA'2011 – provides an interdisciplinary forum for researchers and developers to present and discuss latest advances in research work as well as prototyped or fielded systems of Artificial Intelligence in the wide and heterogeneous field of medicine, health care and surgery. The workshop covers the whole range of theoretical and practical aspects, technologies and systems based on Artificial Intelligence in the medical domain and aims to bring together specialists for exchanging ideas and promote fruitful discussions.

The topics of interest include, but are not limited to:

- Artificial Intelligence Techniques in Health Sciences
- Knowledge Management of Medical Data
- Data Mining and Knowledge Discovery in Medicine
- Health Care Information Systems
- Clinical Information Systems
- Agent Oriented Techniques in Medicine
- Medical Image Processing and Techniques
- Medical Expert Systems
- Diagnoses and Therapy Support Systems
- Biomedical Applications
- Applications of AI in Health Care and Surgery Systems
- Machine Learning-based Medical Systems
- Medical Data- and Knowledge Bases
- Neural Networks in Medicine
- Ontology and Medical Information
- Social Aspects of AI in Medicine
- Medical Signal and Image Processing and Techniques
- Ambient Intelligence and Pervasive Computing in Medicine and Health Care

## PROGRAM COMMITTEE

- Jan Bazan**, University of Rzeszów, Poland  
**Leontios J. Hadjileontiadis**, Aristotle University of Thessaloniki, Greece  
**Hugo Gamboa**, New University of Lisbon, Portugal  
**Florin Gorunescu**, University of Medicine and Pharmacy of Craiova, Romania  
**Jerzy W. Grzymala-Busse**, University of Kansas, USA  
**Aboul Ella Hassanien**, Cairo University, Egypt  
**Yutaka Hata**, Graduate School of Engineering, University of Hyogo, Japan  
**Zdzisław S. Hippe**, University of Information Technology and Management in Rzeszów, Poland  
**Juliusz L. Kulikowski**, Polish Academy of Sciences, Poland  
**Lukasz Piątek**, University of Information Technology and Management in Rzeszów, Poland  
**Thomas Schrader**, University of Applied Sciences in Brandenburg, Germany  
**Andrzej S. Sluzek**, Nanyang Technological University, Singapore  
**Andrzej Skowron**, University of Warsaw, Poland  
**Paweł Strumiłło**, Technical University of Łódź, Poland  
**Ingo Timm**, University of Frankfurt, Germany  
**Daming Wei**, Hangzhou Dianzi University, China  
**Zygmunt Wróbel**, University of Silesia, Poland  
**Jerzy Wtorek**, Gdańsk University of Technology, Poland

**Abstract**—Adverse hospital patient outcomes due to deterioration are often preceded by periods of physiological deterioration that is evident in the vital signs, such as heart rate, respiratory rate, etc. Clinical practice currently relies on periodic, manual observation of vital signs, which typically occurs every 2-to-4 hours in most hospital wards, and so patient deterioration may go unidentified. While continuous patient monitoring systems exist for those patients who are confined to a hospital bed, the false alarm rate of conventional systems is typically so high that the alarms generated by them are ignored. This paper explores the use of machine learning methods for automatically identifying patient deterioration, using data acquired from continuous patient monitors. We compare generative and discriminative techniques (a probabilistic method using a mixture model, and a support vector machine, respectively). It is well-known that parameter tuning affects the performance of such methods, and we propose a method to optimise parameter values using “partial AUC”. We demonstrate the performance of the proposed method using both synthetic data and patient vital-sign data collected from a recent observational clinical study.

**Index Terms**—support vector machine, novelty detection, one-class classification, parameter optimisation, partial AUC.

## I. INTRODUCTION

### A. Detecting Patient Deterioration

**A**DVERSE events in acutely ill hospital patients may occur when their physiological condition is not recognised or acted upon early enough [1]. Clinical guidance in the UK [2] recommends the regular observational recording of certain vital signs (such as heart rate, HR, measured in beats per minute; respiration rate, RR, measured in breaths per minute; blood oxygen saturation, SpO<sub>2</sub>, measured as a percentage; and systolic blood pressure, SysBP, measured in mmHg), combined with the use of early warning score (EWS) systems. The latter involve the clinician applying univariate scoring criteria to each vital sign in turn (e.g., “score 3 if heart rate exceeds 140 beats per minute”), and then escalating care to a higher level if any of the scores assigned to individual vital signs, or the sum of all such scores, exceed some threshold.

This current standard of care has a number of disadvantages. (i) The early-warning scores assigned to each vital sign, and the thresholds against which the scores are compared, are mostly determined heuristically<sup>1</sup>. (ii) EWS systems are used

<sup>1</sup>However, a large evidence base of vital-sign data was used to construct the EWS proposed in [3], which is currently undergoing clinical validation in its own study.

with periodic observation of vital signs, which may be made as infrequently as once every 12 hours in some wards. Patients may deteriorate significantly between observations. (iii) There is a significant error-rate associated with manual scoring, especially in the high-workload setting of a high-dependency clinical ward. (iv) Each vital sign is treated independently and correlations between vital signs are not taken into account.

This paper addresses these four disadvantages by evaluating automated systems, which use novelty detection algorithms.

### B. Novelty Detection for Patient Monitoring

Novelty detection, or one-class classification, involves construction of a model of normality using examples of “normal” system behaviour, and which then classifies test data as either “normal” or “abnormal” with respect to that model. This technique is particularly applicable to the monitoring of high-integrity systems, such as jet engines, manufacturing processes, or human patients.

Monitoring high-integrity systems is difficult due to the variability between individual systems of the same system type (such as different human patients of the same demographic background). The few examples of “abnormal” system behaviour that may exist for some population are often inapplicable to the analysis of previously-unseen individuals. For example, a heart rate of 50 beats per minute may be indicative of considerable physiological abnormality in one hospital patient, while it may be entirely normal for a fitter patient of the same age and background.

Finally, high-integrity systems typically exhibit a high degree of structural complexity, and can often comprise many sub-systems that interact in a non-linear manner. Thus, the potential space of “abnormality” is extremely large, and so the large resultant number of failure modes is often poorly understood. For example, the exact response of a particular human’s physiology to a given failure mode (such as, for example, deterioration leading to myocardial infarction) will vary significantly between patients, and what data exist are insufficient for constructing accurate models of these failure states, typically being derived from a small number of patients, with differing co-morbidities, lifestyles, etc.

Novelty detection avoids such problems by modelling the “normal” mode of operation of the system, which is often well-understood because most high-integrity systems function

“normally” most of the time, and then looking for deviations from that normal model.

This is appropriate for the monitoring of physiological condition in patients, because sufficient data exist from “stable” patients such that a model of the well-understood “normal” state of these patients may be constructed. Physiological deterioration may then be detected as being corresponding departures in the vital signs from that “normal” state.

### C. Overview

This paper considers the one-class support vector machine (SVM), which is a commonly-used method of performing novelty detection. Its formulation is briefly recapped in section II, where disadvantages arising from the setting of its parameters are discussed. Following discussion on the topic of evaluating classifiers in section III, a method of optimising parameter values in a one-class SVM is described in section IV, in light of those evaluation methods. The method is illustrated using simulated data in section V and patient vital-sign data, collected from an observational clinical study, in section VI. Limitations of the method, and potential future extensions, are discussed in section VII.

## II. ONE-CLASS SVMs

The one-class SVM is a frequently-employed method of performing novelty detection, and it has been applied to many such problems, including jet engine condition monitoring [4], signal segmentation [5], and fMRI analysis [6], among many others, a review of which may be found in [7].

### A. Formulation

This paper considers the one-class SVM formulation proposed by [8], in which a quantity  $l$  of  $d$ -dimensional data  $\{\mathbf{x}_1, \dots, \mathbf{x}_l\} \in \mathbb{R}^d$  are mapped into a (potentially infinite-dimensional) feature space  $\mathbb{F}$  by some non-linear transformation  $\Phi: \mathbb{R}^d \rightarrow \mathbb{F}$ . A kernel function  $k$  provides the dot product between pairs of transformed data in  $\mathbb{F}$ :

$$k(\mathbf{x}_i, \mathbf{x}_j) = \Phi(\mathbf{x}_i) \cdot \Phi(\mathbf{x}_j) \quad (1)$$

A Gaussian kernel allows any data-point to be separated from the origin in  $\mathbb{F}$  [8], hence is chosen for us in the work described by this paper:

$$k(\mathbf{x}_i, \mathbf{x}_j) = \exp(-\|\mathbf{x}_i - \mathbf{x}_j\|^2 / 2\sigma^2) \quad (2)$$

where  $\sigma$  is the width parameter associated with the Gaussian kernel.

The decision boundary is a hyperplane in feature space  $\mathbb{F}$ , found by minimising the weighted sum of a support vector-type regulariser and an empirical error term depending on an overall margin variable  $\rho$  and individual errors  $\xi_i$ ,

$$\min_{w \in \mathbb{F}, \xi_i \in \mathbb{R}^l, \rho \in \mathbb{R}} \frac{1}{2} \|w\|^2 + C \sum_{i=1}^l \xi_i - \rho \quad (3)$$

$$\text{subject to } w \cdot \Phi(\mathbf{x}_i) \geq \rho - \xi_i, \quad \xi_i \geq 0 \quad (4)$$

where  $w$  is a weight vector in the feature space, and  $C$  is a user-specified penalty parameter, with a larger  $C$  corresponding to a higher penalty to errors [9].

The decision function in feature space  $\mathbb{F}$  is:

$$z(\mathbf{x}) = w_o \cdot \Phi(\mathbf{x}) - \rho_o \quad (5)$$

with parameters

$$w_o = \sum_{i=1}^{N_s} \alpha_i \Phi(\mathbf{s}_i) \quad (6)$$

$$\rho_o = \frac{1}{N_s} \sum_{j=1}^{N_s} \sum_{i=1}^{N_s} \alpha_i k(\mathbf{s}_i, \mathbf{s}_j), \quad (7)$$

where  $\mathbf{s}_i$  are the support vectors, of which there are  $N_s$ , and where  $k$  is the Gaussian kernel defined in (1). We note that  $w_o \in \mathbb{F}$ ,  $\rho_o \in \mathbb{R}$ , and that  $\alpha_i$  are Lagrangian multipliers used to solve the dual formulation, more details of which may be found in [8] and which are not reproduced here. The “abnormal” data (i.e., those outside the single, “normal” training class) take negative values of  $z(\mathbf{x})$ , while “normal” data take positive values.

We note in passing that this approach is typically employed in favour of the one-class formulation proposed in [10], [11], in which a hypersphere of minimum radius is found to enclose the data in  $\mathbb{F}$ . The interested reader is directed to a useful tutorial for this latter method in [12].

## III. RECEIVER OPERATING CHARACTERISTIC (ROC) CURVES

The performance of a two-class decision rule can be summarised in a receiver operating characteristic (ROC) curve, which plots the true-positive rate on the vertical axis against the false-positive rate (FPR) on the horizontal axis, as the decision threshold varies [13]. Although an ROC curve gives a more thorough evaluation of classifier performance than a confusion matrix, it is difficult to compare two ROC curves. One possible comparison is to consider the area-under-the-ROC-curve (AUC), which integrates the FPR over varying thresholds. AUC is independent of a fixed decision threshold, and is invariant to prior class probabilities [14]. AUC represents the probability that a randomly chosen positive observation is correctly classified, and therefore a higher value of AUC indicates better separation between the two classes [14], [15].

For the novelty detection approach taken by this work, we label the “normal” data as “negative” cases, for ROC analysis, and the “abnormal” data as “positive” cases. Most practical novelty detection systems require low FPRs, and so we are most interested in the ROC curve for low values of FPR when evaluating the performance of a novelty detector. (Its performance at higher FPRs is irrelevant, and possibly confounding, because these represent choices of decision threshold that would never be used in practice.)

We therefore consider *partial AUC*, to restrict evaluation of the classifier only over those ranges of decision threshold that

are likely to be used in practice. Partial AUC is defined as the integral area between two false-positive rates [16]. Unlike AUC, whose maximum value is always 1, partial AUC depends on the two chosen false-positive rates, over which the ROC curve is integrated. We will use this partial AUC metric for optimisation of SVM parameters.

#### IV. PARAMETER OPTIMISATION FOR A ONE-CLASS SVM

##### A. Choosing appropriate parameter values

For the case of a Gaussian kernel  $k(\mathbf{x}_i, \mathbf{x}_j)$ , it is important to choose an appropriate value for the bandwidth parameter  $\sigma$ . Larger values of  $\sigma$  result in smoother decision boundaries, which therefore tend to exhibit lower variance (i.e., better ability to generalise to previously-unseen data), at the expense of increased bias (i.e., under-fitting the “normal” data space, as represented by the “normal” training data). Conversely, smaller values of  $\sigma$  provide decreased bias (i.e., a closer fit to the “normal” data space, as represented by the “normal” training data), but at the expense of increased variance (i.e., they are less able to generalise successfully to previously-unseen data). The “optimal” value for  $\sigma$  will depend on the distribution of the particular dataset under consideration, and it is not usually obvious how one should choose the value of  $\sigma$ . Typically, a cross-validation exercise is performed, where one uses a validation set as an estimation of how well the system will perform in practice, when presented with previously-unseen test data.

For a Gaussian kernel  $k(\mathbf{x}_i, \mathbf{x}_j)$ , the quantity  $-\log k(\mathbf{x}_i, \mathbf{x}_j)$  is the Euclidean distance between two observations scaled by a factor  $1/2\sigma^2$ . Based on this link between  $\sigma$  and Euclidean distance, we propose the following method to determine an appropriate value for  $\sigma$  in our discriminative case, adapted from a similar method proposed in [17] for selecting  $\sigma$  when estimating pdfs for probabilistic inference within a generative framework:

- 1) First, we calculate the local average Euclidean distance  $\Delta_i$  of  $K$  nearest neighbours from each observation in the training set, where  $K = \sqrt{l}$ ,

$$\Delta_i = \frac{1}{K} \sum_{j \in \mathcal{D}} \|\mathbf{x}_i, \mathbf{x}_j\|, \quad \forall i = 1 \dots l \quad (8)$$

where  $\mathcal{D}$  is the set of  $K$  nearest neighbours for  $\mathbf{x}_i$ .

- 2) Next, the global average distance  $\Delta_G$  is found by averaging  $\Delta_i$  over all the training data,  $\Delta_G = l^{-1} \sum_i \Delta_i$ . The value of  $\Delta_G$  provides a guide for the range of  $\sigma$ , where we define  $\sigma = \kappa \times \Delta_G$ , where  $\kappa$  is a linking constant between the value of  $\sigma$  and the global average distance  $\Delta_G$  of any dataset. Therefore,  $\kappa$  provides a guide for the appropriate value of  $\sigma$ , which is independent of  $l$ . Once an appropriate value of  $\kappa$  is chosen for one dataset, it provides a good starting point for another dataset with similar dynamics (e.g., for another patient vital-sign dataset, allowing the value of  $\kappa$  to be reused from previous analyses, when the dataset has changed).

The other parameter to optimise in a one-class SVM is  $\nu$ , which will be defined as follows. The support vector constraints [9] in terms of the penalty parameter  $C$  from (3) are

$$\sum_i \alpha_i = 1, \quad 0 \leq \alpha_i \leq C. \quad (9)$$

allowing us to state<sup>2</sup> that  $1/l \leq C \leq 1$ . Also,  $C$  may be written

$$C = \frac{1}{\nu l} \quad (10)$$

so we have  $1/l \leq \nu \leq 1$ . Therefore,  $\nu$  and  $C$  take values in the same range.

The parameter  $\nu$  serves as an upper bound on the proportion of training observations that lie on the wrong side of the hyperplane, and is also a lower bound on the fraction of support vectors among normal training data [8]; i.e.  $\nu \leq N_s/l$ . Parameter  $\nu$  is used in this investigation instead of  $C$ , due to its clear meaning, as described above; the value of  $C$  can be easily recovered using (10).

Based on the above discussion, we will optimise parameters  $(\kappa, \nu)$  in section IV-B for the SVM approach taken in this paper.

##### B. Parameter optimisation using partial AUC

Combining the suggestions of the previous two sections, we take the following approach to optimising  $(\kappa, \nu)$ .

**STEP 1:** Choose a pair of parameter values  $(\kappa, \nu)$ .

**STEP 2:** Use the chosen  $(\kappa, \nu)$  to train a one-class SVM, which is dependent on a training set of “normal” data.

**STEP 3:** Use the resulting SVM to classify a validation dataset, which comprises both “normal” and “abnormal” data in equal quantity.

**STEP 4:** Compute partial AUC, using the validation results obtained in the previous step.

**STEP 5:** Repeat **STEP 1-4** using different values of  $(\kappa, \nu)$ , typically using a grid search. Choose the  $(\kappa, \nu)$  with the maximum partial AUC.

We assume the presence of *some* examples of “abnormal” behaviour, which are placed within the validation set for the purposes of parameter optimisation. However, as noted previously, these are likely to be small in quantity compared with the number of “normal” observations, and hence the training set is entirely comprised of “normal” data, and a one-class approach is taken.

A commonly-employed alternative which uses only “normal” data [12], [18] is to vary the SVM parameters until some fixed value of the false-positive classification rate is achieved (e.g., 0.05) when presented with the training set of “normal” examples. However, as demonstrated in [4], the overall expected performance of the one-class SVM can be improved by setting parameters by taking into account any available examples of “abnormal” data that may be available, even if they are few in comparison to the number of “normal”

<sup>2</sup>where the lower constraint arises because, in the worst case, we have all training data as support vectors and  $N_s = l$ , and therefore  $C \geq 1/l$  in order for  $\sum_i \alpha_i = 1$ . The upper constraint arises because  $\alpha_i \leq C$ .

training data. Therefore, we adopt the latter approach in our formulation, and include any available “abnormal” data in our validation set, described in the algorithm above.

## V. ILLUSTRATION USING SYNTHETIC DATA

The optimisation method described in the previous section is illustrated in this section using bivariate artificial data. We compare results obtained with the SVM to a commonly-used generative method of novelty, that of the Gaussian mixture model (GMM). The latter technique has been used for novelty detection in many applications, the details of which are surveyed in [7]. It is of particular interest to the investigation described by this paper, because previous work in performing novelty detection in patient vital-signs has used a generative approach, comprising a mixture of Gaussian kernels [19], [20].

### A. Methodology

The dataset employed in this section comprises 200 “normal” and 200 “abnormal” data, with distributions that are concave in support, as shown in figure 1. For the purposes of evaluating novelty detection algorithms, 50% of both datasets were held back for testing. 40% of the “normal” data are used for training, with the remaining 10%, and all remaining “abnormal” data, used for validation.

For the SVM, the training and validation procedures (in which parameter optimisation occurs) proceed as described in section IV-B.

The GMM is defined by the pdf

$$p(\mathbf{x}) = \sum_{i=1}^M \pi_i p(\mathbf{x}|\boldsymbol{\theta}_i) \quad (11)$$

which is comprised of  $M$  component distributions, each of which has a prior probability  $\pi_i$  and a likelihood  $p(\mathbf{x}|\boldsymbol{\theta}_i) = \mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_i, \boldsymbol{\Sigma}_i)$ , where  $\boldsymbol{\mu}_i$  and  $\boldsymbol{\Sigma}_i$  have their usual meanings of the centre and covariance matrix for multivariate Gaussian  $i$ , respectively. The training procedure finds appropriate values for the quantities shown in (11); in this case, the maximum likelihood estimates were determined using expectation maximisation [21].

Novelty detection with a GMM is typically performed by setting a decision threshold on the pdf  $p(\mathbf{x})$ , which, as with the decision boundary of the SVM, may be set (i) using only “normal” data, whereby one finds that threshold that yields some pre-determined false-positive rate, or (ii) using a validation set that contains any available “abnormal” examples. In order to allow a direct comparison with the SVM, the latter approach was taken for setting the GMM decision threshold, and partial AUC was again used as the optimisation metric, the minimum of which (with respect to the validation set) yields the “optimal” value of the decision threshold on the pdf  $p(\mathbf{x})$ .

### B. Results

Figure 1 shows the output of both GMM and SVM novelty detectors when presented with the previously-unseen test dataset. The upper plot shows  $p(\mathbf{x})$  for the GMM, where the decision threshold on the pdf is shown as a black contour

(a) GMM  $p(\mathbf{x})$

(b) SVM  $z(\mathbf{x})$

Fig. 1. (a) GMM output  $p(\mathbf{x})$  using the “optimal” parameter values determined using validation; “normal” training data are shown by white  $\{\cdot\}$ , and “normal” and “abnormal” test data are shown by white  $\{+\}$  and black  $\{+\}$ , respectively. (b) SVM output  $z(\mathbf{x})$  using the “optimal” parameter values determined using validation; labelling scheme as above, with support vectors circled.

on the pdf, which describes the locus of the “normal” training data (shown as white dots). The test data are shown as crosses in white and black for “normal” and “abnormal” classes, respectively. It may be seen that the training and validation procedure resulted in  $M = 3$  component distributions being used, where these distributions were constrained to have isotropic covariance matrices (although each may be assigned a different determinant during training).

The lower plot shows  $z(\mathbf{x})$  for the SVM, as defined in (5), where the decision threshold (which occurs at  $z(\mathbf{x}) = 0$  for a SVM) is shown as a black contour. The symbols used are the same as those for the GMM plot, described above, where training examples that are support vectors ( $\alpha_i > 0$ ) are circled in white.

Table I shows results obtained from both GMM and SVM when applied to the previously-unseen test data. Defining true-

TABLE I

NOVELTY DETECTION PERFORMANCE OF GMM AND SVM APPLIED TO TEST DATA, AT “OPTIMAL” THRESHOLD. ONE STANDARD DEVIATION ON THE RESULT IS SHOWN FOR EACH, USING THE RESULTS OF 50 EXPERIMENTS, IN WHICH EACH EXPERIMENT INVOLVES RANDOM SELECTION OF NEW TEST DATA FROM THOSE AVAILABLE, WITH EQUAL NUMBERS OF TEST DATA DRAWN FROM THE “NORMAL” AND “ABNORMAL” CLASSES.

Classifier	Accuracy	Partial AUC	Sensitivity	Specificity
GMM	$0.95 \pm 0.01$	$0.28 \pm 0.01$	$0.95 \pm 0.01$	$0.93 \pm 0.03$
SVM	$0.96 \pm 0.01$	$0.30 \pm 0.01$	$0.99 \pm 0.01$	$0.88 \pm 0.01$

Fig. 2. ROC curve for results obtained using GMM and SVM to classify previously-unseen artificial test data, shown in blue and red, respectively. The mean of 50 experiments has been shown at each point on the ROC curve, where each experiment involves random selection of new test data from those available, with equal numbers of test data drawn from the “normal” and “abnormal” classes.

positive, true-negative, false-positive, and false-negative to be TP, TN, FP, and FN, respectively, then *accuracy* is defined to be  $(TP + TN) / (TP + TN + FP + FN)$ , *sensitivity* is  $TP / (TP + FN)$ , and *specificity* is  $TN / (TN + FP)$ . It may be seen that both methods perform similarly with this simple bivariate example, with the SVM performing marginally better overall, as shown by slightly higher accuracy and AUC results. It achieves this with a higher sensitivity, at its “optimal” threshold, at the cost of a lower specificity. This is confirmed in figure 2, which shows an overall higher ROC curve for the SVM than the GMM.

We conclude that the training and optimising procedures for both techniques result in stable, usable parameter configurations, and hence we now extend our analysis to consider higher-dimensional patient vital-sign data, as acquired from a recent clinical study.

## VI. PATIENT VITAL-SIGN MONITORING

This section reports results obtained from evaluating both GMM and the proposed SVM method for patient vital-sign monitoring.

TABLE II

NUMBER OF CLINICAL OBSERVATIONS IN THE TRAINING, VALIDATION, AND TEST SETS

	Train	Validate	Test
Normal	1,240	65	65
Abnormal	0	65	65

### A. Dataset

We consider vital-sign data acquired from patients in a “step-down unit” (SDU), which is a level of acuity lower than that of the intensive care unit (ICU). There is a significant need for effective novelty detection systems in such wards, because patient deterioration can go unnoticed by clinical staff, leading to adverse patient outcomes. Existing patient monitors generated univariate alarms whenever vital signs exceeded some pre-defined threshold, and often go unheeded due to the high false-positive rate of such alarms, where [22] reported results of a study in which it was deemed that 84% of alarms from conventional continuous patient monitors were false alarms.

The dataset used for the work described by this section comprises measurements of heart rate, respiratory rate, blood oxygen saturation, and systolic blood pressure, acquired once every four hours by ward staff (as is common practice in most SDU-level wards in the UK and the US) at the Oxford Cancer Hospital, Oxford, UK. 1,500 such clinical observations  $x_i \in \mathbb{R}^4$  were acquired from 19 patients, who were recovering from upper gastro-intestinal surgery.

### B. Methodology

130 of the clinical observations were deemed by clinicians to be sufficiently “abnormal” that the patient would require clinical review. The remaining 1,370 were thus classified as being “normal”. The available “abnormal” data are insufficient to train a multi-class classifier, being small in comparison with the number of “normal” data, and therefore the novelty detection approach is justified for this clinical application.

Table II shows how the 1,500 observations may be assigned to each of the training, validation, and test sets. The available examples of abnormality must be split between the validation set (to enable parameter optimisation, as described in section IV-B) and the test set (to allow evaluation of the results); therefore, the 130 examples of abnormality are split equally between validation and test data. Similar numbers of “normal” data are required for each of the validation and test sets; the remainder of the “normal” data are placed into the training set, as shown in the table.

The split between the training, validation, and test sets was performed randomly. In order to test the variability of the results to this random partitioning, 50 experiments were performed, each experiment containing a different random partition of the data between the three sets, and each experiment requiring retraining, revalidation, and retesting, in order to obtain fully independent results for each experiment.

Fig. 3. The upper plot shows time-series of vital signs for an exemplar patient, showing HR, BR, SpO<sub>2</sub>, and BP in green, purple, blue, and red, respectively, with time (in hours) shown on the horizontal axis. The lower plot shows novelty scores derived from GMM output  $-\log p(\mathbf{x})$  and SVM output  $z(\mathbf{x})$  on the same time-base, in blue and red, respectively. Horizontal lines in the lower plot show the decision thresholds for the GMM and SVM in blue and red, respectively.

### C. Results

An example of the application of the techniques to patient vital-sign data is shown in figures 3 and 4.

The first example shows a patient who enters the ward, following surgery, in a state of physiological derangement, as shown by elevated BP (at around 180 mmHg). The patient begins to stabilise, but, after 10 days, episodes of tachycardia (elevated HR, reaching 150 bpm) may be seen, with a corresponding increase in RR from 10 breaths/min to 20 breaths/min. The patient then stabilises again, but deteriorates significantly after 45 days, showing periods of prolonged hypotension (decreases in BP below 60 mmHg), with corresponding tachycardia (HR reaching 160 bpm), and desaturations (SpO<sub>2</sub> decreasing to 84%).

The output of the GMM and SVM are shown beneath, along with their decision thresholds. For the purposes of visualisation, the output of the GMM, which is a density  $p(\mathbf{x})$ , has been scaled into a novelty score  $-\log p(\mathbf{x})$  such that it takes high values for data with low density; i.e., “abnormal” data will take high novelty scores. The SVM output needs no such transformation, as it takes positive values when data on the “non-normal” side of the decision boundary are presented.

It may be seen from the figure that both the SVM and the GMM increase in value during the initial post-surgical period of abnormality, during the transient period around 10 days, and in the final period of deterioration. The similarity of the GMM and SVM output is not accidental, as the  $-\log p(\mathbf{x})$  scaling of the GMM output makes it a comparable score to the SVM, because the SVM asymptotically approaches the level sets on the pdf in its tails [23].

The second example shows a patient who is similarly unstable at the start of their admission to the Cancer Hospital ward, following surgery. This patient exhibits bradycardia (low HR, decreasing to 40 bpm). After 5 days, periods of apnoea

Fig. 4. The upper plot shows time-series of vital signs for a second exemplar patient, showing vital signs and novelty detection output as in the first example.

TABLE III  
NOVELTY DETECTION PERFORMANCE OF GMM AND SVM APPLIED TO TEST CLINICAL DATA, AT “OPTIMAL” THRESHOLD. ONE STANDARD DEVIATION ON THE RESULT IS SHOWN FOR EACH.

Classifier	Accuracy	Partial AUC	Sensitivity	Specificity
GMM	0.92 ± 0.03	0.25 ± 0.02	0.92 ± 0.04	0.92 ± 0.04
SVM	0.95 ± 0.01	0.28 ± 0.02	0.98 ± 0.01	0.92 ± 0.03

are evident (low BR, decreasing below 10 breaths/min) with corresponding decreases in SpO<sub>2</sub>. Periods of abnormal physiology occur after around 15 days, with transient hypertension (increases in BP over 160 mmHg). Finally, a period of extreme deterioration may be seen at the end of the patient stay, with extreme hypertension (BP exceeding 200 mmHg) and corresponding extreme desaturation (SpO<sub>2</sub> decreasing below 82%).

It may be seen that, again, both the GMM and SVM scores increase above their respective decision thresholds for these periods of abnormality.

Table III shows the overall results for both GMM and SVM after 50 experiments. Unlike the bivariate case considered in section V, there is a significant difference between the results obtained from each method. The SVM achieves higher accuracy and partial AUC, as before, but matches the specificity of the GMM (0.92 to 0.98) while improving on the sensitivity (from 0.92 to 0.98).

This is confirmed by the ROC plots shown in figure 5, in which it may be seen that the ROC curve for the SVM is higher than that for the GMM throughout most of the interval on the horizontal axis.

## VII. CONCLUSIONS AND DISCUSSION

We have proposed a method for optimising SVM parameters in a natural manner, considering  $\nu$  and  $\kappa$ , which, we have argued, have a more intuitive interpretation than the conventional  $C$  and  $\sigma$  parameters (assuming that a Gaussian kernel is used).

Fig. 5. ROC curve for results obtained using GMM and SVM to classify previously-unseen clinical test data, shown in blue and red, respectively. The mean of 50 experiments has been shown at each point on the ROC curve, where each experiment involves random selection of new test data from those available, with equal numbers of test data drawn from the “normal” and “abnormal” classes.

While we have demonstrated the method for one-class SVMs, they are equally applicable to two- and multi-class SVMs.

Clinical data acquired from a recent observational study of Cancer Hospital patients have been used to demonstrate that automated methods can be used to identify patient deterioration. Existing methods, based on generative mixture distributions have been shown to be outperformed by SVM-based novelty detection on the preliminary data considered so far in this study. This is perhaps unsurprising, given that the SVM minimises its objective function so as to result in a small number of misclassifications in the high-dimensional space of the vital signs. In comparison, generative methods, while offering more functionality than a discriminative method, typically exhibit higher misclassification rates.

The on-going clinical study will result in further data on which to confirm these preliminary findings.

#### ACKNOWLEDGEMENTS

LC was supported by the Overseas Research Students Award Scheme, provided by the UK Government, and later by the NIHR Biomedical Research Centre Programme, Oxford. DAC was funded by the Centre of Excellence in Personalised Healthcare funded by the Wellcome Trust and EPSRC under grant number WT 088877/Z/09/Z. The authors wish to thank Sarah Vollam and Deborah Evans for the collection of clinical data used in this investigation.

**Abstract**—Over the last decades has the research on Data Mining made a great progress. Also the Computerized Patient Records (CPR) as part of Hospital Information Systems have improved in terms of usability, content coverage, and diffusion rate. The number of Health Care Organizations using the CPR is growing. Causally determined is the need for techniques and models to provide solutions for decision making based on the data stored from different sources in CPR. This paper provides an overview on the current research trends and shows the impact on the medical domain with the CPR.

## I. INTRODUCTION

INTERNATIONALLY the Computerized Patient Records (CPR) became growingly more important for health care institutions. The number of institutions changing over from the paper based patient files to the CPR are increasing. This evolutionary development will increase with the establishment of Data Mining (DM) and the associated techniques and applications. Before DM the CPR has been known as centralized data storage for patient data with limited the possibilities to analyze, to process, and to use the data for other questions except for some simple cases. This is the reason for using the word CPR instead of Electronic Patient Records which represents the limited analyzability of the patients data in the past.

The amount of medical and patient oriented data stored in CPR has grown strong progressive. The CPR contains medical data, laboratory data, and images from different modalities and organizational data from different sources with the purpose of patients care. DM is the key technology to evaluate, interpret and link information of the large amount of data. DM improves the value of CPR to support the process of decision-making and medical diagnosis [1].

In the context of medical data DM uses algorithms, tools, lifecycles of knowledge, and formalizations to extract patterns, information and knowledge from data stored in the CPR. DM transforms transactional data in the CPR from tacit knowledge into explicit knowledge [2]. In this context it is important to mention the link of DM to Knowledge Management (KM). KM is the system and managerial approach to the gathering, management, use, analysis, sharing, and discovery of knowledge [3]. KM deals with eliciting, representing, and storing explicit data. DM is a subfield of KM and is used as part of the knowledge discovery process. KM and DM have the same fundamental issues and must be com-

binated in the decision making process. Especially in medical applications the interaction and integration of DM and KM is essential [4]-[6].

DM is becoming an area of great interest for clinical practice and research as medical decisions must always be supported by arguments, and the explanation of decisions and predictions should be mandatory for an effective deployment of DM models. DM and KM are the most important technologies for enabling Evidence Based Medicine, which proposes strategies to apply evidence gained from scientific studies for the care of individual patients [7].

There are some scientific research projects with the purpose of merging clinical and research objectives like the I2B2 project at the Harvard University [8].

DM is the essential part of futures CPR. The objective of this paper is to give an overview of current research trends of DM in CPR. Firstly the Computerized Patient Record with its characteristics is described. DM is especially in CRP valuable and essentially necessary. Also the basic tasks of DM will be described in the paper. The following DM models of sophisticated machine learning models will be focused with their impacts on CPR in a separate section: Symbolic Learning vs. Rule induction, Case Based Reasoning, Natural Language Processing, Artificial Neuronal Networks, Bayesian Networks, and Fuzzy Models.

Not in scope of this paper is the view on aspects of technical systems, special tools for the DM techniques, description of underlying methodologies, legal issues, data privacy, and data security.

## II. CHARACTERISTICS OF COMPUTERIZED PATIENT RECORDS

The CPR is a collection of data in a database or repository, which is managed by application programs. It is a key part of hospital information systems. All relevant data and the investigations and interventions for one patient in one health care institute are collected in a structured manner and without redundancy in the electronic patient record. The data is stored on digital media and are always available electronically. The difference to data files in other segments like economical data of a customer is based on the complexity of medical data of patients [1], [4], [9].

The electronic patient file contains data from different areas [10]-[13] like personal details, billing information, case or medical history, clinical test results, diagnoses from dif-

ferent specialists, therapy information, digital pictures from various modalities, pictorial archiving of historical pathologic findings, important treatment data and results of control tests, representation of specific content for the single specialists (Anesthesiology, Radiology, Pathology, Cardiology, Endocrinology, Pharmacology, Odontology, Accident Medicine, ...), and nursing measures.

The complexity is not only based on the broad range and variety of data in the CPR, but also evolved from the input from many different sources of the data. Different sources of technical systems as well as the multiple groups inserting and extracting data in the CPR give a good impression of the complexity of CPR data.

Another characteristic for CPR is the huge amount of medical data. Pictures made with different modalities like Computer Tomography (CT) or Magnetic Resonance Tomography (MRT) as well as the measurement of laboratory and pathological reports produce a very large and storage intensive amount of data for each single patient. Having this in mind it is understandable that data in CPR reach many Giga-Bytes. The trend is rising as the sophisticated technical possibilities are growing and going much and creating more data.

The CPR provides a multidisciplinary information exchange for communication between the different stakeholders in health care institutions like medical doctors, physicians, laboratories, nurses, other members of the health care team and the administration and controlling staff [14].

The purpose of the CPR is divided into following prioritized areas [11]:

1. Patient care: The CPR provides the documented basis for planning care and treatment.
2. Communication: All stakeholders have the same information on a patient. This allows the communication with each other with the same actual data basis on a patient.
3. Legal documentation: Documentation of the treatment as well as the legal forms signed by the patient.
4. Billing and reimbursement: Coded treatment with e.g. International Classification of Diseases (ICD-10) or Diagnosis-related groups (DRG)
5. Research
6. Quality Management

The characteristics of DM in CPR and the uniqueness of medical data are the challenge in this field [4] are the volume and complexity of medical data, the importance of physicians interpretation, the sensitivity and specificity analysis, poor mathematical characterization of medical data, the canonical form, and ethical, legal as well as social issues (Data ownership, privacy and security)

### III. DATA MINING IN CONTEXT WITH KNOWLEDGE MANAGEMENT

Data Mining extracts patterns, explicit knowledge and information from data. The objective of data mining in this context is to support the medical doctor and the health care institution in decision making.

Data mining analyzes data and extracts models that allow the interpretation and transformation of the raw data in the CPR into knowledge. This is the entry point for knowledge management to create tacit knowledge. KM is the system and managerial approach to the gathering, management, use, analysis, sharing, and discovery of knowledge [3], [15]. KM deals with eliciting, representing, and storing explicit data. DM is a subfield of KM and is used as part of the knowledge discovery process. KM and DM have the same fundamental issues and must be combined in the decision making process. Especially in medical applications the interaction and integration of DM and KM is essential [4].

Data analysis in medicine depends more than in other areas on medical background knowledge. Further approaches, such as association and classification rules, joining the declarative nature of rules, and the availability of learning mechanisms are a great potential for effectively merging DM and KM [16].

Over the past years have many ontologies been developed. Ontologies have an important role in DM to facilitate knowledge sharing between different sources. An ontology is a specification of conceptualization. It describes the concepts and relationships that can exist and formalizes the terminology in a domain [17], [18].

### IV. DATA MINING RESEARCH IN COMPUTERIZED PATIENT RECORDS

The shown characteristics of medical and organizational data in CPR lead to the special problem of analyzing and linking data from different sources and qualities together. Especially in the CPR are many information hidden and are important to be revealed. The hidden information in the raw data are also caused by the complexity of the medical domain in CPR. It is easy to lose the track of a disease if different medical doctors make a diagnosis in their own domain and do not compare their findings with each other. Data mining can bridge the important gap and bring together the essence of the information.

Data mining and knowledge creation is more than a set of techniques for data analysis, it is the key for extracting information out of the mentioned data. Without data mining the storage of the data in the CPR would be not necessary as this makes the difference to the patients files based on paper.

Data mining techniques build a group of heterogeneous tools and techniques to different purposes along the process to create knowledge. There are descriptive and predictive models. The descriptive models identify similar patterns in the analyzed date by using classification, association rules and visualization. Predictive models use classification, regression and time series analysis to show the impact of a treatment to a patient based on the data of the past. Another way to categorize most of the data mining techniques distinguishes them into model building and clustering techniques. Model Building seeks to create a predictive model related to a specific question. Depending upon the techniques chosen, a model may be either opaque (results are clear, but the functions are unclear) or transparent (complete knowledge about the model at any prediction). Clustering attempts to segment

a population into one or more groups that have (as far as we are concerned) similar characteristics and are therefore expected to behave in a similar manner.

The following list shows the commonly used techniques of data mining for knowledge discovery [19]-[22]:

1. Summarization: The relevant Data from the CPR have to be generalized and abstracted. The result of this step is the set of task-relevant data.
2. Classification: Classification is the process of assigning data items to one or many predefined classes. The classification model contains a set of classification rules. These rules are also used for future data. It derives a function or model, which determines the class of a model based on its attributes [22]. For the CPR is the definition of the rules a complex task as the rules have to cover a deep understanding of medical and economical knowledge. In the medical diagnosis, the classification is the most critical data mining technique. An example for classification is the definition of a group of patients with high blood pressure and the assignment of equivalent patients to the group. Classification is in the most important task of DM in CPR [20]. Classification is a DK task for which also other Artificial Intelligence approaches like neural networks and decision trees are often used.
3. Association: Search the records and finding association patterns by using defined rules. For example search for a set of symptoms of diseases of patient, hat also occur to patients with other diseases. Automated systems are filtering association rules based on findings from medical transaction databases: Association rules are ranked for medical knowledge by using formal ontologies.
4. Clustering: The clustering identifies classes or groups for a set of objects. The clustering maximizes the similarities of objects assigned to a class. This is based on the criteria defined on the attributes of the objects. After the decision and assignment process of an object to the cluster, the objects are labeled with the corresponding cluster.
5. Trend analysis or time series analysis: The Trend is the result of comparing time related data over a period of time, e.g. blood pressure over a period of one month. The objects are snapshots of entities with certain values that can change over the time.
6. Forecasting: This is the prediction of the value for an object based on the data from the past.
7. Visualization techniques: They help to discover patterns in medical data sets as a starting point. Afterwards other data mining techniques have to be used to determine the details of the patterns.

## V. SETTING THE TREND OF DM WITH A SELECTION OF TECHNIQUES AND MODELS

The selection of DM techniques and models shows the trend of DM in CPR with a brief review of the key concepts.

Since the beginning of DM it was the aim to automatize DM techniques and models and to reduce the participation of human actions to a minimum. The beginning of this chapter describes Machine Learning, before the machine learning methods are described.

Machine Learning algorithms can be divided into supervised and unsupervised learning algorithms. In supervised learning, training examples exist of input-output pair patterns. Learning algorithms try to predict output values based of new examples, based on their input values. In unsupervised there are only input patterns without an explicit output available. Here is the aim of the algorithms to use input values to discover meaningful associations or patterns [3].

### A. Probabilistic and Statistical Models

Probabilistic and statistical analysis techniques and models have a strong theoretical foundation in DM research. Assigned to the statistical techniques are regression analysis, discriminant analysis, time series analysis, principal component analysis, and multi-dimensional scaling. Because of their maturity those models are often used as benchmarks for comparison with newer machine learning techniques [3].

An advanced and popular probabilistic model for CPR is the Bayesian Model. It was originated in pattern recognition research and frequently used to classify different objects into predefined classes based on a set of features. The model stores the probability of each class, each feature, and each feature given each class, based on the training data. New instances will be classified according to the existing probabilities. There are many variations of the Bayesian Model.

An important and popular machine learning technique is the Support Vector Machines (SVM). It is based on statistical learning theory, which aims to find a hyperplane to best separate two or many classes. The applied model has shown encouraging results as it has the performance among other learning methods in document classification [3].

### B. Symbolic Learning

Symbolic learning is implemented by applying algorithms that attempt to induce general concept descriptions that describe different classes of training example [3]. Many algorithms have been developed using algorithms to identify patterns that are useful in generating a concept description. Given a set of objects, symbolic learning created a decision tree that classifies all given objects correctly. At each step, the algorithm finds the attribute that best divides the objects into the different classes by minimizing the uncertainty. This way it is possible to create complete treatment plans in CPR [23]

### C. Case Based Reasoning

CBR is a problem solving paradigm that utilizes the specific knowledge of previously experienced situations or cases. It consists in retrieving past cases that are similar to the current one and in reusing solutions which were used successfully in the past, the current case can be retained. CBR provides a solution for solving new problems and understanding unfamiliar situations.

In medicine, CBR can be seen as a suitable instrument to build decision support tools able to use tacit knowledge [24].

The algorithms find similarities of cases by using tacit knowledge. The data of experiences are compared to similar solutions that were successful in past cases [25].

The classic CBR uses a cycle with the steps of retrieve, reuse, revise, and retain. An example for CBR in using CPR is if a medical doctor wants to decide whether or not to prescribe a special medication for a patient or not. With CBR the decision would include the medical history of the patient and all patients with similar patterns, their physical states, emotional states, observed behaviors, cognitive status, as well as safety concerns. Each case in a CBR application aims to support the decision making process and therefore contains specific information of these factors for an individual patient [25]. The knowledge base is the collection of those cases in a library or the case base. The case base is organized to facilitate retrieval of the most similar, or most useful experiences when a new case arises. The past solutions would be the starting point for solving the new case. This is the first step of CBR, retrieve. Reuse is the step where adjustments are necessary to fit the case to the new situation. The result of the reuse step is a suggested solution. In case of further necessary adjustments is the revise step necessary. Here is the output the tested and repaired case with a confirmed solution. The last step in the CBR cycle enables the system to grow and to learn from the acquired experiences. According to [25] CBR is particularly useful and applicable in health science and the CPR because of established histories for health care professionals, many publications that can be easily encoded in cases, reasoning from many existing examples, extensive data stores are available in CPR, and cases can complement general treatment guidelines to support personalized medical care for individual patients

The formalization of medical facts and their relations results in a high complexity, but there are many examples and cases of diseases, treatments and outcomes. Furthermore, many diseases are not well enough understood in medicine to have universal applicable treatments

The main selection of CBR systems in health care in their order of chronological appearance are SHRINK: Aid with psychiatric diagnosis and treatment [26], MNAOMIA: For diagnosing and treating psychiatric eating disorders [25], PROTOS: Diagnosis of audiological and hearing disorders [25], [27], CASEY: Diagnosis of heart failure patients by comparing them to earlier cardiac patients with known diagnoses [25], ICONS: Therapy planning system that recommends antibiotic therapy for patients with bacterial infections in the intensive care unit (ICU) [28], KASIMIR: Breast cancer decision support system that also takes missing data and the threshold effect into account [29], and HR3Modul: Decision support system for diagnosing stress related disorders, including signal measures like breathing and heart rate expressed as physiological time series [30].

An important trend of CBR for CPR is the integration of multimedia case representation. This allows using CBR for medical image interpretation for comparing pictures of different modalities of different patient [31]. CBR is also useful for including other factors in the decision process like the co-occurrence of multiple diseases, time series features, overlapping diagnostic categories, the need to abstract features

from time series representing temporal history, sensor signals, and continuous data.

#### *D. Natural Language Processing*

The content of CPR include a rich source of data and are often the major bottleneck for the deployment of effective clinical applications because textual information is difficult to access by computerized processes. Natural Language Processing (NLP) systems are automated methods containing some linguistic knowledge that aim to improve the management of information in text [32]. NLP allows the extraction of information and knowledge from medical notes, discharge summaries, and narrative patients reports. Current efforts on the construction of automated systems for filtering rules learned from medical transaction databases is an important area for CPR. The availability of a formal ontology allow the ranking of association rules by clarifying what are the rules confirming available medical knowledge, what are surprising, and which are to be filtered out. Currently, NLP systems in clinical environments process CPR to index and categorize reports, extract, structure, and codify clinical information in the reports to make them usable for other computerized applications, generate text to produce patient profiles and summaries, and improve interfaces to health care systems.

The challenges of NLP in the clinical domain described by [32] are the performance of the application, the availability of clinical text and confidentiality, the evaluation and sharing information across institutions, the Expressiveness as language can describe the same medical concept in many different ways, the heterogeneous formats, as there are no standards for writing a report in CPR, the abbreviated text in medical reports often omit information that can be interfered by health care employees based on their individual knowledge, the interpretation of clinical information as evident part of a medical report, as often further information are necessary to associate findings with potential diagnoses, and rare events can make it difficult to enable enough training examples for stabilization of NLP

NLP is based on in advance prepared formalization of the knowledge. NLP can be useful for ontology development, it can be used as a component in an ontology-driven information system and an NLP application can be enhanced with ontology.

There are different approaches to NLP in the CPR. Most approaches are using a combination of syntactic and semantic linguistic knowledge as well as heuristic domain knowledge [32]. Some use manually developed rules, and others are more statistically oriented. The NLP extraction process has two phases; first the report analyzer processes the report in order to identify segments and to handle irregularities. In the second phase the text analyzer as information extraction component uses linguistic knowledge associated with syntactic and semantic features. Also a conceptual model of the domain is used to structure and encode the clinical information [32]. The output is stored for subsequent use in clinical databases. NLP systems have different components that can vary from case to case. The main components according to [32] are morphological analysis: Process to break up original

words into canonical forms, lexical look up: Words or phrases are matched against a lexicon to determine their syntactic and semantic properties, syntactic analysis: Determination of the structure of a sentence to establish relationships of the words in a sentence, semantic analysis Process to show the clinical relevance of words and phrases, and encoding: Process to map the clinically relevant terms to established concepts. This is important to achieve widespread use of the structured information.

In order for NLP to become a main method in CPR it is important to further develop the standardization of report structures in the CPR as well as the standardization of the information model representing clinical information and vocabularies.

#### *E. Artificial Neural Networks*

Artificial Neural Network (ANN) or Neural Networks are computerized paradigms based on mathematical models with strong pattern recognition capabilities [33]. ANN are also called connectionist systems, parallel distributed systems, or adaptive systems, because they are comprised by a series of interconnected processing elements which work parallel in time [33]. ANN aim to build up information structures according to the human nervous system with a representation of neurons and synapses. An ANN is a graph consisting of many nodes connected to each other by weighted links. The knowledge in the ANN is represented by the totality of nodes and weighted links. Learning algorithms or learning rules can be used to adjust the connection weights in networks to predict or classify unknown examples. ANN work in the training mode and after stabilization in the testing mode. The process of ANN starts with a set of random weights and adjusts its weights automatically according to each learning example in an iterative process until the network stabilizes. This mode is called the learning mode, where the weights of the connections can change in order to respond to a present input.

Different types of ANN can solve many problems, like pattern recognition, pattern completion, determining similarities between pattern and data, interpolation of missing and noisy data, and automatic classification [34].

Many different types of ANN have been developed in the last two decades, e.g. the Self-organizing Map of Kohonen and the Hopfield networks described by Chen [3], [35]. Later in this chapter are Neuro Fuzzy Systems described, that also refer to ANN and are separated because of their growing importance. Particularly in the field of medicine and for usage of DM in CPR are ANN valuable as it is possible to build models with a high complexity, e.g. with multilayer feed forward networks. They can be defined as an array of processing elements arranged in layers. Information flows through each element in an input-output manner, where each element receives signals, manipulates them, and sends the signals to other connected elements.

#### *F. Bayesian Networks*

A particularly useful method for the CPR is represented by the Bayesian Networks (BN) which is used in different areas of medical applications. The BN represents the conjunc-

tion of knowledge representation, automated reasoning, and machine learning. The BN allows to explicitly represent the knowledge available in terms of a directed acyclic graph structure and a collection of conditional probability tables, and to perform probabilistic inference. BN use a directed acyclic graphical model to represent a set of random variables like quantities, latent variables, unknown parameters or hypotheses. Also the conditional relationships and independencies between the random variables are represented in the BN. The graphical structure represents knowledge about an uncertain domain. Each conditional relationship has its own probability function. Learning in BN is performed by intelligent algorithms. Influence diagrams help to generalize BN solve decision problems under uncertainty. In many practical settings the BN is unknown and one needs to learn it from the data. This problem is known as the BN learning problem, which can be stated informally as follows: Given training data and prior information (e.g. expert knowledge, casual relationships), estimate the graph topology (network structure) and the parameters [36]. Graphical models with undirected edges are generally called Markov random fields or Markov networks. These networks provide a simple definition of independence between any two distinct nodes based on the concept of a Markov blanket. Markov networks are popular in fields such as statistical physics and computer vision [36].

Machine learning and system learning for BN is to find the best matching Bayesian network graph with the best data fit for the decision problem.

#### *G. Analytic Learning, Fuzzy Logic, and Neuro Fuzzy Systems*

Knowledge is represented in analytical learning as logical rules and the performance of proofs for the rules. Traditional analytic learning systems depend on hard computing rules. As in the reality there is usually no distinction between values and classes, therefore fuzzy systems have been developed. Other concepts aim to avoid imprecise and vague information as they have a negative influence on the computed results. Fuzzy Systems use deliberately this type of information [34]. The result is often a simpler approach with more suitable models that are easier to handle. In the past Fuzzy Logic was not the first choice for DM in CPR because the simplicity did not fit to the complexity of medical and patient oriented data in CRM, but the trend has changed by combining different simple concepts, eg. Neuro Fuzzy Systems.

Fuzzy logic is an extension of traditional proposition logic. It deals with approximate reasoning by extending the binary membership. In contrast to classical set theory, in which an object or a case either is a member of a given set, fuzzy set theory makes it possible that an object or a case belongs to a set only to a certain degree [34]. Interpretations of membership degrees include similarity, preference and uncertainty. They can state how similar an object or case it to a prototypical one. They can indicate preferences between sub optimal solutions to a clinical problem, or they can model uncertainty in case of an imprecisely described situation or term [34]. For the CPR the set up of a fuzzy system is useful as many medical information are linguistic, vague or imprecisely described because a complete description would be too

complex. However, the limitation of the fuzzy system is reached when fuzzy concepts have to be represented by concrete membership degrees, which ensures that the system works as expected. A fuzzy system can be used to solve a problem, if knowledge exists about the solution in the form of if-then rules.

The development of Neuro Fuzzy Systems enhances the Fuzzy Systems where knowledge is represented in an interpretable manner, by the ability of ANN of learning. The advantage of the combination is that a problem can be solved without the need to analyze the problem itself in detail.

For CPR are the hybrid Neuro Fuzzy models interesting, which combine neuronal networks with fuzzy systems in a homogeneous architecture. The architecture can either be interpreted as a special neuronal network with fuzzy parameters, or as a fuzzy system implemented in a parallel distributed way.

#### H. Evolution Based Models

Evolution based models refer to computer-based methods inspired by biological mechanisms of natural evolution.. Evolution based algorithms have been applied to various optimization problems. They were developed on the basis of genetic principles. A population of potential solutions is initiated in the first step. The iterative process changes the population based on the operations mutation and crossover in different generations. The crossover operation is a high level process that aims at exploitation while mutation is a unary process that aims at exploration [3]. The selection process goes over different generations and selects the best fitting individuals. At the end of the process is the best solution presented. Due to the stochastic and global-search capability this technique is popular in medical informatics research [3].

## VI. CONCLUSION

CPR contain heterogeneous data in heterogeneous information systems and from heterogeneous sources. Not only the information technology improves the complexity of data mining in electronic patient files, but also the business site is very complex in terms of the medical description of doctors who try to describe the disease of a patient. DM is particularly useful in this domain.

The described techniques and methods of DM in CPR prove the fast development of research trends over the last decades. The usage of the research findings and developed new techniques and models will reach the full momentum after the CPR coverage rate has reached a much higher value. Currently, many systems in health care are separated solutions with a low integration rate. The benefits of DM research in CPR will be fully unlocked when the data will be interlinked. All methods have shown that the result of the decision proposal is relying on the quality of the data basis. This is obvious in Data Mining and shows the growing importance for Data Mining research and the usage in CPR. Future internet technologies will allow to use Data Mining in the Web over a broad data basis and link the results to existing CPR. This will allow to access knowledge in a today not known dimension and revolutionize the decision making

process. 'The current solutions of today build the foundation for the future scenarios.

Most of the described examples of DM techniques and methods related to practical problems in CPR are directed on one single problem, e.g. diagnosis for stress related heart attacks. Future trends will be integrating the different approaches, technologies, methodologies, and constructs into a DM framework of methodologies that link together different approaches. The start is already made with the linkage of ANN with Fuzzy Logic into Neuro Fuzzy Systems.

The challenges of data mining will also remain in future to deal with different scientific areas, to understand the patterns, to deal with complex relationships between attributes, interpolate missing or noisy data, mining very large databases, handle changing data and integrate the data with other data base systems. All these challenges are particularly important for CPR.

**Abstract**—The research concerns a computer-based clinical decision support for laryngopathies. The classification process is based on a speech signal analysis in the time domain using recurrent neural networks. In our experiments, we use the modified Elman-Jordan neural network. In the preprocessing step, an original signal is approximated using Bezier curves and next the neural network is trained. Bezier curve approximation reduces the amount of data to be learned as well as removes a noise from the original signal.

**Index Terms**—computer-based clinical decision support; recurrent neural networks; laryngopathies; Bezier curves; approximation

## I. INTRODUCTION

COMPUTER-BASED clinical decision support (CDS) is defined as the use of a computer to bring relevant knowledge to bear on the health care and well being of a patient [1]. Our research concerns designing methods for CDS in a non-invasive diagnosis of selected larynx diseases. Two diseases are taken into consideration: Reinke's edema and laryngeal polyp. In general, the diagnosis is based on an intelligent analysis of selected parameters of a patient's speech signal (phonation). The proposed approach is non-invasive. Comparing it to direct methods shows that it has several advantages. It is convenient for a patient because a measurement instrument is located outside the voice organ. This enables free articulation. Moreover, different physiological and psychological patient factors impede making a diagnosis using direct methods.

The majority of methods proposed to date are based only on the statistical analysis of the speech spectrum (e.g. [2]) as well as the wavelet analysis. In our research, we are going to propose a hybrid approach, which is additionally based on a signal analysis in the time domain. Preliminary observations of signal samples for patients from a control group and patients with a confirmed pathology clearly indicate deformations of standard articulation in precise time intervals. In our previous papers (see [3], [4], and [5]), we have taken into consideration the usage of recurrent neural networks (RNNs), especially, the Elman and Jordan networks [6], [7] also known as "simple

recurrent networks." RNNs can be used for pattern recognition in time series data due to their ability of memorizing some information from the past. The Elman networks (ENs) are a classical representative of RNNs. To improve learning ability of ENs we have modified and combined them with the Jordan networks. Such networks manifest a faster and more exact achievement of the target pattern. Moreover, for the time domain analysis, RNNs have the capability of extracting the phoneme articulation pattern for a given patient (articulation is an individual patient feature) and the capability of assessment of its replication in the whole examined signal.

In contrast to approaches shown in [3], [4], and [5], in the approach presented in this paper, we do not learn the neural network using samples of a speech signal directly. Now, we introduce a preprocessing step. In this step an original signal is approximated using Bezier curves and next the neural network is trained. Bezier curve approximation reduces the amount of data to be learned (by one order of magnitude), as well as, removes a noise from the original signal.

Our paper is organized as follows. After introduction, we shortly describe the medical background related to larynx diseases (Section II). In Section III, we show the procedure used to find approximation of a speech signal using Bezier's curves. Section IV describes the use of the modified Elman-Jordan neural network in finding disturbances in a speech signal. In Section V, we present results obtained by experiments done on real-life data. Some conclusions and final remarks are given in Section VI.

## II. MEDICAL BACKGROUND

A model of speech generation is based on the "source-filter" combination. The source is larynx stimulation, i.e., passive vibration of the vocal folds as a result of an increased subglottis pressure. Such a phenomenon of making speech sonorous in the glottis space is called phonation. The filter is the remaining articulators of the speech canal creating resonance spaces. A signal of larynx stimulation is shaped and modulated in these spaces. A final product of this process is called speech.

Pathological changes appearing in the glottis space entail a bigger or smaller impairment of the phonation functions of the larynx. The subject matter of presented research concerns diseases, which appear on the vocal folds, i.e., they have a direct influence on phonation [8].

We are interested in two diseases: Reinke's edema (*Oedema Reinke*) and laryngeal polyp (*Polypus laryngis*).

#### A. Reinke's Edema

Reinke's edema appears often bilaterally, and usually asymmetrically, on the vocal folds. It is created by transudation in a slotted epithelial space of folds devoid of lymphatic vessels and glands, called the Reinke's space. In the pathogenesis of disease, a big role is played by irritation of the laryngeal mucosa by different factors like smoking, excessive vocal effort, inhalatory toxins or allergens. The main symptoms are the following: hoarseness resulting from disturbance of vocal fold vibration or, in the case of large edemas, inspiratory dyspnea. In the case of Reinke's edemas, conservative therapy is not applied. They are microsurgically removed by decortication with saving the vocal muscle.

#### B. Laryngeal Polyp

Laryngeal polyp is a benign tumor arising as a result of gentle hyperplasia of fibrous tissue in mucous membrane of the vocal folds. In the pathogenesis, a big role is played by factors causing chronic larynx inflammation and irritation of the mucous membranes of the vocal folds: smoking, excessive vocal effort, reflux, etc. The main symptoms are the following: hoarseness, aphonia, cough, tickling in the larynx. In case of very big polyps, dyspnea may appear. However, not big polyps may be confused with vocal tumors especially when there is a factor of the load of the patient voice. The polyp may be pedunculated or may be placed on the wide base. If it is necessary, polyps are microsurgically removed with saving a free edge of vocal fold and vocal muscle.

### III. PHONEME APPROXIMATION USING THE BEZIER CURVES

In order to approximate a speech signal (phoneme), we propose to use 4-point Bezier curves. A Bezier curve is a parametric curve very popular in different applications of computer graphics and related fields. A shape of the 4-point Bezier curve is determined by four control points  $P_0 = [P_0^x, P_0^y]$ ,  $P_1 = [P_1^x, P_1^y]$ ,  $P_2 = [P_2^x, P_2^y]$ , and  $P_3 = [P_3^x, P_3^y]$ . The curve interpolates points  $P_0$  and  $P_3$  and approximates points  $P_1$  and  $P_2$ . Two parametric equations determine the shape of the curve:

$$\begin{aligned} x(t) &= (1-t)^3 P_0^x + 3(1-t)^2 t P_1^x + 3(1-t)t^2 P_2^x + t^3 P_3^x, \\ y(t) &= (1-t)^3 P_0^y + 3(1-t)^2 t P_1^y + 3(1-t)t^2 P_2^y + t^3 P_3^y, \end{aligned}$$

where  $t \in [0, 1]$ . Application of the Bezier curves has the following advantages:

- a signal is encoded using a smaller number of values than a number of samples (by one order of magnitude), this can accelerate a learning process of neural networks,

- some noise from the original signal can be removed,
- due to transformations, signals with different magnitudes and gradients can be compared.

The main disadvantage is the complicated process of finding approximation of a signal in the form of a family of Bezier curves.

In this section, we propose an iterative algorithm for finding a family of Bezier curves best approximating a given signal curve. The algorithm inches forward (from the beginning) along the approximated signal curve (corresponding to a given phoneme) trying to find the best Bezier curve approximating the part of the signal curve. At each stage of searching, if a better curve cannot be found, the current Bezier curve is recorded for a covered part of the curve and new searching for the remaining part is started. In this algorithm, a number of Bezier curves approximating a given signal curve is not given in advance. The presented algorithm can be called the stepping algorithm. Algorithm 1 shows formally our procedure. An error  $\varepsilon$  between the Bezier curve and the signal curve in a given interval of samples (from *start* to *end*) is calculated separately for coordinates  $x$  and  $y$  according to the following formulas:

$$\begin{aligned} \varepsilon^x &= \sum_{i=start}^{end} |t_B^i - t_F^i|, \\ \varepsilon^y &= \sum_{i=start}^{end} |v_B^i - v_F^i|, \end{aligned}$$

where  $\{t_B^i, v_B^i\}_i$ ,  $\{t_F^i, v_F^i\}_i$  are sequences of samples of the Bezier curve  $B$  and the signal curve  $F$ , respectively.

The presented algorithm has a polynomial time complexity.

Algorithm 1 uses Algorithm 2 for finding the best moving of a given control point. This algorithm checks an error between the Bezier curve and the original curve. If the error  $\varepsilon$  is worsened (with respect to the previous one  $\varepsilon_p$ ) after moving a control point, then moving is canceled and its direction for the next step is changed to opposite. A number of searching steps is limited (in our experiments to 100).

### IV. RECURRENT NEURAL NETWORKS FOR LEARNING PHONEME PATTERNS

For each Bezier curve represented by four control points  $P_0 = [P_0^x, P_0^y]$ ,  $P_1 = [P_1^x, P_1^y]$ ,  $P_2 = [P_2^x, P_2^y]$ , and  $P_3 = [P_3^x, P_3^y]$ , we calculate three Euclidean distances:

$$\begin{aligned} D_1 &= \sqrt{(P_1^x - P_0^x)^2 + (P_1^y - P_0^y)^2}, \\ D_2 &= \sqrt{(P_2^x - P_0^x)^2 + (P_2^y - P_0^y)^2}, \\ D_3 &= \sqrt{(P_3^x - P_0^x)^2 + (P_3^y - P_0^y)^2}. \end{aligned}$$

Let  $\mathcal{B}$  be a family of Bezier curves approximating a given phoneme. The phoneme is represented by sequences of distances calculated for each Bezier curve. Such sequences are used to learn the modified Elman-Jordan network. The modified Elman-Jordan network has been proposed in [4].

---

**Algorithm 1:** Algorithm for determining a family of Bezier curves approximating a phoneme.

---

**Input** :  $F = [(t_0, v_0), (t_1, v_1), \dots, (t_{n-1}, v_{n-1})]$  - a phoneme (a vector of speech signal samples),  $\tau$  - error threshold,  $c_{max}$  - a maximal number of attempts of searching,  $[s_1^x, s_1^y], [s_2^x, s_2^y]$  - moving vectors, where  $s_1^x, s_1^y, s_2^x, s_2^y \in [0, 1]$

**Output:**  $\mathcal{B}$  - the family of 4-point Bezier curves approximating  $F$ .

```

 $\mathcal{B} \leftarrow \emptyset;$ 
 $start \leftarrow 0; end \leftarrow 1;$ 
 $P_1 \leftarrow null; P_2 \leftarrow null;$ 
 $\varepsilon_{p1} \leftarrow null; \varepsilon_{p2} \leftarrow null;$ 
 $c \leftarrow 0; stop \leftarrow false;$ 
while  $stop = false$  do
   $P_0 \leftarrow (t_{start}, v_{start});$ 
  if  $P_1 = null$  then
     $P_1 \leftarrow (t_{start}, v_{start});$ 
  end
  if  $P_2 = null$  then
     $P_2 \leftarrow (t_{start}, v_{start});$ 
  end
   $P_3 \leftarrow (t_{end}, v_{end});$ 
  Create a curve  $B$  on the basis of  $P_0, P_1, P_2, P_3$ ;
  Calculate an error  $\varepsilon_1$  between  $B$  and  $F$  in the interval  $[t_{start}, t_{end}]$ 
  Move point  $P_1$  using Algorithm 2 by vector  $[s_1^x, s_1^y]$ ;
  Calculate an error  $\varepsilon_2$  between  $B$  and  $F$  in the interval  $[t_{start}, t_{end}]$ ;
  Move point  $P_2$  using Algorithm 2 by vector  $[s_2^x, s_2^y]$ ;
  if  $(\varepsilon_{p1} < \tau \text{ and } \varepsilon_{p2} < \tau)$  or  $(\varepsilon_{p1} < \tau \text{ and } \varepsilon_{p2} < \tau)$  then
    if  $1 + end < n$  then
       $end \leftarrow end + 1;$ 
    else
       $stop = true;$ 
    end
     $\varepsilon_{p1} \leftarrow null; \varepsilon_{p2} \leftarrow null;$ 
     $c \leftarrow 0;$ 
  else
     $c \leftarrow c + 1;$ 
  end
  if  $c > c_{max}$  then
    if  $1 + end < n$  then
       $\mathcal{B} \leftarrow \mathcal{B} \cup \{B\};$ 
       $start \leftarrow end;$ 
       $end \leftarrow start + 1;$ 
       $P_1 \leftarrow null; P_2 \leftarrow null;$ 
       $\varepsilon_{p1} \leftarrow null; \varepsilon_{p2} \leftarrow null;$ 
       $c \leftarrow 0;$ 
    else
       $stop \leftarrow true;$ 
    end
  end
end
Return  $\mathcal{B}$ ;
```

---

---

**Algorithm 2:** Algorithm for moving a control point.

---

**Input** :  $P$  - a control point to be moved,  $\varepsilon_p$  - a last error,  $\varepsilon$  - a current error,  $[s^x, s^y]$  - a moving vector.

**Output:**  $P$  - a moved control point

```

if  $\varepsilon_p = null$  then
   $\varepsilon_p \leftarrow \varepsilon;$ 
end
if  $\varepsilon^x \geq \varepsilon_p^x$  then
   $P^x \leftarrow P^x - s^x;$ 
   $s^x \leftarrow -s^x;$ 
end
if  $\varepsilon^y \geq \varepsilon_p^y$  then
   $P^y \leftarrow P^y - s^y;$ 
   $s^y \leftarrow -s^y;$ 
end
if  $\varepsilon^x < \varepsilon_p^x$  then
   $\varepsilon_p \leftarrow \varepsilon;$ 
end
if  $\varepsilon^y < \varepsilon_p^y$  then
   $\varepsilon_p \leftarrow \varepsilon;$ 
end
 $P^x \leftarrow P^x + s^x;$ 
 $P^y \leftarrow P^y + s^y;$ 
Return  $P$ ;
```

---

Moreover, some learning abilities were tested in [5]. The modified Elman-Jordan network consists of (see Figure 1):

- an input layer,
- a hidden layer,
- a context layer,
- an output layer,
- feedbacks for a hidden layer through the context layer, such feedbacks are used in the Elman networks,
- feedback between an output layer and a hidden layer through the context layer, such feedback is used in the Jordan networks,
- feedback for an output layer.

Output feedback accelerates a learning process and causes seamless modification of weights. Generally, the modified Elman-Jordan network needs a smaller number of epochs (sometimes by 50 per cent) for learning a given pattern (see [5]).

In the approach presented in this paper, we use similar procedure to that presented in [3], [4], and [5]. A difference is that we use as the input for the neural network sequences of distances calculated for Bezier curves approximating an original speech signal instead of samples of that signal. Articulation is an individual patient feature. Therefore, we cannot train a neural network on the independent patterns of phonation of individual vowels. For each patient, parameters of Bezier curves of a speech signal are used for both training and testing of a neural network. The procedure is as follows. We divide the speech signal of an examined patient into time windows corresponding to phonemes. The next step is

determine a family of Bezier curves approximating it (see Algorithms 1 and 2) and next calculate distances for each curve according to formulas shown at the beginning of this section. Bezier curve parameters of one time window are taken for training the neural network, whereas Bezier curve parameters of the remaining ones, for testing of the neural network. The network learns parameters of a selected time window. If parameters of the remaining windows are similar to the selected one in terms of the time patterns, then for such windows an error generated by the network in a testing stage is small. If significant replication disturbances in time appear for patients with the larynx disease, then an error generated by the network is greater. In this case, the time pattern is not preserved in the whole signal. Therefore, the error generated by the network reflects non-natural disturbances in the patient phonation. Our approach can be expressed formally as it is shown in Algorithm 3. In the algorithm we use the following functions (procedures):

- $Div2Win(S)$  - dividing the speech signal  $S$  into time windows corresponding to phonemes,
- $SelWin(W)$  - selecting randomly a number of time windows from the whole set  $W$ ,
- $Bezier(w)$  - calculating a set of parameters of Bezier curves approximating  $w$ ,
- $Train(N, B)$  - training a neural network  $N$  on a given set  $B$  of parameters of Bezier curves,
- $Test(N, B)$  - testing a neural network  $N$  on a given set  $B$  of parameters of Bezier curves,
- $MSE(E)$  - calculating a mean squared error for the

random selection of a number of time windows. This set of selected windows is used for determining some coefficient characterizing deformations in the speech signal. This coefficient is constituted by an error obtained during testing of the neural network. We propose to use the approach similar to the cross-validation strategy. For each time window we

absolute error vector  $E$ :

$$MSE(E) = \frac{1}{n} \sum_{i=1}^n (E_i)^2,$$

where  $n$  is a number of elements in the vector  $E$ ,  $E_i = y(x_i) - z(x_i)$  and  $y(x_i)$  is the obtained output for  $x_i$  whereas  $z(x_i)$  is the desired output for  $x_i$ .

- $Avg(E)$  - calculating an arithmetic average for the vector  $E$  of errors.

## V. EXPERIMENTS

In the experiments, sound samples were analyzed. Samples were recorded for two groups of patients [2]. The first group included patients without disturbances of phonation. They were confirmed by phoniatriest opinion. The second group included patients of Otolaryngology Clinic of the Medical University of Lublin in Poland. They had clinically confirmed dysphonia as a result of Reinke's edema or laryngeal polyp. The information about diseases was received from patients' documentations. Each recording was preceded by a course of breathing exercises with an instruction about a way of articulation. The task of all examined patients was to utter separately Polish vowels: "A", "I", and "U" with extended articulation as long as possible, without intonation, and each on separate expiration. Samples were normalized to the interval [0.0, 1.0] before providing them to the next block. After normalization, samples (as double numbers) were provided to the block calculating the Bezier curve parameters.

In Tables I and II, we present results of experiments carried out using the modified Elman-Jordan network described in

Section IV. Table I includes results for women from the control group as well as Table II includes results for women with laryngeal polyp. Both tables include results for women uttering vowel "A". We give consecutively the average mean squared error  $\overline{E}_{EJN}$  and an average number  $\overline{n}_{EJN}$  of epochs in the training process.

It is easy to see that the modified Elman-Jordan network trained by parameters of Bezier curves approximating the speech signal has some ability to distinct between normal and disease states. The distinction ability presented here would be comparable with abilities obtained if the neural networks were trained using the original speech signals (cf. [4], and [5]). In the approach presented in this paper, we significantly reduce the amount of data to be learned by the neural network. Such observations are very important for further research, especially in the context of a created computer tool for diagnosis of larynx diseases.

## VI. CONCLUSIONS

In the paper, we have shown the classification process of laryngopathies based on a speech signal analysis in the time domain using recurrent neural networks. In our experiments, we have used the modified Elman-Jordan neural network presented in our earlier papers. In the procedure, we have introduced the preprocessing step. In this step, an original signal is approximated using Bezier curves and next the neural network is trained. Bezier curve approximation reduces the amount of data to be learned as well as removes a noise from the original signal. The quality of the proposed method in terms of differentiating normal and pathological categories is not entirely satisfactory, but it shows the direction of further research. In the future, we will concentrate on two directions. The first one is the optimization of the process of finding a family of Bezier curves approximating the speech signal. The second one is an improvement (tuning) of the proposed method for better differentiating between cases belonging to different categories.

## ACKNOWLEDGMENT

This research has been supported by the grant No. N N516 423938 from the Polish Ministry of Science and Higher Education.

**Abstract**—The purpose of data categorization is to group similar cases (items, examples, objects, etc.) together under a common label so that information can be acted upon in the aggregate form. Sometimes, this process is made arbitrary by an expert. For each case, an expert determines a class (group) to which the case is classified. In the paper, we propose a method for validation of a categorization process. The method is based on extensions of information systems defined in terms of rough sets. Usefulness of the proposed method is shown for the data used in the synthesis of images of melanocytic skin lesions.

**Index Terms**—extensions of information systems, data categorization, rough sets, synthesis of images

## I. INTRODUCTION

**A**N INFORMATION system proposed by Z. Pawlak [1] can represent a finite set of cases described by attributes. Each attribute represents one of features of cases. Besides all cases appearing in the original information system, an extension of it can include new cases, which have not been observed yet, but which are consistent to a certain degree with the knowledge included in the original system. The knowledge can be represented in the form of rules (production, association, etc.). One can consider only the so called consistent extensions of information systems [2], when all new cases are totally consistent with the knowledge included in the original information systems. However, in general case, we can consider partially consistent extensions [3], when some new cases are consistent with the knowledge possessed, only to a certain degree. The important problem is to determine consistency factors of new cases taking into consideration different ways of knowledge representation.

In this paper, we use an approach to computing consistency factors based on rough set theory and proposed in [3]. The algorithm using that approach has been presented in [4]. In Section III we recall it. This algorithm makes use of important results of research on extensions of information systems given in [5]. In the algorithm, we assume that the knowledge included in an original information system  $S$  is expressed by minimal rules true and realizable in  $S$  (see Section III). Computing a consistency factor for a given object is based on determining importance (relevance) of rules extracted from the

system  $S$  which are not satisfied by the new case. We assume that if the importance of these rules is greater the consistency factor of a new object with the knowledge is smaller. The importance of a set of rules not satisfied by the new case is determined by means of a strength factor of this set of rules in  $S$ .

As an example, we consider phenomena related to melanocytic skin lesions. In the process of validation of categorization of cases for respective types of lesions, we can use extensions of information systems. A consistency factor calculated for a given text vector (case) representing combination of colors and structures can be considered in terms of possibility theory proposed by L. Zadeh [6]. This factor enables us to answer a question about possibility with which a given combination of colors and structures appears in a respective melanocytic skin lesion. If we have an information system consisting of information about combinations of colors and diversities of structures appearing for given lesions, it means that we have collected all cases observed until now. In many situations, we have observed only a part of all possible combinations of colors and diversities of structures. In this case, if we take a new combination which has not been observed yet, then the following question  $Q$  arises: "Is it possible that the combination (case) will appear for a given lesion?". In this question, "possible" means "plausible". We wish to answer the question  $Q$  on the basis of the possessed information collected until now in the information system  $S$  (observed combinations for a given lesion). We can determine a possibility distribution on all combinations of colors and diversities of structures.

We can identify consistency factors of cases in the extension of a given information system with a possibility distribution of cases. Possibility theory [6] is a framework for representing vague and incomplete knowledge. Let  $X$  be a set that represents the range of a variable  $x$ . A possibility distribution  $\pi_x$  on  $X$  is a mapping from  $X$  to the unit interval  $[0, 1]$  attached to the variable  $x$ . The variable  $x$  can be treated as some phenomenon  $\mathcal{P}$ . The range of  $x$  represents the set of cases of  $\mathcal{P}$ . The function  $\pi_x$  distinguishes which case of  $\mathcal{P}$  is plausible and which one is less plausible. Let  $u \in X$ ,  $\pi_x(u) = 0$  means

that  $x = u$  is impossible.  $\pi_x(u) = 1$  means that  $x = u$  is totally possible, i.e., plausible. The quantity  $\pi_x(u)$  represents the degree of possibility of the assignment  $x = u$ .

## II. PROBLEM BACKGROUND

In our research, we use a database on melanocytic skin lesions including 548 cases belonging to one of four types of lesions: *Benign nevus*, *Blue nevus*, *Suspicious nevus*, and *Melanoma malignant*. Each case in a database is recorded as a 15-element text vector constituting the input information in the process of synthesis of static images of melanocytic skin lesions (cf. [7], [8], [9]). We have noticed at the current research state that a key role is played by two features of melanocytic skin lesions, namely, *Color* and *Diversity of structure*. These features have a multivalued character and describe the presence or absence of colors and diversities of structures allowed by the ABCD rule [10]. *Color* can have six allowed values: *black*, *blue*, *dark-brown*, *light-brown*, *red*, and *white*, whereas *Diversity of structure* can have five allowed values: *branched streaks*, *pigment dots*, *pigment globules*, *pigment network*, and *structureless area*. Assessment of a tinge of a skin lesion consists in differentiating any number of colors (from the set of six allowed colors). Assessment of structural elements in a skin lesion consists in determining any number of structures (from the set of five allowed diversities of structures). The remaining attributes of the text vector are *Assymetry*, *Border*, and *TDS (Total Dermatoscopy Score)*. In Table I, we present the collation of information about attributes of the text vector used in our experiments. For each allowed *color* and *diversity of structure*, we have one attribute taking one of logical values: 1 (denoting presence) or 0 (denoting absence).

TABLE I  
ATTRIBUTES CORRESPONDING TO FEATURES: *Color* AND *Diversity of structure*

Feature	Attribute	Value set
<i>Color</i>	<i>black</i>	{0, 1}
	<i>blue</i>	{0, 1}
	<i>dark-brown</i>	{0, 1}
	<i>light-brown</i>	{0, 1}
	<i>red</i>	{0, 1}
	<i>white</i>	{0, 1}
<i>Diversity of structure</i>	<i>branched streaks</i>	{0, 1}
	<i>pigment dots</i>	{0, 1}
	<i>pigment globules</i>	{0, 1}
	<i>pigment network</i>	{0, 1}
	<i>structureless area</i>	{0, 1}

Synthesis of colors and structures of a lesion should consider multi-valued character of *Color* and *Diversity of structure* features, capable to create a considerable number of combinations of these parameters, which can simultaneously appear in a given lesion.

According to the ABCD rule, a number of all possible mappings of colors and structures is  $2^{11} - 95$ . 95 is a number of inadmissible combinations. Inadmissible combinations are: combinations without any color (64 cases) and combinations without any structure (32 cases). One of combinations does not have both any color and any structure, hence 95. A real number

of mappings can be greater in view of different mappings of given colors in respective structures. The ABCD rule does not define such mappings. Therefore, a number of all possible combinations is  $2^{30} + 1$  minus 95 inadmissible combinations. Generating over one billion textures is virtually almost impossible. An additional disadvantage of such mapping would be a very frequent repetition of occurrence of selected structures in particular colors, because of its shape, size and place in the generated image. Taking all these circumstances into consideration the synthesis requires a special approach, we should initially (before generating textures) find which colors and structures occur simultaneously in real lesions.

In the process of validation of choices of combinations for respective types of lesions, we use extensions of information systems described in the next section. A consistency factor calculated for a given text vector representing the combination of colors and structures is considered in terms of possibility theory. This factor enables us to answer a question about possibility with which a given combination of colors and structures appears in a respective melanocytic skin lesion.

## III. EXTENSIONS OF INFORMATION SYSTEMS

In this section, we recall crucial notions concerning rough sets, information systems, rules, as well as, extensions of information systems. For more exact description and explanation we refer readers to [5], [11].

An information system is an ordered pair  $S = (U, A)$ , where  $U$  is a non-empty, finite set of objects which is also called universum,  $A$  is a non-empty, finite set of attributes. Each attribute  $a \in A$  is a total function  $a : U \rightarrow V_a$ , where  $V_a$  is a set of values of the attribute  $a$ . Each information system  $S = (U, A)$  can be presented in the form of a data table. Columns are labeled with attributes from  $A$  whereas rows are labeled with objects from  $U$ . Cells of the table include values of appropriate attributes. A decision system is an information system  $S = (U, A)$ , where  $A = C \cup D$  and  $C \cap D = \emptyset$ .  $C$  is a set of condition attributes (in short, conditions) whereas  $D$  is a set of decision attributes (in short, decisions).

Let  $S = (U, A)$  be an information system. Each subset  $B \subseteq A$  of attributes determines an equivalence relation on  $U$ , called an *indiscernibility relation*  $Ind(B)$ , defined as

$$Ind(B) = \{(u, v) \in U \times U : \forall a \in B a(u) = a(v)\}.$$

The equivalence class containing  $u \in U$  will be denoted by  $[u]_B$ .

Let  $X \subseteq U$  and  $B \subseteq A$ . The *B-lower approximation*  $\underline{B}X$  of  $X$  and the *B-upper approximation*  $\overline{B}X$  of  $X$  are defined as

$$\underline{B}X = \{u \in U : [u]_B \subseteq X\}$$

and

$$\overline{B}X = \{u \in U : [u]_B \cap X \neq \emptyset\},$$

respectively.

Dependencies among values of attributes in an information system may be expressed by means of the so-called rules. Each rule  $\rho$  considered by us in the information system  $S = (U, A)$

has the form  $(a_{i_1}, v_{i_1}) \wedge (a_{i_2}, v_{i_2}) \wedge \dots \wedge (a_{i_r}, v_{i_r}) \Rightarrow (a_d, v_d)$ , where  $a_d \in A$  and  $v_d \in V_{a_d}$ , while  $a_{i_j} \in B \subseteq A - \{a_d\}$  and  $v_{i_j} \in V_{a_{i_j}}$  for  $j = 1, 2, \dots, r$ . The rule  $\rho$  is a satisfiable (true) rule if for each object  $u \in U$ : if  $a_{i_1}(u) = v_{i_1} \wedge a_{i_2}(u) = v_{i_2} \wedge \dots \wedge a_{i_r}(u) = v_{i_r}$ , then  $a_d(u) = v_d$ . The rule  $\rho$  is a minimal rule if removing any atomic formula  $(a_{i_j}, v_{i_j})$ , where  $j = 1, 2, \dots, r$ , from the predecessor of a rule makes this rule not true in  $S$ . The rule  $\rho$  is a realizable rule if there exists any object  $u \in U$  such that  $a_{i_1}(u) = v_{i_1} \wedge a_{i_2}(u) = v_{i_2} \wedge \dots \wedge a_{i_r}(u) = v_{i_r}$ . A set of all minimal rules satisfiable and realizable in the information system  $S$  will be denoted by  $Rul(S)$ . By  $Rul_a(S)$  we will denote the set of all rules from  $Rul(S)$  having an atomic formula containing the attribute  $a$  in their successors.

Let  $S = (U, A)$  be an information system. An information system  $S^* = (U^*, A^*)$  is an extension of  $S$  if and only if:

- $U \subseteq U^*$ ,
- $card(A) = card(A^*)$ ,
- for each  $a \in A$ , there exists  $a^* \in A^*$  such that a function  $a^* : U^* \rightarrow V_{a^*}$  is an extension of a function  $a : U \rightarrow V_a$  to  $U^*$ .

We may admit also situation when  $a^* : U^* \rightarrow V_{a^*}$ , where  $V_{a^*} \subset V_a$ , for any  $a^* \in A^*$ . It means that we can add new objects to a given information system  $S$  that have new values of attributes not existing yet in  $S$ . If  $V_{a^*} = V_a$  for each  $a^* \in A^*$ , then  $S^*$  will be called a proper extension of  $S$ , otherwise  $S^*$  will be called a non-proper extension of  $S$ .

A set  $A^*$  of attributes in the extension  $S^* = (U^*, A^*)$  of an information system  $S = (U, A)$  can be also denoted by  $A$  like in the original system  $S$ . So, we write  $S^* = (U^*, A)$  instead of  $S^* = (U^*, A^*)$ . The same applies to attributes of  $A^*$ , i.e.,  $a_1^*, a_2^*, \dots, a_m^* \in A^*$ . So, we write  $a_1, a_2, \dots, a_m$  instead of  $a_1^*, a_2^*, \dots, a_m^*$ , where  $a_1, a_2, \dots, a_m \in A$ .

For any object  $u$  from the extension  $S^*$  of a given information system  $S$ , we define a coefficient called a consistency factor. This coefficient expresses a degree of consistency of  $u$  with the knowledge (expressed by  $Rul(S)$ ) included in the original system  $S$ . The procedure for computing a consistency factor is described here.

For each attribute  $a \in A$  of a given information system  $S$  and a new object  $u^*$  added to  $S$  we can translate an information system  $S$  into the information system  $S_{a,u^*} = (U_a, C_a \cup \{a\})$  with irrelevant values of attributes. Such a system will be called the  $a$ - $u^*$  match of  $S$ .

Let  $S = (U, A)$  be an information system,  $S^* = (U^*, A)$  its extension, and  $u^* \in U^*$  a new object from the extension  $S^*$ . The  $a$ - $u^*$  match of  $S$  is an information system  $S_{a,u^*} = (U_a, C_a \cup \{a\})$  with irrelevant values of attributes created in the following way. Each attribute  $c' \in C_a$  corresponds exactly to one attribute  $c \in A - \{a\}$ . Each object  $u' \in U_a$  corresponds exactly to one object  $u \in U$  and moreover:

$$c'(u') = \begin{cases} c(u) & \text{if } c(u) = c(u^*) \\ * & \text{otherwise} \end{cases}$$

for each  $c' \in C_a$ , and  $a(u') = a(u)$ .

If we create the  $a$ - $u^*$  match of  $S$ , then we create a new information system for which appropriate sets of attribute values are extended by the value  $*$ . The symbol  $*$  means that a given value of the attribute is not relevant.

For simplicity, the attribute  $c \in A - \{a\}$  in  $S$  and the attribute  $c'$  in  $S_{a,u^*}$  corresponding to  $c$  will be marked with the same symbol, i.e.,  $c'$  will be marked in  $S_{a,u^*}$  with  $c$ .

The system  $S_{a,u^*}$  can be treated as a decision system with condition attributes constituting the set  $C_a$  and the decision attribute  $a$ .

For the information system  $S_{a,u^*} = (U_a, C_a \cup \{a\})$ , we define a characteristic relation  $R(C_a)$  similarly to the definition of a characteristic relation in information systems with missing attribute values (cf. [12]).  $R(C_a)$  is a binary relation on  $U_a$  defined as follows  $R(C_a) = \{(u, v) \in U_a \times U_a : \exists c \in C_a c(u) \neq * \text{ and } \forall c \in C_a (c(u) \neq *) \Rightarrow (c(u) = c(v))\}$ . For each  $u \in U_a$ , a characteristic set  $K_{C_a}(u)$  has the form  $K_{C_a}(u) = \{v \in U_a : (u, v) \in R(C_a)\}$ . Let  $X \subseteq U_a$ . The  $C_a$ -lower approximation of  $X$  is determined as  $\underline{C_a}X = \{u \in U_a : K_{C_a}(u) \neq \emptyset \text{ and } K_{C_a}(u) \subseteq X\}$ . Let  $S = (\overline{U}, A)$  be an information system,  $a \in A$ , and  $v_a \in V_a$ . By  $X_a^{v_a}$  we denote the subset of  $U$  such that  $X_a^{v_a} = \{u \in U : a(u) = v_a\}$ .

Let  $S = (U, A)$  be an information system,  $S^* = (U^*, A)$  its extension,  $u^* \in U^*$  a new object from the extension  $S^*$ , and  $a \in A$ . The object  $u^*$  satisfies a rule  $\rho \in Rul_a(S)$  if and only if for each  $v_a \in V_a$  if  $\underline{C_a}X_a^{v_a} \neq \emptyset$ , then  $a(u^*) = v_a$ . A proof can be found in [4].

An approach recalled here does not involve computing any rules from an original information system. The algorithm presented here allows us to determine a set of objects from an original information system  $S$  supporting minimal rules from  $Rul(S)$ , but not satisfied by the object  $u^*$ . A consistency factor is computed as a complement to 1 of the strength of the set of rules not satisfied. Let  $S = (U, A)$  be an information system,  $\{V_a\}_{a \in A}$  is a family of sets of attribute of values in  $S$ ,  $Rul(S)$  a set of all minimal rules true and realizable in  $S$ ,  $S^* = (U^*, A)$  an extension of  $S$ , and  $u^* \in U^*$ . The consistency factor  $\xi_S(u^*)$  of  $u^*$  with the knowledge (expressed by  $Rul(S)$ ) is defined as follows:

$$\xi_S(u^*) = \xi'_S(u^*) \omega_S(u^*),$$

where:

- $\xi'_S(u^*) = 1 - \frac{card(\tilde{U})}{card(U)}$  is a proper consistency,
- $\omega_S(u^*) = \frac{card(\{a \in A : a(u^*) \in V_a\})}{card(A)}$  is a resemblance factor determining some affinity between the object  $u^*$  and objects from  $S$  with respect to values of attributes,

and  $\tilde{U} = \bigcup_{a \in A} \bigcup_{v_a \in V_a} \{\underline{C_a}X_a^{v_a} : \underline{C_a}X_a^{v_a} \neq \emptyset \wedge a(u^*) \neq v_a\}$ .

The estimated time complexity of the algorithm has the form:

$$\Theta(|A|^2|U| + |A||V_a||U|^2),$$

where  $|A|$  is the cardinality of a set of attributes,  $|U|$  is the cardinality of a set of cases,  $|V_a|$  is the maximal cardinality of a set of attribute values.

---

**Algorithm 1:** Algorithm for computing a consistency factor  $\xi_S(u^*)$  of  $u^*$  with the knowledge expressed by  $Rul(S)$

---

**Input :** An information system  $S = (U, A)$ , a new object  $u^*$  added to  $S$ .

**Output:** A consistency factor  $\xi_S(u^*)$  of  $u^*$  with the knowledge expressed by  $Rul(S)$ .

$\tilde{U} \leftarrow \emptyset;$

$i \leftarrow 0;$

**for each**  $a \in A$  **do**

**if**  $a(u^*) \notin V_a$  **then**

$i \leftarrow i + 1;$

**end**

  Create the match  $S_{a,u^*} = (U_a, C_a \cup \{a\})$  of  $S$ ;

**for each**  $v_a \in V_a$  **do**

$X_a^{v_a} \leftarrow \{u \in U : a(u) = v_a\};$

**if**  $C_a X_a^{v_a} \neq \emptyset$  **then**

**if**  $a(u^*) \neq v_a$  **then**

$\tilde{U} \leftarrow \tilde{U} \cup C_a X_a^{v_a};$

**end**

#### IV. EXPERIMENTS

In our experiments, we have used a database on melanocytic skin lesions including 548 cases, each belonging to one of four types of lesions:

- *Benign nevus* - 248 cases,
- *Blue nevus* - 78 cases,
- *Suspicious nevus* - 108 cases,
- *Melanoma malignant* - 114 cases.

Categories have been assigned to cases by clinicians.

The experiments have been carried out according to Procedure 2. We have distinguished two tests:

- 1) One information system containing cases belonging to the same category (melanocytic skin lesion) was an original information systems  $S$ , another one containing cases belonging to another category was treated as an extension of  $S$  (possibly non-proper).
- 2) An information system containing cases belonging to the same category (melanocytic skin lesion) was split randomly into two disjoint subsystems. The first part (greater) constituted an original system, the second one - its extension (possibly non-proper).

For each case from the extension of the original information system  $S$ , we have calculated a consistency factor with the knowledge included in  $S$  according to Algorithm 1. In the

---

#### Procedure for experiments

---

**Input :** An original (training) information system  $S_{train} = (U_{train}, A)$ , a testing information system  $S_{test} = (U_{test}, A)$ .

**Output:** A testing information system  $S_{test}$  with consistency factors assigned to objects in  $S_{test}$  with the knowledge expressed by  $Rul(S_{train})$  using Algorithm 1.

**for each**  $u \in U_{train}$  **do**

  Calculate a consistency factor  $\xi_S(u)$  of  $u$  with the knowledge expressed by  $Rul(S_{train})$  according to Algorithm 1;

  Assign  $\xi_S(u)$  to  $u$ ;

**end**

**return**  $S_{test};$

---

approach presented in this paper, we expect the following situations:

- 1) If a given case belongs to a different category from the category of cases in the original system, then the consistency factor should be smaller.
- 2) If a given case belongs to the same category as cases in the original system, then the consistency factor should be greater.

In Table II and III, we present aggregated results (average consistency factors) of our experiments. Results have partly confirmed our expectations. Some exceptions can indicate two directions for further research:

- 1) Some combinations (cases) of colors and diversities of structures used in the synthesis of images of melanocytic skin lesions are incorrectly categorized. It is indication that an informational data base should be verified.
- 2) The proposed method needs some improvement (tuning) for better differentiating between cases belonging to different categories.

#### V. CONCLUSION

In the paper, we have proposed a method for validation of a categorization process. The method is based on extensions of information systems defined in terms of rough sets. Usefulness of the proposed method has been shown for the data used in the synthesis of images of melanocytic skin lesions. Obtained results have indicated directions for further research. The first direction is a verification of an informational data base of combinations of colors and diversities of structures used in the synthesis of images of melanocytic skin lesions. The second one concerns further developing of the proposed methodology.

**Abstract**—Attribute values may be either discrete or continuous. Attribute selection methods for continuous attributes had to be preceded by a discretization method to act properly. The resulted accuracy or correctness has a great dependance on the discretization method. However, this paper proposes an attribute selection and ranking method without introducing such technique. The proposed algorithm depends on a hypothesis that the decrease of the overlapped interval of values for every class label indicates the increase of the importance of such attribute. Such hypothesis were proved by comparing the results of the proposed algorithm to other attribute selection algorithms. The comparison between different attribute selection algorithms is based on the characteristics of relevant and irrelevant attributes and their effect on the classification performance. The results shows that the proposed attribute selection algorithm leads to a better classification performance than other methods. The test is applied on medical data sets that represent a real life continuous data sets.

**Index Terms**—Attribute selection; Classification, ChiMerge.

## I. INTRODUCTION

ONE OF the major problems in data mining tools is the curse of dimensionality, several attribute reduction algorithms have been developed to solve such problem. The high number of attributes may contain irrelevant or redundant attributes to the classification methods [1]. Attribute reduction algorithms are either attribute selection or attribute extraction algorithms. Attribute selection algorithms determine the importance of the attributes according to the class labels. The first selected attribute that got the highest rank is the most relevant attribute to the class labels, then the relevance degree decreases until the least ranked attribute. If the classifier is applied only on attributes of the highest ranked attributes, the accuracy of the classifier should be better than being applied on all attributes. The reason of the decrease in accuracy when using all attributes is that the attributes with the lowest ranks have a negative impact on the classification result. An interesting observation that appears in [2], [3] that the trend of the classification accuracy of the classifier applied after the attribute selection algorithm increases until a certain peak where the most relevant attributes are used attributes. Then the classification accuracy starts to decrease which shows the effect of the irrelevant attributes, attributes with the lowest ranks, on the classifier.

The input data sets are either contain attributes of continuous values, discrete values or both types. For continuous data sets, attribute selection algorithms like chi-square, gain ration and information gain have to be preceded by a discretization method [4]. The correctness of the selected attributes has a great dependence on such discretization method. The proposed method here is an attribute selection and ranking method of continuous attributes that does not need to be preceded by a discretization method. It depends on a hypothesis that as the non-overlapped interval of values between the classes labels of an attribute increases as the importance of this attribute increases. This algorithm calculates the number of values in these non-overlapped interval for each attribute and accordingly creates a ranking vector. The proposed algorithm will be compared to other algorithms through checking which attribute selection algorithm would lead to the maximum classification accuracy with the least number of attributes. And hence, two numbers will be used in the comparison which are the number of attributes of highest classification accuracy and the value of this accuracy.

The proposed algorithm will be applied on two different medical real life data sets which are the Indian diabetes and HCV data sets. The classification methods used are the Multi-layered Perceptron and Support vector machine implemented by Weka software.

The rest of this paper is organized as follows: Section II shows the proposed interval-based attribute selection algorithm. Classification results and comparisons with different attribute selection algorithms illustrated in section III. Conclusion and future work is discussed in section IV.

## II. THE INTERVAL-BASED ATTRIBUTE SELECTION ALGORITHM

The interval-based attribute selection algorithm depends on a hypothesis that as the intersection between attribute value ranges of different class labels decreases as the importance of this attribute increases. The reason of this hypothesis is that if an attribute has a certain continuous range of values appears only in the case of a certain class label, then this attribute can help as an indication to this class label. Moreover, as the length of this kind of ranges increases as the importance of this

attribute increases. Figure (1) shows an attribute that contains an interval for each class.

Fig. 1. Non overlapping intervals

The dashed areas show the ranges of values that are not overlapped between multiple class, only a single class label is assigned to this label. In order to evaluate the importance of such attribute, the number of values in ranges that falls in a single class will be calculated for every class and summed. i.e. as shown in figure 1, the number of values that falls in the dashed areas are counted. Then the resulted value, after refinement of this count as shown in the equation 5, will be considered as the attribute rank among other attributes.

$$\mu_a = \frac{1}{n} * \sum_{c \in C} \frac{n_{ci}}{n_c} \quad (1)$$

$\mu_a$  represents the rank of attribute  $a$ ,  $n$  is the number of objects in the data set,  $n_c$  is the number of values where the corresponding objects are of class label  $c$ , and  $n_{ci}$  is the number of values in a rang that is completely falls in class  $c$  where this range is not overlapped with other class labels. For a two class data set, algorithm(1) can be used to calculate the interval-based ranking value which is  $\mu_a$ . The algorithm detects, for every class, the range of values for an attribute that are not in the class and hence counts the number of objects in that range.

The removal of misleading values in Algorithm(2) is an optional step as it depends on the collection methodologies whether it is accurate or not. This step decrease the sensitivity to outliers by removing the values that are most far away from the average of the attribute values. This step should remove only a small percentage of the values in the attribute in order not to affect the accuracy of the results.

### III. EXPERIMENTAL RESULTS AND DISCUSSIONS

#### A. Comparison to other attribute evaluation algorithms

A comparison is applied according to such behavior between different attribute selection algorithms and the proposed interval-based algorithm. The best attribute selection algorithm should follow the following criteria:

- The maximum classification accuracy (peak) is reached with the smallest number of attributes.
- This peak should have the highest value among other attribute evaluation algorithms.

The comparison will be applied through the train and test of the data set multiple times, where in the first time, the data set

---

#### Algorithm 1 Calculate Interval-based rank $\mu_a$ of attribute $a$

---

$\mu_a$  : Attribute  $a$ 's rank, initial value is 0  
*AttributeLength* : Number of objects  
 $x_a$  and  $n_a$  : max and min values of attribute  $a$   
**for** Each Class label  $c$  **do**  
  Remove misleading values.  
  Determine the interval that represent the range of values of the attribute in that class label.  
  *IntervalLength* : Number of objects in class  $c$   
   $x_{ac}$  and  $n_{ac}$  : The max and min values of this interval .  
  //Calculate the number of values outside the interval range.  
   $\mu_c$  : Initial value is 0  
  **for** Each value  $v$  in attribute  $a$  **do**  
    **if**  $v < n_{ac}$  **or**  $v > x_{ac}$  **then**  
       $\mu_c = \mu_c + 1$ .  
    **end if**  
  **end for**  
   $\mu_c = \mu_c / \text{IntervalLength}$   
   $\mu_a = \mu_a + \mu_c$   
**end for**  
 $\mu_a = \mu_a / \text{AttributeLength}$

---

---

#### Algorithm 2 Remove percentage $x$ of misleading

---

Input : *Interval* values of an attribute  $a$  for objects lies in class  $c$   
Output : *avg* average of the values of an attribute  $a$  in a class  $c$   
**for**  $x * \text{IntervalLength}$  values **do**  
  Remove the value of max difference from the average *avg* .  
**end for**

---

will contain only the most single relevant attribute, then the number of attributes will be incrementally increasing until the all the attributes are used. This algorithm could be considered as a semi-wrapper method as the evaluation will be applied only on a certain subset of attributes, where the number of this subsets is equal to the number of attributes. The wrapper-based approaches employ induction classifier as a black box using cross-validation or bootstrap techniques. A method has been previously proposed to compare between different attribute selection algorithms through applying genetic algorithm to evaluate the feature subset candidates suggested by different attribute selection algorithms [11]. This algorithm had solved the problem of the high computation but the problem of dealing with the data sets of continuous attributes still a problem in the used attribute selection algorithms.

In the test, two different classifiers will be applied which are the support vector machine (SVM) and multi-layer perceptron. The SVM classifier uses the Gaussian Radial Basis Function kernel as it shows the best classification accuracy. Both have been extensively used as classification tools with a great deal of success from object recognition. The attribute selection

algorithms used are Chi-merge, gain ratio and information gain attribute selection algorithms.

Another test is applied on these two data sets used, where the classification test is applied on all the possible combination of attributes. The combination that shows the best classification accuracy is the one generated by the proposed interval-based attribute selection algorithm.

*B. Data sets used in classification*

The selection of the data sets used are based on the need of a data set of continuous attributes and discrete class label. A medical data sets have used which are considered as real life data sets that have no specific distribution of values and may contain misleading values due to an error in calibrations or collection of data. The first data set used is pima-indians-diabetes data set which is obtained from UCI machine learning repository [12]. The percentage of error in this data set will be considered zero. It consists of 536 objects and 8 attributes. 90% of the input data used for training while the rest of 10% is used in testing. The second data set used is a data about HCV therapy where it is classified according to the response of some patients to the interferon therapy whether they cured or not. It consists of 66 objects and 13 attributes. There is a percentage of error that may occur in this data set, where experts indicate that it falls between 2 to 3%. Due to the low number of objects, 70% of the input data only are used for training while the rest of 30% is used in testing. Both data sets are adjusted such that the number objects in every class is equal in both stages of training and testing, the classification accuracy will be measured by dividing the number of correctly classified objects by the total number of objects in the testing data set.

*C. Classification results*

1) *pima-indians-diabetes data set:* When different attribute selection algorithms are used like information Gain (IG), Chi-Merge (CM) and Gain Ratio (GR), these algorithms shows the same order of ranked attributes. This is because these algorithms are all entropy based attribute selection algorithms. The comparison between the order of features ranks of entropy based attribute selection algorithms and the interval-based attribute selection algorithm is shown in table (I). In this table another SVM-based feature selection method (SVMB) [10] is used, where it shows nearly the same results as Information gain algorithm.

TABLE I

THE ORDER OF ATTRIBUTES ACCORDING TO INFORMATION GAIN IG AND INTERVAL-BASED IB FEATURE SELECTION ALGORITHMS

IG	2	8	6	5	1	7	3	4
SVMB	2	6	1	7	8	3	4	5
IB	2	5	7	1	4	6	8	3

Table (II) shows the results when perform classification using Support vector machine (SVM) and Multi-layer perceptron

(MLP). The first row in table (II) shows the classification results when using the input data set contains only attribute 2 in the case of using IG and attribute 2 in the case of using IB. The second row the input data set contains attributes 2, 8 in the case of using IG and attributes 2, 5 in the case of IB. The attributes are incrementally increased based on the attribute selection algorithm used until all attributes are used in the input data set.

In the case using MLP classifier, the peak of accuracy has reached with 81.4% when the input data set contain only the first three selected attributes by the IB algorithm which are 2, 5, 7. While the peak when using the other feature selection algorithms is 75.9% and the number of selected attributes is five attributes which are 2, 8, 6, 5, 1. In the case of using SVM both attribute selection algorithms, the proposed IB and the IG attribute selection algorithms, have the same accuracy percentage peak when the first attribute only is selected. It is noticed that both algorithms have selected the same attribute 2 as the most relevant attribute. On the other hand, All the

TABLE II  
CLASSIFICATION RESULTS OF THE PIMA-INDIANS-DIABETES

SVM	SVM	SVM	MLP	MLP	MLP
IG	SVMB	IB	IG	SVMB	IB
<b>64.81</b>	64.81	<b>64.81</b>	74.07	74.07	74.07
64.81	61.11	61.11	74.07	74.07	75.92
64.81	<b>66.66</b>	62.96	74.07407	70.37	<b>81.48148</b>

57.40	68.51	57.40	<b>75.92593</b>	75.92	75.92593
57.47	62.96	57.40	74.07407	<b>77.77</b>	74.07407
55.55	55.55	53.70	72.22222	77.77	68.51852
51.85	51.85	51.85	72.22222	70.37	72.22222

possible combination of attributes are tested in the same way as above using MLP classifier, where 90% of the input data is for training while the rest is for testing. the combination that shows the best results is the set of attributes 2, 5, 7 which is the same set and of the same order generated by the proposed IB algorithm.

2) *HCV data set:* Again in the case Information Gain (IG), Chi-Merge (CM) and Gain Ratio (GR) attribute selection algorithms, The attributes are ranked as follows in table (III). The SVM-Based attribute selection shows the same results as the previous algorithms so it is not useful to maintain them in table (III).

TABLE III

THE ORDER OF ATTRIBUTES ACCORDING TO INFORMATION GAIN IG AND INTERVAL-BASED IB FEATURE SELECTION ALGORITHMS

IG	12	13	4	5	1	3	2	9	11	10
IB	3	4	6	13	9	12	1	5	8	7
IG	6	8	7							
IB	11	10	2							

Table (IV) shows the results when perform classification using SVM and MLP after using both entropy based attribute selection algorithm like the IG and the proposed IB algorithms. It shows that in the case of the selected attributes using the proposed IB algorithm, the classification accuracy has the maximum value when using the first four attributes only. Also the peak was 75 % in the case of using MLP, and 65 % in the case of using SVM. So in both classifiers, the selected attributes by IB has a higher peak than those selected by other attribute selection algorithms.

50.0	50.0	37.5	37.5
50.0	50.0	37.5	37.5

#### IV. CONCLUSIONS

The problem of selecting the features that are relevant to the classifier and remove the irrelevant features has been solved using different attribute selection algorithms. The results demonstrate that the proposed interval-based algorithm encouragingly outperforms most of the popular attribute selection algorithms. The proposed algorithm has two phases for feature selection, the first one is to rank all features according

the discussed algorithm, then select the subset of features of the highest classification accuracy. the proposed algorithm depends on two conditions to determine the selected subset of attributes, where the conditions are based on how high is the classification accuracy and how less is the number of selected attributes. The algorithm has been applied on a real life data sets, where it leads to the best classification accuracy with the least number of features.

**Abstract**—Deformation of normal structures in medical images has usually been considered as undesired and even a challenging issue to be tackled in medical image segmentation and registration tasks. With the objective of improving brain tumor segmentation accuracy in human brain magnetic resonance (MR) images, this paper proposes an approach to extract useful information from the correlation between lateral ventricular deformation and tumor. In some cases, comparative experiments show the improved tumor segmentation accuracy when the extracted information is added as an additional feature.

## I. INTRODUCTION

**B**RAIN tumor segmentation in magnetic resonance (MR) image is an important image processing step for both medical practitioners and scientific researchers. Large amounts of research efforts have been made in developing effective segmentation methods in the past years, however, such methods have failed to achieve the accuracy level comparable to analyses performed by human experts [1], [2], [3], [4].

One of the most challenging problems that hinder the development of accurate automatic systems is that MR image lacks strong association between actual anatomical meaning and MR imaging (MRI) intensity, especially for pathology such as brain tumor. Therefore, in addition to intensities, other features which are relevant to anatomical meaning are necessary for more accurate tumor segmentation.

This paper brings forward the idea of utilizing brain lateral ventricular deformation, which has been normally considered as undesired and challenging, as an additional information for tumor segmentation, and proposes to quantify the deformation information as a feature with a design and implementation of a feature extraction component. The created feature data is then incorporated for improving tumor segmentation accuracy.

## II. BACKGROUND

### A. Brain Lateral Ventricles and Tumor

A ventricle is an internal cavity of brain. A normal brain contains a connecting system of ventricles, commonly referred to as the ventricular system, which is filled with cerebrospinal fluid (CSF) [5], [6], [7], [8]. Fig. 1 illustrates scans from sequences of T1- and T2-weighted MR images in axial view where lateral ventricles are located in the brain center. Lateral

Fig. 1. healthy (a) T1- and (b) T2-weighted brain MR image slices in axial view showing the lateral ventricles, images courtesy of [10].

ventricles are the biggest structures that mainly contain CSF in the axial view of the brain center [9].

As can be seen clearly from Fig. 2(a-i), in cases where brain tumors exist, one or two of the lateral ventricles are compressed; whereas for a healthy brain the two lateral ventricles are nearly symmetrical to each other (see Fig. 1). Fig. 2(j) illustrates the direction of compression from brain tumor and the deformed lateral ventricle. It can be seen that, in some cases, lateral ventricle is compressed in the opposite direction of the location of the brain tumor. This suggests the strong correlation between the two structures. However, due to the fact that brain tumours vary substantially in their location and size, and have diverse effects on lateral ventricles, it is not always the case that brain tumour and deformed lateral ventricles appear in the same image plane. Fig. 3 illustrates how this correlation becomes clear when seen from different planes. The positions of the deformed parts of the lateral ventricle in Fig. 3 (c) and (d) are basically the same as that of the brain tumor in Fig. 3 (b). Fig. 3 (a) illustrates the compression caused by a brain tumour on one lateral ventricle (coronal view). It can be seen that correlations between lateral ventricular deformation and the brain tumor still exist, even though it may not be observable in the same plane or view of MR images.

### B. Brain Tumor Segmentation with Lateral Ventricular Deformation

Automatic MR image segmentation systems are typically designed as a combination of several components of pre-processing, feature extraction, segmentation and classification [1]. Feature extraction component which creates relevant data sets is the key to successful segmentation [1]. It can be assumed that, if the correlation between lateral ventricular

Fig. 2. (a-i): Nine axial view MR image slices from different patients showing brain tumor and lateral ventricles; (j): zoomed illustration of a deformed lateral ventricle and a tumor.

Fig. 3. Some selected MR image slices of one patient showing brain tumour and deformed lateral ventricles not in the same plane of axial view [11]: (a) coronal view in middle of the head; (b) axial view from slice near the top area of the head; (c) axial view from slice in the middle area of the head; (d) axial view from slice next to (c).

deformation and tumor is correctly quantified and used, tumor segmentation accuracy will be accordingly improved.

The fact that lateral ventricles constitute one of the major structures with sharp boundaries in the brain allows for their shapes to be easily delineated from their associated MR images [12], [7], [8]. This makes the feature extraction process based on deformation of this structure relatively more reliable. As a result, lateral ventricular deformation caused by the presence of brain tumors provides an intuition that one could exploit the information derived from the correlations between them. By utilizing this derived information, brain tumor segmentation could be improved.

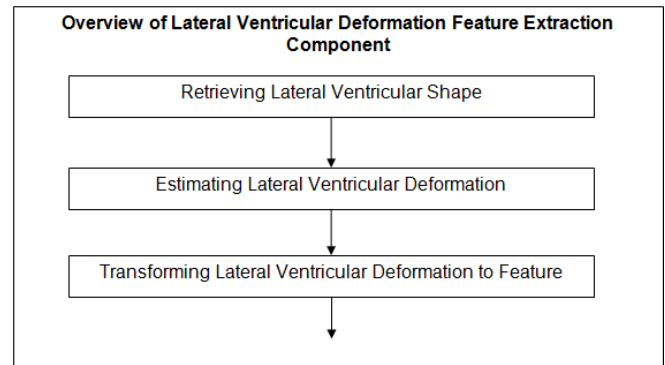

Fig. 4. Overview of the lateral ventricular deformation feature extraction component.

### III. DEFORMATION INFORMATION EXTRACTION

#### A. Overview

The task of extracting the lateral ventricular deformation information should include retrieval of lateral ventricular shape, and transformation of lateral ventricular deformation into feature. To achieve the latter, one process to model and estimate the deformation of the retrieved lateral ventricular shape should be applied.

The step of modeling and estimating lateral ventricular deformation is to associate template and deformed lateral ventricles, and to model, calculate and quantify shape variation. Hence, both healthy and deformed lateral ventricles must be available for shape comparison. However, lateral ventricles of one person are subject to shape variation with age, even with the absence of pathology or abnormality [13]. Furthermore, because of the varieties of size, location and type of brain tumors [14], [15], [16], their compression effects on lateral ventricles are significantly diverse. There are no lateral ventricles that can be used as a general template to perfectly associate the deformed lateral ventricles in all cases. Therefore, an additional step of adjusting feature data is necessary in the lateral ventricular deformation feature extraction component. The design of lateral ventricular deformation feature extraction component actually consists of the three streamlined processes as illustrated in Fig. 4.

#### B. Retrieving Lateral Ventricular Shape

The existing works on brain lateral ventricular shape retrieval generally apply the approach of discriminating tissues of ventricles through the analysis on its intensity and geometric location [17], [18]. In this paper, the lateral ventricular shape retrieval is achieved through three steps: brain MR image tissue segmentation for separating CSF tissue from other tissues, CSF identification for locating the image pixels/regions of which lateral ventricles are composed and lateral ventricles extraction for removing CSF pixels outside the lateral ventricular regions.

In order to separate CSF from other tissues, we can create several clusters by applying a clustering method. In this step, brain tissues are clustered according to the similarity of

Fig. 5. Lateral ventricular shape retrieval results: (a) healthy T1-weighted MR image data; (b) T2-weighted MR image data of (a); (c) after tissue segmentation on (a) and (b); (d) extracted lateral ventricles from (c); (e) tumor-affected T1-weighted MR image data; (f) T2-weighted MR image data of (e); (g) after tissue segmentation on (e) and (f); (h) extracted lateral ventricles from (g).

MRI intensity of tissue types, and one of the output clusters accommodates CSF tissue. This research applies our previous work of feature-weighted Fuzzy C-Means (fwFCM) [19], [20] which provides higher insensitivity to noise and capability of adjusting feature weights. These properties make fwFCM more suitable for MR images than conventional FCM algorithm.

After brain tissue segmentation, CSF extraction can be conducted by selecting the cluster labeled as CSF from the multiple clusters created by the fwFCM method. It can be seen from Fig. 1 that, under the situation of absence of certain types of lesions, within several major tissue types, CSF is the only one that appears bright in T1-weighted and dark in T2-weighted MR images [6]. As a result, intensity values of CSF in T2-weighted MRI are high while those in T1-weighted MRI are low. This selection process can be expressed as:  $\max_i \{V_{T2,i} - V_{T1-i}\}$ , where  $i$  is the cluster number,  $V_{T2}$  and  $V_{T1}$  represent the centroid values in the T2- and T1-weighted features respectively in the input feature set of the fwFCM clustering.

Although from brain MR images of axial view, lateral ventricles are of large volume, CSF can still fall outside the ventricular system [6]. Furthermore, the proposed brain tissue segmentation step may wrongly assign non-CSF pixels to the cluster of CSF. To remove undesired pixels, a global mask is applied to remove pixels outside the area where pixels of lateral ventricles normally reside, thereby leaves the regions as the extracted lateral ventricles. Fig. 5 demonstrates the lateral ventricles extraction results by applying this approach.

### C. Estimating Lateral Ventricular Deformation

The process of estimating lateral ventricular deformation can be decomposed into two steps: lateral ventricles alignment and lateral ventricular deformation measurement. Lateral ventricles alignment is achieved by two sub-steps of linking lateral ventricles and selecting landmark points. The lateral ventricular deformation measurement step is also achieved by two sub-steps of modeling lateral ventricular deformation and calculating estimated deformation.

Fig. 6. Lateral ventricles linking and alignment results: (a) separated left and right lateral ventricles; (b) linked left and right lateral ventricles; (c) template; (d) target; (e) aligned template and target. White circles and grey cross represents control points on template and target lateral ventricles, respectively.

In MR images, left and right lateral ventricles are actually separated [7], [8]. Furthermore, lateral ventricles may be broken. To effectively estimate deformation using modeling functions, left and right lateral ventricles are treated as one single object. Therefore left and right ventricles and the disjointed parts of lateral ventricles need to be linked together. Fig. 6(a, b) demonstrate a sample resultant image after the separated lateral ventricles are linked together through a connecting line with the shortest distance.

Based on the study of anatomical properties of brain lateral ventricles, anterior and posterior horns are employed as key landmark points. The process of lateral ventricles alignment is completed by selecting intermediate landmark points based on these key landmark points. Fig. 6(c, d) show the extracted template and target lateral ventricles, respectively. Fig. 6(e) displays the alignment results by selecting the landmark points and overlapping them in one image. However, misalignment effect caused by the applied imperfect template can be easily observed.

Deformation is usually modeled and represented as a transformation function [21]. Generally, in order to model deformation, both linear and non-linear functions can be used. However, with regards to brain MR images, linear transformation functions, cause the images to be globally smoothed, thereby accommodating only very small and simple deformations [22] and making the process of employing them for modeling deformation undesirable. As a nonlinear deformation modeling function, thin plate splines (TPS) function is employed to perform the nonlinear mapping between template and target lateral ventricular boundary image data set [23]. A TPS  $f(x, y)$  is a smoothing function which interpolates a surface that is fixed at landmark points  $P_i$  at a specific height. TPS can be treated as a process of finding a function  $z(x, y)$  which minimizes the bending energy [23], [24]. In the application for 2-dimensional images, instead of assuming that  $f$  corresponds to a displacement orthogonal to the image plane at the landmark points, one can treat it as a displacement in the image plane [24]. By using two separate TPS functions  $f_x$  and  $f_y$  which model the displacement of the selected landmark points in the  $x$  and  $y$  direction, a vector-valued function  $F$  which maps each

Fig. 7. Example of landmark points with original and deformed TPS meshes formed by  $x$  and  $y$  coordinates: (a) original; (b) deformed. (c) Illustration of the effect of deformation in a zoomed view before and after deformation, solid and dashed lines are segments of the meshes from the original and deformed image, respectively; grey arrows indicate the vector of the displacement due to deformation.

point of the image into a new point in the image plane can be represented using  $(x', y') \rightarrow (f_x(x, y), f_y(x, y))$ , where  $f_x$  and  $f_y$  are the functions causing displacement on  $x$  and  $y$  coordinates respectively.

Once the vector-valued function  $F$  is defined via the selected landmark points with TPS functions, it is then applied to the original coordinates of all pixels in the target image to retrieve new coordinates for all pixels. If one treats some selected horizontal and vertical lines of equal spaces in the original image as a mesh, then a corresponding distorted mesh can be used to describe the displacement of each node of the mesh. This effect is illustrated in Fig. 7(a, b) by visualizing the original and its corresponding deformed meshes after TPS function is applied to all pixels in the image. The effect of the deformation on the lateral ventricles can then be represented by finding out the coordinate displacement value of each pixel in the image. In the deformed image, each pixel is displaced from its original coordinate at specific direction and distance. Therefore, vector can be used for representing the estimated deformation of each point. Fig. 7(c) illustrates an example on a segment of an image using magnitude and direction of vectors to represent the deformation measurement.

#### D. Transforming Lateral Ventricular Deformation to Features

The process of transforming lateral ventricular deformation to features can be decomposed to two indispensable steps: estimated deformation data to feature conversion and lateral ventricular deformation data adjustment.

The estimated deformation data is normalized to the format of image grayscale value of 8 bits, which can be represented as Equation  $I_k = \frac{D_k}{\max\{D\}} \times 255$ , where  $I$  is the normalized intensity value,  $k$  is the index of pixel in the image and 255 is the maximum 8 bits grayscale value of MR image pixels, and  $D$  is the magnitude of displacement vector which can be calculated by using the Euclidean distance as  $D = \sqrt{(P_{o,x} - P_{t,x})^2 + (P_{o,y} - P_{t,y})^2}$ , where  $P_{o,x}$  and  $P_{o,y}$  are the original data point  $x$  and  $y$  coordinate values, while  $P_{t,x}$  and  $P_{t,y}$  are the obtained data point  $x$  and  $y$  coordinate values, respectively.

It can be seen in Fig. 8(b) that that the maximum measured deformation value is not in the area where tumor resides, and the direction of vector denoting the highest displacement value is irrelevant to that of the compression from the brain tumor. This is mainly because of the misalignment between

Fig. 8. Example of estimating lateral ventricular deformation: (a) manual selection of tumor, where round dot is selected by user input; (b) visualized deformation estimation, where magnitude of displacement vector is normalized and visualized as image grayscale value, arrows are showing the directions of displacement vectors, and a cross covered by a circle indicates the maximum displacement vector magnitude; (c) visualized deformation estimation; (d) deformation feature extraction final result.

the template and target lateral ventricles caused by using the imperfect lateral ventricles template (as seen in Fig. 6(e)). To address this problem, as shown in Fig. 8(a), a method for adjusting the estimated deformation data is proposed. The method allows user to select one point in the brain tumor. With this reference point, a line can be drawn from the point to the center of the image, at the direction from the border to the center of the image. Deformation estimation values can therefore be adjusted by  $D' = D |\cos(\frac{\theta}{2})|$ , where  $D$  and  $D'$  are the magnitudes of the original and adjusted displacement vector representing the estimated deformation, respectively.  $\theta$  is the angle between the connecting line and the displacement vector. It can be seen that when  $\theta = \pi$  (the connecting line and the displacement vector are in the opposite directions), adjusted displacement vector magnitude is reduced to 0. And when  $\theta = 0$ , magnitude of the adjusted displacement vector is 1, which means the estimated data is kept without any change.

Fig. 8(c) visualizes the estimated deformation data by normalizing it into grayscale values and Fig. 8(d) illustrates the final feature data of lateral ventricular deformation. It can be seen that, although not perfect, the bright area which indicates the high deformation values is approximately in the same location as brain tumor in the original image. The deformation estimation values can then be used as an additional feature in the feature set the brain MR image tumor segmentation methods that support input data of multiple features.

## IV. BRAIN TUMOR SEGMENTATION WITH LATERAL VENTRICULAR DEFORMATION FEATURE

### A. System Implementation

Structure of the brain tumor segmentation system in this research follows the common MR image segmentation system [1] shown in Fig. 9(a). To investigate the effect of brain tumor segmentation caused by the feature of lateral ventricular deformation, special considerations have to be given to the inclusive components of pre-processing, feature extraction and brain tumor segmentation.

The pre-processing component in this brain tumor segmentation system will need to address the issues of intensity non-standardization, geometrical non-uniformity and redundant data in the image background and skull. These issues are respectively addressed by the four streamlined processes of

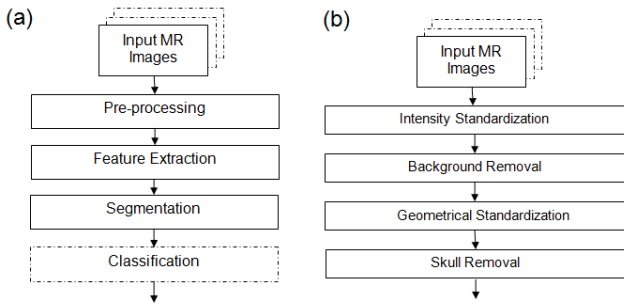

Fig. 9. System structures: (a) structure of a common MR image segmentation system.; (b) overview of the pre-processing component.

intensity standardization, geometrical standardization, background and skull removal processes, as illustrated in Fig. 9(b).

In the segmentation component, selected supervised and unsupervised segmentation methods are used to evaluate the effect of lateral ventricular deformation feature on brain tumor segmentation. In order to achieve that, this research uses two feature sets, one includes the extracted lateral ventricular deformation feature, and the other does not. By comparing the segmentation results using the same segmentation method, i.e., supervised or unsupervised, effectiveness of the feature of brain lateral ventricular deformation can be examined. In this paper, the most frequently used  $k$ -nearest neighbors ( $k$ -NN) [25], [26], [1] and conventional FCM [27], [19], [20] are selected as supervised and unsupervised methods, respectively. The intention of selecting conventional FCM method is to evaluate the segmentation results by the original segmentation method with no interference or adjustment.

### B. Experimentation and Evaluation

To use the supervised  $k$ -NN algorithm on brain tumor segmentation, tumor segmentation results from medical experts are used as training samples in which tumor areas are marked. Therefore all pixels in the images can be labeled as tumor or non-tumor. After the  $k$ -NN classification, each testing image pixel is categorized as tumor or non-tumor. In the experiments using unsupervised FCM algorithm, the number of clusters is set to 6 denoting six clusters of major brain tissues. The cluster of tumor will be identified manually out from 6 clusters after the clustering process due to the fact that there is no training data for the FCM method.

By using input feature set with or without the extracted deformation feature, pixels segmented as tumor which are in the same class as the corresponding pixels in the segmentation by medical expert are treated as correctly segmented tumor pixels; those segmented as tumor but labeled as non-tumor in the segmentation by medical expert are treated as wrongly segmented tumor pixels.

Statistical measures of sensitivity and specificity [28], [29] are applied for evaluating the segmentation results. By treating correctly segmented tumor, wrongly segmented tumor, correctly segmented non-tumor and wrongly segmented non-tumor pixel number as true positive ( $true^+$ ), false positive

Fig. 10. Training data and tumor segmentation results using  $k$ -NN classifier: (a) segmentation by medical expert; (b) training data converted from (a); (c) segmentation result without deformation feature; (d) segmentation result with deformation feature, and segmentation results using FCM clustering method: (e) segmentation by medical expert; (f) visualized segmentation by medical expert; (g) segmentation result without deformation feature; (h) segmentation result with deformation feature.

( $false^+$ ), true negative ( $true^-$ ) and false negative ( $false^-$ ) number respectively, sensitivity and specificity values can be obtained according to:  $Sensitivity = \frac{true^+}{true^+ + false^-}$  and  $Specificity = \frac{true^-}{true^- + false^+}$ , respectively. A sensitivity of 100% means that the test recognizes all actual positives, i.e., all brain tumor pixels are segmented as tumor. And a specificity of 100% means that the test recognizes all actual negatives, i.e., all non-tumor pixels are segmented as non-tumor [28].

The brain tumor segmentation result of one image case is illustrated in Fig. 10. It can be seen from Fig. 10 (d, h) that, the classification results obtained from the feature set with lateral ventricular deformation feature are respectively closer to the results from medical expert than the result shown in Fig. 10 (c, g), which is created from the feature set without lateral ventricular deformation feature.

With more image cases, sensitivity and specificity values tabulated in Table I and Table II provide further evidence of the positive effect from the additional feature. It can be seen from in Table I that from the experiments using supervised  $k$ NN, with the inclusion of the extracted lateral ventricular deformation feature, specificity values in the increase for all eight cases. Except for the decrease in case number 3, sensitivity values increase in 7 out of 8 cases. In the experiments using unsupervised FCM as illustrated in Table II, with the inclusion of the extracted lateral ventricular deformation feature, specificity values increase for all eight cases. However, sensitivity values decrease in 3 out of 8 cases. This is mainly because there is no specific rule created for distinguishing between tumor and non-tumor pixels in clustering [30]. In short, the clusters of tumor or non-tumor are not well defined concepts if no training process is included in the segmentation.

### V. CONCLUSION

This paper establishes and implements the idea of utilizing deformation of lateral ventricles for brain tumor segmentation. The results show that the extracted lateral ventricular deformation information is relevant to the position of brain tumor.

TABLE I  
SPECIFICITY AND SENSITIVITY VALUES OF BRAIN TUMOR SEGMENTATION USING SUPERISED  $k$ NN METHOD

	Specificity		Sensitivity	
	Feature Set			
	without deformation	with deformation	without deformation	with deformation
Case 1	99.9%	100.0%	94.3%	95.3%
Case 2	99.9%	100.0%	90.9%	98.2%
Case 3	99.8%	99.9%	95.3%	94.3%
Case 4	99.1%	99.4%	79.7%	88.2%
Case 5	99.2%	99.7%	61.6%	82.7%
Case 6	99.8%	99.9%	93.7%	96.0%
Case 7	99.2%	99.8%	87.3%	96.6%
Case 8	99.8%	99.9%	91.0%	95.3%

TABLE II  
SPECIFICITY AND SENSITIVITY VALUES OF BRAIN TUMOR SEGMENTATION USING UNSUPERISED FCM METHOD

	Specificity		Sensitivity	
	Feature Set			
	without deformation	with deformation	without deformation	with deformation
Case 1	100.0%	100.0%	80.6%	81.9%
Case 2	99.2%	99.9%	2.29%	12.47%
Case 3	99.9%	99.9%	22.4%	20.2%
Case 4	98.2%	100.0%	13.8%	18.4%
Case 5	99.9%	99.9%	13.8%	15.7%
Case 6	99.2%	99.5%	11.1%	11.0%
Case 7	97.8%	99.2%	80.3%	84.1%
Case 8	100.0%	100.0%	49.1%	36.5%

By incorporating the relevant lateral ventricular deformation as an additional feature in the feature set for pattern recognition segmentation methods, brain tumor segmentation accuracy increases.

**Abstract**—Medline articles are rich resources for discovering hidden knowledge for the treatments of liver specific parasites. Knowledge acquisition from these articles requires complex processes depending on biomedical text mining techniques. In this study, name entity recognition and hierarchical clustering techniques were used for advanced drug analyses. Drugs were extracted from the articles belonging to specific time periods and hierarchical clustering was applied on parasite and drug datasets. Hierarchical clustering results revealed that some parasites have similar in terms of treatment and the others are different. Our results also showed that, there have not been major changes in the treatment of liver specific parasites for the past four decades and there are problems associated with the development of new drugs. Both pharmaceutical initiatives and health-care providers should investigate major drawbacks and develop some strategies to overcome these problems.

**Index Terms**—Biomedical Text Mining, Clustering Analysis, Liver, Parasite.

### I. INTRODUCTION

MEDLINE articles are rich resources for discovering and tracking medical knowledge. Biomedical text mining techniques play an important role to acquire knowledge from these articles and they are applied for numerous studies in biomedical domain so far.

Parasitic diseases affect hundreds of millions of people worldwide and result in significant mortality and devastating social and economic consequences [1]. Parasitic diseases are especially harmful on the liver which supports almost every organ and liver specific parasites also affect many people [2].

In this study, we developed a knowledge discovery on the treatment of parasites affecting liver and we hope that our study makes substantial contributions to all scientists and medical experts working on parasites affecting the efficiency of the liver's mechanism.

### II. METHODS

We used the Medline distribution available through the PubMed Web portal at the National Library of Medicine (NLM)<sup>1</sup> as well as on the in house distribution at the EMBL-

EBI<sup>2</sup>. In the first phase of our article analysis procedure, two clinicians proposed a list of species which induce liver-specific diseases. They also proposed classes of drugs that could be used in the treatment of these diseases.

Medline is a collection of biomedical documents and administered by the National Center for Biotechnology Information (NCBI) of the United States National Library of Medicine (NLM). PubMed web site provides a service of the National Library of Medicine that include over 20 millions bibliographic citations from Medline and other life science journals for biomedical articles back to 1950s. The full text of articles are not stored; rather, links to the provider's site to obtain the full-text articles are given, is available [3-4].

TABLE I  
NUMBER OF ARTICLES FOR SELECTED PARASITES

Parasite	Number of Articles
Clonorchis Sinensis	178
Echinococcus Multilocularis	229
Echinococcus granulosus	400
Entamoeba histolytica	1075
Fasciola Hepatica	917
Schistosoma Japonicum	446
Schistosoma Mansoni	1731
Opisthorchis Viverrini	213
<b>Total</b>	<b>5189</b>

Medline abstracts are in XML format and they contain logical markup to organize meta information such as the journal, author list, affiliations, publication dates and related MeSH headings [5].

We used a complex query for the retrieval of the Medline abstracts that are relevant for the liver specific parasites. The query resulted in a document set of 17,377 articles and all articles were processed with the text mining solution available at

<sup>1</sup> <http://www.ncbi.nlm.nih.gov/pubmed/>

<sup>2</sup> <http://www.ebi.ac.uk/citexplore/>

the EBI (European Bioinformatics Institute) called “Filter Server”. In EBI architecture, a filter server specializes in recognizing the vocabulary of a particular terminology and receives a stream of text and annotates it with XML tags [6].

In our study, the filter servers identified the species mentions and its variants and the mention of drugs in the text. Species in the articles were annotated and parasites’ names affecting liver were selected by two medical doctors. The frequencies of parasites were calculated. The frequency of the parasite provides the number of times a considered parasite appeared in the selected articles. Most ranked eight of them were used for analysis. Relevant articles for each parasite belonging to specific time periods (e.g., 1970-1980, 1980-1990, 1990-2000 and 2000-2009) were collected from PubMed. Table 1 shows the number of articles for selected parasites.

After retrieving the articles in specific time periods, drugs names were found by using drug filter server which tags drugs’ names from DrugBank. The DrugBank database is a bioinformatics and cheminformatics resource that combines detailed drug data with comprehensive drug information<sup>3</sup> [7].

Drugs have some variations such as synonyms and brand names. DrugBank was searched for each drug, synonyms and brand names of drugs were found. After finding variations, these names were mapped to one specific name.

#### A. Clustering Analysis

Clustering analysis is one area of machine learning of particular interest to data mining. It provides the means for the organization of a collection of patterns into clusters based on the similarity between these patterns, where each pattern is represented as a vector in multidimensional space [8].

Hierarchical clustering methods produce a hierarchy of clusters from small clusters of very similar items to large clusters that include more dissimilar items. Hierarchical methods usually produce a graphical output known as a dendrogram or tree that shows this hierarchical cluster structure. Some hierarchical methods are divisive; those progressively divide the one large cluster comprising all of the data into smaller clusters and repeat this process until all clusters have been divided. Other hierarchical methods are agglomerative and work in the opposite direction by first finding the clusters of the most similar items and progressively adding less similar items until all items have been included into a single large cluster [8].

The Euclidean distance is one of the common similarity measures and it is defined as the square root of the squared discrepancies between two entities summed over all variables measured [9].

The pseudo code of agglomerative hierarchical clustering algorithm is as follows:

1. Compute the proximity matrix
2. Merge the closest two clusters
3. Update the proximity matrix to reflect the proximity between the new cluster and the original clusters
4. Repeat step 2 and 3 until only one cluster remains

Figure 1 shows an example of dendrogram for A,B,C,D and E objects [10].

Fig. 1 An Example of Dendrogram for A,B,C,D and E objects

### III. RESULTS

Hierarchical clustering analysis was used to post-process the results from the co-occurrence analysis for the treatment of parasites. R statistical software is used for clustering and heatmap analysis. A heatmap is a graphical way of displaying a table of numbers by using colors to represent the numeric values.

The main categories of drugs that are used for the treatment of parasites comprise anthelmintic, anti-inflammatory and antiprotozoal drugs. Figures 2, 3, 4 and 5 show the heatmaps of the cluster analysis.

According to the observed results, one cluster consists of *Echinococcus Multilocularis*, *Echinococcus Granulosus* and *Fasciola Hepatica*. They share the following commonality:

- Albendazole, mebendazole and praziquantel from the standard treatment for all three parasites. This raises the notion that drugs developed for the treatment of one specie could in principle be exploited for the other two species.

*Clonorchis Sinensis*, *Schistosoma Mansoni* and *Opisthorchis Viverrini* form the second cluster of the analysis. In this cluster, praziquantel is seen as the common treatment. Apart from this drug, these parasites show little treatment with the other antihelmintic drugs. It is possible that these species would still profit from treatment with any of the other drugs.

*Schistosoma Mansoni* forms its own cluster. In the cluster, patients undergo treatment with antiinflammatory drugs similar to patients suffering from *Fasciola Hepatica*, but the type of antiinflammatory treatment differs significantly from the treatment of *Fasciola Hepatica*. Furthermore, patients suffering from *Schistosoma Mansoni* receive additional novel anthelmintic drugs such as levamisole and oxamniquine from 1980 to 2000.

Altogether, the treatment of parasites seems to be fairly stable over the past four decades with regards to the reporting of treatments in the scientific literature.

Fig. 5 Drug heatmap of parasites for 2000-2009 time period

#### IV. DISCUSSION

Infections with parasites are important causes of morbidity and mortality [11]. The control of parasitic disease requires a complex interplay of activities in the fields of public health, education, political will and medicine science. There is a need for treatment, and the search for better drugs is a perpetual process. Advances in science, especially in the field of parasite genomics and its attended technology, have opened up possibilities for new drugs.

We analyzed Medline abstracts to extract hidden knowledge and according to our results, there are no big changes among time periods in the treatment of liver specific parasites. Despite the large global burden of parasitic diseases, there has been very little recent effort by the pharmaceutical industry to develop agents to treat human parasitic infections [12].

Parasitic diseases, though globally massive in their impact, mainly affect poor people in poor regions of the world. As such, they would never be viewed as viable target markets for the pharmaceutical industry, particularly in today's post merger climate. In parallel, funding for basic research on these organisms and the pathogenesis of the diseases they produce has been woefully inadequate compared with funding for diseases of much lower prevalence but more direct impact in the developed countries of Europe and North America [1].

The protection of proprietary rights and the return of investments are also important issues for drug makers. With the long payback period associated with these indications, costs often are not recovered when a compound runs off patent and generic products may be introduced [13].

Regulatory requirements are another major concern that has a considerable impact on the length and costs of the drug development process and, hence, on the ultimate market price of the drug product. Paradoxically, increasingly demanding standards favour the larger wealthy companies which are those least interested in tropical diseases. Nevertheless, dossiers do not always undergo the same level of review worldwide, sometimes because of limited health budgets, and sometimes owing to a misconception about the regulatory process [13].

Medline abstracts are generally publicly available and therefore easy to share and distribute, while full text papers are not always available. However, there are some works to make them easily available and they can be public and sharable soon. As future work, it would be of interest to develop an efficient way to analyze full text papers to compare the results of abstracts [14].

#### V. CONCLUSIONS

Biomedical literature provides valuable knowledge for clinical studies and research. Medical experts can not read all the articles in a specific medical problem and discover hidden connections between entities. In this study, we worked with medical doctors and considered their needs and

the point of view of them. Liver specific parasites were selected for the research. The combination of data mining and text mining techniques were used to get some facts hidden in Medline articles. Drugs which are based on specific time periods were extracted from the articles by using named entity recognition techniques and hierarchical clustering techniques were applied on parasite-drug datasets. Hierarchical clustering results revealed that some treatments of parasites are similar and the others are different. Our results also show that there have not been major changes in the treatment of liver specific parasites for the past four decades. We investigated the reasons for the challenge of drug discovery and development for parasitic diseases. We believe that our results will make an important contribution to medical research, clinical studies and pharmaceutical research.

#### ACKNOWLEDGMENT

We would like to thank Antonio Jose Jimeno Yepes, Dietrich Rebholz Schuhmann and Rabin Saba for their help and contributions.

**Abstract**—Modern system is complex and includes different types of components such as software, hardware, human factor. Reliability is principal property of this system. The importance analysis is one of approaches in reliability engineering. Application of this approach for healthcare system is considered in this paper. The importance reliability analysis allows estimating the influence of every healthcare system component to the system reliability, its functioning and failure.

### I. INTRODUCTION

THE PRINCIPAL goal of IT application in medicine is improvement and conditioning of medical care [1]–[3]. Modern healthcare systems have to reduce problems and difficulties in diagnosing and treatment of diseases, and have to perfect patient care. Therefore the healthcare has to be characterised by high reliability first of all and reliability analysis of such system is important problem.

There are investigations in reliability analysis of healthcare system. This area includes some concepts that can be declared as reliability analysis of medical equipment and devices [3]–[5] and human reliability analysis in medicine [4], [6], [7]. Unfortunately, these concepts develop independently, only in paper [4] problems of reliability analysis of technical part and human factor have been considered but different methods for their analysis have been proposed. It is caused by reliability engineering state, where there are some independent areas of investigation, for example, as software reliability analysis, hardware reliability analysis, human reliability analysis (HRA). Methods of estimation and quantification of these objectives aren't interchangeable. Therefore reliability analysis system with different types of component needs new methods. These methods have to allow estimation of such system based on unified methodology. Declaration of this problem for the healthcare system has been presented in [8].

According to [8] the healthcare system includes four components of different types (Fig.1): hardware, software, human factor and organization factor. In the paper [8] there

have been shown that the hardware and software components unite in one component for the healthcare system. This component is named as technical component, but this component is separated from other two components: special technical component and basic technical component. The first of them includes special equipment, devices and software (for example, magnetic resonance imaging scanners). The second component corresponds with basic equipment and software as personal computer, operating system, database and etc. The human factor and organization factor have been interpreted as two components.

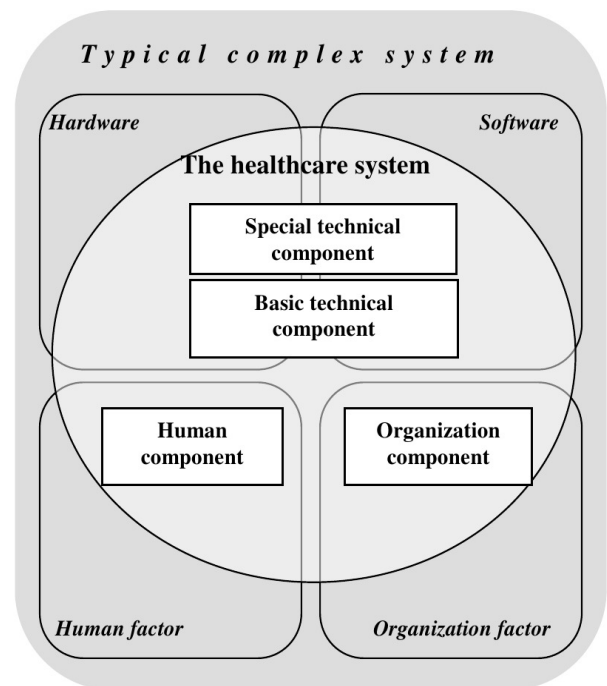

Fig. 1 The healthcare system typical structure for reliability analysis

In this paper reliability analysis of the healthcare system (Fig.1) is developed. The influence of system component states (some levels of functioning and failure) to the system reliability is investigated and quantified based on unified methodology. In other words the probabilities of the healthcare system performance levels are calculated against changes of the system component state changes.

This work was supported by grant VEGA and project "CREATING A NEW DIAGNOSTIC ALGORITHM FOR SELECTED CANCER DISEASES" co-financed from EU sources and European Regional Development Fund.

## II. RELIABILITY ANALYSIS OF HEALTHCARE SYSTEM

### A. Background and mathematical model

The basic reliability concept is defined as the probability that the system will perform its intended function during a period of running time without any failure. A fault is an erroneous state of the system. Although the definitions of fault are different for different systems and in different situations, a fault is always an existing part in the system and it can be removed by correcting the erroneous part of the system. New tendencies in reliability engineering have been defined in [9], some of they are:

- detail analysis of changes of the system reliability states from perfect function to failure;
- priority analysis of causes of the system failure, e.g. discover causes and mechanisms of failure and to identify consequences;
- development of methods for the system reliability analysis in design.

These tendencies have been taken into account in process of any system reliability analysis that includes next steps:

- the quantification of the system model;
- the representation and modelling of the system;
- the quantification of the system reliability (definition of reliability indexes and measures for the system evaluation).

Two steps of the system process analysis considered with definition of the mathematical model. This model has to allow estimation some levels of the system reliability changes. Binary-State System (BSS) and Multi-State System (MSS) are basic mathematical models in reliability analysis. BSS is used for description of initial system as system with two states: reliable and unreliable. But this model doesn't allow quantifying different levels of the system reliability. MSS is mathematical model in reliability analysis that is used for description system with some (more than two) levels of performance (availability, reliability) [9], [10]. MSS allows presenting the analyzable system in more detail than traditional Binary-State System.

The MSS and each of  $n$  components can be in one of  $m$  possible states: from the complete failure (it is 0) to the perfect functioning (it is  $m-1$ ). A structure function is one of typical representations of MSS [10], [11]. This function of a MSS of  $n$  components is denoted as:

$$\phi(x_1, \dots, x_n) = \phi(\mathbf{x}): \{0, \dots, m-1\}^n \rightarrow \{0, \dots, m-1\}, \quad (1)$$

where  $x_i$  is the  $i$ -th component;  $\mathbf{x} = (x_1, \dots, x_n)$  is vector of components states; values of a MSS reliability (structure function  $\phi(\mathbf{x})$ ) and its component state (variables  $x_i, i = 1, \dots, n-1$ ) change from zero to  $(m-1)$ .

Need to say that for the structure function (1) there are next assumptions that will be used in the system reliability estimation [12]:

- the structure function is monotone and  $\phi(\mathbf{s}) = s$  ( $s \in \{0, \dots, m-1\}$ );
- all components are  $s$ -independent and are relevant to the system.

Every system component states  $x_i$  is characterized by probability of the performance rate:

$$p_{i,s} = \Pr\{x_i = s\}, \quad s = 0, \dots, m-1 \quad (2)$$

The principal advantage of the system representation by the structure function (1) is definition of this function for any system with different complexity and structure.

There are different directions for quantification of MSS behaviour. One of them is importance analysis [12]–[14].

Importance analysis is used for MSS reliability estimation depending on the system structure and its components states. Quantification is indicated by importance measure. They have been widely used as tools for identifying system weaknesses, and to prioritise reliability improvement activities. MSS importance measures are probabilities that the system has the reliability level  $h$  ( $h = 1, \dots, m-1$ ) if the  $i$ -th system component states is  $s$  ( $s = 1, \dots, m-1$ ). Different combinations of the system reliability levels  $h$  and components states  $s$  allow investigating boundary system state and system states that take priority of failure.

Note one more significant aspect of the importance analysis. Some types of importance measures can be calculated for the system in design. Therefore this system quantification method can be used for the system reliability estimation in design.

The theoretical aspects of MSS importance analysis have been investigated since first paper in MSS analysis [15]. These investigations were developed in papers [12]–[16]. Importance measures for system with two performance level and multi-state components and their definitions by output performance measure have been considered in [12]. Universal generating function method has been used for importance analysis in [12], [16]. Composite importance measures for MSS estimation have been proposed in [14]. New method based on Logical Differential Calculus for importance analysis of MSS has been considered in paper [11], [17] and new type of importance measures has been proposed. These measures have been named as Dynamic Reliability Indices (DRIs). The importance analysis method based on Logical Differential Calculus is demonstrable, intuitive and is characterized by simple calculation.

Therefore MSS importance analysis is actual approach in reliability engineering because allows:

- to investigate the system behaviour in detail that include the quantification of different level of reliability;
- to examine causes of the system failure;
- to estimate the system reliability analysis in design.

The algorithm for the healthcare system reliability estimation by importance analysis based on typical process of the estimation is in Fig.2.

According to the algorithm in Fig.2 number  $m$  of performance (reliability or availability) levels for the system and its components for estimation of this system is defined firstly. Then the structure function as mathematical model of this system is determined taking into account the number of performance levels. For example, consider the healthcare system for the Decision Support System for Early

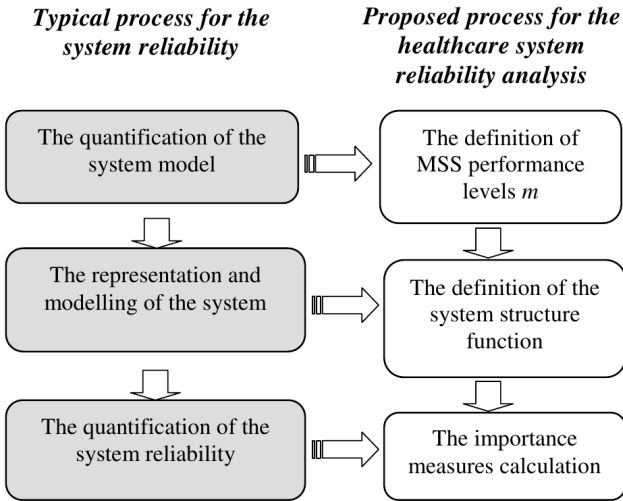

Fig. 2 The healthcare system reliability analysis process

Diagnostics in Oncology (DSSEDO) that have been described in [8]. The system structure can be interpreted as typical for healthcare system in Fig.1. Define for this system number of performance levels as  $m = 3$ . The structure function of this system is defined as:

$$\phi(x) = \text{OR}(\text{AND}(x_1, x_2), \text{AND}(x_1, x_3, x_4)), \quad (3)$$

where  $x_1$  is performance level of the special devices;  $x_2$  is performance level of the basic devices;  $x_3$  and  $x_4$  is performance level of the human and organization components of the system;  $\text{OR}(y, z) = \max(y, z)$ ;  $\text{AND}(y, z) = \min(y, z)$ .

Therefore the structure function (3) is mathematical model for the DSSEDO that is used for estimation and quantification of its performance or reliability (the detail description of this function is in Table I).

*B. Direct Partial Logic Derivative*

The mathematical tool of Multiple-Valued Logic (MVL) as Logical Differential Calculus is used for calculation of importance analysis. The MSS structure function is interpreted as MVL function in this case. The Logical Differential Calculus is mathematical tool that permits to analysis changes in function depending of changes of its variables. Therefore evaluate influence of every system component state change to level of MSS reliability by Direct Partial Logic Derivative (this approach is part of Logical Differential Calculus). Direct Partial Logic Derivative reflects the change in the value of the MVL function when the values of variables change.

A Direct Partial Logic Derivative with respect to  $i$ -th variable for a MSS reliability analysis has been defined in [17] as:

$$\begin{aligned} \partial\phi(j \rightarrow \tilde{j})/\partial x_i(a \rightarrow \tilde{a}) = \\ = \begin{cases} 1, & \text{if } \phi(a_i, x) = j \text{ and } \phi(\tilde{a}_i, x) = \tilde{j} \\ 0, & \text{other} \end{cases} \quad (4) \end{aligned}$$

TABLE I. TRUTH TABLE OF STRUCTURE FUNCTION (3)

$x_1 x_2 x_3 x_4$	$\phi(x)$	$x_1 x_2 x_3 x_4$	$\phi(x)$	$x_1 x_2 x_3 x_4$	$\phi(x)$

0 1 1 2	0	1 1 1 2	1	2 1 1 2	1
0 1 2 0	0	1 1 2 0	1	2 1 2 0	1
0 1 2 1	0	1 1 2 1	1	2 1 2 1	1
0 1 2 2	0	1 1 2 2	1	2 1 2 2	2
0 2 0 0	0	1 2 0 0	1	2 2 0 0	2
0 2 0 1	0	1 2 0 1	1	2 2 0 1	2
0 2 0 2	0	1 2 0 2	1	2 2 0 2	2
0 2 1 0	0	1 2 1 0	1	2 2 1 0	2
0 2 1 1	0	1 2 1 1	1	2 2 1 1	2
0 2 1 2	0	1 2 1 2	1	2 2 1 2	2
0 2 2 0	0	1 2 2 0	1	2 2 2 0	2
0 2 2 1	0	1 2 2 1	1	2 2 2 1	2
0 2 2 2	0	1 2 2 2	1	2 2 2 2	2

where  $\phi(\bullet_i, x) = \phi(x_1, \dots, x_{i-1}, \bullet_i, x_{i+1}, \dots, x_n)$  is value of structure function;  $\tilde{a} \neq a$ ,  $\tilde{j} \neq j$  and  $a, j, \tilde{a}, \tilde{j} \in \{0, \dots, m-1\}$ .

For monotone structure function the changes from  $a$  to  $\tilde{a}$  and from  $j$  to  $\tilde{j}$  can be defined as changes from  $a$  to  $\tilde{a} = (a-1)$  or  $\tilde{a} = (a+1)$  and from  $j$  to  $\tilde{j} = (j-1)$  or  $\tilde{j} = (j+1)$  accordingly. These changes are caused by gradual type of reliability changes without jumps too.

The Direct Partial Logic Derivative allows to calculate the system boundary states for which change the  $i$ -th component state from  $a$  to  $\tilde{a}$  cause changes of the system performance level from  $j$  to  $\tilde{j}$ . These states correspond to the nonzero values of the derivative (4). For example, for the healthcare system with structure function (3) boundary states of the system performance level reduction for the first component are in Table II. These states are computed by Direct Partial Logic Derivative that is indicated in Table II too.

Therefore according to the Table II the first component state change from 2 to 1 doesn't cause the system failure (change from 1 to 0) and the failure of this component doesn't influence to the system performance level change from 2 to 1, because the Direct Partial Logic Derivatives  $\partial\phi(1 \rightarrow 0)/x_1(2 \rightarrow 1)$  and  $\partial\phi(2 \rightarrow 1)/x_1(1 \rightarrow 0)$  have zero value only. But break down of the first component and its deterioration cause failure and degradation of the system

accordantly (derivatives  $\frac{\partial \phi(1 \rightarrow 0)}{\partial x_1(1 \rightarrow 0)}$  and  $\frac{\partial \phi(2 \rightarrow 1)}{\partial x_1(2 \rightarrow 1)}$  have nonzero values that correspond to the boundary system states).

Investigation of the boundary states of the system is important problem but set of boundary state has high dimensionality and isn't acceptable well for practical application. Therefore in engineering problem probability measures for the system reliability or performance are used as a rule.

### III. HEALTHCARE SYSTEM RELIABILITY ANALYSIS

#### A. Healthcare system probability state

MSS probability state,  $R(j)$ , is one of the best known MSS reliability measures [12]. It is the probability that system performance level is equal to the level  $j$ :

$$R(j) = \Pr\{\phi(\mathbf{x}) = j\}, j \in \{0, 1, \dots, m-1\}. \quad (5)$$

For example, for the healthcare system with structure function (3) can be computed system state probabilities based on its structure function:

$$R(0) = p_{1,0} + (p_{1,1} + p_{1,2}) \cdot p_{2,0} \cdot (p_{3,0} + (p_{3,1} + p_{3,2}) \cdot p_{4,0}),$$

$$R(1) = (p_{1,1} + p_{1,2}) \cdot p_{2,0} \cdot (p_{3,1} + p_{3,2}) \cdot (p_{4,1} + p_{4,2}) + p_{1,1} \cdot (p_{2,1} + p_{2,2}) + p_{1,2} \cdot p_{2,1} \cdot (p_{3,0} + p_{3,1}) \cdot (p_{4,0} + p_{4,1}),$$

$$R(2) = p_{1,2} \cdot p_{2,1} \cdot p_{3,2} \cdot p_{4,2} + p_{1,2} \cdot p_{2,2}.$$

#### B. MSS Importance Measures

Probability states (5) don't enable the analysis of the change in system reliability that is caused by a change in component states. Importance analysis of the healthcare system allows estimating the influence of every system component state changes to system performance. Consider some of importance measures and their calculation by Direct Partial Logic Derivative.

*Structural Importance* (SI) is one of the simplest measures of component importance and this measure is concentrated on the topological aspects of the system. According to definition in papers [13], [18] this measure determines the proportion of working states of system in which the working of the  $i$ -th component makes the difference between system failure and its working. SI of MSS for the  $i$ -th component state  $s$  is probability of this system performance level  $j$  decrement if the  $i$ -th component state changes from  $s$  to  $s-1$  depending on topological properties of system:

$$I_S(s_i | j) = \frac{\rho_i^{s,j}}{m^{n-1}}, \quad (6)$$

where  $\rho_i^{s,j}$  is number of system states when the change component state from  $s$  to  $s-1$  results the system performance level decrement and this number is calculated as numbers of nonzero values of Direct Partial Logic Derivatives (4).

There is one more definition of SI [11]. It is modified SI that represent of the  $i$ -th system component state change influence to MSS performance level decrement for boundary system state. In terms of Direct Partial Logic Derivatives (4) modified SI is determined as:

$$I_{MS}(s_i | j) = \frac{\rho_i^{s,j}}{\rho_i^{(s_i, j)}} \quad (7)$$

where  $\rho_i^{s,j}$  is defined in (6);  $\rho_i^{(s_i, j)}$  is number of boundary system states when  $\phi(s_i, \mathbf{x}) = j$  (it is computed by structure function (1)).

Modified SI  $I_{MS}$  is probability of MSS performance decrement depending on the  $i$ -th component state change and boundary system states. A system component with maximal value of the SI measure ( $I_S$  and  $I_{MS}$ ) has most influence to MSS and this component failure causes high possibility of MSS failure [11], [13].

SI and modified SI measures don't depend on components state probability (2) and characterize only topological aspects of MSS performance. These measures are used for prevention system analysis or reliability analysis in step of a system design previously.

*Birnbaum Importance* (BI) of a given component is defined as the probability that such component is critical to MSS functioning [13], [14], [19]. This measure has been defined for traditional system with two states firstly as:

$$I_B(x_i) = |\Pr\{\phi(\mathbf{x}) = 1, x_i = 1\} - \Pr\{\phi(\mathbf{x}) = 1, x_i = 0\}|$$

But mathematical and logical generalization of this measure for MSS has some interpretations. So in paper [12] proposed definition of BI for system with two performance level that consists of multi-state components. Authors of the paper [14] considered definition of BI of MSS failure analysis. Than in paper [18], [20] new modifications of BI and algorithms for calculation based on different methodological approach have been proposed. One more interpretation of BI for MSS in terms of Logical Differential Calculus has been presented in paper [11]. According to this definition, BI is probabilistic measure that can be interpreted as rate at which the MSS fails as the  $i$ -th system component state decreases:

$$I_B(s_i | j) = \left| \Pr\{\phi(x) |_{x_i=s} = j\} - \Pr\{\phi(x) |_{x_i=s-1} = j\} \right|, \quad (8)$$

where

$$\Pr\{\phi(x) |_{x_i=s} = j\} = \sum p_{1,a_1} \cdots p_{i-1,a_{i-1}} p_{i+1,a_{i+1}} \cdots p_{n,a_n}$$

if  $\phi(x) = j$  and  $x_i = s$  for  $a_w = \{0, \dots, m-1\}$ ,  $w = 1, \dots, n$  and  $w \neq i$ ;  $s = \{1, \dots, m-1\}$ .

BI measures (8) depend on the structure of the system and states of the other components, but is independent of the actual state of the  $i$ -th component.

Consider the definition of *Criticality Importance* (CI) that is the probability that the  $i$ -th system component is relevant to MSS performance decrement if it has failed or has diminished state. For the system with two performance level this measure is considered in [19] in detail. For MSS this measure can be defined as probability of the MSS performance reduction if the state of the  $i$ -th system component has changed from  $s$  to  $s-1$ :

$$I_C(s_i) = I_B(s_i | j) \cdot \frac{p_{i,s-1}}{R(j)}, \quad (9)$$

where  $I_B(s_i | j)$  is the  $i$ -th system component BI measure (8);  $p_{i,s-1}$  is probability of the  $i$ -th system component state  $s-1$  (2) and  $R(j)$  is probability of system state  $j$  that is defined in accordance with (5);  $s = \{1, \dots, m-1\}$

The CI measure (9) correct BI for unreliability or lower state of the  $i$ -th component relative. This measure is useful, if the component has high BI and low probability of investigated state with respect of MSS performance decrement. In this case the  $i$ -th component CI is low.

*Fussell-Vesely Importance* (FVI) measure quantifying the maximum decrement in system reliability caused by the  $i$ -th system component state deterioration [12], [14]. By other words this measure represents the contribution of each component to the system and for the system with two performance levels is calculated by next equation [21]:

$$I_{FV}(x_i) = \frac{\Pr\{\phi(x)=0\} - \Pr\{\phi(x)=0 | x_i=1\}}{\Pr\{\phi(x)=0\}}.$$

FVI for MSS represents probabilistic measure of the  $i$ -th component state deterioration influence to the system performance level decrement:

$$I_{FV}(s_i | j) = 1 - \frac{\Pr\{\phi(s_i, \mathbf{x}) = j\}}{R(j)} \quad (10)$$

where

$$\Pr\{s_i, \phi(x) = j\} = \sum p_{1,a_1} \cdots p_{i,s_i} \cdots p_{n,a_n} \quad \text{if}$$

$\phi(x) = j$  and  $x_i = s$  for  $a_w = \{0, \dots, m-1\}$ ,  $w = 1, \dots, n$  and  $w \neq i$ ;  $s = \{1, \dots, m-1\}$ .

The calculation of FVI measure is similar to algorithm for computation of BI measure.

*Reliability Achievement Worth* (RAW) and *Reliability Reduction Worth* (RRW) are two importance measures and both represent adjustments of the improvement potential to MSS unreliability. RAW for Binary-State System (system that has only two performance level as function and failure) indicates the increase in the system unreliability when the  $i$ -th component is failed and this measure is defined as [21]:

$$I_{RAW}(x_i) = \frac{\Pr\{\phi(0_i, x) = 0\}}{F}$$

According to the papers [12], [14] RAW for MSS is defined as the ratio of MSS unreliability if the  $i$ -th component state has decrease:

$$I_{RAW}(s_i | j) = \frac{\Pr\{\phi(s_i-1, x) = j\}}{R(j)}, \quad (11)$$

where  $s = \{1, \dots, m-1\}$ .

RRW can be interpreted as opposite importance measure to RAW and for Binary-State System is defined as [21]:

$$I_{RRW}(x_i) = \frac{F}{\Pr\{\phi(1_i, x) = 0\}}.$$

Generalization of this equation and representation of RRW in [12], [14] allows defining RRW for MSS as importance measure quantifies potential damage caused to the MSS by the  $i$ -th system component:

$$I_{RRW}(s_i | j) = \frac{R(j)}{\Pr\{\phi(s_i, x) = j\}}, \quad (12)$$

where  $s = \{1, \dots, m-1\}$ .

There is one more type of importance measures for MSS that are *Dynamic Reliability Indices* (DRIs). These measures have been defined in paper [11], [17]. DRIs allow to estimate component relevant to MSS and to quantify the influence of this component state change to the MSS performance. There are two groups of DRIs: *Component Dynamic Reliability Indices* (CDRIs) and *Dynamic Integrated Reliability Indices* (DIRIs).

CDRI indicates the influence of the  $i$ -th component state change to MSS performance level change [17]. This

definition of CDRI is similar to definition of modified SI, but CDRI for MSS failure take into consideration two probabilities: (a) the probability of MSS performance level decrease caused by the  $i$ -th component state reduction and (b) the probability of this component state:

$$I_{CDRI}(s_i|j) = I_{MS}(s_i|j) \cdot p_{i,s_i-1} \quad (13)$$

where  $I_S(x_i|j)$  is the modified SI (7);  $p_{i,s_i}$  is probability of component (2).

DIRI is the probability of MSS performance level decrement that caused by the one of system components state deterioration. DIRIs allow estimate probability of MSS failure caused by some system component (one of  $n$ ):

$$I_{DIRI}(s|j) = \sum_{\substack{q \neq i \\ \dot{c}}}^n \dot{c} \dot{c} \quad (14)$$

#### IV. EXAMPLE OF HEALTHCARE SYSTEM IMPORTANCE ANALYSIS

Consider the healthcare system in Fig. 1. The structure function of such healthcare system is declared based on an expertise for every real system. This function is defined based on the expert knowledge and influence form the area of the system application. For example, the Decision Support System for Early Diagnostics in Oncology (DSSEDO) has structure function (3) that is described in Table I. The MSS mathematical model of this system has three levels of performance ( $m = 3$ ) and four components ( $n = 4$ ). In Table I the system component state 0 considers to the component failure; the component state 1 is component functioning with some unimportant restriction; the component state 2 is perfect functioning. The component probabilities in Table III have been determined for this system by the expertise.

TABLE III. COMPONENT PROBABILITIES

$i$	$m$	0	1	2
1		0.1	0.2	0.7
2		0.1	0.4	0.5
3		0.2	0.4	0.3
4		0.3	0.5	0.3

So the system state probabilities (5) for this healthcare system are calculated based on component probabilities in Table III:

$$R(0) = p_{1,0} + (p_{1,1} + p_{1,2}) \cdot p_{2,0} \cdot (p_{3,0} + (p_{3,1} + p_{3,2}) \cdot p_{4,0}) = 0.137,$$

$$R(1) = (p_{1,1} + p_{1,2}) \cdot p_{2,0} \cdot (p_{3,1} + p_{3,2}) \cdot (p_{4,1} + p_{4,2}) + p_{1,1} \cdot (p_{2,1} + p_{2,2}) + p_{1,2} \cdot p_{2,1} \cdot (p_{3,0} + p_{3,1}) \cdot (p_{4,0} + p_{4,1}) = 0.488,$$

$$R(2) = p_{1,2} \cdot p_{2,1} \cdot p_{3,2} \cdot p_{4,2} + p_{1,2} \cdot p_{2,2} = 0.375$$

Therefore the performance level 1 of the healthcare system is more probably than system perfect functioning (the

performance level 2) and system failure that have probabilities 0.137 and 0.375 accordingly.

Importance measures of this system are in Table IV. According to the data in Table IV the first system component change has maximal influence to the system reliability. Therefore correct functioning of special devices is important condition for reliability of the healthcare system with structure function (3). But need to say that the modification of the structure function of this system causes change of the importance analysis result. The positive result of importance analysis will be obtained based on investigation of some structure function of this system. The impediment for this analysis is caused by generation of structure function based on expert knowledge only that is subjective.

TABLE II. IMPORTANCE MEASURES FOR THE SYSTEM WITH STRUCTURE FUNCTION (3)

$i$	1	2	3	4
<b>Importance measures</b>				
$I_S(x_i 1)$	0.222	0.123	0.049	0.049
$I_S(x_i 2)$	0.123	0.099	0.025	0.025
$I_S(x_i)$	0.173	0.111	0.027	0.027
$I_{MS}(x_i 1)$	1	0.588	0.308	0.308
$I_{MS}(x_i 2)$	1	0.889	0.400	0.400
$I_{MS}(x_i)$	1	0.739	0.354	0.354
$I_B(x_i 1)$	0.456	0.248	0.063	0.010
$I_B(x_i 2)$	0.800	0.452	0.050	0.105
$I_B(x_i)$	0.628	0.350	0.032	0.058
$I_C(x_i 1)$	0.095	0.052	0.026	0.006
$I_C(x_i 2)$	0.419	0.473	0.053	0.137
$I_C(x_i)$	0.257	0.263	0.040	0.072
$I_{CDRI}(x_i 1)$	0.100	0.059	0.062	0.062
$I_{CDRI}(x_i 2)$	0.200	0.356	0.160	0.200
$I_{CDRI}(x_i)$	0.150	0.208	0.111	0.131

#### V. CONCLUSION

In this paper new algorithms of IM calculation for MSS analysis are considered. These algorithms are implemented based on methods of MVL as Logical Differential Calculus and MDD. But investigated MSS has one principal assumption: system and all its components have  $m-1$  different performance levels and state unreliability. In next investigation we are going to develop this mathematical approach for estimation of MSS without this assumption. Structure function of such MSS is defined as:

$$\phi(x): \{0, \dots, m_i-1\} \times \dots \times \{0, \dots, m_n-1\} \rightarrow \{0, \dots, M-1\}.$$

In this case MSS consists of  $n$  components and has  $M$  levels of the performance rate from complete failure (this level corresponds with 0) to the perfect functioning (this level is interpreted as  $M-1$ ). Each of  $n$  MSS components is characterized by different performance level and the  $i$ -th component has  $m_i$  possible states: from the complete failure (it is 0) to the perfect functioning (it is  $m_i-1$ ).

# 1<sup>st</sup> International Workshop on Advances in Semantic Information Retrieval

**B**AG-OF-WORDS document representation is still the basis for many information retrieval models. Recent advances in semantic technologies have resulted in methods and tools that allow creating and managing domain knowledge. They influence the way and form of representing documents in the memory of computers, approaches to analyze documents, techniques to mine and retrieve, etc. Searching for video, voice and speech raises new challenging problems to retrieval systems.

The aim of this workshop is to discover new challenges in various branches of Internet technologies applied to semantic information retrieval, to foster opportunities for international collaboration between scientists all over the world, and to explore directions for further research. The workshop addresses semantic information retrieval theory, as well as important matters related to Web tools used in practice.

The topics and areas include but are not limited to:

- Models for document representations
- Ontology for semantic information retrieval
- Ontology alignment, mapping and merging
- Search and ranking
- Semantic multimedia retrieval
- Natural language semantic processing
- Evaluation methodologies for semantic search and retrieval
- Query interfaces
- Visualization of the retrieved results
- Domain-specific semantic applications

**Abstract**—An acceleration of regional and international events contributes to the increasing challenges in political decision making, especially the decision to strengthen bilateral economic relationships between friendly nations. Obviously this becomes one of the critical decisions. Typically, such decisions are influenced by certain factors and variables that are based on heterogeneous and vague information. A serious problem that the decision maker faces is the difficulty in building efficient political decision support systems (DSS) with heterogeneous factors. The basic concept is a linguistic variable whose values are words rather than numbers and therefore closer to human intuition. Fuzzy logic is based on natural language and is tolerant of imprecise data. Furthermore, fuzzy cognitive mapping (FCM) is particularly applicable in the soft knowledge domains such as political science. In this paper, a FCM scheme is proposed to demonstrate the causal inter-relationship between certain factors in order to provide insight into better understanding about the interdependencies of these factors. It presents fuzzy causal algebra for governing causal propagation on FCMs.

### I. INTRODUCTION

THE considerable knowledge has been generated, organized, and digitized in various governmental sectors, but it is still not readily accessible at any time or in any convenient place for decision makers. Existing relationships between countries can be described from a variety of perspectives, such as historical, respectful, friendly, neighboring, traditional, religious, political, and economic aspects. Apart from such a variety of relationships, almost all nations seek to build bridges of cooperation with other countries in various ways. One way to build these relationships is to strengthen the economic relationships, wherein the decision maker must take into consideration many factors and variables that influence the promotion of an economic relationship. This information and these factors are diversified and may involve different sectors. From a research viewpoint, the challenges lie in recognizing, finding and extracting these different variables. A conscientious decision maker who takes responsibility for promoting and strengthening bilateral economic relationships needs access to well-structured information relevant to his/her decisions. Unfortunately, in reality, the basic concept of this information is a linguistic variable, that is, a variable whose values are words rather than numbers across different domains including the political and investment domains. This makes it extremely difficult for the decision

maker to understand the concepts, restraints, and facts that exist in these domains. Due to the various factors that influence the decisions intended to strengthen economic relationships with other countries, there is an urgent need to develop a proper system that analyzes the data gathered from different sectors and produces precise and certain outputs that could be useful to the decision makers. In Kuwait, the scattered data mostly lies in various governmental sectors, including the Kuwait Fund for Development, the Kuwait Investment Authority, the Ministry of Foreign Affairs, the Prime Minister's Office, the Embassies of Kuwait, and the Decision Maker's Office. Due to various forms of political data that exist in so many contrasting domains, certain imperfections, such as imprecision, uncertainty and ambiguity, inevitably appear. A popular way to handle the scattered data is to construct the so-called fuzzy ontology as presented in [20]. Ontology is useful for sharing knowledge, building consensus and constructing knowledge-based systems. So far, many ontology systems have been implemented such as the Semantic Web. More recent work in the field of ontology in governments was presented by Ortiz-Rodriguez [15]. The problem fundamental to develop an ontology system is to respect the diversity of languages and concept presentations in the world while encouraging the exchange of information. Despite initial efforts in this area, there has been little literature concerning fuzzy-logic-based ontology especially from a political domain. The purpose of this paper is, therefore, to shorten such a gap by proposing a prototype architecture for generating ontology in order to extract knowledge from various data sources. These sources may take on various forms, such as textual data, knowledge-based data, and regular documents.

### II. METHODOLOGY

Different methodological approaches for building ontology have been proposed in the literature [3, 6, 11]. Until now, there has been no standard method for building ontology. The approach described in this paper is adopted from the ontology modeling approach of Noy and McGuinness [13] and Fernandez-Lopez [11]. The process begins with the extraction of key concepts and relationships between sets of information, and then proceeds to integrate fuzzy logic with ontology. The ontology includes information about important concepts in each domain. For the purposes of the ontology

we refer the readers to [22]. The framework for bilateral trade ontology with semantic or linguistic relations in the investment domain was first presented in [22] as a case study. In this paper, we aim to present a case study that contains clear concepts for the political and investment domains. On the other hand, Fuzzy Cognitive Mapping (FCM) is especially applicable in the soft knowledge domains (e.g., political science, military science, history, international relations, and political election at governmental levels [24]). For this reason, we propose FCM's simulation to demonstrate the causal inter-relationship between certain factors and variables in the political and investment domains that influence top political decision makers so as to strengthen bilateral economic relationships between friendly nations. Note that the FCM simulation provides insight into and better understanding of the interdependencies of these factors, which provides a constructive contribution to the decision making process. Our proposed ontology will cover the two main important government sectors in Kuwait: the Kuwait Investment Authority and the Ministry of Foreign Affairs. In general, it is important to first know how to model these two sectors and present their major trends, actions, norms and principles. It is crucial to describe the domains and the relationship between them, and to understand the complexity involved in making decisions as well as how ontology building can be helpful and beneficial for decision makers. Ontology editors create and manipulate ontology. Examples of such editing tools include Protégé, which is an ontology editor and knowledge-base framework, and Fuzzy Logic Toolbox, which extends the technical computing environment with tools that design systems based on fuzzy logic. We will integrate the fuzzy logic membership as a value that reflects the strength of an inter-concept relationship and is consistently used to represent pairs of concepts across ontology. More work about fuzzy set and membership can be found in [22], where the concept consistency is dealt with by means of a fixed numeric value. Concept consistency is computed as a function of ngth of all the relations associated to the concept. In [22], an object paradigm (OP) ontology was presented for important concepts in order to capture a high level of knowledge to facilitate the work of decision makers in the decision-making process of the political field. The OP ontology approach was used to determine and specify important concepts in the political and investment domains for ontology conceptualization. A more expressive, reusable, and objective object paradigm ontology was presented by Al Asswad, Al-Debei, de Cesare, and Lycett [23]. Accordingly, in this paper, we will present the concept by using the OWL editing tools ontology. The aim of using OWL is to integrate the concept of the political and investment domains. It is worth mentioning that, according to the World Wide Web Consortium (W3C), the most recent development in standard ontology language is OWL. Like Protégé, OWL makes it possible for users to describe concepts, but it also provides new facilities. More justification in regard to use Protégé was presented in [22]. A survey of existing ontology editing tools was done in Islam et al. [14], and the comparison between them was presented in [13].

#### *A. Fuzzy Cognitive Mapping (FCM)*

FCM is a fuzzy-graph structure for representing causal reasoning with a fuzzy relation to a causal concept [26]. Fuzzy cognitive maps are especially applicable in the soft knowledge domain (e.g., political science, military science, history, international relations, and organization theory [24]). Fuzzy logic generated from fuzzy theory and FCM is a collaboration between fuzzy logic and concept mapping. FCM is used to demonstrate knowledge of the causality of concepts to define a system in a domain starting with fuzzy weights quantified by numbers or words [25]. In [24], FCM was used to demonstrate the impact of drug addiction in America. In fact, FCM is an extension of a cognitive way of representing weighted causal links, where an expert's domain knowledge is merged with a collaborative knowledge that helps in the decision-making process. As a soft-system modeling and mapping approach, FCM combines aspects of qualitative methods with the advantages of quantitative (i.e., causal algebra) methods. In a FCM, the positive (+) and the negative (-) signs above each arrowed line provide a causal relationship whereby each fuzzy concept is linked with another one. In this sense, the FCM is a cognitive map of relations between the elements (e.g., concepts, events, project resources) that enables the computation of the impact of these elements on each other, where the theory behind that computation is fuzzy logic. Since FCMs are signed fuzzy non-hierarchical digraphs [25], metrics can be used for further computations, and causal conceptual centrality in cognitive maps can be defined with adjacency-matrix [26]. So far, FCMs have been used to construct a diagram to represent words, ideas, and variables linked and arranged around a central idea, in order to generate and classify ideas to help the decision-making process. In [27], Khoubati, Themistocleous, and Irani developed a FCM based model to evaluate the adoption of Enterprise Application Integration (EAI) in healthcare organization, where the FCM simulation was conducted to demonstrate the causal interrelationships between the EAI adoption factors that influence the EAI adoption in healthcare organization [27].

#### *B. Fuzzy Cognitive Map Model for Evaluation*

An FCM is a method for graphically representing state variables within a dynamic system through links that signify cause and effect relationships using fuzzy weight quantified via numbers or words [25]. Experts can translate such words into numeric values and present them graphically to show which factors are contributory and to what degree they contribute. The main advantage of FCM is its flexibility. It can always accept additional variables, so factors can be included at any time. Nine steps are employed in designing a cognitive map: (1) identification of factors, (2) specification of relationships, (3) levels of all factors, (4) intensities of causal effects, (5) changeable factors versus dependent factors, (6) simulating the fuzzy cognitive map, (7) modifying the fuzzy cognitive map, (8) simulating the modified fuzzy cognitive map, and (9) conclusion. More description about these steps was presented in [24]. These flexible and efficient steps have been extensively used for planning and decision-making in numerous fields, see e.g. political and Middle East crisis

[24]. In our research, when preparing a fuzzy cognitive map, the first step entails the identification for factors (concepts) and the following eighteen factors (concepts) are selected based on several events in the region. The regional and international events have contributed to the increasing challenges actors face in political decision making, particularly the decision to strengthen bilateral economic relationships with friendly nations. Fig. 1 presents the FCM model that provides insight into factors influencing such decisions, where (F1) means the degree of promoting bilateral economic relationships with friendly nations security and stability, (F2) the political stability, (F3) the threat of terrorism, (F4) the threat of nuclear war, (F5) the threat of provocation, (F6) the multiple parties involved, (F7) the multiple ethnic groups involved, (F8) the multiple sects involved, (F9) the loans, (F10) other financial aid, (F11) the nation regional and international attitudes, (F12) the peace in the Middle East, (F13) the status of agreement, and (F14) type of agreement. Table I shows a number of initial rows vectors (connection-matrix) demonstrations to present the interrelation of some factors with other factors. Table I presents the different factors and the relationship between them. For example, table I shows clearly the negative impact of factor (4) that represent the threat of nuclear war on strengthen the economic relationship. The goal set for this hypothetical fuzzy cognitive matrix is to determine how the threat of nuclear war and others factors impacts the strengthen economic bilateral relationship. Hence, F4 is one of the most critical factors in this fuzzy cognitive map. In addition the threat of terrorism (F3) is the major negative cause of political stability. The value -1 represents full negative causal effect, whereas +1 full positive causal effect. Zero denotes no causal effect.

Table I: Connection-matrix presentation of factors.

	F1	F2	F3	F4	F5	F6	F7
F1	(+) 0.475 Usually	(+) 0.475 Usually	(+) 0.475 Usually	(+) 0.475 Usually	(+) 0.475 Usually	(+) 0.475 Usually	(+) 0.475 Usually

C. Use of Fuzzy Cosal Algebra to Clarify The Relationships Between Factors

This work seeks to clarify the relationships between concepts, and elucidate the positive or negative effects on each concept while enhancing the knowledge clarification of the relationships. Furthermore a FCM graph structure allows systematic causal propagation, (i.e. forward and backward chaining) and arrows sequentially contribute to the convenient identification of the cause's, effects and affected factors. FCM allows knowledge bases to expand by connecting

additional concepts. Fuzzy causal algebra governs causal propagation and causal combination on within FCM Kosko. Fuzzy logic algebra is created by abstracting operations from multiplication and addition that are defined on a fuzzily partially set P of causal values [26].The algebra that is developed depends only on the partial ordering on P, the range set of the fuzzy causal edge function e, and on general fuzzy-graph properties (connections). Bart Kosko presented the indirect and total causal effects on cognitive maps in [26].Koko explained the causal effect on cognitive node  $C_i$  to concept  $C_j$ , say  $C_i \rightarrow C_{k_1} \rightarrow \dots \rightarrow C_{k_n} \rightarrow C_j$ , which can be denoted with ordered indices as  $(i, k_1, \dots, k_n, j)$ . Then the indirect effect from  $C_i$  to  $C_j$  is the causality  $C_i$  imparts to  $C_j$ . The total effect of  $C_i$  on  $C_j$  is all the indirect effect causality that  $C_i$  imparts to  $C_j$ . The operations of indirect and total effect correspond to multiplication and addition of real numbers and a causal calculus of signs (+ and -). Interpreting the indirect effect operator, I, as some minimum operator and the total effect operator, T, as some maximum operator, these operators depending only on P's partial order and the simplest of these operators are the minimum and the maximum value. Formally, let there be m-many causal paths from  $C_i$  to  $C_j$ :  $(i, k^1_1, k^1_2, \dots, k^1_{n_i}, j)$  for  $1 \leq l \leq m$ , let  $I_l(C_i, C_j)$  denote the indirect effect of concept  $C_i$  on concept  $C_j$  on the  $l$ th causal path. Let  $T(C_i, C_j)$  denote the total effect of  $C_i$  on  $C_j$  over all m causal path. Then

$$I_l(C_i, C_j) = \min \{ e(C_p, C_{p+1}) : (p, p+1) \in (i, k^1_1, \dots, k^1_{n_i}, j) \},$$

$$T(C_i, C_j) = \max_{1 \leq l \leq m} I_l(C_i, C_j)$$

Where p and p+1 are contiguous left-to-right path indices. Hence, the indirect effect amounts specify the weakest causal link in a path and the total effect operation amounts to specifying the strongest of the weakest links. For example the concepts variables are represented by nodes, such as: C1: Threat of nuclear war, C2: Security stability, C3: Nation regional and international attitudes, C4: The type of the agreement, C5: The status of the agreement, C6: Relation type and C7: Strengthen investment indicators. Figure 1 has 7 variables that describe the impact of some conditions on strengthening bilateral economic relationships and causal variables. For example  $(C_1 \rightarrow C_2, C_1)$  that are said to impact  $C_4$ . Such is apparent because  $C_1$  is the causal variable where  $C_4$  is the effect variable. Suppose that the causal values are given by p {none  $\leq$  some  $\leq$  much  $\leq$  a lot}. The FCM appears below

In figure 1, phrases such as "much" and "a lot" denote the causal relationship between concepts. A fuzzy rule, causal link, or connection is defined by each arrow in the figure: a plus (+) represents a causal increase and a negative (-) represents a causal decrease. The causal paths from  $C_1$  to  $C_7$  are nine, the direct effect is (1,7), so the eight indirect effects of  $C_1$  to  $C_7$  are : (1,2,4,5,6,7), (1,2,4,6,7), (1,2,6,7), (1,4,5,6,7), (1,3,4,6,7), (1,3,4,5,6,7), (1,4,6,7), and (1,6,7). The eight indirect effects of  $C_1$  on  $C_7$  can be described as follows:

$$I_1(C_1, C_7) = \min \{ e_{12}, e_{24}, e_{45}, e_{56}, e_{67} \} = \min \{ \text{a lot, much, a lot, some, a lot} \} = \text{some}$$

$$I_2(C_1, C_7) = \min \{ e_{12}, e_{24}, e_{46}, e_{67} \} = \min \{ \text{a lot, much, a lot, a lot} \} = \text{much}$$

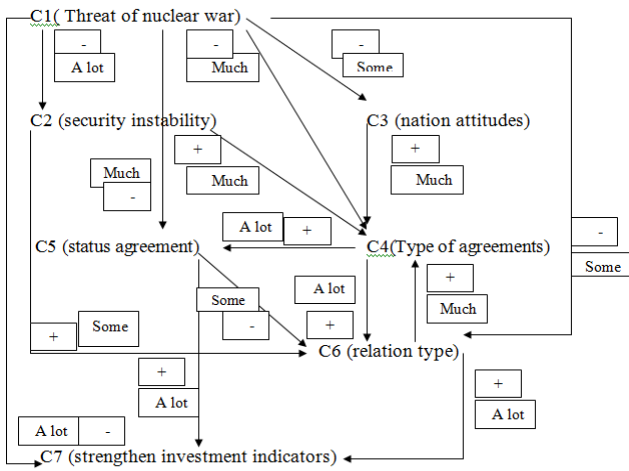

Fig. 1: A fuzzy cognitive map on the impact of strengthening economic bilateral relationship.

$I_3(C_1, C_7) = \min\{e_{12}, e_{26}, e_{67}\} = \min\{\text{a lot, some, a lot}\} = \text{some}$   
 $I_4(C_1, C_7) = \min\{e_{14}, e_{45}, e_{56}, e_{67}\} = \min\{\text{much, a lot, some, a lot}\} = \text{some}$   
 $I_5(C_1, C_7) = \min\{e_{13}, e_{34}, e_{46}, e_{67}\} = \min\{\text{some, much, much, a lot}\} = \text{some}$   
 $I_6(C_1, C_7) = \min\{e_{13}, e_{34}, e_{45}, e_{56}, e_{67}\} = \min\{\text{some, much, much, some, a lot}\} = \text{some}$   
 $I_7(C_1, C_7) = \min\{e_{14}, e_{46}, e_{67}\} = \min\{\text{much, a lot, a lot}\} = \text{much}$   
 $I_8(C_1, C_7) = \min\{e_{16}, e_{67}\} = \min\{\text{some, a lot}\} = \text{some}$   
 Thus the total effect of  $C_1$  on  $C_7$  is  $T(C_1, C_7) = \max\{I_1(C_1, C_7), I_2(C_1, C_7), I_3(C_1, C_7), I_4(C_1, C_7), I_5(C_1, C_7), I_6(C_1, C_7), I_7(C_1, C_7), I_8(C_1, C_7)\} = \max\{\text{some, much, some, some, some, some, much, some}\} = \text{much}$ .

Therefore,  $C_1$  impacts much causality to  $C_7$ . Now that the fuzzy conceptual  $C_i$  has been computed, the advantage is that the causal quality is established.

*D. Fuzzy Logic and Membership*

In recent years, the number and variety of applications of fuzzy logic have increased significantly. The most basic variables underlying fuzzy logic are linguistic variables. A linguistic variable is a variable whose values are words rather than numbers. Although words are inherently less precise than numbers, humans intuit the meaning of words more easily than that of numbers. Furthermore, computing with words exploits the tolerance for imprecision inherent in language. The aim of this section is to present a proposal that integrates fuzzy logic into ontology. Undoubtedly, the success of fuzzy logic applications lies in their ability to handle vague information. Fuzzy logic is especially useful in government applications, since information within governmental sectors is generally vague and requires a common language. In the political domain, one is unlikely to find a document that provides a precise definition for a fuzzy value, but one can usually find a linguistic qualifier. For example, one would not find information in a document numerically char-

acterizing the relation between country x and country y, but one might find the following information in such a document: “country x has a good relation with country y,” “country x has a very good relation with country y,” or “country x has weak relation with country y.” As another example, one might describe “existing bilateral relations” between countries from a variety of perspectives using a set of properties including the following: “historical,” “respectable,” “coalition country,” “antibody state” and “friendly.” Table II presents some examples of such semantic relations. It lists “StrongFriend” as a property of the concept “RelationName” to describe the nature of a relation in the bilateral relation domain. Thus, “StrongFriendRespect,” “WeakRespect,” “Respect,” and “StrongFriend” are properties describing the type of relation between two countries, which require human knowledge for interpretation. Table III presents causal weight to demonstrate FCM model in politic domain.

Table II:

Presentation of some semantic relations in “CountryClassification” and “RelationName” classes

Country Classification	Relation name	Country name
Coalition countries	Strong-Friend-Respect	a b c d e f
sectarian States	Respect	J k l
investment states	Strong-friend	b c d e a g y t
Arab states	Respect-culture	a b x b p k d
EU states	Strong-respect-friend	a b c d r
GCC	History-neighbour- Religion	A b d f c
States voted in favour of the issue of Kuwait	Encourage very strong	A b c e
Crisis States	weak	G w

So a method of making use of this kind of information is needed, especially in the political domain to help decision makers strengthen bilateral economic relationships between friendly nations. In the political domain, associating a numeric membership modifier to many situations is often necessary. Fuzzy logic allows users to model imprecise and vague data, combine different priority functions, and use any value between 1 and 0 as a logic value. It is based on natural languages in order to provide convenient methodologies for representing human knowledge [12]. Fuzzy logic is comprehensible, flexible, and tolerant of imprecise data. A fuzzy ontology describes the relation between the political domain and the investment domain with the semantic relation presented in Fig. 2. More description of this diagram can be seen in [22]. Here, we present the integration of data across different sectors and produce a seamless system permitting valid design support for top political decision makers by employing natural languages. One can convert an ontology into a fuzzy ontology by adding a relation weight to any relation, as discussed in [12, 19].

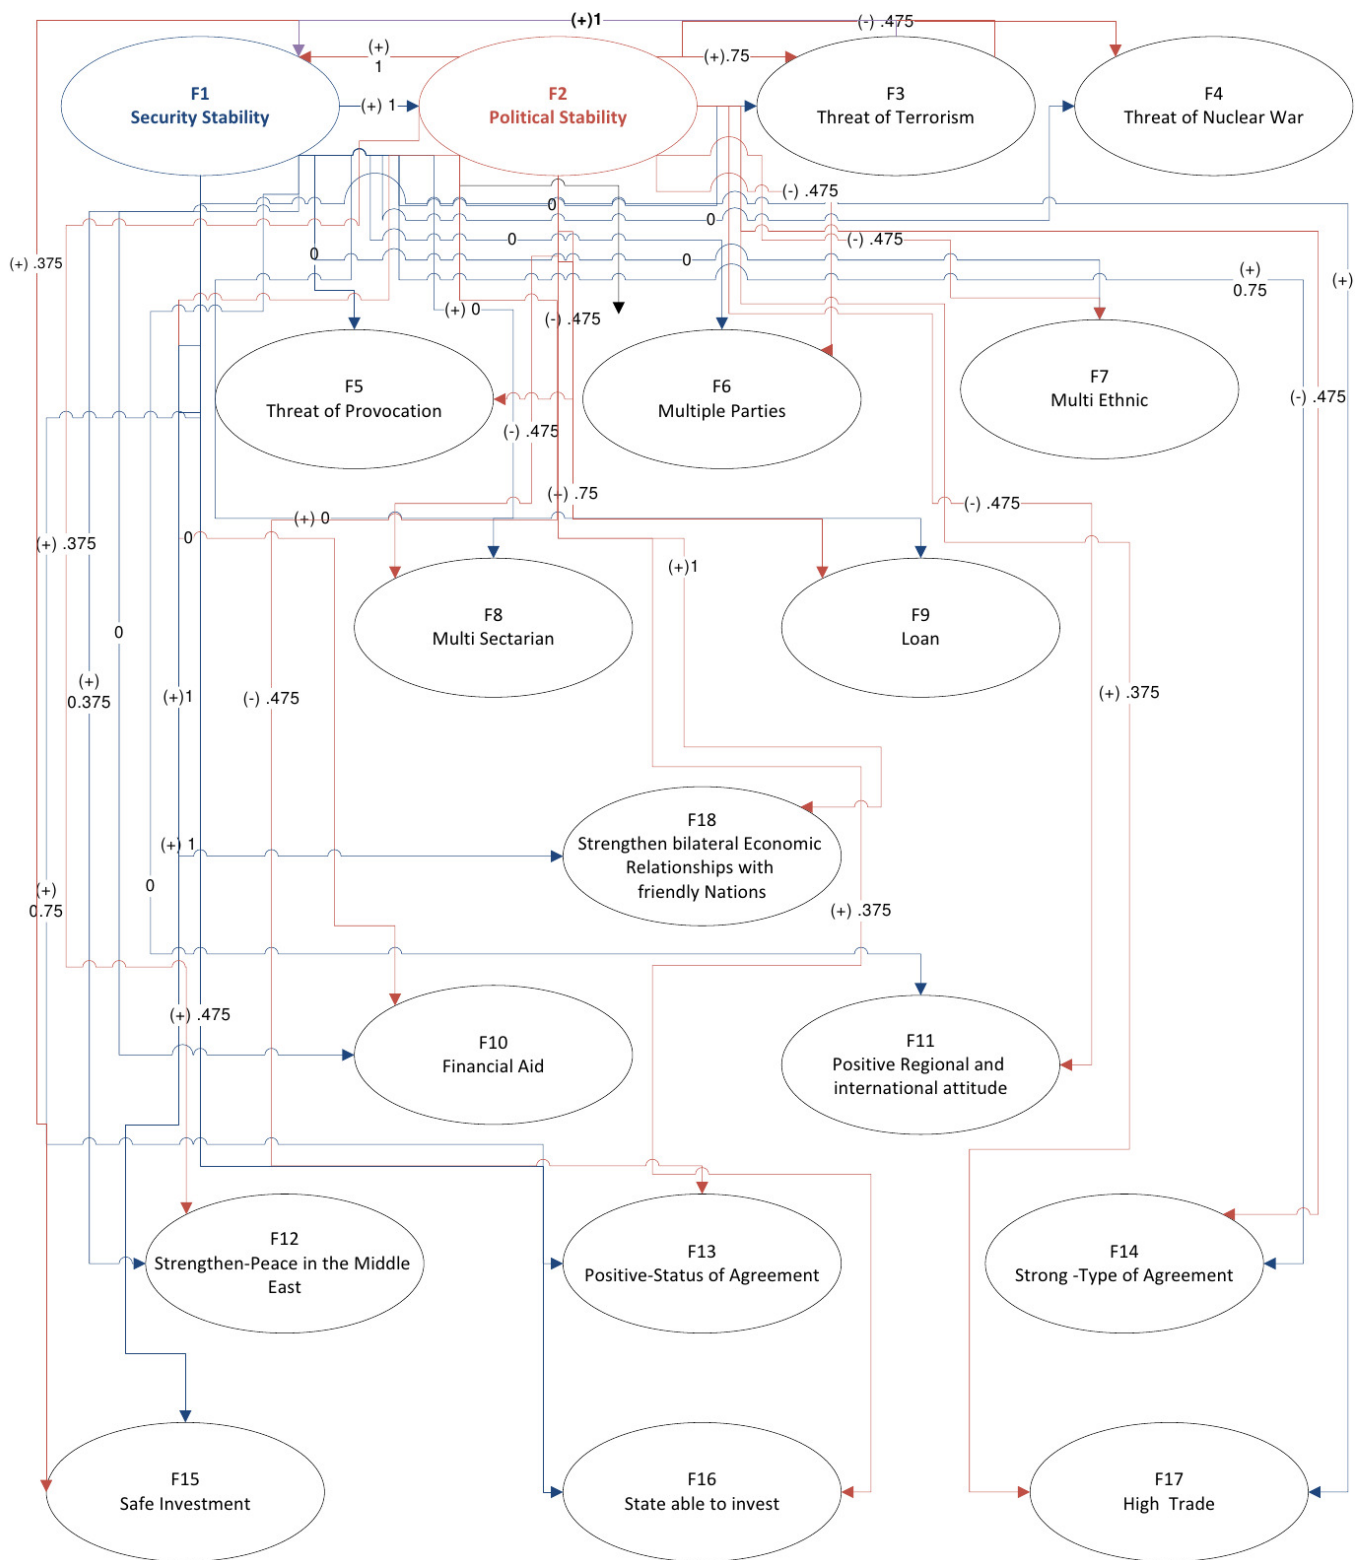

Fig. 1: FCM model presenting certain factors in the political and investment domains.

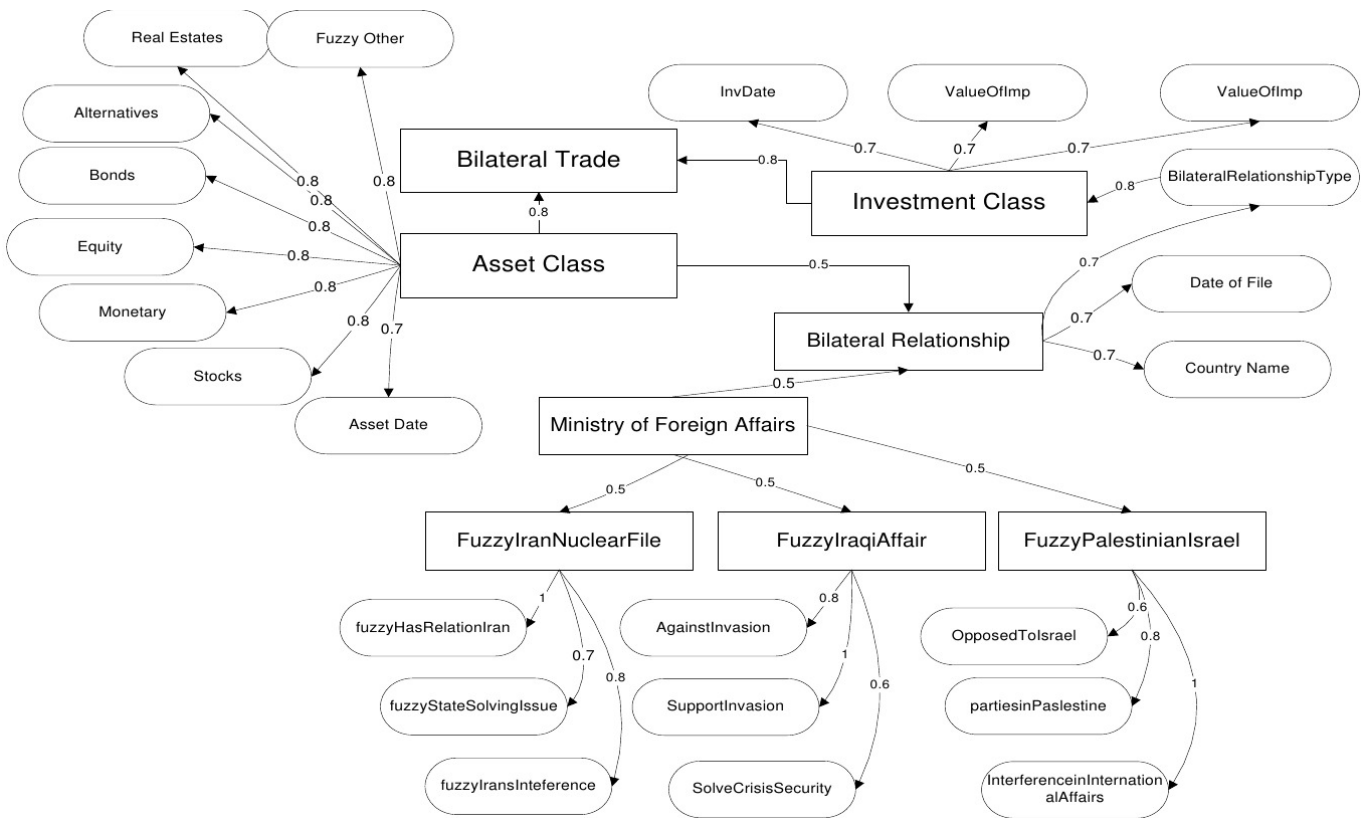

Fig. 2: Fuzzy ontology for the relation between the Ministry for Foreign Affairs and the Kuwait Investment Authority

Table III:  
Causal weight used for FCM model

Des	Weight
Never	0
Not Much	0.125
Sometimes	0.375
Usually	0.475
very much	0.75
Always	1

### III. THE MINISTRY OF FOREIGN AFFAIRS DOMAIN

In the Ministry of Foreign Affairs domain, one might ask questions during the decision-making process when attempting to strengthen bilateral economic relationships with other nations, especially about Iranian affairs, Iraqi affairs, and peace in the Middle East. For example, one might ask the following: Is this country interested in security and stability? Does this country intervene in the affairs of other countries? Will the strengthening of bilateral economic relationships lead to a reactivation of the peace process in the Middle East? The following subsections present each concept in detail.

#### A. Nuclear Affairs

To understand the position of other countries concerning nuclear issues, much information needs to be taken into account. Let us consider the cases that 1) country  $y$  deals with the nuclear power issue; and 2) the investment might be with country  $x$ . For example, does country  $x$  have an interest in the development of nuclear power? Does country  $x$  have a special relationship with who has nuclear power? Does country  $x$  influence actors in country  $y$ ? Does country  $y$  intervene in country  $x$  internal affairs? Does country  $x$  receive benefits from funding sources from  $y$ ? Is country  $x$  keen to solve the nuclear issue with country  $y$  peacefully? Is country  $x$  keen to call on  $y$  to disclose its nuclear reactors to international inspectors? Does country  $x$  agree with country  $y$  about the use of nuclear reactors for military purposes? Does country  $x$  agree with  $y$  about the use of nuclear reactors for peaceful purposes? Does country  $x$  have economic investments in or other relationships with country  $y$ ? Does  $y$  spend indirectly on country  $x$ ? Does country  $x$  agree with  $y$  provocative? Does country  $x$  agree with the positive international resolutions on the nuclear dossier? Does country  $x$  refuse to engage in military action against  $y$ ? Does country  $x$  refuse to participate in an economic blockade against  $y$ ? Does country  $x$  support  $y$  politically? Does country  $x$  have an established relationship with  $y$ ?

To answer these questions, one might use common primitive data types, such as the Boolean “yes,” “no,” “sometimes,” “always,” and “never.” As mentioned above, the Ministry of Foreign Affairs sector includes descriptions of the bilateral relations of other countries over time and information concerning international agreements, with dates and names. One can describe existing bilateral relations from a variety of perspectives using a set of properties including the following: “historical,” “respectful,” “friendly,” “solid,” “common interests,” “excellent,” “very good,” “good,” “acceptable,” “weak,” “diplomatic,” “political,” “economic,” “political and economic,” “strongly supports,” “sometimes supports,” “never supports,” “opponent,” and “unclear.”

#### B. Relation between neighboring countries

To understand the position of a country toward another, one might ask certain questions during the decision-making process (deciding whether to support or help the strengthening of bilateral economic relationships with other nations). For example, the friendly relations between two neighboring countries can turn sour due to several economic and diplomatic reasons. After the Iraqi invasion of Kuwait, for example, If the invasion occurs between two neighbors (x and y) and country z want to make investment with country x, this let country x has to consider many elements before making a decision to strengthen the economic relationship, for example was country z against the invasion? Did country z support the invasion? Does country z undertake efforts to end the crisis over country x or country y security plan? Does country z interfere in country x or country y internal affairs? Does country z endeavor to ensure the unity and the independence of country x or country y or both of them? Did country z vote to resolve the issue concerning country x or country y? Does this country support the withdrawal of U.S. troops from country x or country y under their security plan? Was this country against (or support) the recent invasion?

#### C. Peace in the Middle East

To understand the country’s position regarding the issue of peace in the Middle East, one might ask certain questions during the decision-making process (deciding whether to support or help to strengthen bilateral economic relationships with other nations). For example, does this country support the Arab Peace Initiative? Does this country work to unify Arab stances? How would one describe this country’s position on the reactivation of the peace process? Does this country look forward to seeing stability in the region? Does this country have a positive position regarding the challenges facing the region (yes, no, sometimes, or never)? What is this country’s position on dialogue and negotiation (positive or negative)? How would one describe this country’s position on the European Peace Initiative (positive or negative)? Does this country have interests in common with other countries in the region? Answers to these questions could include “yes,” “no,” “sometimes,” “never,” and “not clear.”

At the same time, one must understand the country’s position toward Palestinian issues. One might ask certain questions during the decision-making process (deciding whether

to support or help to strengthen bilateral economic relationships with other nations). For example, what is this country’s position on the occupation of Palestine? Does this country interfere in Palestine’s internal affairs? Does this country work for the realization of the Palestinian people’s rights? Does this country take the initiative to ensure a peaceful Palestine? Does this country support efforts for Palestinian reconciliation? Does this country seek a comprehensive peaceful solution to help Palestine?

#### IV. CONCLUSION AND FUTURE WORK

In this paper, we have proposed a fuzzy ontology approach and discussed how to conduct this approach in two important governmental sectors in Kuwait: the Kuwait Investment Authority and the Ministry of Foreign Affairs. To build this ontology, we have provided a quantitative way of understanding how these sectors represent major trends by breaking them down into classes and subclasses. This helps to identify the proper ontological concepts for each sector and characterize the properties and elements the different sectors share, the entities in those classes, and the domain and relationships between them. A fuzzy ontology approach has been employed to provide insight into how knowledge can be represented and handled in order to offer decision makers the aid of an intelligent decision-making process. The application of FCM has helped to demonstrate the inter-relationships of influencing factors that political decision makers must take into account when deciding whether to support or help to strengthen bilateral relationships between Kuwait and friendly nations. A detailed analysis of this FCM model has been conducted to provide such decision makers with knowledge and understanding of the factors of successful investment. The present research has contributed to the process of making the decision to strengthen bilateral economic relationships with friendly countries.

**Abstract**—The paper describes a methodology of building a semantic model of disease symptoms. The fundamental techniques used for creating the model are text analysis and learning from examples. The text analyser is used for extracting a set of symptom descriptions. The descriptions are a foundation for delivering a user interface, necessary for collecting patient cases. Given the cases a semantic model is built, which is achieved through clusterisation and statistical analysis of cases. The approach to creating the model eliminates the need of direct model manipulation, because the meaning is retrieved from association to diseases instead of purely linguistic interpretation of symptom descriptions. Detection of synonyms is also completely automatized.

## I. INTRODUCTION

**B**UILDING models of knowledge is a very important topic in the domain of artificial intelligence and knowledge management systems. The most common approach is associated with the intensively developed Semantic Web technology. This technology requires representing knowledge in the form of an ontology. Such models are typically built for some specific domains such as biomedical sciences, or various branches of business and industry. The fundamental element of every ontology is a set of concepts from the particular domain. The concepts are combined using a set of semantic relations defined within the ontology. As a result we get a hierarchic structure in the form of a directed graph with nodes being the ontology concepts (semantic classes), and the edges being the semantic relations.

Unfortunately the task of ontology building requires a lot of effort, and engagement of experts from the given field. One of the most important obstacles, that the ontology builders have to overcome, is the proper identification of concepts which should be used as the ontology nodes. It is assumed, that the nodes have to represent particular meanings instead of their possible verbal descriptions. Thus the ontology building process requires identifying synonyms among the verbal descriptions. To represent the meaning, usually one of the possible descriptions is chosen. The problem is, however, that particular verbal expressions can represent multiple meanings depending on the context of their use. As a consequence they can be classified as representatives of completely different meanings. Another difficulty are the subtle differences in meaning between the particular expressions. In consequence it is frequently very difficult to decide, whether the particular

expressions should be considered representatives of the same concept or their meaning is distinctive enough to separate them. All such decisions are left to the person constructing the ontology, and are the reason of frequent hesitations, which slow down the whole process.

The high labour consumption is not the only consequence of the difficulties mentioned above. The drawback of most ontologies constructed today is their highly subjective character. All individual decisions about defining particular classes and the possible relations between them influence the final shape of the constructed ontology. As a result a given domain can be described by many different models. This is obviously not what is desired. The domain knowledge is only one, and the properly constructed model should be independent of the particular persons building it.

Another obstacle against efficient ontology building is the large size of the models that need to be developed for real world problems. The size is a simple consequence of the huge number of concepts and the possible relations between them. Considering that the domain knowledge is usually contained in resources like books, technical articles, or the Internet, the ontology building process can be supported by extracting the important information from text. This approach is founded on a number of techniques coming from the natural language processing field (NLP). The purpose of using such methodologies is identification of concepts important for the domain and the possible relations between the terms. This approach resulted in a number of ontology learning systems that have already been created. Some of the most well known examples are: OntoLearn [1], Text-to-Onto [2], OntoGen [3], ASIUM [4], TextStorm/Clouds [5], SYNDIKATE [6], ISOLDE (Information System for Ontology Learning and Domain Exploration) [7]. There is number of approaches based on utilising clustering algorithms [8]–[10] for building ontologies. A good overview of the current state of the art in the field of ontology learning can be found in [11], [12]. To assess the ontology learning methodologies, several surveys have been made [13]–[15]. According to their findings most of the systems are semi-automated tools for supporting domain experts in creating ontologies. Complete automation and elimination of user involvement is hard and can be applied only in cases where high quality of the knowledge model is not obligatory.

In this paper we demonstrate an approach to building a model of medical symptoms in association with a set of diseases. The obstacles encountered during building this type of a model belong to the categories already mentioned. The first of them is the reach vocabulary used for describing symptoms, which takes effect in a huge size of the model to be created. The particular symptoms can be described by different combinations of words. The additional difficulty results from the fact that the descriptions which could be considered synonymic, do not always represent exactly the same meaning. There are frequently subtle differences in meaning between the possible alternatives. This results in additional difficulties in indentifying the important concepts. In consequence using standard methodologies requires a lot of effort and time to complete the task. Moreover the final result is always influenced by the personal habits, and knowledge of the model creator.

In our approach a different methodology is employed. It allows for avoiding the most important problems. One of the main assumptions is using NLP methods for text analysis and extracting information which could be important for the assumed task. This delivers a huge database of verbal constructions which are potential descriptions of symptoms. The second stage of the work is based on utilizing the database of verbal constructions. This approach is however completely different than the standard methodologies. It does not assume any direct manipulation of the model by human experts. This stage is replaced by collecting patient cases, and completing the model construction by training the system on these cases. The identification of concepts is achieved by applying clustering algorithm in the space of possible descriptions. In this way the clusters represent the particular meanings, which are the building blocks of the model. The advantage of this approach is that no human is responsible for identifying the meaning standing behind the verbal descriptions. The only expectation from the experts entering the cases is that they should describe the symptoms according to their best knowledge. To do that they can use the set of descriptions delivered by the text analyzer, but they are not restricted to it. They do not need to obey any special restrictions on the verbal constructions to be used. It is even advantageous if the cases are entered by different specialists having different habits. In this way the model structure is resistant to the subjectivity of experts taking part in its creation. Also the human effort during construction of the model is lesser than required during direct manipulation of the model. This is a consequence of the fact that conscious analysis of a complex model is replaced with a relatively simple task of describing cases.

It should also be mentioned that the described system is build for the Polish language. To be more precise, the language specific features are implemented in the module used for text processing. This module is responsible for identifying associations between words in text. The main features of the language, which influence the module structure is extensive inflection and free order of words in sentence. Using linguistic rules and sentence schemas, we are able to identify sets of

associated words forming tree structures. These structures are potential symptom descriptions. Of course a tree of words is not a natural knowledge representation for a human user. To increase the readability of the symptom representation, the tree structures are reduced to flat sequences of words, which resemble the original representation of knowledge extracted from sentences. Such descriptions form the initial database of symptoms which is further purified during the process of collecting cases and learning from examples. Except of the method of creating trees of associated words, the remaining part of the system is universal and free of language specific features. Thus it can easily be moved to another language, if an appropriate method of identifying associations between words would be developed.

The paper is organized as follows. Sec. II discusses the methodology of text processing used for extracting symptom descriptions. In Sec. III the process of collecting patient cases is presented. Sec. IV presents how the semantic model of diagnostic knowledge is built through clusterization and statistical analysis of cases. In Sec. V the results of experiments with text processing are presented.

## II. EXTRACTION OF SYMPTOM DESCRIPTIONS FROM TEXT

The text searching mechanism is founded on the observation, that from the perspective of verbal construction, every symptom descriptions have a common structure. This structure has a form of a tree of words with root being a noun in the nominative case. The case of course can be determined for inflective language like Polish. Every symptom description contains at least one noun in nominative. The branches of the symptom description tree are formed of the words associated to the root noun.

The discussed text analysis methodology has some common elements with other known algorithms. First of all it includes gramatical tagging of words. This task can be solved using several different approaches. Some of the examples are the Stanford POS tagger [16] or the MXPOST [17]. For Polish the most well known tagger is the TaKIPI [18]. Another issue is the analysis leading to finding the relations between words in a sentence. An example of a system realizing this task is the Multiparser [19]. Our approach is not directly based on any of the existing solutions, however, it contains some of their elements. The discussed system is strictly task specific, and developing our own solution allowed for introducing the necessary optimizations. Although this does not mean that the solution is not applicable to other domains after some minor modifications. We do not do any comparisons to other algorithms here. This is because the paper is devoted to presenting the general idea of the methodology designed to build the model of medical diagnostic knowledge. Although we realize that the comparison of the text analysis algorithms from the computational linguistics perspective is a very important issue and this will be the subject of separate study.

The process of extracting symptom descriptions from text consists of the following steps:

- 1) decomposition of text into sentences;

- 2) reading individual sentences, and morphological analysis of words;
- 3) disambiguation of morphological tags;
- 4) discovery of morphologically related words;
- 5) discovering relations using sentence schemas;
- 6) identification of nouns in the nominative case and building trees of words associated to every such noun;
- 7) reduction of every tree to a flat sequence of words;

The details of every step will be described in subsequent sections.

#### A. Specifics of the Polish Language

As already mentioned the text analysis strongly depends on the specific features of the language for which the system is developed. There is a number of characteristic elements of the Polish language which were taken into account while building the module. Below are listed the most important of them for the defined task [20]:

- inflection  
This is a language feature meaning, that words are inflected by case, number, person, etc. The Polish language belongs to the group of inflectional languages. Inflectional properties of words influence parsing sentences. The inflection allows for determining roles of words in sentences.
- discontinuity of phrases  
Elements of noun and verb phrases do not have to occur directly next to each other in a sentence.
- free order of words in sentences  
Words of a sentence may appear in different order without affecting the meaning of the whole sentence.
- lexical polysemy  
Lexical polysemy occurs when two or more words have the same form. For example, the form *drogi* (eng. *roads*) has two lexemes:
  - a) *droga* (eng. *the road*) - noun, plural, feminine gender,
  - b) *drogi* (eng. *dear*) - adjective, singular, masculine gender.
- syntactic polysemy  
Syntactic polysemy occurs when several forms of the same lexeme are identical. For example, morphological analysis of the form *okna* (eng. *windows*) will give a number of interpretations, including: *noun:singular:genitive*, *noun:plural:nominative*, *noun:plural:locative*.

#### B. Morphological Analyzer

The morphological analyzer is a very important resource used during text processing. Our system uses the Morfeusz software package [21]. It assigns one or several tags expressing potential morphological interpretations to the analyzed word (lexeme form). The analyzer is based on a system of tags developed for the IPI PAN Corpus [22], [23]. The contents of the tags includes the basic form of the lexeme, information about the part of speech (lexeme class - noun, adjective, verb,

etc.), number (singular or plural), case (nominative, genitive, etc.), gender (feminine, masculine, etc.), and a several other pieces of information. The analyzer data are represented in the form of finite state machines, which makes new word forms analysis impossible. Also analysis of the word context is not done (the program is not a tagger). So the problem of lexical and syntactic polysemy remains to be resolved.

#### C. Disambiguation of Words

Polysemy is an important factor influencing the effectiveness of discovering verbal associations. The morphological analyser generates multiple morphological tags for many of the words found in text, while only one of them is the correct one. Taking the incorrect tag leads to erroneously constructed tree of verbal associations, and as a result incorrectly extracted description. Disambiguation is thus important for reducing the number of errors in the results of text analysis.

Some of the tags can be eliminated *a priori* taking into account the character of the domain to which the text corpus refers. In this way we are able to eliminate all the tags including the vocative case, as this case is not used in medical texts. An example of a lexeme form eliminated in this way is *szybko* (eng. *fast*), which is an adverb, but could also be interpreted as the noun *szybka* (eng. *glass*) in the vocative case. Other examples of tags eliminated in this way include verbs in the imperative mood. An example is the lexeme form *dym* (eng. *smoke*) which can be interpreted as a noun in the nominative case, as well as a verb in the imperative mood. Of course for the medical texts only the first interpretation makes sense. Yet another example are depreciative forms of nouns, which tend to diminish in value the described entity. An example is *inne* (eng. *different*), which in medical texts is used only as an adjective, so the noun interpretation can be eliminated.

The second method of word disambiguation allows for reducing lexical polysemy. It is based on the observation, that the lexeme form interpretation which is inappropriate for the given context is not a subject of declination (by case, by number, by person, or by gender). As a result the number of forms in which a given lexeme appears in the text corpus is very limited (usually to one of the possible forms). As a result we are able to create a disambiguation dictionary consisting of lexemes inappropriate for the given domain. The lexemes are ignored when appropriate word interpretation is searched for. The examples of such lexemes are: *lewy* - the interpretation as an adjective is correct (eng. *left*), while the noun interpretation is ignored (bulgarian currency), *mały* - the adjective interpretation is correct (eng. *small*), the noun interpretation is ignored (eng. *young*), *normalna* - the adjective interpretation is correct (eng. *normal*), the noun interpretation is incorrect (eng. *normal (line)*).

The two presented methods of disambiguation do not guarantee removing the polysemy completely. The remaining ambiguities we try to resolve using linguistic rules, which is discussed in the subsequent section.

#### D. Identification of Word Associations

The objective of this stage is to eliminate the lexical and syntactic polysemy and identify relations between words using linguistic rules. There is a number of such rules which are characteristic for the Polish language, and their use in sentence construction indicates related words. Below are some of the most important rules used for disambiguation:

- linking preposition  
A compound consisting of preposition and a noun is expressed by inflectional noun ending, which is specific for the case acceptable in this link.
- links between nouns and nouns in genitive  
As it can be observed, when two nouns are directly next to each other in a sentence, the last of them is usually in the genitive case. This feature allows to disambiguate the category of the case for the second noun.
- links between nouns and adjectives  
The dependency between a noun and an adjective is expressed by the characteristic inflectional endings. These endings are characteristic for the number, case and gender, which are common for both of the words.

When the linguistic rules are applied we are able to identify the lexeme forms which are related and eliminate the lexemes which do not create relations. Of course this method does not allow for elimination of ambiguities completely. Sometimes there is more than one alternative of word association, which is allowed by the linguistic rules. In such a case all the possible variants of word associations are built, assuming that one of them is the one we are searching for. After applying the linguistic rules also the knowledge about the subject and the predicate of a sentence is collected. This knowledge will be used when applying sentence patterns.

Except the tasks mentioned above using the linguistic rules allows for establishing relations between words. Some of the most important relation types, resulting directly from the rules are listed below:

- noun - adjective  
It is a relation which occurs between a noun and the corresponding adjective, e.g. *pluco prawe* (eng. *right lung*), *wydzielina ropna* (eng. *purulent discharge*), *ciśnienie niskie* (eng. *low pressure*), etc.
- noun - noun in locative  
It is a relation between two nouns, where the second noun is in the locative case. Morphological analysis discovers only the argument in the locative case, which in case of symptoms specifies the place of occurrence, e.g. *w płucach* (eng. *in lungs*), *na powierzchni* (eng. *on surface*), *we krwi* (eng. *in blood*), etc. The argument specifying what occurred in the specified place remains to be found in the sentence. As it could be observed the noun in the locative case has also an associated preposition, which is a result of a separate rule.
- noun - noun in genitive  
This type of relation associates two nouns occurring in the text immediately next to each other, where the second

Fig. 1. Word associations extracted from a sample sentence

noun is in the genitive case. For example: *skóra głowy* (eng. *skin of the head*), *masa ciała* (eng. *body weight*), *grzybica stóp* (eng. *mycosis of feet*), etc.

Let us analyze a sample sentence:

*Podwyższone leukocyty we krwi i utrata masy ciała są najczęstszymi objawami.* (eng. *Increased leukocytes in blood and body weight loss are the most frequent symptoms.*)

The linguistic rules allow for generating the following set of relations from the sentence:

- noun - adjective: *objawami najczęstszymi* (eng. *frequent symptoms*);
- noun - noun in genitive: *utrata masy* (eng. *weight loss*);
- noun - noun in genitive: *masy ciała* (eng. *body weight*);
- noun - adjective: *leukocyty podwyższone* (eng. *increased leukocytes*);
- preposition - noun in locative *we krwi* (eng. *in blood*);
- noun - noun in locative: *? we krwi* (eng. *? in blood*).

In the last relation the preposition and the noun in locative were treated as one entity. This is because the relation refers to them as a whole. It can also be observed that the last relation has an unidentified element which is not indicated by any linguistic rule. Assuming that the noun fitting the relation is the closest noun before the noun in locative, we get the missing argument of the relation. The resulting relation is thus: *leukocyty we krwi*. It should be remembered, however, that in general case resolving the missing argument of the rule is not so simple, because of free word ordering.

The obtained word associations are presented in Fig. 1. As we can see the mechanism delivers three separate graph structures. To identify the graphs which are interesting for our purposes, we need to remember, that every symptom description contains at least one noun in the nominative case. This noun is the main element of the description verbal construction. In terms of the graph structures this means that it is the root node of the tree of words. When looking at the structures from Fig. 1 we can see that only two of them contain nouns in nominative. The nouns are: *utrata* and *leukocyty*. As a result only these two trees are considered to be the desired descriptions. The selected trees are then reduced to the flat sequences of words, which originally appeared in the text. As a result two descriptions are extracted from the sentence: *utrata masy ciała* and *podwyższone leukocyty we krwi*.

One element from the example sentence has not been discussed yet. This is the verb *są*. It cannot be associated to the other sentence elements using linguistic rules. It can,

however, be associated using sentence schemas, which allow to identify the sentence subject, predicate and object. We defined a set of the most typical sentence schemas to associate verbs to the rest of the sentences. The discussed sentence contains two subjects, which are the nouns *leukocyty* and *utrata*. The sentence schema detects only the first one, and associates it to the verb. As a result we get the association *leukocyty sq.* Unfortunately the schema assumes a noun in accusative to be the object of the activity expressed by the verb. No such noun could be found in the example sentence. As a result the construction retrieved by the schema is incomplete, and thus ignored.

Another thing which has not been considered yet are the ambiguities resulting from imprecision of the linguistic rules. The ambiguities lead to generating some additional word associations, which for conscious reader are obvious mistakes. Such mistakenly created associations could be the following: *objawami krwi*, *utrata krwi*, and *masy krwi*. This delivers some alternatives to descriptions, which could be extracted from text. If the ambiguities are not possible to be resolved, all the possible variants are generated, assuming that one of them is the correct one.

### III. COLLECTING CASES

The collection of descriptions extracted from text is of course far from perfect. It strongly depends on the actual contents of text corpus. It is obvious, that medical text contains not only symptom descriptions, but a lot of other information, including descriptions of medical procedures, patient treatment, etiology, or pathogenesis of diseases. All that information is unimportant for the diagnostic purposes. Unfortunately, the mechanism extracting information from text is based only on morpho-syntactic rules and is not able to interpret the meaning of extracted information. As a result the collected descriptions include except symptoms, also a lot of other unwanted information. Also some part of the descriptions is incorrect due to ambiguities which we were not able to resolve.

Fortunately the unwanted information is not so huge problem, as it could initially seem. The condition is an efficient search mechanism, which allows for quick finding of the desired description in the database. Given such mechanism, medical experts can quickly describe symptoms observed in patients. The most efficient search mechanism that we are able to deliver is based on suggestions to a typed sequence of characters. This mechanism is well known from the Google search web site. Using this mechanism the user is always able to find the desired description after typing an adequate number of characters. The search mechanism is additionally supported by weights assigned to the descriptions. The weights indicate the descriptions, which are frequently used, and should be moved to the front of the search list. Using the described tool the experts create a database of patient cases, which can be considered training patterns for the system.

Of course we are not able to guarantee that any possible symptom description, that an expert could ever think of,

is available in the collection extracted from text. Thus the description chosen by the user should be open for edition. In this way it is always possible to complete or correct the missing parts of the expression, or even build it from scratch. Every new description is then registered in the system and available for other users.

The training phase of the system is necessary for identifying the descriptions correctly describing symptoms. This is easily learned from the cases. The descriptions which were frequently used are considered to be correct. The descriptions which were not used, or used occasionally, are considered to be incorrect and removed from the system. It is assumed that some level of human errors is possible, and thus the rarely used descriptions are removed, as considered to be erroneous. In this way the system is resistible to occasional human mistakes. Of course we should distinguish the erroneous descriptions, from description of rare symptoms. The descriptions of rare, but important symptoms, are identified given the correlations with diseases. If a rare description is strongly correlated with some disease, it should not be eliminated.

## IV. BUILDING THE SEMANTIC MODEL OF SYMPTOMS

### A. Identification of Concepts

For building any semantic model it is necessary to identify the set of concepts. In our case the concepts of the model are the symptoms and the diseases. The descriptions remaining in the system after collecting a reasonable number of cases, although correct, are not symptoms yet. The reason is that some of them have the same or similar meaning. The meaning of a given description is considered to be a symptom. To discover the symptoms among the set of collected descriptions, it should be noted, that the descriptions with close meaning, have similar statistical distribution with respect to the set of diseases. This distribution is easily retrievable from the set of training cases. For practical reasons the set of diseases, which can be diagnosed is fixed, and *a priori* defined. The considered system has a modular structure, and a single module contains diseases from one domain. Currently we are experimenting with two domains: allergology and pulmonology. As a consequence we collect two sets of cases with diagnosed diseases from one of the two domains. The *a priori* defined set of diseases allows for ignoring the problem of synonymic names of diseases, and makes them immediately the set of the model concepts.

The problem remaining to be resolved is identification of symptoms. As already noted the synonymic descriptions have similar distributions of their occurrence in particular diseases registered in training cases. Identification of sets of such descriptions is possible through clusterisation. As a result of this process we get a set of symptoms, represented by identified clusters. It is of course possible that some descriptions, with different meaning, are closely correlated by occurring in the same diseases. Such descriptions are easily distinguished from synonyms. This is possible by observing, that synonymic descriptions are not used in the same cases, as no one describes the same symptom twice.

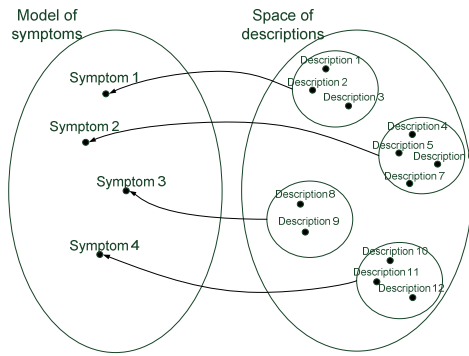

Fig. 2. Schematic mapping between clusters in the space of natural language descriptions, and the model of symptoms

After clusterisation, every description is easily assignable to its respective symptom. It is thus easy to determine the statistical distribution of symptoms with respect to diseases. This is just a result of simple summation of the distributions obtained for the synonymic descriptions. Such distribution can be utilised for construction of a Bayesian network, which can further be used as a diagnostic decision support tool.

### B. Identification of Vertical Relations

The simple clusterisation leads to a model of flat list of symptoms, where no relations between them are taken into account. Such a model is good for building a Bayesian network, but is not the most accurate for more complicated purposes, like semantic reasoning. The basic element of every semantic model is a vertical hierarchy of concepts. Such a hierarchy arranges concepts in the form of a tree, where the concepts with wider meaning are parent nodes of the concepts with more narrow meaning. This type of relation seems to exist also between symptoms. For example the symptom *allergic reaction to the animal fur* could be considered a superclass of the more narrow symptom *allergic reaction to the dog's fur*. This indicates that hierarchic model of symptoms is more accurate than the flat one. The hierarchy of symptoms can be built by applying hierarchic clusterisation algorithm. The clusters obtained in this way are directly transformed into hierarchy of semantic classes.

One should be careful, however, when trying to interpret the meaning of the classes from different levels of the model hierarchy. It should be underlined that the meaning of particular descriptions is resolved not on the foundation of the linguistic interpretations, but on the foundation of statistical association to diseases. It might seem strange at first, as most of the approaches to building semantic models are founded on purely linguistic interpretation of meaning. However, the presented way of meaning determination is much better, if we have in mind, that the model is build for diagnostic purposes. The linguistic interpretation can sometimes be misleading, when one would try to associate it with possible diagnoses. There are many symptoms which could be interpreted as subsymptoms of other symptoms from the linguistic point of view, while at the same time they are associated to significantly

differing diseases. In other words the diagnostic hierarchy of classes does not need to agree with the linguistic hierarchy of classes. In the diagnostic hierarchy of classes the wider meaning refers to occurrence of a symptom in a wider set of diseases, while the subclasses are more specific in the sense that they are associated with a more narrow set of diseases. When considering the mentioned example of the allergic reaction symptoms, we actually do not know if the two symptoms are actually related diagnostically. This is suggested by the linguistic interpretation, because the *dog's fur* is a subclass of the *animal fur*. But cannot be sure if the *allergic reaction to the dog's fur* indicates a subset of the diseases indicated by the *allergic reaction to the animal fur*. As a result, we cannot determine the vertical relations from the purely linguistic interpretations.

The identification of symptoms (i.e. the model concepts) on the foundation of association to diseases also influences the contents of particular synsets (i.e. the sets of synonymic descriptions). The descriptions belonging to individual clusters do not need to be actual synonyms from the linguistic point of view. It is enough if they are used as synonyms from the diagnostic perspective, i.e. their occurrence indicates the same diseases.

To underline the importance of diagnostic meaning determination on the foundation of association to diseases, it should be noted that the structure of a semantic model based purely on a linguistic perspective interpretation is always arguable. This is a result of the fact, that in the standard approach such models are built by choosing one of the possible verbal descriptions of the world. No matter how objective the model constructor tries to be, the final result is always subjective, because he is forced to choose between one of alternatives. The model built according to our approach is objective, in the sense that no individual can directly influence its structure. The structure is an outcome of the cumulated knowledge of all the experts taking part in collecting patient cases. The experts also mutually verify themselves by using or ignoring particular descriptions.

This of course does not mean that models based on linguistic relations are wrong. Everything depends on the purpose of the model. If a system is aimed at doing some kind of linguistic analyses it should be constructed in this way. In our case the aim is doing patient diagnoses, and the system should be constructed in a way which maximizes the accuracy of results.

### C. Adding Restrictions to Semantic Relations for Semantic Reasoning

The foundation for knowledge representation in semantic networks is description logics. This allows for expressing all the dependencies between semantic classes in terms of logical expressions. The logical expressions are then used by semantic reasoning engines. Semantic knowledge representation is thus a powerful tool in decision support systems. Such a tool can also be used for diagnosing patients on the foundation of their symptoms.

The way of constructing the model structure has already been described. What is missing is the set of restrictions of particular semantic relations. Such restrictions are expressed with the aid of a set of logical quantifiers. What is necessary to identify the restrictions, is to find mutual dependencies between symptoms which can easily be transformed onto a set of logical expressions. Such expressions are then associated with particular relations, and in this way the model structure becomes complete and ready for performing semantic reasoning. The input for this process is the set of symptoms observed in a patient, while as a result we get the suggested diseases. Appropriately constructed reasoning could also indicate the missing symptoms, which would significantly improve the diagnosis. In this way the system is able to suggest the medical tests necessary to perform for improving diagnosis.

The construction of the logical restrictions can be determined on the foundation of statistical distribution of symptoms with respect to particular diseases. Again the patient cases are the key resource to identify the model construction elements. Given a set of cases with a particular disease diagnosed it is possible analyse mutual occurrence of the symptoms in particular cases. This data is transformable into a set of logical expressions, such as logical sum, product, or any other statistically relevant dependency. These are the restrictions we are searching for. Such an analysis should be performed for all the diseases from the domain of interest. As a result we get a powerful tool of semantic reasoning.

## V. RESULTS OF EXPERIMENTS

The experiments that we are able to describe at this stage of the work refer to extraction of descriptions from text corpus. The results of clustering and building the semantic model will be described later. Currently we are working on collecting appropriately large collection of patient cases.

The text corpus used for the experiments came from two domains of medicine: allergology and pulmonology. To be more precise the experiments were carried out separately on texts from the two domains. The size of the corpora is rather small. For allergology it is 95kB, and for pulmonology it is 265kB. The main text resources were [24] for allergology and [25] for pulmonology. We selected only the book chapters and paragraphs, which actually describe symptoms. Including any other fragments of texts would deteriorate the results. This results from the fact that the analyser is based only on the foundation of the grammatical construction of the sentences. It is not able to interpret the meaning of the analysed text. The grammatical structure of symptom descriptions is no different than grammatical structure of any other entity described in the text. As a result any text processed by the analyser delivers a set of descriptions, no matter if it refers to symptoms or not. The careful selection of texts is thus important, if we want to avoid getting too many useless descriptions.

As a result of text processing we got 1080 descriptions for allergology and 2810 descriptions for pulmonology. The difference in numbers is the obvious consequence of the

corpora sizes. The average number of words in every description was 5.4 for allergology, and 4.8 for pulmonology. The number of retrieved descriptions is not the only factor which is important. As already mentioned the analyser is not able to distinguish, whether the extracted descriptions refer symptoms or to anything else. It is thus important to assess the rate of the number of symptom descriptions to the number of other descriptions. This rate strongly depends on the specifics of the analysed text. In some texts the symptoms appear rather sparsely, while other are almost entirely devoted to describe symptoms. Thus the observed rate ranges from 10-20% up to 80-90%. The assessed overall rate is about 50%. This amount is huge enough to cover significant part of the possible verbal descriptions of symptoms from the given domain, and be the basis for describing patient cases. The missing element will be completed during collecting cases.

## VI. CONCLUSION

The paper describes a methodology of building a model of diagnostic knowledge. The idea of the system assumes two stages in the model creation process. The first of them is text analysis in order to extract verbal constructions describing symptoms. The second stage aims to collect patient cases and build the model of symptoms on the foundation of the patient cases. As a result of the whole we get a semantic model built of symptoms and diseases. What distinguishes this approach from other solutions typically applied in building semantic models, is that no direct manipulation of the model is required. The system structure is learned from examples. The key tool for extracting the model structure is clusterisation and statistical analysis of particular symptoms occurrence in the cases.

The model is designed for diagnostic purposes. In the simplest case the diagnostic process can be supported by the Bayesian network constructed on the foundation of the data collected during the model construction. The more advanced algorithms lead to construction of a semantic network with hierarchic structure of symptoms, and description logics rules. This allows for performing reasoning based on a semantic inference engine. It should be underlined, that the meaning of the particular concepts forming the model, is not determined on the foundation of their linguistic interpretation. The meaning is a result of associations between the symptoms and the diseases. Such solution is the required when diagnosing a patient is the task. The natural language descriptions are used for human communication only, while the computational model is subordinated the diagnostic purposes. Trying to interpret the model structure in terms of natural language associations could be even misleading, so no one is supposed to do it.

The method of meaning determination not only rises the quality of the model. It also simplifies the model construction process. This is due to eliminating the task of the direct model manipulation by experts. In this way no human needs to care about choosing the most accurate world description method. Carrying about synonyms is also not required. These tasks are completely automatized. The model constructed in the

described way is also resistant to the subjectivity. This is a problem which appears when a model is constructed by a human expert which has to choose among one of possible model structures. In our approach the knowledge is extracted from cases, which are entered by more than one person. In this way the model is a resultant of all the individual habits and knowledge represented by the human users.

The experiments described in the paper refer to extraction of textual descriptions from the text corpus. The lexical analyser is able to extract the required information from text. The criterion for assessing the quality of the set of extracted descriptions is the rate of descriptions actually describing symptoms, to the other descriptions. This parameter does not depend only on the analyser, but also on the quality of the text. By quality of the text we mean the density of symptom descriptions which appear in the text. This factor depends on the authors' writing style. The density of symptom descriptions is important, because the analyzer works only on the foundation of grammatical rules of sentence construction. It is not able to interpret the meaning of the extracted descriptions. As the grammatical construction of a symptom description is no different than description of any other entity, we are not able to filter the undesired descriptions. Such a mechanism would be very helpful, but currently we are not able to deliver it.

The undesired descriptions are, however, not an obstacle which would make impossible delivering the user interface with a collection of symptom descriptions. This interface is necessary for describing the patient cases. The extracted set of descriptions is huge enough, to cover significant range of possible symptom descriptions. The key which allows for efficient entering of cases is an efficient search mechanism and system of weights. Of course we are not able to guarantee that all the required descriptions are extracted from text, thus during collecting the training cases the descriptions are open for edition. In this way it is possible to correct existing descriptions, or create new descriptions from scratch. Such descriptions are immediately available to other users entering the cases. This allows for mutual verification within the team responsible for collecting the cases.

The work on collecting a reasonable number of cases is in progress, so the effects of the second stage of building the model were not described here. This will be a field of experiments with clusterisation, and statistical analysis of cases in order to build the final model, which further will be used as a part of a decision support system.

**Abstract**—This paper investigates the efficiency of the EWC semantic relatedness measure in an ad-hoc retrieval task. This measure combines the Wikipedia-based Explicit Semantic Analysis measure, the WordNet path measure and the mixed collocation index. In the experiments, the open source search engine Terrier was utilised as a tool to index and retrieve data. The proposed technique was tested on the NTCIR data collection. The experiments demonstrated promising results.

## I. INTRODUCTION

A BAG-of-words representation of documents by information retrieval systems results in queries expressed utilising the language of keywords. Users face a vocabulary problem: A keyword language is not adequate to describe the information needs. Statistical analysis of user behaviors showed that the queries submitted to search engines are short (2 to 3 terms, on average) and ambiguous, and users rarely look beyond the first 10 to 20 links retrieved [20].

To improve user queries, search engines provide many tools.

Manuals and instructions are among them. They help a little, although ordinary users do not like reading.

A query suggestion feature is common for general purpose search engines. Its disadvantage is in the way to generate recommended terms. They are based on the first term typed by the user, which is always the first one in all expanded queries [22].

The relevance feedback feature is another instrument to help users. There are at least two steps in the interaction with a search engine: The first one is the submission of the original query, and the second one is the user reaction on the results retrieved in order to provide the system with the user opinion (marking some documents as relevant). This feature is not popular among users because the mechanisms of changing queries are not clear and users cannot control the process [9].

In addition, query suggestion and relevance feedback are used to modify the queries in order to make them more accurate to express the user information needs.

Query expansion is a well-known and popular technique to reformulate the user query in order to reduce the number of non-relevant pages retrieved by information retrieval systems. Another goal of query expansion is to provide the user with additional relevant documents. Automatic query expansion is an important area of information retrieval: Many sci-

entists are involved in designing new methods, techniques, and approaches.

This paper presents authors' technique to automatically expand the user queries. This technique is based on the EWC semantic relatedness measure [21]. This measure takes into account encyclopedic, ontological, and collocational knowledge about terms. The environment for the experiments includes Terrier as a search engine and NTCIR-1 CLIR data collection for the Japanese-English cross-lingual retrieval task.

The rest of the paper is organised as follows. The next section reviews the approaches to automatic query expansion. Section 3 describe the nature of the measure used. Section 4 provides the necessary details related to this technique to expand the queries. The tools and data utilised in the experiments are presented in Section 5. The results of the experiments are discussed in Section 6 and comments on ongoing experiments are presented in Section 7. Concluding remarks are presented in Section 8.

## II. RELATED WORK

A comprehensive review of the classical approaches to expand queries can be found in [9]. They propose different ways to obtain semantically (topically) related terms, techniques to evaluate importance of the terms found, mechanisms to define the number of terms to add (expand) the user query, and strategies to evaluate the quality of obtained results.

Generally, the semantics of the terms are clear when they are in the sentences because the meanings of the words are fixed and only one is usually selected from the set of all possible variants. However, in the queries, the terms are separate instances, and their semantics are unclear. This is called the polysemy problem. On the other hand, the same things can be described by using different terms. This is the nature of the synonymy problem. The query should be rich enough to include the possible candidates for expressing user information needs.

The general goal of query expansion is to find a solution for these two aforementioned problems. The classical solution for the synonymy problem is to apply thesauri as instruments to obtain the candidates for expansion. WordNet is widely used for this purpose [19]. Modern techniques suggest Wikipedia as a valuable source to find synonyms [12].

Many techniques are used to solve the polysemy problem. Approaches described in [13] and [16] are based on the analysis of the query log files of search engines and clicked URLs. Authors of this study [18] utilised WordNet for a deep analysis of the queries submitted to the information retrieval system in order to find the concepts and then obtain the candidate terms for expansion. The involvement of users is the feature of the approach discussed in [17]. They should select the correct ontology for each query submitted to expand the query. The authors of this study [14] also pointed out that the information exploited by different approaches differs, and combining the different query expansion approaches is more efficient than the use of any of them separately. They investigated techniques to rank the terms extracted from the retrieved documents. One is based on the measures of occurrence of the candidate and query terms in the retrieved documents. The other one utilises the differences between the probability distribution of terms in the collection and in the top ranked documents retrieved by the system. A similar idea is discussed in [15].

The authors of [10] combined the concept-based retrieval, based on explicit semantic analysis (ESA), with keyword-based retrieval. At the first step, they use keyword-based retrieval to obtain the candidates for query expansion. Then, they tune queries applying ESA. After that, they perform the final retrieval in the space of concepts.

It is difficult to compare the aforementioned approaches, because different data sets were used to evaluate them. In many cases, it is not clear wherever the test queries cover a wide range of data set topics. The performance evaluation is done automatically for some approaches, whereas for others, the authors involve the users to judge the quality of retrieval.

### III. MEASURE DESCRIPTION

In study [21], the new measure of words relatedness is introduced. It combines the ESA measure  $\mu_{ESA}$  [10], the ontological WordNet path measure  $\mu_{WNP}$ , and the collocation index  $C_{\xi}$ . This measure is called EWC (ESA plus WordNet, plus collocations) and is defined as follows:

$$\begin{aligned}\mu_{EWC}(w_1, w_2) &= \mu_{ESA}(w_1, w_2) \cdot \alpha \\ \alpha &= (1 + \lambda_{\sigma}(\mu_{WNP}(w_1, w_2))) \cdot \gamma \\ \gamma &= (1 + \lambda'_{\sigma}(C_{\xi}(w_1, w_2)))\end{aligned}$$

where  $\lambda_{\sigma}$  weights the WordNet path measure (WNP) with respect to ESA, and  $\lambda'_{\sigma}$  weights the mixed collocation index with respect to ESA. This index is defined as follows:

$$C_{\xi} = \frac{2 \cdot f(w_1 w_2)}{f(w_1) + f(w_2)} + \xi \frac{2 \cdot f(w_2 w_1)}{f(w_1) + f(w_2)}$$

where  $f(w_1, w_2)$ ,  $f(w_2, w_1)$  are the frequency of the collocations of  $w_1 w_2$  and  $w_2 w_1$  in the corpus,

and  $f(w_i)$  is the frequency of word  $w_i$ . The values for constants  $\lambda_{\sigma}$ ,  $\lambda'_{\sigma}$ , and  $\xi$  were set to 5.16, 48.7, and 0.55, respectively.

Study [21] demonstrated the superiority of this measure over ESA on the WS-353 test set.

### IV. EXPANSION METHOD

Assume that  $Z$  is a pool of term-candidates for query expansion. The formulas below present the method to select terms to expand queries.  $N$  is a number of original query terms, and  $j$  is an index of them. Values for the WordNet component and collocation component should be above zero in order to choose related terms. Thresholds  $t_2$  for EWC values and  $t_1$  are parameters adjusted in the experiments. For every word  $w_i \in Z$ , the weight is calculated. Word  $w_i$  is selected for expansion if its weight is equal to 1.

$$\begin{aligned}\text{weight}(w_i) &= \begin{cases} 1, & \text{if } \sum_{j=0}^N \frac{\text{score}(w_i, w_j)}{N} > t_1, \\ 0, & \text{otherwise} \end{cases} \\ \text{score}(w_i, w_j) &= \begin{cases} 1, & \text{if } \mu_{WNP} > 0; C_{\xi} > 0; \mu_{EWC} > t_2, \\ 0, & \text{otherwise} \end{cases}\end{aligned}$$

This approach can be interpreted as follows: A term is selected from the list of term-candidates, if the similarity score between this term and the majority of original query terms is higher than a given threshold  $t_1$ . The term-candidate should have non-zero values for  $\mu_{WNP}$  and  $C_{\xi}$  components.

### V. TOOLS AND DATA SETS USED

The open source search engine Terrier [1] was used as a tool to index and retrieve data. It provides the different retrieval approaches. TF-IDF and Okapi's B25 schemas [6, 9] are among them. As a data set for experiments, the NTCIR CLIR data collection [2] was used. It consists of 187,000 articles in English. These articles are summaries of papers presented at scientific conferences hosted by Japanese academic societies. The collection covers a variety of topics such as chemistry, electrical engineering, computer science, linguistics, and library science. The size of the collection is approximately 275.5 MB. A total of 83 topics are in Japanese. A structure of the dataset and topics is similar to that of TREC [3]. A Porter Stemmer algorithm was applied to the documents and queries, and a standard stop word list provided by Terrier was also utilised. Only the title fields were considered as a source of the queries. They are relatively short, each query consists of a few keywords. The authors of the study reported in [5] experimented with Terrier applying the

same conditions to the TREC data. To measure the term similarities, an experimental tool described in [21] was utilised.

## VI. RESULTS OF EXPERIMENTS

The authors implemented the proposed technique to expand queries as follows.

A straightforward approach was applied to translate queries into English: Google's translation service [4] generated queries in English. This method was selected because online dictionaries do not work well with terms in katakana and specific terminology [7]. Katakana is one of four sets of characters used in Japanese writing. It is primarily applied for the transcription of foreign language words into Japanese.

To obtain the candidates for query expansion, a query expansion functionality offered by Terrier was adopted. It extracts the most informative terms (in this case 10) of the top-ranked documents (in this case 3) by using a particular DFR (divergence from randomness) term weighting model [8].

Table 1 provides the list of original queries (topics 1, 12, and 24), terms-candidates for expansion (arranged by the decreasing score calculated by Terrier), and the final sets of terms used to expand queries (they are in bold). One to five terms were selected by this method. As one can see from this table, this technique does not usually select the top-ranked terms as candidates for expansion from the Terrier engine point of view.

As mentioned in Section V, a total of 83 topics are available to retrieve documents from the collection. The original goal of topics 0001 to 0030 is to tune the parameters of the retrieval system. Their relevance judgments are known in advance. Topics 0031 to 0083 were used in official runs at the NTCIR 1 Workshop. Organisers found that the number of relevant documents for 13 topics of the 53 contained less than five relevant documents per topic in cross-lingual retrieval. Hence, they discarded these topics from evaluation [25]. The full set was used in these experiments because the goal is to compare the performance of different methods implemented in the same environment. In the evaluations, the partially relevant documents were considered as irrelevant. To archive this, the corresponding file was applied when evaluating the retrieval results.

Table 2 summarises the results of retrieval to tune thresholds  $t_1$  and  $t_2$ . The test queries were generated from topics 0001 to 0030. It is important to note that when the queries are expanded with all the terms proposed by Terrier, the retrieval results drop to zero. The retrieval utilising the TF-IDF schema produced better results for the original queries (without expansion) compared to the BM25 and InL2 models [1]. The line *system* shows this result. The first number in the cells is the value of average precision, and the second one is the value of R-precision. The performance of retrieval with expanded queries utilising the ESA and EWC approaches for the threshold values ( $t_1$  equals 0.67 and

$t_2$  is ranges from 0.08 to 0.15) is better compared to the variant without expansion. For the EWC measure, the maximum of the retrieval performance is reached when the values

of thresholds  $t_1$  and  $t_2$  are set to 0.67 and 0.12. For ESA, the optimal threshold values are 0.67 and 0.08. The performance of ESA is higher than EWC.

Table 3 summarises the results of retrieval for topics 31 to 83. The threshold values were set to the optimal parameters (see Table 2). Six runs were executed. Figure 1 shows an averaged precision/recall graph across 53 queries. The EWC measure demonstrated better performance over ESA in both cases. The line *system* shows the retrieval results without expansion for TF-IDF and BM25 schemes.

To summarize, one can conclude that the EWC measure provides little benefit over ESA, as the results of the retrieval are better. Ontological knowledge combined with collocational knowledge helps in the selection of expansion terms.

## VII. ONGOING EXPERIMENTS

The authors are conducting experiments on the translation of queries from Japanese into English. The Mecab system [24] is utilised to segment the queries and extract Japanese terms. An on-line dictionary Space ALC [23] was also applied to retrieve all English variants for the corresponding Japanese terms. The EWC metrics are applied to pairs in order to select the most closely related elements from the sets of the meanings (terms with the highest sum of weights between pairs). For the queries consisting of only one term, the most common English variant is selected. Queries generated in this way will be submitted to the search engine, and comparison will be done with the results of retrieval for queries obtained from Google's translation service.

## VIII. CONCLUSION

This study tested the semantic relatedness measure when selecting the terms to expand queries. Key components of this measure are the ESA measure, the WordNet path measure, and the mixed collocation index. Results produced by the Terrier search engine were a base line in the experiments.

Fig 1. Averaged 11-point precision-recall graph across topics 31 to 83

Term candidates for the expansion were also generated by Terrier. The proposed techniques were applied to the ad-hoc retrieval task. As a data set, the NTCIR-1 CLIR Test collection was used. The initial English queries were obtained automatically applying Google translate. The queries were expanded by applying the Wikipedia-based Explicit Semantic Analysis measure, and the DFR mechanism, and the semantic relatedness measure. The retrieval results showed superiority of the last one over ESA and DFR.

**Abstract**—Semantic information retrieval requires that we have a means of capturing the semantics of documents; and a potentially useful feature of the semantics of many documents is the temporal information they contain. In particular, the *temporal expressions* contained in documents provide important information about the time course of the events those documents describe. Unfortunately, temporal expressions are often context-dependent, requiring the application of information about the context in order to work out their true values. We describe a representational formalism for temporal information that captures what we call the *local semantics* of such expressions; this permits a modularity whereby the context-independent contribution to meaning can be computed independently of the global context of interpretation, which may not be immediately or easily available. Our representation, LTIMEX, is intended as an extension to widely-used TIMEX2 and TimeML representations.

## I. INTRODUCTION

**A**N IMPORTANT part of the meaning of many documents is the temporal information they contain. In particular, many documents present narratives over sequences of events, and specifications of dates and times in the form of *temporal expressions* provide timestamps for these events; these are of significant utility for any application that aims to mine information about events across a large document set. From the information retrieval perspective, time is an important notion that can be used for indexing, organizing, retrieving and, finally, presenting the content of documents; these issues have been the topic of recent studies (see, for example, [1]).

Unfortunately, not all such temporal information is expressed in easy-to-capture and easy-to-interpret expressions. While fully-specified expressions, such as dates like *25th November 2010*, are not uncommon in text, far more common are context-dependent temporal expressions, like *yesterday*, *10th June*, and *the previous summer*. Properly assigning values to such expressions is the aim of *temporal expression tagging*; the TIMEX2 standard (introduced as annotation guidelines in [2]) and TimeML (see [3], [4]) have been developed as forms of representation for such values, and a considerable body of research focuses on developing tools that can accurately annotate such expressions with their absolute values (see, for example, [5]–[10]).

The assumption underlying the processing carried out by existing tools is that there are two distinct stages involved: first the *extent* of the temporal expression must be determined—in other words, it must be properly recognised—and then its value may be computed, taking into account both the lexical content of the expression and the wider context in which it is situated.

This second step conflates knowledge from two sources: information that can be derived from the content of the temporal expression itself, and arbitrary real-world reasoning that takes account of contextual information. As a simple example, the meaning of *yesterday* depends crucially on the time at which is uttered; however, common to all instances of its use is that it means ‘the day before today’. Based on this observation, we can compute the partial meaning of such expressions, thus permitting a modularisation of the process into a part that computes the context-independent *local semantics* of the expression, and a part which uses the wider context to determine the *global semantics*. The first of these can proceed in the absence of the second. However, we then require an interface between the two levels of processing; for this we propose what we call LTIMEX, an extension of the TIMEX2 and TimeML representations that allows us to capture partial meanings.

In this paper, which further develops our earlier work presented in [11], we describe the LTIMEX representation in some detail. Section II explains the relationship between LTIMEX and the existing TIMEX2 and TimeML standards; Section III describes in detail how we represent a wide variety of categories of temporal expressions using LTIMEX; and Section IV draws some conclusions about the utility of the scheme.

## II. BACKGROUND: THE TIMEX2 REPRESENTATION

TIMEX2, developed by the information extraction community, is a widely-used annotation standard for temporal expressions in text; it serves as a target representation for temporal expression taggers. For the purpose of its use in this standard, a temporal expression is defined as a linguistic expression which

TABLE I  
ENCODING OF POINTS AND PERIODS IN TIMEX2.

Attribute Value	Meaning
1	The second millennium AD
19	The 20th century AD
199	The 1990s
1992	Year 1992
1992-06-27	27 June 1992
1992-06-27T18:04	27 June 1992 18:04
1992-06-27T18:04:56	1992-06-27 18:04:56
1992-06-27TMO	morning of 27 June 1992
1992-W04	The fourth week of 1992
1992-SU	Summer of 1992
1992-H1	1st half of 1992
1992-Q3	3rd quarter of 1992
BC0346	Year 346 BCE
MA6	6 million years ago
PAST_REF	vague reference to past
T19:00	7pm (used in a non-specific context)
XXXX-06-XX	a day in June (non-specific context)
P2Y3M	2 years and 3 months
P2DT6H	2 days and 6 hours
PT3.5H	3.5 hours
P2DE	2 decades

references a *point in time* (such as a calendar date or time of day) or a *period* (also called a *duration*).<sup>1</sup>

TIMEX2 defines five attributes to represent the meaning of a temporal expression: `VAL`, `ANCHOR_VAL`, `ANCHOR_DIR`, `MOD`, `SET`. These attributes are used, respectively, to encode the temporal location of a point on a timeline or a duration of a period; to encode the temporal location of one of the period's end-points; to capture the direction of temporal reference from the anchoring point; to express modifications to more basic temporal values; and to flag whether the temporal expression refers to a set of temporal entities.

Values of the `VAL` and `ANCHOR_VAL` attributes use a string representation based on formats defined in the ISO-8601 standard: calendar date (`YYYY-MM-DD`), week date (`YYYY-Www-D`), time of day (`hh:mm:ss`), date and time (`YYYY-MM-DDThh:mm:ss`), and duration (`PnYnMnDTnHnMnS` or `PnW`). The individual character positions in the date and time strings correspond to particular granularities of temporal information, as demonstrated by the examples in Table I. TIMEX2 extends the encodings provided in the ISO standard by introducing tokens representing additional temporal granularities: for example, in place of a month number, TIMEX2 also permits codes for year seasons (e.g. `SU` for summer), half-years (e.g. `H1`), and quarter-years (e.g. `Q3`). It also adds support for BCE years, references to the distant past (i.e. billions, millions, and thousands of years ago) and general references to the past, present and future. For non-specific

<sup>1</sup>The distinction between a point and a period in TIMEX2 is different from the distinction often made in artificial intelligence and work on the philosophy of time. In contrast to usage in those areas, here a point is not a durationless instant, but a point on a timeline of some granularity. For example, a month is annotated as a point, not a period, when referenced as an element of a calendar (e.g. *He graduated in November*).

use of expressions (as in, for example, *a sunny day in June*) TIMEX2 uses an uppercase X to fill the slots at the unspecified granularities (for example, `XXXX-06-XX`). In regard to the encoding of duration, TIMEX2 adds new temporal units for decades, centuries and millennia.

In documents, a temporal expression tagger encodes these values as attributes of inline XML annotations, as in the following example:

(1) I left town on `<TIMEX2 VAL="2010-07-15">15th July 2010</TIMEX2>`.

What is notable about this temporal expression is that it is *fully-specified* or *explicit*: the temporal value can be computed using the lexical content of the string alone, without any reference to context.<sup>2</sup>

Not all temporal expressions are of this kind; rather, many are context-dependent, in that they only partially specify a temporal value, and require incorporation of information available in the context in order to derive their full interpretation. Unfortunately, the nature of the TIMEX2 representation means that there is no way of annotating the value of temporal expressions until this full interpretation has been carried out.

To address this problem, in this paper we describe an extension of TIMEX2 that uses a few simple notational devices to permit the representation of partially-interpreted temporal expressions in a way that is consistent with the original TIMEX2 specification. This has the benefit that it is easy to learn for those already familiar with TIMEX2 annotation; it can also take advantage of existing tools for evaluating the performance of temporal expression taggers. Most importantly, though, it provides us with an interface language that enables a modularisation of the process of temporal expression interpretation, so that we can use distinct components for determining the local semantic interpretation of a temporal expression and for the process of incorporating contextual information.

In TimeML, temporal expressions are annotated inline using TIMEX3 tags. TIMEX3 is a subsequent annotation standard to TIMEX2 which uses a different set of attributes. A detailed description is not appropriate here, but we note that its `value` attribute is used in exactly the same way as TIMEX2 uses the `VAL` attribute, which is the most important and relevant attribute for the development of LTIMEX. TIMEX3 represents the end-points of a period by means of additional TIMEX3 annotations, so its `value` attribute also replaces the `ANCHOR_VAL` attribute in TIMEX2. Thus, although LTIMEX was originally developed as an extension to TIMEX2, it is also compatible with TimeML and TIMEX3.

### III. REPRESENTING PARTIAL INTERPRETATIONS

TIMEX2 was designed to annotate temporal expressions with their global semantics, i.e. the temporal value obtained by interpreting the expression in the context of the content of the document in which it is used. Our experience with the

<sup>2</sup>This is not entirely true, since at least a particular calendar and a particular timezone are assumed, so values will always be relative to these. For most practical purposes, however, this makes the expressions context-free.

TABLE II  
A SUMMARY OF THE LTIMEX ATTRIBUTES.

Attribute	Comments
L-VAL	Encodes the local semantics of expressions concerning the temporal location of points: for underspecified values, the missing slots are filled with x; underspecified time is separated from the date components with t; for offsets, the encodings start with +, -, > or <; ordinally-specified elements are encoded with the pattern \$nu. Encoding of durations is the same as in TIMEX2.
L-ANCHOR_VAL	Local semantics of temporal location of end-points; see the description of L-VAL.
L-ANCHOR_DIR, L-MOD, L-SET	Same values as for the corresponding attributes in TIMEX2.
L-TYPE	Encodes the taxonomical type of an expression. The possible values are: EXPLICIT, UNDERSPECIFIED, OFFSET, OFFSET-DEICTIC, OFFSET-ANAPHORIC, EVENT-BASED, EVENT-BASED-POINT, EVENT-BASED-PERIOD, PERIOD, SET, SET-POINTS, SET-PERIODS.
L-EVENT_ID	Stores an identifier of an event for event-based expressions.
L-ANCHOR_TYPE	For anchored period expressions where the anchor is an offset, indicates the type of the offset; the possible values of the attribute are DEICTIC and ANAPHORIC.

development of a temporal expression tagger (presented in [9]) revealed that it is beneficial for both design and evaluation to explicitly recognize the semantics of the expression with no context involved; we refer to this as the *local semantics*, representing the partial and underspecified context-free meaning of the expression.

LTIMEX extends the set of attributes from TIMEX2 to provide a vocabulary for capturing partially-specified meaning. Some of these local attributes simply mirror the existing attributes; others, however, add new types of information that are intended to be of use to a subsequent processing stage that determines the global semantics of the temporal expression. The attributes provided by LTIMEX are shown in Table II.

A key feature here is the L-TYPE attribute, which stores the type of an expression; this captures the essential distinctions between different kinds of expressions, so that this information can be used to guide subsequent processing. In Table III we present the types of temporal expressions that we distinguish in this work, along with examples of each. These do not represent a flat taxonomy: the major types are expressions referring to single point and duration temporal entities, each of which may have subtypes; but there are also expressions referring to sets of such temporal entities, as well as ordinally-specified, modified and non-specific expressions.

Many of these types are introduced in TIMEX2 at the level of what we refer to as global semantics. The literature on temporal expression tagging identifies subtypes of point expressions that require different interpretation algorithms to derive their global semantics: *explicit*, *underspecified*, and *deictic* and *anaphoric offsets*.<sup>3</sup> We follow these taxonomic distinctions for the purpose of representing the local semantics. For the same reason, we also identify *ordinally-specified* expressions, allowing a further level of distinction for explicit, underspecified and offset expressions.

<sup>3</sup>The terminology used in literature in this regard varies; in this work we use what we believe are the most intuitive terms.

TABLE III  
THE TYPES OF TEMPORAL EXPRESSIONS.

Expression Type	Example Expression
Explicit Point	<i>Friday, 3 April 1998</i>
Underspecified Point	<i>23rd June</i>
Deictic Offset	<i>tomorrow</i>
Anaphoric Offset	<i>the next month</i>
Event-based Point	<i>the day when the last fortress fell</i>
Duration	<i>six months and two days</i>
Event-based Duration	<i>the first two minutes of the meeting</i>
Ordinally-specified	<i>the last Tuesday in 1997</i>
Modified Points	<i>the middle of August</i>
Modified Durations	<i>nearly two decades</i>
Non-specific Point	<i>a sunny day in July</i>
Set	<i>every Tuesday</i>

TABLE IV  
VALUES ASSIGNED TO EXPLICIT DATES AND TIMES IN TIMEX2.

No	Expression	Representation (VAL)
1	3rd January 1987	1987-01-03
2	Friday, 3 April 1998	1998-04-03
3	24/03/1980	1980-03-24
4	03/24/1980	1980-03-24
5	November 1996	1996-11
6	1960s	196
7	12th January 2001 11:59 pm	2001-01-12T23:59

Below, we present the LTIMEX scheme by discussing the representation of local semantics for a wide variety of types of temporal expressions that are found in real texts.

#### A. Explicit Expressions

These expressions are the only context-independent point expressions. For these, the local semantics is always the same as the global semantics, so our L-VAL simply mirrors the VAL in TIMEX2. We present some examples in Table IV.

TABLE V  
EXAMPLES OF UNDERSPECIFIED EXPRESSIONS IN LTIMEX.

No	Expression	Representation (L-VAL)
1	January 3	xxxx-01-03
2	the nineteenth	xxxx-xx-19
3	November	xxxx-11
4	summer	xxxx-SU
5	'63	xx63
6	the '60s	xx6
7	9 pm	xxxx-xx-xxT21
8	11:59 pm	xxxx-xx-xxT23:59
9	eleven in the morning	xxxx-xx-xxT11:00
10	ten minutes to 3	xxxx-xx-xxt02:50
11	15 minutes after the hour	xxxx-xx-xttx:15
12	Friday	xxxx-Wxx-5
13	8:00 p.m. Friday	xxxx-Wxx-5T20:00
14	eight o'clock Friday	xxxx-Wxx-5t08:00

### B. Underspecified Expressions

Underspecified expressions differ from explicit expressions in that they omit elements of information, which then have to be recovered from the context by some process of interpretation. LTIMEX provides for the representation of underspecified expressions by marking those elements of the temporal value that are missing with a special symbol; here we use a lowercase *x*, reminiscent of its common use as a variable.<sup>4</sup> Table V presents examples of a range of underspecified expressions along with their L-VAL attributes using this encoding.

For underspecified expressions referring to times that do not indicate the part of day (either 'am' or 'pm'), such as those in Rows 10, 11 and 14 of the table, we use a lowercase *t* separator (instead of the standard *T* separator) between the date and time parts of the representation. Together, these notational conventions indicate explicitly those parts of a temporal value that remain uninstantiated.

A few other elements of this representation are worthy of mention. The local semantics of bare weekday names, such as *Monday* or *Friday*, can not be represented in the standard month-based format *yyyy-mm-dd*, and therefore must be represented in the week-based format *yyyy-Wnn-d*, where *nn* is the ISO week number and *d* is the number of the weekday within that week (1 denotes Monday and 7 is used for Sunday).

### C. Offset Expressions

*Offset expressions*, as we call them, encode a function which, when applied to a *reference time*, returns the global semantic value denoting the temporal location of the entity referred to by the expression. This temporal function either adds or subtracts a number of units at some granularity: for example, *last*

<sup>4</sup>Underspecified expressions should not be confused with non-specific expressions; these represent two quite independent semantic phenomena. The former omits some information because it is assumed the reader will be able to retrieve it from the context (e.g. *14th June*), while the latter is typically used generically (e.g. 'The dry season starts in *May*'). In the string-based semantic representation, the underspecified expressions we introduce in LTIMEX use lowercase *xs* (e.g. *xxxx-06-14*), while non-specific expressions, already part of TIMEX2, are annotated with uppercase *Xs* (e.g. *XXXX-WXX-7TMO*).

TABLE VI  
LOCAL SEMANTICS OF OFFSET EXPRESSIONS OF DATES.

No	Deictic Expression	Anaphoric Expression	L-VAL
1	today	the same day	+0000-00-00
2	tomorrow	the following day	+0000-00-01
3	yesterday	the previous day	-0000-00-01
4	five days ago	five days earlier	-0000-00-05
5	last month	the previous month	-0000-01
6	last summer	the previous summer	-0001-SU
7	two weeks ago	two weeks earlier	-0000-W02
8	(in) two weeks	two weeks later	+0000-W02
9	this weekend	that weekend	+0000-W00-WE
10	this year	that year	+0000
11	three years ago	three years earlier	-0003
12	next century	the following century	+01

*year* is equivalent to subtracting one year from the year of the reference date, and *three days later* means adding three days.

Based on the reference time used, we further distinguish two kinds of offsets: these may be either *deictic* or *anaphoric*. For deictic expressions the reference time is the time-stamp of the utterance<sup>5</sup> (*S* in the Reichenbachian framework [12, pp. 291–298]) and for anaphoric expressions the reference is to be found somewhere in the context. For example, *yesterday* is deictic, but *the previous day* is an anaphoric expression.

In LTIMEX, both these expressions have the same offset encoded as the value of the L-VAL attribute; the L-TYPE attribute indicates whether the expression is *OFFSET-DEICTIC* or *OFFSET-ANAPHORIC*. The interpretation algorithm can use the value of this attribute to decide whether to apply the offset to the time-stamp of the document or to use a temporal focus tracking mechanism to select the correct reference time. If, for any reason, the annotator or a temporal expression tagger cannot decide on the subtype of the offset, L-TYPE can be specified simply as *OFFSET*, leaving the decision about the subtype to the interpretation module.

Table VI presents pairings of deictic and anaphoric date expressions which share the same value for the L-VAL attribute. A leading + or - indicates whether the operation to be performed is addition or subtraction; for consistency with TIMEX2, we use the ISO-based format to encode the magnitude of the offset. The number of filled slots determines the granularity of the unit of the operation. For example, +0000-00-05 encodes the addition of five days and -0002 encodes the subtraction of two years. Of course, for expressions with zero offset (e.g. *today*) one could use either + or -; by convention we use +.

An offset date expression may be accompanied by unambiguous (e.g. *6 a.m.*) or ambiguous (e.g. *6 o'clock*) information about the time within the referred-to day; see Rows 1–9 of Table VII. In these cases only the date component of the expression (e.g. *today* or *tomorrow*) has the form of an offset; here the *T* and *t* separators combine an offset on their left with an absolute value on their right.

<sup>5</sup>In practical terms, the utterance time may be the time of speaking, the date of publication, the date and time of sending an email, and so on.

TABLE VII  
THE LOCAL SEMANTICS OF OFFSET EXPRESSIONS WITH REFERENCES TO TIMES OF DAY.

No	Expression	Representation (L-VAL)	Type
1	6 a.m. today	+0000-00-00T06:00	deictic date offset + explicit time
2	6 p.m. that day	+0000-00-00T18:00	anaphoric date offset + explicit time
3	6 p.m. two days ago	-0000-00-02T18:00	deictic date offset + explicit time
4	6 o'clock two days ago	-0000-00-02t06:00	deictic date offset + underspecified time
5	tomorrow morning	+0000-00-01TMO	deictic date offset + explicit time
6	morning the day before	-0000-00-01TMO	anaphoric date offset + explicit time
7	last night	-0000-00-01TNI	deictic date offset + explicit time
8	11pm last night	-0000-00-01T23:00	deictic date offset + explicit time
9	2am last night	+0000-00-00T02:00	deictic date offset + explicit time
10	two hours earlier	+0000-00-00T-02	anaphoric time offset
11	an hour and twenty minutes later	+0000-00-00T+01:20	anaphoric time offset
12	in six hours time	+0000-00-00T+06	deictic time offset
13	five minutes ago	+0000-00-00T-00:05	deictic time offset
14	in sixty seconds	+0000-00-00T+00:00:60	deictic time offset
15	sixty seconds later	+0000-00-00T+00:00:60	anaphoric time offset
16	tomorrow two hours later	+0000-00-01T+02	deictic date offset + time offset
17	the next day two hours later	+0000-00-01T+02	anaphoric date offset + time offset
18	8 May 2001, one hour later	2001-05-08T+01	explicit date + time offset
19	17 May, one hour earlier	xxxx-05-17T-01	underspecified date + time offset

Just as there can be date offsets that have no time information, we can also have time offsets with no date information; for example, *five minutes ago*. In such cases we add the operator (+ or -) just after the T separator. Consider the representation of *eighteen hours and fifteen minutes later*: this has the value +0000-00-00T+18:15, making it distinct from the representation of *6:15pm today*, which is +0000-00-00T18:15. More examples are provided in Rows 10–15 of Table VII.

A time offset may also appear together with a date offset, as shown in Rows 16 and 17 in Table VII, or even with an explicit or underspecified date, as shown in Rows 18 and 19. In the first case the representation combines a non-zero date offset with a time offset; in the second case we have a non-offset representation of a date followed by the encoding of the time offset.

Finally, we also need to be able to represent offset expressions built on cycle-based calendar elements (weekday and month names), such as *last Monday* or *next March*. In Table VIII we present examples with the proper encodings. In our representation we only indicate the direction (< for *last*, > for *next*) and the weekday or month name mentioned in the expression ( $D_n$  and  $M_{nn}$ , respectively). It will be the task of the interpretation stage to determine which calendar week and year is intended. Expressions using the determiner *this* (e.g. *this Wednesday* or *this June*) are treated as underspecified expressions unless the determiner is used together with other tokens indicating the direction of interpretation (e.g. *this coming Wednesday*).

#### D. Event-based Point Expressions

An event-based expression identifies a temporal entity by means of a reference to an event. In such expressions, the L-TYPE attribute has the value

TABLE VIII  
THE LOCAL SEMANTICS OF OFFSET EXPRESSIONS INVOLVING ELEMENTS OF CYCLE-BASED CALENDARS.

No	Deictic Expression	Anaphoric Expression	L-VAL
1	last Monday	the previous Monday	<D1
2	next Wednesday	the next Wednesday	>D3
3	this coming Wednesday	that coming Wednesday	>D3
4	this Wednesday	that Wednesday	xxxx-Wxx-3
5	last June	the previous June	<M06
6	next June	the next June	>M06
7	this June	that June	xxxx-06

L-TYPE=EVENT-BASED-POINT, and we provide the identifier of the event in the L-EVENT\_ID attribute. If an application does not perform event recognition, or in a given circumstance is unable to identify the event in question, then the value of this attribute is left empty.

In some cases the temporal value is expressed as an offset to the time of an event, as in Example (2):

- (2) *Ten seconds after the second explosion* the plane hit the ground.

L-VAL=+0000-00-00T+00:10

L-TYPE=EVENT-BASED-POINT L-EVENT\_ID=e

- (3) Jane got a salary raise *the day after Michael lost his job*.

L-VAL=+0000-00-01 L-TYPE=EVENT-BASED-POINT

L-EVENT\_ID=e

Here the L-VAL attribute encodes the offset, just as it does in offset point expressions. The specified type of the expression indicates that the reference time to be used in the interpretation is the time of the event indicated by the  $e$  event variable.

In cases when the time denoted by the expression can be computed from the time-stamp of the event simply by refining its granularity, we use a zero-offset just to indicate the granularity (temporal unit) of the result. Consider the

following example:

- (4) I met my wife *the year when I bought my house*.  
 L-VAL=+0000  
 L-TYPE=EVENT-BASED-POINT L-EVENT\_ID=e

The temporal value of the expression is to be calculated here by adding zero years to the year of the event time-stamp, and discarding any more detailed information that the time-stamp might provide (e.g. the month and day).

In other cases, the time denoted by the expression may be exactly the time of the event, as in the following example:

- (5) *At the time of the peace agreement* the United States agreed to replace equipment on a one-by-one basis.  
 L-VAL=EVENT\_TIME  
 L-TYPE=EVENT-BASED-POINT L-EVENT\_ID=e

Note that the expression does not indicate the granularity. In such cases, the L-VAL attribute contains the EVENT\_TIME token, which means that the temporal value is the time of the underlying event.

For point temporal expressions which refer to a part of an event, as in Example (6), we use the encoding of ordinaly-specified expressions, which we discuss in detail in Section III-G:

- (6) The casualties included 19,240 dead on *the third day of the Battle of the Somme*.  
 L-VAL=3D L-TYPE=EVENT-BASED-POINT  
 L-EVENT\_ID=e

The 3D value tells us that, of the whole time span of the event, the expression refers only to the third day.

#### E. Period Expressions

For expressions that denote periods, L-VAL takes the same values as the corresponding VAL attribute in TIMEX2; this also covers those cases where the duration mixes different units, as in the following example:

- (7) This project will run for *one year and two months*.  
 L-VAL=P1Y2M

The anchoring attributes are to be filled in only if the anchor is mentioned within the extent of the expression. The anchor may be provided in various forms, including an explicit (see Example (8)), underspecified (see Example (9)) or offset (see Examples (10) and (11)) point. In each case, the L-ANCHOR\_VAL attributes encode that anchoring point in one of the formats we have already introduced:

- (8) The accounts are paid in full for *the six months ended 31 March 2009*.  
 L-VAL=P6M  
 L-ANCHOR\_VAL=2009-03-31 L-ANCHOR\_DIR=ENDING
- (9) The accounts are paid in full for *the six months ended March 31*.  
 L-VAL=P6M  
 L-ANCHOR\_VAL=xxxx-03-31 L-ANCHOR\_DIR=ENDING
- (10) The renovations will last *five days starting tomorrow*.  
 L-VAL=P5D L-ANCHOR\_TYPE=DEICTIC  
 L-ANCHOR\_VAL=+0000-00-01  
 L-ANCHOR\_DIR=STARTING

- (11) The movie festival will end on *18 July*, but then we have the theatre workshops that will run for *a whole week starting just the very next day*.  
 L-VAL=P1W L-ANCHOR\_TYPE=ANAPHORIC  
 L-ANCHOR\_VAL=+0000-00-01  
 L-ANCHOR\_DIR=STARTING

In the last example above we also use the L-ANCHOR\_TYPE attribute to encode the type of the offset of the anchor; the possible values here are DEICTIC and ANAPHORIC. The expression may be also anchored implicitly, as in the following example:

- (12) *The next three days* were extremely hot and humid.  
 L-VAL=P3D  
 L-ANCHOR\_VAL=+0000-00-00  
 L-ANCHOR\_DIR=STARTING

In such cases we provide the offset in the L-ANCHOR\_VAL attribute, but leave it to the interpretation algorithm to decide (for example, based on the tense of the sentence) whether the anchor is deictic or anaphoric.

If the expression itself does not state when the period starts or ends, then no anchor-related attributes are specified:

- (13) The Nile Movie Festival lasted *five days*. L-VAL=P5D

If the rest of the document provides such information, the anchor is to be determined in the interpretation stage, when the global semantics is derived; this also means that the final annotation does not have the L-ANCHOR\_VAL and L-ANCHOR\_DIR attributes, it only has ANCHOR\_VAL and ANCHOR\_DIR.

#### F. Event-based Period Expressions

For event-based periods, we encode the duration in the L-VAL attribute just as in the case of other durations discussed in Section III-E, but the type of the expression in the L-TYPE attribute is specified as EVENT-BASED-PERIOD. Similarly to the annotation of event-based point expressions, we provide the identifier of the underlying event in the L-EVENT\_ID attribute. The time of the event, however, does not serve here as the reference time to be used in the following interpretation stage to calculate the value of the VAL attribute; rather, it determines the location of the period, and is used to compute one of the period's anchors. Consider the following examples:

- (14) The rate of US combat deaths in Baghdad nearly doubled in *the first seven weeks of the "surge" in security activity*.  
 L-VAL=P7W  
 L-ANCHOR\_VAL=EVENT\_START  
 L-ANCHOR\_DIR=STARTING  
 L-EVENT\_ID=e L-TYPE=EVENT-BASED-PERIOD
- (15) *The last three days of the battle* were extremely brutal.  
 L-VAL=P3D  
 L-ANCHOR\_VAL=EVENT\_END L-ANCHOR\_DIR=ENDING  
 L-EVENT\_ID=e L-TYPE=EVENT-BASED-PERIOD
- (16) I was so panicked I could not take a single step for *30 minutes after the earth quake*.  
 L-VAL=PT30M  
 L-ANCHOR\_VAL=EVENT\_END

TABLE IX  
THE LOCAL SEMANTICS OF ORDINALLY-SPECIFIED REFERENCES.

No	Expression	Representation (L-VAL)
1	the first Tuesday	1D2
2	the third day	3D
3	the last Tuesday	\$1D2
4	the last day	\$1D
5	the last but one day	\$2D
6	the penultimate day	\$2D
7	the last month	\$1M
8	the last February	\$1M02

L-ANCHOR\_DIR=STARTING

L-EVENT\_ID=e L-TYPE=EVENT-BASED-PERIOD

- (17) There was no terrorist warning in *the three years before the bombing in the underground.*

L-VAL=P3Y

L-ANCHOR\_VAL=EVENT\_START

L-ANCHOR\_DIR=ENDING

L-EVENT\_ID=e L-TYPE=EVENT-BASED-PERIOD

To handle the fact that events themselves span over some periods of time, we introduce two tokens, `EVENT_START` and `EVENT_END`, to be used in the `L-ANCHOR_VAL` attribute. These tokens indicate which end of the period of the event is to be used as the anchor.

### G. Ordinally-specified expressions

Some temporal expressions use what we call *ordinally-specified elements*; for example, the expressions in Examples (18a)–(18c) make reference to a specific day by means of selecting the third day of some coarser temporal unit or an event.

- (18) a. *the third day of the next month*  
 b. *the third day of the previous decade*  
 c. *the third day of the trip*

To encode such ordinally-specified elements we use the format `$nu`, where `n` is a number, `u` indicates the temporal unit to be used, and `$` is an optional marker used when the ordinal is to be counted from the end of some chunk of time (e.g. *last*, *penultimate*). Examples of ordinally-specified elements of expressions and their representations are shown in Table IX.

Expressions using ordinally-specified elements are annotated with multiple `TIMEX2` annotations, as shown in Examples (19)–(21). The ordinally-specified format is recorded only in the outermost annotation; the inner expression, which may be, for example, underspecified or an offset, receives its own proper representation of its local semantics.

- (19) `<TIMEX2 L-VAL="3D">the third day of`  
`<TIMEX2 L-VAL="+0000-01">the next month`  
`</TIMEX2></TIMEX2>`  
 (20) `<TIMEX2 L-VAL="$1D1">the last Monday of <TIMEX2`  
`L-VAL="xxxx-05">May</TIMEX2></TIMEX2>`  
 (21) `<TIMEX2 L-VAL="1D">the first day of`  
`<TIMEX2 L-VAL="2M">the second month of`

`<TIMEX2 L-VAL="+0001">next year</TIMEX2>`  
`</TIMEX2></TIMEX2>`

When deriving the global semantics from the local semantics, the individual values of the nested expressions must be combined together; the process is carried out recursively from the outermost to the innermost, resolving the temporal references while backtracking from the innermost to the outermost.

The type recorded in the `L-TYPE` of an expression whose `L-VAL` is ordinally specified is the same as the type of its innermost expression; Example (19) is an anaphoric offset, Example (20) is underspecified, and Example (21) is deictic.

### H. Non-Specific Expressions

In many cases the decision that a temporal expression is non-specific can be only made when analysing the whole sentence, or even the entire document. For example, consider the generic references to months in the following sentence:

- (22) In the southern hemisphere *days* are much longer in *January* than in *July*.

These are not obviously non-specific when we consider only the extent of the expressions themselves. The local semantic representations are therefore underspecified, i.e. `xxxx-01` and `xxxx-07`. In the interpretation stage, the lowercase `xs` must not be instantiated with a specific year, but must be converted into markers of non-specificity (uppercase `Xs`, for example, if `TIMEX2` is the scheme used for global semantics representation).

Indefinite noun phrases, on the other hand, can already be recognized as non-specific at the level of local semantics:

- (23) a. I was born on *a Sunday*. `L-VAL=XXXX-WXX-7`  
 b. I met my wife on *a sunny day in July*.  
`L-VAL=XXXX-07-XX`

In such cases, we can already mark the relevant slots as non-specific, obtaining the same value as expected in `VAL`.

Periods of indefinite duration, such as *a few days*, can also be recognized as non-specific without reference to the context. The encoding of such durations uses `X` instead of a specific number, e.g. `PXD`.

Similarly, some set expressions can be identified as non-specific already at the stage of local semantic analysis; for example, *every few days* or *some Mondays in 2004*. Unfortunately, `TIMEX2` is unable to represent the semantics of these expressions correctly,<sup>6</sup> and in consequence our representation fails here too.

### I. Set Expressions

The semantic representation of set expressions is complex, because these expressions do not refer to a single entity, but to a set of entities. Neither `TIMEX2` nor `TimeML` express the semantics of these expressions sufficiently well to make these schemes applicable to all set expressions. As an alternative, Pan's [13] first-order logic representation for set expressions, which is formally sound and has much broader coverage, can

<sup>6</sup>For example, *some Mondays in 2004* is represented just in the same way as *all Mondays in 2004*: `VAL=2004-WXX-1`, `SET=YES`.

be encoded in OWL; but the complexity of OWL goes far beyond the goals of TIMEX2 and TimeML.

As indicated earlier, our aim is to provide a representation for local semantics that is compatible with the use of TIMEX2 for representing the global semantics of temporal expressions. Inevitably, this compromises the expressiveness of our representation.

We indicate the set type by assigning the value YES to the L-SET attribute (following the use of the SET attribute in TIMEX2), and we specify any underspecification or offset that might appear, as in the following examples:

- (24) a. *every winter in the 80s* L-VAL=xx8-WI L-SET=YES  
 b. *monthly* L-VAL=xxxx-XX L-SET=YES

In some cases we may be able to obtain a reliable representation by using values or attribute combinations not authorized in TIMEX2. For instance, in Example (25a) the expression is represented by means of any period of two years with its ending anchored on years having zero as their final digit (e.g. 1960, 1990, 2000). In Example (25b) we do something similar, but we anchor the periods on the last day of a month (and in doing so we specify the anchor with the format used for ordinal-specified references).

- (25) a. *the last two years of every decade*  
 L-VAL=P2Y L-SET=YES  
 L-ANCHOR\_VAL=XXX0 L-ANCHOR\_DIR=ENDING  
 b. *the last two days of every month*  
 L-VAL=P2D L-SET=YES  
 L-ANCHOR\_VAL=XXXX-XX-\$1D  
 L-ANCHOR\_DIR=ENDING

This, however, already goes beyond the TIMEX2 rules, which prohibit using the anchor attributes for set expressions [2, p. 42].

#### IV. CONCLUSION

We have developed a string-based representation of the context-independent semantics of temporal expressions, which we call LTIMEX. It can be easily integrated with the existing annotation schemes (specifically, TIMEX2 and TimeML) which currently allow only for the representation of fully-interpreted semantics. We are thus proposing an extension to these schemes that provides a means of support for an additional level of semantic representation; this in turn leads to a modular design of temporal expression tagging, with a well-defined interface between the recognition and interpretation modules, and allows for more detailed evaluation of taggers.

Table II summarises the attributes used in LTIMEX and their values. We use in total eight attributes: three are used in the same way as their TIMEX2 counterparts (L-MOD, L-SET and L-ANCHOR\_DIR); L-VAL represents the partial<sup>7</sup> context-independent meaning of the expression; similarly, L-ANCHOR\_VAL encodes information about the temporal location of an anchor of a period; and three attributes are

<sup>7</sup>It is partial in the sense that it does not capture information about temporal modifiers and anchors, which are encompassed in separate attributes: L-MOD, L-ANCHOR\_DIR, and L-ANCHOR\_VAL.

completely new: L-TYPE, which encodes the taxonomical type of the expression; L-EVENT\_ID, which for event-based expressions stores the identifier of the event; and L-ANCHOR\_TYPE, which, for durations with the anchor expressed by means of an offset, encodes whether it is deictic or anaphoric.

The first obvious task that arises as possible future work is to use LTIMEX for a significant data annotation task; possible candidate corpora already annotated with temporal expressions are WikiWars [14] (TIMEX2) and TimeBank<sup>8</sup> (TimeML).

Another area left for future work is the improvement in the representation of set expressions. This could perhaps be aligned with further development of TimeML, which is to become an ISO standard (see the discussion in [15]); although this goes further than TIMEX2, it still does not have a proper means to represent the global semantics of set expressions.

# Dependency-Based Rules for Grammar Checking with LanguageTool

Maxim Mozgovoy  
University of Aizu  
Tsuruga, Ikki-machi, Aizu-Wakamatsu,  
Fukushima, 965-8580 Japan  
Email: mozgovoy@u-aizu.ac.jp

**Abstract**—This paper describes a possible extension of well-known open source grammar checking software LanguageTool. The proposed extension allows the developers to write grammar rules that rely on natural language parser-supplied dependency trees. Such rules are indispensable for the analysis of word-word links in order to handle a variety of grammar errors, including improper use of articles, incorrect verb government, and wrong word form agreement.

## I. INTRODUCTION

GRAMMAR checking is a well-recognized problem of natural language processing. Grammar checkers are helpful in a variety of scenarios, such as text authoring and language learning. The purpose of such tools is to find grammatical errors in the input text: incorrect use of person, number, case or gender, improper verb government, wrong word order, and so on. A grammar checker normally works in combination with a spellchecker—a module that detects spelling errors in individual words. As a rule, spell checker cannot correct even basic grammatical flaws, such as erroneous choice of article (like in the expression “an box”).

While a spellchecker is already an essential part of a modern text authoring system, a grammar checking module is still found only in large commercial packages like Microsoft Office or WordPerfect Office. Certain grammar checkers are also available as additional software packages or online services, offered by independent companies [1-3]

This situation is slowly changing nowadays. With the growing popularity of open source software, more natural language processing systems should become available for wider use. Open spellchecking libraries, such as JOrtho and GNU Aspell already exist, and anyone can extend own software with their capabilities. Grammar checking is a more challenging task, and most open projects are still far beyond well-established proofing tools, such as offered in MS Word.

### A. Rule-Based Grammar Checking

Probably, the predominating approach to grammar checking today consists in testing the input text against a set of handcrafted rules [4, 5]. For example, the rule

I + Verb (3<sup>rd</sup> person, singular form)

corresponds to the incorrect verb form usage, as in the phrase “I has a dog”. In order to emphasize the nature of

such rules as erroneous patterns, they are often called “mal-rules”.

This method has several attractive features: (a) rules can be easily added, modified or removed; (b) every rule can have a corresponding extensive explanation, helpful for the end user; (c) the system is easily debuggable, since its decisions can be traced to a particular rule; (d) the rules can be authored by the linguists, possessing limited or no programming skills. An obvious disadvantage of a rule-based system is a large amount of manual work, needed to build an extensive rule set.

An alternative approach is represented with several varieties of statistical systems that analyze existing collections of grammatically correct and incorrect texts, attempting to find word patterns and/or text features that correspond to correct sentences [6, 7]. The simplest statistical grammar algorithm consists in analyzing N-grams—chains of N consecutive words [8]. If a certain word chain is common in the master text corpus, it is considered correct.

Statistical grammar checkers have their own advantages and drawbacks, but their analysis is beyond the scope of this article.

### B. Introducing LanguageTool

The purpose of the present work is to design a possible extension for LanguageTool grammar checker [9]. LanguageTool is a modern rule-based open source grammar checking system, available both as a plug-in for OpenOffice.org and as a downloadable library, which makes it ready for use in any software projects. Currently LanguageTool supports 21 languages, though the number of ready grammar rules ranges from 4 for Lithuanian to 1810 for French (as of April, 2011). The rules can be authored by any interested contributors.

Unfortunately, the syntax of rules in LanguageTool does not allow formulating certain grammatical phenomena. In the subsequent sections, we will consider these limitations and a possible method to reduce them.

## II. BASIC DESIGN PRINCIPLES OF LANGUAGE TOOL

LanguageTool defines an XML-based language for describing mal-rules. In its simplest form, a mal-rule is just a sequence of tokens to be matched in the text:

```
<!-- "all be it" instead of "albeit" -->

<pattern>
  <token>all</token>
  <token>be</token>
  <token>it</token>
</pattern>
<message>Did you mean 'albeit'?</message>
```

The syntax of the rules is flexible and powerful: it is possible to use OR and NOT logic operations (“match token A or token B”; “match any token except C”), skip optional tokens, and, to some extent, use regular expressions.

Several syntactic elements are backed with additional linguistic modules — *sentence splitter* and *part-of-speech tagger*. Sentence splitter determines the boundaries of each sentence, thus allowing the user to find certain tokens exactly at the beginning or at the end of a sentence:

```
<!-- "another words," instead of
      "in other words,"
      at the beginning of a sentence -->

<pattern>
  <token postag="SENT_START"></token>
  <token>another</token>
  <token>words</token>
  <token>,</token>
</pattern>
<message>Did you mean
      'in other words'?</message>
```

Part-of-speech tagger determines every word’s part of speech, helping the user to find tokens that belong to a certain class:

```
<!-- "ca" + [personal pronoun] instead of
      "can" + [personal pronoun] -->

<pattern>
  <token>ca</token>
  <token postag="PRP"></token>
</pattern>
<message>Did you mean 'can'?</message>
```

LanguageTool makes use of third-party libraries for splitting and tagging the input text. Fortunately, a number of ready solutions are available for this purpose (e.g., Ratnaparkhi’s MXPOST and MXTERMINATOR [10, 11]).

### III. INTRODUCING DEPENDENCY-BASED RULES

Despite the high expressive power and flexibility, LanguageTool’s rule system has a notable shortcoming: it treats the input text as a sequence of tokens, ignoring tree-like nature of natural language sentences.

Consider, for example, the following problem. In English, a/an article should never be used with a noun in a plural form. The current LanguageTool rule to detect such a case is defined as follows:

```
<!--"a/an" article, then a plural noun -->

<pattern>
  <token regexp="yes">a|an</token>
  <token postag="NNS|NNPS"></token>
</pattern>
<message>Don't use indefinite articles
      with plural words.</message>
```

However, this rule ignores the fact that there can be any number of words between a/an and the corresponding noun (“a box”, “a wooden box”, “a simple wooden box”). The rule definition can be improved if we allow any number of optional adjectives between the article and the noun, but in general case this solution is inadequate.

In order to handle such problems, the grammar checker should analyze nonlinear structure of the phrase. An article is logically linked with a noun, regardless of any words between them. This nonlinear structure can be obtained with an additional module, known as *dependency parser*. This instrument represents the structure of every sentence with a *parse tree*, having words as nodes and logical links between them as edges (see Fig. 1).

Fig. 1 Parse tree for the phrase “I made a simple wooden box”.

As it can be seen, the article “a” is linked directly to the noun “box”. Having such a tree, it is possible to extend the syntax of LanguageTool grammar rules, enabling the developers to analyze word-word relationships.

### IV. TECHNICAL APPROACH

In order to achieve our goals, we had to solve three sub-problems: 1) select a suitable dependency parsing instrument; 2) develop an appropriate syntax for dependency-based rules; 3) design the corresponding rule-matching algorithm.

### A. Selecting a Practical Dependency Parser

After examining currently available solutions, we decided to use one of two parsers: MaltParser [12] or LDPaR [13]. Both of them are high-quality dependency parsers, available as open source.

MaltParser is written in Java, and thus suits better for the use in combination with the current implementation of LanguageTool, also made with Java. LDPaR distribution contains cross-platform C++ code, providing compilable efficient implementation. Both parsers are based on machine learning: the parser first has to be trained with a collection of correctly parsed sentences (a *treebank*). MaltParser and LDPaR also share the same format of input and output data.

### B. Suggested Syntax for Dependency-Based Rules

Dependency-based rules should provide syntactic means for the following basic functions:

- 1) Match a link between two given words, optionally labeled with a given label. This function should be generalizable to the matching of the whole subtree.
- 2) Make sure that a certain word appears before or after another word, in order to control word precedence.
- 3) Ensure the absence of the given subtree in the parse tree.

In order to satisfy these requirements, we suggest the following syntax for an individual dependency-based rule. The rule definition is split into chunks, each representing a separate subtree to be matched:

```
CHUNK1
CHUNK2
...
CHUNKN
```

Every  $CHUNK_i$  is represented with a sequence of tokens, defined with token XML tag:

```
<token [attributes]>token-value</token>
```

Currently our system supports the following attributes:

- **pos**: the token should belong to the specified part-of-speech class;
- **label**: the link to the token's parent (according to the parse tree) should have the specified label;
- **parent**: the token should have the specified token as a parent (according to the parse tree);
- **except**: the token's value should not match token-value;
- **before**: the token should appear in the sentence before the specified token;
- **after**: the token should appear in the sentence after the specified token;
- **chunk\_start**: start-of-chunk marker;

- **inverse**: the current chunk (subtree) should not be found in the parse tree.

Attributes **parent**, **before**, and **after** expect a token's cardinal number within the current chunk as an argument. By default, every chunk of the rule has to be matched in the parse tree in order to satisfy the rule.

### C. Examples

The following examples illustrate the capabilities of dependency-based rules:

```
<!-- Example 1:
in non-interrogative sentences
the subject should be placed before
the predicate -->
```

```
<token pos="VB|VBP|VBZ|VBD"
label="ROOT"></token>
<token after="1" label="SUB"></token>
```

```
<token chunk_start="" inverse=""
label="ROOT"></token>
<token parent="1"?></token>
```

The first chunk ensures that the system has found a subject (labeled SUB), placed after the main verb. The second chunk asserts the absence of "?" mark, linked to the tree root.

```
<!-- Example 2:
"a/an" should not be used
with plural nouns -->
```

```
<token>a|an</token>
<token pos="NNS|NNPS" parent="1"></token>
```

This mal-rule finds a/an articles, linked to plural nouns (marked as NNS or NNPS by a part-of-speech tagger). Note that the determiner (such as an article) is always directly linked with the corresponding word, even if they are not adjacent in the original sentence.

```
<!-- Example 3:
the gerund should be used in conjunction
with auxiliary verbs -->
```

```
<token pos="VBG" label="ROOT"></token>
```

If a gerund (verb ing-form) is considered a parse tree root, this means the absence of an obligatory auxiliary verb (such as "is", "was"). If an auxiliary verb is present, it becomes a root element of the tree.

```
<!-- Example 4:
improper personal verb form used -->
```

```
<token pos="VBZ"></token>
<token parent="1"
label="SUB">I|we|you|they</token>
```

If the subject of a certain verb is I/we/you/they, the verb should not be in the 3<sup>rd</sup> person singular form.

Concerning the design of the actual subtree matching algorithm, it is implemented as a straightforward recursive depth-first search routine.

## V. DISCUSSION

LanguageTool is a good example of an extensible rule-based grammar checker. Basic grammatical rules can be expressed by means of standard regular expressions. If their expressive power is insufficient to describe a certain rule, one can make use of additional natural language processing-powered syntactic elements, backed with sentence splitter and part-of-speech tagger.

This architecture can be extended further by incorporating other language processing modules. An obvious candidate for this role is natural language parser that shows immediate word-word relationships. We have demonstrated several examples of grammar errors, detectable with parser-powered mal-rules.

Since we consider rule-based grammar checking to be an established technology, the discussion of its advantages and drawbacks is beyond the scope of our work. However, our experiments have revealed weak points of the language tools we use (parser and part-of-speech tagger, mainly).

Normally, these tools, being based on machine learning algorithms, need initial training on annotated text data. Most such training collections are represented with grammatically correct sentences. Thus, ungrammatical phrases may contain previously unseen patterns, causing incorrect results. For example, a part-of-speech tagger cannot reliably determine a tag for the word "like" in the phrase "he like dogs", since such a pattern never appears in the training collection.

Since processing ungrammatical sentences is a crucial feature for a grammar checking module, this issue needs further research. One of the possible solutions would be to extend the training collection with ungrammatical sentences.

## VI. CONCLUSION

We have designed and implemented the mechanism of natural language parser-backed rules for a LanguageTool-based grammar checking module. Our syntax allows writing rules that analyze word-word dependencies in a given phrase. We have shown real examples of language phenomena, where such rules are much more helpful than built-in LanguageTool instruments.

# Preserving pieces of information in a given order in HRR and $GA_c$

Agnieszka Patyk-Łońska

**Abstract**—Geometric Analogues of Holographic Reduced Representations (GA HRR or  $GA_c$ —the continuous version of discrete GA described in [16]) employ role-filler binding based on geometric products. Atomic objects are real-valued vectors in  $n$ -dimensional Euclidean space and complex statements belong to a hierarchy of multivectors. A property of  $GA_c$  and HRR studied here is the ability to store pieces of information in a given order by means of trajectory association. We describe results of an experiment: finding the alignment of items in a sequence without the precise knowledge of trajectory vectors.

**Index Terms**—distributed representations, geometric algebra, HRR, BSC, word order, trajectory associations, bag of words.

## I. INTRODUCTION

OVER the years several attempts have been made to preserve the order in which the objects are to be remembered with the help of binding and superposition. While some solutions to the problem of preserving pieces of information in a given order have proved ingenious, others are obviously flawed. Let us consider the representation of the word *eye*—it has three letters, one of which occurs twice. The worst possible choice of binding and superposition would be to store quantities of letters, e.g.

$$eye = twice * e + once * y, \quad (1)$$

since we would not be able to distinguish *eye* from *eey* or *yee*. Another ambiguous representation would be to remember the neighborhood of each letter

$$eye = before_y * e + between_e * y + after_y * e. \quad (2)$$

Unfortunately, such a method of encoding causes words *eye* and *eyeye* to have the same representation

$$\begin{aligned} eyeye &= before_y * e + 2 \cdot between_e * y + \\ & (before_y + after_y) * e + after_y * e \\ &= 2(before_y * e + between_e * y + after_y * e) \\ &= 2 eye. \end{aligned} \quad (3)$$

Real-valued vectors are normalized in most distributed representation models, therefore the factor of 2 would be most likely lost in translation. Such *contextual roles* (Smolensky [19]) cause problems when dealing with certain types of palindromes. Remembering positions of letters is also not a good solution

$$eye = letter_{first} * e + letter_{second} * y + letter_{third} * e \quad (4)$$

as we need to redundantly repeat the first letter as the third letter, otherwise we could not distinguish *eye* from *ey* or *ye*.

Secondly, this method of encoding will not detect similarity between *eye* and *yeye*.

A quantum-like attempt to tackle the problem of information ordering was made in [1]—a version of semantic analysis, reformulated in terms of a Hilbert-space problem, is compared with structures known from quantum mechanics. In particular, an LSA matrix representation [1], [10] is rewritten by the means of quantum notation. Geometric algebra has also been used extensively in quantum mechanics ([2], [4], [3]) and so there seems to be a natural connection between LSA and  $GA_c$ , which is the ground for future work on the problem of preserving pieces of information in a given order.

As far as convolutions are concerned, the most interesting approach to remembering information in a given order has been described in [12]. Authors present a model that builds a holographic lexicon representing both word meaning and word order from unsupervised experience with natural language texts comprising altogether 90000 words. This model uses simple convolution and superposition to construct  $n$ -grams recording the frequency of occurrence of every possible word sequence that is encountered, a window of about seven words around the target word is usually taken into consideration. To predict a word in a completely new sentence, the model looks up the frequency with which the potential target is surrounded by words present in the new sentence. To be useful,  $n$ -gram models need to be trained on massive amounts of text and therefore require extensive storage space. We will use a completely different approach to remembering information order—trajectory association described by Plate in [18]. Originally, this technique also used convolution and correlation, but this time items stored in a sequence are actually superimposed, rather than being bound together.

## II. GEOMETRIC ANALOGUES OF HRR

Holographic Reduced Representations (HRR) and Binary Spatter Codes (BSC) are distributed representations of cognitive structures where binding of role-filler codevectors maintains predetermined data size. In HRR [17], [18] binding is performed by means of circular convolution

$$(x \circledast y)_j = \sum_{k=0}^{n-1} x_k y_{j-k \bmod n}. \quad (5)$$

of real  $n$ -tuples or, in ‘frequency domain’, by componentwise multiplication of (complex)  $n$ -tuples,

$$(x_1, \dots, x_n) \circledast (y_1, \dots, y_n) = (x_1 y_1, \dots, x_n y_n). \quad (6)$$

Bound  $n$ -tuples are superposed by addition, and unbinding is performed by an approximate inverse. A dual formalism, where real data are bound by componentwise multiplication, was discussed by Gayler [9]. In BSC [13], [14] one works with binary  $n$ -tuples, bound by componentwise addition mod 2,

$$\begin{aligned} (x_1, \dots, x_n) \oplus (y_1, \dots, y_n) &= (x_1 \oplus y_1, \dots, x_n \oplus y_n), \\ x_j \oplus y_j &= x_j + y_j \pmod{2}, \end{aligned} \quad (7)$$

and superposed by pointwise majority-rule addition; unbinding is performed by the same operation as binding.

One often reads that the above models represent data by *vectors*, which is not exactly true. Given two vectors one does not know how to perform, say, their convolution or componentwise multiplication since the result depends on basis that defines the components. Basis must be fixed in advance since otherwise all the above operations become ambiguous. Geometric Analogues of Holographic Reduced Representations (GA HRR) [5] can be constructed if one defines binding by the geometric product, a notion introduced in 19th century works of Grassmann [11] and Clifford [8].

In order to grasp the main ideas behind GA HRR let us consider an orthonormal basis  $b_1, \dots, b_n$  in some  $n$ -dimensional Euclidean space. Now consider two vectors  $x = \sum_{k=1}^n x_k b_k$  and  $y = \sum_{k=1}^n y_k b_k$ . The *scalar*

$$x \cdot y = y \cdot x \quad (8)$$

is known as the *inner product*. The *bivector*

$$x \wedge y = -y \wedge x \quad (9)$$

is the *outer product* and may be regarded as an oriented plane segment (alternative interpretations are also possible, cf. [7]).  $\mathbf{1}$  is the identity of the algebra. The geometric product of  $x$  and  $y$  then reads

$$xy = \underbrace{\sum_{k=1}^n x_k y_k}_{x \cdot y} \mathbf{1} + \underbrace{\sum_{k < l} (x_k y_l - y_k x_l) b_k b_l}_{x \wedge y}. \quad (10)$$

Grassmann and Clifford introduced geometric product by means of the basis-independent formula involving the *multivector*

$$xy = x \cdot y + x \wedge y \quad (11)$$

which implies the so-called Clifford algebra

$$b_k b_l + b_l b_k = 2\delta_{kl} \mathbf{1}. \quad (12)$$

when restricted to an orthonormal basis. Inner and outer product can be defined directly from  $xy$ :

$$x \cdot y = \frac{1}{2}(xy + yx), \quad x \wedge y = \frac{1}{2}(xy - yx).$$

The most ingenious element of (11) is that it adds two apparently different objects, a scalar and a plane element, an operation analogous to addition of real and imaginary parts of

a complex number. Geometric product for vectors  $x, y, z$  can be axiomatically defined by the following rules:

$$\begin{aligned} (xy)z &= x(yz), \\ x(y+z) &= xy + xz, \\ (x+y)z &= xz + yz, \\ xx &= x^2 = |x|^2, \end{aligned}$$

where  $|x|$  is a positive scalar called the magnitude of  $x$ . The rules imply that  $x \cdot y$  must be a scalar since

$$xy + yx = |x + y|^2 - |x|^2 - |y|^2.$$

Geometric algebra allows us to speak of inverses of vectors:  $x^{-1} = x/|x|^2$ .  $x$  is invertible (i.e. possesses an inverse) if its magnitude is nonzero. Geometric product of an arbitrary number of invertible vectors is also invertible. The possibility of inverting all nonzero-magnitude vectors is perhaps the most important difference between geometric and convolution algebras.

Geometric products of *different* basis vectors

$$b_{k_1 \dots k_j} = b_{k_1} \dots b_{k_j},$$

$k_1 < \dots < k_j$ , are called *basis blades* (or just *blades*). In  $n$ -dimensional Euclidean space there are  $2^n$  different blades. This can be seen as follows. Let  $\{x_1, \dots, x_n\}$  be a sequence of bits. Blades in an  $n$ -dimensional space can be written as

$$c_{x_1 \dots x_n} = b_1^{x_1} \dots b_n^{x_n}$$

where  $b_k^0 = \mathbf{1}$ , which shows that blades are in a one-to-one relation with  $n$ -bit numbers. A general multivector is a linear combination of blades,

$$\psi = \sum_{x_1 \dots x_n=0}^1 \psi_{x_1 \dots x_n} c_{x_1 \dots x_n}, \quad (13)$$

with real or complex coefficients  $\psi_{x_1 \dots x_n}$ . Clifford algebra implies that

$$c_{x_1 \dots x_n} c_{y_1 \dots y_n} = (-1)^{\sum_{k < l} y_k x_l} c_{(x_1 \dots x_n) \oplus (y_1 \dots y_n)}, \quad (14)$$

where  $\oplus$  is given by (7). Multiplication of two basis blades is thus, up to a sign, in a one-to-one relation with exclusive alternative of two binary  $n$ -tuples. Accordingly, (14) is a projective representation of the group of binary  $n$ -tuples with addition modulo 2.

GA HRR is based on binding defined by geometric product (14) of blades while superposition is just addition of blades (13). The discrete  $GA_d$  is a version of GA HRR obtained if  $\psi_{x_1 \dots x_n}$  in (13) equal  $\pm 1$ . The first recognition tests of  $GA_d$ , as compared to HRR and BSC, were described in [16]. In the present paper we go further and compare HRR and BSC with  $GA_c$ , a version of GA HRR employing “projected products” [5] and arbitrary real  $\psi_{x_1 \dots x_n}$ .

Throughout this paper we shall use the following notation: “\*” denotes binding roles and fillers by means of the geometric

product and “+” denotes the superposition of sentence chunks, e.g.

$$“Fido bit Pat” = bite_{agt} * Fido + bite_{obj} * Pat. \quad (15)$$

Additionally, “⊗” will denote binding performed by circular convolution used in the HRR model and  $a^*$  denotes the involution of a HRR vector  $a$ . A “+” in the superscript of  $x^+$  denotes the operation of reversing a blade or a multivector  $x$ :  $(b_{k_1 \dots k_j})^+ = b_{k_j} \dots b_{k_1}$ . Asking a question will be denoted with “‡”, as in

$$\begin{aligned} “Who bit Pat?” \\ &= (bite_{agt} * Fido + bite_{obj} * Pat) ‡ bite_{agt} \quad (16) \\ &\approx Fido. \end{aligned}$$

The *size* of a (multi)vector means the number of memory cells it occupies in computer’s memory, while the *magnitude* of a (multi)vector  $V = \{v_1, \dots, v_n\}$  is its Euclidean norm  $\sqrt{\sum_{i=1}^n v_i^2}$ .

For our purposes it is important that geometric calculus allows us to define in a very systematic fashion a hierarchy of associative, non-commutative, and invertible operations that can be performed on  $2^n$ -tuples. The resulting superpositions are less noisy than the ones based on convolutions, say. Geometric product preserves dimensionality at the level  $2^n$ -dimensional *multivectors*, where  $n$  is the number of bits indexing basis vectors. Moreover, all nonzero vectors are invertible with respect to geometric product, a property absent for convolutions and important for unbinding and recognition. A detailed analysis of links between GA HRR, HRR and BSC can be found in [5].

### III. THE GA<sub>C</sub> MODEL

The procedure we employ was suggested in [5]. The space of  $2^n$ -tuples is split into subspaces corresponding to scalars (0-vectors), vectors (1-vectors), bivectors (2-vectors), and so on. At the bottom of the hierarchy lay vectors  $V \in \mathbb{R}^n$ , having rank 1 and being denoted as  $\overset{1}{V}$ . An object of rank 2 is created by multiplying two elements of rank 1 with the help of the geometric product. Let  $\overset{1}{V} = \{\alpha_1, \alpha_2, \alpha_3\}$  and  $\overset{1}{W} = \{\beta_1, \beta_2, \beta_3\}$  be vectors in  $\mathbb{R}^3$ . A multivector  $\overset{2}{X}$  of rank 2 in  $\mathbb{R}^3$  comprises the following elements (cf. [15])

$$\overset{2}{X} = \overset{1}{V} \overset{1}{W} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} = \begin{bmatrix} \alpha_1 \beta_1 + \alpha_2 \beta_2 + \alpha_3 \beta_3 \\ \alpha_1 \beta_2 - \alpha_2 \beta_1 \\ \alpha_1 \beta_3 - \alpha_3 \beta_1 \\ \alpha_2 \beta_3 - \alpha_3 \beta_2 \end{bmatrix}, \quad (17)$$

the first entry in the array on the right being a scalar and the remaining three entries being 2-blades. For arbitrary vectors in  $\mathbb{R}^n$  we would have obtained one scalar (or, more conveniently:  $\binom{n}{0}$  scalars) and  $\binom{n}{2}$  2-blades.

Let  $\overset{2}{X} = \{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$  and  $\overset{1}{V} = \{\alpha_1, \alpha_2, \alpha_3\}$  be two multivectors in  $\mathbb{R}^3$ . A multivector  $\overset{3}{Z}$  of rank 3 in  $\mathbb{R}^3$  may

be created in two ways: as a result of multiplying either  $\overset{1}{V}$  by  $\overset{2}{X}$  or  $\overset{2}{X}$  by  $\overset{1}{V}$ . Let us concentrate on the first case

$$\overset{3}{Z} = \overset{1}{V} \overset{2}{X} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} \begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \\ \gamma_4 \end{bmatrix} = \begin{bmatrix} \alpha_1 \gamma_1 - \alpha_2 \gamma_2 - \alpha_3 \gamma_3 \\ \alpha_1 \gamma_2 + \alpha_2 \gamma_1 - \alpha_3 \gamma_4 \\ \alpha_1 \gamma_3 + \alpha_2 \gamma_4 + \alpha_3 \gamma_1 \\ \alpha_1 \gamma_4 - \alpha_2 \gamma_3 + \alpha_3 \gamma_2 \end{bmatrix}. \quad (18)$$

Here, the first three entries in the resulting matrix are 1-blades, while the last entry is a 3-blade. For arbitrary multivectors of rank 1 and 2 in  $\mathbb{R}^n$  we would have obtained  $\binom{n}{1}$  vectors

and  $\binom{n}{3}$  trivectors. We cannot generate multivectors of rank higher than 3 in  $\mathbb{R}^3$ , but it is easy to check that in spaces  $\mathbb{R}^{n>3}$  a multivector of rank 4 would have  $\binom{n}{0}$  scalars,  $\binom{n}{2}$

bivectors and  $\binom{n}{4}$  4-blades. The number of  $k$ -blades in a multivector of rank  $r$  is described by Table I. It becomes clear that a multivector of rank  $r$  over  $\mathbb{R}^n$  is actually a vector over a  $\sum_{i=0}^{\lfloor \frac{r}{2} \rfloor} \binom{n}{2i+r \bmod 2}$ -dimensional space.

As an example let us consider the following roles and fillers being normalized vectors drawn randomly from  $\mathbb{R}^n$  with Gaussian distribution  $N(0, \frac{1}{n})$

$$\begin{aligned} Pat &= \{a_1, \dots, a_n\}, & name &= \{x_1, \dots, x_n\}, \\ male &= \{b_1, \dots, b_n\}, & sex &= \{y_1, \dots, y_n\}, \\ 66 &= \{c_1, \dots, c_n\}, & age &= \{z_1, \dots, z_n\}. \end{aligned} \quad (19)$$

*PSmith*, who is a 66 year old male named Pat, is created by first multiplying roles and fillers with the help of the geometric product

$$\begin{aligned} PSmith &= name * Pat + sex * male + age * 66 \\ &= name \cdot Pat + name \wedge Pat + sex \cdot male + \\ &\quad sex \wedge male + age \cdot 66 + age \wedge 66 \end{aligned} \quad (20)$$

$$\begin{aligned} &= \begin{bmatrix} \sum_{i=1}^n (a_i x_i + b_i y_i + c_i z_i) \\ a_1 x_2 - a_2 x_1 + b_1 y_2 - b_2 y_1 + c_1 z_2 - c_2 z_1 \\ a_1 x_3 - a_3 x_1 + b_1 y_3 - b_3 y_1 + c_1 z_3 - c_3 z_1 \\ \vdots \\ a_{n-1} x_n - a_n x_{n-1} + b_{n-2} y_n - b_n y_{n-1} + c_{n-1} z_n - c_n z_{n-1} \end{bmatrix} \\ &= [d_0, d_{12}, d_{13}, \dots, d_{(n-1)n}]^T \\ &= d_0 + d_{12} e_{12} + d_{13} e_{13} + \dots + d_{(n-1)n} e_{(n-1)n}, \end{aligned} \quad (21)$$

where  $e_1, \dots, e_n$  are orthonormal basis blades. In order to be decoded as much correctly as possible, *PSmith* should have the same magnitude as vectors representing atomic objects, therefore it needs to be normalized. Finally, *PSmith* takes the form of

$$PSmith = [\hat{d}_0, \hat{d}_{12}, \hat{d}_{13}, \dots, \hat{d}_{(n-1)n}]^T, \quad (22)$$

where  $\hat{d}_i = \frac{d_i}{\sqrt{\sum_{j=0,12}^{(n-1)n} d_j^2}}$ .

TABLE I  
NUMBERS OF  $k$ -BLADES IN MULTIVECTORS OF VARIOUS RANKS IN  $\mathbb{R}^n$

rank	scalars	vectors	bivectors	trivectors	4-blades	...	data size
1	0	$\binom{n}{1}$	0	0	0	...	$o\left(\binom{n}{1}\right)$
2	$\binom{n}{0}$	0	$\binom{n}{2}$	0	0	...	$o\left(\binom{n}{0} + \binom{n}{2}\right)$
3	0	$\binom{n}{1}$	0	$\binom{n}{3}$	0	...	$o\left(\binom{n}{1} + \binom{n}{3}\right)$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$	$\vdots$
$2r$	$\binom{n}{0}$	0	$\binom{n}{2}$	0	$\binom{n}{4}$	...	$o\left(\sum_{i=0}^r \binom{n}{2i}\right)$
$2r + 1$	0	$\binom{n}{1}$	0	$\binom{n}{3}$	0	...	$o\left(\sum_{i=0}^r \binom{n}{2i+1}\right)$

$PSmith$  is now a multivector of rank 2. The decoding operation

$$\begin{aligned} & name^+PSmith \\ &= name^+(name \cdot Pat + name \wedge Pat + sex \cdot male \\ & \quad + sex \wedge male + age \cdot 66 + age \wedge 66) \end{aligned} \quad (23)$$

will produce a multivector of rank 3 consisting of vectors and trivectors. However, the original  $Pat$  did not contain any trivector components—they all belong to the noise part and the only interesting blades in  $name^+PSmith$  are vectors. The expected answer is a vector, therefore there is no point in calculating the whole multivector  $name^+PSmith$  and only then comparing it with items stored in the clean-up memory. To be efficient, one should generate only the vector-part while computing  $name^+PSmith$  and skip the noisy trivectors.

Let  $\langle \cdot \rangle_k$  denote the projection of a multivector on  $k$ -blades. To decode  $PSmith$ 's  $name$  we need to compute

$$\begin{aligned} & \langle name^+PSmith \rangle_1 \\ &= name^+namePat + \langle name^+(name \wedge Pat \\ & \quad + sex \cdot male + sex \wedge male + age \cdot 66 + age \wedge 66) \rangle_1 \\ &= Pat + noise = Pat'. \end{aligned} \quad (24)$$

The resulting  $Pat'$  will still be noisy, but to a lesser degree than it would have been if the trivectors were present.

Formally, we are using a map  $*_{1,2}^1$  that transforms a multivector of rank 1 (i.e. an  $n$ -tuple) and a multivector of rank 2 (i.e. a  $(1 + \frac{(n-1)n}{2})$ -tuple) into a multivector of rank 1 without computing the unnecessary blades. Let  $X$  be a multivector of rank 2

$$X = \langle X \rangle_0 + \langle X \rangle_2 = x_0 + \sum_{l < m} x_{lm} e_l e_m, \quad (25)$$

where  $x_{lm} = -x_{ml}$ . If  $A = (A_1, \dots, A_n)$  is a decoding vector (actually, an inverse of a role vector), then

$$\begin{aligned} A *_{1,2}^1 X &= x_0 A + \sum_{l,m} A_l x_{lm} e_m \\ &= \sum_k (x A_k + \sum_l A_l x_{lk}) e_k \\ &= \sum_k Y_k e_k = Y, \end{aligned} \quad (26)$$

with  $Y = (Y_1, \dots, Y_n)$  being an  $n$ -tuple, i.e. a multivector of rank 1. More explicitly,

$$Y_k = (A *_{1,2}^1 X)_k = x_0 A_k + \sum_{l=1}^{k-1} A_l x_{lk} - \sum_{l=k+1}^n A_l x_{kl}. \quad (27)$$

The map  $*_{1,2}^1$  is an example of a *projected product*, introduced in [5], reconstructing the vector part of  $AX$  without computing the unnecessary parts. The projected product is basis independent, as opposed to circular convolutions. In general,  $*_{l,k}^m$  transforms the geometric product of two multivectors  $A$  and  $B$  into a multivector  $C$ .

We now need to compare  $Pat'$  with other items stored in the clean-up memory using the dot product, and since  $Pat'$  is a vector, we need to compare only the vector part. That means, if the clean-up memory contained a multivector  $M$  of an odd rank, we would also need to compute  $Pat' \cdot \langle M \rangle_1$  while searching for the right answer.

This method of decoding suggests that items stored in the clean-up memory should hold information about their ranks, which is dangerously close to employing fixed data slots present in localist architectures. However, a rank of a clean-up memory item can be “guessed” from its size. In a distributed model we also should not “know” for sure how many parts the projected product should reject, but it can certainly reject parts spanned by blades of highest grades.

Before providing formulas for encoding and decoding a complex statement we need to introduce additional notation for the projected product and the projection. We have already introduced the projected product  $*_{l,k}^m$  transforming the geometric product of two multivectors of ranks  $l$  and  $k$  into a multivector of rank  $m$ . This will not always be the case for complex statements, since we can produce a multivector that will not be of any given rank. Let  $*_{l,\{\alpha_1, \alpha_2, \dots, \alpha_k\}}^m$  denote the projected product transforming the geometric product of a multivector  $A$  and a multivector  $B$  containing  $\alpha_1$ -blades,  $\alpha_2$ -blades, ... and  $\alpha_k$ -blades into a multivector  $C$ . In this way, the projected product  $*_{1,2}^1$  may be written down as  $*_{1,\{0,2\}}^1$ . By analogy, let  $\langle \cdot \rangle_{\{\alpha_1, \alpha_2, \dots, \alpha_k\}}$  denote the projection of a multivector on components spanned by  $\alpha_1$ -blades,  $\alpha_2$ -blades, ... and  $\alpha_m$ -blades.

Let  $\Psi$  denote the normalized multivector encoding the sentence “*Fido bit PSmith*”, i.e.

$$\Psi = \underbrace{\text{bite}_{agt} * \text{Fido}}_{\text{rank 2}} + \underbrace{\text{bite}_{obj} * \text{PSmith}}_{\text{rank 3}}. \quad (28)$$

Multivector  $\Psi$  will contain scalars, vectors, bivectors and trivectors and can be written down as the following vector of dimension  $\sum_{i=0}^3 \binom{n}{i}$

$$\Psi = \underbrace{\alpha}_{\text{a scalar}} + \underbrace{\sum_{i=1}^n \beta_i e_i}_{\text{vectors}} + \underbrace{\sum_{1 \leq i < j} \gamma_{ij} e_{ij}}_{\text{bivectors}} + \underbrace{\sum_{1 \leq i < j < k} \delta_{ijk} e_{ijk}}_{\text{trivectors}} \quad (29)$$

#### IV. TRAJECTORY ASSOCIACION

In the HRR model vectors are normalized and therefore can be regarded as radii of a sphere of radius 1. If we attach a sequence of items, say  $A, B, C, D, E$  to arrowheads of five of those vectors, we obtain a certain *trajectory* on the surface of a sphere, that is associated with sequence  $ABCDE$ . This is a geometric analogue to the *method of loci* which instructs to remember a list of items by associating each term with a distinctive location along a familiar path. Let  $k$  be a randomly chosen HRR vector and let

$$k^i = k \otimes k^{i-1} = k^{i-1} \otimes k, \quad i > 1 \quad (30)$$

be its  $i$ th power, with  $k^1 = k$ . The sequence  $S_{ABCDE}$  is then stored as

$$S_{ABCDE} = A \otimes k + B \otimes k^2 + C \otimes k^3 + D \otimes k^4 + E \otimes k^5. \quad (31)$$

Of course, each power of  $k$  needs to be normalized before being bound with a sequence item. Otherwise, every subsequent power of  $k$  would be larger or smaller than its predecessor. As a result, every subsequent item stored in a sequence would have a bigger or a smaller share in vector  $S_{ABCDE}$ . Obviously, this method cannot be applied to the discrete GA model (described in [16]) or to BSC, since it is impossible to obtain more than two distinct powers of a vector with the use of XOR as a means of binding.

This technique has a few obvious advantages present in HRR but not in GA<sub>C</sub> had we wished to use ordinary vectors as first powers—different powers of a vector  $k$  would then be multivectors of different ranks. While  $k^i$  and  $k^{i \pm 1}$  are very similar in HRR, in GA<sub>C</sub> they would not even share the same blades. Further, the similarity of  $k^i$  and  $k^{i+m}$  in HRR is the same as the similarity of  $k^j$  and  $k^{j+m}$ , whereas in GA<sub>C</sub> that similarity would depend on the parity of  $i$  and  $j$ . In the light of these shortcomings, we need to use another structure acting as a first power in order to make trajectories work in GA<sub>C</sub>. Let  $t$  be a random normalized full multivector over  $\mathbb{R}^n$  and let us define powers of  $t$  in the following way

$$t^1 = t, \quad t^i = (t^{i-1})t \quad \text{for } i > 1. \quad (32)$$

We will store vectors  $a_1 \dots a_l$  in a sequence  $S_{a_1 \dots a_l}$  using powers of the multivector  $t$

$$S_{a_1 \dots a_l} = a_1 t + a_2 t^2 + \dots + a_l t^l. \quad (33)$$

To answer a question “*What is the second item in a sequence?*” in GA<sub>C</sub> we need to use the projected product

$$\langle S_{a_1 \dots a_l} (t^2)^+ \rangle_1 \approx a_2, \quad (34)$$

and to find out the place of item  $a_i$  we need to compute

$$(a_i)^+ S_{a_1 \dots a_l} \approx t^i. \quad (35)$$

Some may argue that such encoding puts a demand on items in the clean-up memory to hold information if they are roles or fillers, which is dangerously close to employing fixed data slots present in localist architectures. Actually, elements of a sequence can be recognized by their size, relatively shorter than the size of multivector  $t$  and its powers.

#### V. ITEM ALIGNMENT

We present an experiment using trajectory association and we comment on test results for HRR and GA<sub>C</sub> models. We tested whether the HRR and GA<sub>C</sub> models were capable of performing the following task:

*Given only a set of letters  $A, B, C, D, E$  and an encoded sequence  $S_{????}$  comprised of those five letters find out the position of each letter in that sequence.*

We assumed that no direct access to  $t$  or its powers is given—they do belong to the clean-up memory, but cannot be retrieved “by name”. One may think of this problem as a “black box” that inputs randomly chosen letter vectors and in return outputs a (multi)vector representing always the same sequence, irrespectively of the dimension of data. Inside, the black box generates (multi)vectors  $t, t^2, t^3, t^4, t^5$ . Their values are known to the observer but their names are not. Since we can distinguish letters from non-letters, the naive approach would be to try out all 120 alignments of letters  $A, B, C, D$  and  $E$  using all possible combinations of non-letters as the powers of  $t$ . Unfortunately, powers of  $t$  are different each time the black box produces a sequence. We will use an algorithm based on two assumptions:

- $t^x$ , if not recognized correctly, is more similar to highest powers of  $t$ ,
- letters lying closer to the end of the sequence are often offered as the incorrect answer to questions concerning letters, as in  $S \# t^n$ .

Assumption (a) can be easily justified: since lower powers of  $t$  are recognized correctly more often, higher powers of  $t$  come up more often as the incorrect answer to  $S \# A$ . Vector  $t^3$  is the correct answer to  $S_{xxAxx} \# A$ . However, if  $t^3$  is not recognized, the next most similar answer will be  $t^5$  because it contains three “copies” of  $t^3$ , indicated here by brackets

$$\{ t * ( t * [ t ] * t ) * t \}. \quad (36)$$

The second most similar item will be  $t^4$  because it contains two “copies” of  $t$ , and so on. The item least similar to  $t^3$  will

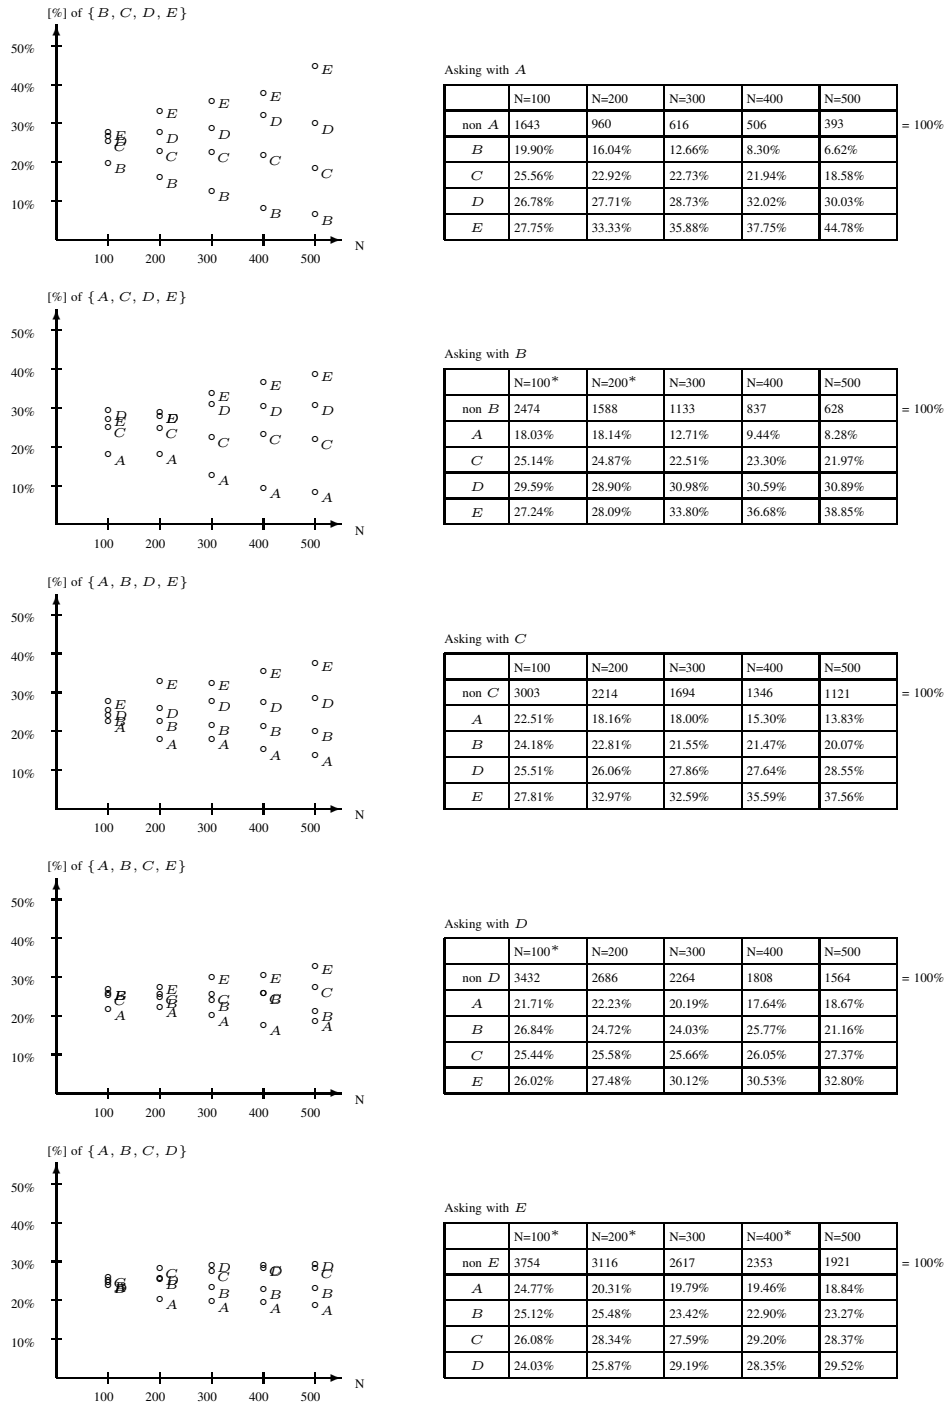

Fig. 1. Finding letter alignment in a sequence  $S_{ABCDE}$  in HRR, 10000 trials.

be  $t$ . Assumption (b) comes exactly from the same fact—a letter multiplied by one of the highest powers of  $t$  will be stored more “prominently” than other letters.

The clean-up memory  $\mathcal{C}$  for this experiment consists of all five letters and the five powers of  $t$ . We will also use an auxiliary clean-up memory  $\mathcal{L}$  containing letters only.

Since the normalization using the square root of the number of chunks proved very noisy in initial tests on statements containing powers of the trajectory vector, we decided to improve the HRR model. The HRR vectors in our tests were normalized by dividing them with their magnitude.

 *B \prec D \\
 *C \prec E \\
 *D \prec B \\
 *E \prec C
 \end{array}
 \Rightarrow
 \begin{array}{l}
 A \prec E
 \end{array}$$

The algorithm for finding out the position of each letter begins with asking a question

$$\begin{aligned}
 S_{????} \# L_x &= \left\{ \begin{array}{l} S_{????} \otimes (L_x)^* \quad \text{in HRR} \\ (L_x)^+ S_{????} \quad \text{in GA}_c \end{array} \right\} \\
 &= (t^x)' \approx t^x \quad (37)
 \end{aligned}$$

for each letter  $L_x \in \mathcal{L}$ . Next, we need to find the item in the clean-up memory  $\mathcal{C} \setminus \mathcal{L}$  that is most similar to  $(t^x)'$ . Let us denote this item by  $z$ . With high probability,  $z$  is the power of  $t$  associated with the position of the letter  $L_x$  in the sequence  $S_{????}$ , although, if recognized incorrectly,  $z$  will most likely point to some other  $t^{y>x}$ . Now let us ask a second question

$$\begin{aligned}
 S_{????} \# z &= \left\{ \begin{array}{l} S_{????} \otimes z^* \quad \text{in HRR} \\ \langle S_{????} z^+ \rangle_1 \quad \text{in GA}_c \end{array} \right\} \\
 &= L' \approx L_x. \quad (38)
 \end{aligned}$$

We use the projected product in GA<sub>C</sub> because we are looking for a letter vector placed on the position indicated by  $z$ . In HRR the resulting  $L'$  should be compared with letters only. In most cases  $L'$  will point to the correct letter. However, in a small fraction of test results,  $L'$  will point to letters surrounding  $L_x$ , because  $z$  has been mistakenly decoded as  $t^y$  for some  $y \neq x$ . Also, letters preceding  $L_x$  should come up less often than letters proceeding  $L_x$ .

Figure 1 presents test results for HRR. The data in Figure 1 should be interpreted as follows: the first row of each table next to a graph contains the vector lengths of the data used in 5 consecutive experiments (10000 trials each). The second row contains the number of faulty answers within those 10000

trials. The next 4 rows present the percentage of occurrence of a "faulty" letter within all faulty answers presented in the second row.

Faulty alignments (i.e. those, for which the percentages corresponding to letters do not align increasingly within a single column) have been marked with a "\*" in the table headings. We used  $S_{ABCDE}$  as the mysterious encoded sequence  $S_{????}$ . In each case we crossed out the most frequently occurring letter and we concentrated on the frequency of the remaining letters. In HRR, for sufficiently large vector sizes, the frequencies  $f_L$  of all letters  $L \in \mathcal{L}$  aligned correctly

$$f_B < f_C < f_D < f_E \quad \text{asking with A,} \quad (39)$$

$$f_A < f_C < f_D < f_E \quad \text{asking with B,} \quad (40)$$

$$f_A < f_B < f_D < f_E \quad \text{asking with C,} \quad (41)$$

$$f_A < f_B < f_C < f_E \quad \text{asking with D,} \quad (42)$$

$$f_A < f_B < f_C < f_D \quad \text{asking with E.} \quad (43)$$

It was straightforward that these inequalities lead to  $f_A < f_B < f_C < f_D < f_E$  and correctly identify the encoded sequence as  $S_{ABCDE}$ . Test results are less accurate when we asked about letters lying closer to the end of a sequence, therefore the size of the vector should be adequately long. Moreover, the longer the vector, the larger the difference between the frequencies.

GA<sub>C</sub> was expected to perform worse in this experiment, because we can construct powers of a multivector  $t^{i-1}$  by

multiplying it with  $t$  from one side only. Indeed, at the first glance Table II shows that letter frequencies do not align correctly at all. We therefore needed to slightly modify the algorithm for finding letter alignment in  $GA_c$ : we concentrated on two largest frequencies in each series of asking questions—the largest frequency represents the letter  $L$  that was used to ask the question and the second largest frequency indicates letter  $\hat{L}$  that most likely proceeds letter  $L$ .

Table II presents the frequencies of letters recognized as the most probable answer to Equation (38), the second largest frequency in each row is printed in bold. Partial letter alignments have been placed next to each table and contradictory alignments have been preceded with a “\*”. When being asked with the last letter of the sequence, HRR provided less accurate answers and so did  $GA_c$  by yielding more contradictions than in case of previous letters. It is impossible to avoid contradictory alignments in  $GA_c$  because we do not know which letter is the last one and the algorithm for recovering letter alignment in  $GA_c$  instructs us to write down the partial alignment with that letter being preceded by some other letter. The remaining alignments point correctly to the sequence  $S_{ABCDE}$

$$\left. \begin{array}{l} A \prec B \\ C \prec D \prec E \\ A \prec B \prec C \prec D \\ A \prec C \\ B \prec D \prec E \\ A \prec E \end{array} \right\} \Rightarrow A \prec B \prec C \prec D \prec E. \quad (44)$$

## VI. CONCLUSION

We have shown that multivector powers in  $GAC$  have properties similar to convolutive powers of HRR vectors

- (multi)vectors  $t^{i-r}$  and  $t^i$  are similar in much the same way as  $t^i$  and  $t^{i+r}$ ,
- items placed near the beginning of a sequence are remembered more prominently and thus, are recognized correctly more often,
- items placed near the end of a sequence are remembered less precisely and often come up as the most probable answer when the correct item is not recognized.

We have used the last two properties to find the alignment of sequence items without the explicit knowledge of (multi)vector powers. While HRR retrieved the original alignment without greater problems,  $GA_c$  left us with an easily soluble logical puzzle providing fragmentary alignments.

These properties can be used to build holographic lexicons, dictionaries and other structures that require storing order information and word meaning in the same pattern.

# A comparison of geometric analogues of Holographic Reduced Representations, original Holographic Reduced Representations and Binary Spatter Codes

Agnieszka Patyk-Łońska, Marek Czachor, and Diederik Aerts

**Abstract**—Geometric Analogues of Holographic Reduced Representations (GA HRR) employ role-filler binding based on geometric products. Atomic objects are real-valued vectors in  $n$ -dimensional Euclidean space and complex statements belong to a hierarchy of multivectors. The paper reports a battery of tests aimed at comparison of GA HRR with Holographic Reduced Representation (HRR) and Binary Spatter Codes (BSC). Firstly, we perform a test of GA HRR which is analogous to the one proposed by Plate in [13]. Plate’s simulation involved several thousand 512-dimensional vectors stored in clean-up memory. The purpose was to study efficiency of HRR but also to provide a counterexample to claims that role-filler representations do not permit one component of a relation to be retrieved given the others. We repeat Plate’s test on a continuous version of GA HRR –  $GA_c$  (as opposed to its discrete version described in [12]) and compare the results with the original HRR and BSC. The object of the test is to construct statements concerning multiplication and addition. For example, “ $2 \cdot 3 = 6$ ” is constructed as  $times_{2,3} = times + operand * (num_2 + num_3) + result * num_6$ . To look up this vector one then constructs a similar statement with one of the components missing and checks whether it points correctly to  $times_{2,3}$ . We concentrate on comparison of recognition percentage for the three models for comparable data size, rather than on the time taken to achieve high percentage. Results show that the best models for storing and recognizing multiple similar statements are  $GA_c$  and Binary Spatter Codes with recognition percentage highly above 90.

**Index Terms**—distributed representations, geometric algebra, HRR, BSC, scaling.

## I. INTRODUCTION

**H**OLOGRAPHIC Reduced Representations (HRR) and Binary Spatter Codes (BSC) are distributed representations of cognitive structures where binding of role-filler codevectors maintains predetermined data size. In HRR [13] binding is performed by means of circular convolution

$$(x \otimes y)_j = \sum_{k=0}^{n-1} x_k y_{j-k \bmod n}. \quad (1)$$

of real  $n$ -tuples or, in ‘frequency domain’, by componentwise multiplication of (complex)  $n$ -tuples,

$$(x_1, \dots, x_n) \otimes (y_1, \dots, y_n) = (x_1 y_1, \dots, x_n y_n). \quad (2)$$

Bound  $n$ -tuples are superposed by addition, and unbinding is performed by an approximate inverse. A dual formalism, where real data are bound by componentwise multiplication,

was discussed by Gayler [6]. In BSC [8], [9] one works with binary  $n$ -tuples, bound by componentwise addition mod 2,

$$\begin{aligned} (x_1, \dots, x_n) \oplus (y_1, \dots, y_n) &= (x_1 \oplus y_1, \dots, x_n \oplus y_n), \\ x_j \oplus y_j &= x_j + y_j \bmod 2, \end{aligned} \quad (3)$$

and superposed by pointwise majority-rule addition; unbinding is performed by the same operation as binding.

One often reads that the above models represent data by *vectors*, which is not exactly true. Given two vectors one does not know how to perform, say, their convolution or componentwise multiplication since the result depends on basis that defines the components. Basis must be fixed in advance since otherwise all the above operations become ambiguous. It follows that neither of the above reduced representations can be given a true and meaningful geometric interpretation. Geometric Analogues of Holographic Reduced Representations (GA HRR) [2] can be constructed if one defines binding by the geometric product, a notion introduced in 19th century works of Grassmann [7] and Clifford [5].

The fact that GA HRR is intrinsically geometric may be important for various conceptual reasons — for example, the rules of geometric algebra may be regarded as a mathematical formalization of the process of *understanding* geometry. The use of geometric algebra in distributed representations has been inspired by a well-known fact, that most people think in pictures, i.e. two- and three-dimensional shapes, not by using sequences of ones and zeroes.

In order to grasp the main ideas behind GA HRR let us consider an orthonormal basis  $b_1, \dots, b_n$  in some  $n$ -dimensional Euclidean space. Now consider two vectors  $x = \sum_{k=1}^n x_k b_k$  and  $y = \sum_{k=1}^n y_k b_k$ . The *scalar*

$$x \cdot y = y \cdot x \quad (4)$$

is known as the *inner product*. The *bivector*

$$x \wedge y = -y \wedge x \quad (5)$$

is the *outer product* and may be regarded as an oriented plane segment (alternative interpretations are also possible, cf. [4]).  $\mathbf{1}$  is the identity of the algebra. The geometric product of  $x$

and  $y$  then reads

$$xy = \underbrace{\sum_{k=1}^n x_k y_k}_{x \cdot y} \mathbf{1} + \underbrace{\sum_{k < l} (x_k y_l - y_k x_l)}_{x \wedge y} b_k b_l. \quad (6)$$

Grassmann and Clifford introduced geometric product by means of the basis-independent formula involving the *multivector*

$$xy = x \cdot y + x \wedge y \quad (7)$$

which implies the so-called Clifford algebra

$$b_k b_l + b_l b_k = 2\delta_{kl} \mathbf{1}. \quad (8)$$

when restricted to an orthonormal basis. Inner and outer product can be defined directly from  $xy$ :

$$x \cdot y = \frac{1}{2}(xy + yx), \quad x \wedge y = \frac{1}{2}(xy - yx).$$

The most ingenious element of (7) is that it adds two apparently different objects, a scalar and a plane element, an operation analogous to addition of real and imaginary parts of a complex number. Geometric product for vectors  $x, y, z$  can be axiomatically defined by the following rules:

$$\begin{aligned} (xy)z &= x(yz), \\ x(y+z) &= xy + xz, \\ (x+y)z &= xz + yz, \\ xx &= x^2 = |x|^2, \end{aligned}$$

where  $|x|$  is a positive scalar called the magnitude of  $x$ . The rules imply that  $x \cdot y$  must be a scalar since

$$xy + yx = |x + y|^2 - |x|^2 - |y|^2.$$

Geometric algebra allows us to speak of inverses of vectors:  $x^{-1} = x/|x|^2$ .  $x$  is invertible (i.e. possesses an inverse) if its magnitude is nonzero. Geometric product of an arbitrary number of invertible vectors is also invertible. The possibility of inverting all nonzero-magnitude vectors is perhaps the most important difference between geometric and convolution algebras.

Geometric products of *different* basis vectors

$$b_{k_1 \dots k_j} = b_{k_1} \dots b_{k_j},$$

$k_1 < \dots < k_j$ , are called basis blades (or just blades). In  $n$ -dimensional Euclidean space there are  $2^n$  different blades. This can be seen as follows. Let  $\{x_1, \dots, x_n\}$  be a sequence of bits. Blades in an  $n$ -dimensional space can be written as

$$c_{x_1 \dots x_n} = b_1^{x_1} \dots b_n^{x_n}$$

where  $b_k^0 = \mathbf{1}$ , which shows that blades are in a one-to-one relation with  $n$ -bit numbers. A general multivector is a linear combination of blades,

$$\psi = \sum_{x_1 \dots x_n=0}^1 \psi_{x_1 \dots x_n} c_{x_1 \dots x_n}, \quad (9)$$

with real or complex coefficients  $\psi_{x_1 \dots x_n}$ . Clifford algebra implies that

$$c_{x_1 \dots x_n} c_{y_1 \dots y_n} = (-1)^{\sum_{k < l} y_k x_l} c_{(x_1 \dots x_n) \oplus (y_1 \dots y_n)}, \quad (10)$$

where  $\oplus$  is given by (3). Multiplication of two basis blades is thus, up to a sign, in a one-to-one relation with exclusive alternative of two binary  $n$ -tuples. Accordingly, (10) is a projective representation of the group of binary  $n$ -tuples with addition modulo 2.

GA HRR is based on binding defined by geometric product (10) of blades while superposition is just addition of blades (9). The discrete  $GA_d$  is a version of GA HRR obtained if  $\psi_{x_1 \dots x_n}$  in (9) equal  $\pm 1$ . The first recognition tests of  $GA_d$ , as compared to HRR and BSC, were described in [12]. In the present paper we go further and compare HRR and BSC with  $GA_c$ , a version of GA HRR employing “projected products” [2] and arbitrary real  $\psi_{x_1 \dots x_n}$ . We also repeat Plate’s scaling test ([13], Appendix I) and compare test results for  $GA_c$ , HRR and BSC models.

Throughout this paper we shall use the following notation: “\*” denotes binding roles and fillers by means of the geometric product and “+” denotes the superposition of sentence chunks, e.g.

$$“Fido bit Pat” = bite_{agt} * Fido + bite_{obj} * Pat. \quad (11)$$

Additionally, “ $\otimes$ ” will denote binding performed by circular convolution used in the HRR model and  $a^*$  denotes the involution of a HRR vector  $a$ . A “+” in the superscript of  $x^+$  denotes the operation of reversing a blade or a multivector  $x: (b_{k_1 \dots k_j})^+ = b_{k_j} \dots b_{k_1}$ . Asking a question will be denoted with “ $\sharp$ ”, as in

$$\begin{aligned} “Who bit Pat?” \\ &= (bite_{agt} * Fido + bite_{obj} * Pat) \sharp bite_{agt} \quad (12) \\ &\approx Fido. \end{aligned}$$

The *size* of a (multi)vector means the number of memory cells it occupies in computer’s memory, while the *magnitude* of a (multi)vector  $V = \{v_1, \dots, v_n\}$  is its Euclidean norm  $\sqrt{\sum_{i=1}^n v_i^2}$ .

For our purposes it is important that geometric calculus allows us to define in a very systematic fashion a hierarchy of associative, non-commutative, and invertible operations that can be performed on  $2^n$ -tuples. The resulting superpositions are less noisy than the ones based on convolutions, say. Such operations are in general unknown to a wider audience, which explains popularity of tensor and convolution algebras. Geometric product preserves dimensionality at the level  $2^n$ -dimensional *multivectors*, where  $n$  is the number of bits indexing basis vectors. Moreover, all nonzero vectors are invertible with respect to geometric product, a property absent for convolutions and important for unbinding and recognition. A detailed analysis of links between GA HRR, HRR and BSC can be found in [2]. In particular, it is shown that both GA HRR and BSC are based on two different representations (in

group theoretical sense) of the additive group of binary  $n$ -tuples with addition modulo 2. Actually, the latter observation was the starting point for studying geometric algebra forms of reduced representations [3].

## II. THE $GA_c$ MODEL

Multivector (9) associated with  $n$ -dimensional Euclidean space can be represented by the  $2^n$ -tuple  $(\psi_{0_1\dots 0_n}, \dots, \psi_{1_1\dots 1_n})$ . Geometric product of two such  $2^n$ -tuples is again a  $2^n$ -tuple. In this sense geometric product is analogous to bindings employed in HRR or BSC, but we can still proceed in several inequivalent ways. For example, since a product of two basis blades is again a basis blade multiplied by  $\pm 1$ , we can require that  $\psi_{x_1\dots x_n} = \pm 1$ . Such a discrete version of GA HRR was tested vs. HRR and BSC in [12], and will be denoted here by  $GA_d$  (discrete GA HRR).

The continuous  $GA_c$  model differs greatly from  $GA_d$ . First of all, we do not begin with a general  $2^n$ -dimensional multivector. Atomic objects are real-valued vectors in  $n$ -dimensional Euclidean space, in practice represented by  $n$ -tuples of components taken in some basis. A hierarchy of multivectors is reserved for complex statements, formed by binding and superposition of atomic objects. An  $n$ -dimensional vector, when seen from the multivector perspective, is a highly sparse  $2^n$ -tuple: Only  $n$  out of  $2^n$  components can be nonzero.

The procedure we employ was suggested in [2]. The space of  $2^n$ -tuples is split into subspaces corresponding to scalars (0-vectors), vectors (1-vectors), bivectors (2-vectors), and so on. At the bottom of the hierarchy lay vectors  $V \in \mathbb{R}^n$ , having rank 1 and being denoted as  $\overset{1}{V}$ . An object of rank 2 is created by multiplying two elements of rank 1 with the help of the geometric product. Let  $\overset{1}{V} = \{\alpha_1, \alpha_2, \alpha_3\}$  and  $\overset{1}{W} = \{\beta_1, \beta_2, \beta_3\}$  be vectors in  $\mathbb{R}^3$ . A multivector  $\overset{2}{X}$  of rank 2 in  $\mathbb{R}^3$  comprises the following elements (cf. [10])

$$\overset{2}{X} = \overset{1}{V} \overset{1}{W} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} = \begin{bmatrix} \alpha_1\beta_1 + \alpha_2\beta_2 + \alpha_3\beta_3 \\ \alpha_1\beta_2 - \alpha_2\beta_1 \\ \alpha_1\beta_3 - \alpha_3\beta_1 \\ \alpha_2\beta_3 - \alpha_3\beta_2 \end{bmatrix}, \quad (13)$$

the first entry in the array on the right being a scalar and the remaining three entries being 2-blades. For arbitrary vectors in  $\mathbb{R}^n$  we would have obtained one scalar (or, more conveniently:  $\binom{n}{0}$  scalars) and  $\binom{n}{2}$  2-blades.

Let  $\overset{2}{X} = \{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$  and  $\overset{1}{V} = \{\alpha_1, \alpha_2, \alpha_3\}$  be two multivectors in  $\mathbb{R}^3$ . A multivector  $\overset{3}{Z}$  of rank 3 in  $\mathbb{R}^3$  may be created in two ways: as a result of multiplying either  $\overset{1}{V}$  by  $\overset{2}{X}$  or  $\overset{2}{X}$  by  $\overset{1}{V}$ . Let us concentrate on the first case

$$\overset{3}{Z} = \overset{1}{V} \overset{2}{X} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} \begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \\ \gamma_4 \end{bmatrix} = \begin{bmatrix} \alpha_1\gamma_1 - \alpha_2\gamma_2 - \alpha_3\gamma_3 \\ \alpha_1\gamma_2 + \alpha_2\gamma_1 - \alpha_3\gamma_4 \\ \alpha_1\gamma_3 + \alpha_2\gamma_4 + \alpha_3\gamma_1 \\ \alpha_1\gamma_4 - \alpha_2\gamma_3 + \alpha_3\gamma_2 \end{bmatrix}. \quad (14)$$

Here, the first three entries in the resulting matrix are 1-blades, while the last entry is a 3-blade. For arbitrary multivectors of

rank 1 and 2 in  $\mathbb{R}^n$  we would have obtained  $\binom{n}{1}$  vectors and  $\binom{n}{3}$  trivectors. We cannot generate multivectors of rank higher than 3 in  $\mathbb{R}^3$ , but it is easy to check that in spaces  $\mathbb{R}^{n>3}$  a multivector of rank 4 would have  $\binom{n}{0}$  scalars,  $\binom{n}{2}$  bivectors and  $\binom{n}{4}$  4-blades. The number of  $k$ -blades in a multivector of rank  $r$  is described by Table I. It becomes clear that a multivector of rank  $r$  over  $\mathbb{R}^n$  is actually a vector over a  $\sum_{i=0}^{\lfloor \frac{r}{2} \rfloor} \binom{n}{2i+r \bmod 2}$ -dimensional space.

As an example let us consider the following roles and fillers being normalized vectors drawn randomly from  $\mathbb{R}^n$  with Gaussian distribution  $N(0, \frac{1}{n})$

$$\begin{aligned} Pat &= \{a_1, \dots, a_n\}, & name &= \{x_1, \dots, x_n\}, \\ male &= \{b_1, \dots, b_n\}, & sex &= \{y_1, \dots, y_n\}, \\ 66 &= \{c_1, \dots, c_n\}, & age &= \{z_1, \dots, z_n\}. \end{aligned} \quad (15)$$

$PSmith$ , who is a 66 year old male named Pat, is created by first multiplying roles and fillers with the help of the geometric product

$$\begin{aligned} PSmith &= \\ &= name * Pat + sex * male + age * 66 \\ &= name \cdot Pat + name \wedge Pat + sex \cdot male + \\ &\quad sex \wedge male + age \cdot 66 + age \wedge 66 \end{aligned} \quad (16)$$

$$\begin{aligned} &= \begin{bmatrix} \sum_{i=1}^n (a_i x_i + b_i y_i + c_i z_i) \\ a_1 x_2 - a_2 x_1 + b_1 y_2 - b_2 y_1 + c_1 z_2 - c_2 z_1 \\ a_1 x_3 - a_3 x_1 + b_1 y_3 - b_3 y_1 + c_1 z_3 - c_3 z_1 \\ \vdots \\ a_{n-1} x_n - a_n x_{n-1} + b_{n-2} y_n - b_n y_{n-1} + c_{n-1} z_n - c_n z_{n-1} \end{bmatrix} \\ &= [d_0, d_{12}, d_{13}, \dots, d_{(n-1)n}]^T \\ &= d_0 + d_{12}e_{12} + d_{13}e_{13} + \dots + d_{(n-1)n}e_{(n-1)n}, \end{aligned} \quad (17)$$

where  $e_1, \dots, e_n$  are orthonormal basis blades. In order to be decoded as much correctly as possible,  $PSmith$  should have the same magnitude as vectors representing atomic objects, therefore it needs to be normalized. Finally,  $PSmith$  takes the form of

$$PSmith = [\hat{d}_0, \hat{d}_{12}, \hat{d}_{13}, \dots, \hat{d}_{(n-1)n}]^T, \quad (18)$$

where  $\hat{d}_i = \frac{d_i}{\sqrt{\sum_{j=0,12}^{(n-1)n} d_j^2}}$ .

$PSmith$  is now a multivector of rank 2. The decoding operation

$$\begin{aligned} name^+ PSmith &= \\ &= name^+ (name \cdot Pat + name \wedge Pat + sex \cdot male \\ &\quad + sex \wedge male + age \cdot 66 + age \wedge 66) \end{aligned} \quad (19)$$

will produce a multivector of rank 3 consisting of vectors and trivectors. However, the original  $Pat$  did not contain any trivector components — they all belong to the noise part and the only interesting blades in  $name^+ PSmith$  are vectors. The expected answer is a vector, therefore there is no point in

TABLE I  
NUMBERS OF  $k$ -BLADES IN MULTIVECTORS OF VARIOUS RANKS IN  $\mathbb{R}^n$

rank	scalars	vectors	bivectors	trivectors	4-blades	...	data size
1	0	$\binom{n}{1}$	0	0	0	...	$\mathcal{O}\left(\binom{n}{1}\right)$
2	$\binom{n}{0}$	0	$\binom{n}{2}$	0	0	...	$\mathcal{O}\left(\binom{n}{0} + \binom{n}{2}\right)$
3	0	$\binom{n}{1}$	0	$\binom{n}{3}$	0	...	$\mathcal{O}\left(\binom{n}{1} + \binom{n}{3}\right)$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$	$\vdots$
$2r$	$\binom{n}{0}$	0	$\binom{n}{2}$	0	$\binom{n}{4}$	...	$\mathcal{O}\left(\sum_{i=0}^r \binom{n}{2i}\right)$
$2r+1$	0	$\binom{n}{1}$	0	$\binom{n}{3}$	0	...	$\mathcal{O}\left(\sum_{i=0}^r \binom{n}{2i+1}\right)$

calculating the whole multivector  $name^+PSmith$  and only then comparing it with items stored in the clean-up memory. To be efficient, one should generate only the vector-part while computing  $name^+PSmith$  and skip the noisy trivectors.

Let  $\langle \cdot \rangle_k$  denote the projection of a multivector on  $k$ -blades. To decode  $PSmith$ 's name we need to compute

$$\begin{aligned} & \langle name^+PSmith \rangle_1 \\ &= name^+namePat + \langle name^+(name \wedge Pat \\ & \quad + sex \cdot male + sex \wedge male + age \cdot 66 + age \wedge 66) \rangle_1 \\ &= Pat + noise = Pat'. \end{aligned} \quad (20)$$

The resulting  $Pat'$  will still be noisy, but to a lesser degree than it would have been if the trivectors were present.

Formally, we are using a map  $*_{1,2}^1$  that transforms a multivector of rank 1 (i.e. an  $n$ -tuple) and a multivector of rank 2 (i.e. a  $(1 + \frac{(n-1)n}{2})$ -tuple) into a multivector of rank 1 without computing the unnecessary blades. Let  $X$  be a multivector of rank 2

$$X = \langle X \rangle_0 + \langle X \rangle_2 = x_0 + \sum_{l < m} x_{lm} e_l e_m, \quad (21)$$

where  $x_{lm} = -x_{ml}$ . If  $A = (A_1, \dots, A_n)$  is a decoding vector (actually, an inverse of a role vector), then

$$\begin{aligned} A *_{1,2}^1 X &= x_0 A + \sum_{l,m} A_l x_{lm} e_m \\ &= \sum_k (x A_k + \sum_l A_l x_{lk}) e_k \\ &= \sum_k Y_k e_k = Y, \end{aligned} \quad (22)$$

with  $Y = (Y_1, \dots, Y_n)$  being an  $n$ -tuple, i.e. a multivector of rank 1. More explicitly,

$$Y_k = (A *_{1,2}^1 X)_k = x_0 A_k + \sum_{l=1}^{k-1} A_l x_{lk} - \sum_{l=k+1}^n A_l x_{kl}. \quad (23)$$

The map  $*_{1,2}^1$  is an example of a *projected product*, introduced in [2], reconstructing the vector part of  $AX$  without computing the unnecessary parts. The projected product is basis independent, as opposed to circular convolutions. In general,  $*_{l,k}^m$  transforms the geometric product of two multivectors  $A$  and  $B$  into a multivector  $C$ .

We now need to compare  $Pat'$  with other items stored in the clean-up memory using the dot product, and since  $Pat'$  is a vector, we need to compare only the vector part. That means, if the clean-up memory contained a multivector  $M$  of an odd rank, we would also need to compute  $Pat' \cdot \langle M \rangle_1$  while searching for the right answer.

This method of decoding suggests that items stored in the clean-up memory should hold information about their ranks, which is dangerously close to employing fixed data slots present in localist architectures. However, a rank of a clean-up memory item can be "guessed" from its size. In a distributed model we also should not "know" for sure how many parts the projected product should reject, but it can certainly reject parts spanned by blades of highest grades. Unfortunately, since the geometric product is non-commutative, questions concerning roles and fillers need to be asked on different sides of a sentence, forcing atomic objects to hold information on whether they are roles or fillers and thus, forcing them to be partly hand-generated. We can either ask question always on the same side of a sentence and be satisfied with less precise answers or always ask about only the roles or only the fillers. It becomes clear, that recognition based on the hierarchy of multivectors and the projected product is best applicable to tasks in which questions need to be asked only on one side of the sentence or in which sentences have predetermined structure.

Before providing formulas for encoding and decoding a complex statement we need to introduce additional notation for the projected product and the projection. We have already introduced the projected product  $*_{l,k}^m$  transforming the geometric product of two multivectors of ranks  $l$  and  $k$  into a multivector of rank  $m$ . This will not always be the case for complex statements, since we can produce a multivector that will not be of any given rank. Let  $*_{l,\{\alpha_1, \alpha_2, \dots, \alpha_k\}}^m$  denote the projected product transforming the geometric product of a multivector  $A$  and a multivector  $B$  containing  $\alpha_1$ -blades,  $\alpha_2$ -blades, ... and  $\alpha_k$ -blades into a multivector  $C$ . In this way, the projected product  $*_{1,2}^1$  may be written down as  $*_{1,\{0,2\}}^1$ . By analogy, let  $\langle \cdot \rangle_{\{\alpha_1, \alpha_2, \dots, \alpha_k\}}$  denote the projection of a multivector on components spanned by  $\alpha_1$ -blades,  $\alpha_2$ -blades, ... and  $\alpha_m$ -blades.

Let  $\Psi$  denote the normalized multivector encoding the sentence “*Fido bit PSmith*”, i.e.

$$\Psi = \underbrace{\text{bite}_{agt} * \text{Fido}}_{\text{rank 2}} + \underbrace{\text{bite}_{obj} * \text{PSmith}}_{\text{rank 2}}. \quad (24)$$

Multivector  $\Psi$  will contain scalars, vectors, bivectors and trivectors and can be written down as the following vector of dimension  $\sum_{i=0}^3 \binom{n}{i}$

$$\Psi = \underbrace{\alpha}_{\text{a scalar}} + \underbrace{\sum_{i=1}^n \beta_i e_i}_{\text{vectors}} + \underbrace{\sum_{1 \leq i < j} \gamma_{ij} e_{ij}}_{\text{bivectors}} + \underbrace{\sum_{1 \leq i < j < k} \delta_{ijk} e_{ijk}}_{\text{trivectors}} \quad (25)$$

The following example illustrates how to ask questions in the  $GA_c$  architecture.

“*Who was bitten?*”

The answer to that question will be a multivector of rank 2

$$\begin{aligned} \Psi \# \text{bite}_{obj} &= \langle \text{bite}_{obj}^+ \Psi \rangle_{\{0,2\}} = \text{bite}_{obj}^+ *_{1,\{0,1,2,3\}}^2 \Psi \\ &= \text{PSmith}' \approx \text{PSmith}. \end{aligned} \quad (26)$$

Let  $\text{bite}_{obj} = \{y_1, \dots, y_n\}$ ,  $\text{PSmith}'$  will then have the form

$$\begin{aligned} \text{PSmith}' &= (y_1 e_1 + \dots + y_n e_n) *_{1,\{0,1,2,3\}}^2 \\ &= \left( \sum_{i=1}^n \beta_i e_i + \sum_{1 \leq i < j < k} \delta_{ijk} e_{ijk} \right) \end{aligned} \quad (27)$$

$$= \underbrace{\sum_{k=1}^n y_k \beta_k}_{\text{a scalar}} + \underbrace{\sum_{1 \leq i < j} \theta_{ij} e_{ij}}_{\text{bivectors}}, \quad (28)$$

where

$$\theta_{ij} = y_i \beta_j - y_j \beta_i + \sum_{\substack{t=1 \\ t \notin \{i,j\}}}^n y_t \delta_{ijt} \quad (29)$$

with  $\delta_{ijt} = \delta_{tij} = -\delta_{itj}$ . As previously,  $\text{PSmith}'$  should be compared with appropriate items from the clean-up memory to produce the most probable answer.

### III. OVERVIEW OF PLATE’S SCALING TEST

Plate [13] describes a simulation in which approximately 5000 HRR 512-dimensional vectors were stored in the clean-up memory. The purpose of his simulation was to study efficiency of the HRR model but also to provide a counterexample to the claim that role-filler representations do not permit one component of a relation to be retrieved given the others. We will repeat Plate’s test on several models and compare the results.

Let us consider the following atomic objects

$$\left. \begin{array}{l} \text{num}_x \text{ (for } x = 0, \dots, 2500), \\ \text{times}, \\ \text{plus}, \end{array} \right\} \text{ fillers}, \quad (30)$$

$$\left. \begin{array}{l} \text{result}, \\ \text{operand}. \end{array} \right\} \text{ roles} \quad (31)$$

At the beginning of the scaling test, relations concerning multiplication and addition are constructed. For example, “ $2 \cdot 3 = 6$ ” is constructed as

$$\text{times}_{2,3} = \text{times} + \text{operand} * (\text{num}_2 + \text{num}_3) + \text{result} * \text{num}_6. \quad (32)$$

Generally, relations are constructed in the following way

$$\begin{aligned} \text{times}_{x,y} &= \text{times} + \text{operand} * (\text{num}_x + \text{num}_y) \\ &\quad + \text{result} * \text{num}_{x \cdot y}, \end{aligned} \quad (33)$$

$$\begin{aligned} \text{plus}_{x,y} &= \text{plus} + \text{operand} * (\text{num}_x + \text{num}_y) \\ &\quad + \text{result} * \text{num}_{x+y}. \end{aligned} \quad (34)$$

$x$  and  $y$  range from 0 to 50 with  $y \leq x$  making a total of 2501 number vectors and 2652 instances of each  $\text{times}_{x,y}$  and  $\text{plus}_{x,y}$ . As one can notice, the same *operand* role is used for both  $x$  and  $y$  to preserve commutativity of multiplication and addition.

Plate writes, that a relation can be “looked up” by supplying enough information to distinguish a specific relation from others. For example, to look up “ $2 \cdot 3 = 6$ ” one needs to find the most similar relation  $R$  to any of the following fragmentary statements

$$\begin{aligned} \text{(case 1)} \quad &\text{times} + \text{operand} * \text{num}_2 \\ &\quad + \text{operand} * \text{num}_3, \end{aligned} \quad (35)$$

$$\begin{aligned} \text{(case 2)} \quad &\text{times} + \text{operand} * \text{num}_2 \\ &\quad + \text{result} * \text{num}_6, \end{aligned} \quad (36)$$

$$\begin{aligned} \text{(case 3)} \quad &\text{times} + \text{operand} * \text{num}_3 \\ &\quad + \text{result} * \text{num}_6, \end{aligned} \quad (37)$$

$$\begin{aligned} \text{(case 4)} \quad &\text{operand} * \text{num}_2 + \text{operand} * \text{num}_3 \\ &\quad + \text{result} * \text{num}_6. \end{aligned} \quad (38)$$

Retrieving the missing piece of information in the first three cases can be done by asking any of the subquestions

$$\text{(case 1)} \quad R \# \text{result}, \quad (39)$$

$$\text{(case 2)} \quad R \# \text{operand}, \quad (40)$$

$$\text{(case 3)} \quad R \# \text{operand}. \quad (41)$$

Case 4 is somewhat more problematic — to look up a missing relation name (*times* or *plus*) one needs to have a separate clean-up memory containing only relation names or to use an alternative encoding in which there is a role for relation names. We will alter Plate’s test by using the latter method.

Plate states that he had tried one run of the system making a query for each component missing in every relation — this amounted to 10608 queries. A further 7956 queries had been made to decode the missing component except for the relation name. Plate goes on to claim, that the system made no errors.

There appear to be two misstatements in Plate’s claims. Firstly, we cannot treat subquestions regarding cases 2 and 3 separately, as there are two equally probable answers to each of these subquestions, provided that relations  $R_2$  and  $R_3$  point

correctly to  $times_{x,y}$ . Secondly, consider a fragmentary piece of information

$$times + operand * num_0 + result * num_0. \quad (42)$$

In this situation, the missing component can be any of the numbers  $num_x$  where  $x \in \{0, \dots, 50\}$  and thus, there are 51 atomic objects that are equally probable to be the right answer. This suggests that Plate regards several answers as valid ones, as long as the similarity of these answers exceeds some threshold. To work out the missing component, one then needs to check which of those potential answers is not in the original set used for retrieval.

Such a method of investigating scaling properties has more than a few advantages:

- Inaccuracies mentioned above act as a test if all atomic objects are created and treated equally. Ideally, every atomic object of the  $num_x$  form should be recognized as a correct answer to the “zero problem” for  $\frac{\text{number of trials}}{51} \cdot 100\%$  of the time.
- Prime numbers greater than 100 do not appear in any of  $times_{x,y}$  and  $plus_{x,y}$  relations, therefore they test if the model is immune to garbage data.
- Numbers ranging from  $num_0$  to  $num_{100}$  may be constructed in a multitude of ways by addition ( $num_0$  by multiplication) and any given sentence chunk  $result * num_z$  will appear quite often in the  $plus_{x,y}$  relation. Hence, this is a great way of checking if the model deals with excessive similarity of a number of complex statements.
- Atomic objects bound with  $operand$  and  $result$  range in variety. On the other hand, there are just two atomic objects acting as an  $operation$  — does it affect in any way the recognition of  $operation$  filler? Indeed, it will be shown in Section V that recognition of the  $operation$  chunk turns out to be quite interesting depending on the choice of the architecture.

#### IV. NOTATION

For the purpose of explaining test results, let us introduce the following notation. Let  $S_{x,y}^*$  and  $S_{x,y}^+$  denote relations

$$S_{x,y}^* = operation * times + operand * (num_x + num_y) + result * num_{x,y}, \quad (43)$$

$$S_{x,y}^+ = operation * plus + operand * (num_x + num_y) + result * num_{x+y}, \quad (44)$$

for  $y \leq x$ . We chose to use a separate role for a relation name to enable encoding the information given only operands and the result. Let  $F_{i,x,y}^{op}$  denote fragmentary statements for  $i \in \{1, 2, 3, 4\}$  and  $op \in \{*, +\}$

$$F_{1,x,y}^{op} = S_{x,y}^{op} - result * num_{x \ op \ y}, \quad (45)$$

$$F_{2,x,y}^{op} = S_{x,y}^{op} - operand * num_x, \quad (46)$$

$$F_{3,x,y}^{op} = S_{x,y}^{op} - operand * num_y, \quad (47)$$

$$F_{4,x,y}^{op} = S_{x,y}^{op} - operation * op. \quad (48)$$

If  $v$  is an element of the clean-up memory, then let  $N(v)$  denote the closest *neighbor* of  $v$ , i.e. an element of the clean-up memory that is most similar to  $v$ . If  $v$  has more than one neighbor, then all subquestions during the test are asked to all of  $v$ 's neighbors. In HRR,  $GA_d$  (with the Hamming measure of similarity) and  $GA_c$  it is extremely unlikely for an element of the clean-up memory to have more than one neighbor due to the continuous nature of data in these architectures. Let  $Q_{i,x,y}^{op} = N(F_{i,x,y}^{op})$  for  $i \in \{1, 2, 3, 4\}$  and  $op \in \{*, +\}$ . During the test we asked subquestions concerning components missing in  $F_{i,x,y}^{op}$  and obtained the following (sets of) answers

$$q_{1,x,y}^{op} = N(Q_{1,x,y}^{op} \# result), \quad (49)$$

$$q_{2,x,y}^{op} = N(Q_{2,x,y}^{op} \# operand), \quad (50)$$

$$q_{3,x,y}^{op} = N(Q_{3,x,y}^{op} \# operand), \quad (51)$$

$$q_{4,x,y}^{op} = N(Q_{4,x,y}^{op} \# operation). \quad (52)$$

We assume that a missing component is identified correctly if it is the only neighbor to appropriate answer  $q_{i,x,y}^{op}$  or it belongs to the set of neighbors of  $q_{i,x,y}^{op}$ .

#### V. TEST RESULTS

The software for all tests was developed by A. Patyk-Łońska in Java language. All tests were performed on an ordinary PC with dualcore AMD processor with 2 GB RAM.

Tables II through IV compare scaling test results for

- $GA_c$  and HRR, both using dot-product as a similarity measure.
- BSC using Hamming distance as a similarity measure.

Although BSC and HRR models need only  $n$ -dimensional vectors, this is not quite the case for and  $GA_c$ , which needs  $1 + \frac{n(n-1)}{2}$  numbers to represent multivectors of rank 2 over  $\mathbb{R}^n$ . We present recognitions test results close to 100% and comment on vector length required for each model to achieve such percentage. The real number of memory cells used up by each model is given in brackets in the table headings.

The answers to subquestions  $Q_{2,x,y}^{op} \# operand$  and  $Q_{3,x,y}^{op} \# operand$  were considered to be correct if any of the two possible operands came up as the item most similar to those subquestions. In case of other questions and subquestions only exact answers were taken into consideration.

50 runs of the test were performed on each model. Unlike in Plate's test,  $x$  and  $y$  ranged from 0 to only 20. Hence, there are 401 number vectors and 462 relation vectors.

The “zero problem” is clearly visible in each tested model, as the recognition percentage of  $Q_{3,x,y}^*$  barely exceeds 90%. Nevertheless,  $Q_{3,x,y}^*$  almost always contains at least one of the operands from the original sentence  $S_{x,y}^*$  since the recognition percentage of  $q_{3,x,y}^*$  reaches 100% for sufficiently large data size. On the whole, the recognition percentage of  $q_{2,x,y}^*$  and  $q_{3,x,y}^*$  does not differ greatly from the recognition percentage of  $q_{2,x,y}^+$  and  $q_{3,x,y}^+$  in any model.

Table entries marked with a “ $\Delta$ ” indicate that despite the wrong recognition of a fragmentary sentence, the missing component has been identified correctly. In all tested models such situations arise for sentences with one of the operands missing.

For HRR, however the missing item has been “accidentally” correctly identified also in cases of missing *operation\*times* and *result\*times<sub>x,y</sub>* components. Such recognition did not occur in cases of missing *operation\*plus* and *result\*plus<sub>x,y</sub>* components, which is distressingly asymmetric.

HRR turned out to be the worst model during this experiment. The recognition percentage of  $Q_{1,x,y}^*$  and  $Q_{1,x,y}^+$  is dangerously low when compared to other  $Q$ 's. Both  $Q_{1,x,y}^*$  and  $Q_{1,x,y}^+$  are retrieved from the clean-up memory given only two operands and the operation type. Since we have only two operation types,  $Q_{1,x,y}^*$  and  $Q_{1,x,y}^+$  will not differ greatly from each other. This phenomenon is also observable in BSC (but not in  $GA_c$ ), where the recognition percentage of  $Q_1$ 's is only slightly lower than that of the other  $Q$ 's. Apart from that weakness, BSC performs as well as  $GA_c$  for adequate data size.

## VI. CONCLUSION

Authors developed a new model of distributed representations based on geometric algebra. Although the data representations of sentences encoded in this model may have varying lengths (as opposed to HRR and BSC), it can be justified by the fact that it is quite logical for sentences that hold more information to have larger “volume”.

Tedious calculations presented in Section 2 imply that the  $GA_c$  model is best applicable to sentences having a similar or identical complexity structure, otherwise it may be hard to make the process of asking questions and retrieving answers automatic. Because of this limitation, this construction seems to be a promising candidate for a holographic database.

# Workshop on Computational Optimization

**M**ANY real world problems arising in engineering, economics, medicine and other domains can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints which ask for adequate computational methods.

The aim of this workshop is to stimulate the communication between researchers working on different fields of optimization and practitioners who need reliable and efficient computational optimization methods.

We invite original contributions related to both theoretical and practical aspects of optimization methods.

The list of topics includes, but is not limited to:

- unconstrained and constrained optimization
- combinatorial optimization
- global optimization
- multiobjective optimization
- optimization in dynamic and/or noisy environments
- large scale optimization
- parallel and distributed approaches in optimization
- random search algorithms, simulated annealing, tabu search and other derivative free optimization methods
- nature inspired optimization methods (evolutionary algorithms, ant colony optimization, particle swarm optimization, immune artificial systems etc)
- hybrid optimization algorithms involving natural computing techniques and other global and local optimization methods
- optimization methods for learning processes and data mining
- computational optimization methods in statistics, econometrics, finance, physics, medicine, biology, engineering etc

# Task Scheduling with Restricted Preemptions

Tomasz Barański

Email: tbaransk@poczta.onet.pl

**Abstract**—One of basic problems in task scheduling is finding the shortest schedule for a given set of tasks. In this paper we analyze a restricted version of the general preemptive scheduling problem, where tasks can only be divided into parts at least as long as a given parameter  $k$ . We introduce a heuristic scheduling method TSRP3. Number of processors  $m$ , number of tasks  $n$  and task lengths  $p_i$  are assumed to be known. If  $n \geq 2m$  and  $k$  is sufficiently small, TSRP3 finds shortest possible schedule with  $O(m)$  divisions in polynomial time. In addition we introduce a more robust algorithm TSRP4 based on combining TSRP3 with multi-fit.

## I. INTRODUCTION

UNRESTRICTED scheduling on parallel processors is solved in linear time using McNaughton's [7] algorithm. Unfortunately this approach often leads to processing of some tasks only for a very short time before or after preemption. Preemptions are usually costly in some way, so we introduced "granularity" threshold  $k$ , so that no part of any divided task can be shorter than  $k$ , which should be large enough to make any preemption times and costs negligible. Unless  $k$  is  $0^1$  this problem is in general NP-hard (see [4]). This paper is based on research thesis by Tomasz Barański [2].

## II. THE MODEL

In this paper we consider deterministic scheduling problem of type<sup>2</sup>

$$P \mid k - pmtn \mid C_{MAX}$$

We schedule  $n$  tasks with known lengths  $p_i$  on  $m$  identical processors<sup>3</sup> numbered from 1 to  $m$ . Tasks can be divided, but no part of any task may be shorter than some given parameter  $k$ . Any processor can work on at most one task at any given time, and tasks cannot be executed in parallel. All tasks must be completed. The aim is to find a schedule of minimum makespan  $C_{MAX}$ . There is also a secondary goal of decreasing number of divisions, and out of 2 schedules with the same  $C_{MAX}$  we prefer the one with fewer divisions.

We assume task lengths  $p_i$ , division threshold  $k$  and lengths of all divided task parts to be integer. This doesn't make our solution less general, since real numbers within

<sup>1</sup>Actually 1, since we assume lengths of all tasks and their parts are integer.

<sup>2</sup>See [6] or [8] for description of three-field notation of scheduling problems.

<sup>3</sup>By that we mean some abstract portions of work to be done on abstract machines, not actual microprocessors.

Fig. 1. Example of divisible task (left) and non-divisible task (right). First task can be divided anywhere within the grated area.

a few orders of magnitude can be scaled to integers with reasonable precession. Using integers eliminates rounding errors and simplifies calculations.

In [4] two similar models were presented. In first tasks could be preempted after being processed for at least  $k$  time. In second tasks could be preempted after being processed for a multiple of  $k$ , which allowed for easier task switching. Algorithms for solving both models were proposed, however there were no restriction on lengths of final parts of tasks, so in some cases they could be processed for a very short time after preemption.

## III. TSRP3 ALGORITHM

### A. TSRP3 introduction

TSRP3 was developed by Tomasz Barański while working on research thesis [2] and based on earlier work by Michał Bakałarczyk [1]. It is basically a heavily modified version of McNaughton's algorithm with best-fit heuristics, and it never divides any task in more than 2 parts.

1) *Sorting and grouping Tasks*: Before TSRP3 begins scheduling all tasks are sorted and divided into four groups:

$T_{SK}$	$p_j \leq k$	Shorter than $k$
$T_{ND}$	$k < p_j < 2k$	Not divisible
$T_{DIV}$	$2k \leq p_j < 3k$	Divisible
$T_{GD}$	$3k \leq p_j$	Well divisible

Divisible tasks in groups  $T_{GD}$  and  $T_{DIV}$  are generally scheduled shortest to longest, while non-divisible  $T_{ND}$  and  $T_{SK}$  are generally scheduled longest to shortest. The longer a divisible task is, the easier it is to divide in such a way, that schedule of current processor has desired length. The shorter a non-divisible task is, the easier it is to fit into schedule on current processor. Indivisible tasks from  $T_{ND}$  generally cause the most problems while scheduling, so TSRP3 tries to schedule them first.

2) *Estimating  $C_{MAX}$* : TSRP3 starts scheduling from the first processor and in each step either assigns some task or task fragment to current processor or closes it,

and moves to next processor. This decision is based on task lengths and current approximation of schedule length  $worst \geq C_{MAX}$ . After TSRP3 finishes scheduling tasks on a processor it moves to next one, and never returns to any previous processor. To explain  $worst$  we first need to introduce a few other estimates.

While scheduling tasks we always know the number of current processor  $proc$ , hence the number of processors on which we can still schedule tasks  $prc$  is (2). We also know the sum of lengths of all unscheduled tasks<sup>4</sup>  $\sigma$  and loads of all processors  $t_Z^j$  including current  $t_Z^{proc}$ .

$$C^* := \max \left\{ \max_j p_j, \left\lceil \frac{1}{n} \sum_{j=1}^n p_j \right\rceil \right\} \quad (1)$$

McNaughton's lower bound on schedule length is defined in (1). Since only one processor can work on each task at any given time, no schedule can be shorter than the longest task. All schedules must also be at least as long as the sum of all task lengths divided by the number of processors.<sup>5</sup>  $C^*$  is calculated only once, while (2) to (6) must be recomputed once for each processor.

$$prc := m + 1 - proc \quad (2)$$

Number of processors where we can still schedule tasks  $prc$  must account for current processor as well, hence in (2) we add 1 to  $m - proc$ .

$$slack := prc \cdot C^* - \sigma - t_Z^{proc} \quad (3)$$

In (3)  $slack$  is the total amount of extra space that we could in theory allocate among remaining processors without going over  $C^*$ . To put it another way:  $slack$  tells how "sloppy" we can be scheduling tasks, while still (in theory) being able to complete optimal schedule.

$$hb := \begin{cases} \left\lceil \frac{\sigma}{prc} \right\rceil & \text{if } slack \leq 0, \\ C^* & \text{if } slack > 0. \end{cases} \quad (4)$$

As was shown in explanation of McNaughton's lower bound on  $C_{MAX}$ , any schedule must be at least as long as the sum of task lengths divided by the number of processors, hence from  $prc$  and  $\sigma$  we can derive approximation  $hb$  (4). If  $slack < 0$  definition (4) is equivalent to  $hb := C^* + \left\lceil \frac{-slack}{prc} \right\rceil$ .

$$slack^{eff} := \begin{cases} \left\lfloor \frac{slack}{prc} \right\rfloor & \text{if } hb = C^* \text{ and } slack > 0, \\ 0 & \text{else.} \end{cases} \quad (5)$$

Effective slack  $slack^{eff}$  (5) is  $slack$  divided among processors that we have left. It is assumed, that if on

<sup>4</sup>In some cases we may not change processor after task division, so  $\sigma$  has to include  $t_Z^{proc+1}$

<sup>5</sup>We compute *ceiling* to get an integer value. For example if sum of task lengths is 31 and we have 3 processors,  $C_{MAX}$  with integer task parts' lengths cannot be less than 11.

current processor we have  $t_Z^{proc} \geq worst - slack^{eff}$ , it is safe to close current processor and move to next one without increasing  $C_{MAX}$ .

$$lwb := \begin{cases} C^* - slack - (hb - C^*)(prc - 1) & \text{if } slack < 0, \\ C^* - slack & \text{if } slack \geq 0. \end{cases} \quad (6)$$

Approximation  $lwb \geq 0$  in (6) is defined as "What is the shortest schedule on current processor that won't increase  $hb$  when we change processor to next one".

$$worst := \max \left\{ C^*, hb, \max_{j \in 1..prc+1} t_Z^j \right\} \quad (7)$$

Our final estimate of  $C_{MAX}$  is  $worst$  defined in (7). It is the smallest number that is at least as big as  $C^*$  and current  $hb$  and greatest processor load so far. *TSRP3 tries to make load of current processor as close to worst as possible before closing it, and moving to next processor.* This is explained in detail in next subsection.

3) *Load zones:* TSRP3 behaves differently depending on the load of current processor  $t_Z^{proc}$ . Load zones are based on our current estimate  $worst$ . They are:

$$\begin{array}{llll} (S_1) & 0 & \leq & t_Z^{proc} < worst - 2k \\ (S_2) & worst - 2k & \leq & t_Z^{proc} < worst - k \\ (S_3) & worst - k & \leq & t_Z^{proc} < worst \\ (S_4) & worst & \leq & t_Z^{proc} \end{array}$$

4) *Choosing the task that fits best on current processor and goal function  $dist(x)$ :*<sup>6</sup>

TSRP3 uses best-fit heuristics to determine which task or task part is the best candidate to schedule on active processor before moving to next one. It is generally best to close processor when  $lwb \leq t_Z^{proc} \leq worst$  and  $t_Z^{proc}$  is as close to  $worst$  as possible. As can clearly be seen in (7) increasing  $t_Z^{proc}$  above  $worst$  will increase  $worst$  and thus possibly  $C_{MAX}$ . This is still the best course of action under some circumstances, but should be severely discouraged when it comes to choosing among other options. If current processor is closed when its load was below  $lwb$ , future  $hb$  will increase. This is almost as bad as going above  $worst$ , but its effects may be spread among all remaining  $prc - 1$  processors. The "punishment" for schedule length beyond  $[lwb, worst]$  can be some sufficiently big number, like  $4k$  or  $2k + worst - lwb$ . The former is more convenient, and the latter more correct. From these considerations we get the following function that can choose the best candidate (or no candidate) to schedule on current processor:

$$dist(x) := \begin{cases} 4k + \frac{lwb-x}{prc-1} & \text{if } x < lwb, \\ worst - x & \text{if } x \in [lwb, worst], \\ 4k + x - worst & \text{if } worst < x. \end{cases} \quad (8)$$

<sup>6</sup>This is actually  $dist(x, worst, lwb, prc)$ , but we abbreviated it to  $dist(x)$

TABLE I  
EXPLANATION OF USED SYMBOLS

Symbol	Meaning	See	Upd.
$n$	Total number of tasks	—	No
$m$	Total number of processors	—	No
$p_j$	Durations of tasks $j \in 1 \dots n$	—	No
$C_{MAX}$	Schedule length	—	No
$C^*$	Lower bound on $C_{MAX}$	(1)	No
$proc$	Current processor $proc \in 1 \dots m$	—	Proc.
$prc$	Number of processors left	(2)	Proc.
$t_Z^j$	Load of processor $j$ . Usually $t_Z^{proc}$	—	Yes
$\sigma$	Sum of unscheduled task durations	—	Yes
$slack$	Amount of “Slack space” under $C^*$	(3)	Proc.
$hb$	Estimate $C_{MAX}$ from $\sigma$ and $prc$	(4)	Proc.
$lwb$	Lowest $t_Z^{proc}$ that won't increase $hb$	(6)	Proc.
$worst$	Current estimate of $C_{MAX}$	(7)	Yes.
$slack^{eff}$	Amortized slack space on $proc$	(5)	Proc.

When choosing task or task part  $z_i$  to assign to current processor, TSRP3 finds  $z_i$ , for which  $dist(t_Z^{proc} + p_i)$  or  $dist(t_Z^{proc} + length)$  is the lowest. If  $dist(t_Z^{proc})$  is lower than for any task part we can schedule, TSRP3 moves to the next processor without scheduling anything on current one. It is more convenient to make  $dist(x)$  a real function. Integer values can be used, but for  $x < lwb$  you have to use  $\lceil dist(x) \rceil$  and choose the longest task among those with the same (lowest) value of  $dist()$ .

Table I presents a list of symbols used by TSRP3, along with references to equations defining these symbols. Column Upd. says how often a variable is updated: No means a fixed parameter, Proc. means update once per processor, and Yes means update before scheduling another task.

### B. TSRP3 Step by step

TSRP3 begins from the first processor. It assigns tasks to the current (open) processor, trying to make its load as close to  $worst$  as possible. When current processor is sufficiently loaded, TSRP3 closes it, and moves to (opens) next processor, which in turn becomes the current processor. For each assignment it generally chooses some task or task part  $z_i$ , for which  $dist(t_Z^{proc} + z_i)$  is lowest. This task or task part is called candidate, and may be compared to more tasks, scheduled, or discarded if  $dist(t_Z^{proc} + z_i) > dist(t_Z^{proc})$  where  $t_Z^{proc}$  is the load of current processor. If a task is divided, it's remaining part is assigned to the next processor. TSRP3 can be presented in the following steps:

- 1) Sort and divide tasks in groups  $T_{SK}$ ,  $T_{ND}$ ,  $T_{DIV}$ ,  $T_{GD}$ . Compute  $C^*$ .
- 2) If there are at least  $m$  well divisible tasks  $T_{GD}$ , schedule all tasks of length  $C^*$  on separate processors.
- 3) If there are no unscheduled tasks, finish.
- 4) If  $m \geq n$ , schedule all remaining tasks on separate processors and finish.
- 5) If  $proc = m$ , schedule all remaining tasks on  $proc$ , and finish.
- 6) Recompute  $slack$ ,  $slack^{eff}$ ,  $hb$ ,  $lwb$ ,  $worst$ , updating them once per processor.

- 7) Update  $t_Z^{proc}$  and  $worst$ . If  $(worst - slack^{eff}) \leq t_Z^{proc}$  and  $0 < t_Z^{proc}$  change processor to next one and go to step 5.
- 8) Take action depending on zone in which  $t_Z^{proc}$  is. This is explained in detail below, and may result in scheduling some task or task part, changing processor to the next one, or choosing a candidate task to schedule.
- 9) Choose candidate task to schedule. Take into account:
  - Candidate from step 8 if chosen
  - Longest and shortest tasks in each group.
  - Task division
  - *combo* (divides 2 or 3 tasks at once, explained later).

If  $dist(t_Z^{proc} + z_i) \leq dist(t_Z^{proc})$  for chosen candidate  $z_i$ , schedule it on current processor, otherwise move to next processor. Go to step 3

In step 2 we slightly reduce number of divisions in special cases, with lots of well divisible tasks. Step 4 takes care of some trivial cases. It is better to compare the number of unscheduled tasks to number of open processors except current one, rather than total numbers of processors and tasks. Steps 3 to 9 constitute the main loop of TSRP3. Step 7 is there to avoid divisions where not necessary. If  $slack^{eff}$  is positive, we have a good chance to complete optimal schedule. Step 8 is the most complex, and is explained below.

Following subsections are divided by zones  $S_1$  to  $S_4$ , and in one run of step 8 only one subsection gets executed depending on  $t_Z^{proc}$ . When a task is scheduled, it is considered to be removed from appropriate task set, therefore “ $T_{SK} \neq \emptyset$ ” means “there is at least one unscheduled task shorter than  $k$ ”. In some cases we use term “divisible task”  $z_i$ . It means that  $z_i \in T_{DIV} \cup T_{GD}$ , and we generally use it, when we want to select as candidate the shortest task, that we can conveniently divide to make load of current processor equal to  $worst$ . Each subsection consists of sequentially checking some conditions and executing some instructions, such as scheduling a task. If conditions for an item are met, then its instructions are executed, including possibly jump to step 3 described above. If conditions for an item are not met, ignore it's instructions, and jump to next item on the same level. By making some task  $z_i$  a candidate to assign in step 9 we mean comparing it first to current candidate (if any) with  $dist()$  and only making  $z_i$  candidate, if it's  $dist(p_i + t_Z^{proc})$  is lower than for current candidate.

1) Step 8, zone  $S_1$ :  $t_Z^{proc} \in [0, worst - 2k)$ :

- If  $T_{ND} \neq \emptyset$ , choose as candidate the longest non-divisible task  $z_i$  such that either  $p_i \leq (worst - k - t_Z^{proc})$  or  $(worst - slack^{eff} - t_Z^{proc}) \leq p_i$ . If the latter condition is met, or  $z_i$  is the longest task in  $T_{ND}$ , schedule that task on current processor and go to step 3.

- If there are at least  $prc$  well divisible unscheduled tasks left in  $T_{GD}$ 
  - Find the shortest divisible task  $z_i \in T_{DIV} \cup T_{GD}$  such that either  $(p_i + t_Z^{proc}) \in [worst - slack^{eff}, worst]$  or  $(p_i + t_Z^{proc}) \leq (worst - k)$ . If such a task exists schedule it and go to step 3.
  - Find the shortest divisible task  $z_i$  such that  $(p_i + t_Z^{proc}) \geq (worst + k - slack^{eff})$  If it exists divide it, scheduling part of length  $\min\{worst - t_Z^{proc}, p_i - k\}$  on processor  $proc$  and the rest on  $proc + 1$ , change current processor to next one and go to step 3.
- If there are more unscheduled tasks in  $T_{SK}$  than in  $T_{DIV} \cup T_{GD}$ , schedule the longest task from  $T_{SK}$  on current processor and go to step 3.
- If  $T_{DIV} \cup T_{GD} \neq \emptyset$ 
  - If the shortest divisible task  $z_i$  is longer than  $(worst - k - t_Z^{proc})$  and shorter than  $(worst + k - slack^{eff} - t_Z^{proc})$  and  $(p_i + t_Z^{proc}) \notin [worst - slack^{eff}, worst]$  and there are unscheduled tasks in  $T_{SK}$ , keep scheduling them on current processor until they run out, or one of above conditions is no longer satisfied or scheduling even shortest task would cause  $t_Z^{proc}$  to increase above  $(worst - k)$ .<sup>7</sup>
  - Choose the shortest divisible task  $z_i$  as candidate.
  - If task  $z_i$  is longer than  $(worst - k - t_Z^{proc})$  and shorter than  $(worst + k - slack^{eff} - t_Z^{proc})$  and  $(p_i + t_Z^{proc}) \notin [worst - slack^{eff}, worst]$ , choose as candidate  $z_i$  the shortest divisible task of length at least  $(worst + k - slack^{eff} - t_Z^{proc})$ . If it does not exist, then make the longest divisible task candidate.<sup>8</sup>
  - If  $(p_i + t_Z^{proc}) \leq (worst - k)$  or  $(p_i + t_Z^{proc}) \in [worst - slack^{eff}, worst]$ , schedule  $z_i$  on current processor and go to step 3.<sup>9</sup>
  - If  $(p_i + t_Z^{proc}) \geq (worst + k - slack^{eff})$  divide  $z_i$ , scheduling part of length  $\min\{worst - t_Z^{proc}, p_i - k\}$  on processor  $proc$  and the rest on  $proc + 1$ , change current processor to next one and go to step 3.
  - If there are at least 2 unscheduled divisible tasks and  $(worst - t_Z^{proc}) \geq 2k$  and  $t_Z^{proc} \geq k$ , try dividing 2 or 3 tasks using *combo*<sup>10</sup> heuristics. If successful, change processor to the next one and go to step 3.
  - Find the longest divisible task such that  $(p_i + t_Z^{proc}) \leq worst$ . If it exists, make it candidate to add  $z_i$ .
- Go to step 9.

<sup>7</sup>If there is a problem with division,  $t_Z^{proc}$  can be increased by scheduling some short tasks.

<sup>8</sup>By dividing task as short as possible, we preserve longer divisible tasks to be scheduled on another processor.

<sup>9</sup>We avoid zone  $S_3$  with this check.

<sup>10</sup>Explained in III-C.

Operations in this zone are the most complex, because we are actively avoiding zones  $S_3$  and  $S_4$  except for range  $[worst - slack^{eff}, worst]$ . We also divide long tasks, if scheduling them would make  $t_Z^{proc} \geq (worst + k - slack^{eff})$ . Before going to step 9, where we do some operations common to all zones, we may or may not choose a task as candidate to schedule. If selected, it is compared in step 9 to other possibilities, including scheduling nothing and moving to next processor.

2) Step 8, zone  $S_2$ :  $t_Z^{proc} \in [worst - 2k, worst - k]$ :

- If  $T_{ND} \neq \emptyset$ , find the longest task  $z_i \in T_{ND}$  such that  $(p_i + t_Z^{proc}) \leq worst$ . If it exists make it candidate to schedule. If it satisfies  $(p_i + t_Z^{proc}) \geq (worst - slack^{eff})$  schedule it, and go to step 3.
- If there is some divisible unscheduled task left.
  - If the shortest divisible task is shorter than  $(worst + k - slack^{eff} - t_Z^{proc})$ , and there are unscheduled tasks in  $T_{SK}$ , keep scheduling them on current processor until they run out, or the above condition is no longer satisfied or scheduling even the shortest task would cause  $t_Z^{proc}$  to increase above  $worst - k$ .
  - Find the shortest divisible task  $z_i$  such that  $(p_i + t_Z^{proc}) \geq (worst + k - slack^{eff})$ . If it exists, divide  $z_i$ , scheduling part of length  $\min\{worst - t_Z^{proc}, p_i - k\}$  on processor  $proc$  and the rest on  $proc + 1$ , change current processor to next one and go to step 3.
- Go to step 9.

In this zone we first try to find a non-divisible task of length  $(p_i + t_Z^{proc}) \in [worst - slack^{eff}, worst]$ . If that fails, we try to divide some task instead, possibly increasing  $t_Z^{proc}$  with tasks from  $T_{SK}$ . Other actions, common to all zones, are considered in step 9.

3) Step 8, zone  $S_3$ :  $t_Z^{proc} \in [worst - k, worst)$ :

- If there is at least one unscheduled task in  $T_{SK}$ , find the longest task  $z_i$  in  $T_{SK}$  such that  $(p_i + t_Z^{proc}) \leq worst$ . If it exists, make  $z_i$  the candidate to schedule. If  $(p_i + t_Z^{proc}) \geq (worst - slack^{eff})$  schedule  $z_i$ , and go to step 3.
- Go to step 9.

Here the only actions that make sense are: fitting a task from  $T_{SK}$  or scheduling task part of length  $k$  or changing current processor to next one without scheduling anything. Only the first option is not covered in step 9.

4) Step 8, zone  $S_4$ :  $t_Z^{proc} \geq worst$ :

- Move to next processor, and go to step 9.

We never actually get to this zone, because condition  $t_Z^{proc} \geq (worst - slack^{eff})$  is checked in step 7, but it is safer to include this check.

### C. Dividing 2 or 3 tasks with *combo*

Description of TSRP3 algorithm has two references to *combo* heuristics, that tries to divide 2 or 3 tasks before changing current processor to next one. This is useful,

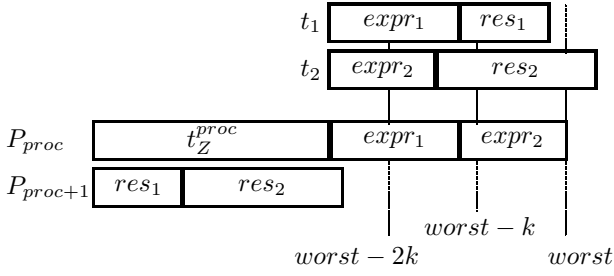

Fig. 2. Dividing two tasks with combo.

when there are some short divisible tasks, and scheduling any one task, divided or not, will guarantee  $t_Z^{proc}$  to be in either zone  $S_3$  or  $S_4$  and outside  $[worst - slack^{eff}, worst]$ . While this is counter to our stated goal of reducing the number of divisions, our *primary* aim is still to minimize  $C_{MAX}$ .

Consider the following example:  $slack^{eff} = 0$ ,  $t_Z^{proc} = (worst - 2k - \epsilon)$ , all indivisible tasks have lengths  $p_i > (k + \epsilon)$ , and all divisible tasks have lengths  $p_i = (2k + \lambda_i)$ , where  $\epsilon, \lambda \geq 0$  and  $\epsilon \neq \lambda_i$  and  $\forall i \epsilon - k < \lambda_i < \epsilon + k$ . No single task can be assigned or divided so as to avoid zones  $S_3$  and  $S_4$  or make load of current processor equal to  $worst$ . This can be done by increasing  $t_Z^{proc}$  by about  $k$ , or more precisely between  $\epsilon + k - \lambda_i$  and  $\epsilon + k$  for some  $i$ . It can be achieved by double division of tasks, as shown in Fig. 2.

If there are 2 divisible tasks  $z_1$  and  $z_2$  such that  $p_1 + p_2 \geq 4k + \epsilon - slack^{eff}$ <sup>11</sup> and they can be divided in a way that satisfies (9) to (12), and scheduled like in Fig. 2, then it won't result in any conflicts (overlapping task execution on different processors).

$$t_Z^{proc} \geq k \quad (9)$$

$$expr_1, res_1, expr_2, res_2 \geq k \quad (10)$$

$$t_Z^{proc} \geq res_1 \quad (11)$$

$$res_1 + res_2 \leq t_Z^{proc} + expr_1 \quad (12)$$

$$res_1 + res_2 + expr_2 \leq worst \quad (13)$$

Inequality (9) is a sanity check derived from (10) and (11). Inequality (10) ensures that there are no task parts shorter than  $k$ . Inequality (11) is more precise than (9) and makes conflict between  $expr_1$  and  $res_1$  impossible. Inequality (12) does the same for  $expr_2$  and  $res_2$ . Finally inequality (13) forbids *combo* on too long tasks, and makes sure that  $t_Z^{proc+1} \leq (worst - k)$ .

<sup>11</sup>This is a bit too restrictive. In some cases the next best course of action chosen with  $dist()$  is so bad, that it is better to use *combo* anyway, even if it makes  $t_Z^{proc} \notin [worst - slack^{eff}, worst]$ . If this next best thing would be assigning whole task  $z_i$  longer than  $(worst - t_Z^{proc})$ , scheduling 2 task parts shorter than  $p_i$  may be a better option. On the other hand when there are few processors left, and we are to either move to next processor while  $t_Z^{proc} < lvb$ , or assign some task  $z_i$  and land in zone  $S_3$  or  $S_4$ , scheduling 2 task parts whose sum is longer than  $p_i$  and shorter than the resulting  $hb$ , may also be better.

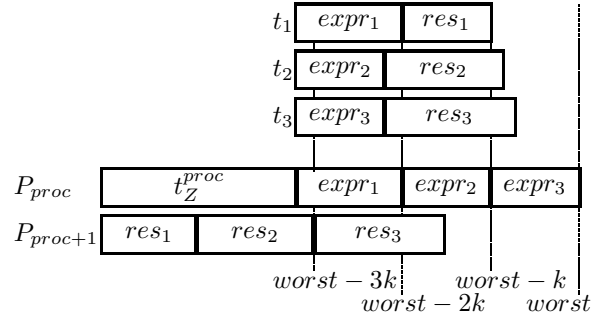

Fig. 3. Dividing three tasks with combo.

As it turns out, sometimes dividing 2 tasks with *combo* is not enough to make  $t_Z^{proc} = worst$ . Such situation arises when there are only divisible tasks left, there is at least 3 of them,  $t_Z^{proc} = (worst - 3k + \epsilon)$  and  $p_i = (2k + \lambda_i)$  where  $\forall i 0 \leq \epsilon < \lambda_i < \frac{k + \epsilon}{2}$ . In this case scheduling whole task or dividing 2 tasks causes  $t_Z^{proc}$  to be in zone  $S_3$ , which is undesirable. To solve this problem we find 3 tasks that satisfy inequalities (14) to (19) and assign their parts like in Fig. 3.

$$t_Z^{proc} \geq k \quad (14)$$

$$expr_1, res_1, expr_2, res_2, expr_3, res_3 \geq k \quad (15)$$

$$t_Z^{proc} \geq res_1 \quad (16)$$

$$t_Z^{proc} + expr_1 \geq res_1 + res_2 \quad (17)$$

$$t_Z^{proc} + expr_1 + expr_2 \geq res_1 + res_2 + res_3 \quad (18)$$

$$res_1 + res_2 + res_3 + expr_3 \leq worst \quad (19)$$

It is generally best to choose for *combo* as short a tasks as possible, divide shortest first and longest last, and always make *expr* as long as possible, while reserving  $k$  space for all future *expr*.

Scheduling  $res_i$  on different processors would relax some restrictions, but it would complicate computing  $\sigma$ ,  $hb$ ,  $lvb$ , and require keeping track of loads on too many processors. We do not recommend it, and in practice task divisions between current and next processors suffice.

It is never necessary to divide more than three tasks at once. If scheduling any divisible task  $z_i$  would cause  $t_Z^{proc}$  to end up in  $S_3$  or  $S_4$ , than increasing  $t_Z^{proc}$  by at most  $2k$  by dividing at most two other tasks, makes  $(t_Z^{proc} + p_i) \geq (worst + k)$ . Therefore dividing at most 3 tasks will always suffice, provided it is possible.

#### D. Sufficient conditions of optimality for TSRP3

With  $k = 0$  (or  $k = 1$  for all task parts' lengths integer) optimal schedule can be completed in  $O(n)$  time with McNaughton's algorithm. Scheduling indivisible tasks is in general an NP-hard problem (although there are reasonably good rough algorithms). The question arises of where is the threshold value  $k_l$  between these two cases or how many well divisible tasks are needed for guaranteed

completion of optimal schedule in polynomial time. This subsection addresses these questions by showing sufficient conditions for TSRP3 to complete an optimal schedule. As shown in section V these conditions are very restrictive, and in fact TSRP3 often completes optimal schedule with fewer than  $m$  divisible tasks.

Case a)

$$\text{For } 0 \leq l \leq m \text{ tasks } p_i = C^* \quad (20)$$

$$\text{For other tasks: } p_i \leq C^* - 2k \quad (21)$$

$$\text{There are } 2(m-l-1) \text{ tasks in } T_{GD} \quad (22)$$

$$\text{For pairs of them } p_a + p_b \leq (C^* + k) \quad (23)$$

All tasks (20) of length  $C^*$  are assigned to separate processors. This way we will decrease number of divisions while still getting optimal schedule. Condition (23) stands for this: We have at least  $2(m-l-1)$  well divisible tasks, and we can form  $(m-l-1)$  pairs, such that sum of their lengths is  $\leq (C^* + k)$ . This may be done by choosing some subset  $M$  of  $T_{GD}$ , and pairing longest and shortest tasks in  $M$ . They may be used for *combo*. Let us consider what actions TSRP3 will take depending on  $t_Z^{proc}$ . If  $t_Z^{proc} = 0$ , then after scheduling any task we have  $t_Z^{proc} \leq C^* - k$  because (21), so we avoid zones  $S_3$  and  $S_4$ . If  $t_Z^{proc} \leq C^* - 2k$  and by scheduling some task  $z_i$  we would end up in zone  $S_3$ , we can do a double division instead. If  $C^* - 2k < t_Z^{proc} \leq C^* - k$ , we can divide one task from (22). Therefore we never get to zones  $S_3$  and  $S_4$ , and we always have enough long tasks to make  $t_Z^{proc} = C^*$  by dividing one or two of them.

Case b)

$$\text{For } 0 \leq l \leq m \text{ tasks } p_i = C^* \quad (24)$$

$$\text{For other tasks: } p_i \leq C^* - 2k \quad (25)$$

$$\text{There are } (m-l-1) \text{ well divisible tasks} \quad (26)$$

$$\text{And } 2(m-l-1) \text{ more divisible tasks} \quad (27)$$

$$\text{Sum of 1 (26) and 2 (27) is } \leq C^* + 2k \quad (28)$$

Now we have at least  $(m-l-1)$  well divisible tasks and additionally at least  $2(m-l-1)$  divisible tasks. This is different from above case in that we can have fewer well divisible tasks, but need more divisible tasks overall. We also need to be able to combine these tasks in triplets satisfying (28). Reasoning proceeds as above, but if necessary we divide 3 tasks.

Case c)

$$\text{For } 0 \leq l \leq m \text{ tasks we have } p_i = C^* \quad (29)$$

$$\text{For other tasks: } p_i \leq C^* - 2k \quad (30)$$

$$\text{There are } (m-l-1) \text{ well divisible tasks} \quad (31)$$

$$\text{Sum of tasks in } T_{SK} \text{ is } \geq 2(m-l-1) \quad (32)$$

If by scheduling a well divisible task  $z_i$  we get  $t_Z^{proc} > (C^* - k)$ , then we need to extend  $t_Z^{proc}$  by at most  $2k$  to divide  $z_i$  and make  $t_Z^{proc} = C^*$ . Tasks shorter than  $k$  are useful for this. Since zone of possible division as shown in Fig. 1 for well divisible task is at least  $k$  long, and  $T_{SK}$  are at most  $k$  long, there never will be any trouble fitting some  $T_{SK}$  on current processor to divide  $z_i$  as long as there are enough of them.

Case d)

$$\text{For } 0 \leq l \leq m \text{ tasks } p_i = C^* \quad (33)$$

$$\text{For other tasks: } p_i \leq C^* - 2k \quad (34)$$

$$\text{We have } (m-l-1) \text{ tasks of length } p_i \geq 4k \quad (35)$$

$$\text{And } (m-l-1) \text{ tasks of length } p_i \geq k \quad (36)$$

Tasks (36) are there to avoid some malicious cases. Long tasks (35) have division zone of length at least  $2k$ . This makes it easy to make loads of all processors at most  $C^*$ . If by scheduling an indivisible task, we would get to zone  $S_3$ , we can instead divide one of tasks (35). If by scheduling a divisible task we would get to zone  $S_3$ , we can do a double division instead.

Case e)

$$|a| + |b| + |c| + |d| \geq (m-l-1) \quad (37)$$

We have a combination of cases a) b) c) d) and the sum of number of processors, for which at least one of them can be used to make  $t_Z^{proc} = C^*$  is at least  $(m-l-1)$ . We use different methods to complete optimal schedule.

1) *Conclusions:* These are sufficient, but not necessary conditions for completion of optimal schedule by TSRP3. As shown in section V, in practice TSRP3 will usually find optimal schedule as long as there are at least  $m/2$  divisible tasks and  $2m$  other tasks. Having at most  $l$ , where  $0 \leq l \leq m$  tasks of length  $C^*$  and other tasks no longer than  $C^* - 2k$  is forced just to exclude malicious data sets.

A simple rule for finding  $k_l$  for which TSRP3 will complete optimal schedule is as follows (38):

$L(i) :=$  Length of  $i$ -th longest task

$$\begin{aligned} k_a &= \left\lfloor \frac{L(2m)}{3} \right\rfloor \\ k_b &= \min \left\{ \left\lfloor \frac{L(3m)}{2} \right\rfloor, \left\lfloor \frac{L(m)}{3} \right\rfloor \right\} \\ k_l &= \max \{k_a, k_b\} \end{aligned} \quad (38)$$

As shown in [2], computational complexity of TSRP3 is  $O(n \cdot \log(n))$ , which is comparable to sorting. Memory requirements depend on data structures used for schedule, but are around 100b or less per task.

#### IV. TSRP4 ALGORITHM

TSRP3 works well when there are many long divisible tasks, but noticeably worse when there are few or none. TSRP4 is a method for making TSRP3 more robust with indivisible tasks. As can be concluded from (7) on page 2 *worst* either increases or stays the same when we move to the next processor. TSRP3 tries to make the load of current processor as close to current *worst* as possible, which may lead to overloading last processors while underloading first processors. To address this we introduce parameter  $C_{OGR} \geq C^*$ , and modify (7) to make sure that  $worst \geq C_{OGR}$ . Our goal then becomes to find such  $C_{OGR}^*$  that modified TSRP3 can complete a schedule of length  $C_{OGR}^*$ , but not  $C_{OGR}^* - 1$ .

This is accomplished by first setting  $C_{OGR}$  to  $C^*$ , and running TSRP3. If the length of resulting schedule  $len$  is  $C^*$  then finish, else  $C^* < C_{OGR}^* \leq len$  and  $C_{OGR}^*$  can be found with bisection of  $(C^*, len]$  by completing  $O(\log(len - C^*))$  schedules with modified TSRP3. Schedule completed with TSRP4 is never longer than completed with TSRP3 for the same input.

#### V. EXPERIMENTAL COMPARISON OF TSRP3 WITH OTHER SCHEDULING ALGORITHMS

To show behavior of TSRP3 and TSRP4 depending on  $k$ , they were tested for 10 randomly generated data sets. Each contained 500 tasks with Gauss distribution with  $\mu = 100$  and  $\sigma = 30$  to schedule on 100 processors. If there are fewer tasks than processors then scheduling is trivial, and if there are many (10+) tasks of wildly varying lengths, there is usually a good schedule without task divisions. Scheduling is most problematic, when there are few tasks per processor. Even statistically small sample of 10 data sets is enough to form opinion on behavior of TSRP3 and TSRP4 for changing  $k$ . The results were averaged and are shown in Fig. 4. They were taken from [2], where a slightly different version of TSRP3 was implemented.

Some labels in Fig. 4 require explanation.  $C^*$  is McNaughton's lower bound on schedule length (1). LPT and Multi-fit are algorithms scheduling tasks without dividing them. LPT assigns the longest task to the first processor that becomes idle. Multi-fit was our inspiration for TSRP4. It has "superior" and "subordinate" parts. Superior part manipulates parameter  $C_{OGR}$  to find  $C_{OGR}^*$  as described in IV. Subordinate part starts from the first processor and in each step either schedules on current processor the longest task that fits under  $C_{OGR}$  or moves to the next processor.

In Fig. 4 there are two main areas. Below  $k = 60$  there are at least  $m$  divisible tasks, and there are some well divisible tasks. Above  $k = 80$  the number of divisible tasks drops rapidly.

In III-D it was shown, that with sufficient number of divisible tasks TSRP3 can complete optimal schedule of length  $C^*$ . There may however exist some optimal schedules with fewer task divisions. Sufficient conditions

for completing optimal schedule given in III-D turn out to be very restrictive. During tests and barring maliciously chosen data sets TSRP3 was generally not failing at completing optimal schedules until number of divisible tasks dropped below  $m/2$ . When there are few or none divisible tasks, TSRP3 usually completes schedules longer than LPT, which does not divide tasks at all. When there are no divisible tasks, and  $k$  changes, length of TSRP3 schedule fluctuates, because border between  $T_{SK}$  and  $T_{ND}$  moves, so tasks are scheduled in different order. This leads to a somewhat paradoxical observation that sometimes a shorter schedule may be completed by increasing  $k$ . These fluctuations generally stop well before all tasks are classified as  $T_{SK}$ .

Algorithm TSRP4 was written to mitigate shortcomings of TSRP3 when there are few or none divisible tasks. As you can see in Fig. 4 schedule completed with TSRP4 is never longer than with TSRP3. For relatively short  $k$  TSRP4 schedule length is optimal, and as  $k$  grows,  $C_{MAX}$  approaches length of schedule completed with Multi-fit. This shows similarity of these two algorithms. Fluctuations with changing  $k$  and no divisible tasks are also smaller. This is an improvement over TSRP3, but it may require completing several schedules to find  $C_{OGR}^*$ .

In paper [2] an even better scheduling algorithm was devised by completing 2 schedules: one with TSRP4 and another with a good scheduling algorithm that doesn't divide tasks: "LPT + PSS", and choosing shorter one, or one with fewer divisions, if both schedule lengths were the same. In short LPT + PSS uses local search to balance loads of processors in schedule completed by LPT.

Algorithm LPT + PSS doesn't divide tasks, and was developed by Tomasz Barański and presented in [2]. It has proven to be superior to both multi-fit and LPT in terms of  $C_{MAX}$ , but takes longer to compute. Several speed improvements were proposed to mitigate this. LPT + Presistent Simple Swap starts by computing a schedule with LPT and sorting processors by load. In each step it chooses the most loaded processor  $P_{MAX}$ , and the least loaded  $P_{MIN}$  and tries to balance their loads by either moving one task from  $P_{MAX}$  to  $P_{MIN}$  or switching a pair of tasks between them. It tries to balance loads of these two processors as much as possible. If successful it updates  $P_{MAX}$  and  $P_{MIN}$  and continues balancing loads, otherwise it changes  $P_{MIN}$  to another processor with schedule shorter than that of  $P_{MAX}$ . PSS stops when  $C_{MAX}$  reaches  $C^*$  or no further balancing can be done. Any feasible schedule without tasks division can be used as starting point for PSS, such as multi-fit or even scheduling all tasks on a single processor, but in [2] LPT + PSS produced the best results. For data sets used in Fig. 4 in 9 out of 10 cases LPT + PSS produced schedule with  $C_{MAX} = C^*$ . It may seem superior to TSRP4, but in some cases optimal schedule can only be obtained by dividing tasks.

Fig. 4. Relation between  $k$  (horizontal axis) and  $C_{MAX}$  (vertical axis) for TSRP3 and TSRP4. Less is better. Results are averaged for 10 data sets with similar  $C^*$ . While  $k$  was gradually increased, Task durations stayed the same.  $C^*$  is lower bound on schedule length. LPT and Multi-fit don't divide tasks, and are shown for comparison. As  $k$  increases, number of divisible tasks drops, and TSRP3 produces worse results. TSRP4 is much more robust.

## VI. CONCLUDING REMARKS

In this article we proposed TSRP3, a heuristic algorithm for completing schedules with partial task division. As we have shown in (III-D) it is guaranteed to find optimal schedule if there are at least  $2m$  tasks  $3k$  long or longer.

While schedules completed with TSRP4 may be satisfactory in general, and optimal with enough divisible tasks, in some cases dividing tasks in at most two parts is not enough. We will illustrate this with a simple example: We have  $m = 3$  processors and  $n = 7$  tasks, with  $k = 4$ . There is one task of length  $p_1 = 12$  and six tasks  $p_i = 6$ . To get optimal schedule we need to divide the longest task in 3 parts of length 4 and schedule one on each machine with two indivisible tasks. This way we get  $C_{MAX} = C^* = 16$ . If we divide the longest task in at most 2 parts, then no part of it will be on one processor  $P_3$ . Therefore we either schedule 2 or 3 indivisible tasks on that processor. If we schedule 3 tasks, their combined length is  $6 \cdot 3 = 18$ . If we schedule only 2 tasks, then we need to divide tasks of length  $12 + 6 \cdot 4 = 36$  among 2 processors, so schedule won't be shorter than 18. Therefore in this example we need to cut some task in more than 2 fragments to get optimal schedule. A method of doing this is hinted in [2].

TSRP3 or TSRP4 may be used to solve one-dimensional bin-packing problem, like cut-weld problem, by changing  $m$ , running TSRP4 and comparing resulting  $C_{MAX}$  to target bin size. This is similar to method used in TSRP4

to find  $C_{OGR}^*$ . Please note, however, that in bin-packing problem there are no conflicts. We recommend using a dedicated algorithm for bin-packing rather than TSRP4. We suggest introducing some cost of dividing tasks for further study of TSRP3. Division of tasks in more than two parts is also worth investigating.

**Abstract**—In this work we present a branch-and-cut-and-price algorithm for the compression of fingerprint minutiae templates, in order to embed them into passport images by watermarking techniques as an additional security feature. For this purpose the minutiae data, which is a set of characteristic points of the fingerprint, is encoded by a spanning tree whose edges are encoded efficiently by a reference to an element in a dictionary (*template arc*) and a small correction vector. Our proposed branch-and-cut-and-price algorithm creates meaningful template arcs from a huge set of possible ones on demand in the pricing-procedure. Cutting-planes are separated in order to obtain connected subgraphs from which spanning trees can then be easily deduced. Our computational experiments confirm the superior performance of the algorithm in comparison to previous approaches for the spanning tree based encoding scheme.

## I. INTRODUCTION

THIS work is based on [1], where the authors introduced a combinatorial model to perform data compression specifically for a (small) set of unordered, multidimensional data-points. The need for such a kind of compression arises for instance when fingerprint minutiae data should be encoded in a way permitting this data to be embedded into images by watermarking techniques as additional security feature. For a detailed description of the application background we refer the reader to [1].

The compression model is based on a special kind of tree structure, connecting a subset of certain size of the given nodes. The nodes themselves correspond to the set of input data-points, i.e. the fingerprint minutiae. Compression is achieved by computing a suitable small set of *template arcs*, which enable a more efficient encoding of the intended tree structure. The compression model can thus be seen as a dictionary approach. Decompression is achieved by reconstructing the according subset of data-points from this particular tree structure. In section II we review the problem model.

In this work we focus on a more efficient solution of the underlying combinatorial optimization problem (COP). The model is actually a combination of two well-known COPs, the *minimum label spanning tree problem* [2] and the *k-cardinality minimum spanning tree problem* [3]. The resulting problem is called *k-minimum label spanning arborescence* (*k-MLSA*) problem.

The contribution of this article is a *branch-and-cut-and-price* (BCP) framework, detailed in section III, to solve the *k-MLSA* problem, and has for the first time been investigated

in the theses [4]–[6]. Within this framework we use cutting-planes to obtain validity of the initially incomplete model and dynamically create and add new label variables in the pricing phase. In section III-A we present efficient methods to solve the according pricing subproblem, and the experimental results in section IV show that the presented exact algorithm is able to solve the problem to provable optimality within a reasonable amount of time for practical purposes.

## II. PROBLEM MODEL

The following general compression model as well as the underlying combinatorial optimization model have originally been proposed in [1]. The input data is given as a vector of  $n$   $d$ -dimensional points  $V = \{v_1, \dots, v_n\}$  from a discrete domain  $\mathbb{D} = \{0, \dots, \tilde{v}^1 - 1\} \times \dots \times \{0, \dots, \tilde{v}^d - 1\}$ , with  $\mathbb{D} \subseteq \mathbb{N}^d$ . In our application these points correspond to the given minutiae data, where a single minutia is defined as a 4-tuple  $(x, y, \theta, t)$  with  $x$  and  $y$  being the Cartesian coordinates of the point,  $\theta$  its orientation and  $t$  its type. Within our compression model we usually only use  $x$  and  $y$  and eventually  $\theta$ , and store the further data unprocessed.

Our aim is to select a subset of exactly  $k$  points to be stored in the compressed fingerprint template; i.e., our compression is not lossless, but with a suitable selection of  $k$  this can usually be considered sufficient for a reliable verification, i.e. matching to the features extracted by a fingerprint scanner. For this purpose we start with a complete directed graph  $G = (V, A)$  with  $A = \{(u, v) \mid u, v \in V, u \neq v\}$  on which we search for an optimal directed tree (outgoing arborescence), spanning at least  $k$  nodes, by optimization. Thus, all nodes and arcs in the graph have a topological as well as a geometrical interpretation. In the following, we emphasize the context we primarily refer to by denoting these elements in normal and bold letters, respectively.

Furthermore, we use a small set  $T$  of template arcs which act as dictionary elements for our compression approach. Instead of directly storing the coordinate values of the mutual difference vectors of the tree nodes for each tree arc, we encode these arcs by a reference to a *template arc* in combination with a *correction vector* from a prespecified small domain. Compression is achieved by optimizing the selection of the  $k$  points, as well as building up a feasible dictionary of template arcs  $T$  of minimal cardinality.

Consequently, a solution to our problem consists of

- 1) an ordered set of template arcs  $T = (\mathbf{t}_1, \dots, \mathbf{t}_m) \in \mathbb{D}^m$ , and
- 2) an outgoing arborescence  $G_T = (V_T, A_T)$  with  $V_T \subseteq V$  and  $A_T \subseteq A$  connecting exactly  $|V_T| = k$  nodes, in which each tree arc  $(i, j) \in A_T$  has associated
  - a template arc index  $\kappa_{i,j} \in \{1, \dots, m\}$  and
  - a correction vector  $\delta_{i,j} \in \mathbb{D}'$  from a prespecified, small domain  $\mathbb{D}' \subseteq \mathbb{D}$  with  $\mathbb{D}' = \{0, \dots, \delta^1 - 1\} \times \dots \times \{0, \dots, \delta^d - 1\}$ .

For any two points  $\mathbf{v}_i$  and  $\mathbf{v}_j$  connected by a tree arc  $(i, j) \in A_T$  the relation

$$\mathbf{v}_j = (\mathbf{v}_i + \mathbf{t}_{\kappa_{i,j}} + \delta_{i,j}) \bmod \bar{\mathbf{v}}, \quad \forall (i, j) \in A_T, \quad (1)$$

must hold; i.e.  $\mathbf{v}_j$  can be derived from  $\mathbf{v}_i$  by adding the corresponding template and correction vectors. We use the modulo-calculation to avoid negative values and to be able to cross the domain-border within the arborescence. Our main objective now is to find a feasible solution with a smallest possible dictionary size  $m$ .

Details about encoding and decoding of the solution and the calculation and results regarding achieved compression ratios are given in the preceding work [1]. Here, we focus on an improved exact solution method, a new branch-and-cut-and-price algorithm.

#### A. The $k$ -Minimum Label Spanning Arborescence Problem

Based on the corresponding section in [1], we summarize the problem formulation in the following. To be able to choose the root node of the arborescence by optimization we extend  $V$  to  $V^+$  by adding an artificial root node 0. Further we extend  $A$  to  $A^+$  by adding arcs  $(0, i)$ ,  $\forall i \in V$ . We use the following variables for modeling the problem as an integer linear program (ILP):

- For each candidate template arc  $\mathbf{t} \in T^c$ , we define a variable  $y_t \in \{0, 1\}$ , indicating whether or not the arc is part of the dictionary  $T$ .
- Further we use variables  $x_{ij} \in \{0, 1\}$ ,  $\forall (i, j) \in A^+$ , indicating which arcs belong to the tree.
- To express which nodes are covered by the tree, we introduce variables  $z_i \in \{0, 1\}$ ,  $\forall i \in V$ .

Let  $A(t) \subset A$  denote the set of tree arcs a template arc  $t \in T^c$  is able to represent when considering the allowed domains for the correction vectors, and let  $T(a)$  be the set of template arcs that can be used to represent an arc  $a \in A$ , i.e.  $T(a) = \{t \in T^c \mid a \in A(t)\}$ . Hence, we can consider the template arcs  $t \in T^c$  as the *labels* of their corresponding arcs  $T(a)$ , revealing the strong relation to the minimum label spanning tree problem.

We can now formulate the  $k$ -MLSA problem as follows:

$$\min \sum_{t \in T^c} y_t \quad (2a)$$

$$\text{s.t.} \quad \sum_{t \in T(a)} y_t \geq x_a \quad \forall a \in A \quad (2b)$$

$$\sum_{i \in V} z_i = k \quad (2c)$$

$$\sum_{a \in A} x_a = k - 1 \quad (2d)$$

$$\sum_{i \in V} x_{(0,i)} = 1 \quad (2e)$$

$$\sum_{(j,i) \in A^+} x_{ji} = z_i \quad \forall i \in V \quad (2f)$$

$$x_{ij} \leq z_i \quad \forall (i, j) \in A \quad (2g)$$

$$x_{ij} + x_{ji} \leq z_i \quad \forall (i, j) \in A \quad (2h)$$

$$\sum_{a \in C} x_a \leq |C| - 1 \quad \forall \text{ cycles } C \text{ in } G, |C| > 2 \quad (2i)$$

$$\sum_{a \in \delta^-(S)} x_a \geq z_i \quad \forall i \in V, \forall S \subseteq V, \quad i \in S, 0 \notin S \quad (2j)$$

Inequalities (2b) ensure that for each used tree arc  $a \in A$  at least one valid template arc  $t$  is selected. Equalities (2c) and (2d) enforce the required number of nodes and arcs to be selected. Equation (2e) requires exactly one arc from the artificial root to one of the tree nodes, which will be the actual root node of the outgoing arborescence.

Equations (2f) state that selected nodes must have in-degree one. Inequalities (2g) ensure, that an arc may only be selected if its source node is selected as well. Inequalities (2h) forbid cycles of length two, and finally inequalities (2i) forbid all further cycles ( $|C| > 2$ ).

In order to strengthen the ILP we can additionally add (directed) connectivity-constraints, given by inequalities (2j), where  $\delta^-(S)$  represents the ingoing cut of node set  $S$ . These constraints ensure the existence of a path from the root 0 to any node  $i \in V$  for which  $z_i = 1$ , i.e. which is selected for connection. In principle, equations (2j) render (2f), (2g), (2h) and (2i) redundant [7], but using them jointly turned out to be sometimes beneficial in practice.

#### B. Candidate Template Arcs

The set of candidate template arcs  $T^c$  used in ILP (2) is, however, not explicitly given within the input data. The requirements to  $T^c$  are that it has to be sufficiently large to permit an overall optimal solution with regard to the pre-specified correction vector domain  $\tilde{\mathbf{d}}$ . Let  $B = \{\mathbf{v}_{ij} = (\mathbf{v}_j - \mathbf{v}_i) \bmod \tilde{\mathbf{v}} \mid (i, j) \in A\} = \{\mathbf{b}_1, \dots, \mathbf{b}_{|B|}\}$  be the set of different vectors we eventually have to represent. Let further  $D(\mathbf{t}) \subseteq \mathbb{D}$  be the subspace of all vectors a particular template arc  $\mathbf{t} \in \mathbb{D}$  is able to represent when considering the restricted domain  $\mathbb{D}'$  for the correction vectors, i.e.  $D(\mathbf{t}) = \{t^1, \dots, (t^1 + \delta^1 - 1) \bmod \tilde{v}^1\} \times \dots \times \{t^d, \dots, (t^d + \delta^d - 1) \bmod \tilde{v}^d\}$ . The subset of vectors from  $B$  that a particular template arc  $\mathbf{t}$  is able to represent is denoted by  $B(\mathbf{t}) = \{\mathbf{b} \in B \mid \mathbf{b} \in D(\mathbf{t})\}$ . The set of candidate template arcs  $T^c$  must have the property that all possible elements  $\mathbf{t}$  with mutually different and non-dominated  $B(\mathbf{t})$  should be included. Within this context a template-arc  $\mathbf{t}'$  is said to be dominated by  $\mathbf{t}''$  iff  $B(\mathbf{t}') \subset B(\mathbf{t}'')$ .

In a previous branch-and-cut approach [1] the set of candidate template arcs  $T^c$  has been computed in a relatively time-consuming preprocessing step. Within the approach presented in this work, this preprocessing is not necessary anymore.

Suitable candidate template arcs are on demand derived in the pricing-step, described in Section III.

### C. Cutting-plane Separation

The description of the cutting-plane separation again follows [1]. As there are exponentially many cycle elimination and connectivity inequalities (2i) and (2j), directly solving the ILP would be only feasible for very small problem instances. Instead, we apply branch-and-cut [8], i.e. we just start with the constraints (2b) to (2h) and add violated cycle elimination constraints and connectivity constraints only on demand during the optimization process.

Cycle elimination cuts (2i) can be easily separated by shortest path computations with Dijkstra's algorithm. Hereby we use  $(1 - x_{ij}^{\text{LP}})$  as the arc weights with  $x_{ij}^{\text{LP}}$  denoting the current value of the LP-relaxation for  $(i, j)$  in the current node of the branch-and-bound tree. We obtain cycles by iteratively considering each edge  $(i, j) \in A$  and searching for the shortest path from  $j$  to  $i$ . If the value of a shortest path plus  $(1 - x_{ij}^{\text{LP}})$  is less than 1, we have found a cycle for which inequality (2i) is violated. We add this inequality to the LP and resolve it. In each node of the branch-and-bound tree we perform these cutting plane separations until no further cuts can be found.

The directed connection inequalities (2j) strengthen our formulation. Compared to the cycle elimination cuts they lead to better theoretical bounds, i.e. a tighter characterization of the spanning-tree polyhedron [7], but their separation usually is computationally more expensive. We separate them by computing the maximum flow (and therefore minimum  $(0, i)$ -cut) from the root node to each of the nodes with  $z_i > 0$  as target node. If the value of this cut is less than  $z_i^{\text{LP}}$ , we have found an inequality that is violated by the current LP-solution. Our separation procedure utilizes Cherkassky and Goldberg's implementation of the push-relabel method for the maximum flow problem [9] to perform the required minimum cut computations.

The branch-and-cut algorithm has been implemented using C++ with CPLEX in version 11.2 [10].

## III. BRANCH-AND-CUT-AND-PRICE

The former branch-and-cut algorithm presented in [1] has two major shortcomings. First, the preprocessing method is quite time-consuming, and second, the large amount of template-arc-variables yields large LPs to be solved within every node of the branch-and-bound tree. These observations support the idea to develop a branch-and-cut-and-price (BCP) approach, where after starting with a small, very restricted set of template arcs, further template arcs are dynamically added on demand. This approach has for the first time been investigated in the theses [4]–[6].

Following the idea of the valid inequalities proposed in [11], we introduce inequalities

$$\sum_{t \in T(\Gamma^-(v_i))} y_t \geq z_i - x_{ri}, \quad \forall i \in V, \quad (3)$$

to provide (besides inequalities (2b)) further information for the pricing step, but also to further strengthen the LP. Inequalities (3) state that for each selected node except the artificial root node, the sum over the template-arc variables associated to the nodes ingoing arcs, must be greater or equal than one.

### A. Pricing Problem

Let  $\pi_a$  denote the dual variables corresponding to inequalities (2b), and  $\mu_j$  denote the dual variables corresponding to inequalities (3). The reduced costs for each template arc  $t$  are then given by

$$\bar{c}_t = 1 - \left( \sum_{a \in A(t)} \pi_a + \sum_{j \in \{v | (u,v) \in A(t)\}} \mu_j \right). \quad (4)$$

Any template arc with negative reduced costs  $\bar{c}_t$  may potentially improve the current objective function value; if there are no such template arcs, the solution cannot be further improved. We define the pricing problem as finding the template arc with maximal negative reduced costs.

*Definition 1 (Pricing Problem):*

$$t^* = \operatorname{argmin}_{t \in T} \left\{ 1 - \left( \sum_{a \in A(t)} \pi_a + \sum_{j \in \{v | (u,v) \in A(t)\}} \mu_j \right) \right\} \quad (5)$$

### B. Solving the Pricing Problem

A nice geometrical interpretation for the pricing problem arises, when considering the two-dimensional case. Each tree arc corresponds to a point in  $\mathbb{D}$  according to its associated geometric information. Furthermore, each point in  $\mathbb{D}$  in the same way corresponds to a potential template arc. Hence, we will use the terms tree/template arc and their corresponding points interchangeably within this section. All template arcs potentially representing an arbitrary tree arc  $\mathbf{b}$  must have their endpoint in the rectangle  $D(\mathbf{b} - \delta + \epsilon)$  with  $\mathbf{b}$  corresponding to its upper right corner, and  $\epsilon$  denoting the  $d$ -dimensional vector with all components being one. Let  $T'(\mathbf{b})$  denote this area whose points correspond to the potential template arcs able to represent  $\mathbf{b}$ . To each  $T'(\mathbf{b})$  we now associate the value

$$\zeta_b = \sum_{i \in \{a | a \in A \wedge a = b\}} \pi_i + \sum_{j \in \{v | (u,v) \in A \wedge (u,v) = b\}} \mu_j. \quad (6)$$

The first term on the right hand side in (6) corresponds to the sum of all dual values associated to the constraints for the tree arcs corresponding to  $\mathbf{b}$ , given by inequalities (2b). The second term results from the dual values of all nodes according to constraints (3) which are incident to a tree arc corresponding to  $\mathbf{b}$ . We can now imagine these rectangles  $T'(\mathbf{b})$  as transparently shaded with a color of intensity  $\zeta_b$ , where higher values corresponding to darker shades. See Fig. 1 for an example of two elements  $\mathbf{b}_1$  and  $\mathbf{b}_2$  and their corresponding regions  $T'(\mathbf{b}_1)$  and  $T'(\mathbf{b}_2)$  being drawn in the domain.

Let us now consider the situation of all  $\mathbf{b} \in B$  and their corresponding  $T'(\mathbf{b})$ , shaded accordingly with  $\zeta_b$ , being drawn in the area corresponding to the two-dimensional domain  $\mathbb{D}$ . Due to the transparency of the rectangles, regions of

Fig. 1. Example of two elements  $b_1$  and  $b_2$  and corresponding regions  $T'(b_1)$  and  $T'(b_2)$  drawn in the domain  $\mathbb{D}$ . (Image with minor modifications taken from [4])

overlapping rectangles will obtain darker colors. Formally we define for each uniform region  $R$  a corresponding value

$$\zeta_R = \sum_{b \in A(t), t \in R} \zeta_b \quad (7)$$

for some arbitrary  $t$  being located in region  $R$ . Figure 2 shows an example with two overlapping elements  $b_i$ . We can now see that the pricing problem given by Definition 1 exactly corresponds to finding the darkest such area. This analogy remains valid even in the higher dimensional case if we use regions of corresponding dimensionality instead of areas with dimensionality two. The correspondence of the presented illustration to the pricing problem becomes evident by considering the correspondence of equation (6) to the two sums in (5). The only difference is that (6) is formulated in terms of unique points  $b$  and (5) in terms of template arcs  $t$ , which we actually want to determine.

Based on this observation, we now outline an algorithm to solve the pricing problem. This algorithm was primary subject of the diploma thesis [4]; for details according to the implementation of the algorithm, the reader is referred to this work.

The underlying data structure is a  $k$ -d tree [12] which is used to partition the domain into the corresponding regions resulting from  $T'(b)$ , for all  $b \in B$  and resulting overlapping regions. Here  $k$  denotes the number of dimensions to be used within the tree, and should not be mixed up with the number of nodes to be connected to the arborescence. However, as the term  $k$ -d tree is commonly used for this data structure, we refrain from referring to it as  $d$ -d tree. For convenience, we briefly review the principles of  $k$ -d trees. Their primary application is to store multidimensional data points and allow efficient range and nearest neighbor searches. The tree defines a hierarchical partitioning of the underlying domain. Each node of the binary tree defines a division of the subspace in which it is located into exactly two further subspaces.

Within each level  $l$  coordinate  $l \bmod k$  is used to define this subdivision. At the root node the whole domain is subdivided according to some coordinate of the first dimension. Each child node then defines a subdivision according to a coordinate of the second dimension, and so forth. For our purpose we define each node to have either two children, or to be a leaf node. In our case, a leaf node may either correspond to a region that cannot contain a template arc, or otherwise, a region that contains all possible template arcs representing a unique subset of elements  $b_i \in B$ .

Fig. 2. This illustration shows the situation after the insertion of a further element ( $b_7$ ) into the segmentation tree shown in Figures 1 and 3. (Image with minor modifications taken from [4])

Figures 1 and 2 show examples of two and three elements being drawn in the domain, respectively. These figures illustrate how the domain is segmented into subregions according to  $T'(b_1)$  and  $T'(b_2)$  (and  $T'(b_7)$  in Figure 2). Corresponding  $k$ -d trees, which we will from now on call *segmentation trees*, are depicted in Figures 3 and 4. As each node of the tree subdivides its subspace into two subspaces, it defines a *hyperplane*, which we will also call *splitting-hyperplane*. In the two-dimensional examples of Figures 1 and 2 these hyperplanes correspond to lines. In the example of Figure 1 the first split is performed according to the second coordinate at point  $r_1 = b_1$ . Nodes  $r_i$  denote the coordinates corresponding to each node  $i$  of the segmentation tree. The area  $T'(b_1)$  is finally defined by nodes  $r_2$ ,  $r_3$  and  $r_4$ , area  $T'(b_2)$  by nodes  $r_5$ ,  $r_6$ ,  $r_7$  and  $r_8$ . In the figure all points  $r_i$  correspond to the corner points of areas  $T'(b)$  for all elements  $b$  in the tree, which is, however, an arbitrary decision for a better illustration. In fact, only one coordinate is required to define a hyperplane being orthogonal to the basis vector of the considered dimension, which is always the case in the segmentation tree. Besides the intermediate “splitting” nodes, the tree in Figure 3 also contains the leaf nodes, with corresponding regions depicted in Figure 1. The second example, given by Figures 2 and 4 shows the resulting tree after the insertion of element  $b_7$ . Again, splitting nodes and leaves (corresponding to regions) are contained in the visualization of the tree, as well as in

Fig. 3. Segmentation tree corresponding to the example shown in Figure 1. (Image credits: [4])

the corresponding illustration of the fragmented domain. To build up the whole tree, regions  $T'(b)$  for all  $b \in B$  are iteratively inserted. For each such  $T'(b)$  we need to find the correct position for inserting it into the tree. This is done by checking at each tree node  $r$  if  $T'(b)$  is entirely located in one of the subspaces defined by  $r$ . If a region is entirely contained in a region defined by a current leaf of the tree, this leaf is replaced with an according subtree corresponding to the splitting hyperplanes required to properly define  $T'(b)$ . However,  $T'(b)$  is part of both subspaces defined by the current node  $r$ , we need to split  $T'(b)$  accordingly, and insert the resulting subregions into both branches of  $r$ . Having now described, how the segmentation tree is created, we focus on how the tree can be used to efficiently search for the best template arc.

At this point we assume that the whole segmentation tree has been created in advance. As we will see later, this is not a real requirement. Our goal is to find the region  $R$  with maximum  $\zeta_R$ , which is the solution to the pricing problem. As the pricing problem needs to be solved many times, the search has to be efficient. In particular we want to avoid to assign  $\zeta_B$  to all leaves (corresponding to regions)  $B$  in the tree according to the values  $\zeta_b$  derived by the dual values. Therefore the search is based on upper and lower bounds used to prune branches at an early stage. Let  $R(r)$  denote the subspace corresponding to node  $r$  of the segmentation tree. Upper and lower bounds for each node  $r$  of the tree can be derived based on the following definitions.

*Definition 2 (Upper Bound Set):* The upper bound set is given by all elements  $b \in B$  which can be represented by some potential template arc in the subspace corresponding to tree node  $r$ .

$$UB(r) = \{b \in B \mid \exists t \in R(r) \wedge b \in B(t)\}$$

*Definition 3 (Lower Bound Set):* The lower bound set is given by all elements  $b \in B$  which can be represented by all potential template arcs in the subspace corresponding to tree node  $r$ .

$$LB(r) = \{b \in B \mid \forall t \in R(r) \wedge b \in B(t)\}$$

These bound sets are stored for each node of the search tree. In Figures 1 and 2 these sets are denoted in braces at each node.

Based on these sets we can immediately derive numeric bounds, based on the dual values.

*Definition 4 (Upper Bound):*

$$ub(r) = \sum_{b \in UB(r)} \zeta_b$$

*Definition 5 (Lower Bound):*

$$lb(r) = \max_{b \in UB(r)} \zeta_b$$

The search process is performed based on these upper and lower bounds. Starting at the root node, the set  $B$  is divided into two not necessarily disjoint sets. These sets  $UB(r)$  correspond to the nodes which are representable by some template arc of the subspaces introduced by the splitting-hyperplane defined by the current tree node  $r$ . With  $ub(r)$  we directly obtain a numeric value being the upper bound for this particular branch. A lower bound is given by  $lb(r)$ , i.e. the element with maximal  $\zeta_b$  in this branch. For each node we check if  $UB(r) = LB(r)$  which implies that we have found a leaf node. A global lower bound  $lb^*$  is used to prune the search tree, as we do not have to follow branches with  $ub(r) < lb^*$ . Initialization of the global lower bound can be performed with  $lb^* = \max_{b \in B} \zeta_b$ . The search strategy to be used is *best first search* based on the upper bounds  $ub(r)$ .

Within the description of the algorithm, we have omitted many implementation issues. One important aspect to be considered is the fact that regions may cross the domain border. This needs to be checked in advance, and corresponding subregions must be inserted in this case. Furthermore a lot of design issues are involved in order to implement the bounding procedure efficiently. Also the reconstruction of the coordinate values of the corner points of each region requires to take care of some special cases. For a detailed presentation and analysis of this issues we refer to [4].

A further substantial improvement of the overall process can be achieved if the entire tree is not completely built in advance, but rather in a dynamic on demand way during the

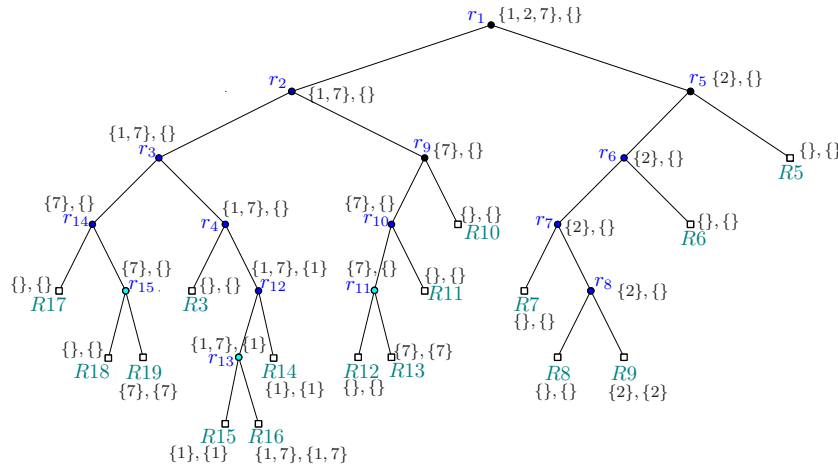

Fig. 4. Segmentation tree corresponding to the example shown in Figure 2. (Image credits: [4])

search process. Each time the search is according to the bounds directed toward a certain branch of the tree, we check if this branch has already been created. If this is not the case, it is expanded as needed. Hence construction and traversing the tree is performed in an intertwined way. This has not only the advantage of the initial construction step to be omitted, but will also result in smaller trees to operate with. As certain regions of the domain will not contain any useful template arcs, corresponding branches are unlikely to be created during the whole BCP solution process, saving space and time.

Corresponding pseudocodes are omitted within this presentation, as they would require a more detailed formal description and notation. In the following section we show how this algorithmic framework for solving the pricing problem can be used within a branch-and-cut-and-price approach.

### C. Branch-and-Cut-and-Price Algorithm

The first step of the entire branch-and-cut-and-price (BCP) is to determine a feasible starting solution. Any connected subgraph of  $k$  nodes is sufficient for this purpose. Hence, we determine a starting solution by connecting arbitrary  $k$  nodes by a star-shaped spanning tree, assign big values to the dual variables corresponding to this set of arcs, and use the pricing algorithm to determine a feasible starting solution.

The restricted master problem (RMP) is defined according to the ILP from Section II-A, however the entire set  $T^c$  is replaced by  $T^p$  denoting the set of template arc variables that have already been priced in. Within each node of the branch-and-bound-tree directed connection cuts and cycle elimination cuts are separated to obtain a feasible LP-relaxation. Afterwards new template arc variables are priced in as long as such variables with negative reduced costs according to Equation (5) can be found and no further cutting-planes can be added. It turned out to be advantageous to add all variables with negative reduced costs within each pricing iteration.

## IV. RESULTS

In this section we present the results of our computational experiments with the outlined branch-and-cut-and-price algorithm. For this purpose two different data sets have been used. The first set of 20 instances was provided by the Fraunhofer Institute Berlin and is in the following referred to as *Fraunhofer Templates*. Furthermore 14 randomly selected instances from the U.S. National Institute of Standards and Technology [13] have been used.

All test runs have been performed on an Intel Core 2 Quad running at 2.83 GHz with 8 GB RAM and Ubuntu 11.04. The branch-and-cut-and-price algorithm has been implemented in C++ within the SCIP framework [14], and CPLEX in version 11.2 [10], which is also used for the comparison to the branch-and-cut (BC) algorithm from [1].

For each run a time-limit of two hours has been imposed. Table I shows average solution values for various parameter settings ( $k$ ,  $\tilde{\delta}$ ) and groups of instances. These averages are taken over all instances that have been solved within the time limit (indicated in the last column). The Fraunhofer instances with  $|V| < 30$  are not included in the corresponding groups with  $k = 30$ . Column “pit” reports the average numbers of pricing iterations, column “pvar” the average numbers of priced in variables, and column “bbn” the average branch and bound nodes. Column “cuts” reports the numbers of applied cuts, which consist of directed connection cuts (“DCC”) and cycle elimination cuts (“CEC”).

Table II shows the comparison of the new BCP algorithm to the branch-and-cut algorithm presented in [1]. The average running times of the BC algorithm do not include the preprocessing step. The reported average running times and numbers of branch-and-bound nodes are not directly comparable, as not always the same number of instances has been solved by both algorithms. The BCP method is, however, clearly superior to the BC algorithm w.r.t. the number of solved instances, and also yields to significantly lower average running times and numbers of branch-and-bound nodes.

The results clearly show that the new BCP approach is able to solve a significantly larger number of instances and also requires shorter running times on average for most classes of instances.

## V. CONCLUSIONS

In this work we have presented a branch-and-cut-and-price framework to solve the problem of compressing a relatively small unordered set of multidimensional points with the application background of embedding fingerprint minutiae data into passport images by watermarking techniques as an additional security feature. Compared to a previously used exact branch-and-cut algorithm, a significant speedup of solving the underlying combinatorial optimization problem ( $k$ -MLSA problem) could be achieved. Furthermore the preprocessing step being necessary for the preceding approach needs not to be performed anymore. As a result more instances can be

solved to proven optimality within the considered time limit by the new method.

Although the overall compression ratios achieved by our particular model are rather limited, they are clearly superior to other popular compression mechanisms, which cannot perform any compression on the considered data at all. Further improvements regarding compression ratios can possibly be achieved by devising refined models and algorithms. However, in consideration of being a new approach to data compression by combinatorial optimization techniques, as well as being a novel approach of directly exploiting the property that the order of the underlying data needs not to be preserved, our approach can be regarded a successful proof-of-concept to be able to compress weakly structured data sets and appears to be a promising origin for further research in the field of combinatorial optimization based compression methods.

**Abstract**—We consider the SUMT (*Sequential Unconstrained Minimization Technique*) method using extrapolations to link successive unconstrained sub-problems. The case when the extrapolation is obtained by a first order Taylor estimate and Newton's method is used as a correction in this predictor-corrector scheme was analyzed in [1]. It yields a two-steps super-linear asymptotic convergence with limiting order of  $\frac{4}{3}$  for the logarithmic barrier and order two for the quadratic loss penalty.

We explore both lower order variants (approximate extrapolations correction computations) as well as higher order variants (second order and further) Taylor estimate.

First, we address inexact solutions of the linear systems arising within the extrapolation and the Newton's correction steps. Depending on the inexactness allowed, asymptotic convergence order reduces, more severely so for interior variants.

Second, we investigate the use of higher order path following strategies in those methods. We consider the approach based on a high order expansion of the so-called central path, somewhat reminiscent of Chebyshev's third order method and its generalizations. The use of higher order representation of the path yields spectacular improvement in the convergence property, even more so for the interior variants.

## I. INTRODUCTION

WE CONSIDER non linear programs (NLP) of the form

$$\begin{aligned} \min_{x \in \mathbb{R}^n} f(x) \\ \text{subject to } g(x) \leq 0 \end{aligned} \quad (1)$$

or

$$\begin{aligned} \min_{x \in \mathbb{R}^n} f(x) \\ \text{subject to } g(x) = 0 \end{aligned} \quad (2)$$

with  $g : \mathbb{R}^n \rightarrow \mathbb{R}^m$ .

We will address both formulations using SUMT, Eq.(1) using the classical log barrier method and Eq.(2) will be developed using the quadratic loss penalty function. A slight emphasis is put on the logarithmic barrier variant.

Fiacco and McCormick [5] pioneered the study of SUMT, and obtained the important result that close to a solution, the unconstrained sub-problems induce differential trajectories, and proposed the use of extrapolation to follow the trajectories. In linear programming, Mehrotra [6] popularized the use of so called predictor-corrector algorithms, intimately related to the extrapolations of the SUMT trajectory.

This research was partially supported by NSERC grant OGP0005491

We present asymptotic results related to inexact versions of both variants, looking for super-linear convergence of order lower than 2, as well as high order extrapolations to aim for faster asymptotic convergence.

Results from [1] state that interior variants achieve a limiting convergence order of two-steps  $\frac{4}{3}$  while exterior variants reach a limiting 2-steps quadratic order. We call two-steps convergence since the convergence order requires the solution of two linear systems, one to compute the extrapolation and another one to compute the Newton step.

Asymptotic order is not all, and interior variants are known to yield polynomial complexity in a wide variety of contexts while exterior variants could be plagued by combinatorial aspects related to active set identification when applied to inequality constrained problems.

We will first analyze inexact versions of SUMT, and conclude that the deterioration with respect to the asymptotic order is more severe for interior variants, exterior variants' degradation being benign.

On the other hand, high order versions bring both variants comparable with respect to their asymptotic behavior. For example, the second order extrapolation allows to bypass any Newton correction asymptotically. The second order correction involves solving two linear systems, but both systems share the same matrix. Therefore, only one factorization is require. For unstructured dense problems, factorisation of a matrix in a linear system entails  $\mathcal{O}(n^3)$  arithmetic operations while solving the system needs a further  $\mathcal{O}(n^2)$  operations. The second order extrapolation requires only one factorization, much better than two independant linear systems.

Finally, we propose an approximate high order version based on the Shamanskii approach which is simple to implement and shares the good asymptotic improvements of the exact high order versions.

## II. SUMT BASIC EXTRAPOLATIONS

We now recall two path following approaches, allowing to settle our notation and present some basic properties. Path following methods are related to the so-called central path, and involves steps named as predictor, corrector, centrality corrector, higher order predictor. We will detail below the terms we will use.

We stress that the results for the exterior quadratic loss penalty function and the interior log-barrier function are very

similar. The only difference is the limiting convergence order,  $\frac{4}{3}$  for the interior approach and 2 for the exterior penalty.

#### A. Log-Barrier

The log barrier approach to solve Eq.(1) consists in solving a sequence of sub-problems of the form

$$\min_{g(x)<0} \phi(x, \rho_k) = f(x) - \rho_k \sum \log(-g_i(x)) \quad (3)$$

in the interior of the feasible set  $E = \{x : g(x) \leq 0\}$ . Writing out the optimality conditions

$$\nabla_x \phi(x, \rho_k) = \nabla f(x) - \rho_k \sum \frac{1}{g_i(x)} \nabla g_i(x) = 0 \quad (4)$$

and by making the substitution  $y_i = \frac{\rho_k}{g_i(x)}$  and introducing the residual  $\Phi_k$ , one arrives at the primal-dual equations

$$\Theta(x, y, \Phi_k, \rho_k) = \begin{cases} \nabla f(x) - y \nabla g(x) = \Phi_k \\ y G(x) = \rho_k e \end{cases} \quad (5)$$

where  $e = (1, 1 \dots 1)^t$  and  $G(x) = \text{diag}(g_i(x))$ .

Under suitable assumptions, this last system of equations implicitly defines differentiable trajectories  $x(\rho, \Phi)$  and  $y(\rho, \Phi)$  close to  $\rho = 0$ .

#### B. Quadratic loss

The quadratic loss approach to solve Eq.(2) consists in solving a sequence of sub-problems of the form

$$\min \phi(x, \rho_k) = f(x) + \frac{1}{\rho_k} \|g(x)\|^2. \quad (6)$$

Writing out the optimality conditions

$$\nabla_x \phi(x, \rho_k) = \nabla f(x) + \frac{g(x)^t}{\rho_k} \nabla g(x) = 0 \quad (7)$$

and by making the substitution  $y = \frac{g(x)^t}{\rho_k}$  and introducing the residual  $\Phi_k$ , one arrives at the primal-dual equations

$$\Theta(x, y, \Phi_k, \rho_k) = \begin{cases} \nabla f(x) + y \nabla g(x) = \Phi_k \\ g(x) = \rho_k y \end{cases} \quad (8)$$

Under suitable assumptions, this last system of equations implicitly defines differentiable trajectories  $x(\rho, \Phi)$  and  $y(\rho, \Phi)$  close to  $\rho = 0$ .

#### C. Common properties

Penalty and barriers trajectories share much properties. Those may be expressed conveniently using the  $\Theta$  function in a unified way. In the following result,  $g_{I^*}$  refers to the active constraints in the log barrier case, and the whole  $g$  vector in the quadratic penalty case.

*Theorem 2.1:* [1] Let  $x^*$  be a regular point of the constraints  $g_{I^*}(x) = 0$  which satisfies to the second order sufficient optimality conditions for (1) as well as to the strict complementarity condition  $y_{I^*} > 0$  for the log barrier case. If the functions  $f$  and  $g$  are  $C^p(\mathbb{R}^n)$ , then there exists differentiable trajectories  $x(\rho, \Phi)$  and  $y(\rho, \Phi)$  of class  $C^{p-1}(\mathbb{R}^n)$  such that

- 1)  $x(0, 0) = x^*$  and  $y(0, 0) = y^*$ ;

- 2) if  $\rho$  and  $\|\Phi\|$  are small enough,  $x(\rho, 0)$  satisfies to the second order sufficient optimality conditions for the penalized sub-problems  $\min f(x) - \rho \sum_{i=1}^m \log(-g_i(x))$ , where  $x(r, \Phi)$ ,  $y(r, \Phi)$  are solutions of the following equations:

$$\Theta(x, y, \Phi, 0) = 0 \quad (9)$$

Moreover, the following bounds hold asymptotically:

- a)  $\|x(\rho, \Phi) - x^*\| \sim \mathcal{O}(\max(\rho, \|\Phi\|))$ ;
- b)  $\|y(\rho, \Phi) - y^*\| \sim \mathcal{O}(\max(\rho, \|\Phi\|))$ ;
- c)  $\|g_{I^*}(x(\rho, \Phi))\| \sim \mathcal{O}(\rho)$ .

*Remark 2.1:* Although we use primal-dual equations, in this SUMT variant, the dual variables  $y$  are dependent on the primal  $x$ , so that global convergence is inferred from the fact that the penalty or barrier is minimized (using globally convergent algorithms), allowing to prove that cluster points of the generated sequence are indeed stationary.

We will denote  $G(x) = \text{diag}(g_i(x))$  and for the log barrier,

$$\Phi(x, \rho) = \nabla_x \phi(x, \rho) \quad (10)$$

$$= \nabla f(x) - \sum \frac{\rho}{g_i(x)} \nabla g_i(x) \quad (11)$$

$$= \nabla f(x) - \rho \nabla g^t(x) G(x)^{-1} e. \quad (12)$$

$\phi$  is closely related to the Lagrangian  $l(x, \lambda) = f(x) + g(x)\lambda$ , and by defining  $\lambda = -\rho G(x)^{-1} e$ , i.e.  $\lambda_i = -\frac{\rho}{g_i(x)}$ ,  $\nabla_x l(x, \lambda) = L(x, \lambda) = \nabla f(x) + \lambda \nabla g(x) = \Phi(x, \rho)$ .

Similarly, for the quadratic penalty,  $\lambda = \frac{g(x)^t}{\rho}$  and  $\Phi(x, \rho) = \nabla f(x) + \frac{g(x)^t}{\rho} \nabla g(x)$ .

We are concerned with approximate solutions  $x(\rho, r)$  which satisfy  $\Phi(x(\rho, r), \rho) = r$ . In the sequel the residual  $r$  is assumed to satisfy  $\|r\| \sim \rho$ .

The basic predictor-corrector path following approach consists then in having an estimate  $x(\rho, r)$  which satisfy  $\Phi(x(\rho, r), \rho) = r$  and then iterate the following two steps:

pred	extrapolate $\hat{x}^1 = x + \frac{\partial x}{\partial \rho}(\rho^+ - \rho) + \frac{\partial x}{\partial r}(-r)$
corr	perform Newton corrections from $\hat{x}^1$ on the problem Eq.(6) or Eq.(3) for $\rho^+$ until $\ \Phi(x, \rho^+)\  \leq \rho^+$ .

For this basic scheme and the log barrier case, a single Newton correction asymptotically yields  $x(\rho^+, r^+)$  with  $\|\rho^+\| \leq \rho^+$  provided that  $\frac{\rho^+}{\rho^{\frac{4}{3}}} \rightarrow 0$  yielding a two-steps super-linear convergence of limiting order  $\frac{4}{3}$ . If one is prepared to perform two Newton corrections, then the limiting order is improved to  $\frac{\rho^+}{\rho^{\frac{5}{3}}} \rightarrow 0$  [4] yielding a three-steps super-linear convergence of limiting order  $\frac{5}{3}$ . Using a measure similar to Ostrovski efficiency, the optimal strategy for this family of algorithms is to aim for two Newton corrections following an extrapolation [4].

For the quadratic loss case, a single Newton correction asymptotically yields  $x(\rho^+, r^+)$  with  $\|\rho^+\| \leq \rho^+$  provided that  $\frac{\rho^+}{\rho^2} \rightarrow 0$  yielding a two-steps super-linear convergence of limiting quadratic order.

#### D. Terminology

First order extrapolations are usually named “predictor” steps. Higher order terms are sometimes named “corrections” to the predictor, but we will stick to the terminology “higher order”. Once a predictor (of arbitrary order) is computed, sometimes it is necessary to perform Newton iterations, referred to as a “corrector” steps. This is sometimes named “centrality correction” steps.

Predictor steps aim at changing the trajectory parameter  $\rho$  to a smaller value while corrector steps aim at improving the parametric solution for a given  $\rho$ -value.

### III. INEXACT VERSIONS

Since extrapolations (predictor steps) and Newton corrections are related to Newton steps, one may devise strategies to approximately compute the steps. We address in this section the asymptotic convergence order of such variants where both (predictors and correctors) steps are computed approximately.

#### A. Inexact SUMT

We now address inexact extrapolations and corrections. By solving approximately the equations defining the first order extrapolation  $\hat{x}^1$ , we get an extrapolate, denoted  $\hat{x}$  with  $\|\hat{x} - x(\rho^+, 0)\| \sim \rho^{a+1}$ . If  $a = 1$ , we get as good a prediction as  $\hat{x}^1$  while if  $\hat{x}$  is computed cheaply, we insist to at least obtain an order  $a + 1$  for some  $a > 0$ .

Assume that the Newton’s direction is computed approximately such that  $\nabla_x \Phi(\hat{x}, \rho^+) d_N + \Phi(\hat{x}, \rho^+) = R$  with  $\|R\| \leq \rho^{1+c} = \gamma$ .

*Lemma 3.1:* Let  $\hat{x}$  such that  $\|\hat{x} - x(\rho^+, 0)\| \sim \rho^{a+1}$ . Then,  $d_N \sim \mathcal{O}(\gamma + \rho^{a+1})$ .

1) *Details for the log barrier:* We first provide a proof of lemma 3.1

*Proof:* The primal-dual Newton’s direction is written

$$\begin{pmatrix} \nabla_x L(\hat{x}, \hat{\lambda}) & \nabla \hat{g} \\ \hat{\Lambda} \nabla \hat{g}^t & \hat{G} \end{pmatrix} \begin{pmatrix} d_x \\ d_y \end{pmatrix} = \begin{pmatrix} -L(\hat{x}, \hat{\lambda}) + R \\ 0 = \hat{G} \hat{\lambda} - \rho^+ e \end{pmatrix}, \quad (13)$$

where  $\hat{\lambda}_i = \frac{\rho^+}{\hat{g}_i}$ . Define also  $\lambda_i = \frac{\rho^+}{g_i}$ , where  $g_i = g_i(x(\rho^+, 0))$ . By defining  $\bar{d}_y = d_y - \lambda + \hat{\lambda}$ , we may rewrite Eq.(13) as

$$\begin{pmatrix} \nabla_x L(\hat{x}, \hat{\lambda}) & \nabla \hat{g} \\ \hat{\Lambda} \nabla \hat{g}^t & \hat{G} \end{pmatrix} \begin{pmatrix} d_x \\ \bar{d}_y \end{pmatrix} = \begin{pmatrix} -L(\hat{x}, \lambda) + R \\ \hat{G}(\lambda - \hat{\lambda}) \end{pmatrix}, \quad (14)$$

We now observe that  $L(\hat{x}, \lambda) = \mathcal{O}(\rho^{a+1})$  and  $\hat{G}(\lambda - \hat{\lambda}) = \rho^+ G^{-1}(\hat{g} - g) = \mathcal{O}(\rho^{a+1})$  and  $\|R\| \leq \gamma$  which concludes the proof.  $\blacksquare$

Now consider the effect of an inexact Newton correction.

*Lemma 3.2:* Let  $\hat{x}$  such that  $\|\hat{x} - x(\rho^+, 0)\| \sim \rho^{a+1}$ . Then,  $\Phi(\hat{x} + d_N, \rho^+) \sim \mathcal{O}\left(\frac{(\gamma + \rho^{(a+1)})^2}{\rho^+}\right)$ .

*Proof:* We write

$$\Phi(\hat{x} + d_N, \rho^+) = \Phi(\hat{x}, \rho^+) + \nabla_x \Phi(\hat{x}, \rho^+) d_N + \mathcal{O}\left(\frac{\|d_N\|^2}{(\rho^+)^2}\right), \quad (15)$$

noting the last denominator  $(\rho^+)^2$  which comes from derivating twice  $\frac{\rho^+}{g_i(\hat{x})}$ . The first two terms are bounded by  $\gamma$  and using the bound on  $d_N$  from the lemma 3.1 we get  $\frac{(\gamma + \rho^{(a+1)})^2}{\rho^+}$ .  $\blacksquare$

Consider  $\rho^+ = \rho^b$ . If we want to be as cheap as possible while ensuring super-linear convergence ( $b > 1$ ), we deduce that  $b < \frac{2(1+c)}{3}$  while  $c \leq a$ . Therefore, to get super-linear convergence, one has to pick  $0.5 < c \leq a$ .

2) *Details for quadratic loss:* The proof of lemma 3.1 is very similar to the proof of the Lemma 3 in [2].

Now consider the effect of an inexact Newton correction.

*Lemma 3.3:* Let  $\hat{x}$  such that  $\|\hat{x} - x(\rho^+, 0)\| \sim \rho^{a+1}$ . Then,  $\Phi(\hat{x} + d_N, \rho^+) \sim \mathcal{O}\left(\frac{(\gamma + \rho^{(a+1)})^2}{\rho^+}\right)$ .

*Proof:* We write

$$\Phi(\hat{x} + d_N, \rho^+) = \Phi(\hat{x}, \rho^+) + \nabla_x \Phi(\hat{x}, \rho^+) d_N + \mathcal{O}\left(\frac{\|d_N\|^2}{\rho^+}\right), \quad (16)$$

The first two terms are bounded by  $\gamma$  and using the bound on  $d_N$  from the lemma 3.1 we get  $\frac{(\gamma + \rho^{(a+1)})^2}{\rho^+}$ .  $\blacksquare$

Consider  $\rho^+ = \rho^b$ . If we want to be as cheap as possible while ensuring super-linear convergence ( $b > 1$ ), we deduce that  $b < (1 + c)$  while  $c \leq a$ . Therefore, to get super-linear convergence, one has to pick  $0 < c \leq a$ .

### IV. HIGH ORDER VARIANTS

Instead of solving approximately the predictor and-or corrector steps, we investigate here the effect of using higher order Taylor expressions of the central path. We reformulate slightly the equations to parametrize the path with the scalars  $\rho$  and  $\tau$ . At the current point,

$$\Phi(x, \rho) = \tau \bar{r} \quad (17)$$

for some residual vector  $r = \tau \bar{r}$  with  $\bar{r} = \frac{r}{\|\bar{r}\|}$ . Equation Eq.(17) induces a bi-parameter equation  $x(\rho, \tau)$  and the solution searched for is  $x^* = x(0, 0)$ .

$$\begin{aligned} \hat{x}^1 &= x + \frac{\partial x}{\partial \rho}(\rho^+ - \rho) + \frac{\partial x}{\partial \tau}(-r) \\ \hat{x}^2 &= \frac{1}{2} \left( \frac{\partial^2 x}{\partial \rho^2}(\rho^+ - \rho)^2 + \frac{\partial^2 x}{\partial \rho \partial \tau}(\rho^+ - \rho)(-r) + \frac{\partial^2 x}{\partial \tau^2}(-r)^2 \right) \\ \hat{x}^p &= \sum_{j=0}^p \binom{p}{j} \frac{\partial^p x}{\partial \rho^{p-j} \partial \tau^j} (\bar{\rho}^+ - \bar{\rho})^{p-j} (-\bar{r})^j \end{aligned}$$

We are now concerned with higher order extrapolations  $\sum_{i=1}^a \hat{x}^i$  for  $a > 1$ . Postponing the actual computations of such a  $\hat{x}^a$  for  $a \neq 1$ , we already may obtain the following.

*Lemma 4.1:* Let  $\hat{x}$  such that  $\|\hat{x} - x(\rho^+, 0)\| \sim \rho^{a+1}$  with  $\frac{\rho^{a+1}}{\rho^+} < \infty$ . Then,  $\nabla \phi(\hat{x}, \rho^+) \sim \mathcal{O}\left(\frac{\rho^{a+1}}{\rho^+}\right)$ .

This result allows to claim that by using  $(a > 1)$ -order extrapolations, we get a  $\frac{(a+1)}{2}$  order of convergence without even recourse to Newton corrections, and this both for the log barrier and the quadratic loss variants. Using a first order extrapolation is not enough, and requires a further Newton correction. Indeed, to reach the required approximation criterion,

$\nabla\phi(\hat{x}, \rho^+)$  has to be lower than  $\|r^+\| = \rho^+$ , which implies that  $\rho^{a+1} < \rho^{+2}$ .

Observe in particular that a second order extrapolation ( $\hat{x}^1 + \hat{x}^2$ ) yields a predictor only algorithm achieving the limiting order  $\frac{3}{2}$ . This improves the exterior variant and even more so the interior variant since in this context, both interior and exterior variants share the same improved asymptotic behavior.

#### A. Proof of Lemma 4.1 for the log-barrier

*Proof:* Denote  $x = x(\rho^+, 0)$ ; then  $\Phi(x, \rho^+) = 0$  and write:

$$\begin{aligned}\Phi(\hat{x}, \rho^+) &= \Phi(\hat{x}, \rho^+) - \Phi(x, \rho^+) \\ &= \nabla\hat{f} - \nabla f + \sum \frac{\rho^+}{\hat{g}_i} \nabla\hat{g}_i - \sum \frac{\rho^+}{g_i} \nabla g_i \\ &= \mathcal{O}(\rho^{a+1}) + \sum \frac{\rho^+(g_i - \hat{g}_i)}{\hat{g}_i g_i} \nabla\hat{g}_i \\ &\quad + \sum \frac{\rho^+}{g_i} (\nabla\hat{g}_i - \nabla g_i) \\ &= \mathcal{O}(\rho^{a+1}) + \sum \frac{\mathcal{O}(\rho^{a+1})\rho^+}{\hat{g}_i g_i} \nabla\hat{g}_i \\ &\quad + \sum \lambda_i \mathcal{O}(\rho^{a+1}).\end{aligned}$$

We have  $g_i \sim \Theta(\rho^+)$  and  $\hat{g}_i = g_i + \mathcal{O}(\rho^{a+1})$ , so that  $\hat{g}_i \sim \Theta(\rho^+)$  since  $\frac{\rho^{a+1}}{\rho^+}$  is bounded. ■

#### B. Proof of Lemma 4.1 for the quadratic loss

*Proof:* Denote  $x = x(\rho^+, 0)$ ; then  $\Phi(x, \rho^+) = 0$  and write:

$$\begin{aligned}\Phi(\hat{x}, \rho^+) &= \Phi(\hat{x}, \rho^+) - \Phi(x, \rho^+) \\ &= \nabla\hat{f} - \nabla f + \sum \frac{\hat{g}_i}{\rho^+} \nabla\hat{g}_i - \sum \frac{g_i}{\rho^+} \nabla g_i \\ &= \mathcal{O}(\rho^{a+1}) + \frac{(g_i - \hat{g}_i)}{\rho^+} \nabla\hat{g}_i \\ &\quad + \sum \frac{g_i}{\rho^+} (\nabla\hat{g}_i - \nabla g_i) \\ &= \mathcal{O}(\rho^{a+1}) + \frac{\mathcal{O}(\rho^{a+1})}{\rho^+} \nabla\hat{g}_i \\ &\quad + \sum \lambda_i \mathcal{O}(\rho^{a+1}).\end{aligned}$$

We have  $g_i \sim \Theta(\rho^+)$  and  $\hat{g}_i = g_i + \mathcal{O}(\rho^{a+1})$ , so that  $\hat{g}_i \sim \Theta(\rho^+)$  since  $\frac{\rho^{a+1}}{\rho^+}$  is bounded. ■

### V. COMPUTING EXTRAPOLATIONS

The actual extrapolation computations for the quadratic loss function is presented in details in [3]. To avoid derivatives of the  $\frac{1}{\rho}$  factor involved in the penalty term, we resorted to primal-dual equations in [3]. We develop in this section the details for the high order derivatives for the log barrier.

We rewrite equation Eq.(10) in a simplified notation:

$$\Phi(x, \rho) = c - \rho A^t G^{-1} e. \quad (18)$$

For linear programs,  $c$  and  $A$  are constant while otherwise,  $c = \nabla f(x)$  and  $A = \nabla g(x)$ .  $G = \text{diag}(g_i(x))$ , and for linear programs,  $g(x) = Ax - b$ . We note for the sequel

$$\nabla_x \Phi(x, \rho) = \rho A^t G^{-2} A + \nabla_{xx}^2 l(x, \rho G(x)^{-1} e) \quad (19)$$

$$\nabla_\rho \Phi(x, \rho) = -A^t G^{-1} e \quad (20)$$

and remark that the Lagrangian term vanishes for linear programs.

The implicit function theorem yields

$$\begin{aligned}\nabla_x \Phi(x, \rho) \dot{x}_\rho + \nabla_\rho \Phi(x, \rho) &= 0 \\ \nabla_x \Phi(x, \rho) \dot{x}_\tau - \bar{\mathbf{r}} &= 0.\end{aligned} \quad (21)$$

Thus, the combined extrapolation step reduces to

$$\begin{aligned}\nabla_x \Phi(x, \rho) (\dot{x}_\rho (\rho^+ - \rho)) + \dot{x}_\tau (-\tau) \\ + \nabla_\rho \Phi(x, \rho) (\rho^+ - \rho) + \tau \bar{\mathbf{r}} &= 0,\end{aligned} \quad (22)$$

which, for this first order candidate, simplifies to  $\nabla_x \Phi(x, \rho) \hat{x}^1 + \Phi(x, \rho^+) = 0$ .

In order to go further to the expressions of higher order extrapolates, we first note the following for the log barrier case:

$$\begin{aligned}\nabla_{x\rho}^2 \Phi(x, \rho) = \nabla_{\rho x}^2 \Phi(x, \rho) &= A^t G^{-2} A + \nabla_{xx}^2 l(x, G(x)^{-1} e) \\ \nabla_{\rho\rho}^2 \Phi &\equiv 0 \\ \nabla_{\tau}^2 \Phi = \nabla_{\tau}^2 \Phi &\equiv 0\end{aligned}$$

In a nutshell, any derivative of  $\Phi$  with respect to  $\tau$  vanishes since  $\Phi$  does not involve  $\tau$ , and any high order derivative of  $\Phi$  with respect to  $\rho$  more than once also vanishes since  $\Phi$  is linear in  $\rho$ .

Now, still using the implicit function theorem, this time to equations Eq.(21), we get the following, in which we use  $\Phi$  without arguments as a shorthand notation for  $\Phi(x, \rho)$ :

$$\begin{aligned}\nabla_{xx}^2 \Phi \dot{x}_\rho \dot{x}_\rho + (\nabla_{x\rho}^2 \Phi + \nabla_{\rho x}^2 \Phi) \dot{x}_\rho + \nabla_x \Phi \ddot{x}_{\rho\rho} &= 0 \\ \nabla_{xx}^2 \Phi \dot{x}_\tau \dot{x}_\rho + \nabla_{\rho x}^2 \Phi \dot{x}_\tau + \nabla_x \Phi \ddot{x}_{\tau\rho} &= 0 \\ \nabla_{xx}^2 \Phi \dot{x}_\rho \dot{x}_\tau + \nabla_{x\rho}^2 \Phi \dot{x}_\tau + \nabla_x \Phi \ddot{x}_{\rho\tau} &= 0 \\ \nabla_{xx}^2 \Phi \dot{x}_\tau \dot{x}_\tau + \nabla_x \Phi \ddot{x}_{\tau\tau} &= 0\end{aligned} \quad (23)$$

Observe that the four relations above all imply a linear system defined by the same matrix  $\nabla_x \Phi(x, \rho)$  and the following four right hand sides, conveniently expressed using  $\bar{x}_\tau$  which denotes a constant vector of value  $\dot{x}_\tau$ , and similarly  $\bar{x}_\rho$  is a constant vector of value  $\dot{x}_\rho$ :

$$\nabla_\rho (\nabla_x \Phi \bar{x}_\rho + \nabla_\rho \Phi) = \nabla_{xx}^2 \Phi \dot{x}_\rho \bar{x}_\rho + \nabla_{x\rho}^2 \Phi \bar{x}_\rho + \nabla_{\rho x}^2 \Phi \dot{x}_\rho \quad (24)$$

$$\nabla_\tau (\nabla_x \Phi \bar{x}_\rho + \nabla_\rho \Phi) = \nabla_{xx}^2 \Phi \dot{x}_\tau \bar{x}_\rho + \nabla_{\rho x}^2 \Phi \dot{x}_\tau \quad (25)$$

$$\nabla_\rho (\nabla_x \Phi \bar{x}_\tau - \bar{\mathbf{r}}) = \nabla_{xx}^2 \Phi \dot{x}_\rho \bar{x}_\tau + \nabla_{x\rho}^2 \Phi \bar{x}_\tau \quad (26)$$

$$\nabla_\tau (\nabla_x \Phi \bar{x}_\tau - \bar{\mathbf{r}}) = \nabla_{xx}^2 \Phi \dot{x}_\tau \bar{x}_\tau \quad (27)$$

Hereafter, we use the ‘‘bar’’  $\bar{\rho}$  and  $\bar{\tau}$  to represent actual extrapolation steps values, as opposed to variables within the equations. Now,  $\hat{x}^2 = \ddot{x}_{\rho\rho} (\bar{\rho}^+ - \bar{\rho})^2 + 2\ddot{x}_{\tau\rho} (\bar{\rho}^+ - \bar{\rho}) (-\bar{\tau}) + \ddot{x}_{\tau\tau} (\bar{\tau})^2$  so that the right hand sides involving the second derivatives may be combined into  $(\bar{\rho}^+ - \bar{\rho}) ((\bar{\rho}^+ - \bar{\rho}) Eq.(24) - \bar{\tau} Eq.(26))$

and  $-\bar{\tau}((\bar{\rho}^+ - \bar{\rho})Eq.(25) - \bar{\tau}Eq.(27))$  and, also using the notation that  $\hat{x}^1$  is a constant vector of value  $\hat{x}^1$ , is expressed:

$$\begin{aligned} & \nabla_{\rho} (\nabla_x \Phi(x, \rho) \hat{x}^1 + \nabla_{\rho} \Phi(x, \rho) (\bar{\rho}^+ - \bar{\rho}) - \bar{\mathbf{r}} \bar{\tau}) (\bar{\rho}^+ - \bar{\rho}) \\ & + \nabla_{\tau} (\nabla_x \Phi(x, \rho) \hat{x}^1 + \nabla_{\rho} \Phi(x, \rho) (\bar{\rho}^+ - \bar{\rho}) - \mathbf{r} \bar{\tau}) (-\bar{\tau}) \end{aligned} \quad (28)$$

To establish a recurrence relation to compute the  $\hat{x}^p$ , it is convenient to define a family of functions

$$\Phi^0(x, \rho, \tau) = \Phi(x, \rho) - \tau \bar{\mathbf{r}} \quad (29)$$

$$\Phi^p(x, \rho, \tau) = (\bar{\rho}^+ - \bar{\rho}) \nabla_{\rho} \Phi^{p-1}(x, \rho, \tau) - \bar{\tau} \nabla_{\tau} \Phi^{p-1}(x, \rho, \tau) \quad (30)$$

*Theorem 5.1:*

$$\hat{x}^p = \sum_{j=0}^p \binom{p}{j} \frac{\partial^p x}{\partial \rho^{p-j} \partial \tau^j} (\bar{\rho}^+ - \bar{\rho})^{p-j} (-\bar{\tau})^j$$

satisfies  $\nabla_x \Phi(x, \rho) \hat{x}^p + \Phi^p(x, \rho, \tau) = 0$ .

*Proof:* The inductive proof has its base verified by the relation Eq.(28). The induction step will use the relation:

$$\hat{x}^{p+1} = \frac{\partial \hat{x}^p}{\partial \rho} (\bar{\rho}^+ - \bar{\rho}) + \frac{\partial \hat{x}^p}{\partial \tau} (-\bar{\tau})$$

The equations  $\Phi^p$  includes a term  $\nabla_x \Phi(x, \rho) \hat{x}^p$  defining the linear system, the remaining of  $\Phi^p$  corresponding to the right hand side of the linear equation. ■

The recurrence  $\Phi^p$  may be explicitly written as

$$\nabla_x \Phi(x, \rho) \hat{x}^p + \hat{\Phi}^p$$

where  $\hat{\Phi}^p$  involves terms of the form  $\nabla_{x^j \rho^j \tau^j} \Phi(x, \rho) v_1^{i_1} v_2^{i_2} \dots v_l^{i_l}$  with  $\sum_{k=1}^l i_k = j$ ,  $j_x + j_{\rho} = j$  and  $1 < j \leq p$ . Moreover, each  $v_k$  is composed of partial derivatives of  $x$  with respect to  $\rho$  and/or  $\tau$  up to order  $j_x - 1$ . As it happens, the recurrence may be written using only the  $\hat{x}^p$  without explicit reference to the (mixed) partials derivatives of  $x$  wrt  $\rho$  or  $\tau$ :

$$\Phi^0(x, \rho, \tau) = \Phi(x, \rho) + \tau \bar{\mathbf{r}} \quad (31)$$

$$\Phi^1(x, \rho, \tau) = \nabla_x \Phi(x, \rho) \hat{x}^1 + (\bar{\rho}^+ - \bar{\rho}) \nabla_{\rho} \Phi(x, \rho) + \bar{\mathbf{r}} \bar{\tau} \quad (32)$$

$$\begin{aligned} \Phi^2(x, \rho, \tau) = & \nabla_x \Phi(x, \rho) \hat{x}^2 + 2(\bar{\rho}^+ - \bar{\rho}) \nabla_{x\rho}^2 \Phi(x, \rho) \hat{x}^1 \\ & + \nabla_{xx}^2 \Phi(x, \rho) \hat{x}^1 \hat{x}^1 \end{aligned} \quad (33)$$

$$\begin{aligned} \Phi^3(x, \rho, \tau) = & \nabla_x \Phi(x, \rho) \hat{x}^3 + 3(\bar{\rho}^+ - \bar{\rho}) \nabla_{x\rho}^2 \Phi(x, \rho) \hat{x}^2 \\ & + 3 \nabla_{xx}^2 \Phi(x, \rho) \hat{x}^1 \hat{x}^2 \\ & + 3(\bar{\rho}^+ - \bar{\rho}) \nabla_{xx\rho}^3 \Phi(x, \rho) \hat{x}^1 \hat{x}^1 \\ & + \nabla_{xxx}^3 \Phi(x, \rho) \hat{x}^1 \hat{x}^1 \hat{x}^1 \end{aligned} \quad (34)$$

$$\begin{aligned} \Phi^4(x, \rho, \tau) = & \nabla_x \Phi(x, \rho) \hat{x}^4 + 4(\bar{\rho}^+ - \bar{\rho}) \nabla_{x\rho}^2 \Phi(x, \rho) \hat{x}^3 \\ & + 3 \nabla_{xx}^2 \Phi(x, \rho) \hat{x}^2 \hat{x}^2 \\ & + 4 \nabla_{xx}^2 \Phi(x, \rho) \hat{x}^1 \hat{x}^3 \\ & + 12(\bar{\rho}^+ - \bar{\rho}) \nabla_{xx\rho}^3 \Phi(x, \rho) \hat{x}^1 \hat{x}^2 \\ & + 6 \nabla_{xxx}^3 \Phi(x, \rho) \hat{x}^2 \hat{x}^1 \hat{x}^1 \\ & + 4(\bar{\rho}^+ - \bar{\rho}) \nabla_{xxx\rho}^4 \Phi(x, \rho) \hat{x}^1 \hat{x}^1 \hat{x}^1 \\ & + \nabla_{xxxx}^4 \Phi(x, \rho) (\hat{x}^1)^4 \end{aligned} \quad (35)$$

*1) Implementation for linear programming:* By introducing the notation  $v^1 = A\hat{x}^1$ , and  $V = \text{diag}(v)$ , we may express the high order terms using the following lemma.

*Lemma 5.2:*

$$\nabla_x (v^t V_{\rho} G^{-p} u) = -p A^t V V_{\rho} G^{-(p+1)} u \quad (36)$$

This allows to write equation Eq.(33) as

$$\rho A^t G^{-2} A \hat{x}^2 - 2\rho A^t V^1 G^{-3} v^1 + 2(\bar{\rho}^+ - \bar{\rho}) A^t G^{-2} v^1 = 0 \quad (37)$$

Similarly, equation Eq.(34) leads to the following expression:

$$\begin{aligned} & -6\rho A^t V^1 G^{-3} v^2 - 6(\bar{\rho}^+ - \bar{\rho}) A^t V^1 G^{-3} v^1 \\ & + 3(\bar{\rho}^+ - \bar{\rho}) A^t G^{-2} v^2 + 6\rho A^t (V^1)^2 G^{-4} v^1 \end{aligned} \quad (38)$$

As we may observe, each term involves a single matrix–vector computation in addition to several  $\mathcal{O}(n)$  diagonal matrices and vector operations, overall yielding cheap right hand sides to compute higher order derivatives. This was to be expected.

*2) General implementation using automatic differentiation (AD):* Using AD tools, we may evaluate higher order derivative cheaply too. Assuming full dense Hessian’s—constraint jacobians, the linear system requires  $\mathcal{O}(n^3)$  arithmetic operations to factorizes, and further on, back–front substitutions together with right hand side computations reduce to  $\mathcal{O}(n^2)$  arithmetic operations. As it happens, we may get the high order right hand sides required for the Taylor coefficients in  $\mathcal{O}(n^2)$  complexity, leaving the main burden to obtain and factorize the Jacobian Matrix.

## VI. SHAMANSKII INSPIRED EXTRAPOLATIONS

In the context of unconstrained optimization using Newton’s method, reusing the Hessian matrix is closely related to Shamanskii’s method, sometimes refered to as composite Newton method. Shamanskii’s consists in reusing the Hessian two or more times; this is interesting since factorizing the Hessian has a much superior computational cost than using the factorization to solve a linear system. From an asymptotic point of view, then, high order extrapolations (reminiscent of Chebychev method) or Shamanskii method share the same improvement with respect to the convergence order. The simplicity of Shamanskii’s approach is appealing.

We will provide a Shamanskii approximation to the second order extrapolation. This yields an approximate second order predictor algorithm reaching the limiting convergence order  $\frac{3}{2}$ .

We analyze the following scheme.

$$\begin{aligned} \nabla_x \Phi(x, \rho) \tilde{x}^1 + \Phi(x, \rho^+) & = 0 \\ \nabla_x \Phi(x, \rho) \tilde{x}^2 + \Phi(x + \tilde{x}^1, \rho^+) & = 0 \end{aligned}$$

Thus, we reuse  $\nabla_x \Phi(x, \rho)$  and only change the right hand sides. We recognize that  $\tilde{x}^1 = \hat{x}^1$  previously defined.

*Proposition 6.1:* The second order  $\tilde{x}^2$  is an  $\mathcal{O}(\rho^3)$  approximation to the second order extrapolation  $\hat{x}^1 + \hat{x}^2$ .

*Proof:* We express the right hand side using a Taylor expansion. All the terms in the right hand side are functions evaluated at  $x$  and  $\rho$ , and thus the various  $\Phi(x, \rho)$  will be shorthanded to  $\Phi$ .

$$\begin{aligned} \Phi(x + \tilde{x}^1, \rho^+) &= \Phi \\ &+ \nabla_x \Phi \tilde{x}^1 + \nabla_\rho \Phi (\rho^+ - \rho) \end{aligned} \quad (39)$$

$$+ \nabla_{xx}^2 \Phi \tilde{x}^1 \tilde{x}^1 \quad (40)$$

$$+ 2 \nabla_{x\rho}^2 \Phi \tilde{x}^1 (\rho^+ - \rho) \quad (41)$$

$$+ \nabla_{\rho\rho}^2 \Phi (\rho^+ - \rho)^2 \quad (42)$$

$$+ \mathcal{O}(\max(\tau, \rho)^3)$$

Now, we already have seen that  $\nabla_{\rho\rho}^2 \Phi = 0$ , and by the definition of  $\tilde{x}^1$ , Eq.(39) vanishes, which yields that  $\hat{x}^2$  Eq.(33) and  $\tilde{x}^2$  Eq.(40) and Eq.(41) differ by  $\mathcal{O}(\rho^3)$ . ■

The second order Shamanskii direction is thus a suitable approximation of the second order extrapolation. The conclusion of the lemma 4.1 then still holds.

*Corollary 6.2:*  $\nabla \phi(\tilde{x}^2, \rho^+) \sim \mathcal{O}(\frac{\rho^3}{\rho^+})$

The process may be continued,

$$\nabla_x \Phi(x, \rho) \tilde{x}^3 + \Phi(x + \tilde{x}^1 + \tilde{x}^2, \rho^+) = 0,$$

and in general,

$$\nabla_x \Phi(x, \rho) \tilde{x}^{p+1} + \Phi(x + \sum_{i=1}^p \tilde{x}^i, \rho^+) = 0.$$

We conjecture that the  $\tilde{x}^p$  may be used and preserve the good properties of the  $\sum_{i=1}^p \hat{x}^i$ .

## VII. NUMERICAL ILLUSTRATION

We now provide a simple numerical example to exhibit the benefits of using a Shamanskii like extrapolation.

We consider the simple example

$$\begin{aligned} \min_{x \in \mathbb{R}^6} \quad & f(x) = \sum_{i=1}^6 ix^i \\ \text{s.t.} \quad & g_1(x) = (x_1 + x_3 + x_5)^2 - 1 = 0 \\ & g_2(x) = (x_2 + x_3 + x_4)^2 - 1 = 0 \\ & g_3(x) = x_1 x_6 - 1 = 0 \end{aligned}$$

We use the quadratic penalty function. Therefore, we hope two-steps superlinear convergence almost quadratic using a first order extrapolation and almost  $\frac{3}{2}$  convergence order using a Shamanskii variant. The two steps in the first order variant require factorization and solution of two distinct linear systems while the Shamanskii variant uses a single factorization to solve two related linear systems.

We compare a sub- $\frac{3}{2}$  sequence  $\rho_k$  using both a first order extrapolation and a Shamanskii-2 extrapolation. We may observe in table I that the extrapolation does not require any Newton correction for the last four two-steps extrapolations.

In the tables, the first 7 iterations are identical and thus are omitted. We observe that the first order variant requires a few more iterations to reach our (tight) tolerance.

The first order variant could be improved by considering a sub-quadratic sequence for  $\rho_k$ , and we exhibit the results in table III. The first 13 iterations are identical with those from table II, and we confirm that overall, this variant betters the slower sequence  $\rho_k$ , but the Shamanskii variant is still the most efficient. The limiting order when considering two factorizations is quadratic for the linear extrapolation and  $\frac{9}{4}$  for the Shamanskii version, which is coherent with our example.

As a final remark regarding this simple illustration, the quadratic penalty using Shamanskii strategy benefits much less than log-barrier algorithms. Nevertheless, our example suggests that it (Shamanskii) may improve upon the plain first order extrapolation.

## VIII. CONCLUSION AND FUTURE WORK

In this paper, we summarized known results about the asymptotic behavior of SUMT algorithms in non-linear optimization. We considered both interior and exterior penalty variants. Overall, exterior variants enjoy better asymptotic properties.

As can be seen from the table, interior variants suffer from poorer asymptotic convergence order. In particular, for the inexact predictor-corrector strategy, one has to impose  $c > 0.5$  i.e. the residual of the extrapolation and the Newton correction has to be reduced to an order at least 1.5 merely to provide an overall two-steps superlinear behavior. The exterior variant is somewhat more forgiving in this context.

High order predictors make interior and exterior approaches competitive. Actually, the use of higher order predictors allow to bypass any Newton corrector step asymptotically, and for both the interior and exterior variant, allow to reach the same order of convergence limit, namely  $\frac{k+1}{2}$  for order  $k > 1$  extrapolates.

Nwt	18	1.8e-01	5.6e-14	1.7e-11
Nwt	19	3.1e-02	5.6e-14	4.8e-15

It should be recalled that order- $k$  predictor incur a computational cost of  $\mathcal{O}(n^3)$  arithmetic operation to factorize the jacobian matrix plus  $k$  times  $\mathcal{O}(n^2)$  to obtain the high order terms while the corrector steps involve the solution of a linear system, again  $\mathcal{O}(n^3)$ . Therefore, from a complexity per iteration point of view, high order predictors are far preferable to their first order predictor-corrector counterpart: they require only one  $\mathcal{O}(n^3)$  factorization and  $k$   $\mathcal{O}(n^2)$  substitutions while

the first order approach requires two  $\mathcal{O}(n^3)$  factorization and two  $\mathcal{O}(n^2)$  substitutions.

The results presented suggest that the use of the Shamanskii approximation to the higher order trajectory derivatives is a simple solution to reach good asymptotic convergence properties, equivalently good for interior and exterior variants of SUMT. This contrasts with the usage of a simple extrapolation, or approximate computations of the predictor and corrector steps.

The analysis may be combined into a mixed penalty approach to treat programs involving both equality constraints and inequalities. This new strategy outperforms (from an asymptotic analysis point of view) previous studies using mixed interior and exterior penalties. The analysis also may be applied to the exponential penalty as well as other variations.

Future works will involve implementation and comparisons with primal-dual methods. Primal-dual interior point methods have very good convergence properties, but require skill to ensure global convergence while exhibiting good asymptotic behavior.

TABLE IV  
LIMITING CONVERGENCE ORDERS FOR VARIANTS DISCUSSED IN THE PAPER

**Abstract**—A thorough numerical assessment of Finite Difference Time Domain and Complex-Envelope Alternating-Direction-Implicit Finite-Difference-Time-Domain Methods has been carried out based on a basic single mode Plane Optical Waveguide structure. Simulation parameters for both methods were varied and the impact on the performance of both numerical methods is investigated.

## I. INTRODUCTION

DIFFERENT numerical modelling techniques have been proposed in literature to analyse optical and photonic devices, such as Beam Propagation method (BPM) [1], Finite-Element-Time-Domain (FETD) method [2] and Finite-Difference-Time-Domain [3] method. The Finite Difference Time Domain (FDTD) is a very popular method mainly because of its ability to simulate ultra-complicated structures in a very simple and straightforward manner. However, as main drawback, FDTD requires high computational resources due to Courant criterion which limits the time step size in order to preserve the numerical stability of the scheme. As an efficient alternative to FDTD, Complex-Envelope Alternating-Direction-Implicit Finite-Difference-Time-Domain (CE-ADI-FDTD) method [4] has been proposed in literature. The main advantage of CE-ADI-FDTD is the time step sizes not bounded by the Courant criterion making virtually possible to employ larger time step sizes with low impact on accuracy and great saving in terms of computational resources. But the approach proposed in [4] has been proven to suffer from numerical instability due to the Absorbing Boundary Conditions (ABCs) [4]-[7]. This instability affects the maximum time step size that is possible to use in order to maintain the scheme stable limiting the numerical efficiency of the method itself. In [5], an improved formulation of the ABCs has been implemented in the context of CE-ADI-FDTD making the numerical scheme stable even for very large time step sizes. The focus in this paper is to assess and investigate the performance of FDTD and CE-ADI-FDTD methods against Courant,

Friederich, Levy Criterion (CFL) and different parameters of Uniaxial Perfectly Matched Layer (UPML). Parameters such as geometric coefficient (g), number and size of PML cells were varied for a number of simulations and the obtained results are presented in this paper.

## II. ASSESSMENT OF FDTD METHOD

A simple waveguide structure shown in Fig. 1 is simulated using the developed FDTD code to investigate the performance of the FDTD method. As shown in this figure, the refractive indices of the core and cladding are 3.2 and 1, respectively. The structure is discretised into a uniform mesh and is terminated by 20 cells UPML to absorb the reflected power. To ensure the single mode propagation at 1.55 $\mu\text{m}$  wavelength, the width (W) of the waveguide chosen to be 0.2 $\mu\text{m}$ . All the results for the reflected power are obtained by injecting a source-field along the transverse x direction, modulated at wavelength 1.55 $\mu\text{m}$  and 5-fs wide Gaussian pulse. The source-fields for TE and TM used is presented by the equations given below;

$$E_{z_{i,j}}^{n+1} = E_{z_{i,j}}^n \phi_j \sin(2\pi f n \Delta t) e^{((n\Delta t - 3T)/T)^2} \quad (1a)$$

$$H_{z_{i,j}}^{n+1} = H_{z_{i,j}}^n \phi_j \sin(2\pi f n \Delta t) e^{((n\Delta t - 3T)/T)^2} \quad (1b)$$

As shown in Fig. 1, the detector point is labelled as D1 to record the incident and the reflected power inside the waveguide. Once the incident and reflected power recorded in D1, the ratio of FFT of the reflected to incident field is calculated to compute the spectrum variation of the reflected power coefficient.

As shown in Fig. 1, the reference point is labelled as D1 to record the incident field transmitted and reflected power from the PML inside the waveguide, respectively. Once the transmitted power reaches the output terminal of the waveguide, the ratio of FFT of the reflected to incident field is calculated to compute the spectrum variation of the reflected power coefficient.

Fig. 1 Basic single mode waveguide, width ( $W$ ) =  $0.2\mu\text{m}$  and refractive index,  $n=3.2$

#### A. Assessment of FDTD against Courant, Friederich, Levy Criterion (CFL)

In order to investigate the effect of CFL criterion on the performance of the FDTD, the waveguide structure, shown in Fig. 1 is simulated using the developed FDTD code. The TE-mode and TM-mode source field given by equations (1a) and (1b) are injected inside the waveguide along the transverse  $x$  direction [8], modulated at wavelength  $1.55\mu\text{m}$  and  $5\text{-fs}$  wide. At the first simulation  $\Delta t$  chosen to be larger than the CFL criterion and the structure is discretised into a uniform mesh with cell size of  $20\text{nm}$ .  $\Delta t$  used in the simulation can be calculated as follows;

$$\Delta t > \frac{1}{c \sqrt{\frac{1}{(\Delta x)^2} + \frac{1}{(\Delta y)^2}}} \quad (2)$$

Based on the parameters stated above, field profile shown in Fig. 2 is obtained. As it may be observed from the Figure, the field profile inside the waveguide is unstable and constantly increases as the time step increases. As a result of this stability problem, the propagation of the field profile inside the waveguide can not be simulated. The FDTD code has been tested when  $\Delta t > 2 * (\Delta t)_{\text{CFL}}$ , and  $\Delta t > 3 * (\Delta t)_{\text{CFL}}$  and it has been observed that field profile is extremely unstable when CFL criterion not applied. On other words FDTD is absolutely useless to simulate wave propagation if CFL criterion is not applied.

The simulation parameters modified and  $\Delta t$  chosen to be less than  $(\Delta t)_{\text{CFL}}$  and the obtained result is presented in Fig. 3. As it may be observed that the field profile presented in Fig. 3 represents a Gaussian pulse which is given by the equation (1) and therefore a stable field profile will propagate inside the waveguide and the transmitted and reflected power can be observed along the waveguide.

#### B. Assessment of UPML Reflection.

For further assessment of the FDTD scheme, the reflected power coefficient of the UPML is investigated for both TE-mode and TM mode. In order to investigate

Fig. 2: Time variation of the electric field recorded at point detector D1 inside the waveguide presented in Fig. 1, when

$$\Delta t > (\Delta t)_{\text{CFL}}$$

Fig. 3 Time variation of the electric field recorded at point detector D1 inside the waveguide presented in Fig. 1, when

$$\Delta t < (\Delta t)_{\text{CFL}}$$

the effect of the scaling factor ( $g$ ) on the reflected power coefficient, the structure presented in Fig.1 is simulated for three different values of scaling factor ( $g$ ) for both TE and TM mode of propagation. The central wavelength,  $\lambda$  is  $1.55\mu\text{m}$ , the size of discretisation cell ( $\Delta x$  and  $\Delta y$ ) are  $30\text{nm}$ , and the number of UPML cells is 20.

As it may be observed from Fig. 4a, the reflected power coefficient for TE-mode is obtained for a different scaling factor,  $g=1.5$ ,  $2.5$  and  $3.5$ . The reflected power coefficients obtained are about  $-37\text{dB}$ ,  $-25\text{dB}$  and  $-19\text{dB}$ , respectively. From the obtained results, it can be observed that minimum reflected power coefficient is obtained when  $g$  is equal to  $1.5$  and therefore this figure is considered for the rest of the simulations in this research study.

Fig. 4a: Variation of UPML reflected power coefficient for TE-Mode against the wavelength for three different values of “g” at central wavelength 1.55µm.

Similarly, the reflected power coefficients for TM-mode are obtained for the same values of (g) and as presented in Fig. 4b, the values of the reflected power coefficients obtained for TM-mode are about -40dB, -30dB and -27dB respectively. From both figures it can be observed that the reflected power coefficient for both propagation modes ( TE and TM ) is very low and the UPML gives a higher performance when the scaling factor (g) chosen around 1.5 and therefore this figure is considered for the rest of the simulations.

Fig. 4b: Variation of UPML reflected power coefficient for TM-Mode against the wavelength for three different values of “g” at central wavelength 1.55µm.

For further assessments of the reflected power coefficient of UPML for both TE and TM mode of propagation, the structure presented in Fig. 1 is simulated for 10, 20, 30 and 40 UPML cells. The central wavelength, λ is 1.55µm, the size of discretisation cell ( Δx = Δy=30nm), and the scaling factor ( g ) is 1.5. As it may be observed from Fig. 5a, the lowest reflected power

coefficient or TE-mode is obtained when number of UPML cells used is 20, 30 and 40. The reflected power coefficient obtained is about (-38dB). The highest reflected power coefficient is obtained when 10 UPML cells are used and the obtained is about (-20dB).

Fig. 5a: Variation of UPML reflected power coefficient of TE-Mode against wavelength, λ when the number of UPML cells is a parameter

When the number of UPML cells increased the UPML layers thickness increases and the ability to absorb incident power on the boundaries increases, this improves the performance of the UPML layer and minimise the reflected power from the UPML boundaries. Similarly, the reflected power coefficients for TM-mode are obtained for the same numbers of UPML cells. As presented in Fig. 5b, the values of the reflected power coefficient are slightly different from TE-mode. When the number of UPML cells used is 20, 30 and 40 reflected power coefficient is slightly below (-40db) and when UPML cells chosen to be 10, the reflected power coefficient obtained about (-35dB). Overall the reflection ratios for both TE and TM propagation mode are very low and this will help the accuracy of the results obtained by the simulations in more complex structures.

For further investigation the structure presented in Fig. 1 is simulated using different sizes of discretisation cell (Δx = Δy) at central wavelength, λ is 1.55µm and the scaling factor, g is 1.5. As it may be observed from Fig. 6a, Δx and Δy values used in the simulations are 10, 20 and 30 nm and the obtained reflected power coefficients are -28dB, -35dB and -39dB respectively. Experimentally Δx and Δy need to < 0.05a. Generally, for the TE-mode the reflected power coefficients for the three different values of Δx and Δy are very low. However it can be concluded that the reflected power coefficients are inverse proportional to the size of the discreti-

Fig. 5b: Variation of UPML reflected power coefficient for TM-Mode against the wavelength,  $\lambda$  when the number of UPML cells is a parameter.

sation cell, in other words the larger the cell the lowest the reflected power coefficients.

Fig. 6a: Variations of UPML reflected power coefficient of TE-Mode against wavelength,  $\lambda$  when  $\Delta x$  and  $\Delta y$  size is a parameter.

Fig. 6b presents the variation of reflected power coefficient with the wavelength for different values of discretisation cells. As it may be observed from the graphs, when  $\Delta x$  and  $\Delta y$  value is 10 nm, the reflected power coefficient reaches the lowest value (-40dB) at the central wavelength,  $\lambda$  is 1.55 $\mu\text{m}$ , when  $\Delta x$  and  $\Delta y$  value is 30 nm, the reflected power coefficient at the central wavelength is about - reflected power coefficient 40dB, however it reaches the lowest value (-50dB) at the wavelength,  $\lambda$  is 1.55 $\mu\text{m}$ . Meanwhile, when  $\Delta x$  and  $\Delta y$  value is 20 nm, the is about -36dB and similar cross the bandwidth.

### III. ASSESSMENT OF CE-ADI-FDTD METHOD.

The same waveguide structure presented in Fig. 1 is simulated using the developed CE-ADI-FDTD code to

Fig. 6b: Variations of UPML reflected power coefficient of TM-Mode against the wavelength,  $\lambda$  when  $\Delta x$  and  $\Delta y$  size is a parameter.

investigate the performance of the CE-ADI-FDTD method. As shown in this figure, the refractive indices of the core and cladding are 3.2 and 1, respectively. The structure is discretised into a uniform mesh and is terminated by 20 cells PML to absorb the reflected power. To ensure the single mode propagation at 1.55 $\mu\text{m}$  wavelength, the width of the waveguide is chosen to be 0.2 $\mu\text{m}$ .

#### A. Assessment of CE-ADI-FDTD against CFL Criterion.

In order to investigate the effect of CFL criterion on the performance of the CE-ADI-FDTD, the waveguide structure presented in Fig. 1 is simulated using the developed FDTD code. The TE-mode source-field given by equation (1a) injected inside the waveguide along the transverse  $x$  direction, modulated at wavelength 1.55 $\mu\text{m}$  and 5-fs wide. The structure is discretised into a uniform mesh with cell size of 20nm.

For the first simulation,  $\Delta t$  chosen to be ten times larger than the CFL criterion, ( $\Delta t = 10(\Delta t)_{CFL}$ ) and the structure is discretised into a uniform mesh with cell size of 20nm. Based on the parameters stated above the CE-ADI-FDTD tested for ( $\Delta t = 10(\Delta t)_{CFL}$ ) and ( $\Delta t = 30(\Delta t)_{CFL}$ ) and the field profile shown in Fig. 7 is obtained. As it may be observed from the Figure, the field profile inside the waveguide is very stable and the CFL criterion is completely eliminated. Furthermore the same structure simulated with  $\Delta t$  chosen to be less than the CFL criterion, ( $\Delta t = 0.9(\Delta t)_{CFL}$ ) and the obtained field profile shown in Fig. 8 is very stable.

Fig. 7: Time variation of the envelopes of the electric field recorded at point detector D1 inside the waveguide presented in Fig. 1, when  $\Delta t > (\Delta t)_{CFL}$

Fig. 8: Time variation of the envelopes of the electric field recorded at point detector D1 inside the waveguide presented in Fig. 1, when  $\Delta t < (\Delta t)_{CFL}$

*B. Assessment of PML Reflection*

For further assessment of the CE-ADI-FDTD scheme, the reflected power coefficient of the PML is investigated for TE-mode. In order to investigate the effect of the scaling factor ( $g$ ) on the reflected power coefficient, the structure presented in Fig. 1 is simulated for three different values of scaling factor ( $g$ ). The central wavelength,  $\lambda$  is  $1.55\mu\text{m}$ , the size of discretisation cell,  $\Delta x$  and  $\Delta y$  is  $30\text{nm}$ , and the number of PML cells is  $20$ . As it may be observed from Fig. 9, that the lowest reflected power coefficient obtained when the scaling factor ( $g$ ) is equal to  $1.5$ , it is about  $(-50\text{dB})$ .

In order to investigate the effect of time step ( $\Delta t$ ) on the reflected power coefficient, the structure presented in Fig. 1 simulated for three different values of  $\Delta t$ . The central wavelength,  $\lambda$  is  $1.55\mu\text{m}$ , the size of discretisation cell,  $\Delta x$  and  $\Delta y$  is  $30\text{nm}$ , and the number of PML cells is  $=20$ . It may be observed from Fig. 10 the reflected power coefficients obtained for three different values of  $\Delta t$  are about the same and therefore it may be

Fig. 9: Variations of PML reflected power coefficient of TE-Mode against the wavelength for three different values of “ $g$ ” at central wavelength  $1.55\mu\text{m}$ .

concluded that using a large  $\Delta t$  value it will have no major impact on the accuracy of the CE-ADI-FDTD scheme.

Fig. 10: Variations of PML reflected power coefficients with the wavelength for different values of  $\Delta t$  at central wavelength  $1.55\mu\text{m}$ .

Furthermore, the same structure presented in Fig. 1 is simulated to investigate the effect of the size of the discretisation cells on the reflected power coefficient. Discretisation cells in  $x$  and  $y$  direction are chosen to be equal and the structure simulated three times using cell size  $10, 20$  and  $30\text{nm}$ . As it may be observed from Fig. 11, the lowest value of reflected power coefficient obtained is about  $-55\text{dB}$  when the cell size is  $20\text{nm}$ .

IV. CONCLUSION

In this paper a number of simulations have been carried out in order to investigate the performance of the FDTD and CE-ADI-FDTD for different simulation parameters such as, Courant, Friederich, Levy Criterion, scaling factor ( $g$ ), size and number of discretisation cells. From the simulation results presented can be observed that the applying of Courant, Friederich, Levy

Fig. 11: Variations of PML reflected power coefficients with the wavelength for different values of  $\Delta x$ ,  $\Delta y$  at central wavelength  $1.55\mu\text{m}$

Criterion has a big impact on the stability of the simulation in FDTD method but has no impact on CE-ADI-FDTD in terms of stability. The scaling factor ( $g$ ), cell size and thickness of PML layer have an impact on the reflected power coefficient for both FDTD and CE-ADI-FDTD and have to be selected carefully.

**Abstract**—Conjoint Analysis is heavily used in many different areas: from mathematical psychology, economics and marketing to sociology, transportation and medicine trying to understand how individuals evaluate products/services and as well as on predicting behavioral outcomes by using statistical methods and techniques. Nowadays is not much agreement about best practice, which in turn has led to many flavors of CA being proposed and applied. The goal of this paper is to offer a solution to perform Adaptive Conjoint Analysis inside CQQL, a quantum logic based information framework. We describe an algorithm to compute a logical CQQL formula capturing user preferences and use this formula to derive decision rules.

## I. INTRODUCTION AND MOTIVATION

NOWADAYS, the term *Conjoint Analysis* (CA) is used in many different ways. While in the past it was mostly on the interest of marketers and psychologists, today's variants are used in many fields including applied economics, sociology, transportation and medicine. The origins of Conjoint Analysis come from developments in several disciplines, most notably economics ([27], [26]) and mathematical psychology ([30], [31], [2]).

Much of the Conjoint Analysis work was used trying to understand how individuals evaluate products/services and form preferences (see, [18], [22], [33] and possibly others). In the last thirty years the CA literature focused more on predicting behavioral outcomes by using statistical methods and techniques ([3]) and this resulted in a widespread variation in CA practice. Recently, applications in innovation market were developed ([4]). The result today is that there is not much agreement about best practice, which in turn has led to many flavors of CA being proposed and applied.

The regular case involves a compositional model (see [17], [20], [16]) where the respondents provide the necessary information to be able to compute *local utilities*. Various ACA interpretations define a *conjoint*(or *utility*) function  $U$  that aggregates the local utilities to an *overall utility* i.e., if  $o$  is

This work is supported by German Federal Ministry of Education and Research, ForMaT project (Forschung für den Markt im Team), Phase II, Innovationslabor: Multimediale Ähnlichkeitssuche zum Matchen, Typologisieren und Segmentieren, <http://www.unternehmen-region.de/de/4818.php> and by DFG Project SQ-System: Entwicklung von Konzepten für ein quantenlogikbasiertes Retrieval-Datenbank-Anfragesystem: Anfragesprache, interaktive Suchformulierung sowie effiziente Anfragesauswertung

a product representation then  $U(o)$  denotes the overall utility of this product. The main condition for such a function is to be monotonic with respect of preferences i.e.,  $U(o_1) \geq U(o_2)$  whenever  $o_1 \succeq o_2$  (see [17], [8], [9]). There is a large literature concerning the way the overall score of a product should be computed (see [3], [13], [17], [19], [16], [20], and many other). A well known model for such a utility function is the additive linear model (see [3] for a survey of models). Basically, the overall utility is an additive linear combination on local utilities adjusted with attribute weights and compensated with a constant depending on interview:

$$U_p(o_j) = \mu + \sum_{k=1}^n \sum_{l=1}^{n_k} \beta_{kl} \cdot x_{jkl} + e_j$$

where  $\mu$  is the mean preference value across all profiles,  $U_p(o_j)$  – is the total score on product profile  $o_j$  with respect to respondent  $p$ ,  $\beta_{kl}$  – is the weight of value  $a_{kl}$  of attribute  $A_k$ ,  $x_{jkl} = \begin{cases} 1, & \text{if } o_j.A_k = a_{kl} \\ 0, & \text{otherwise} \end{cases}$  and  $e_j$  is the measurement error.

Therefore the problem reduces to find all  $\beta_{kl}$  and  $\mu$ . We need estimates and not crisp values because we cannot offer all possible product profiles in a user interview simply because they can be too many([22]). Traditional conjoint uses full profiles (complete product descriptions) as basis for user surveys, but such an approach suffers by description complexity in the presence of many attributes ([22], [23], [24] and [25]), the adaptive conjoint introduces a "partial evaluation" i.e., requesting respondents to evaluate only partial profiles, named *stimuli* by using trade-off matrix approaches, with emphasis on pair comparisons.

A solution of the above model will entitle experts to compute a measure of acceptance of a product by the consumer. However, such a solution is not able to provide explanations on product features and how they may influence the consumer final decision. Logical languages offers qualitative and symbolic methods to complement these standard approaches of economic decision theory.

The goal of this paper is to offer a heuristic to perform Adaptive Conjoint Analysis inside a logic based framework. We use the Commuting Quantum Logic Language,

TABLE I  
PRODUCT ATTRIBUTES AND USER RATINGS

AttrId	Attr Weight	Attr. Name	Attr. Value	ValueId	Value Weight
1	6	Operating system	Android	1	7
			Windows Phone	2	6
			other(proprietary)	3	3
2	7	WiFi	yes	1	6
			no	2	3
3	7	Screen size	less than 3.5"	1	3
			3.5"-4.0"	2	7
			greater than 4.0"	3	8
4	5	Battery life	12 hours	1	9
			6 hours	2	6
			4 hours	3	5
			2 hours	4	1
5	8	PriceLevel	less than 150 EUR	1	9
			150 EUR - 250 EUR	2	8
			250 EUR - 500 EUR	3	5
			greater than 500 EUR	4	0

CQQL([35]), to learn a logical formula  $U$  such that the CQQL evaluation of this formula against a specific set of database objects (product profiles) should monotonically correlate with the user preferences on objects i.e. if  $o_1$  and  $o_2$  are two product profiles  $eval(U, o_1) \geq eval(U, o_2) \Leftrightarrow o_1 \succeq o_2$ . Next section shows an illustrating example of our approach.

A. A simple scenario: Which smartphone they may prefer?

*Example 1 (Which smartphone do you prefer?):* A smartphone manufacturer aims understanding which smartphone is preferred by a specific target group. It performs adaptive conjoint analysis with CQQL using a product decomposition and user scores to compute a logical formula fulfilling the user preferences. This formula can be easily interpreted towards obtaining design decisions.

The initial data consists of a product decomposition into a set attribute values (e.g., "Operating System" is a product attribute with three possible values: "Android", "Windows Phone" and "other(proprietary)") and an initial user rating of attributes and values (e.g., attribute "WiFi" has score 7 and value "Android" has score 7) as shown in the Table I.

Product decomposition is an important stage in conjoint analysis. Many papers emphasize that the decomposition should be chosen carefully to satisfy a property known as *preferential independence*. Preferential independence is extremely important because if each set of attributes is preferentially independent of its complement set, then the attribute utility can be represented by an additive or multiplicative decomposition ([26]). If the attributes are not independent, according to [14], [15], and [5], the utility is more difficult to be estimated. It is not the goal of this paper to analyze methodologies and techniques for product decomposition, therefore we assume an initial a set of attributes together with their possible values.

The last step of our ACA-CQQL learning process yields the following DNF formula<sup>1</sup>:

$$U = (A_1 \wedge \overline{A_2} \wedge A_3 \wedge \overline{A_4} \wedge A_5) \vee (\overline{A_1} \wedge A_2 \wedge A_3 \wedge \overline{A_4} \wedge \overline{A_5})$$

<sup>1</sup>for sake of simplicity, in this example,  $U$  covers the two most important minterms.

After logical transformations such as distributivity, double negation, transforming to implication and dual implication the following set of decision rules are produced:

$$\begin{aligned} R_1 : \overline{A_2} \vee A_5 \rightarrow A_1; & R_2 : A_2 \rightarrow \overline{A_1}; & R_3 : A_1 \vee \overline{A_2} \rightarrow A_5; \\ R_4 : A_2 \rightarrow \overline{A_5}; & & \\ R_5 : \overline{A_2} \vee A_5 \rightarrow A_1; & R_6 : A_2 \rightarrow \overline{A_1} \wedge \overline{A_5}; & R_7 : A_5 \rightarrow A_1; \\ R_8 : \overline{A_2} \rightarrow A_1 \wedge A_5; & & \\ R_9 : A_3, & R_{10} : \overline{A_4} \end{aligned}$$

These rules are interpreted according with the user's level of importance of attribute values, e.g.,  $R_9$  and  $R_{10}$  requests that your product should definitely have a high level of  $A_3$  (i.e. "large screen") and may have a low level of  $A_4$  ("2 hour").  $R_1$  means "whenever you have a low level of  $A_2$  and a high level of  $A_5$ , you should have a high level of  $A_1$  too" that is "if the phone has no WIFI and a low price then it should have OS Android".

In addition, each minterm of the the learned formula  $U$  defines a logical interpretation satisfying  $U$ . Each such interpretation recommends product profiles. For example,  $\mathcal{I} = \{\overline{A_1}, A_2, A_3, \overline{A_4}, \overline{A_5}\}$  (introduced by the second minterm in our example) recommends

("proprietary OS", "WIFI", "> 4.0\"", "2 hours", "high price") While these rules are suitable to be processed by rule engines, we can also derive logically equivalent representations tailored to human interpretation:

$$\begin{aligned} F_1 : A_3 \wedge \overline{A_4}; \\ F_2 : A_1 \oplus \overline{A_2}; \\ F_3 : A_1 \leftrightarrow A_5; \\ F_4 : \overline{A_2} \oplus A_5; \end{aligned}$$

## II. OVERVIEW OF OUR APPROACH

Let  $\mathcal{A} = \{A_1, \dots, A_n\}$  be a set of mutually independent attributes. Let  $dom(A_i)$  the value space of attribute  $A_i$ . Let  $\mathcal{O} = \{(a_1, \dots, a_n) | a_k \in dom(A_k), k = 1, \dots, n\}$  a set of possible objects built over  $\mathcal{A}$ . Let  $\mathcal{S}$  be a finite set of *incomplete objects* or *stimuli* i.e.  $s \in \mathcal{S}$  is a database tuple with nulls. The *null* interpretation related to these objects is in the sense of missing information, e.g., considering 6 attributes a

possible stimuli is the tuple  $s = (a_1, null, null, a_4, null, null)$  where  $a_i$  are specific attribute values.  $\mathcal{S}$  is built by extracting incomplete objects from  $\mathcal{O}$ . Let  $\mathcal{P}$  be a set of respondents. The *ACA-CQQL conjoint representation* is the weighted full DNF<sup>2</sup>,  $U = \bigvee_{w_k} m_k$  where  $m_k$  denotes the  $k$ -minterm and  $w_k \in [0, 1]$  is the weight of minterm  $m_k$ . Each minterm is a conjunction of exactly  $n$  literals (positive attribute occurrence or negative attribute occurrence) each corresponding to one of the  $n$  attributes of ACA-CQQL problem.

The overall approach we use is briefly described below:

- 1) For each respondent  $p \in \mathcal{P}$ , use an interview to derive a preference relation  $P_{\mathcal{S},p} : \mathcal{S} \times \mathcal{S} \rightarrow \{0, 1, unknown\}$ ;
- 2) Use a stimuli preference relation  $P_{\mathcal{S},p}$  to compute a rank  $\rho_{\mathcal{S},p}$  on  $\mathcal{S}$ . A stimuli  $s$  is better ranked by  $\rho_{\mathcal{S},p}$  when the user likes  $s$  better than other one (with a lower rank);
- 3) Derive an induced rank on  $\mathcal{O}$ ,  $\rho_{\mathcal{O},p}$ ; This step computes a rank on full objects by considering the computed rank in Step 2.
- 4) Use CQQL evaluation to obtain  $P_{\mathcal{M},p}$  a preference relation on minterms of  $U$ ; This step allows to express a respondent preference relation on minterms and by consequence to compute an overall preference as described in Step 5.
- 5) Compute an overall minterm preference  $P_{\mathcal{M}}$  by aggregation of all  $P_{\mathcal{M},p}$ ;
- 6) Use  $P_{\mathcal{M}}$  to compute,  $\rho_{\mathcal{M}}$ , a rank on CQQL formula minterms; This is one of the core steps of our solution. Ranking minterms of the full DNF allows to select significant minterms and as such to derive an approximation of interests.
- 7) Create and interpret decision rules considering the best ranked minterms.

Methods for learning and predicting preferences are addressed by the machine learning community [21] and recommender systems [1]. These communities provides solutions such as approximating the scoring function by using interviews (*preference elicitation*) to *collaborative filtering*, where the user preferences are estimated from the preferences of other users. The steps 1–3 are described in Section III while steps 4–7 are described in Section V.

### III. ORDERING FROM PREFERENCES ON INCOMPLETE INFORMATION

Conjoint Analysis associates each respondent  $p \in \mathcal{P}$ , with a set of *pairwise comparisons* (2–stimuli questions), each comparison being rated on a Likert scale [28]. Each question may have its own scale. Likert scales are bipolar scaling methods therefore we can straightforward derive a preference from ratings.

Let  $p \in \mathcal{P}$  be a respondent. Let  $(s_i, s_j)$  be a comparison rated

<sup>2</sup>Any logical formula can be converted to a disjunctive normal form (DNF) by using logical equivalences, such as the double complement elimination, De Morgan’s laws, and the distributive law. Recall that CQQL provides rewriting rules to translate from weighted operations to into CQQL Boolean calculus. Therefore we are going to learn a formula directly in the DNF form.

Fig. 1. Graph of preferences

with  $r$  on a Likert scale  $1..K_p$ ,  $K_p \in \mathbb{N}$ . One traditional scale is 1..9 but other choices can be used too (e.g. 1..5). On scale 1..9,  $r = 1$  means "I like very much  $s_i$ ",  $r = 5$  is neutral ("I equally like both  $s_i$  and  $s_j$ ") while  $r = 9$  means "I like very much  $s_j$ ". Then

$$P(s_i, s_j) = \begin{cases} 0, & r < \lfloor K_p/2 \rfloor + 1, (s_i \succ s_j) \\ unknown, & r = \lfloor K_p/2 \rfloor + 1 \\ 1, & r < \lfloor K_p/2 \rfloor + 1, (s_j \succ s_i) \end{cases}$$

The first step is to use the given initial preference  $P_{\mathcal{S}}$  to learn an ordering function  $\rho_{\mathcal{S}}$ . We use the Algorithm 1, a greedy ordering introduced by [6].

This algorithm is based on viewing preferences as a directed

**Data:**  $\mathcal{S}$ , binary preference  $P_{\mathcal{S}}$

**Result:**  $\rho_{\mathcal{S}}$

Let  $V = \mathcal{S}$ ;

**foreach**  $v \in V$  **do**

$\pi(v) = \sum_{u \in V} P_{\mathcal{S}}(v, u) - \sum_{u \in V} P_{\mathcal{S}}(u, v)$ ;

**end**

**while**  $V \neq \emptyset$  **do**

    Let  $t = \text{argmax}_{u \in V} \pi(u)$ ;

    Let  $\rho_{\mathcal{S}}(t) = |V|$ ;

$V = V - \{t\}$ ;

**foreach**  $v \in V$  **do**

$\pi(v) = \pi(v) + P_{\mathcal{S}}(t, v) - P_{\mathcal{S}}(v, t)$ ;

**end**

**end**

**Algorithm 1:** *orderByPrefs*( $\mathcal{S}, P$ ), [6]

weighted graph where the initial set of vertices  $V$  is equal of set of stimuli  $\mathcal{S}$  and each edge  $u \rightarrow v$  has weight  $P_{\mathcal{S}}(u, v) = 1$  ( $v$  is preferred to  $u$ ). Each vertex  $v$  gets a "potential"  $\pi(v)$  which is the sum of the incoming edges minus the sum of outgoing edges. The Algorithm 1 picks some node  $t$  that has a maximum potential, assigns it a rank  $\rho_{\mathcal{S}}(t) = |V|$  and then ordering in the same way the remaining nodes, after updating the nodes potentials.

The potentials define a stratification of the directed weighted graph into node sets of the same potential. The stratum

with the highest potential is processed first. However when processing the nodes in the same stratum all of them have the same potential, therefore the algorithm must choose between them. For example, considering the preferences as in Figure 1 (the initial potential of each stratum is shown too) it is easy to see that node 5 will be processed first (it gets a rank of 4) but then we have a nondeterministic selection because either 4 or 3 can be a choice (both will have the same updated potential). Therefore the output ordering provided by Algorithm 1 depends on the *argmax* implementation<sup>3</sup>. Among others, orderings  $\{0, 1, 2, 3, 4, 5\}$  and  $\{0, 2, 1, 4, 3, 5\}$  can be produced.

*Definition 1 (Incomplete Objects Equality and Membership):*

Two incomplete objects  $s_1, s_2 \in \mathcal{S}$  are *equal*, and we write  $s_1 = s_2$ , when all their correspondent values are the same i.e. if  $s_1 = (a_1, \dots, a_n)$  and  $s_2 = (b_1, \dots, b_n)$  then  $s_1 = s_2$  iff  $a_k = b_k$  for all  $k = 1, \dots, n$ . The values equality interpretation is defined as in the below table:

=	<i>v</i>	<i>null</i>
<i>v</i>	true	false
<i>null</i>	false	true

Let  $s = (a'_1, \dots, a'_n) \in \mathcal{S}$  and  $o = (a_1, \dots, a_n) \in \mathcal{O}$ . We say that  $s$  is *contained by*  $o$  (or  $o$  *contains*  $s$ ) and we denote  $s \subseteq o$  iff  $a'_k \neq null$  implies  $a'_k = a_k$  for all  $k = 1, \dots, n$ . Therefore an incomplete object is contained by an object when its non-null values are the same in the related object.

The following definition introduces an extension from an order on incomplete objects to an order on complete objects.

*Definition 2 (Ordering Extension):* Let  $\mathcal{O}$  be a set of complete objects,  $\mathcal{S}$  be a set of incomplete objects and  $P_{\mathcal{S}}$  a binary preference. Let  $\rho_{\mathcal{S}}$  obtained by Algorithm 1. Then, the ordering  $\rho_{\mathcal{O}}$  defines the *extension of*  $\rho_{\mathcal{S}}$  from  $\mathcal{S}$  to  $\mathcal{O}$ :

$$\rho_{\mathcal{O}}(o) = \sum_{s_i \in \mathcal{S}, s_i \subseteq o} u_{s_i} \rho_{\mathcal{S}}(s_i)$$

where  $u_{s_i}$  is the stimuli utility. If no stimuli belong to object  $o$  then  $\rho_{\mathcal{O}}(o) = 0$ .

Stimuli utility is an additive linear combination of attribute value weight i.e. if  $m_s$  is the number of distinct attribute values of  $s \in \mathcal{S}$ , then  $u_s = \frac{1}{m_s} \sum_{i=1}^N \theta_i \cdot (\sum_{k=1}^{n_i} \theta_{ik} \cdot x_{ik})$  where  $x_{ik} = 1$  when  $A_i$  is present (with value  $a_{ik}$ ) in stimuli  $s$ , otherwise is 0 (null values are ignored).  $\theta_i \in [0, 1]$  is the weight of attribute  $A_i$  and  $\theta_{ik} \in [0, 1]$  is the weight of value  $a_{ik} \in \text{dom}(A_i)$ . The reader may notice that  $\theta_i$  and  $\theta_{ik}$  are obtained from the respondent initial ratings of attributes and attribute values as requested by traditional ACA typically by using a  $[0, 1]$  mapping from ratings on Likert scales.

*Proposition 1:* Let  $o_1, o_2 \in \mathcal{O}$  such that  $s_1, \dots, s_k \subseteq o_1$  and  $s_1, \dots, s_k, s_{k+1} \subseteq o_2$ . Then  $\rho_{\mathcal{O}}(o_2) > \rho_{\mathcal{O}}(o_1)$ .

*Proof:* Easy to see that  $\rho_{\mathcal{O}}(o_2) = \rho_{\mathcal{O}}(o_1) + u_{s_{k+1}} \rho_{\mathcal{S}}(s_{k+1})$ . ■

<sup>3</sup>While Algorithm 1 successfully applies when we have a binary preference as input (see [7] for an optimality proof), in practical cases we work with non binary preferences i.e., there are pairwise comparisons  $(x, y)$  which are rated neutral, therefore  $P_{\mathcal{S}}(x, y) = \text{unknown}$ . In this work we will ignore neutral rated questions.

Any ordering induce a preference as below:

$$P_{\rho}(x, y) = \begin{cases} 1, & \rho(x) < \rho(y) \\ 0, & \rho(x) > \rho(y) \\ \text{unknown}, & \rho(x) = \rho(y) \end{cases}$$

When  $\rho$  is strict then,  $P_{\rho}$  is binary (the *unknown* case does not occur).

In the rest of the paper we assume as given  $\rho_{\mathcal{O}}$  and  $P_{\mathcal{O}}$ . The next step is to use CQQL minterm evaluation to obtain a preference on formula minterms. The goal of the next section is to give basic information about CQQL language, particularly on CQQL evaluation rules.

#### IV. COMMUTING QUANTUM QUERY LANGUAGE (CQQL)

Introduced in [35], CQQL is an extension of the relational calculus using quantum logic paradigm which defines *metric* (or *similarity*) predicates, weighted conjunction ( $\wedge_{\theta_1, \theta_2}$ ), weighted disjunction ( $\vee_{\theta_1, \theta_2}$ ) and quantum negation. CQQL extends relational calculus by allowing for complex logical formulas mixing classical first-order logic predicates with metric predicates. Score values from  $[0, 1]$  results from the evaluation of metric predicates on data objects. On the other hand, traditional database predicates (*non-metric* predicates) provide 1 for true and 0 for false. A significant advantage of the language derives from the capabilities of quantum measurement results to be interpreted as probability values. Therefore conjunction, disjunction and negation conforms with the probability calculus. As a consequence, many concepts of information retrieval, already embedded into linear algebra and probability theory, can be addressed.

Processing *non-metric attributes* i.e. attributes not requiring any degree of neighborhood between their values, therefore we follow the classical database query processing. When processing *metric attributes* i.e. data for which we are interested in distinguishing comparisons between two values which are close neighbors from those which lie far away from each other we follow the CQQL approach of similarity evaluation based on quantum measurement. An example of a *non-metric attribute* (or *database attribute*) is "Operating System" as shown in Section I-A.

Attributes such as "Price" comes naturally as *metric attributes* (or *similarity attributes*) because the users are definitely interested in low prices, therefore they are evaluated by means of similarity predicates: it becomes easy to derive an order of the values of these attributes and to use a continuous, and monotonic predicate  $p_{Price} : \text{dom}(Price) \rightarrow [0, 1]$  to associate their values with truth degrees.

*Definition 3 (Database Values Evaluation):* Let  $o$  be a database object. If  $A$  is a non-metric attribute such that  $o.A = a$ , then

$$\text{eval}(A = v, o) = \begin{cases} 1, & \text{if } v = a \\ 0, & \text{otherwise} \end{cases}$$

whenever  $a = null$  or  $v = null$  we take

$$\text{eval}(A = v, o) = \text{unknown}.$$

Let  $A$  be a metric attribute. Any value  $a \in \text{dom}(A)$ , is mapped by quantum encoding into a vector state  $\bar{a}$ . This give the

user a means to assign its own semantics to the resulting proximity values. The CQQL framework allows evaluation of similarity values by using any similarity measure  $s$  satisfying the following conditions:

- 1) for all  $a, b \in \text{dom}(A)$ ,  $s(\bar{a}, \bar{b}) \in [0, 1]$ .
- 2) for all  $a, b \in \text{dom}(A)$ ,  $s(\bar{a}, \bar{b}) = 1 \Leftrightarrow \bar{a} = \bar{b}$ .
- 3) for all  $a, b \in \text{dom}(A)$ ,  $s(\bar{a}, \bar{b}) = s(\bar{b}, \bar{a})$ .

A widely used such similarity measure is the cosine similarity  $s(\bar{a}, \bar{b}) = \frac{\bar{a} \cdot \bar{b}}{\|\bar{a}\| \|\bar{b}\|}$ .

*Definition 4 (Retrieval Values Evaluation):*

$$\text{eval}(A \approx v, o) = \begin{cases} s(\bar{v}, \bar{o.a}), & \text{if } v \neq \text{null and } a \neq \text{null} \\ \text{unknown}, & \text{otherwise} \end{cases} \quad (1)$$

Before a CQQL formula can be evaluated it has to be normalized. The normalization requires a special syntactical form starting with a formula that is in the prenex and disjunctive normal form. Then all common atoms  $\varphi$  are removed by applying the rule  $(\varphi \wedge \varphi_1) \vee (\varphi \wedge \varphi_2) = \varphi \wedge (\varphi_1 \vee \varphi_2)$  (derived from distributivity and absorption). The normalization algorithm is based on Boolean transformation rules and is described in [35].

*Definition 5 (Formula Evaluation):* Let  $\varphi_1 \wedge \varphi_2$ ,  $\varphi_1 \vee \varphi_2$  and  $\varphi$  normalized formulas. Then

$$\begin{aligned} \text{eval}(\varphi_1 \wedge \varphi_2, o) &= \text{eval}(\varphi_1, o) * \text{eval}(\varphi_2, o) \\ \text{eval}(\varphi_1 \vee \varphi_2, o) &= \text{eval}(\varphi_1, o) + \text{eval}(\varphi_2, o) - \\ &\text{eval}(\varphi_1, o) * \text{eval}(\varphi_2, o) \\ \text{eval}(\neg \varphi, o) &= 1 - \text{eval}(\varphi, o) \end{aligned}$$

Applying CQQL evaluation against a set of database objects we get a rank of all objects according to their score value. Integrating weights into CQQL can be achieved simply. The core idea is the direct transformation of a weighted conjunction or disjunction into a logical expression in which weight values are converted into 0-ary predicates using the rewriting rules below:

$$\begin{aligned} \varphi_1 \wedge_{\theta_1, \theta_2} \varphi_2 &\Rightarrow (\varphi_1 \vee \neg \theta_1) \wedge (\varphi_2 \vee \neg \theta_2) \\ \varphi_1 \vee_{\theta_1, \theta_2} \varphi_2 &\Rightarrow (\varphi_1 \wedge \theta_1) \vee (\varphi_2 \wedge \theta_2) \end{aligned}$$

These rules provide a way to transform weighted conjunction, weighted disjunctions into CQQL Boolean calculus. More technical details on these transformations and examples can be found in [37]. An intuitive interpretation of rewriting rules when considering only Boolean weights (0 and 1) is described in the below table.

$\theta_1$	$\theta_2$	$\varphi_1 \wedge_{\theta_1, \theta_2} \varphi_2$	$\varphi_1 \vee_{\theta_1, \theta_2} \varphi_2$	Explanation
0	0	1	0	none of $\varphi_1$ and $\varphi_2$ counts
0	1	$\varphi_2$	$\varphi_2$	only $\varphi_2$ counts
1	0	$\varphi_1$	$\varphi_1$	only $\varphi_1$ counts
1	1	$\varphi_1 \wedge \varphi_2$	$\varphi_1 \vee \varphi_2$	both $\varphi_1$ and $\varphi_2$ counts

Existential quantification and universal quantification in a CQQL query are evaluated by computing maximum respectively minimum of the weight values of the appropriate objects.

## V. CONJOINT ANALYSIS WITH CQQL

This scenario is centered on a weight learning algorithm, an adaptation of the weighted majority algorithm proposed in [29] and discussed in [6] and [7]. The main assumption, introduced by [29] and conforming with conjoint analysis principles ([22], [23]) is the compositional approach to overall preference as a weighted sum of individual preferences.

Let  $\mathcal{A} = \{A_1, \dots, A_n\}$  be a set of mutually independent attributes. Let  $\text{dom}(A_i)$  the value space of attribute  $A_i$ . Let  $\mathcal{O} = \{(a_1, \dots, a_n) | a_k \in \text{dom}(A_k), k = 1, \dots, n\}$  a set of possible objects built over  $\mathcal{A}$ . Let  $\mathcal{S}$  be a set of stimuli and  $\mathcal{M}$  be the set of all minterms over  $\mathcal{A}$ . The overall idea of the conjoint process is to obtain an aggregated preference on possible minterms and use this preference to compute an ordering on  $\mathcal{M}$ . Given minterm preferences  $P_{\mathcal{M}, p}$  for all respondents  $p \in \mathcal{P}$  the algorithm learn optimal  $\{w_p \in [0, 1] | p \in \mathcal{P}\}$  such that

$$P_{\mathcal{M}}(m_1, m_2) = \sum_{p \in \mathcal{P}} w_p \cdot P_{\mathcal{M}, p}(m_1, m_2), \quad m_1, m_2 \in \mathcal{M}$$

such that a specific loss function is minimized. This solution uses a loss function defined as the [0,1] normalization of the number of discordant preferences between  $\hat{P}_{\mathcal{M}}$  – a preference function computed from experts evaluations, and  $P_{\mathcal{M}}$  – the preference computed by the learner:

$$\text{Loss}(P_{\mathcal{M}}, \hat{P}_{\mathcal{M}}) = \frac{\sum_{\hat{P}_{\mathcal{M}}(x, y)=1} (1 - P_{\mathcal{M}}(x, y))}{|\hat{P}_{\mathcal{M}}|}$$

As largely discussed in [6] and [7], this loss function has a probabilistic interpretation: if  $P_{\mathcal{M}}(x, y)$  is interpreted as the probability that  $y$  is preferred to  $x$  then  $\text{Loss}(P_{\mathcal{M}}, \hat{P}_{\mathcal{M}})$  is the probability of disagreement of  $P_{\mathcal{M}}$  with the feedback on  $(x, y)$  from  $\hat{P}_{\mathcal{M}}$ .

As we use this algorithm on minterm preferences, at first, we need a mechanism to compute minterm preferences from object preferences.

Recall that the goal is to learn a formula as a disjunction of most important minterms. It defines a logical representation of the respondent interests and offers an explanation on user's interests. To compute it we compute a ranking of formula minterms from preferences on database objects and take the most dominant minterms.

Fig. 2. Geometric Interpretation of Rule 1 on minterm preferences

### A. Computing Minterm Preferences

**Definition 6 (Minterm Preference):** Let  $P_{\mathcal{O}}$  be a preference. Let  $\mathcal{M}$  be the set of minterms of  $U$ . Let  $o_1, o_2 \in \mathcal{O}$  and  $m_i, m_j \in \mathcal{M}$ . The minterms preference  $P_{\mathcal{M}}$  is computed according with the following rules:

$$\left. \begin{array}{l} P_{\mathcal{O}}(o_1, o_2) = 0 \\ eval(m_i, o_1) > eval(m_j, o_2) \\ eval(m_i, o_1) > eval(m_j, o_1) \end{array} \right\} \Rightarrow P_{\mathcal{M}}(m_i, m_j) = 0$$

$$\left. \begin{array}{l} P_{\mathcal{O}}(o_1, o_2) = 0 \\ eval(m_j, o_1) > eval(m_i, o_2) \\ eval(m_j, o_1) > eval(m_i, o_1) \end{array} \right\} \Rightarrow P_{\mathcal{M}}(m_i, m_j) = 1$$

All remaining unassigned preferences are considered *unknown*.

Basically, "minterms that are more similar in CQQL evaluation against preferred objects are preferred". This heuristic has a geometric interpretation. Figure 2 shows minterms  $m_i$  and  $m_j$  such that  $P_{\mathcal{M}}(m_i, m_j) = 0$ . We consider only the regions where the CQQL minterm evaluation of the preferred object ( $o_1$  in Figure 2) is better than minterm evaluation on the less preferred object ( $o_2$ ) and inside these regions we compute preferences induced by the the ordering produced by CQQL minterm evaluation.

**Proposition 2:** The minterm preference and object preference are monotonic with respect of CQQL evaluation i.e.,

$$P_{\mathcal{O}}(o_1, o_2) = P_{\mathcal{M}}(m_i, m_j) = 0 \text{ iff } eval(m_i, o_1) > eval(m_j, o_2)$$

and

$$P_{\mathcal{O}}(o_1, o_2) = P_{\mathcal{M}}(m_i, m_j) = 1 \text{ iff } eval(m_j, o_2) > eval(m_i, o_1).$$

**Proof:** The first relation yields directly using the first rule from Definition 6. The second comes from the preference symmetry ( $P(x, y) = 0 \Leftrightarrow P(y, x) = 1$ ) and second rule. ■

### B. Performing Conjoint Analysis

The conjoint process takes place in a sequence of rounds, one for each interview question and for all respondents. The complete description is depicted in Algorithm 2. Basically, on the  $q$ -th iteration we have  $\mathcal{M}$  the set of minterms and  $P_{\mathcal{M},p}^{(q)}$  the (computed) respondents preferences on  $\mathcal{M}$ . Then, the learner receives feedback from the environment. We assume that this feedback comes as a preference function on minterms, previously computed using the same techniques from experts

**Data:**  $\mathcal{O}, \mathcal{S}, \mathcal{Q}$  interview

**Data:**  $r \in [0, 1]$ . Initial  $w^{(1)} \in [0, 1]^{|P|}$  with

$$\sum_{j=1}^{|P|} w_j^{(1)} = 1$$

**Result:**  $U, R_1, \dots, R_l$

**foreach**  $q \in \mathcal{Q}$  **do**

Update preferences  $\{P_{\mathcal{S},p}^{(q)} | p \in \mathcal{P}\}$ ;

Compute minterm preferences  $\{P_{\mathcal{M},p}^{(q)} | p \in \mathcal{P}\}$ ;

Aggregate

$$P_{\mathcal{M}}(m_i, m_j) = \sum_{p \in \mathcal{P}} w_p^{(q)} \cdot P_{\mathcal{M},p}^{(q)}(m_i, m_j);$$

$$L_{(q)} = Loss(P_{\mathcal{M}}^{(q)}, \hat{P}_{\mathcal{M}});$$

$$\text{Update } w_p^{(next(q))} = \frac{1}{C^{(q)}} w_p^{(q)} \cdot r^{L_{(q)}}, \text{ for all } p \in \mathcal{P};$$

**end**

Compute  $k\_means\_Lloyd(P_{\mathcal{M}}, [0, 1],$

$\{0, 1, unknown\}$ );

Compute ordering  $\rho_{\mathcal{M}} = orderByPrefs(\mathcal{M}, P_{\mathcal{M}})$ ;

Compute  $U$  as a disjunction of the first  $k$  minterms ordered by  $\rho_{\mathcal{M}}$ ;

Compute decision rules  $R_1, \dots, R_l$ ;

**Algorithm 2:** CA inside a Logical Framework

inputs. At each step we update the new weight vector as  $w_p^{(next(q))} = \frac{1}{C^{(q)}} w_p^{(q)} \cdot r^{Loss(P_{\mathcal{M}}^{(q)}, \hat{P}_{\mathcal{M}})}$  for all  $p \in \mathcal{P}$  where  $r \in [0, 1]$  is a calibration constant and  $C^{(q)}$  is an normalization constant chosen so that  $\sum_{p \in \mathcal{P}} w_p^{(next(q))} = 1$ .

The "majority weighted" solution for preference aggregation is largely used by machine learning community. It obtains a partial preference  $P_{\mathcal{M}} : \mathcal{M} \times \mathcal{M} \rightarrow [0, 1]$ . However, Algorithm 1 works with binary preferences, therefore we have to perform a clustering from  $P_{\mathcal{M}}(m_1, m_2) \in [0, 1]$  to  $P_{\mathcal{M}}(m_1, m_2) \in \{0, 1, unknown\}$ . There is large literature on clustering methods ([34] is a recent survey). By now, because our clustering space is Euclidean and one dimensional we considered standard k-means clustering procedure (Lloyd's algorithm) to produce three clusters: "0", "0.5" ("unknown") and "1".

### C. Creating and Interpreting Decision Rules

Following the above learning process we get a formula  $U$  as a disjunction of the most  $K$  dominant minterms,  $m_{i_1}, \dots, m_{i_K}$ . To obtain a ruleset based on  $U$ :

- 1) *Compute a conjunctive normal form.* Applying the distributivity laws to  $U$ , then eliminate duplicates ( $L \vee L \Rightarrow L$ ) and tautology (delete  $L \vee \bar{L}$ ). As a result of this step we obtain  $U$  in the CNF form.
- 2) *Find unit clauses.* (i.e. the clauses containing only one literal). All these unit clauses (or facts) are mandatory rules of our ruleset.
- 3) *Simplify unit clauses.* All unit clauses must be true therefore we replace the corresponding literals from  $U$ , then apply the usual Boolean computation. As a result all clauses of  $U$  do not contain any literals from unit clauses. Let  $\mathcal{C}$  be the set of all clauses of  $U$ .
- 4) *Transform each clause to a rule.* For each  $C \in \mathcal{C}$ , let  $C = L_1 \vee \dots \vee L_j$  and let  $L_1$  be the desired conclusion of

the rule<sup>4</sup>. Then the rule corresponding to  $C$  is obtained by simple transformation to implication i.e.

$$\overline{((L_2 \vee \dots \vee L_j))} \vee L_1 \Rightarrow \overline{(L_2 \wedge \dots \wedge L_j)} \vee L_1 \Rightarrow R_C : \overline{L_2} \wedge \dots \wedge \overline{L_j} \rightarrow L_1.$$

Eliminate possible double negation of the rule literals (apply  $\overline{\overline{L}} \Rightarrow L$ ).

## VI. EXPERIMENTAL RESULTS

Our experiments were related to an use case considering 15 attributes. We considered one scale (1..9) for all attribute ratings and the experiment uses a slightly modified variant of logistic function  $f(n) = \frac{1}{(1+e^{-n+5})}$  for rating mapping. This maps the scale 1..9 into 0.0179, 0.0474, 0.1192, 0.2689, 0.5, 0.7310, 0.8808, 0.9525, 0.9820.

The training data had 16 objects previously ranked by experts, from which we derived 32 stimuli. Each interview had 15 pairwise comparisons containing stimuli of similar utility, i.e., a pair comparison  $(s_1, s_2)$  was generated iff  $|u_{s_1} - u_{s_2}| < \varepsilon_p$  where  $\varepsilon_p$  is a threshold depending on the respondent. All questions used the same evaluation scale, 1..9. We computed a CQQL formula based on 1,2,3,5, and 10 most dominant minterms. The respondents scores and preferences were set up at random and we performed 100 simulations.

The result quality was measured by using Spearman's correlation, to compare the training data rank obtained by CQQL evaluation with the experts evaluation as shown in the below table:

No. of minterms	Best Spearman	Worse Spearman	Average
1	0.4814	0.1231	0.4002
2	0.7871	0.3612	0.72
3	0.91	0.7713	0.8724
5	0.9159	0.7023	0.8813
10	0.9921	0.7718	0.8763

The actual results show that using the first 3 or 5 dominant minterms give a correlation comparable with the case when the first 10 most dominant minterms were used. When creating decision rules the main complexity parameter is the number of minterms to be used: using the first two dominant minterms as a starting base will produce the simplest rules, as the ones described in Section I-A<sup>5</sup>. Such rules can be easily interpreted both by a human expert or a rule engine. However, when four or more dominant minterms were used then a much larger ruleset is computed and the complexity of each rule increase too. Typically such a ruleset will be processed by means of a rule engine although if a human expert is interested only in partial decisions he can use only a subset of these rules ([12]). The settings of the decision rules creation process considered

<sup>4</sup>This choice is related to the human expert interests on one or other attribute. Other solutions may consider the user's high rated attributes as a choice.

<sup>5</sup>Notice that the rules produced as described in Section V-C can also be grouped by head towards a much compact writing. This is easy when two or three minterms were used in the CQQL formula, but becomes not so much useful when more minterms were considered.

the first two dominant minterms of the obtained full DNF formula and the first three user high rated attributes as rule conclusions.

## VII. CONCLUSIONS AND FUTURE RESEARCH

This article has shown how conjoint analysis can be modeled using the tools offered by CQQL, a logic-based similarity query language. The advantage of the approach lies in the expressive power and flexibility of logic to encode the conjoint model. We obtained an ACA-CQQL interpretation as ranking of potential products according with some preexistent pattern (CQQL query) and used some learning algorithms to compute the solution. Doing conjoint analysis inside a logic-based framework creates opportunities to apply such data analysis strategy to other kind of problems such as delivering recommendations inside social networks, and deriving user's profiles from mining social activities.

We plan to extend our approach. The model formulation offers the opportunity to tune the conjoint problem by performing a choice on a number of parameter as discussing below.

*Attribute classification and preferences normalization.* CQQL supports both metric and non-metric attributes therefore both crisp and non-crisp data can be handled. In addition, each metric attribute may come with his own rating scale. The length of the scale might have to be considered while creates much more granularity of weights. The actual experiment uses classical exponential utility but other normalization approach should be considered in the future research.

*Stimuli and pairwise comparisons.* While in our experiments we've extracted stimuli on a heuristic base, possibly a more systematic approach (using techniques already provided in economics research) may yield to better results. Stimuli with two conjuncts are very easy to be understood by respondents, but using 3 or more conjuncts in the stimuli will improve the quality of the extended ordering on the training objects (see Definition 2). Secondly, CA also considers questions with more than 2 stimuli choices: in this case, we cannot use bipolar scales, therefore the preference order induced by question rating is not unique<sup>6</sup>. Finally, in the present work we ignore neutral rated comparisons but we aim to investigate other approaches in further research.

*The interview creation.* This work does not impose any restrictions on the interview creation, therefore the list of questions composing the respondent interview may support various orderings such as "by question importance" or "by question difficulty". In all cases a strategy should not violate the transitivity property of preferences: non-transitive pairs creates inconsistent problems (not all preferences can be simultaneously satisfied). An interview creation strategy

<sup>6</sup>Receiving a question  $q = (s_1, s_2, s_3)$  after scoring  $r_1 < r_2 < r_3$  we get  $s_1 \preceq s_2 \preceq s_3$  but we have to understand how to derive ratings for pairs such as  $s_1 \preceq s_2$ .

should detect this issue in the interview creation stage (immediately after the user rated a new pair comparison) and not during the learning stage. In addition, because during an interview, traditional ACA may also ask respondents to rate individual products (complete objects) on a purchase likelihood scale, we aim to generate these by considering intermediary learned formulas for tuning the preferences set towards fasten the convergence to an acceptable solution.

*The learning strategy.* Actually, the algorithm uses a loss function previously tested by other research. However we intend to investigate the performance of other loss functions such as

$$Loss(P, \hat{P}) = \frac{\sum_{(x,y) \in X \times X} (\hat{P}(x,y) - P(x,y))}{|X \times X|}$$

which is similar with Kendall's  $\tau$  rank correlation coefficient. The learning strategy implementation supports parallelization by distributing processing on persons or person groups, therefore an ACA-CQQL application should be able to offer fast answers. We also intend to investigate other learning algorithm such as ones described by [21]. Obtaining various ACA-CQQL conjoint representation that can be interpreted and explained is one of the powerful achievements of the proposed solution. We get explanations both in terms of user's most preferred attributes/values, and preferred products/services. In future research alternative solutions to derive minterm preferences have to be examined.

*Decision rules.* The obtained rule set can be subject of interpretation in various ways from simpler (as seen in Example 1) to solutions involving different semantics such as incomplete/imprecise information, [36], probabilistic models [32], or plausibility-based models [10], [11]). We plan to address some of these alternatives in subsequent research.

# Extending the definition of $\beta$ -consistent biclustering for feature selection

Antonio Mucherino<sup>‡</sup>

<sup>‡</sup>CERFACS, Toulouse, France.  
 mucherino@cerfacs.fr

**Abstract**—Consistent biclusterings of sets of data are useful for solving feature selection and classification problems. The problem of finding a consistent biclustering can be formulated as a combinatorial optimization problem, and it can be solved by the employment of a recently proposed VNS-based heuristic. In this context, the concept of  $\beta$ -consistent biclustering has been introduced for dealing with noisy data and experimental errors. However, the given definition for  $\beta$ -consistent biclustering is coherent only when sets containing non-negative data are considered. This paper extends the definition of  $\beta$ -consistent biclustering to negative data and shows, through computational experiments, that the employment of the new definition allows to perform better classifications on a well-known test problem.

## I. INTRODUCTION

CLASSIFICATION problems in data mining aim at finding a suitable partition of the samples contained in a certain set of data. Various classification techniques have been proposed over the last years, and they have been applied to various problems arising in applied fields [8], [13]. Recently, a new approach for classification have been proposed in [2], [3], which is based on the concept of *consistent biclustering*. Samples and features of a set of data are organized on the columns and on the rows, respectively, of a matrix, and a partition in biclusters of this matrix (the so-called *biclustering*) can be found with the aim of performing supervised classifications. If the biclustering is *consistent*, then the knowledge acquired by finding the biclustering can be exploited for performing good-quality classifications (see Section II for more details).

When real data are considered, i.e. data obtained by experimental techniques, the matrix representing the whole set of data does not usually admit any consistent biclustering. This may be due to the fact that some of the features which are considered for describing the samples are actually not pertinent to the problem. A way to overcome to this issue is then to remove all these features from the set of data. During this process, however, useful features should not be discarded [2].

Since experimentally obtained data are usually noisy, even small errors introduced in the set of data may cause the loss of the consistency of the found biclusterings. This issue has been firstly addressed in [2] and, successively, the concepts of  $\alpha$ -consistent biclustering and  $\beta$ -consistent biclustering have been introduced in [15] with the aim of efficiently managing noisy data and errors. When looking for biclusterings satisfying the  $\alpha$ -consistency or the  $\beta$ -consistency property, a larger number of features (depending on the parameters  $\alpha$  and  $\beta$ ) need to be discarded from the set of data, because all the features that are

sensitive to experimental errors are supposed to be identified and removed.

While the  $\alpha$ -consistency property helped in the management of errors and noise, biclusterings satisfying the  $\beta$ -consistency property showed instead a weird behavior [12], [15]. While larger  $\alpha$  values allowed for finding  $\alpha$ -consistent biclusterings in which *better* features were selected, so that better-quality classifications were actually possible by exploiting the biclustering,  $\beta$ -consistent biclusterings with larger  $\beta$  values did not follow this general trend. In fact, the definition of  $\beta$ -consistent biclustering given in [15] is coherent only if the considered set contains non-negative data only. The aim of this paper is therefore to extend the definition of  $\beta$ -consistent biclustering to negative data. The definition given in this paper actually allows for finding correct  $\beta$ -consistent biclusterings even when negative data are available, as it is usually the case when real-life problems are considered.

The rest of the paper is organized as follows. Section II will provide some more details about how to find consistent biclusterings and how to use this knowledge for performing supervised classifications. Section III will briefly describe a recently proposed heuristic for the solution of the combinatorial optimization problem for the identification of consistent biclusterings of training sets. Then, the concept of  $\beta$ -consistent biclustering will be deeply discussed. In Section IV, an extended version of its formal definition will be presented. In Section V, a well-known set of data will be scaled so that it only contains non-negative entries, and an existing algorithm will be employed for finding  $\beta$ -consistent biclusterings. The experiments show that better classifications can be obtained by exploiting these new biclusterings. Results show that the new  $\beta$ -consistent biclusterings allow to obtain classifications with no misclassified elements, as it was instead the case in previous works. Section VI concludes the paper.

## II. CONSISTENT BICLUSTERING FOR SUPERVISED CLASSIFICATIONS

Let  $A \equiv \{a_{ij}\}$  be an  $m \times n$  matrix representing a set of data. The matrix  $A$  contains  $n$  samples (column by column) and  $m$  features (row by row). A *bicluster* is a submatrix of  $A$ , which is able to group together a subset of samples (a class  $S_r$ ) and a subset of features (a class  $F_r$ ) of the set of data. Finally, a *biclustering*

$$B = \{(S_1, F_1), (S_2, F_2), \dots, (S_k, F_k)\}$$

is a partition of  $A$  in disjoint biclusters which covers  $A$ , i.e. the following conditions must be satisfied:

$$\bigcup_{r=1}^k S_r \equiv A, \quad S_\zeta \cap S_\xi = \emptyset \quad 1 \leq \zeta \neq \xi \leq k,$$

$$\bigcup_{r=1}^k F_r \equiv A, \quad F_\zeta \cap F_\xi = \emptyset \quad 1 \leq \zeta \neq \xi \leq k,$$

where  $k \leq \min(n, m)$  is the considered number of biclusters [2].

Biclusterings of sets of data are usually searched by unsupervised techniques, where it is supposed that no information about the data is available. The interested reader can refer to [10] for a recent survey. In this approach, it is instead supposed that the set of data  $A$  is a training set, i.e.  $A$  is a set for which the classification of its samples is already known. The corresponding biclustering is therefore computed by employing a supervised technique, and the found biclustering is then exploited for classifying samples having no known classification.

Let us suppose that  $A$  is a training set. Therefore, the classification of its samples in  $k$  classes is known. From this classification, it is possible to construct a classification of its features in  $k$  classes. The basic idea is to assign each feature to the class  $F_{\hat{r}}$  (with  $\hat{r} \in \{1, 2, \dots, k\}$ ) such that it is mostly expressed (i.e. *it has higher value*), in average, in the class of samples  $S_{\hat{r}}$ . The reader is referred to [2], [12], [15] for details about this supervised procedure. Note that the same procedure can be inverted and it can be used for finding a classification of the samples of  $A$  from a known classification of its features.

By combining the two classifications, the one for the samples of  $A$  and the other one for the features of  $A$ , a biclustering can be defined for the matrix  $A$ . The supervised procedure mentioned above can construct classifications of the samples from classifications of the features, and vice versa. If the biclustering remains unchanged when the supervised procedure is applied, then it is said to be *consistent*. In other words, the biclustering is consistent if the classification of the samples (the features) suffices for correctly reconstructing the biclustering.

Consistent biclusterings can be very useful for performing supervised classifications. Let  $\hat{A}$  be a set of data which is not a training set and that it is related to the same classification problem as the set  $A$ . No information regarding the classification of the samples in  $\hat{A}$  is available, but  $\hat{A}$  contains the same features of  $A$  and a classification of these features is known because a biclustering for  $A$  is available. By using the supervised procedure, then, a classification for the samples of  $\hat{A}$  can be found from the known classification of its features. Since the biclustering of  $A$  is consistent, the procedure is able to find the correct classification for the samples in  $A$ , and therefore it should be able to do most likely the same for the samples in  $\hat{A}$  [2].

Let  $f_{ir}$  be a binary parameter which indicates if the  $i^{th}$  feature belongs to the class  $F_r$  of features ( $f_{ir} = 1$ ) or not

( $f_{ir} = 0$ ). Let  $x \equiv \{x_1, x_2, \dots, x_m\}$  be a binary vector of variables, where  $x_i$  is 1 if the  $i^{th}$  feature of  $A$  is selected, and it is 0 otherwise. Let us also indicate with the symbol  $A[x]$  the submatrix of  $A$  obtained by selecting only the features (rows) of  $A$  for which  $x_i = 1$ .

### II.1 Definition

A biclustering for  $A[x]$  is consistent if and only if,  $\forall \hat{r}, \xi \in \{1, 2, \dots, k\}, \hat{r} \neq \xi, j \in S_{\hat{r}}$ , the following inequality is satisfied [2]:

$$\frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} > \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i}. \quad (1)$$

Note that the two fractions in (1) are used for computing the *centroids* of the considered biclusters (for each sample in  $S_{\hat{r}}$ , the average over the features belonging to the same class is computed). On the left hand side of (1), the  $j^{th}$  component of the centroid of the bicluster  $(S_{\hat{r}}, F_{\hat{r}})$  is computed. On the right hand side of (1), the  $j^{th}$  component of the centroid of the bicluster  $(S_{\hat{r}}, F_\xi)$  is computed. In order to have a consistent biclustering, all components of the centroid of  $(S_{\hat{r}}, F_{\hat{r}})$  must have a larger value.

In order to overcome issues related to sets of data containing noisy data, the concepts of  $\alpha$ -consistent biclustering and  $\beta$ -consistent biclustering have been introduced in [15]. The basic idea is to artificially increase the margin between the centroids of the different biclusters in the constraints (1). In this way, small variations due to noisy data and errors should not be able to spoil the classifications performed by exploiting the found biclusterings.

### II.2 Definition

A biclustering for  $A[x]$  is  $\alpha$ -consistent if and only if,  $\forall \hat{r}, \xi \in \{1, 2, \dots, k\}, \hat{r} \neq \xi, j \in S_{\hat{r}}$ , the following inequality is satisfied [15]:

$$\frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} > \alpha + \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i}, \quad (2)$$

where  $\alpha > 0$ .

The additive parameter  $\alpha > 0$  is used to guarantee that the margin between the centroid of  $(S_{\hat{r}}, F_{\hat{r}})$  and any other bicluster concerning  $S_{\hat{r}}$  is at least greater than  $\alpha$ , independently from the considered data. Similarly, in the case of  $\beta$ -consistent biclustering, a multiplicative parameter  $\beta$  is used.

### II.3 Definition

A biclustering for  $A[x]$  is  $\beta$ -consistent if and only if,  $\forall \hat{r}, \xi \in \{1, 2, \dots, k\}, \hat{r} \neq \xi, j \in S_{\hat{r}}$ , the following inequality is

satisfied [15]:

$$\frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} > \beta \times \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i}, \quad (3)$$

where  $\beta > 1$ .

Note that different values for the parameters  $\alpha$  and  $\beta$  could be used for different components of the centroids. Usually, however, only one value is set up for all the components. More details about  $\alpha$ -consistent and  $\beta$ -consistent biclustering are given in Section IV.

In real-life applications, there are usually no biclusterings which are consistent,  $\alpha$ -consistent or  $\beta$ -consistent if all the features are selected (this situation corresponds to a binary vector  $x$  with all its components equal to 1). As already mentioned in the Introduction, this is consequence of the fact that some of the considered features may not be pertinent. Such features must therefore be removed from the set of data, while the total number of considered features must be maximized in order to lose the minimum amount of information.

To this aim, the following combinatorial optimization problem can be considered:

$$\max_x \left( f(x) = \sum_{i=1}^m x_i \right), \quad (4)$$

subject to constraints (1), (2) or (3) depending on the fact that a consistent,  $\alpha$ -consistent or  $\beta$ -consistent biclustering, respectively, is searched. These three optimization problems are all NP-hard [9], and different heuristic algorithms have been proposed in order to solve such problems [2], [12], [15]. In previous works, consistent biclusterings have been found for sets of data related to:

- gene expressions of human tissues from healthy and sick (affected by cancer) patients [12], [16];
- patients diagnosed with acute lymphoblastic leukemia (ALL) or acute myeloid leukemia (AML) diseases [2], [4], [12], [15];
- the Human Gene Expression (HuGE) Index [2], [6], [15];
- wine fermentations [14], [17].

### III. A VNS-BASED HEURISTIC FOR FINDING BICLUSTERINGS

The optimization problems (4)-(1), (4)-(2) and (4)-(3) are combinatorial problems with fractional constraints and binary decision variables. In order to solve these optimization problems, we employ a recently proposed heuristic [12], which is based on a reformulation of these problems as bilevel programs.

Let us introduce new continuous variables

$$y_r, r = 1, 2, \dots, k.$$

Each variable  $y_r$  is related to the bicluster  $(S_r, F_r)$  of a possible biclustering, and it represents the percentage of features

that are selected in that bicluster. The bilevel reformulation can be written for problem (4)-(1) as follows:

$$\min_y \left( g(x, y) = \sum_{r=1}^k \left[ (1 - y_r) + \sum_{\xi=1: \xi \neq r}^k c(x, r, \xi) \right] \right)$$

s.t.:

$$x = \arg \max_x \left( f(x) = \sum_{i=1}^m x_i \right)$$

$$\text{s. t. } \begin{cases} \sum_{i=1}^m f_{ir} x_i = \lfloor y_r \sum_{i=1}^m f_{ir} \rfloor \quad \forall r \in \{1, \dots, k\} \\ \frac{1}{y_{\hat{r}}} \sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i > \frac{1}{y_{\xi}} \sum_{i=1}^m a_{ij} f_{i\xi} x_i \end{cases}$$

$$\sum_{r=1}^k y_r \leq 1,$$

where

$$c(x, \hat{r}, \xi) = \sum_{j \in S_{\hat{r}}} \left| \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i} - \frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} \right|_+,$$

and the symbol  $|\cdot|_+$  represents the function which returns its argument if it is positive, and it returns 0 otherwise. Solving this bilevel program is equivalent to solving the original problem (4)-(1). For more details, the reader is referred to [12].

Reformulating a single optimization problem in a bilevel program may not seem convenient, because the complexity of the problem might increase. However, this reformulation allowed the development of an efficient heuristic for the solution of the problem. The inner problem of this bilevel program is linear, and therefore it can be solved by standard methods for linear optimization. The heuristic is inspired by the Variable Neighborhood Search (VNS) [5], [11] and it only acts on the new introduced variables  $y_r$ , with  $r = 1, 2, \dots, k$ . At each iteration of the algorithm, the inner problem is exactly solved and a set of values for the original variables  $x_i$ , with  $i = 1, 2, \dots, m$ , is obtained. The main intuition is that the exact solution of the inner problem helps the heuristic in converging towards the desired biclusterings.

Algorithm 1 gives a sketch of this VNS-based heuristic [12]. It is composed by two VNS's which are nested. An adaptive value for the percentage of unselected features, *unsel*, is kept small at the beginning (*unsel*  $\simeq$  0) of the heuristic, and then it increases when no better solutions can be found. In this way, the algorithm firstly tries to find solutions where the number of selected features is high. After, solutions where fewer features are selected are also allowed. For each neighbor of the first VNS, there is a full execution of the second VNS. The neighbors of the second VNS are generated so that the set of variables  $y_r$  can be slightly perturbed at the beginning (*range* = *starting\_range*), and larger perturbations can be performed only when no better solutions can be found by

**Algorithm 1** A VNS-based heuristic for feature selection.

considering the current neighbor. As for all heuristics, there is no guarantee that the biclusterings that are found by the heuristic are the ones with the largest number of selected features. However, multi-start techniques may be for example used for improving the quality of the found solutions.

#### IV. EXTENDING THE DEFINITION OF $\beta$ -CONSISTENT BICLUSTERING

The constraints (1) guarantee that all the components of the centroid of  $(S_{\hat{r}}, F_{\hat{r}})$  are larger than their homologous components in any other bicluster  $(S_{\hat{r}}, F_{\xi})$ , for any  $\xi \in \{1, 2, \dots, k\}$ , with  $\xi \neq \hat{r}$ . In the case of  $\alpha$ -consistent biclustering (see constraints (2)), this requirement is strengthened by introducing a minimum margin between pairs of homologous components of the centroids. This prevents to have the constraints unsatisfied after small variations in the data, and it leads to the following immediate result:

##### IV.1 Proposition

Any  $\alpha$ -consistent biclustering of  $A[x]$  (see Definition II.2) is also a consistent biclustering of  $A[x]$  (see Definition II.1).

The basic idea behind the  $\beta$ -consistent biclustering is the following. Instead of using an additive parameter  $\alpha$ , the multiplicative parameter  $\beta$  is employed, which must be greater than 1. In this case (see constraints (3)), each component of the centroid of  $(S_{\hat{r}}, F_{\hat{r}})$  must be larger than  $\beta$  times the

value of its homologous component in any other bicluster  $(S_{\hat{r}}, F_{\xi})$ . However, if some of these components are negative, the multiplication by  $\beta$  can give an undesired effect. When this happens, even if the constraints (3) are all satisfied, the original set of constraints (1) may not be satisfied. Therefore, even though the found biclustering may be  $\beta$ -consistent by Definition II.3, it might actually be not even consistent.

The incorrectness of Definition II.3 for  $\beta$ -consistent biclustering is also reflected in the results of the experiments reported in [12], [15]. While the rate of correct classifications constantly increased when  $\alpha$ -consistent biclusterings with larger  $\alpha$  values were searched, this rate had a *strange* behaviour in correspondence with  $\beta$ -consistent biclusterings with larger  $\beta$  values. After a certain threshold for  $\beta$ , the number of correct classifications performed with the found biclustering started to decrease. Since the considered matrix  $A$  contains both positive and negative elements, this phenomenon can most likely be explained by the fact that the found  $\beta$ -consistent biclusterings were actually not consistent.

Consider for example this simple matrix:

$$A = \begin{pmatrix} -2 & 2 \\ -1 & 8 \end{pmatrix}.$$

Suppose that there are two classes of samples and features. Suppose that the two biclusters of the considered biclustering contain, respectively, the element -2 and the element 8 of  $A$ . It is very easy to verify that this biclustering is  $\beta$ -consistent with  $\beta = 3$ , because  $-2$  is greater than  $\beta \times (-1)$ . However, it is not consistent, because  $-2$  is not greater than  $-1$ . This incoherence is due to the fact that  $A$  contains negative entries.

The following is the definition of  $\beta$ -consistent biclustering that extends the one given in [15] to matrices  $A$  containing negative elements.

##### IV.2 Definition

A biclustering for  $A[x]$  is  $\beta$ -consistent if and only if,  $\forall \hat{r}, \xi \in \{1, 2, \dots, k\}, \hat{r} \neq \xi, j \in S_{\hat{r}}$ , the following condition is satisfied:

$$\left\{ \begin{array}{l} \frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} > \beta \times \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i} \quad \text{if } c > 0 \\ \frac{\sum_{i=1}^m a_{ij} f_{i\hat{r}} x_i}{\sum_{i=1}^m f_{i\hat{r}} x_i} > (2 - \beta) \times \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i} \quad \text{if } c < 0 \end{array} \right. \quad (5)$$

where

$$c = \frac{\sum_{i=1}^m a_{ij} f_{i\xi} x_i}{\sum_{i=1}^m f_{i\xi} x_i}$$

and  $\beta > 1$ .

If  $c$  is positive, then Definition II.3 is coherent. If  $c$  is instead negative, its product by  $\beta$  would produce a decrease of its value. Suppose that  $\beta = 1 + \gamma$ , with  $\gamma > 0$ . Then,  $\beta \times c$  can be divided in two parts:  $c$  itself, and  $\gamma \times c$ , which represents the *variation* on the original value of  $c$  obtained by performing the product. Definition IV.2 is able to correct this variation when  $c$  is negative by inverting the sign of  $\gamma \times c$ . Indeed, when  $-\gamma \times c$  is added to  $c$ , the multiplicative factor is actually  $1 - \gamma$ , which corresponds to  $2 - \beta$ . The following theoretical result can now be stated:

### IV.3 Proposition

Any  $\beta$ -consistent biclustering of  $A[x]$  (see Definition IV.2) is also a consistent biclustering of  $A[x]$  (see Definition II.1).

## V. COMPUTATIONAL EXPERIMENTS

The heuristic algorithm discussed in Section III is employed in the following experiments for finding  $\beta$ -consistent biclusterings of sets of data (Definition IV.2) containing a maximal number of selected features. The heuristic has been implemented in AMPL [1], where the ILOG CPLEX11 solver [7] has been used for solving the linear inner problem at each iteration of the VNS-based heuristic. The set of data which is considered in the experiments is related to patients diagnosed with acute lymphoblastic leukemia (ALL) or acute myeloid leukemia (AML) diseases [4]. All the experiments are carried out on an Intel Core 2 CPU 6400 @ 2.13 GHz with 4GB RAM, running Linux.

The set of data is divided in a training set, which can be used for finding the biclusterings, and a validation set, which can be used for checking the quality of the classifications performed by the exploiting the knowledge acquired by finding the biclusterings (see Section II). The training set contains 38 samples: 27 ALL samples and 11 AML samples. The validation set contains 34 samples: 20 ALL samples and 14 AML samples. The total number of features is 7129. This is a well-known test problem, and experiments on this problem can be found, for example, in [12], [15], where found biclusterings have been employed for performing supervised classifications. In these experiments, the number of misclassifications on the validation set gets higher when the parameter  $\beta$  reaches a certain threshold.

In order to use the heuristic described in Section III without any modification, the training set is scaled in the experiments so that it only contains non-negative data. This practically solves the issue related to negative data, but it does not allow for directly comparing the experiments presented in this paper to those in [12], [15]. In fact, the degree of magnitude of the data changes with scaling, and the values for the parameter  $\beta$  are not comparable anymore. However, the important result which is presented in this paper is that completely correct classifications can be performed with the newly found biclusterings. The  $\beta$  value that allows for obtaining correct classifications in the original scaling of the training set is only a marginal information.

Table I shows the experiments. The total number  $f(x)$  of features that are selected in each experiment is reported,

TABLE I  
COMPUTATIONAL EXPERIMENTS ON A SET OF SAMPLES FROM PATIENTS DIAGNOSED WITH ALL AND AML DISEASES. THESE ARE THE FIRST EXPERIMENTS IN WHICH THE NUMBER OF MISCLASSIFIED SAMPLES IS 0.

$\beta$	$f(x)$	$err$	$mis. samples$
1.001	7011	2	{3,31}
1.002	6984	2	{3,31}
1.003	6946	1	31
1.004	6702	1	31
1.005	5914	1	31
1.006	5072	1	31
1.007	4524	0	-
1.008	3932	0	-
1.009	3443	0	-
1.010	3033	0	-

together with the number  $err$  of misclassifications occurring when the samples of the validation set are classified accordingly with the found  $\beta$ -consistent biclusterings. Moreover, the labels of the misclassified samples (if any) are reported in the last column (each sample is labeled by an integer number between 1 and 34 and by following the ordering in which they are stored in the set of data [4]). Each experiment took no more than 10 minutes of CPU time.

When  $\beta$  is rather small, two samples of the validation set, the one labeled by 3 and the one labeled by 31, are misclassified even though the found biclustering is  $\beta$ -consistent. When  $\beta$  increases, fewer samples are misclassified. In particular, when  $\beta$  is equal to 1.007 (notice that this value is strongly related to the new scaling of the training set), and even for larger values, there are no misclassifications on the validation set when the found  $\beta$ -consistent biclustering is employed for performing the classifications. For the very first time, there are no misclassifications on the validation set when its samples are classified accordingly to  $\beta$ -consistent biclusterings of this training set.

## VI. CONCLUSIONS

This paper extends the definition of  $\beta$ -consistent biclustering previously given in [15]. More accurate classifications can be performed by using this extended definition. The paper presents a theoretical study, which includes a new definition for the  $\beta$ -consistency, as well as an experimental study. A subset of features was found for a well-known classification problem related to gene expression data that allowed for performing classifications with no mistakes.

## ACKNOWLEDGMENTS

I am grateful to Sonia Cafieri for the fruitful discussions.

# International Workshop on Advances in Business ICT

**A**BICT focuses on Advances in Business ICT approached from a multidisciplinary perspective. It will provide an international forum for scientists/experts from academia and industry to discuss and exchange current results, applications, new ideas of ongoing research and experience on all aspects of Business Intelligence.

We kindly invite contributions originating from any area of computer science, information technology and computational solutions for different applications areas, data integration and organizational implementation of ABICT, as well as practical ABICT solutions.

Topics include (but are not limited to):

- Advanced Technologies of Data Processing, Content Processing and Information Indexing
- Business Applications of Social Networks
- Business Data Mining and Knowledge Discovery
- Business Intelligence, Business Analytics
- Business Rules
- Business-oriented Time Series Data Mining, Analysis, and Processing
- Data Warehousing
- Information Forensics and Security, Information Management, Risk Assessment and Analysis
- Information Systems in Enterprise Management
- Information Technologies in Enterprise Logistics
- Information Technologies in Enterprise Management, Information Systems,
- Service Oriented Architectures (SOA)
- Knowledge Management
- Recommender Systems
- Semantic Web and Ontologies in Business ICT
- Virtual Enterprise
- Web-Based Data Management Systems

# Formal Verification of Business Processes as Role Activity Diagrams

Amelia Bădică\* and Costin Bădică†

\*University of Craiova, Romania, Email: ameliabd@yahoo.com

†University of Craiova, Romania, Email: costin.badica@software.ucv.ro

**Abstract**—Business process modeling is performed during the requirements analysis and specification of business software systems. Checking qualitative aspects of business processes is required for quality assurance, as well as for compliance with non-functional requirements. We show how business process models represented as Role Activity Diagrams can be formally checked using process algebras and temporal logics.

## I. INTRODUCTION

MODERN organizations are process-centered and the truth of the statement “process precedes information” [1] is now widely recognized. This explains why most of the frameworks for organizational modeling and design emphasize the role of processes and process modeling from the high level description of the organization to the underlying IT support systems. Nevertheless, most often, the mapping of business process models to IT applications is defined in an ad-hoc way and the support for managing this mapping is poor. Even if the importance of a separate modeling stage was recognized and a preliminary business process modeling activity is carried out, the resulting model does not have a formal computational semantics and thus it is difficult to map it onto an IT language. On the other hand, the language spoken by IT specialists is too technical, so it is hard to link it up to higher level goals of the organization stated by business analysts.

Consider for example the requirements analysis for an IT system supporting a process-centered business organization. The set of resulting requirements usually contains functional, non-functional, as well as domain specific requirements. According to [2] (i) non-functional requirements may be very hard to verify, as the customers describe them using high-level and informal goals that usually apply to the system or process as a whole, rather than to a specific functionality, and (ii) domain requirements are usually very difficult to understand and specify by non-experts of the application domain. Recent works proposed methods to link non-functional requirements to business process models via goal analysis [3], although the support for automated verification is lacking.

Second, during the last decade, several formal approaches for business process modeling and design were proposed, relying on sound logical approaches. We classified them into (i) lightweight formalizations that use classic first-order logics [4], (ii) heavyweight formalizations based on temporal logics [5], and (iii) hybrid approaches that combine first-order and more advanced (e.g. dynamic or temporal) logics [6].

Third, software engineering provides sound formal modeling and verification techniques for the modeling and verification of software specifications. These methods are now well-supported by model checking technologies [5] and their practical application was improved by introduction of property verification patterns that can be expressed using temporal logics [7]. Recently, the application of formal methods was extended to business processes [8], [9]. A significant step ahead was achieved by introduction of property verification patterns for business process models [10], recently enhanced with visual notations [11], [12]. In particular, model checking can be applied for quality assurance of business processes [13], [9].

We conclude that business process modeling is necessary during the requirements analysis and specification of a business software system for a process-centered organization. Checking qualitative aspects of business processes is required for quality assurance, as well as for compliance with non-functional or domain specific requirements. However, although the software technology that could help to automate this verification exists, the main difficulty is the semantic gap between the languages “spoken” by the business analysts and the IT people. While business analysts are using high-level diagrammatic notations with an intuitive meaning and closer to the business world, IT people are using low-level computational languages that are closer to the computing world. We claim that the missing bit that hinders their clean interaction is the lack of, broadly understood, formal rigor of the current notations used by both business and IT communities.

We propose our contribution for bridging this gap by focusing on formal modeling and verification of business processes represented as Role Activity Diagrams (RAD) [1]. We are aware of the large variety of modeling languages that were proposed for the business and software engineering communities, including the most recent Business Process Modeling Notation (BPMN)<sup>1</sup>. Our chose RAD because: (i) RAD was used for modeling requirements of business processes [12], [14], [15]; (ii) RAD has formal semantics that we introduced in [8]; thus the extension of this work to formal verification is quite natural and straightforward; moreover RAD is at the core of the formalism for knowledge-based modeling of organizations proposed in [6]; (iii) RAD is intuitive and more appropriate for business analysts [1]; (iv) while the focus of other process

<sup>1</sup><http://www.bpmn.org/>

Fig. 1: Sample RAD model for a design project

notations, like UML activity diagrams and BPMN is set on the technical aspects including standardization, interoperability, and integration with software modeling languages, the focus of RAD is set on addressing the high-level needs of a process modeler from business rather than technical perspective.

## II. AN EXAMPLE OF FORMAL VERIFICATION

RAD is a visual notation for business process modeling [1]. We consider the Finite State Process algebra (FSP) model of a RAD process and show how it can be checked against qualitative properties represented using temporal logics. FSP is introduced in [16] and the mapping of RAD to FSP is presented in [8].

**Sample Formal Model.** Let us consider the RAD model of the design process shown in Figure 1. Its FSP model is shown below. Note that the meaning of the actions used in this FSP model is given in Table I.

$$\begin{aligned} & \|DD_0 = SS/\{npa/o\}. \\ & \|DD_1 = L/\{npa/i, atp/o\}. \\ & \|DD_2 = E/\{atp/i\}. \\ & \|DivisionalDirector = (DD_0 \parallel DD_1 \parallel DD_2). \end{aligned}$$

$$\begin{aligned} & \|D_0 = SS/\{atdd/o\}. \\ & \|D_1 = L/\{atdd/i, dp/o\}. \\ & \|D_2 = L/\{dp/i, cm/o\}. \\ & \|D_3 = L/\{dp/i, pe/o\}. \\ & \|D_4 = L/\{cm/i, ds/o\}. \\ & \|D_5 = L/\{pe/i, re/o\}. \\ & \|D_6 = L/\{re/i, gpd/o\}. \\ & \|D_7 = L/\{gpd/i, ds/o\}. \\ & \|D_8 = L/\{ds/i, pdm/o\}. \\ & \|D_9 = L/\{\{nok, pdm\}/i, cdqc/o\}. \\ & \|D_{10} = L/\{cdqc/i, \{nok, ok\}/o\}. \\ & \|D_{11} = L/\{ok/i, paef/o\}. \\ & \|D_{12} = L/\{paef/i, psaeef/o\}. \\ & \|D_{13} = E/\{psaeef/i\}. \\ & \|Designer = (D_0 \parallel D_1 \parallel D_2 \parallel \dots \parallel D_{13}). \\ & \|PM_0 = SS/\{atp/o\}. \\ & \|PM_1 = L/\{atp/i, wtd/o\}. \\ & \|PM_2 = L/\{wtd/i, atdd/o\}. \\ & \|PM_3 = L/\{atdd/i, re/o\}. \\ & \|PM_4 = L/\{re/i, pp/o\}. \\ & \|PM_5 = L/\{pp/i, gpd/o\}. \\ & \|PM_6 = L/\{gpd/i, psaeef/o\}. \\ & \|PM_7 = L/\{psaeef/i, pdr/o\}. \\ & \|PM_8 = E/\{pdr/i\}. \\ & \|ProjectManager = (PM_0 \parallel PM_1 \parallel PM_2 \parallel \dots \parallel PM_8). \\ & \|System = (DivisionalDirector \parallel Designer \parallel ProjectManager). \end{aligned}$$

**Sample Verification.** Formal modeling of business processes has the advantage that models can be systematically checked against user-defined properties. A property is defined by a statement that should be true for all the possible execution paths of the process. A property is used to describe a desirable feature of the system behavior. Formal definition of business process properties has the advantage that it enables their concise, rather than speculative analysis.

Properties of software systems are expressed as temporal logic formulas [5]. Temporal logics are used for declarative specification of properties of dynamic systems defined as labeled transition systems, including business processes. A property holds if the associated formula is true for all the possible executions of the system, as it is described by the system model. For system models captured using FSP it was shown that a convenient logic for property specification is *fluent linear temporal logic* (FLTL) [16].

In FLTL primitive properties are expressed using *fluents*. A fluent is a property whose truth is triggered by an initiating event and that holds until the signalling of a terminating event. In FSP it is natural to model initiating and terminating events by execution of specific actions. Every action  $a$  defines a singleton fluent  $F(a)$  having  $a$  as the single initiating action and the rest of all actions as terminating actions. A singleton fluent  $F(a)$  is usually written as  $a$  in FLTL formulas.

FLTL formulas are built over fluent propositions using the logical operators  $\wedge, \vee, \rightarrow, \neg$  and temporal operators **X** (next), **U** (until), **W** (weak until), **F** (eventually) and **G** (always) [16]. A property  $P$  is specified using an FLTL formula  $\Phi$ .

At the core of a verification task is the activity of property specification. This activity is recognized as very difficult, because on one side it requires special skills in formal specification using temporal logics, while on the other side it requires a good understanding of the target application domain. Nevertheless, some steps have been made in order to help the human modeler to produce specifications of properties by the introduction of specification patterns [7], [10], [11]. However,

TABLE I: Mapping of RAD elements onto FSP actions.

Action	RAD entity name	RAD entity type	Role
<i>npa</i>	<i>New project approved</i>	External event	<i>Divisional Director</i>
<i>atp</i>	<i>Agree TOR for project</i>	Interaction	<i>Divisional Director, Project Manager</i>
<i>wtd</i>	<i>Write TOR for Designer</i>	Activity	<i>Project Manager</i>

<i>pacf</i>	<i>Prepare Actual Effort Figures</i>	Activity	<i>Designer</i>
<i>psacf</i>	<i>Pass Actual Effort Figures</i>	Interaction	<i>Designer, Project Manager</i>
<i>pp</i>	<i>Prepare a plan</i>	Activity	<i>Designer</i>
<i>gpd</i>	<i>Give Plan to Designer</i>	Interaction	<i>Designer, Project Manager</i>
<i>nok</i>	<i>Not ok</i>	Case refinement	<i>Designer</i>
<i>ok</i>	<i>Ok</i>	Case refinement	<i>Designer</i>
<i>pcd</i>	<i>Project completed and debriefed</i>	State description	<i>Project Manager</i>

in our opinion even with the availability of visual specification patterns [12] we are still far from bridging the gap between requirements analysis and verification, as pointed out in the introduction of this paper. Nevertheless, we found very useful the use of patterns to specify simple properties for the process example considered in this paper.

In our case we considered two sample properties:

- P1 Each project approved must be eventually completed and debriefed.
- P2 Each project cannot be completed and debriefed without being approved by a design quality check.

Based on a rigorous analysis of the business domain, [10] proposed four classes of property specification patterns for business process models; tracing, consequence, combined occurrence, and precedence. Those two properties were formalized using consequence and precedence patterns by reformulating them as follows:

- P1 The action “New project approved” leads to reaching the state “Project completed and debriefed”.
- P2 The state “Project completed and debriefed” requires the action “Carry out design quality check” to return a positive response.

Their formal description using FLTL is as follows:

$$\begin{aligned} \text{assert } P1 &= \mathbf{G} (npa \rightarrow \mathbf{F} pcd) \\ \text{assert } P2 &= ((\neg pcd \mathbf{U} ok) \vee \mathbf{G} \neg pcd) \end{aligned}$$

We have checked the sample process model against these two properties with the help of Labelled Transition System Analyser (version 3.0)<sup>2</sup>. Both P1 and P2 were found as not violated by the process model. However, the analysis of P2 revealed a deadlock that can be explained as follows. A property check assumes three steps: (i) construction of a new process corresponding to the given property; (ii) computation of the parallel composition of the original process with the property process; (iii) performing a graph analysis of the resulting parallel composition. In our case, the resulting parallel composition has a deadlock because the property P2 does not

explicitly check that action *pcd* actually occurs, while in the original process this action will always eventually occur.

This simple experiment revealed a number of difficulties with the application of formal specification to requirements verification of business process models.

- The formal business process model is very difficult to understand and maintain. Without a proper management of the links between the formal model and the initial RAD model, it is impossible to manage large and complex process models.
- The formalization of requirements is very difficult to realize, even with the availability of property specification patterns. Additional support, beyond patterns, is needed to better manage the requirements and their mapping to formal properties.
- The results of the verification process are very difficult to interpret. Special support to link them back to the RAD model, as well as to explain them to the human modeler is lacking.

### III. CONCLUSIONS

We introduced a method for checking qualitative properties of business processes represented as RADs using the formal specification languages of process algebras and temporal logics. We presented our initial analysis of the problems encountered during the application of formal verification for checking requirements of business processes. In our opinion the core technologies already exist. However, the necessary links between them are lacking. We think that the main cause is the gap between the languages spoken by the business and computing communities. We plan to address this issue as medium term future work. In the short term we plan to enhance our results by considering more complex processes and properties.

# Virtualization as an approach in the development of IT system implementation process

Iwona Chomiak-Orsa, Wiesława Gryniewicz, Maja Leszczyńska  
University of Economics ul. Komandorska 118/120, 53-345 Wrocław, Poland  
Email: {iwona.chomiak, wieslawa.gryniewicz, maja.leszczyńska}@ue.wroc.pl

**Abstract**—Virtual administration of IT system implementation processes is now possible in small and micro-companies, characterized by relative simplicity and marked recurrence of business processes. Popularity of such approach to implementation is largely due to the wide availability of IT solutions offering remote administration of authorized IT resources. Virtual form of implementation offers significant reduction of both cost and time, compared with traditional approach. Consequently, it seems reasonable to expect further development of this trend, addressing larger economic entities and servicing more complex IT systems.

## I. INTRODUCTION

COMPANIES competing on modern markets face increased dynamics of changes, fierce competition and the need of making fast decisions. To meet those challenges, it is necessary to make good use of the available Information Technology (IT) solutions. IT instruments open up new potential for company operation and are a driving force of transformation. By implementing modern technological solutions, companies re-organize their activities not only in the B&C context, but also in relation to other companies, through value-creation chain [1]. The potential offered in this respect by the Internet and networking is widely and readily employed for optimization of business processes, namely the minimization of process cost and maximization of profit. Processes conducted via information and communications technologies (most notably, the Internet), due to the nature of the medium, are subject to potential virtualization. Through virtualization, both the entrepreneurs and their customers can profit from delocalization of business processes, i.e. freeing them up from the geographic constraints and focusing on customer needs and key competences of process supervisors [2].

The potential of virtualization can be readily deduced from the etymology of the term. Virtualization is a word derived from Latin *virtus*, *virtuti* standing for proficiency, efficiency, courage, fortitude and *virtualis* – effective [3]. The aim of this paper is to offer an insight into potential of virtualization of business processes through the evaluation of the IT system implementation process. Determinants, possibilities and tools for virtualization of this process are analyzed. Definition of system implementation process virtualization is presented, together with benefits implied by the use of this method. Deliberations presented in this paper refer to the practice of IT system implementation, with main focus on

the recent trend to virtualize the co-operation between the provider and the client and employ remote implementation procedures and processes based on large potential of modern IT solutions – a trend observed and not yet sufficiently addressed in professional literature.

## II. DETERMINANTS OF VIRTUALIZATION OF THE IT SYSTEM IMPLEMENTATION PROCESS

At present, straight majority of companies, especially large and medium-sized, employ consolidated application suites to service the main areas of their business activities, mainly in the sphere of accounting, personnel and wages, and sales [4]. Due to good saturation of IT solutions in this area, software providers seek to extend their offer to cover the sector of small and micro-companies. This interest takes the form of adapting the IT solutions to the specificity and needs of this particular segment as well as development of trade-specific IT instruments, evident even on the part of the largest software providers. Moreover, IT providers offer a range of supplementary services (business consultancy, support in the acquisition of EU structural funds), and their applications, when properly implemented, warrant increased effectiveness of business processes. This trend is manifested in the increased interest of IT providers in commercialization of their knowledge and implementation expertise, by offering services that complement IT systems' functionality, such as best practices in organization of specialized business processes, process maps for trade-specific activities and supplying predefined sets of procedures for their IT systems. This range of services is particularly attractive for small companies seeking to improve their market standing by implementing IT solutions combined with extensive knowledge of best practices in their line of trade [4].

However, solutions tailored to the needs and requirements of small and micro-companies, from the viewpoint of IT providers, offer significantly lower per-unit profit. Financial resources available to small and micro-companies for IT system implementation (need analysis, product modification and configuration, training, assistance, etc.) are decidedly sub-par compared to those of larger companies. Moreover, their business processes are of significantly lower complexity, coupled with trade-specific large-scale recurrence of procedures. IT systems addressed to this sector are definitely cheaper. Consequently, for optimization of business activi-

ties in this sector to be profitable, the IT providers need to minimize the cost and maximize the number of recipients. Cost minimization requires, on the one hand, standardization and simplification of system functionality and, on the other hand, simplification and time-effectiveness of implementation procedures.

The search for cost-minimization of implementation procedures has led to the present market trend, observed in this sector. In general, the trend is manifested in virtualization of implementation procedures or their constituents. This approach allows for delocalization of implementation, regardless of geographic location of both parties – in practice, the whole implementation process can be accomplished remotely, with significant reduction of implementation time. In addition, the IT system provider can service a large group of clients in a relatively short time, and at marginal cost.

Virtualization of IT system implementation process can be defined as remote realization of individual implementation procedures using modern telecommunications and IT solutions as well as the Internet potential (detailed analysis below). Thus, the need of personal contact between IT provider and the customer is effectively eliminated. The consultant, using a set of IT instruments and the Internet connection, communicates in real time with the customer. Both parties not only communicate with each other, but are also linked with the same physical machine, sharing the desktop view on their respective monitors and working hand in hand. It must be noted that this particular form of cooperation is made possible by the user-friendly, intuitive applications tailored to the requirements of virtual IT system implementation. Those instruments typically do not require specialized IT knowledge; the only requirement is the efficiency of communication via the Internet.

It should be noted that virtualization of IT system implementation processes is available and applicable mainly to small companies operating within a standard set of business activities or those that seek to modify their operation in accordance with best practices of the trade. IT systems dedicated to this sector are characterized by simple, straightforward functionality, intuitive and user-friendly interface and a range of predefined, typically trade-specific standard business processes. End users of such systems, for the majority of tasks, adapt their processes to the knowledge and expertise provided within the system, rather than vice versa. This is in clear opposition to the practice of system implementations in medium and large companies, where IT systems are often adapted to particular requirements of the user, resulting in costly modifications.

The interest in virtualization of implementation processes on the part of small and micro-companies stems from their need to minimize the cost involved. In this respect, both customers and system providers are motivated by similar aims. Moreover, the typically low cost of such projects allow the client to take the risk of virtualization and accept the lack of direct contact with the provider. Such constraints would be considered unacceptable in the case of large projects.

It must be noted that virtualization, among other things, is aimed at building the implementation process on the particular needs of the client. In addition, the client is an active participant of the process, taking part in realization of individual implementation tasks. Consequently, virtualization of IT system implementation processes obliges the provider to offer a suitable level of security and work comfort to the client. This should be reflected in proper organization of implementation tasks and – most of all – a reliable hot-line service offering fast and effective solutions for most of the client's problems and inquiries. In virtual context, this is a substitute for direct contact between clients and consultants.

It must also be remembered that virtualization of implementation processes for standard IT products dedicated to small and micro-companies carries a large potential for development, since the procedures and methodologies developed in the course of system implementation may help streamline future implementation processes targeted to medium and large companies.

### III. POTENTIAL FOR VIRTUALIZATION OF IT SYSTEM IMPLEMENTATIONS

As already mentioned above, the owners of small and micro-companies typically purchase trade-specific or highly standardized IT solutions. Such decisions result from the lack of funds to carry out pre-implementation analyses, offering detailed evaluation of organizational needs, information needs of individual user groups and elaborate design of business processes. In such cases, the implementation becomes a key stage in the system life-cycle. In the sector of small and micro-companies, the awareness of the need to implement IT solutions is a first step in the implementation process. Identification of user needs is carried out from "within" the organization itself – typically through involving company employees and owners in identification and evaluation of operational areas that may benefit from IT support.

The self-induced awareness typically leads the potential users to independently penetrate the market of trade-specific IT products. Users seek products that are not only adequate to their needs, but – most of all – products that place within the reasonable price range. After initial selection, the potential clients contact individual IT system developers or distributors. Nowadays, such contact is accomplished via predefined, interactive contact forms made available on IT providers' web sites. This contact constitutes the first stage of remote client-provider communication. More often than not, the interactive forms include questions that offer initial verification of the client's expectations towards the system's functionality.

The classic approach to implementation process identifies the following sequence of activities [5]:

- preparatory proceedings – involving analysis and preparing the way for the organization to adopt the system, preparation of the system itself and ensuring proper technical infrastructure for future use of the system,

- testing the system – involving trial runs and elimination of errors,
- system exploitation.

In traditional approach, preparatory proceedings required frequent on-site visits, with consultants preparing specifications of user requirements in terms of system functionality [6]. In modern approach, the initial evaluation of user requirements is verified via specific questions included in the interactive contact form. Hence, virtualization of this stage of system implementation process, in the case of small and micro-companies, may limit the number of direct contacts to only one pre-implementation meeting, to clarify user expectations and settle the financial conditions of the contract. In the case of small and micro-companies, preparing the organization for adopting the system is typically reduced to appointing the client representative to supervise the implementation procedures and remotely co-operate with the consultant representing the IT system provider.

Since the IT market at present offers a large number of IT solutions for remote automation of the installation process, the prospective user may choose to open the technical resources of the company to the IT provider and have the system installed remotely. The IT instruments also offer trial run assistance as well as verification of data structure and correctness of implemented algorithms. The functionality of selected IT instruments offering virtualization of system implementation process is presented in the next section of this paper.

One of the key stages of IT system implementation is employee training. This area can also benefit from remote cooperation between system provider and end user. Modern software is typically equipped with elaborate help modules and detailed user manuals with detailed presentation of system functionality features. The increased focus on user self-improvement during standard system operation effectively reduces the time needed to familiarize the user with the system. The end users (employees) effectively take over parts of the implementation procedures but, at the same time, are made responsible for the progress [7]. By limiting or eliminating the number of training sessions supervised by IT provider, the company can largely reduce the cost of system implementation.

Moreover, virtualization of IT system implementation offers the prospect of remote assistance. Since the end user cannot benefit from direct contact with the IT consultant, the latter is often equipped with remote desktop instruments to better support the user during the initial trial runs and help eliminate errors and problems. The on-line consultants can also remotely address any errors found in data structure or business algorithms implemented in the system.

#### IV. SELECTED IT TOOLS OFFERING VIRTUALIZATION OF IMPLEMENTATION PROCESS

Virtual accomplishment of the aforementioned stages of IT system implementation is made possible by the dynamic development of information and communications technolo-

gies. At present, the market of IT products features a large number of solutions for remote administration of shared computers. Those applications vary in terms of operating system support, functionality features, ease of use, built-in security level and licensing fees.

Companies intent on using virtual approach in implementing new software need only satisfy the requirement of leased line Internet connection, with bandwidth playing a major part in the efficiency and facility of remote cooperation. The Internet in this process is perceived as global channel, providing real-time information exchange between the parties [Jurga 2010, pp. 49-53]. There are also dedicated IT solutions for remote administration via LAN and WAN (local and wide area networks), but – since software providers are outside the reach of such networks, the Internet remains a fundamental communication medium.

The most popular applications used for the purpose of virtual implementation are presented in the table 1. They were divided into two groups, depending on the type of license: freeware and commercial software. Many of them are available for use at no cost or for an optional fee. All of the commercial solutions have also trial versions, which can be used for free for a predetermined time.

TABLE 1.  
THE MOST POPULAR SOFTWARE USED BY IT PROVIDERS FOR THE PURPOSE OF VIRTUAL IMPLEMENTATION

Type of license	Software
Freeware	<ul style="list-style-type: none"> <li>• TeamViewer<sup>1</sup></li> <li>• CrossLoop</li> <li>• TightVNC</li> <li>• Remote Desktop Connection</li> </ul>
Commercial	<ul style="list-style-type: none"> <li>• pcAnywhere</li> <li>• NetOp Remote Control</li> <li>• Radmin</li> <li>• Atelier Web Remote Commander</li> <li>• YuuGuu</li> </ul>

TeamViewer offers facilitated connectivity without the need of installing client/server applications on the remote machine. The provider needs access to full version of Team Viewer application, but the customer needs only to install a Team Viewer QuickSupport module. The client-side module is user-friendly and does not require advanced skills nor knowledge. Moreover, TeamViewer allows for generation of customized client modules, with provider's logo and welcome message, thus offering optimal presentation of contact details. In the case of non-commercial use Team Viewer is free [<http://www.teamviewer.com>].

Another example of remote administration software based on the Internet connection is CrossLoop. The package offers access and/or administration of remote computers, with the administrator having unrestrained view of the remote desktop with mouse and keyboard functionality. The CrossLoop

<sup>1</sup> It is free only for non-commercial use

package is an ideal tool for specialized technical assistance services during system implementation. It is available for free, but requires a certain degree of IT knowledge to operate. There is also CrossLoop Pro – the commercial version of this application with more complex functionality [<http://www.crossloop.com>].

TightVNC is another free remote control package based on the VNC software. It allows the user to take over remote desktop functionality. Compared with RealVNC (based on similar code), TightVNC offers improved image compression, which helps perform standard operations on remote systems with low-bandwidth connection. Similarly to RealVNC, the package includes two modules: Server (image generation and transfer) and Viewer (image reception) [<http://www.tightvnc.com>].

Remote Desktop Connection, a client software for remote administration offered by Microsoft, is less popular due to limited functionality, such as the lack of shared control (mouse, keyboard, desktop) and OS restrictions (the software offers connectivity with systems working in Windows Server 2003 or Windows XP Professional environment).

Symantec's pcAnywhere package is the market leader of remote administration software. By using efficient data encryption and authentication mechanisms, the software offers a high degree of security during remote access sessions. The most recent version of pcAnywhere offers improved directory search capabilities and AutoTransfer for automated batch transfers of files [<http://www.symantec.com/business/pcanywhere>].

NetOp is a family of software products for remote computer administration, with cross-platform capabilities, i.e. the potential to administer computers working under different operating systems. From the remote location, the provider can control workstations and servers, with remote desktop access, keyboard and mouse control, chat functionality (both text and audio), bi-directional file transfer, session recording, etc. NetOp Remote Control offers administration of any remote corporate network, with support for over 20 various operating systems at minimal system resource load. This is the only remote administration package with a centralized security system. This means that the user can control not only access authorization, but also set individual authorization rights for any remote operation – all from a single location. The package includes two basic modules: Host – for sharing computer resources; and Guest – for remote connectivity. Similarly to Time Viewer QuickSupport, the Guest module is easy to install and very user-friendly [<http://www.netop.pl>].

Other packages offering fast, reliable and secure administration of remote systems include Radmin, Atelier Web Remote Commander and Yuuguu.

Radmin is one of the safest, fastest and most popular remote access software solutions designed for Windows. A remote computer screen can be viewed on a local monitor in either a window or a full-screen display. All mouse movements and keystrokes are transferred directly to the remote

computer. Files can be transferred to and from the remote computer, and communication with the remote computer's user is possible by either Text Chat or Voice Chat [<http://www.radmin.com/products/radmin>].

Atelier Web Remote Commander lets manage servers and workstations from local computer and does not require to install any software on the remote machine. This turns the software particularly useful for accessing remote computer without any previous preparation. This application provides lots of powerful tools for remote management and audit [<http://www.atelierweb.com/rcomm/index.htm>].

Yuuguu is the simple to use service for screen sharing, remote support and collaboration. It is a little different than the options outlined above, because it allows to share screen via instant messenger. It also supports all of the major communication platforms such as Yahoo, MSN, AIM, GTalk and more. It also doesn't require to download and install anything, which should save lots of time [<http://www.yuuguu.com/home>].

Regardless of the IT solution chosen for the purpose of remote implementation of systems, both parties can also communicate via standard channels used in traditional implementation processes, such as e-mail, instant messengers, sets of frequently asked questions and answers (FAQ), helpdesk and hotline. Direct forms of contact in virtual implementation sessions are typically limited to minimum.

## V. CONCLUSIONS

Virtualization of business processes represents an effective use of information technologies, as one of the key determinants of success and a strategic resource of modern company. Information technologies open up new potential for operation and transform both means and methods of economic activities [3]. The use of virtualization potential in the process of IT system implementation offers ways for improving the operational capabilities of software providers and profitability of services addressed to small and micro-companies. In this respect, the IT providers, despite certain financial restrictions of their potential customers, can offer efficient implementation of IT solutions which would prove unprofitable for both parties if they were to employ traditional implementation methodology based on direct contact and carried out on-site. Through remote accessibility, the customer can benefit from consultant services, and the IT provider can carry out the implementation at the lowest possible cost. Another benefit of virtualization lies in the fact that the consultants can fully focus on using their key competences to address and satisfy the needs of the customer.

For obvious reasons, virtual implementation is typically limited to simple systems with low complexity and a range of predefined standard business processes. However, the skill and expertise resulting from such virtual implementations, coupled with best practices and methodologies developed in the course of servicing the small and micro-companies sector can bring profits in the foreseeable future, when

the IT providers decide to carry the virtual approach over to more advanced projects targeted to larger companies. Standardization of internal procedures on the part of IT providers, resulting from financial constraints and virtualization of services rendered to small companies, may effectively lead to optimization of procedures that take effect regardless of the scope of implementation processes and the targeted sectors. This approach, in effect, can bring about general reduction of implementation cost as well as considerable time savings. In this respect, the trend to virtualize IT system implementations seems a good direction, offering high potential for development on the part of IT providers as well as improvement and facilitation of the process from the viewpoint of future customers.

Case study of the virtualization of the IT system implementation process will be published in the AITM 2011 proceedings.

**Abstract**—In this paper we propose a concept of a web e-commerce system that collects and uses, in the process of making recommendations, data obtained from social network profiles of its users. This architecture modeling approach was developed within the project of a mashup Web application that integrates with Facebook API. We describe which data could be obtained from Facebook, propose the way to store it and suggest how the information from user profile could improve the effectiveness of a e-commerce recommender system.

## I. INTRODUCTION

NOWADAYS more and more e-commerce platforms use recommender modules to propose their clients products that they would presumably buy, therefore expecting to increase their sales and incomes. Web e-commerce systems have access only to limited scope of demographic data, which users provide when registering.

These data are insufficient to use most of methods of recommendation. To widen this area, web platforms provide advanced user tracking, gathering all information about user activity in the system like searched phrases and browsed products. With the growing need of knowing more about their clients, e-commerce extends social network marketing and pursues to stay in touch with their clients on social services. Analyzing clients activities on social network services gives e-commerce an opportunity to create more personalized offer and help their clients to cope with huge informational overload problems continuously occurring in Internet shopping.

## II. RECOMMENDATION METHODS

Among many approaches to recommendation problems authors of [6] list most popular methods as follows:

- demographic filtering (DF),
- content-based filtering (CBF),
- collaborative filtering (CF),
- hybrid approach (HA),
- case-based reasoning (CBR),
- and rule-based filtering (RBF).

Modern web e-commerce systems mostly compute recommendations with the use of a hybrid strategy which for the most part is a mixture of three basic strategies called demographic, content-based and collaborative filtering [1, 2].

Demographic filtering is the group of least precise methods [13] that aim to find regularity among profiles of users who like particular object.

In content-based filtering strategy, an object is classified as relevant to a user, if it is similar to objects that, in the past, were recommended to him and accepted by him. System implementing CBF approach builds recommendations by analyzing a set of data previously rated by a given user.

Collaborative recommenders differ from content-based ones in that user opinions are used instead of content. CF approach assumes that an object should be suggested to a user, if it was rated as relevant by a group of users (neighbours) with a profile similar to the given user, provided that it has not yet been rated by him.

Despite the widespread use, above-named methods has two major limitations related to sparsity and scalability [5]. Sparse data environment causes that recommendation methods can't properly identify the products to recommend. Data derived from social network services can extend and enhance input data sets for demographic, content-based and collaborative filtering strategy.

## III. CONCEPT OF THE SYSTEM

Fig. 1 presents the overview of the e-commerce system integrated with the social network service.

### A. E-commerce

E-commerce platform (EC) contains core modules for implementing functionalities supporting the transaction of goods or services through electronic communication. These features include product catalogue, category browsing, product searching, basket and checkouts, online payments, order tracking, etc.

### B. Middleware

The architecture of proposed system is obviously distributed, therefore we distinguish the special tier that links core e-commerce module with Facebook web services. This middleware provide an uniform interface for the system to request for data from social network service and send them back to e-commerce system in the proper format, facilitating collaboration of both parts. Acquired data are stored in the profile system within the e-commerce platform.

Fig. 1 Architecture of a Web system integrating e-commerce platform with Facebook

The role of middleware and example of its part in communication between both layers of the system is presented on Fig. 2.

### C. Social network service

Facebook, like most of Web 2.0 applications, moves towards Representational State Transfer (REST) based communications. Last year (2010) Facebook introduced new changes within its Open API, implementing the Open Graph Protocol [15] and the next generation of programming interface - Graph API.

Graph API provides developers a set of objects, on which they can operate to search data. This list includes: [14]

- all public posts,
- people,
- pages,
- events,
- groups,
- places,
- checkins.

The API is RESTful, therefore, when the agent has sufficient permissions, it can access to those objects simply by using HTTP request:

```

https://graph.facebook.com/search?
q=QUERY&type=OBJECT_TYPE
  
```

## IV. PROFILE SYSTEM

### A. Data structure

Fig. 3 presents the data structure model for the profile system. Clients of e-commerce platform who have Facebook account (and decided to provide us access data at registration or later, editing their preferences) and use social network service are additionally stored in *User* table in the profile system. Profile system collects keywords used by client and/or his friends and tries to determine the proper fields of his interests. Gathered keywords can have various context based on user activity in social network service or activity of his friends. All keywords are also categorized by the source of appearance on Facebook (e.g. post, link, comment). Profile

Fig. 2 Communication between tiers in e-commerce platform using Web services

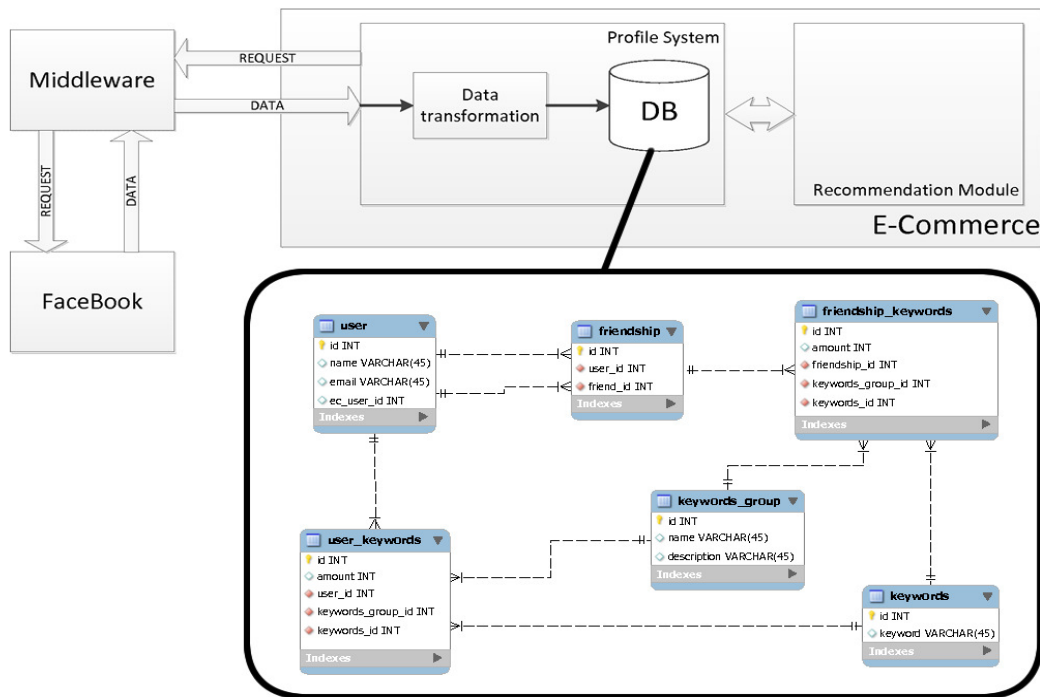

Fig. 3 Database model of profile system in e-commerce platform

system module is connected with the rest of e-commerce application by the *ec\_user\_id* key in *User* table.

In the profile system single client is identified by an email address that is used as a login to Facebook account. This gives us the possibility to automatically recognize, whether the user friends are already registered in e-commerce system. With this information final recommendation process can be improved.

#### B. Data source

Keywords obtained from Facebook can be categorized by their source of appearance:

- from user posts,
- from links published by the user,
- from comments added by the user,
- from user friends posts that the user likes (marked with 'I like it'),
- from links published by user friends that the user likes (marked with 'I like it'),
- from comments added by user friends that the user likes (marked with 'I like it'),
- from user messages (sent and received).

Each group presented above has its own weight representing significance of occurrence of words from particular group.

#### C. Web service application

The activity diagram of the middleware is shown on Fig. 4.

At first, the EC platform executes middleware application by sending a request for user data. Middleware makes a series of various Facebook API calls, dependent on how many data source sorts mentioned in part B are available for a given user. After receiving each response, data are

parsed from Facebook JSON format and processed. In this process, the combined user profile is being created in a middleware data layer. This temporary scheme reflects the structure required to integrate acquired data with EC user data. When the process is complete, the prepared user profile can be exported from temporary database structure and resend to EC platform in JSON format. This last call could also remotely invoke procedure that will update EC user profile subsystem with the latest obtained data.

#### D. Technical implementation notes

As it was mentioned earlier, Facebook gives developers access to the RESTful API, therefore the simplest way to obtain data is to invoke the service by HTTP request. Accordingly, any Web development programming language can be used to implement the middleware (e.g. PHP, Ruby, Java, Python). The authors suggest using PHP due to its stable position as a Web programming language on the market and a full support of Web services by language native libraries. Furthermore, as the most of websites are built with PHP, using this language to create own modified implementations of proposed middleware application could help to facilitate development process (e.g. some parts or single functions of data processing algorithms required by the middleware could already exist in EC platform). PHP is a cross-platform language, which can access various databases through consistent interface of PHP Data Objects (PDO) extension [16]. PDO database-specific drivers include i.a. opensource products like MySQL and PostgreSQL as well as commercial databases MS SQL Server and Oracle. However, such abstract interfaces exist in all modern Web programming languages and the use of Web services represent another abstraction layer. Therefore, the proposed architecture of middleware sys-

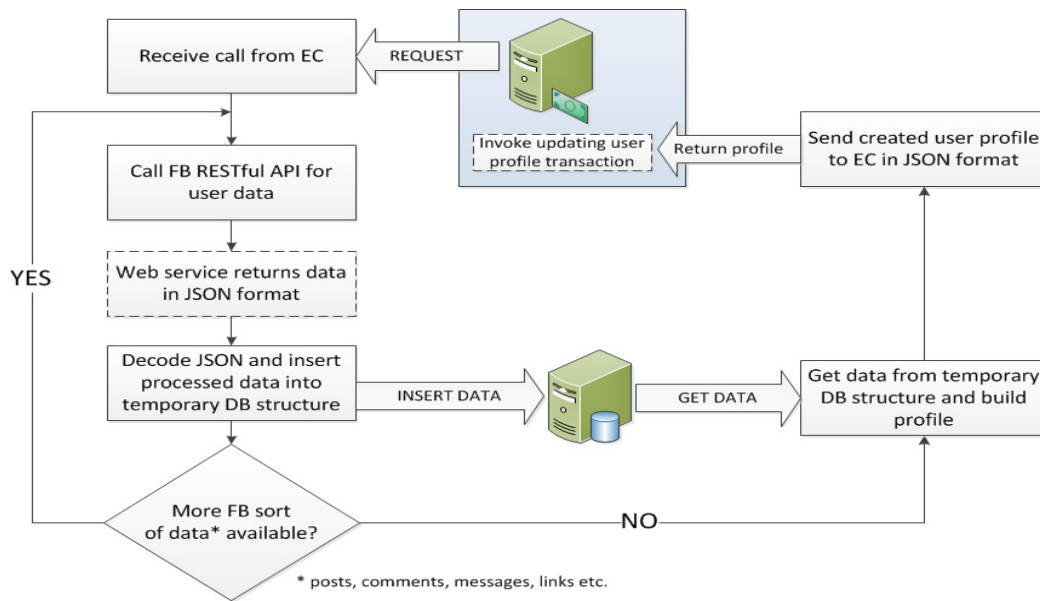

Fig. 4 Web service middleware application activity diagram

tem is flexible and does not require any fixed technical assumption concerning specific programming language and database system used in implementation.

#### V. RECOMMENDATION MODULE IN E-COMMERCE SYSTEM

Proposed system provides list of keywords which add new contexts to data sets. User profiles extended by the data obtained from Facebook are better inputs for demographic filtering.

Information concerning what user likes (objects marked by 'I like it' on Facebook) can be valuable for content-based approach recommendations.

Due to acquiring information regarding user friends on Facebook relations between users in e-commerce system can be discovered. Basing on those relations, it can be assumed that these users have similar interests. Moreover, this similarity is narrowed down to particular fields of interests based on keywords list in the context of particular friendship. As a consequence, collaborative filtering can be performed on enriched set of data.

#### VI. FURTHER WORKS

Further works should focus on defining weights for particular groups of keywords. Weights will represent significance of these groups and will have influence on values of keywords in those groups in recommendation process.

**Abstract**—This paper presents a simple automatic system for small and middle Internet companies selling goods. The system combines temporal sales data with its geographical location and presents the resulting information on a map. Such an approach to data presentation should facilitate understanding of sales structure. This insight might be helpful in generating ideas on improving sales strategy; consequently improving revenues of the company. The system is flexible and generic – it can be adjusted to process and present the data within different levels of administrative division areas, using different hierarchies of sold goods. While describing the system, we also present its prototype that visualizes the data in an interactive way on a three-dimensional map.

## I. INTRODUCTION

COMPANIES selling goods have many possible ways to devise strategies of improving their business model and adjusting it to changing business conditions. One of them is to use business intelligence tools to automatically gather, process, analyze and visualize data that is important for the company in hope of obtaining useful insights that can be used to improve company's functioning. One of the most promising and simple approaches to this problem is to combine company's private data with publicly available data in order to obtain a useful synthesis of these two. An independent problem is how to handle and integrate different dimensions of company's data. One of the dimensions is the temporal one: the business conditions change over time and the company's decision-makers have to be able to follow changing trends in order to e.g. predict future behavior of the market. Another important dimension is the spatial one: different administrative regions have different business environments, and different business strategies might be more or less suitable for different sales areas (e.g. some regions might need more billboard advertisements while others might need more on-line advertisements).

In this paper, we describe an idea for an automatic system that combines private and publicly-available data of spatial and temporal type and visualizes it on a map. The main goal of the system is to present sales data of a company in an useful and interactive way. The system is simple but generic – it can be adjusted to process and present data within different levels of administrative division areas, using different hierarchies of goods sold by the company. Apart from describing the general idea, we also present a prototype of such a system that uses

data from one of the Polish companies. The company is one of the largest Internet sellers of tires in Poland.

An overall process of data acquisition and transformation in the system is presented in Fig. 1. Our system automatically combines purchase transaction records data with information about spatial placement of administrative division areas of region of interest to locate an approximate place where each purchase was delivered. To be more precise, we use the information about delivery town and zip code of a purchase to determine which administrative division area the buyer is situated in. Each area has GPS coordinates assigned to, so the data related to this area can be easily placed on a map. The data is saved in a form of a relational database. Next, a geographic data visualization application is used to present the data in an interactive and user-friendly way. Since there are many mature applications which can be used as a visualization engine, we decided not to implement our own in the prototype. Public and free tools, although not perfect, are mature enough to be used in a professional solution. Their displaying capabilities are not limited to any particular area and can usually show different geographical regions all over the Earth. One of the most popular tools of this type, i.e. spatial data viewer equipped with ability to load user data, is Google Earth [1]. It proved to meet our requirements and we used it in our prototype (the prototype allows also sharing the visualization on-line via Google Maps).

### A. Related Research

Problem of storing and presenting spatiotemporal data is generally addressed by dedicated systems: SOLAP (Spatial On-Line Analytical Processing) being *a visual platform built especially to support rapid and easy spatiotemporal analysis and exploration of data following a multidimensional approach comprised of aggregation levels available in cartographic displays as well as in tabular and diagram displays* [2]. As all OLAP-based solutions, they require wide knowledge of data processing and data mining, in this case often combined with expertise in cartography. Another drawbacks of these systems are high licence fee and maintenance costs and therefore low return on investment values which are not acceptable for small companies.

Our lightweight data processing components try to answer spatiotemporal data analysis demands in much simple and cheaper way.

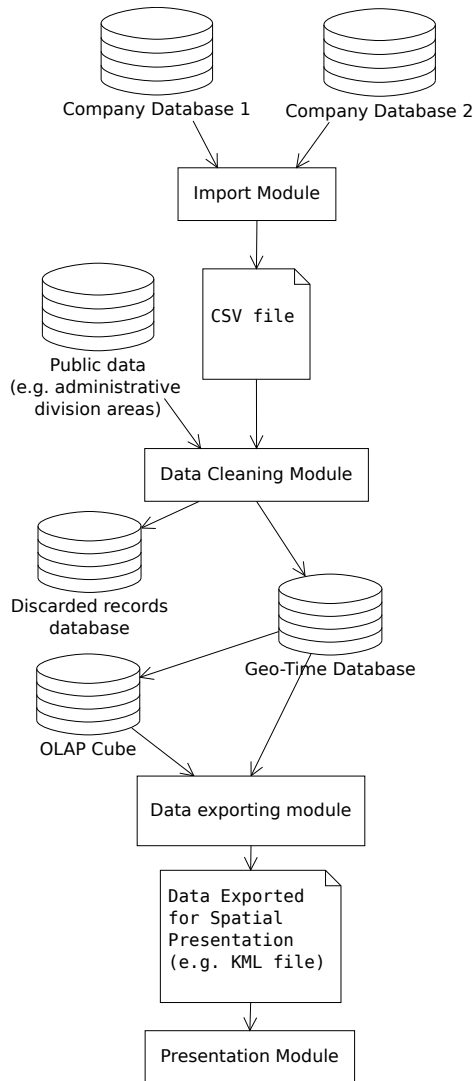

Fig. 1. Data processing phases

An important research was done to allow for fast and precise spatiotemporal aggregation calculation. This task is not easy due to imprecise querying and spatial selection criteria. Especially R-Tree structure [3] with many improvements is used to store spatial information [4]. Adding the time dimension was analyzed in many works i.e.: [5], [6], [7], [8]. Another path in research is devoted to streaming data systems and calculation of incremental spatial aggregates [9].

In our research, we focus mostly on Internet transaction data cleaning and coupling it with spatial information leaving an effective data storage and querying methods as open topics. Usage of R-Trees is still possible and could improve performance for large datasets. However, currently we do not consider this to be an important problem since our data comes from small companies and does not exceed volumes that can be effectively processed by a simple relational database management system. We tend towards simplicity for users processing Internet transactions.

Available tools for modeling and visualization of spatial data can be categorized as a stand-alone and web-based [10]. Typical stand-alone commercial products are ArcGIS and MapInfo. Both are expensive and dedicated for advanced users. As an alternative, PyNGL and PyNio applications, developed using Python programming language, are available. These applications generate 2D visualizations in several formats.

Among web-based visualization applications there are also solutions, which are based on commercial products (Bentley Map, ESRI) but many of these systems work only with their own datasets [11]. The prototype proposed in this paper is based on free software and allows presentation of user's data against a background of a third-source data.

## II. DATA EXTRACTION, TRANSFORMATION, AND LOADING

In this section we describe an algorithm which is used to process input data and prepare presentation layer in our system.

To create the final presentation, we gather data from different sources:

- 1) company's private database of transactions,
- 2) administrative areas with zip codes,
- 3) statistical data for administrative regions.

The most important data comes from a transactional database of a company. Obviously, this information contains quantities, products, categories, clients, prices, values, etc. An initial data transformation module processes the data and prepares it to be imported into our tool. Possibly, the most simple way to import this data is to use a \*.csv file where each row of the file describes a single purchase transaction. Each transaction in such a file is described by: time of the purchase, delivery zip code, delivery town, price of the purchase, quantity of the ordered product, and localization of a product in a hierarchy of types of products (see Fig. 2, *Purchase* table). In case of the data used by our prototype, we have two levels of the product. The product is the tire in this case. The top-level type is a brand of the tire while second-level type is the name of the tire, unique within the bounds of a single brand.

Each purchase can be approximately located on a map, and as such it is presented with respect to different levels of administrative division. Our system allows defining custom hierarchy of levels suitable for given application domain (see Fig. 2, *Administrative division hierarchy* group of tables). For example, in case of a company selling products in the USA, the hierarchy might look as follows: "state" → "county" → "city, town, or village". In case of our prototype, the data comes from a company selling products exclusively on the territory of Poland. Thus, while visualizing the spatial information, we use the information about Polish administrative territorial division. Polish territory consists of 16 voivodeships or provinces. Each voivodeship, called "województwo" in Polish, consists of a number of second level of local government administration areas, each one called "powiat". There is a total number of 379 powiats in Poland. For each considered administrative area, we

have obtained map coordinates of its center. A center for an administration region is calculated automatically as a centroid of administration area border taken from public government database [12]. For each powiat, we have also gathered a list of zip codes belonging to the powiat and town names connected with each zip code (see Fig. 2, *ZipCodeTown* table).

Because some town names can be written in a number of different but equivalent ways, we also use a simple text file in a \*.csv format to store information about alternative spelling of names of some of the towns. In case of our prototype, two sample entries in this text file are: 12-220, Ruciane Nida, Ruciane-Nida and 80-299, Gdansk-Osowa, Gdansk where the first element is the zip code, the second one is the alternative spelling, and the last one is the canonical name (see Fig. 2, *TownNameAlias* table).

Our main goal in processing the above-mentioned data is to assign suitable administrative division areas of each level to each purchase transaction (i.e. delivery destination). To achieve this goal, we clean the data (described in Section II-A), then we transform and combine it (described in Section II-B), and finally we load into a final database used by an application that visualizes the data (see Fig. 3). In the description of the data processing, we concentrate mainly on the spatial dimension, but the temporal information is still present in the data, although its processing is limited mainly to generating the final summary statistics from selected time interval.

The last source of data is the statistical data of administrative division regions important for particular business. This could include for example population, climate, or number of high schools. If we possess an information connected to given administration area, it can be imported and presented together with statistical transaction information. It can also be used to normalize presented data, like for example displaying number of sold bottles of water per person.

#### A. Data Cleaning

Due to characteristics of the input data i.e.: large influence of the human factor, possible mistakes, uncertainties, and ambiguity, the imported data has to be cleaned. The general approach is to accept correct records, repair the records that we know how to repair, and discard all others. The discarded data is saved in an auxiliary database along with information why each record was discarded. By inspecting this auxiliary database, we can check if the cleaning process improperly throws out useful records, and if it is the case, we can try to improve the cleaning algorithm.

Among all of the fields in the input records, the zip code and the town name have to be given a special care since normally they are entered by hand by each buyer using a web order form, and as a result there might be many possible versions of the same information entered. In case of our prototype, we deal with Polish zip code. It has a format of XX-XXX, where X is a single digit. While cleaning the zip code value, we: 1) remove all the spaces; 2) replace \*, \_, =, / symbols with hyphen; 3) remove textual zip code suffix (if any) consisting

of e.g. town name; 4) replace letters “o” and “O” with zero; 5) add hyphen in appropriate place; 6) add leading zero and a hyphen in a four-digit zip code without hyphen.

Next, while cleaning the town name value, we: 1) remove excessive spaces; 2) convert the name to a title format (a capital letter at the beginning of each word); 3) convert the name to the canonical name if it is in the table of the names with alternative spelling. In case of our prototype, the name of the analyzed town is sometimes “test” which is not a real name, but just a marker of a record created for test purposes. In such situations, the analyzed record is discarded.

Additionally, if type hierarchy of a purchased product is not fully specified in the record, the record is discarded. In case of our prototype, we discard the record if either brand or type name of a tire is absent.

#### B. Combining Geospatial and Time Information

After doing the basic cleaning of the data, we try to assign administrative division area of the lowest level to each purchase record. It is worth noting that the higher-level administrative areas do not have to be assigned explicitly since each lower-level area is assigned to a single higher-level area. In case of our prototype, this task is done in two steps. In the first step, we look for a powiat identified uniquely by the given zip code only. If it fails, we proceed to the second step and look for the powiat identified uniquely by the purchase’s (zip code, town name) pair. A more precise description of this process is presented as a pseudocode below:

```

p ← {get powiat names associated with given zip code}
if |p| = 1 then
  {assign powiat to the given record}
else if |p| = 0 then {Given zip code was not found in the
  database}
  {discard record}
else {There was more than one powiat found for given zip
  code}
  {We were unable to uniquely identify the powiat using
  zip code only, so we will try to do it using also the town
  name}
p ← {get powiat names associated with given zip code
and town name}
if |p| = 1 then
  {assign powiat to the given record}
else if |p| = 0 then {powiat for given (zip code, town
name) pair was not found}
  {discard record}
else {There was more than one powiat found for given
(zip code, town name) pair}
  {discard record}
end if
end if

```

As can be seen, the data is discarded in various points of the cleaning and transformation process. Since we are storing discarded data in an auxiliary database, we can easily generate some high-level statistics showing how much data was discarded and what was the reason of the rejection.

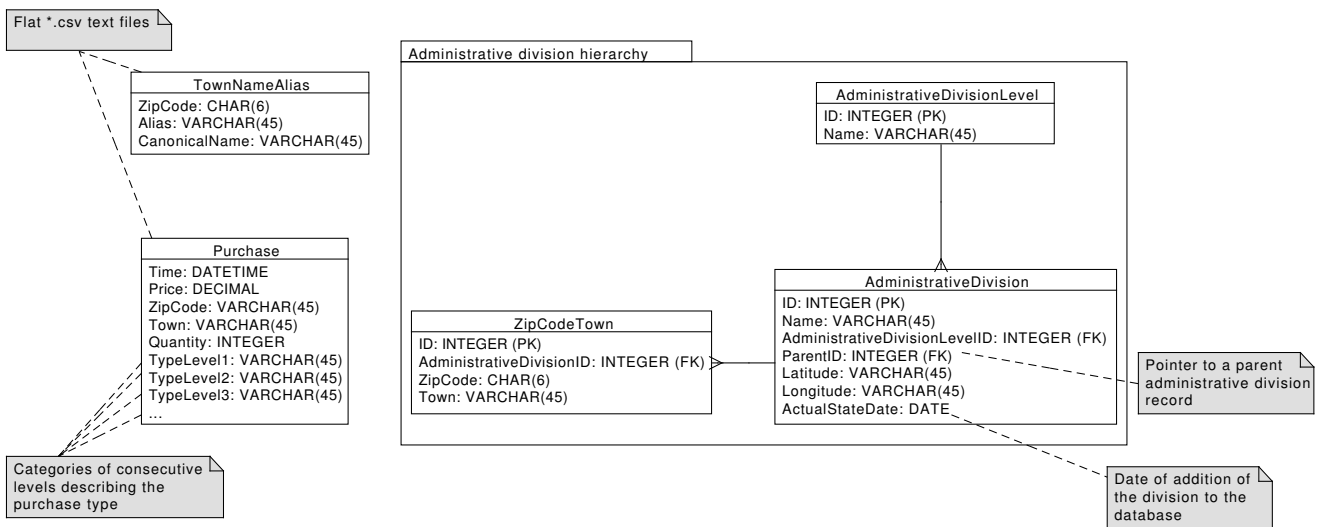

Fig. 2. A schema of the input data that we use to create the final database. Each box represents a logical database table. The following structures are presented: *Purchase* – a table of purchase transactions, *TownNameAlias* – a table of alternative spelling of names of selected towns, *Administrative division* – group of tables describing the administrative division of the area.

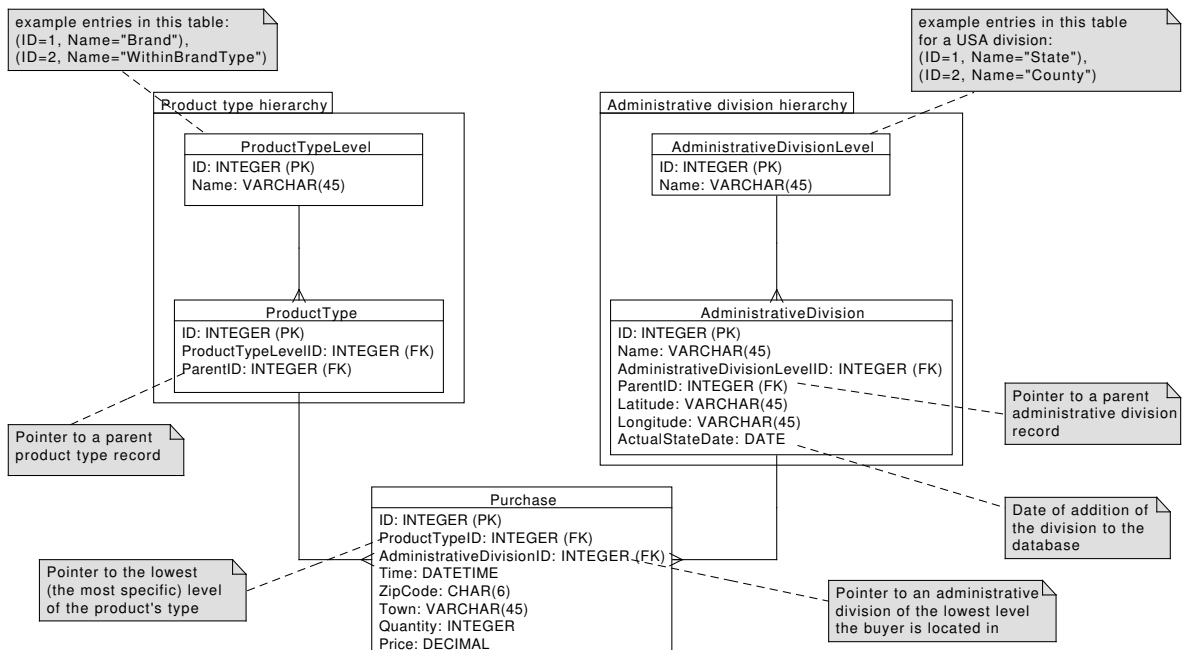

Fig. 3. A schema of the final database used by the application.

Overall, just a small percentage of the data is discarded in the cleaning process.

C. Statistical Processing and Data Output

After the transactions data is cleaned and stored in a database, we can start extracting statistical information. In many cases, for most of the small companies, this step will just calculate simple aggregates like sum of transactions or average

purchase value. A set of simple queries may be used to process this information and send it to the presentation layer. However, in various situations a more complicated statistics like growth of value per product category may be needed. In these cases an additional OLAP system may be used to store temporal aggregates.

A map feeder module uses all available information to create the presentation layer. It combines area, transactions,

and statistics to automatically produce results. Due to possibly large volume of data to be processed it should work offline and in a batch mode. Output data, depending on a time window involved and length of analysed period, may have from tens to hundreds of megabytes.

The output data is prepared in a format acceptable by the presentation module (see the next section for details).

### III. PRESENTATION LAYER OF WORKING PROTOTYPE

The final database (see Fig. 3) comprising of integrated data from different sources is used as a basis for producing input data for the visualization module. Although any tool can be used to display the data, it should have at least basic capabilities required for user-friendly operations:

- zooming in and out with administration areas appearing automatically,
- panning around the map,
- displaying of user data values,
- time axis and ability to move in time and display data for given time window,
- ability to divide user data into layers or provide data grouping.

The Google Earth (GE) application has all the above-mentioned characteristics, that is why we use it as a visualization engine in our prototype. The data accepted by the GE is described in an XML file in a format called OpenGIS KML Encoding Standard (abbreviated simply as “KML”). This format is specifically designed to describe a way of visualizing geographic data. We use its basic capabilities to visualize sales data bars as three-dimensional polygons on a three-dimensional map of Poland.

After loading the \*.kml file generated from our database into the GE, the user sees sales performance bars placed on each administrative area. There are four bars per area, each one corresponds to sales performance in one of four consecutive months (see Fig. 4). The user can utilize many options implemented in GE to navigate and manipulate data:

- change viewed time frame,
- run month-by-month animation showing changes in sales performance (see Fig. 5),
- change point of view,
- select subset of the data to visualize,
- get detailed information about a selected sale (number of transactions, total value, etc.).

One of the most important limitations of GE as a visualization tool in our system is that data subsets may only be defined as disjoint groups in XML format. Therefore data must be repeated in many so-called folder structures in order to achieve visualization of the same property in different layers or areas. This could result in a huge KML files if one would like to see different products divided into different areas. Also, adding time dimension multiplies the file size by the number of time steps. We observed in our prototype a file size growth of two orders of magnitude when using 24 time steps (each corresponding to a single month) instead of using a single aggregated step.

However, the system should also work with larger datasets. KML-based models can manage datasets with millions of records [13]. This is especially true when a network links technique is used [14].

### IV. CONCLUSIONS AND FUTURE WORKS

We presented a lightweight automatic system for combining, processing and presenting sales-related data. The presented prototype of the system relies on batch processing for data analysis and on Google Earth application as a viewing module. Our solution, although very simple, could be used by most of Internet sellers providing them a simple and convenient way to observe spatial and temporal relationships in sales data. Future work on the system involves a more thorough incorporation of the statistical data of the administrative regions into the system. Another idea is to provide visualization of results of some basic data mining processing of the analyzed data (e.g. showing clusters of regions that are similar in some specified way).

### ACKNOWLEDGMENT

The authors would like to thank one of the largest Internet sellers of tires in Poland: ORZEŁ S.A., Ćmiłów ul. Willowa 2-4, 20-388 Lublin, Poland. The company made available approximately two years of Internet purchase transactions data to us.

# Explaining MCDM acceptance: a conceptual model of influencing factors

Martina Maida, Konradin Maier, Nikolaus Obwegeser and Volker Stix  
Vienna University of Business and Economics, Institute for Information Business,  
Augasse 2-6, 1090 Wien, Austria

**Abstract**—The number of newly developed Multi-Criteria Decision Making (MCDM) methods grew considerably in the last decades. Although their theoretical foundations are solid, there is still a lack of acceptance and application in the practical field. The objective of this research is the development of a conceptual model of factors that influence MCDM acceptance that serves as a starting point for further research. For this purpose, a broad diversified literature survey was conducted in the discipline of technology adoption and related topics (like human computer interaction) with special focus on MCDM acceptance. The constructs collected within the literature survey were classified based on a qualitative approach which yielded a conceptual model structuring the identified factors according to individual, social, technology-related, task-related and facilitating aspects.

**Index Terms**—Technology Acceptance, Multi Criteria Decision Making, Decision Support.

## I. INTRODUCTION

RESEARCH in the field of technology acceptance has been subject to numerous developments in the last decades. Additionally, research in this specific area is of quite broad nature, such that it builds on various contributing domains like innovation-research, human-computer interaction (HCI) and many others.

Moreover, the advent of decision support technologies in the early 70s has been the start of what should become an active research field in both information systems (IS) and operations research (OR). While theoretical contributions show significant advancements in this area, the adoption rate of sound decision support methodologies in the practical field remains on a rather poor level. Thus, the acceptance of decision support systems (DSS) evolved as a special case of technology acceptance research.

The underlying paper aims at analyzing and integrating the main research streams in the fields affected. Therefore, a comprehensive literature survey was conducted to identify the inner structure of this field. This laid the groundwork for the design of our conceptual model. We started the survey by examining the most prominent models in the discipline of technology acceptance. These basic publications then served as a starting point for a snowball-technique based literature search. We reviewed all major journals for research of technology acceptance-related topics for the time span of 1980 until today. Furthermore, special attention was given to those research efforts that were concerned with multi-criteria decision-making

(MCDM) problems. Although the term MCDM emphasizes the complexity of the decision problems targeted, both terms DSS and MCDM are often used synonymously (as in the underlying paper). This initial phase resulted in a compendium of over 100 constructs that were found in literature to have an influence on technology acceptance, respectively MCDM acceptance.

In a second phase we performed a qualitative analysis on the (at this point) inhomogeneous collection of influencing constructs. There were also many variables with different levels of semantic granularity. Thus, the main objectives of this analysis were (i) to clearly define the semantics and denotation of each construct as intended by the original author, (ii) to identify any redundancies and (iii) to mark different levels of detail within the constructs. Furthermore, we established a mapping over the course of the analysis that builds up to a network-like structure and allows us to depict related constructs and parent-child relationships.

In a third phase, the consolidated and non-redundant list served as a basis for a process of inductive category formation [1]. We therefore discussed various schemata and concepts that could fit the underlying data along with a review of classifications proposed by other researchers or theories. The category formation process led to valuable insights on the details of the constructs and its interdependencies and eventually resulted in the categorization scheme and conceptual model that will be described in Section III.

The remainder of this paper is structured as follows. First, we present a review of the major streams that constitute the basis for our research, as described in Section II and with special focus on technology acceptance and MCDM acceptance. Section III presents and discusses the conceptual structure and the developed model. A detailed description of each group is given along with exemplified member constructs. Section IV provides a conclusion and points out promising research areas for ongoing investigations.

## II. LITERATURE SURVEY

This section describes two of the major streams of research that were examined within the literature review. As stated before, special focus was on technology acceptance models, related domains and on topics concerning MCDM acceptance.

### A. Technology Acceptance Models

Research in the field of technology acceptance has been an active field of research for the last decades. It is a telling observation that the original reason for academics to perform research in this area was mainly of practical nature: What are the driving factors for failure or success of technology? This was soon adapted to a behavioral, human-centered view on the problem, changing the main research question to: How do individuals perceive software, their surroundings and what beliefs ultimately lead to usage of a technology? Consequently, much research effort was put into psychological analysis and theory-building of cognitive processes that resulted in numerous models and theories in the respective field. While these advancements are undoubtedly valuable for the forthcoming of the scientific field, some researchers call for more diversification in this research area. When Orlikowski and Iacono titled their heavily discussed research paper “Desperately seeking the ‘IT’ in IT research: A call to theorizing the IT Artifact” [2], they intended to break the ice for what is often prematurely dismissed as system-building task: research on the actual IT artifact. Although the area of technology acceptance can be considered a rather broad research field with numerous drivers for successful acceptance, the usage of a certain technology is at the very core of it. Prominent behavioral models try to explain the lack of acceptance from a human centered perspective. While these models do not differentiate much from a technological point of view, research in human-computer interaction (HCI) focuses on the investigation of specific characteristics. Additionally, investigations on the influence of individual traits, the social environment and task specifics have been successfully added to the field.

1) *Behavioral models*: One of the most prominent and disputed contribution to the area of technology acceptance has been made by F.D. Davis with the proposal of the technology acceptance model (TAM) [3]. TAM is a psychological model based on the theory of reasoned action (TRA), developed by Ajzen and Fishbein [4]. It tries to illustrate the abstract relationships that lead to failure or success of a technology. The original version of TAM is limited to only a few very high-level constructs, such as perceived usefulness or perceived ease of use, and has hence been subject to criticism and further development. Follow-up models such as TAM2 and TAM3 basically augment the initial high-level model with the integration of numerous fine-grained influence factors [5], [6]. TAM and its successors have been used intensively in empirical research and therefore constitute one major part in the field of technology acceptance. Alongside, DeLone and McLean proposed the information systems success model, integrating six major categories of measures that affect IS success [7]. In contrast to TAM, the IS success model is not only focused on acceptance of a technology but rather on the individual and organizational impacts. After numerous contributions following the initial proposal a revised model of the IS success model was proposed ten years later that replaced

the orientation on impacts with net benefits and allows for feedback loops [8].

In addition to these specialized works many other contributions from psychology and cognitive sciences have found their way into technology acceptance research (e.g. Bandura’s social cognitive theory (SCT) or the motivational model (MM) proposed by Davis et al. [9], [10]).

2) *Technological research*: Due to the fact that the technological artifact is at the center of technology acceptance research, many contributions from the field of human-computer interaction (HCI) are valuable when adopted and integrated into acceptance research. HCI research can be considered the intersection between behavioral sciences and computer science, therefore offering insights into the design and perception of IS-artifact characteristics. Especially when considering visual representations for IS, the cognitive fit theory (CFT) proposed by Vessey allows for a deeper understanding of the possible disadvantages that come with the utilization of such [11], [12]. Moreover, the computers are social actors (CaSA) approach shows how different levels of perceived social presence can influence acceptance and usability of a technology [13].

3) *Other contributions to the field*: As follows from the above, technology acceptance research is embedded in a rather broad social environment and subject to numerous influencing factors. Many other research streams aside from the aforementioned behavioral and technological research areas are providing promising contributions to this field. A prominent example is the model of task-technology fit (TTF), that focuses explicitly on the degree of compatibility between task and technology [14]. While most research attempts incrementally add to the forthcoming of the field, others try to abstract existing knowledge to form a more holistic approach. This strategy has been pursued by the authors of the unified theory of acceptance and use of technology (UTAUT), who tried to integrate the findings of eight existent models/theories (including TRA, TAM, MM, etc.) to establish a single but comprehensive approach [15].

### B. MCDM Acceptance

Within the broad field of technology adoption the usage behavior of decision support systems (DSS) has emerged as an important subfield of research. We argue that several reasons account for this development. First, the problem of supporting decision makers in making good decisions has always attracted many researchers. On the other hand, the acceptance of decision support methods and systems (further referred to as DSS acceptance) within the practical field is rather low. Therefore, it does not come as a surprise that the gap between theoretical advancements in decision support and poor adoption of DSS in the practical field has become its own research area. A second reason for this development is that there are several major differences between most conventional information systems and decision support technologies. Conventional IS technologies (e.g. mail clients, word processing, etc.) are rather simple in terms of control. This

means, that the user usually has the ability to understand and to predict the system's reaction to inputs. Therefore, the user perceives nearly absolute control over the outputs generated by the system. In contrast, most DSS are based on complex mathematical models to process information which reduces the understandability and predictability of the system's reactions. Thus, the user perceives substantially less control of the decision support system's behaviour and outputs than he perceives using a conventional IS technology.

As DSS acceptance is considered a special case of technology acceptance, research in DSS usage behavior evolves around similar main constructs as research in technology adoption (e.g. intention to use decision aid [16], decision quality [17], perceived usefulness [18]). However, research in DSS acceptance differs distinctly from other areas of technology adoption due to the explicit separation of the acceptance of the system from the acceptance of the underlying theory implemented in the system. The rationale for this is that the user has to accept both the MCDM method (theory) and the technology (tool) implementing this process [18].

A prominent model in the context of evaluating the acceptance of decision making methods is the effort-accuracy model of cognition developed by Payne et al. [19]. This model suggests that decision makers are naturally capable of several decision making strategies and select one of these strategies based on trade-off considerations between the effort to implement a strategy and its accuracy. This model has been extensively used in the context of decision support acceptance, for example by Benbasat and fellows (e.g. [20], [21], [16]) but also by others (e.g. [18]). Based on this model, it was shown that a certain decision making strategy is more likely to be used if a DSS reduces the cognitive effort to employ this strategy relative to other strategies [20].

On the system-side of DSS acceptance, much research focuses on the identification and evaluation of design features that influence the acceptance of DSS technologies. This includes, for instance, the design of the user interface (e.g. [22], [23]) and other topics related to human-computer interaction like the wording and structuring of the dialogue with the user [24]. An important concept within DSS acceptance literature is the decisional guidance framework developed by Silver [25]. Decisional guidance is defined as the way how a DSS guides and directs its users as they execute their decision processes. It has been the groundwork for much empirical research (e.g. [18], [16]) and has been incorporated in Benbasat's concept of explanation facilities, which provide the user with how and why explanations as well as with process guidance [26], [16].

### III. A CONCEPTUAL PERSPECTIVE ON MCDM ACCEPTANCE

Research in technology acceptance is closely related to and often based on psychological concepts that target human cognition and perception. Due to the broad area of possible influences on the usage of technology, most researchers try to narrow down the scope of their research by limiting empirical

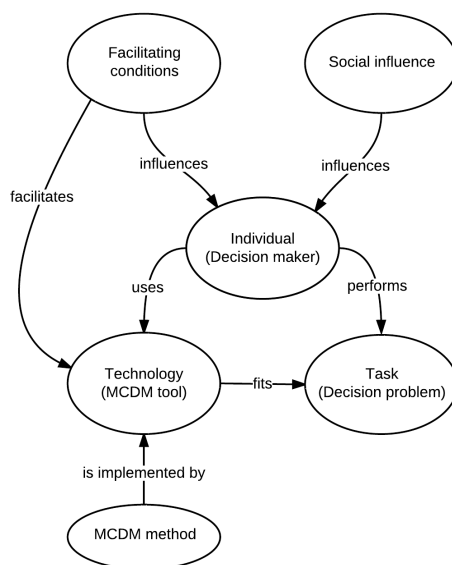

Fig. 1. Conceptual model of factors involved in MCDM tool usage behavior

investigations to certain areas of technology acceptance (e.g. visualization capabilities, individual differences). As a result of this practice a great number of models and theories have spawned that explain small parts of this research area. This process led to a rather unstructured research field where it seems hard to identify clear streams and future research possibilities. Therefore, as stated in Section I, one main goal of this research attempt is to synthesize and structure the list of possible influence factors and to conceptualize a model. Using an inductive categorization formation approach, we established the following major groups of influencing factors: individual, task, technology, method, social and facilitating conditions. These groups are intended to serve as a conceptual categorization for low-level constructs. High-level constructs (e.g. intention to use or perceived ease of use) tend to be an aggregation or a result of the combination of multiple low-level constructs and are therefore not clearly assignable to a single group. Due to the focus on MCDM systems the technical terms of this research area are used when applicable (individual - decision maker, technology - MCDM tool, task - decision problem).

The model presented in Fig. 1 provides a static perspective on the system at hand. It is not intended to explain or hypothesize on causalities or dependencies. It depicts a conceptualized overview of the field of MCDM acceptance and its key influences. Each ellipse represents one group that has been identified as described above. Edges between the groups model their associations and are labeled to describe the respective semantics of their relationship. The edge "uses" represents the most important relationship concerning acceptance, that is, the actual usage of the MCDM tool by the decision maker. In fact, this edge represents the core of MCDM acceptance research. Of course, this research includes not only the acceptance of tools but also the acceptance of MCDM methods. The

method itself, however, is used (and perceived) only via the MCDM tool which implements the method. The same line of arguments also applies to the relationship between the MCDM method and the decision problem (task) at hand. While the MCDM method supports solving the decision problem for sure, this relationship is conveyed by the tool implementing the method and assisting the solving of the task. Thus, there is only an arrow, from MCDM tool to decision problem, but no arrow from MCDM method to decision problem. The edge “performs” reflects the original problem situation or motivation for the usage of most IS, that is an individual has to carry out a specific task. While the relation between the decision maker and the MCDM tool as well as the relation between the decision maker and the decision problem are shown as activities by the decision maker (“uses” and “performs”), the groups facilitating conditions and social factors influence the decision maker (edges pointed towards DM). The edge labeled “facilitates” accounts for the need of certain enabling resources for some MCDM tools.

In the following we will give a short definition of our understanding of each group along with a presentation of key concepts and exemplary constructs.

#### A. Individual

The group of individual characteristics covers relevant aspects of the individual (decision maker) that influence the willingness to use a technology. This covers a quite wide range of factors like personality traits, demographic criteria, abilities, knowledge and affects.

For example, individual characteristics like *computer self-efficacy* (beliefs of being able to perform a specific task by using an IT system) or *computer playfulness* (describing the degree of cognitive spontaneity in microcomputer interaction) have been found to show a significant effect on perceived ease of use and therefore on technology adoption behavior (TAM3, [6]). Furthermore, constructs like *age*, *gender* or *experience* (moderating the individual’s usage behavior) establish this group (UTAUT, [15]).

From the five factor model’s point of view (FFM [27]) there are five individual traits that represent a personality in a highly aggregated manner: *openness*, *conscientiousness*, *agreeableness*, *extraversion* and *neuroticism*. Combined with general models of technology acceptance, the “big five” have been used to show that the personality traits of an individual have a significant influence on the willingness to use a certain technology [28].

Since research on the individual is part of various academic disciplines, many other models and researchers contributed characteristics to this group. For example, *attitude* (TRA, [4]), *affect* ([29]) or *propensity to trust* (Integrative Model of Organizational Trust, [30]) are constructs which are summarized within this group.

#### B. Task

The group of task-related constructs covers relevant aspects of the task (decision problem) at hand, which effect the

user’s evaluations of technologies intended to support him in performing the task.

For example, *task difficulty* (non-analyzable search behavior) and *task variety* (number of exceptions) distinguish routine tasks from non-routine task. A prominent model, which is based on this characterization of tasks, is the task-technology-fit model (TTF, [14]). Based on former research, this model also characterizes tasks by their *task interdependence* (with other organizational units). The TTF states that the more users are engaged in non-routine and interdependent tasks the more they demand from the technology, which in turn leads to lower evaluations of the respective technology. The model further states that this lower evaluations will effect the perception of usefulness and thus the utilization of the technology.

A behavioral model focusing on decision making, which is based on task characteristics, is the effort-accuracy model of cognition [19]. Within this model, decision tasks are characterized by their complexity which increases with constructs like *number of alternatives* or *number of dimensions*. The effort-accuracy model of cognition states that the complexity of the decision problem has a significant influence on the decision strategy used by decision makers [31]. Thus, we argue that a DSS which does not provide decision strategies (MCDM tool) appropriate to the complexity of the decision problem at hand, is not likely to be used.

Besides these basic models, task-related characteristics are subject to active research. For instance, the *risk* inherent to a task can affect the willingness to delegate the task to others, which also might be true for technologies [30], [16]. Another example is the degree to which a DM is *accountable* for the decision, which also influences the behavior of the decision maker [19]. We subsume such and similar abstract properties of tasks under this category of task-related characteristics, and argue that these characteristics have a major influence on the perception of the system’s usefulness.

#### C. Technology

The group of technology-related characteristics covers relevant aspects of the IT-artifact influencing the individual’s willingness to use the respective IT-artifact (MCDM tool).

For example, *visualization* capabilities can be regarded as one key-characteristic of a technological system and is therefore subject to active research. Following a long discussion on whether to prefer graphical vs. tabular representations, Vessey proposed the theory of cognitive fit (CFT, [11]) to integrate the different perspectives on which type of visualization fits to different types of data and task (spatial vs. symbolic). It states that a picture is not always worth a thousand words but in fact hinders cognition when used for the wrong purpose. Based on CFT, Speier found that visual representations not only have to fit the underlying type but also the complexity of the task [22].

*Social presence*, to name another construct, states that humans frequently apply social norms and rules towards computers. Nass, Steuer and Tauber presented this new paradigm called computers are social actors (CaSA, [13]) and triggered a

series of research attempts to investigate on how to increase or decrease the perceived social presence of computers in various fields of application (e.g. e-learning software, [32]).

Among a number of other constructs, we found that *job relevance* (degree of fit between technology and task [5]), *explanation facilities* (integration of how, why and process explanations into the software [33]) or *process guidance* (active guidance through the complete decision process [34]) belong to this group as well. Following the understanding that these characteristics of an IT artifact carry the potential to influence the degree of acceptance substantially, we subsume these factors within the group of technology-related influences.

#### D. Method

The group of methodical influences covers relevant aspects of the MCDM method influencing the individual's willingness to use the MCDM tool at hand. This group is a special case of technology related factors which can be distinctly attributed to the MCDM method underlying the respective technology.

For example, constructs like the *decision strategy* and perceived *decision strategy restrictiveness* and their respective influence were investigated by Wang and Benbasat on the basis of the effort-accuracy framework of cognition [16]. Their results showed that the more a user perceives a decision aid as being restrictive regarding the freedom to apply their preferred decision process the lesser is the user's intention to use the DSS.

Kotteman and Davis, on the other hand, found evidence in the literature that the degree of *decisional conflicts*, which increases with the salience of trade-offs, has a direct influence on the failure or success of decision support systems. They conclude that prominent constructs like perceived usefulness are not suitable indicators for actual performance of a DSS [35].

The constructs belonging to this group have an important influence on the acceptance of a DSS, since the user has to accept both, the decision strategy and its implementation (see Section II-B). Following this line of reasoning, we separate factors which can be attributed to the method from those that are attributed to the tool. We bear in mind, however, that this segregation is mainly conceptual since both groups are highly interconnected in empirical settings.

#### E. Social influence

The group of social influence covers relevant aspects of the social system influencing the decision maker's willingness to use the technology at hand.

For example, *subjective norm* (the degree to which an individual perceives social pressure to perform or not perform a behavior) is a major influence of the social system on the individual's behavior. Beside individual factors, *subjective norm* has been used within TRA and its successor, the theory of planned behavior, to explain intention to perform a behavior [36], [4].

*Image* (the degree to which an individual believes that using the technology will enhance one's social status) is another construct which falls into the category of social influence. Among other constructs, image and subjective norm have been integrated into TAM2 to explain perceived usefulness [5]. TAM2 accounts for the relatedness of image and subjective norm by pointing out that image is partly determined by subjective norm.

By incorporating the group of social factors, we acknowledge that individuals are always part of a social system which significantly influences their behavior and thus their technology usage.

#### F. Facilitating conditions

The group of facilitating conditions represent the organizational and technical support that is available to a decision maker or tool for the usage of a technology.

For example, *perceptions of external control* as proposed in TAM3 is used in a similar way, expressing the degree to which an individual believes that organizational and technical resources exist to support the use of the system [6]. Taylor and Todd propose further constructs in the decomposed TBP, like *resource facilitating conditions* (regarding beliefs about the availability of general resources such as time and money) and *technology facilitating conditions* (regarding technology compatibility) [37]. The construct of *end user support*, introduced in the work of Igarria and Iivari [38], also suggests that organizational support for using a system can enhance acceptance.

Although the existence of facilitating conditions is not necessarily a prerequisite for general MCDM acceptance, these factors can directly influence the individual's perception of the technology. Hence, consistent with our findings, *facilitating conditions* have already been presented as a highly-aggregated factor in UTAUT [15].

Table I summarizes the assignment of constructs from the respective models/theories to the categorization proposed. It can be observed that while some models pursue a comprehensive approach and hence integrate constructs from many categories, others specialize on certain areas.

## IV. CONCLUSION AND FURTHER RESEARCH

The objective of this study was to conceptualize a structural model that reflects the various research areas and perspectives on decision support acceptance. The model-building followed an extensive literature survey in the area of technology acceptance with special emphasis on MCDM acceptance. We could identify six major groups of influencing criteria that were put into context using a graphical representation. This conceptualization is consistent with former research results. For example, the UTAUT model also incorporates social influence, facilitating conditions and individual characteristics (the latter split into multiple detailed characteristics) as major determinants of technology adoption behavior. Furthermore,

TABLE I  
SAMPLE MAPPING OF MODELS/THEORIES TO FACTOR GROUPS

	individ.*	social	facil. cond.*	technology	method	task
UTAUT	X	X	X	X		
TAM3	X	X	X	X		
TPB	X	X	X			
MPCU	X	X	X	X		
FFM	X					
EAMC					X	X
CFT				X		
CaSA				X		
TTF	X			X		X

\*individ. = individual, facil.cond. = facilitating conditions

UTAUT=Unified Theory of Acceptance and Use of Technology, TAM3=Technology Acceptance Model 3,

TPB=Theory of Planned Behavior, MPCU=Theory of PC Utilization, FFM=Five Factor Model,

EAMC=Effort-Accuracy Model of Cognition, CFT=Cognitive Fit Theory, CaSA=Computer are Social Actors,

TTF=Task-Technology Fit

the TTF model is based on similar groups of characteristics (task, technology and individual) to explain IS utilization. That there is some agreement on major factors driving technology acceptance in general and MCDM acceptance in particular is a promising result towards a more unified view of and research in technology acceptance.

However, our findings also show that most research focuses on the individual's perception and related behavioral consequences. Rather little effort has been put into the analysis of the actual IT-artifact and how its characteristics influence its perception of the user. This also holds true for other drivers of technology acceptance. For example, questions like how to design user support services to increase the users' perception of facilitating conditions do not receive much attention although they have the potential to substantially increase user acceptance of technologies in the practical field. Thus, the analysis of how the design of concrete artifacts influences user evaluations seems to be a promising area for further research.

**Abstract**—In the coming years, the German traffic situation will undergo a challenging addition. Major car manufacturers have scheduled the year 2013 as cutoff for electric mobility. Yet, current studies indicate that range limitations and insufficient charging infrastructure endanger the acceptance for electric vehicles (EV). This is regrettable, and not only for the producer, but also for less obvious parties such as local energy providers which consider electric vehicles as remedy to one of their most severe problems of managing the grid load balance. In this paper we introduce a mobile accessible EV management system which accounts for the mobility of the user and also integrates web-based (commercial) services of third parties. Our objective is to counter the limitations of electric mobility and also to facilitate all of its (business) perspectives. We want to render electric mobility a success and support its trendsetting character.

**Index Terms**—Mobile environments, Mobile commerce, Distributed system, Web-based services, Electric vehicles, Charging station

## I. THE AGE OF ELECTRIC MOBILITY

IN THE coming years the traffic situation on German roads will undergo a ground-breaking, futuristic, and yet ambiguous change. Major car manufacturers have scheduled the year 2013 as cutoff for electric mobility. This ambitious aim is facilitated by the German government, which proposes the magic number of one million electric vehicles on German roads by the year 2020 [1]. However, to the day, the optimism regarding the acceptance of electric mobility is most often cushioned by results of market analysis. One of these studies [2] has been performed by *Ernst & Young* most recently. Figure 1 illustrates the answers to one of the study’s key question: “Which factors would make you most hesitant to choose a Plug-in Hybrid Electric Vehicle (PHEV) or EV as your next vehicle?”.

The presented numbers imply that, e-mobility is up against a set of severe problems. Beside the pricing issues, potential buyers are mainly scared by the limited range of electric vehicles and also by limited access to charging capabilities. Both problems necessitate considerations and planning of each intended ride. To support a driver in this task, we have developed an automated management system which operates on the daily schedule of the user.

Based on the location, the timing and the priority of the scheduled appointments, the system computes a fitting

		Access to charging stations	Price	Battery driving range	Reliability/service ability	Performance and handling
China		69%	57%	73%	64%	57%
Japan		60%	73%	43%	36%	35%
US		75%	74%	75%	57%	49%
Europe	France	74%	63%	81%	26%	46%
	Germany	74%	66%	75%	46%	52%
	Italy	64%	62%	62%	42%	54%
	UK	71%	60%	71%	47%	50%
<b>Average</b>		69%	67%	66%	49%	48%

■ Highest response rate for each factor    ■ Lowest response rate for each factor

Fig. 1. Answers to the question: “Which factors would make you most hesitant to choose a PHEV or EV as your next vehicle?”, raised within an *Ernst & Young* study [2].

“driving-strategy”, proposes alternative charging intervals, and is also able to recommend optimised appointment sequences by rearranging less prior, non time-critical tasks. The computation also accounts for infrastructural conditions and proposes charging intervals only in close distance to charging capabilities. We applied a web-based approach for the management of the user’s appointments and allow access not only from desktop computers but also from mobile devices in order to facilitate the system’s flexibility and to ensure its application to real world situations.

However, the domain of electric vehicles is complex and not only affects the driver, but also opens new business perspectives and opportunities. Energy providers for example have high hopes in electric mobility and consider EVs as remedy for one of their most critical problems: Grid load balance. By using electric vehicles as “rolling batteries”, energy providers currently develop area-wide mechanisms to charge electric vehicles when there is little grid load and much energy (and preferably a lot of volatile energy) available, and avoid charging periods when there is large demand from the energy grid. Yet, having in mind the restrictions of EVs, it is obvious that an according mechanism has to account for the

driver and his intended rides. For the reason of data integrity, it is also clear, that scheduled appointments undergo the privacy of the driver and cannot directly be forwarded to energy providers for optimisation purposes. We have designed our management system to act as loosely coupled middleware, able to comprehend many input channels, such as schedules provided by users, priority signals provided by an energy provider, infrastructure availabilities provided by energy infrastructure providers and many more.

We provide mobile access and allow users to manipulate their schedule at any time, each addition comprising re-optimisation. Previously computed charging intervals are again measured against the provided priority signal and possibly shifted to more effective time slots. Of course the shifting of already advised charging intervals can only be interesting for the energy provider to regulate his grid load. For the driver there seems to be no apparent benefit, yet, having dynamic energy tariffs in mind, the appeal becomes more obvious. With special conditions for the beforehand booking of particular charging intervals, customers may profit monetarily, while energy providers gain advantage in grid load regulation.

To sum up, electric mobility faces a lot of challenges, but also opens a lot of business perspectives. With our scheduling system we aim to do both, counter limitations and facilitate further possibilities. In this paper we describe the principle of our scheduling system and show how we designed the application to access web-based energy provider services (see Section II). To clarify our approach and to evaluate or work we use an exemplary scenario in which we also motivate the necessity for mobile access (see Section III). Subsequently we will classify and distinct our approach from related works (see Section IV). Finally, we wrap up with a conclusion (see Section V).

## II. SUPPORTING THE DRIVER

The challenge of managing the usage of electric vehicles and their related limitations and potential benefits is a complex one that is dependent to different actors with sometimes conflictive interests. Further, due to the nature of each scheduling problem, the system has to be highly dynamic in order to adapt its decisions to changes in the environment. In the following we will first describe the structure of our management system approach followed by a definition of the distributed services that are relevant within our domain. Further the charging management approach will be described in detail and finally we point out the mobile aspects of our system and its interaction with third party services.

### A. The management system approach

In order to support the driver comprehensively regarding the management of charging issues while utilising an electric vehicle, the management system requires access to various resources providing information about charging options, preferences and necessities. More specifically these can be prognosticated driving patterns, energy progression curves, energy price curves, wind energy curves and infrastructural

availabilities. Such a distinct set of data types is typically not provided by a single party or company and therefore the different information parts have to be requested from multiple sources. In some cases – for example the energy price curve – it might be even reasonable to request the data from different providers in order to build up a larger amount of planning options.

The major challenge for the management system lies in the creation of a charging schedule for the driver's EV out of the provided information. Thereby the result has to satisfy the driver's standards. But how is the driver's standards be defined?

The biggest issue in that context is certainly the mobility warranty in terms of the driver's driving patterns. This means the driver wants to travel with his EV without any sorrow about the state of charge. Out of this reason the management system undertakes the task of selecting a charging interval within the day guaranteeing that the vehicle will have enough energy until then. At the same time, however, the system has to validate that at the place, where the driver aims to be during a potential charging interval, there can be found a respective charging station nearby, which has to be available furthermore. This is why the management system not only searches for charging intervals, but at the same time for concrete charging stations. If the properties of the station are appropriate our approach triggers the reservation of the desired time slots. Another aspect are the energy costs that arise for charging transaction. It can be assumed that in the near future the energy provider will propose variable power prices in order to regulate the demand according to their infrastructural needs. Doing so, the purchase of expensive regulating energy can be avoided and regenerative energy, with the disadvantage of unsteady production, can be adapted monetarily to the demand and is therefore more attractive even at unusual energy consumption times. In that context it makes sense to the driver of an EV to fall back on low priced time slots in times he is flexible. Therefore the charging management has to select a solution that fulfills either the mobility warranty as well as the monetary aspect with flexible weightings on both parameters depending on the driver's profile.

However, in order to be able to trigger the charging management process the management system must find a way to evaluate the energy progression curve of the EV's battery for a certain prospective time interval. This is in turn only possible, if some kind of driving pattern can be assumed. In our approach we decided to deduce the expected journeys out of the driver's personal calendar. Doing so, the appointments and its location information are being extracted in order to know where to drive to. In order to compute the journeys in an automated way we defined a tag pattern within the appointments location field. If the driver writes down only one location the system assumes that this is the target place and the journey will start from a predefined standard location. But if two locations are being named within the field, the system computes a route from the first to the second named location. Based on that, the system is able to build up a prospective en-

ergy progression curve and check whether additional charging events are necessary or not.

### B. It's all about services

Due to the high level of distribution, which evolves from the different kinds of services being invoked, our management system is based upon a modular, service-oriented approach, which can be extended anytime with additional functionalities.

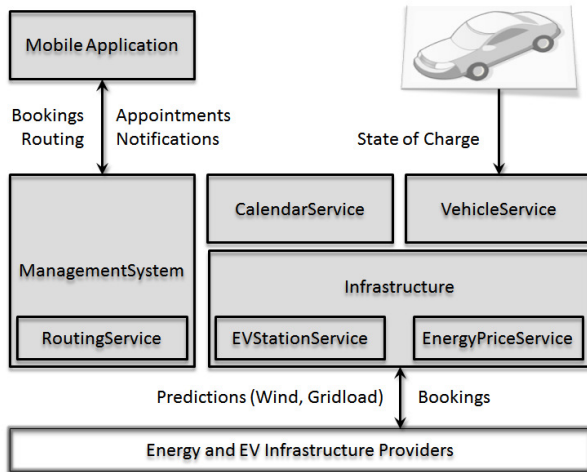

Fig. 2. The electric vehicle management system and related services

Figure 2 illustrates its structure and the external services which are being accessed during runtime. In the following the services and its functionalities are being described shortly.

- **Calendar Service:** The calendar service accesses a user-defined calendar resource and requests all prospective appointments from it. Furthermore the calendar service offers the possibility to easily add additional appointments to the source calendar.
- **Routing Service:** Proprietary service that provides the computation of routes regarding different preferences, such as length and speed. The result is the fundament for the computation of the energy progression curve.
- **Vehicle Service:** Wraps two separate services, namely the energy consumption service and the vehicle state service. The energy consumption service relies on the energy profile of the vehicle's battery and computes the energy consumption of routes in dependency to the expected state-of-charge. The vehicle state service is able to provide dynamic information like the actual SoC and position to the requester.
- **Charging Station Service:** Provides information about existing charging stations of a specific supplier near a requested location. Furthermore, offers information about the technical properties of the charging station and enables to book the charging station access for a certain time interval. According to this a charging station availability check is also possible.

- **Energy Price Service:** Provides a variable, time-dependent energy price curve of the energy provider, which is being continuously.

### C. Charging interval selection

The charging management process is triggered by the management system after certain events. These can be the appearance of new appointments (initial planning) or the dynamic and significant change of the energy provider's price function (potential rescheduling). In these cases the charging management behaves as follows.

The starting point for the algorithm is the prospective energy progression function of the EV, deduced by the driver's appointments. By means of that, it is checked whether the EV's SoC is expected to fall below a predefined, fixed threshold somewhere in the future. If so, the system extracts all time slots, where the EV is being parked before the threshold violation will occur and where a potential charging event will lift the curve above the threshold. Each of the possible charging options is now analysed regarding the location of the driver at that time and whether there is a charging station located nearby. At the same time, the charging station related energy price curve is being requested and checked for the prices with the desired interval. Out of these information, a set of potential charging options is generated, sorted by the cheapest charging station - energy price combination. Finally the system selects the cheapest charging interval that is available for the current price conditions. Since the price curve might change for the selected time interval dynamically, we defined in our approach that the energy provider sells the energy at maximum for the current price and might be even cheaper if the curve is being corrected downwards. Afterwards the driver is being informed about the updated charging planning via the mobile accessible application and after a confirmation the necessary bookings will be performed.

### D. Mobile user control

In our approach the user has two possibilities to control and interact with the management system. On the one hand, he is able to do that indirectly by inserting appointments in his personal calendar, which leads to a deduction of driving necessities and therefore to a triggering of the charging management process. On the other hand he can interact dynamically via a mobile EV management application. Doing so, the mobile application enables the user at every time to request the current planning state, to configure it and to initiate and control replanning actions due to dynamic events.

So the mobile application provides the configuration of user preferences, which enables the driver to orient the charging management more on the monetary aspects or the absolute mobility warranty. Further, a list of energy providers and their respective charging station infrastructure the system is planning on can be selected as well as a definition of a standard location the route planning is computing the journey from by default. Each modification within the user preferences leads to a rescheduling process.

In addition the user can look at his appointments in a calendar view. Within this perspective not only the synchronised appointments from the user's personal calendar are displayed but also the evaluated journeys and charging events. If the driver wants to start a journey he can select the appropriate one from the calendar, whereupon a route overview is being opened. Furthermore, it is possible to add new appointments directly within the mobile application calendar, which are finally synchronised to the user's background calendar.

The driver is also able to check the current state of his electric vehicle, if an activated vehicle state service is installed within the car. This offers the possibility being always informed about the current state of charge, even when not being at the vehicle's location. Therefore driver keeps a total overview about the processes that are happening within the car, for example when the car is charging and the user thinks about leaving the charging station a bit earlier than initially planned.

A very important task for the mobile application is the completion of charging booking decisions by interacting with the user. After the system has evaluated the optimal charging slot based upon the user preferences the driver gets an inquiry for confirmation. In that situation the driver can overview the costs for that event and compare them to alternate options. If he confirms a booking for the selected charging station time interval combination is being booked. Alternatively the driver can select other charging options if he is not satisfied with the system's decision. Consequently the driver is always able to fully control the planning of charging events and can also define charging events without any request to the charging management module.

Another aspect, which is covered by the mobile application, are the interaction mechanisms between user and system when unexpected events occur. These can be initiated either by the system or the user. So, for example, the driver is always able to cancel a booking if he recognises that he will not be at the place for the defined charging interval. In other cases the system initially informs the driver about some relevant state changes (unexpected, increased energy consumption, cheaper price curve, malfunctioning charging station) and proposes alternatives to him. For example, let us regard the price curve which changes during time. If some charging slots have been already booked and the system recognises that the price curve is now cheaper during another, later charging slot option than actual selected one, the user gets informed about that dynamically and can decide whether to change his booking or not.

Therefore the mobile management application can be described as a comprehensive interface to the user, which enables, besides configuration of the management system, the access to information about the energy providers infrastructure and the performance of usage rights transactions.

### III. EVALUATION

In order to evaluate our approach of a mobility management system with a mobile application for user system interaction

regarding the user's benefits, we describe a typical scenario in the following, where our application is intended to be used. In particular, we compare the differences to a static charging management system which does not provide *Mobile Commerce* access to energy providers and finally elaborate the advantages of our mobile solution.

Fig. 3. The driver's appointment schedule and the initial journey and charging event results.

Figure 3 illustrates the appointment schedule of an electric vehicle holder. Taking the appointments into account the management system has deduced all relevant journeys and computed its expected energy consumptions (with regard to the specific vehicle characteristics). Out of it a time dependent energy progression curve for the specific day and without any charging events in it yet has been build up.

Based on these information the charging management algorithm analyses when a charging event has to be scheduled at latest in order to adhere the mobility warranty and not to undercut a predefined lower energy threshold. Doing so, different time intervals come into play for charging. In our case the undercut of the energy threshold without charging occurs during the journey from 13:30 to 14:00 h. In this respect all parking events before that journey are left for consideration as long as there exist charging stations nearby the respective appointment locations. Now the energy price curve is relevant for further decisions. Fig. 4 shows the curve for our scenario indirectly. In the foreground there are two curves, one of them representing the overall load within the energy network, the other the amount of wind energy. In our case both curves are the fundament for the energy price curve, which is represented by the different types of shade in the background. Darker intervals indicate expensive charging slots while bright ones are cheap.

The charging management now computes the quality of the remaining, potential charging events in consideration of the mobility warranty and the energy price curve. In our scenario the algorithm evaluates a charging event during the meeting from 12:30 to 13:30 h as optimal. When looking at the energy price indicator in the figure, it is obvious that these interval is brighter than all the other potential intervals before. Another aspect the algorithm looked at when selecting a charging event is the distance from the charging station to the appointment location. If it exceeds a certain length the solution option is discarded, which was not the case in our scenario. If nothing changes on the user's appointment schedule until the start of the first journey the charging management is finished after the confirmation of the user, which triggers the system to

Fig. 4. Absolute amount of regenerative energy (line with dots; in MW) within the grid and its load. The background colors indicate the deduced energy price signal (Bright intervals represent cheap prices, dark intervals expensive ones)

communicate with the energy provider and to book the selected time interval at the actual conditions.

Until now, the management system has solely performed an initial charging event planning. In reality, however, cases will occur when the initial planning is not sufficient anymore and the user has to be involved in an interaction process. This will be shown in the following.

In our scenario the user starts his day and drives with his electric vehicle to his first meeting without any charging event being scheduled for that time. At 09:30 h he drives to the next appointment. Shortly before arriving, the appointment at 16:00 h is canceled by the organiser. The management system triggers the charging management process, which computes again the energy progression curve for the day and recognises, that, of course, no changes in the charging planning has to be done due to the omission of the journeys for the canceled meeting. But at the same time the management system checks for a energy price curve and notices a significant difference to the old price curve. Meanwhile, especially the prices at the current scenario time are much cheaper than our booked charging interval at 12:30 h. Therefore the system checks whether it is possible due to the omission of the late scheduled journeys to charge already earlier without triggering an energy threshold violation. Since this is the case in our scenario the charging management system searches for a charging station of the same energy provider nearby the immediately impended appointment. The system contacts the driver via his mobile application and offers him to shift his charging event to now and to directly drive to the evaluated charging station (see Figure 5). As a motivation the application displays the monetary benefit the user has when charging right now in comparison to the initial booked time slot. The driver confirms and drives immediately to the proposed charging station. When arriving he notices that the charging station parking lot has been illegally occupied by another vehicle and he is therefore not able to charge there. Because of that the user opens his mobile application and requests the cancellation of his booking and the search for an alternative charging station nearby. After processing the cancellation, the system checks for different charging stations and finds one from a different energy provider, which is available and has just a slightly

more expensive energy rate than the occupied one. The mobile application informs the driver and shows the route to the aimed spot, whereby the user confirms the booking and drives to the charging station. After the arrival, the user authenticates itself with his personal RFID chip and the charging station opens the loading hatch. After connection is set up and the charging has started the user walks the few hundred metres to the appointment location.

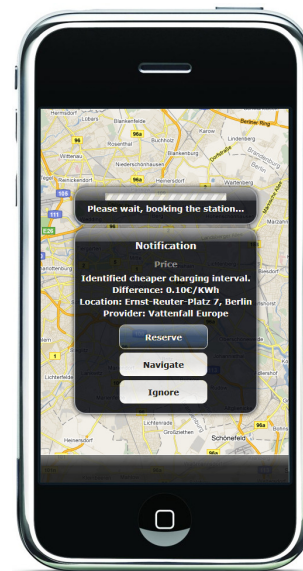

Fig. 5. Screenshot of our mobile application. Offering the driver to shift a charging event to now due to cheaper price.

The above described scenario shows in several respects how mobile interaction can serve the user when utilising electric vehicles in daily life. Especially in situations, when events occur very shortly like the cancellation of an appointment or the change of the energy price curve, the charging management can propose the result of his replanning process dynamically to the user, which can lead to a monetary benefit or simply keep the mobility warranty up. Using a static system, where the driver is just able to check the plans for example at the computer at his working place, such use cases can not be handled. This shows that a static system collapses every time when changes occur shortly, since they cannot be communicated between user and system. Within the scenario the driver is in the unpleasant situation that the aimed charging station, though booked, is physically not reachable. With the help of the mobile application the user was able to directly request a solution from the management system. In a static system the user would have had to search for an alternative charging station by himself which leads to significant additional expenses. In conclusion, the usage of dynamic, mobile management applications with an integration of *Mobile Commerce* services in the context of electric mobility leads to an significant additional benefit for the driver by supporting him comprehensively at every time and every place.

#### IV. RELATED WORK

It is difficult to provide a clear structure to this section since our work touches many different topics and domains of research. While the distributed nature of our system is to be assigned to the field of agent-oriented software development, the introduced scheduling and optimisation algorithms are unmistakably related to the comprehensive realm of operations research.

However, what our application clearly offers is mobile access to services which simplify, facilitate and support the management of electric vehicles. These services are web-based and in the case services provided by energy providers, feature a commercial character, since “rights to use services” are transferred.

Literature refers to this principle as *Mobile Commerce* for which *Tiwari* and *Buse* provide the following definition:

“*Mobile Commerce is any transaction, involving the transfer of ownership or rights to use goods and services, which is initiated and/or completed by using mobile access to computer-mediated networks with the help of an electronic device.*” [3]

Compared to the more common and superordinate domain of *Electronic Commerce* (or *E-Commerce*), *Mobile Commerce* emphasises on services which can be accessed at any time and from anywhere. As a matter of fact, *Mobile Commerce* accounts for an entire set of promising capabilities, such as location- and context-awareness.

In the following we present driver assistance systems which are similar to the one we have developed. In this survey, we try to answer the question in how far principles of *Mobile Commerce* have been applied for this type of application.

The *Blink Mobile Application* [4] is a mobile app from ECOItality<sup>1</sup> introduced at the Electronic Drive and Transportation (EDTA) conference<sup>2</sup>. It allows to access the Blink Network<sup>3</sup> anywhere and will be soon available for free via all major mobile device application stores. The Blink Network is an EV charging infrastructure including EV charging stations, software and online services. The mobile application allows to find available public and commercial charging stations. This can be done location-based via the mobile device’s wireless or GPS coordinates or manually. Furthermore it allows to reserve charging stations, to receive charging status updates, to view additional informations about the charging station and to route to the chosen station. Nevertheless, the Blink Mobile Application do not cover all functions of the Blink Network. So it is not possible to use the scheduling function of the network from mobile access. However, many mobile devices can still access this feature using the website of the Blink Network. There they user is able to schedule a charge or plan reservations based on travel routes.

The *ChargePoint App* [5],[6] developed by Coulomb Technologies<sup>4</sup> allows to locate Charge Point Networked charging stations. It’s available for Apple iPhone ad BlackBerry. The app allows to find charging stations near to a specified address (US, Europe, Australia), to receive status informations about the stations, to trigger the charging process and to receive real-time notifications of the running process. As the supported devices have the possibility to route, the app can show directions to charging stations, too. Also it can calculate the cost of a charge.

The *PlugShare App* [7],[8] helps EV drivers to find charging stations and homes or lots that will allow them to recharge for free. It is not developed by a EV infrastructure provider like the both introduced before and is driven by the idea to build up a community of people how share there resources (under the term *plug-share*). This is much similar to the couchsurfing<sup>5</sup> project and is driven by the idea that “...*the infrastructure to charge is everywhere.*”[7].

Similar to this approaches there exists several others that allow to find charging stations by web or mobile access. The *Alternative Fueling Station Locator* [9] use Google Maps technology to show locations of EV charging and other alternative fueling stations. The *DriveAlternatives App* [10] does pretty much the same and offers additional features like favorite stations, photos, comments and email alerts for station changes. *CarStations* [11] offers a user driven international directory and mapping service for EV charging stations. Unlike the preliminary introduced approaches, these ones offer no functions to initiate or complete transaction in the purpose of *Mobile Commerce*.

To sum up, none of the examined approach provides dynamic planning which is triggered by environmental or user dependent changes. Nevertheless, the *Blink Mobile Application* combines scheduling features which *Mobile Commerce* aspects. In detail this means that the user is able to plan and reserve charging stations. In contrast to our approach this must be done manually and there is no automated planning behaviour based on variable price signal curves, which supports the user. As with the *ChargePoint App* the customer is able to initiate a charging process, monitor the costs of the running process and stop them if needed. Scheduling is widely missing here. Both applications have been developed by EV infrastructure providers and their extend of *Mobile Commerce* is limited to the manufacturer’s products. The developers of *PlugShare App* present a different approach, which complies with the “rights to use services” specification. Locations for charging electric vehicles are proposed and can be booked free of charge via SMS, email or a call. The cost are actually borne by the provider of the charging station. The approach is based on the idea to provide a community-based backup network in case a driver measures his consumption wrong. No scheduling mechanism is implemented here.

## V. CONCLUSION

In this paper we introduced a management system for electric vehicles. We motivated the necessity for such an application with the restrictions and limitations of the first EV generation. We also provided figures on the common acceptance towards electric mobility in order to emphasise the severity of its shortcomings and to support our motivation. Subsequently we introduced our management system and its basic functionality of optimising the use of an electric vehicle by accounting for the driver's appointments and additional data from a web-based energy provider service. After outlining the basic idea and functionality we described our implementation in detail and described a simple, yet expressive example in order to evaluate our work and to clarify its principle. Finally we compared our work to related approaches.

### A. Implications

As mentioned above, we used a rather simple scenario to evaluate our work. The idea was to clarify the functionality of our approach and to emphasise our main objective of providing mobility for the driver. However, by integrating the web-service of the energy provider for the optimisation routine we showed that e-mobility provides business perspectives beyond those of the car manufacturer and their customers. In our example both, the driver and the energy provider were able to profit from our management system. While the driver gained profit in a better pricing, the energy provider managed to shift one particular charging interval to a — from his perspective — far better period of time. Admittedly, the benefit of shifting a single charging interval is infinitesimal small, yet, on a large scale the principle is considered a remedy to one of their most severe problems of managing the grid load balance. Currently, there many research projects trying to provide solutions for this exact challenge. In fact, this work was actually done as a part of this initiative [12].

### B. Contribution

The contribution of our approach is twofold. To start with, we have managed to support the driver of an electric vehicle in his daily routine. It was our objective to counter the limitations of electric mobility and based on our evaluation we can say, that we have managed to utilise the capabilities of electric vehicles in a far more effective way. Of course, the reliability of fuel driven cars is a dream of the future, but improvement here rather lies with the car manufacturers and battery producers.

Beside a more effective utilisation, we have shown, that our approach is able to support business perspectives around e-mobility. It is our belief, that the target group of electric mobility exceeds that of common "vehicle customers" and opens perspectives beyond that. We also think, that these services are not explicitly geared towards e-mobility, but also affect regular traffic. For our work we used a prototypical implementation from a national energy provider as an example, but many ground-breaking services are available today already. As an example, consider the many available parkingspot services

(i.e. *Parkingspots*<sup>6</sup>), which are able to retrieve the best fitting parking lot (tariff and location) for a given online query. Another example is the *Waze*<sup>7</sup> service, which provides routing functionality, based on real-time traffic flow. It is our belief that service-based guidance systems as those, mentioned above will establish in the near future. In this work we presented a concrete way to merge the interests of a person with the recommendation of a guidance system.

### C. Future Work

In short, we plan to extend our work to comprehend more third party services.

In some scenarios we had to deal with the problematic that the user's schedule exceeded the range capabilities of the electric vehicle. As an alternative we intend to propose multi-modal strategies to the user — involving public transport. It is our idea, to access online time-tables of a local public transport operator and use the data for our computation and to provide the user with detailed information on the planned journey (line, departure times, estimated arrival times, walking distances, parking lot, etc.).

As a second extension, we plan to integrate a car sharing capability for our system. We want to give users the chance to offer their scheduled rides to others, which are able to check in for desired rides by some mobile interface.

# NotX

## Service Oriented Multi-platform Notification System

Filip Nguyen, Jaroslav Škrabálek

Faculty of Informatics

Masaryk University

Brno, Czech Republic

Email: [nguyen.filip@mail.muni.cz](mailto:nguyen.filip@mail.muni.cz), [skrabalek@fi.muni.cz](mailto:skrabalek@fi.muni.cz)

**Abstract**—This report describes NotX—service oriented system, that applies ideas of CEP and SOA to build highly reusable, flexible, both platform and protocol independent solution. Service oriented system NotX is capable of notifying users of external information system via various engines; currently: SMS engine, voice synthesizer (call engine) and mail engine. Adaptable design decision makes it possible to easily extend NotX with interesting capabilities. The engines are added as plug-ins written in Java. There are plans to further extend NotX with following engines: Facebook engine, Twitter engine, content management system engine. Also the design of NotX allows to notify users in their own language with full localization support which is necessary to bring value in today's market. Most importantly, the core design of NotX allows to run under heavy load comprising thousands of requests for notification per second via various protocols (currently Thrift, Web Services, Java Client). Thus NotX is designed to be used by state of the art Enterprise Applications that require by default certain properties of their external systems as scalability, reliability and fail-over.

**Index Terms**—information system, soa, notx, cep, sms, voice, phone, mail, notification, enterprise, java, active mq, jms, jee, j2ee

### I. INTRODUCTION

NOTIFICATIONS have been studied as valuable tool in context of *ubiquitous computing* [3] and little more simplistic version of them (email notifications) are present in almost every *information system* as a standard approach to notify (and prompt) user in the case of password change, registration approval or account state change. But the real power of notifications come when there is more sophisticated business logic associated with generation of these events such as in [4]. Other useful applications of such a notification service are areas where traditional paper based communication/notification means are used [5]. Consider simple example—in information system dedicated to organize academic conferences important criterion for usability would be for user to receive notifications about paper submission and paper approval or rejection. They would also expect to be notified about other more real-time events like reschedule of certain presentation. This kind of business logic is usually system-specific but means of delivering these notifications are usually the same: email or SMS (short message service for cellular network). There is one additional channel that we find very useful (also indicated in [1]) and that is voice channel, namely text to speech synthesis delivered into cellular network. Because of repetitive use of

this notification infrastructure (e.g. [6]) it would be beneficial to create service that would provide all these notification means.

In this report we describe service that complies to above description—NotX. In the first part of the paper we describe business requirements that are relevant for such service. Then the actual architecture and technological details of NotX are presented. The last part of paper is dedicated to discussing the development process used to drive NotX development and possible directions of further work on NotX.

### II. BUSINESS REQUIREMENTS

NotX's first deployment hence first real use case is to serve as a notification service to Takeplace [11] information system to send various notifications including:

- emails with password change/registration
- rescheduling of presentation (this is typically delivered by SMS or voice)

Notification is sent dynamically via appropriate engine according to user settings and global NotX settings. Voice and SMS engines are a very fast way to notify the user but uses of these engines are charged so their use is limited and must be controlled.

Voice notifications can be delivered into cellular network or to SIP (Session Initiation Protocol - signaling protocol for internet phone communication). Motivation for SIP can be found in [7].

Because it is anticipated that the use of notifications will be massive and certain groups of users will be repetitively notified (for example attendees of certain conference) we demand *tagging* of users. Information system developer (IS developer) should be able to send notifications to either specific user or to specific tag.

Required operations to be performed via NotX are:

- tag (userid, tag)
- unTag (userid, tag)
- sendNotification (dest, msgType, templateName, placeholderVals)

The *tag* parameter in *tag* and *unTag* is text with '.' characters permitted, e.g. *ConfernceA.attendee* or *ConferenceA.speaker*. The first part of *tag* parameter up to '.' is called *domain*. The tag does not have to include the domain, the domain is

used only for billing and statistical purposes. The *userid* is unique identifier of user to be tagged. The *sendNotification* operation is used to send notification itself. The parameter *dest* is used to specify to which entity the message should be sent. It can be either *userid* prefixed with ':' or it can be tag. When tag is used in this parameter the message will be sent to all tagged users. Parameter *msgType* is used to add more semantic to message, e.g.: *important*. Administrator of NotX can use this semantic parameter to configure NotX to send all *important* messages via predefined engine, e.g for TTS (text to speech synthesis). Next parameter *templateName* is used to specify which message should be sent, for example template for registration approval *registration\_approval* is template of message that is sent when registration process is successful. Lastly *placeholderVals* is associative array that is used to inject values into template.

Takeplace itself is a distributed web application, and has many different developers that are experienced in various technologies (ranging from PHP to Servlets) hence every one of these developers is used to a different way of accessing services. NotX should take this into account and make it as easy as possible to access NotX service.

Next important requirement is concerned with internationalization. Because academical conferences are usually attended by participants from various countries it is convenient for them to receive notifications in their own language. This is important equally for voice, sms and email notifications.

Because NotX uses charged services like cellular network the NotX has to keep track of sent notifications with information about domain to which they were sent.

Regarding nonfunctional requirements, the most important is to handle peaks of notifications with persistent fail-over. Usually if there is one big notification for all participants of major conference there can be thousands of various messages sent via email, SMS or voice synthesizer (TTS). It's not necessary to deliver all notifications at once but system should not render unresponsive or shouldn't crash and all messages should be delivered.

### III. ARCHITECTURE

NotX is developed to be a scalable platform and protocol independent Service. Currently the NotX is deployed to serve as a service for Takeplace so thousands of messages can arrive per second at peak hours.

Necessary attribute of reusable software service is its platform independence. That's why NotX and its components are built using Java programming language. NotX itself is web application that is built using build tool Maven [2].

The main output of the build process are two WAR (Web Application Archive) files: *Notx.war* and *Communication.war* which is web application that exposes protocols used as an interface into NotX. These main components are depicted in Figure 1. These WAR archives correspond to main components of NotX architecture - the core logic itself (NotX) and communication module (the *Communication.war*).

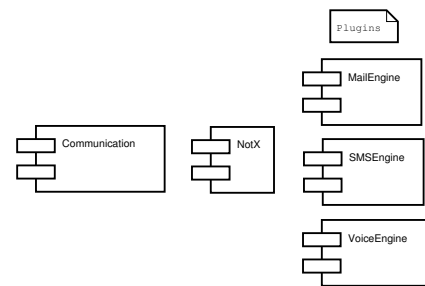

Fig. 1. Components of NotX

JMS (JSR 914) is specification for messaging API between loosely coupled components of information system. We are using Apache Active MQ implementation which supports persistent fail-over. Considering fail-over there are several fails that can happen during NotX's lifecycle:

- 1) Problem with external engine provider (SMS or voice)
- 2) Problem with connectivity to communication module with NotX
- 3) Bug in NotX logic
- 4) Any fail of hardware while processing notification

To address all of these problems our architecture is queue centric as seen in overall design in figure 2. After receiving request for notification the communication module immediately sends the request into persistent queue.

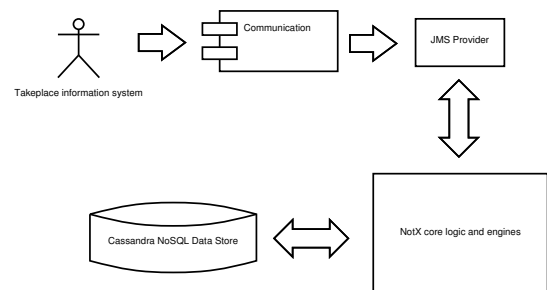

Fig. 2. Overall design

The most important operation of NotX is *sendNotification*. We will describe core logic behind this operation in more detail. As noted in business requirements this operation takes four parameters: *dest*, *msgType*, *templateName*, *placeholderVals*. Important logic takes place when *sendNotification* is called and destination is set to some specific tag, for example *ConferenceA.attendees*. Following steps take place after request has arrived to communication module:

- 1) Communication module recognizes the request as notification request and puts new notification request message *A* into message queue
- 2) NotX logic starts processing *A* by looking up *N* users which are to be notified by notification in *A*. Then NotX generates *N* messages  $\{A_1, \dots, A_N\}$  and puts them back into message queue.

- 3) Note that up to this point there was no interaction with any engine. Now NotX will be continuously receiving messages  $A_x \in \{A_1, \dots, A_N\}$  from message queue and each such message is processed as follows:
  - a) Find language  $L$  of user for whom  $A_x$  is dedicated.
  - b) Look up template for  $A_x$  according to  $L$
  - c) Now NotX injects *placeholderVals* into template and uses selected engine to notify the user. If this whole process is successful then notification statistic is saved into data store.

If there would be any kind of problem with data store or connectivity the messages are kept in message queue for administrator to manually decide how to deal with them.

Step number two is very important. The generation of  $A_1, \dots, A_N$  messages helps to more evenly distribute load on the system and also helps traceability of the system. For example when notification request is to be processed for *ConferenceA.attendees* that can mean notification of 1000 users. When even 1 notification fails it is beneficial to know which one failed and why. After bug fixing it's important to be able to swiftly retry sending exactly the same notification as failed previously.

#### A. Protocol access

Requirement for protocol access may occur in many contexts. NotX provides following interfaces (as depicted in Figure 3):

- JSON (JavaScript Object Notation) interface via HTTP POST for simple notification sending
- Thrift interface for higher level languages (framework for cross-language service development)
- native Java libraries
- web services

Fig. 3. Protocols

Adding new communication protocol is fairly easy. It means modifying Communication module, which resides in directory *src/notx-communication*. When adding new protocol, it is necessary to implement all NotX methods. Each method implementation usually just creates standard JMS message and puts it into MQ. Then only modification of *Communication-Main* class will make sure that after launch of communication module the interface into NotX will be functional.

#### B. Data storage

NotX uses data store for:

- information about users - contacts and tags
- statistics

- fail-over

Each user has his contacts stored in data store. This way NotX is able to send notifications by any engine for this particular user.

Statistics are saved mainly to charge users of paid services and performance tinkering.

Data storage is also used as a fail-over mechanism. Whenever a notification message is not sent successfully it is saved into data store and can be viewed via web interface with exception that caused the failure. It's possible to send specific failed notifications back to the message queue to retry the sending.

The data store itself is implemented using Cassandra NoSQL database. Decision to choose this storage type was led by need for multi-platform and highly scalable data store.

#### IV. DEVELOPMENT PROCESS

The development process of NotX was driven by SCRUM methodology. This agile process introduced by Schwaber and Shuterland [8] suits development of the NotX best because requirements were from start more about searching of possibilities instead of launching repeatable processes.

SCRUM itself is being used with two week sprints (sprint is one iteration in SCRUM). Each sprint starts with sprint planning, where spring goal is presented (major functionality, or tangible goal that is to be produced by this sprint) and product backlog items for this sprint are presented (product backlog item is high level business requirement). SCRUM itself doesn't give many hints how to specify backlog items, but there are publications addressing this issue e. g. [9] which introduce *user stories* into SCRUM.

Then development proceeds and at the end of the sprint *sprint review* takes place where output of an iteration is presented. In NotX settings the sprint review and sprint planning took place same day, usually on Wednesday.

Product backlog as well as sprint backlog are kept in Open Office spreadsheet. This low tech approach always yields less administration and more focus on actual work. From backlog it can be derived how much work was spent on specific product backlog item each day and how well estimated the task was.

To our knowledge there are no major modifications of SCRUM methodology for web development (also in [10] no consistent difference was reported in decision making for web projects). There are however some subtle differences when developing system such as NotX in general (not just with agile practices):

- External tools spike first
- Sprint review should contain technological details
- Sprints to refactor code has to be more explicitly specified
- More focus on automatized integration testing

It's essential that each external tool like TTS system or SMS gateway that are used to carry out notifications are spiked first before adding any product backlog items that are dependent on this TTS. We recommend to have a sprint in which external tools are examined. Such a sprint helps in planning next

sprints because developers of NotX can help product owner to prioritize and estimate product backlog items that will include external tool usage.

Sprint review should include technological details because product owner represents technologically experienced users (developers of information system).

Sprints to refactor code has to be specified very explicitly with carefully formulated sprint goal. Sprint goals of these sprints shouldn't be vague or not measurable like: create more readable code. But there should be measurable goals e. g.:

- write automated test that will fire up in-memory database and perform CRUD (Create Read Update Delete) operations
- rewrite logic of configuration loading and present this new design using class diagram and sequence diagram at sprint review

Focus on integration testing comes from the fact that NotX itself uses several external systems and lot of logic is simple orchestration between JMS provider and external engines. This makes unit testing less effective.

All points above can be addressed with SCRUM by managing content of product backlog and sprint reviews.

#### V. FURTHER WORK

In future, we plan to extend NotX to be publicly available service to be used by any IS developer. Technically it is possible right now because NotX supports lot of protocols for communication. There are, however, some missing functionalities like IS developer registration or billing reports.

Last important way to add more functionality to NotX is extending its communication module. There are many possibilities:

- Facebook engine—engine that notifies directly into accounts wall or private message
- Twitter engine—sends the notification to twitter
- FTP/SCP engine—puts the notification on FTP server or via SCP on some server
- IRC engine
- Skype engine—calling by skype. We didn't tested feasibility of this option yet.

The design of NotX, especially fact that it stores user information is preparation of NotX to become fully publicly available service that won't disclose users contacts. By managing contacts NotX is also single point where user can change his contacts and single point in which user can cut off potential notifications from various sources.

#### VI. CONCLUSION

In this paper we reported state of NotX - Service with capability of sending notifications via various engines. NotX gives value added to information system developers by taking burden of setting up infrastructure to send SMS, voice and email notifications. Additionally NotX helps with contacts management as it stores the contact information about users and doesn't reveal those contacts to IS developer.

NotX reduces time to integrate interesting functionality for any new information system with low development time and bring out of the box governance capabilities like fail-over, statistics and large scale notification sending in various languages. While doing all this NotX doesn't disclose any information about the user except his identifier that will be used to send notification.

#### ACKNOWLEDGMENT

The authors would like to thank Pavol Grešša for refining architecture of NotX and also to Lukáš Rychnovský for ideas from CEP and experience with building large scale distributed application that he shared.

**Based on reviewing foremost literature, the paper discusses various design science research methodologies along with their case studies. It concentrates on activities (tools, methods, actions) that are used while constructing an artefact. We have identified common activities occurring across ‘design’ steps, which were not indicated in their methodologies. Combining them and drawing on that finding, we propose a concept of reference model, which gives more insights and additionally dissipates design science high level of abstraction.**

### I. INTRODUCTION

**O**VER the last years design science (DS) research has received increased attention in computing and information systems (IS) research [1,2]. It has become an accepted approach for research in the IS discipline, with dramatic growth in recent, related literature [3,4,5,6].

Research, as a process, is “the application of scientific method to the complex task of discovering answers (solutions) to questions (problems)” [7]. We can differentiate between the study of natural systems, such as physics, biology, economics and sociology [8], and the creation of artificial ones, such as medicine and engineering [8,9]. The core mission of the former is to develop valid knowledge to understand the natural or social world, or to describe, explain and possibly predict. The centre of the latter is to develop knowledge that can be used by professionals in the field in question to design solutions to their field problems. Understanding the nature and causes of problems can be a great help in designing solutions, and is the focus of design science [10]. However, design science does not limit itself to the understanding, but also aims to develop knowledge on the advantages and disadvantages of alternative solutions [10]. Though literature reflects healthy discussion around the balance of rigor and relevance [11] in DS research, agreement on the DS fundamentals aspects such as definition, methods, outputs has yet to be achieved [12]. The area is still being shaped [2,13].

Views and recommendations on the methodology of DS research vary among papers, e.g. [14,15,16,7,17,18,19,20,21,22]. One set of guidelines by Hevner [11] has been widely cited, there being concern with

their high-level and lack of specificity [23]; however, some papers reveal few instances of their actual applications [24].

Thus, though generally highly regarded and widely cited, DS methodological guidance from the precursors Hevner [11] and Walls [25] is seldom ‘applied’, suggesting that existing guidelines and methods are insufficiently clear, or inadequately operationalised - still too high a level of abstraction [18]. Alturki [23], inspired by Winter [12] stating that there was a “lack of a commonly accepted reference process model for DS research”, structured DS Roadmap to guide researchers across the DS lifecycle. In our opinion, this is the most comprehensive collection of design science paradigms to date. However, we argue that some proposed DS methodologies concentrate on developing artefacts for specific aspects of IS [26,14,5] and therefore we still take others into account.

In this paper we discuss common activities that occur across various DS methodologies in a step in which an actual artefact is being created/produced/developed. Some authors refer to the step as build [17], design & development [18], design solution [27], or develop (construction) [23] For the purpose of this paper we refer to it as the construction step.. The paper is organized as follows. First, following Offerman’s [16] claim that not much guidelines is provided in IS literature on construction step, we will present the lack of details by discussing selected DS methodologies. Next, we identify activities of that step in case studies that were conducted in order to evaluate those methodologies. By activities, we mean tools, methods, and/or actions taken by researchers to gain sufficient knowledge in order to create/produce/develop an artefact. It’s worth noticing, that these activities, even actually used, were not mentioned in those methodologies, but Offerman’s [27]. Then, we distinguish these activities that are common across DS methodologies and propose a concept of a reference model for the construction step. It could be seen as a guideline for this step regardless of selected methodology. Finally, we will discuss further research on the reference model and its application to DS.

### II. VARIOUS DESIGN SCIENCE METHODOLOGIES

Methodology is the philosophy of the research process which “includes the assumptions and values that serve as a

rationale for research and the standards or criteria the researcher uses for interpreting data and reaching conclusion” [28]

A number of researchers, both in and outside of the Information Systems (IS) discipline, have sought to provide some guidance to define design science research [11]. Their work in engineering [29,30,31,32], computer science [33,34], and IS [35,36,33,17,20,25,22] have aimed to collect and distribute the appropriate reference literature [19]; characterize its purposes, differentiate it from theory building and testing research and from other research

paradigms.

They enhanced its essential elements; and claim its legitimacy. Some researchers in IS and other disciplines have contributed ideas for process elements [29,34,30,25,20,33]. These papers include some component in the initial stages of research to define a research problem. Figure 1 illustrates the most influential papers helping shape design science tenet over two decades, in our opinion. Nunamaker et al. [7] and Walls et al. [25] emphasized theoretical bases, whereas engineering researchers [29,30] focused more on applied problems. Takeda et al. [34]

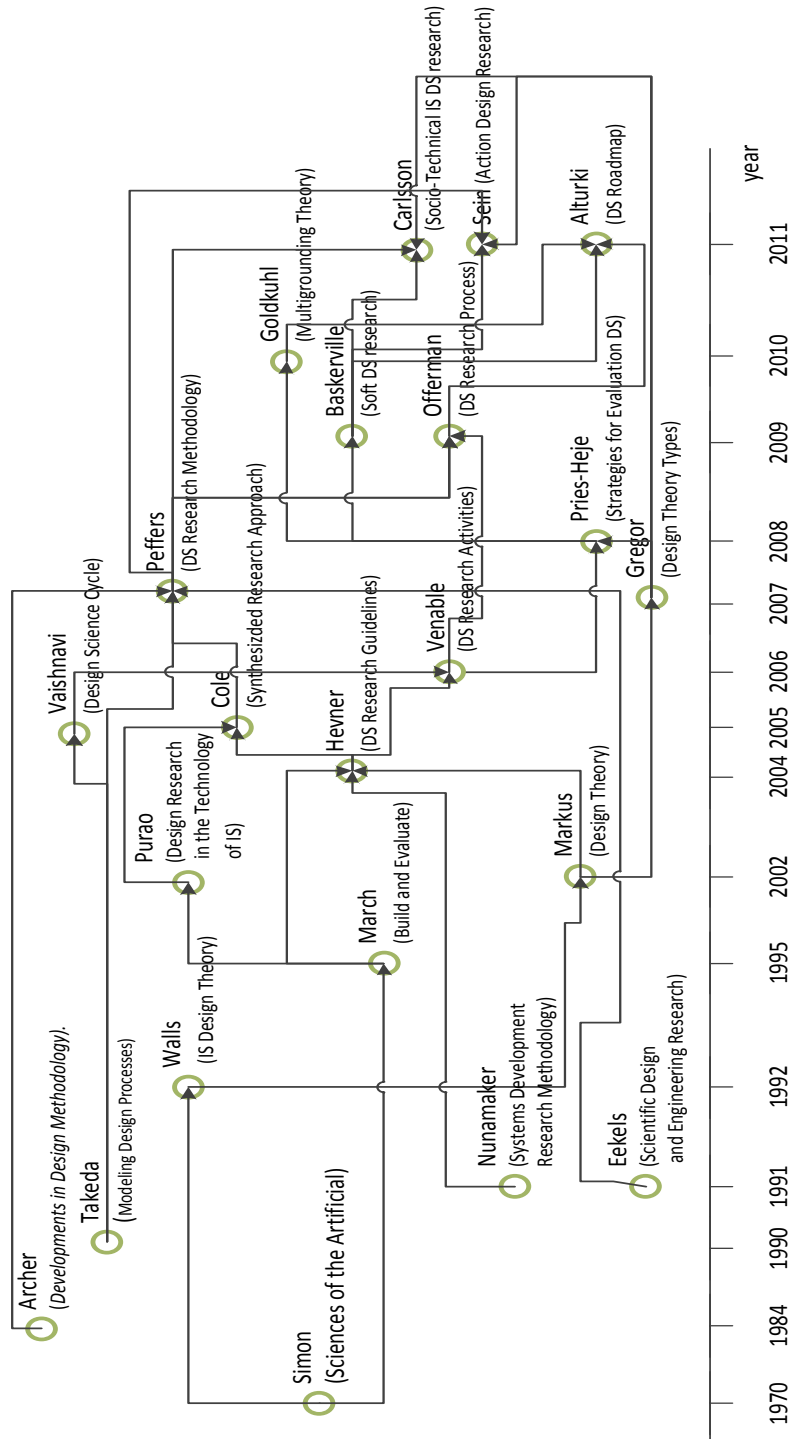

Figure 1 Design Science paradigms over years

suggested the need for problem enumeration. Hevner et al. [11] asserted that design science research should address important and relevant problems. Based on those representative papers which stated or suggested process elements, the components of the design science research methodology (DSRM) were synthesized by Peffers [18].

Even though there were different methodologies, we observed a common agreement on their outcomes. Researchers define the DS outcome as an artefact, in form of a construct, model, method, and an instantiation [17,11]. Some researchers understand artefacts as “things”, i.e. entities that have some separate existence [31]. Constructs are defined as “concepts” and “conceptualizations” [17] and “vocabulary and symbols” [11]. These constructs are abstracted concepts aimed for theorizing and trans-situational use. “Conceptualizations are extremely important in both natural and design science. They define the terms used when describing and thinking about tasks” [17]. Models are not conceived as abstract entities in the same way as constructs. “Models use constructs to represent a real world situation – the design problem and its solution space...” [11] “Models aid problem and solution understanding and frequently represent the connection between problem and solution components enabling exploration of the effects of design decisions and changes in the real world.” [11]. A method is defined as “a set of steps (an algorithm or guideline) to perform a task” [17]. An instantiation is a prototype or a specific working system or some kind of tool [31]. Most researchers agree on those form of artefacts (e.g. [19,3,23]); however, the methodology to achieve them varies [18,26,14].

### III. COMMONALITY IN ARTEFACT CONSTRUCTION

Having thoroughly read articles from Figure 1 we observed that researchers (e.g. [26,19,21]) clearly pointed out to the *construction* step as the one where the artefact is formed; however, without giving much details on how to approach it. To gain additional details, we decided to connect those steps with case studies of their methodologies. We excluded papers that did not present design science methodologies or put forward case studies that did not provide enough insight to withdraw seeking activities. Then, we created a table that provided only names of the construction steps in proposed design science methodologies and descriptions of undertaken activities in relevant case studies. Commonalities in different steps were out of scope in our search. Upon constructing the table, we analysed those activities in regards to the source from which information about artefact is gathered. We observed that two main streams could be distinguished. Researchers either reached to relevant literature or collaboration with relevant practitioners in order to construct artefacts.

Upon constructing the table we observed that the main activities in construction steps concerned literature review and collaboration with practitioners. By literature review we understand activities that lead to review the critical points of current knowledge and or methodological approaches on a

particular topic (e.g. the seeking solution). It may be seen as preparation, gathering knowledge, or building foundation on which the artifact is being constructed. Collaboration with practitioners reveals that the act of designing does not occur in isolation. It is a living process engaging practitioners from the field. The bilateral construction of an artefact falls within the scope of engaged scholarship presented by Van de Ven. [37]. The level of engagement may depend on the nature of seeking artefact. Nonetheless the conducted activities, such as focus group discussions, semi-structured interviews, and workshops will still be concerned as the main facilitators in the act of design. Our search indicated, that in 78% of all case studies, the researchers gathered relevant information, for constructing artefacts, from literature and contacting practitioners from the field. The rest 22% focuses mainly on relevant literature. Those facts and the commonality that we discovered from various design science methodologies led us to suggest a concept of the reference model that could facilitate the construction step in DS research.

Figure 2 illustrates a place of our concept model in DS. The reference model will provide description of activities and the proper order that should be undertaken in construction step regardless of used DS research methodology. It will play role of facilitator guideline rather than a solution adviser.

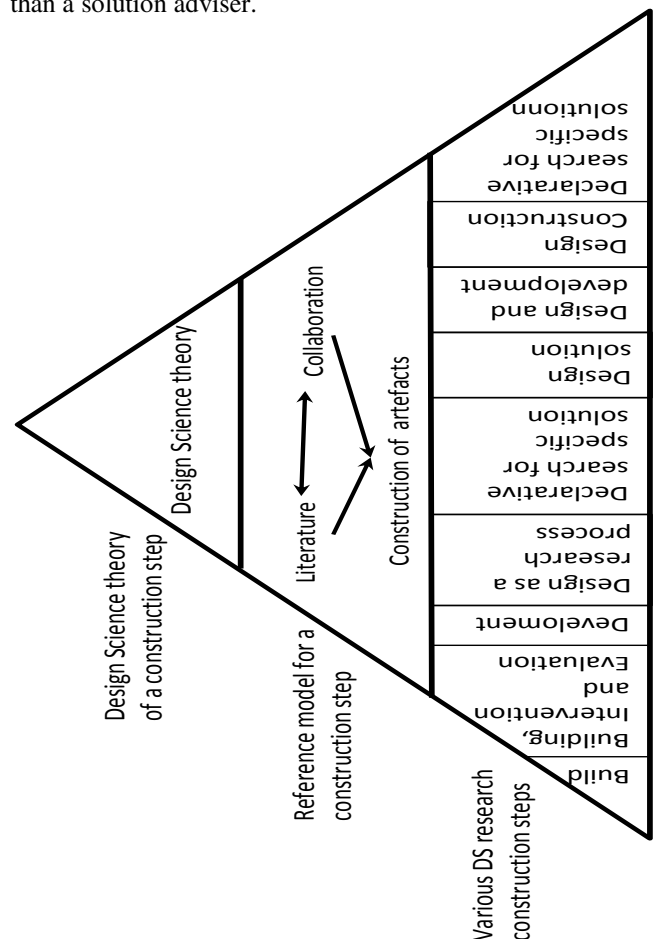

Figure 2 Place of Reference Model in DS

#### IV. CONCLUSION

In summary, we observed that literature and collaboration with practitioners play an important role in constructing/producing/developing an artefact. However, since our concept was made on case studies from various design science research methodologies, additional research on these activities is advised. The reference model can be further constructed upon investigating how these activities impact on DS research methodologies and particular artefact. In other words, to get reference model we need filter out all factors which occurrences are caused by specific solutions rather than constitute a solid path.

In this paper we discussed commonality that occurs in various design science methodologies in respect to a construction step. This is the step when information on and construction of solution is produced. We stated that DS methodology should not only indicate directions of research, but provides detailed steps on how to conduct this research. We identified common activities of construction step in case studies, which were conducted and presented throughout variety of DS papers. We proposed that these activities could be used as a reference model that would facilitate construction step regardless of selected DS research methodology. Before designing such a model, we suggested additional research, which would focus on the potential impact of those activities on particular methodologies. This is required in order to state a proper order and detail those activities further. Next the reference model will be validated via case studies in our future work.

# A Hybrid Algorithm for Detecting Changes in Diagnostic Signals Received From Technical Devices

Tomasz Pełech-Pilichowski  
AGH University of Science and  
Technology, Faculty of  
Management, ul. Gramatyka 10,  
30-067 Kraków, Poland  
Email: tomek@agh.edu.pl

**Abstract**—In this paper, a hybrid two-level algorithm of the original changes in diagnostic signals received from multiple technical devices is presented. Research are aimed at identification of the changes, deviations or patters (events), through concurrent diagnostic signals processing, which occur in one selected signal (proposed algorithm is adjusted to omit concurrent and time-lagged changes). In the first stage, detection is based on non-stationarity detection with the short-term prediction comparison. In the second stage, dedicated distance-like measure is employed. Detection results obtained for sample random signals including simulated large deviations are presented.

## I. INTRODUCTION

TECHNICAL systems, for example Intelligent buildings ones, are often consist of technical networked devices supervised by a central unit or controller. Efficient system working depends on the reliable installed devices operation which may be successfully provided by the diagnostic signals concurrent monitoring. Such processing of available set of diagnostic signals, in particular in real time systems, may indicate the work status of devices or results in alarm notification resulting from defective device work, faults, power instability, loss of network security or generated signal reliability. On the other hand, selected signals may contain random, temporary changes, statistically insignificant, being response to the irrelevant devices interferences, networked and supervised by a central unit. Such changes can trigger false alarms or can directly influence the work of other connected devices (provide incorrect input signal) thus endanger unstable operation of the whole system.

Event detection from diagnostic signals is usually based on implementation of a detection algorithm capable of identify the well-defined, expected unusual behavior of the processed signal (short or long-term non-stationarities) [5]. Detection algorithms are often based on a statistical and frequency domain data characterization [2], [21], [8], adapted to sampling frequency and consistency of available dataset. In such cases, complex system monitoring is based on the individual signal processing which is not sufficient to identify coincidence of events in other analyzed time-series.

This work was supported by the European Regional Development Fund, Grant no. UDA-POIG.01.03.01-12-171/08/00

Considering diagnostic signals produced by multiple system devices, a reliable detection requires the use of dedicated algorithms based on concurrent or parallel processing of all available signals to capture non-random and relevant changes in selected (real-time monitored) one, strictly including time lags between occurring events as a possible effect of transmission delays, data queuing, assumed real-time regime disturbances.

The aim of this paper is to describe and present research progress on detection algorithms dedicated to capture original changes, deviations, or patterns, i.e. which are not an effect of the same external factors, thus occurring in the only one diagnostic signal – including time-delays between possible changes (avoiding changes presented in both signals – concurred or lagged). In the paper, a hybrid detection algorithm is presented, based on concurring processing of pairs of signals in a moving window of a fixed length where detection task splits into two levels: (1) a non-stationarity detection and (2) its confirmation with distance-like similarity method. Proposed approach is focused on reducing false alarms and early efficient detection of emergency situations in multiple diagnostic signal sets.

This idea is a development of earlier work aimed at the significant event detection from time series based on statistical signal analysis [5], distance-like methods [6], short-term prediction efficiency comparison [16],[18],[15], immune paradigm employed to event detection support [17], [20], [10], [22] and two-level algorithms dedicated to process signals in real time systems [19].

## II. EVENT DETECTION FROM SIGNALS RECEIVED FROM MULTIPLE DEVICES

Event detection from time series is based on the processing of subsequent samples to identify an unusual process behavior, i. e. non-stationarities caused by external non-random factors. To achieve reliable results, the signal analyzes should be performed in a moving window of a fixed length [3], [5], [4] depending on intended impact of historical data. Event detection may be viewed as the unsupervised classification task where one class is described (one-class classification) and a formal method dedicated to distinguish between normal and anomaly class [10], [19].

Assuming that signals are generated by technical devices (for example intelligent building ones), during “normal” system behavior stationary is identified (lack of long-term and short-term abrupt changes of the mean value or variance); an appearance of non-stationarity may be recognized as the alarm signal or a specific event, i.e. pattern or unexpected change. Such sequences of changes may be visible as the deviations from the short/long term mean value exceeding a fixed threshold as the standard deviation multiplicity of arbitrary selected value. Depending on event detection task, changes of the same sign (positive or negative ones), different sign (or its absolute values) or patterns – i.e. original configuration of deviations are tested (lack of changes between series of deviations of fixed length is often assumed).

To detect short and long-term changes in a selected diagnostic signal, one may use classical, robust procedures (for example, Page-Hinkley one [1]) which reasonable employing is often limited by the computation time or a need of long data sets processing which results in usually unacceptable time-delays [14]. Implementation of the detection algorithm strongly depends on the signal characterization (statistical, frequency), properties (dimensionality, completeness), attributes of possible events (amplitude, duration, periodicity, delay) or the assumed detection error [19].

Change detection from one signal is produced with implementation of the detection algorithm and usually it is sufficient for a short-term changes identification, especially when one diagnostic signal from one device is obtained. For multiple signals, such approach may result in a number of false alarms or undetected events as a result of random signal changes (for example, short-term power differences, time delays during wire/wireless data transmission) or inability to identify a complex alarm situation (i.e. to detect a real device damage, multiple signals are often needed – temperature, input/output, revolutions per minute of central processing unit fan etc.). Moreover, significant changes may be announced by the short-term deviations in another signal. Thus, processing of a diagnostic series sets seems to be a promising way to capture such changes, deviations or patterns in a target signal.

Event detection from a selected diagnostic signal from the large available signals set (including heterogeneous ones) can be based on the concurrent, parallel or distributed time-series processing, to identify both single changes and dependencies between events detected from individual signals (with suitable algorithms). Such complex processing may be a way to faster detection through the short-term “announcing” events recognition which can precede long-term changes of time series the statistical properties [14].

There is a number of methods dedicated to time series quantitative analyzes [19], like the statistical analysis of the frequency of events [12], trends, deviants and outliers, the patterns and characteristics similarity comparison [14]. Algorithms based on neural networks [7], genetic algorithms [13] and other data mining techniques including similarity measures and distance ones [23], [9] also may be employed [8], [12]. Although such results can provide the reliable detection; their efficiency depends on dimensionality of the set of signals, the estimation of statistical parameters (mean value,

standard deviations, trend parameters), dynamics [21] and for selected ones – the learning period [17], [19].

For specific, not well-defined changes or patterns, processing of the set of signals with such standard algorithms are often not sufficient because of existing different signal properties, attributes of events, time-delays between changes in different signals and dependencies between them. Moreover, in many cases the aim is to detect only changes in one selected signal, excluding the synchronous changes in other signals and time-lagged ones. Such situations are encountered – for example – when reported statuses from the monitored devices don’t match.

### III. A HYBRID EVENT DETECTION ALGORITHM

In this paper, a hybrid event detection algorithm is proposed. It is based on the processing of pair of signals in two levels (see listing 1): first – the preliminary non-stationarity detection in individual signals, and then – the second one – the confirmation with distance-like similarity method, computed for both signals. Such approach relies on an the assumption that all signals of available dataset (or some of them) can be paired. Thus, summarized detection results (at a time instant) will indicate the complex dependencies within data set. Moreover, such computation is suitable for the distributing and employing one of many computational intelligence paradigms (like multi-agent systems).

In the first level (for sample  $n$ ) the non-stationarity is identified with the short-term prediction errors comparison obtained from the one-step-ahead zero-order-prediction (ZOP)/zero-order-hold (ZOH) model [2], [15] and the adaptive Holt predictor [11] in a moving window of constant length, suitable for non-stationary data analysis (in particular, trended time series). This preliminary detection procedure is suitable for time series which consist of the non-random components [19].

When short-term non-stationarity is recognized for a fixed number of samples (arbitrary adjusted threshold value), the second level detection is triggered (see listing 1, lines 9-15). To confirm change initial signal, the distance-like method is proposed.

The distance-like detection method – denoted as measure  $Z$  (or  $dZ$ ) and first mentioned in [6] – is dedicated to two signals similarity monitoring. It is based on the synchronous processing of two signals (denoted as  $x$  and  $y$ ) of fixed length in a moving window. For both signals  $x$  and  $y$ , the mean values of sub-sequences of absolute deviation values are calculated (the positive ( $x_{pm}, y_{pm}$ ) and the negative ( $x_{nm}, y_{nm}$ ) signs). The deviation is recognized when the absolute value exceeds a fixed threshold  $\rho_{zd}$  at the time-instant. For deviations smaller than threshold, zero value is assumed. As a result, two pairs of the positive values ( $x_{pm}, y_{pm}$ ) and negative ( $x_{nm}, y_{nm}$ ) are obtained.

```

16 }
17 UNTIL n = N

```

Listing 1. Pseudo-code of the proposed event-detection hybrid algorithm for two signals of the length  $N$ . A fixed threshold  $p_z$  value is assumed.

The temporary similarity  $dZ$  is calculated as follows:

$$dZ = \sqrt{(x_{pm} - y_{pm})^2 + (x_{nm} - y_{nm})^2} \quad (1)$$

Processed data received from technical devices may contain the phased (time-lagged) events. To avoid such time delays between events/changes, during computing a final value of the measure  $dZ$ , a tolerance (denoted as  $L_{tol}$ ) is assumed. Such tolerance may be viewed as a permissible time delay between occurring changes in both signals. For each subsequent sample  $n$ , to compute  $dZ_n$  a  $L_{tol}$  number of the measures  $dZ_t$  is calculated in a moving window ( $t = n - L_{tol} + 1 \dots n$ ) giving a set of the  $dZ$  values. Finally,  $dZ_n$  is chosen as the smallest  $dZ_t$  value between two sub-series:

$$dZ_n = \min_{t=n-L_{tol}+1 \dots n} dZ_t \quad (2)$$

“Distance measure” term is used (instead of “distance” or “metric”) [19] because all formal definition of metric conditions are not satisfied (i.a. symmetry condition).

#### IV. CALCULATION RESULTS

To verify the effectiveness of the proposed hybrid detection procedure, the algorithm was implemented and tested on the random-simulated data. Signals were generated as time series of the length 144 containing pseudo-random values drawn from the standard normal distribution  $N(0;1)$ . Such relatively short length of the signal allows for a reliable analysis of the algorithm efficiency using data visualization.

To obtain data sets similar to real diagnostic signals (i.a. avoid negative values), a constant  $c = 30$  was added to each sample. In the next step, diagnostic signals were modified by adding the simulated changes for random generated time instants (randomly selected samples were increased). The length of simulated change was fixed to 5 in an experimentally way.

In this paper, presented detection results are chosen from among many possible ones, and they are depended on arbitrary parameter adjusting. In particular, in the first stage (the short-term prediction comparison computed for differences

between adjacent elements of processed series), the moving window width was fixed to 22. The second detection stage is triggered after recognition of series of – at least – three consecutive samples for which the non-stationary was found. To process the data in the same order of magnitude, signals were unified with their dispersions (in the moving window).

In the presented case, it was assumed that the preliminary detection performing in the first stage causes no need to use of the threshold value of the method  $dZ$ . Therefore, event detection is based on choosing the final  $dZ$  value from the set of length  $L_{tol}$  which was fixed to 5.

In the paper, four sample diagnostic signals are examined (see fig. 1-4) representing different event sets illustrated in the appropriate parts of the figures 1-16.

Fig. 1. Random-generated signals – part 1 (depicted with the solid and dotted lines), containing four simulated changes – the input (original) data (upper large sub-figures) and the differences between adjacent elements of the processed signals (2nd and 3rd sub-figure rows).

Fig. 2. Random-generated signals – part 2. Description of the symbols and lines – see Fig. 1.

Fig. 3. Random-generated signals – part 3. Description of the symbols and lines – see Fig. 1.

Fig. 4. Random-generated signals – part 4. Description of the symbols and lines – see Fig. 1.

It may be seen in fig. 5-8 that employing the detection performed in the first step results in the identification of the large deviations.

Fig. 9-12 illustrate the  $dZ$  value changes in the moving window. The basic assumption of the method is illustrated – especially – in fig. 10 (100-120th sample) where the  $dZ$  value is strongly depend on the samples included in the moving window. If changes in both signals are covered, the  $dZ$  value is near to zero; otherwise, abrupt  $dZ$  changes are visible.

Fig. 5. Detection results obtained with the short-term prediction comparison (part 1) depicted in the row 2 and 3. Single non-stationarity detection (advantage Holt over ZOH) is denoted as black 'dots'.

Fig. 6. Detection results obtained with the short-term prediction comparison (part 2). Description of the symbols and lines – see Fig. 5.

Fig. 7. Detection results obtained with the short-term prediction comparison (part 3). Description of the symbols and lines – see Fig. 5.

Fig. 8. Detection results obtained with the short-term prediction comparison (part 4). Description of the symbols and lines – see Fig. 5.

Fig. 9. Change detection performed with the proposed event-based similarity method dZ (part 1). Changed detected with short prediction comparison depicted as ‘circles’ and ‘asterisk’.

Fig. 10. Change detection performed with the proposed event-based similarity method dZ (part 2). Additional description – see Fig. 9

Fig. 11. Change detection performed with the proposed event-based similarity method dZ (part 3). Additional description – see Fig. 9

Fig. 12. Change detection performed with the proposed event-based similarity method dZ (part 4). Additional description – see Fig. 9

Fig. 13. Change detection from processed signals (part 1): 1 (depicted in the upper subfigure with solid line) and 2 (dotted line, the lower sub-figure). Description of used symbols: detected non-stationarities from signal no. 1 confirmed with  $d_{Z1}$  ( $H_1/d_{Z1}$ ) denoted as ‘cross’, confirmed with  $d_{Z2}$  ( $H_1/d_{Z2}$ ) depicted as ‘dot’; detected non-stationarities from signal no. 2 confirmed with  $d_{Z1}$  ( $H_2/d_{Z1}$ ) denoted as ‘asterisk’, confirmed with  $d_{Z2}$  ( $H_2/d_{Z2}$ ) – as ‘circle’.

Fig. 14. Change detection from processed signals (part 2). Extended description – see Fig. 13.

Fig. 15. Change detection from processed signals (part 3). Extended description – see Fig. 13.

Fig. 16. Change detection from processed signals (part 4). Extended description – see Fig. 13.

As mentioned in the earlier part of this paper, research aimed at detection of the original changes in the one processed signal. Figures 13-16 show such event selection. Proposed hybrid algorithm is capable of detecting large, single

changes (see fig. 13 – for about 60th and 80th sample; in fig. 14 – about 100th sample, fig. 15 – about 95th sample). Notice, that few detection results may be viewed as false alarms (for example – fig. 16, about 100th sample), nevertheless, in such cases the interpretation will be connected with the analysis of small deviations that may be invisible in assumed figure resolutions.

## V. CONCLUSIONS

Event detection from signals received from computer systems can be focused on – depending on detection task – the independent signal processing (the identification of short and long-term changes in signals separately) or the available diagnostic signals set processing – which is more complex and allows to identify the changes in the analyzed (target) signal environment, including implicit events. The proposed detection idea is related to the second detection approach and it is a part of wide (realized and planned) research on event detection from time series through concurrent and parallel environment of analyzed signal monitoring. Summarized detection results will indicate the significant and insignificant changes and the dependencies within processed data set.

In this paper it was shown that proposed two-level algorithm is suitable to detect the changes in diagnostic signals which occur in the one signal only. The procedure efficiency was tested on the random generated signals containing simulated changes, however, for real signals, peer analysis of available signals set may be valuable.

The intention was to show the most relevant properties of the hybrid algorithm rather than data acquisition process mapping and further processing according to the real computing conditions and limitations.

Presented detection results are obtained using the algorithm whose parameters were adjusted in an experimentally way. Therefore, the parameters adapting is a promising way to effectiveness improvement. Further research will be focused on algorithm adaptation (corresponding to processed signals properties) and the stage 2 modifications towards the elimination of the false alarms (in particular, changes of the moving window width will effect in the detection resolution).

The proposed idea of multiple signal processing can be developed (especially taking into account the detection task complexity when processing large datasets) with the distributed processing of signals from networked devices as i.e. multi-agent systems or artificial immune systems (such paradigm appears to be helpful for detection viewed as an unsupervised classification, especially for signals contain many random and non-random components).

**Abstract**—Large number of scientific publications and press releases demonstrate that organizations are adopting the Scrum software development method with success in almost all areas. Nevertheless, traditional Scrum method is not sufficient for managing work in Network Organizations where Third Party Service providers may know nothing about the Scrum. This paper describes the findings of a field study that explores the Scrum in Network Organizations. We extended Scrum core roles and proposed changes in Scrum artifacts that help in adapting the Scrum method to work in Network Organization where changes and high competition are the cornerstone of the entire process.

## I. INTRODUCTION

SELECTING appropriate approach to systems development is crucial for success of the project [1]. Fortiori this is especially important when firms are working as a Network Organization where the environment is turbulent and uncertain. Moreover, the firms that make up that kind of cooperation are likely to be using disparate methods for their internal development projects.

In this paper we propose an adaptation of the Scrum method that suits best for managing development of software applications in Agile environment in a Network Organization using third party internal and external services:

- We refer to the Network Organization and determine how the Third Party Services and the Scrum are interrelated.
- We take a *holonic view* [2][3] on the process and method of software development.
- We propose a Scrum-based software development model that specifically includes some novel and excludes some conventional artifacts and rules.
- We propose a set of metrics (i.e. Key Performance Indicators) that help to control and coordinate proposed model.

The proposed model offers an innovative approach for systems development in Network Organizations. The model has evolved from the Scrum method and has been checked in practice.

## II. NETWORK ORGANIZATION AND THIRD PARTY SERVICES IN TERMS OF SOFTWARE APPLICATION DEVELOPMENT

### A. Network Organization

“A pattern of social relations over a set of persons, positions, groups, or organizations” [4]

This definition proposed by Lee Douglas Sailer [4] and further elaborated by Marshall van Alstyne [5] is very useful because it emphasizes structure and different levels of analysis. The Network Organization is a collection of autonomous firms or units that behave as a single large entity (i.e. structure), using specific mechanisms to control and coordinate the entire project. The entities that make up that kind of organization are usually legally independent entities (separate companies). However, this is not the rule because some of them may be divisions within the company (sub-organization) that sell to outside customers, or they may be wholly owned subsidiaries providing the third party services to the entire network.

Some advantages of software development in network environment are customization, task basis, and the Structural Embeddedness [6]. These advantages are favouring individual firms and their members. Network Organizations occur in the situation when technology and markets are changing very fast, so consequently, all participants have to coordinate and control the units in some other way, for instance by mechanism design, trust, and Macro-Culture [5].

### B. Third Party Services

Network Organizations fall halfway between vertical integration and market disaggregation. They facilitate building packets of services, according to the nature of provided services and relations between them as shown in “Fig. 1”.

For the purpose of discussion, we have distinguished two types of third party services provided for software development in Network Organizations:

- Internal Services: time-consuming activities, which are important but additional to the entire project. Usually those are provided by subunits of a large company (e.g. internal UX expertise, internal testing, ICT support, etc.)
- External Services: all those issues that must not be covered by Internal Services and should be handled by other firms (e.g. authorized computer service, external testing service, translations, etc.)

We observe that companies that see their units as separate cost or profit centres (providers of internal services), may encourage the units to sell their services outside the company. The reason is that if the units have to operate within market, they will improve performance, better manage the prices, and of course earn money for the entire organization. The cooperation between services providers, usually establishes a long-term relationship between suppliers (i.e. providers of external services), who may then participate in planning sessions and influence the workload and schedule.

Fig 1. Relationship between Third Party Services in Network Organization

Both internal and external services may involve other third party services (internal or external) so the amount of dependencies, risk and uncertainties may be fast increasing. This in turn may adversely affect software development process by deterioration of quality, changes in the scope, delays in the schedule, and all this may contribute to the project failure.

In the next sections, we will explain the holistic nature of the Scrum. Based on an example of Network Organization and services, we will present the dependencies between key entities in the Scrum process and third party service providers.

### III. AGILITY IN NETWORK ORGANIZATION

#### A. Agile, Scrum and Engineering Practices

To highlight differences in the impact of Agile, scrum and Engineering Practices in Network Organizations we take advantage of the “*Three Level Framework*” designed by Geary A. Rummmler and Alan Brache [7]. We propose the framework that takes the Scrum viewpoint and distinguishes three types of layers:

- Organization Level: all activities that are additional for Scrum (e.g. Human Resources, financial, capability, management, etc.), and identify the organization point of view (i.e. market, competitive advantage, priorities, products and services).
- Process Level: series of steps, rules and artifacts, which are used by the Scrum team to produce the product or service. The goals of this level are developed from customer requirements (i.e. Sprint Planning) and benchmarking information (i.e. during Sprint Review/Retrospective Meeting).

Fig 2: Scrum and Engineering Practices in the context of Agile implementation in Network Organization

- Job/Performer Level: all undertakings and instrumentation essential to achieving the goals of the process (e.g. code review, pair programming, continuous integration, etc.).

For the research presented here, we have assumed that Network Organization is following Agile principles and implements Scrum as a method for managing the software development team (Job/Performer Level in “Fig. 2”). Therefore, all Engineering Practices are considered separately, as not covered by Scrum but used as external or internal services (as discussed next).

#### B. Scrum Roles – Core and Additional

We would like to clarify that describing all Scrum principles and artifacts is not the subject of this paper, therefore we will not focus on default core Scrum roles (i.e. Product Owner (SM), Scrum Master (SM) and Scrum Team (ST)), but only on additional roles that are essential for further consideration.

In addition to core roles, we consider the groups of people known as: managers [8] and stakeholders (i.e. “... *any group or individual, who can affect or is affected by the achievement of the organisation's objectives.*” [9]).

For the sake of proper adaptation of Scrum to work with Third Party Services in Network Organization, we propose another core role, excluded from stakeholders group:

- Third Party Service Provider (S): organization or individual who provide your organization with specialized third party services (e.g. lawyers, accountants, coaches, consultants, translators, internal and external service providers, etc.).

From our point of view, this new role S is crucial for the success of the Scrum performed in Network Organizations. This role should be involved in the entire software development process.

### IV. HOLISTIC NATURE OF SCRUM

#### A. Holons and Holarchies

“*Living systems are organized in such a way that they form multi-levelled structures, each level consisting of sub-systems which are wholes in regard to their parts, and parts with respect to the larger wholes.*” [10]

The idea of holon entity was introduced by Arthur Koestler in [11]. He coined the term “*holon*” for those entities, which might be simultaneously a part and a whole [2].

We can imagine that each holon has two opposite habits (tendencies): an integrative habitude to exist as a part of compound system and a self assertive habitude to preserve its individuality. Those two tendencies are complementary, although they also are opposite. The balance between habits is not static, but is adapting based on influence of two complementary tendencies. This makes the whole system open to change and very adaptive.

Thirty years after Koestler's original idea, another philosopher Ken Wilber generalized the idea of holons by highlighting its relative and conceptual nature. In [12], he considered that holon must have four basic characteristics [3]:

- Self-preservation: to maintain own structure, independently of the material that holon is made of.
- Self-adaptation (community): to adapt and link up with other superordinate holons, in order to react biologically, mechanically or intentionally to their stimuli.
- Self-transcendence: the holon has its own characteristics and qualities, which are new and emerging; new properties emerge in superordinate holons and create new classes of holons.
- Self-dissolution: the holons break up along the same vertical lines that they are formed.

Due to their nature, holons are connected to other holons in a typical vertical arborising structure known as a holarchy, which can be viewed as multilayer system, with tree-structure. From the holonic point of view, each member of the organization (e.g. Network Organization), can be considered a holon. It means that each member is a whole if observed as a separate unit and a part if looked at as a member of larger organization. Therefore, the core and ancillary Scrum roles can be interpreted as holons forming a holarchy, when taking into account communication network designed between holons.

*B. Holistic View of Scrum and Third Party Services in Network Organizations*

*“The holonic view of the world forms a middle ground between atomism and holism and the holonic structures form a middle-ground between network and hierarchic structures. The stratified order of holonic layers resembles a hierarchy of layers and allows flat networks within layer, but it is different from both. The stratified order is not about rigid transfer of control or about free interconnectedness of nodes, but it is rather about the self-organization of complexity and adaptation.”* [13]

Considering Network Organization as a network of intercommunicating elements, we can easily show that the amount of communication paths grows exponentially with addition of new elements [14].

Because network is an overly complex structure, we need some form of hierarchy with some aspects of superiority between elements. Holarchies seem to be the most suitable structures to manage complexity due to their special form of stratified hierarchy without traces of ranking between its elements (holons) and without cycles.

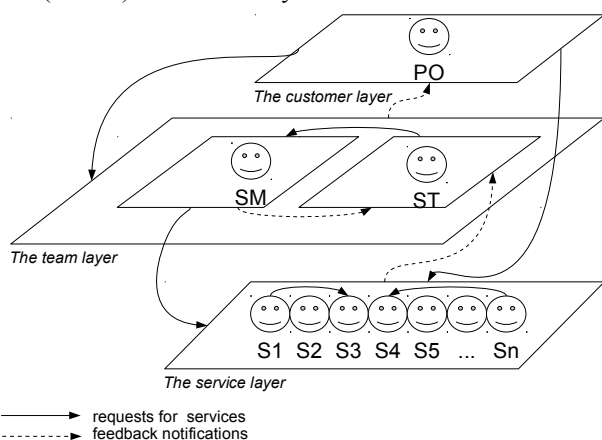

Fig 3: Scrum based model of Information Network

We propose simple three layers model of holarchy (“Fig. 3”), where default core roles(PO, SM, ST) are placed in first two layers and the new core role(S) is placed in the lowest layer. In this model, we skip ancillary roles of Managers and Stakeholders, because of low importance for further consideration.

Layers in a holarchy have an autonomy that enables them to adapt to new circumstances and changes in the environment. All communication that represents request for third party services is downward. Superordinate layers depend on the sub-ordinate layers for third party services, however not vice-versa. The lower layers inform about its state changes by providing the feedback to requesters, possibly but not necessarily from the upper layers.

Wherein our model all dependency relationships between layers are downward, and upper communication is only by providing the feedback, that helps in avoiding cycles of messages and makes communication more efficient.

The proposed model consists of three layers that refer to core Scrum roles:

- The customer layer: with Product Owner (PO) as the main requester. Third party services might be requested directly from this layer, however results (feedback) will be delivered to ST layer.
- The team layer: includes two sub-layers where entities (holons) are Scrum Master (SM) and Scrum Team (ST). ST receives results from S, requested by PO or SM.
- The service layer: this layer represents third party services and third party services providers (S). It is possible that entities in this layer will have interconnectedness between each other (e.g. some S might request services from other S).

The same solution can be used in software development of distributed projects what is shown in “Fig. 4”.

The difference occurs in additional interconnectedness between entities from middle-layer (e.g. Scrum of Scrums Meeting may be represented as SM request service from another SM). In addition to model proposed in “Fig. 3” the middle-layer is represented by two multi-entity sub-layers of SM's and ST's with interconnectedness between them. The main information flow has been kept without any changes.

We propose the model, which supports building trust, multi-culture and massive design (section II.A.). This is very important when technology and markets are changing very fast. The impact of S on the “The Team Layer” results is essential and should not be omitted (e.g. estimates proposed by ST during Sprint Planning should take into account S and dependencies associated with delivering results of third party services - delays in layer S affect results from layer ST).

*C. Scrum Artifacts*

In this paper we assume that the reader is already familiar with Scrum [1][8][15][16][17][18][19][20][21], therefore we describe only those Scrum artifacts that we propose to change to work better in Network Organizations:

- Task-feasibility instead of time-estimation: we skip using formal time-estimates and try to commit only those User Stories that we are able to deliver before next

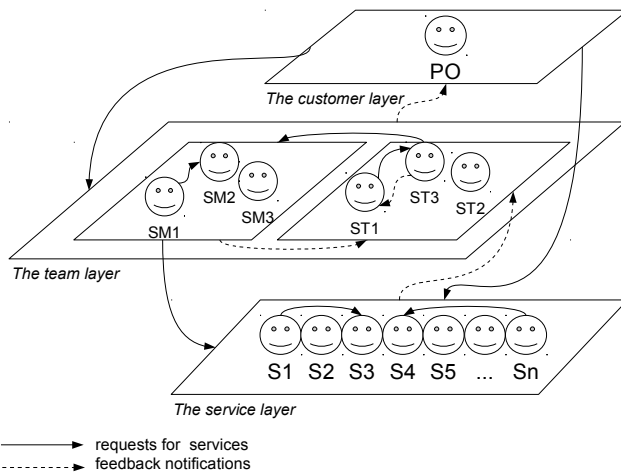

Fig 4: Scrum based model of Information Network in distributed projects

demo session. Through this change, we want to limit commitment, which we are not able to provide.

- Report Meeting instead of Sprint Review Meeting: because regular Sprint Planning session involves many resources (i.e. a lot of participants), we propose to limit participants only to representatives of the customer and the team. In our opinion that kind of meeting should be held more frequently than Sprint Review Meeting (e.g. every week) in order to improve information flow between the customer and the team.
- Planning on demand instead of Sprint Planning Meeting: because we skipped time-estimations we also propose to limit number of Sprint Planning Meetings and hold them only if really needed (i.e. when the customer needs help from the team, because is not able to prioritize Product Backlog without an additional Team's expertise).

We agree with Scrum advocates that planning up-front the Sprint is very important. However we suggest limiting this action only to prioritizing the scope (i.e. Product Backlog), so that the most important User Stories are on top of the Product Backlog list. Of course, the team is committed to delivering proposal of items, feasible for the next Sprint, but without specifying how much time will spend on each item.

Instead of regular Sprint Review Meeting held after each cycle, we propose more frequent Report Meeting (e.g. Weekly Meeting). During this meeting, the team representative is reporting actual status and points out all unsolved issues (i.e. impediments). The shortest but more frequent meetings, with reduced number of participants result in better communication and better overall understanding of project goals.

Skipping time-estimates interferes with regular Scrum Planning Meeting. Therefore, as an alternative, we propose organizing planning sessions on demand, only if required (i.e. planning the scope of next release) instead of time-consuming regular meeting before each cycle.

The proposed changes arise from the fact that we adopted a holistic view (mentioned in section IV.B.) that reduces the dependencies between the layers (e.g. no information cycles, stable workload during the Sprint, etc.). In our approach the feedback notifications from S to PO must go through "the

team layer", thus ensuring that ST and SM are fully involved in providing deliveries. For instance, the ST will not be able to deliver implementation of new wizard until they get all required translated texts from translators (i.e. S), so this implies that ST and SM must keep an eye on S and their deliveries.

#### D. Key Performance Indicators

"A performance indicator can be defined as an item of information collected at regular intervals to track the performance of a system." [22]

Within original Scrum we use only one metric (i.e. indicator). This is the time-estimate of the amount of remaining work that needs to be done versus amount of User Stories or Tasks that are set as "done" in Sprint Backlog [21]. We propose to use the following KPI's (i.e. Key Performance Indicators) that help better control software development in Network Organization:

- Reliability: to measure if the team is delivering what they said they will. We compare the difference between the amount of committed Story Points ( $c_i$ ) and delivered Story Points ( $d_i$ ) like shown in (1). The values might be presented as the percent of reliability calculated per Sprint ( $R_i$ ).

$$R_i = \frac{c_i}{d_i} * 100\% \quad (1)$$

- Productivity: to measure project velocity. We measure amount of fixed bugs ( $b_i$ ) and newly implemented requirements ( $s_i$ ) like shown in (2). The value of productivity ( $P_i$ ) should be calculated after each Sprint.

$$P_i = b_i + s_i \quad (2)$$

- Effectiveness: to measure effectiveness of testing service. The measure includes the amount of defects delivered to the customer. Based on this KPI we can calculate the effectiveness of internal testing service (like shown in (3)), by measuring the ratio between all found defects and those found by external S providing complementary testing. This shows effectiveness ( $E_i$ ) of software development team and testing services.

$$E_i = \frac{a_i - e_i}{a_i} * 100\% \quad (3)$$

We believe that the introduced KPI's are crucial to maintaining customer satisfaction. From our point of view, the required data should be collected at the end of each Sprint. We would like to point out that the same KPI's can be measured for S (section III.B.) and their findings can be used by the team for increasing customer satisfaction and for coordinating and controlling workload status.

#### V. CASE STUDY

Our approach to using Scrum in Network Organization is best illustrated by a real life example of two similar projects managed in two different variants of Scrum:

- In the project A: the pure implementation of Scrum.
- In the project B: the Scrum extended to our guidelines.

The company used in this study is a large multi-national organization (over 17000 employees all over the world) specialising in R&D services, telecommunication and mobile solutions. The customer is a large multi-national organization specialising in telecommunication and mobile solutions. The contract between companies was a typical outsourcing service.

A. Structure and Scope of Projects

The project A was a software application, dedicated for care centres for upgrading mobile device software via computer. It was a user-friendly application with an ergonomic presentation layer (UI) and very complex middle-layer to handle hundreds of different variants of mobile devices. The presentation and middle-layer text contents were localised for 40 different languages.

The project B was very similar to the project A, however it was not a stand-alone application, but a part of bigger software application (i.e. software update plug-in) dedicated for end users managing their mobile devices via computer. The plug-in was using the same middle-layer as in project A. The presentation layer was also represented by a user friendly UI localized for 40 languages.

At the time we conducted the case study, the two projects were in maintenance and support phase (i.e. about 70% of workload was bug-fixing and 30% implementation of new functionalities), so the case study did not relate to implementation from the scratch but to maintenance of the existing products.

The projects started with a short initiation phase during which the product backlog was set, general architecture was established, Scrum roles were assigned, and Scrum principles were known for all involved persons.

Iteration length was set at two week interval throughout the project, therefore after first two weeks of project initiation, the team finished the first iteration (i.e. Sprint 0).

In both cases A and B the Scrum Teams were following engineering practices (referred to in section III.A.).

B. Roles Assignment

Both projects were using services S (section III.B.), such as: translations, complementary external testing service, User eXperience expertise service.

The team composition had not changed since its inception, and for the moment of data collection, the number of persons in software development teams was the same for both projects: three software engineers and one test engineer.

The software development teams and Scrum Masters were co-located (i.e. based in Poland) that allowed building personal relationship between all team members inside their teams.

The customer (i.e. Product Owner) was remotely involved in the project, due to different location (i.e. based in Finland).

C. Meetings

The project A was following all Scrum principles; therefore, all meetings were held as defined.

The project B was performed as we suggest in this paper: instead of Sprint Review was Weekly Meeting and instead of regular Sprint Planning meeting was Planning Meeting on demand.

D. KPI's Results

We measured reliability, productivity and effectiveness values, known as KPI's (introduced in section IV.D.) to compare approaches taken by teams A and B. All presented metrics were collected for 13 consecutive Sprints (i.e. each Sprint was two weeks long). We present results of measuring reliability in "Fig.6", by comparing deviation of the reliability calculated for both projects (i.e. A and B). In both projects expected values were 100% of reliability per each Sprint.

Fig 6: Reliabilities KPI values (deviation of the reliability)

We note that the approach taken by team A, was affected by large number of cases that the team promised but it was not able to deliver committed stories. We also note that our approach was not "the silver bullet". Therefore, in "Fig.6" the bars are shown to indicate when team promised less than was able to deliver.

The approach taken by team B (i.e. ~46%) was three times more accurate than approach taken by team A (i.e. ~15%).

We checked the productivity of teams A and B. The results are presented in "Fig. 5". The amount of work realized by the teams (i.e. fixed defects and implemented user stories) was comparable and their values depended on the release scope.

Because the quality was crucial for both projects we measured effectiveness of our internal testing service (i.e. internal S) and compared the amount of found defects to effectiveness of external testing service (i.e. external S). In "Fig. 7" we present the ratio of leaked defects to the number of defects found by our internal testing service.

Fig 5: Productivity KPI values

TABLE I.  
CUSTOMER SATISFACTION SURVEY – QUESTION FORM

ID	Questions	Project A Scores (1-4)	Project B Scores (1-4)
<b>Project Quality:</b>			
1	What was the quality of project work in general?	3	4
2	How good was schedule estimation accuracy (timeliness)?	3	4
3	How good was effort estimation accuracy?	3	N/A
4	Tasks in the project were professionally accomplished?	3	4
5	The supplier managed the delivery well (delivery management and control)?	3	4
6	Possible changes in project personnel did not have any effect on the delivery?	N/A	4
7	Project's actual total cost corresponds to the expectations in the beginning of the project?	N/A	4
8	Work as a whole correspond to my expectations	3	4
<b>Project Personnel:</b>			
9	Project personnel accomplished their issues/tasks as promised?	3	4
10	Project personnel had a good knowledge of their own professional area?	3	3
11	Project personnel were easy to reach?	4	4
12	Project personnel worked professionally and efficiently?	4	3
13	Project personnel were genuinely interested in solving my issues and/or my problems?	4	4
14	Project personnel had the ability to cooperate?	3	4
15	Project Manager was reliable?	4	4
16	Communication between the project personnel was fluent and there were no information barriers in place?	3	4
17	Project personnel as a whole correspond to my expectations?	3	4
<b>Customer Input:</b>			
18	As the customer, we were able to accomplish our won tasks and obligations as promised?	3	3
19	As the customer, we were able to provide enough time for the delivery?	3	2
20	As the customer, we were satisfied with our won specifications in the beginning of the project?	N/A	3
21	As a customer, we were successful in guiding the third parties (e.g. the subcontractors that were our responsibility)?	4	4
<b>Average (Questions 1-17):</b>		3,26	3,88
<b>Average for customer input (questions 18-21):</b>		3,33	3,00
<b>Overall average:</b>		3,27	3,70

We found that internal service testing was more effective in project B than A. This means that the external testing service found more defects in project A than B.

#### E. Survey Results

After every six months, the customer satisfaction was monitored by internal Customer Satisfaction Survey (CSS).

During the interview the customer evaluates the level of satisfaction in three different areas (questions and areas are presented in Table I) by assigning the score from 1 (i.e. very unsatisfied) to 4 (i.e. very satisfied). The customer was able to comment on all questions, by providing additional feedback.

The scores and comments collected during CSS sessions are a kind of justification for what we have noticed during measuring KPI's. The customer feedback is always welcome and has high importance for further improvements of entire process.

The average results from both CSS's were quite impressive and show that both teams and projects were managed very well.

We note that all sections in CSS were scored higher for team B. However team A also collected high values.

#### F. Findings

To compare these two projects we used data collected regularly after each Sprint to measure KPI's (section IV.D.) and survey data collected after six months period (i.e. Customer Satisfaction Survey) to measure customer satisfaction.

We noticed that switching to "task-feasibility" from "time-estimation" (section IV.C.) and taking into account the possibility of delays caused by S (section III.B.) influence positively the amount of "empty promises".

This finding has been also noticed in high values of CSS in question 2, where the customer was more satisfied from schedule estimation accuracy in project B (e.g. the customer commented that: "it was very helpful in planning scope of software application releases").

The customer was disappointed due to bad effort estimations in project A, because that affected the scope (timeliness) of scheduled releases. In the project B the customer was satisfied and got positive feeling that schedule estimations were very good, although time-estimations were not applicable in this approach. The team limited their estimations only to committing that the proposed tasks will be finished and included in next release. Dissatisfaction of the customer

was also visible in question 9 in the section “Project Personnel” (i.e. “*Project personnel accomplished their issues/task as promised?*”), where the team A collected lower score than B – probably due to bad estimations.

In both cases (i.e. both projects A and B) the most crucial were quality and timeliness. The key incentives for the client were high visibility (transparency) and an empirical project control that Scrum delivers. Based on the presented results we can conclude that in general the customer satisfaction was higher in the project B.

## VI. RELATED WORK

During the last 30 years, many approaches have been proposed to software application development. Starting from “Code and Fix” [1][23], to the waterfall model, spiral model, rapid prototyping, incremental model, extreme programming, scrum, etc. These can be classified as representatives of general life cycle models: heavyweight, middleweight, and lightweight. We cannot say that one model is better than another, because the approach suitable for one project may not be suitable for another. However we can assume, on the basis of the research results and experience [15][16][17][18][19], that the best choice for almost all kinds of software development projects, starting from scratch and executed in continuously changing environment, is an adaptive and flexible life cycle model (i.e. Agile) and a strongly prescriptive method (e.g. Scrum, eXtreme Programming, etc.) [15][17][18]. We agree with Scrum advocates that using time-boxed delivery cycles (i.e. Sprints), visualization of the project scope (i.e. Product Backlog), prescribed roles (e.g. Scrum Master, Product Owner, Scrum Team), essential meetings (e.g. Sprint Retrospective, Sprint Review, Daily Meetings), and following Scrum rules is necessary for project's success.

However, conventional Scrum is not sufficient when daily work results depend on external third party services (e.g. Translation, Testing, Technical Support, etc.) as it is the case in “*Network Environment*”. In contemporary landscape in which Network Organizations are more and more popular and IT projects are realized in inter-cultural environment, distributed services multiply the risks and uncertainties. That makes some Scrum artifacts useless, because of dependencies between third party services and service providers.

In literature, a few researchers have already studied the way to adapt the agile practices in Network Organizations.

We observe that usually Agile software development methods are introduced as a set of principles that need to clarify a lot of different interpretations of Agile Manifesto [24]. Because of that it is very difficult to say what exactly is an Agile methodology and how to adapt it to Network Organization environment, usually based on the Scrum as an example of Agile methods.

The originators of Scrum in software development are Hirotaka Takeuchi and Ikujiro Nonaka. In [20] they defined a new approach to software development, called: rugby approach. They presented the whole process as performed by one cross-functional team across multiple phases, where the team tries to “*go the distance as a unit, passing the ball back and forth*” [20].

We consider that Scrum, as one of the representatives of Agile life cycle model, matches up perfectly to principles of “*Manifesto for Agile Software Development*” [17][18][24]. Following the Agile Manifesto principles is possible only because Scrum defines precisely the essential roles, principles and artifacts that make it very prescriptive method for managing software development teams.

We agree with Scrum advocates, but in addition we propose to add one new role (Third Party Services providers) for adapting Scrum and Third Party Services to Network Organization.

Piero Mella studied the holonic perspective in organization and management. In [3] he examined six different examples of holonic networks in terms of manufacturing systems. This paper was an inspiration to consider the Network Organization as Holonic Network, seen as “*comprised of autonomous firms that are variously located—characterized by different roles and different operations and connected through an holonic network, real or virtual, often oriented, in order to achieve a common objective through the sharing of resources, information, and necessary competencies*” [3].

Dirk S. Hovorka and Kai R. Larsen in [25] present the study that examined the influence of network organization environment on the ability to develop agile adoption practices. They use exploratory case study design to “*investigate the interactions between network structure, social information processing, organizational similarity (homophily), and absorptive capacity during the adoption of a large-scale IT system in two network organization environments*” [25]. They propose Agile Adoption Practice Model (i.e. APM) that proposes interactions within the inter-organizational network that enable Agile adoption practices. We adopted a more detailed approach, and instead of treating Agile life cycle model as a set of good practices, we proposed a more detailed analysis of one selected method of software development (i.e. Scrum) and propose Scrum-based model that suits better Network Organizations.

Wojciech Cellary and Willy Picard presented in [26] the way to achieve agility and pro-activity by introducing the model of Collaborative Network Organizations in its two forms: Virtual Organizations (VO) and Virtual Organization Breeding Environments (VOBE). They presented idea of public administration “*playing a role of Virtual Organization customer on the one hand, and a Virtual Organization member on the other hand*” [26]. This publication was a stimulus for reflection about third party service providers (i.e. S role) as an entity that might be simultaneously a part and a hole in Network Organizations.

## VII. CONCLUSION

In this paper, we proposed a holonic view based on which we adapted Scrum for 3<sup>rd</sup> part services and the Network Organization.

We developed a new service layer in the holonic structure and recommended new Scrum principles. In an industrial case study, we demonstrated the advantages of our model and method.

We believe that big differences in the level of satisfaction of the customer using our approach were caused by very prescriptive way of working with the pure Scrum.

There is no easy way to adapt Scrum software development method to work in Network Organization; however, we believe that presented results will serve to advance research and help in finding the best solution.

**Abstract**—With current complex real time software problems, the need for reliable software specification becomes crucial. This paper overviews the use of formal methods to specify requirements and the advantage of using an executable formal specification language processor to develop a process model for the development of a software system. The paper presents how a software process can be described using the Descartes specification language, an executable specification language, and the language extensions made to Descartes to make it suitable to describe a software process.

**Index terms**—software specification; software process model;

## I. INTRODUCTION

Software development is a complex and creative effort. A software process is a sequence of steps that are used to manage the development of software. A software process should be handled effectively to deliver the software on time and with good quality. Time, cost, and quality are some reasons why software development should be automated. Software process modeling focuses on what occurs during software creation and evolution. The basis for process models includes the individuals involved in the development of software, the assigned work, tools required to do the work, and the final results of the work.

Requirements analysis is a significant phase of software development because if any fault in the specification is left undetected, it can be carried over into the next phase. Thus, later correction of the fault would involve fixing the fault and fixing the effects of the fault in subsequent phases. Apart from consumption of a large amount of resources, for a change in a specification, the entire code will have to be rewritten by the developers. Also, since there is no actual system to verify the requirements provided by the user in a conventional software life cycle, development of such unverified requirements can cause errors in the program code.

The remainder of this paper is structured as follows. In Section II, related work that has been done in developing agent systems using formal methods is discussed. Section III discusses the research methodology used in this research effort. Section IV describes the extensions made to the Descartes specification language for specifying process modelling. Section V gives a comparative study with several existing methodologies. Section VI concludes the paper with a summary and future research.

## II. RELATED WORK

Software process models are expressed formally by process modeling languages (PML). Many process modeling languages have been developed. The following section briefly describes the earlier work done similar to this research effort. This section includes APER-2, CSPL, DPEL, Marvel, Merlin, VRPML, and YAWN.

APER-2 [3] is a developer centered and object-oriented process language. A process program in APER-2 is composed of classes. CSPL (Concurrent Software Process Language) [2] is a process modeling language that uses Ada95-like syntax. CSPL integrates object-oriented Ada95 for modeling support and UNIX shell scripts for enactment support.

DPEL (Decentralized Process Enactment Language) [4] is a process modeling language which is used to model activities and activity synchronization. In DPEL, modeling of a process is based on developers. The process programs are converted into DPEL segments for enactment in DPEM. Marvel [8, 9, 1] is a process modeling technique based on rules. Marvel has three types of rules: project rule set, project type set, and project tool set. Process specific issues are described by project rule set. Project type set is used to specify the data with object-oriented classes.

MERLIN [7, 6] has a knowledge base which describes a process that is built using a rule based technique. Rules and facts are interpreted as forward and backward chaining. Backward rules and facts are interpreted in a Prolog-like manner. VRPML (Virtual reality process modeling language) [12] is a process modeling language that uses graphs to specify a soft-

ware process. YAWN (Yet Another Workflow Notation) [11] is a graphical PML which uses directed graphs to represent a process interaction model.

A process model should enable effective communication, facilitate reuse, support evolution, and facilitate management [5]. Extensions were made to Descartes, such that it represents all the process entities and their relationships. The Descartes constructs are to support the basic elements of the software process.

Descartes [14] is an executable specification language that is based on three data structuring methods proposed by Hoare: direct product, discriminated union, and sequence. The language uses a tree structure notation to perform analysis and synthesis within a specification.

### III. EXTENSIONS TO THE DESCARTES SPECIFICATION LANGUAGE FOR PROCESS MODELING

In order to describe a software process, basic elements of the software process must be modeled. The basic elements of the software process are activities, products, role, human, and tool. The following describes extensions to Descartes that support software processes.

#### A. Activities and products

An activity is a step of a process that produces changes to the software product. The product is the set of artifacts developed and maintained in a project. The product is the input and output of an activity. A pre-pended unary reserve word “activity” is included in a Descartes module for declaring an activity module. After the module title, the module contains the specification for the other process elements. The input PRODUCTS consist of software products.

```
activity ACTIVITY_NAME_USING_(PRODUCTS)
  PRODUCTS
    inputs
```

#### B. Human actor

An actor is a person who is responsible for a software process activity. The reserved keyword “actor” is used to specify the person responsible for that activity. Consider the example of “modify\_design” activity which is performed by the actor “design\_eng1”. The “design\_eng1” is responsible for performing the activity “modify\_design”.

```
activity MODIFY_DESIGN_USING_(PRODUCTS)
  PRODUCTS
    requirement_change
      FILE
    design_document
      FILE
  actor
    ‘design_eng1’
```

#### C. Role

A role is the rights and responsibility of a person who is

going to perform a software process activity. The “role” construct introduced by Medina and Urban [10] is used for specifying the role of the actor in an activity.

```
activity MODIFY_DESIGN_USING_(PRODUCTS)
  PRODUCTS

    ‘design_eng1’
  role
    ‘design_engineer’
```

In the above example, the activity “modify\_design” is performed by a “design\_eng1” who is a “design\_engineer”.

#### D. Tool

The tools used in the software production, such as textual editors and case tools, should be represented. The reserved keyword “tools” is used to specify the tools used in that activity. Consider the example of “modify\_activity” in which “textual\_editor” is used to edit the “design\_document”.

```
activity MODIFY_DESIGN_USING_(PRODUCTS)
  PRODUCTS
    requirement_change
      FILE

  tools
    ‘textual_editor’
```

#### E. Process example

In this example, the process of designing a library management system is used. Suppose a library management system consists of two subsystems ‘subsystem1’ and ‘subsystem2’.

When the process starts, subsystem1 is designed by ‘design\_eng1’ and subsystem2 is designed by ‘design\_eng2’. Then the design of subsystem1 is reviewed by ‘design\_rev1’ and the design of subsystem2 is reviewed by ‘design\_rev2’. If the subsystem1 fails the review, the changes are made to subsystem1 by ‘design\_eng1’. If the subsystem2 fails the review, the changes are made to subsystem1 by ‘design\_eng2’. Changes are made to subsystem1 and subsystem2 until the subsystems pass the review. If subsystem1 and subsystem2 passes the review, the whole system is reviewed by the ‘design\_rev1’ and ‘design\_rev2’. If the whole system fails the review, the changes are made to the system by ‘design\_eng1’ and ‘design\_eng2’. Changes are made to the system until the system passes the review.

At the start of the process, the DES\_SS1 and the DES\_SS2 activities are started concurrently as shown in the specification below. The “parallel” construct introduced by Sung [13] is used to express the concurrent execution.

DESIGN\_LIBRARY\_SYSTEM

```

return
  parallel
    DES_SS1_USING_(PRODUCTS)
    DES_SS2_USING_(PRODUCTS)

```

In the DES\_SS1 activity, the ‘design\_eng1’ takes the requirement\_document as input and designs the subsystem1\_design\_document.

The subsystem1\_design\_document is modified using the tools ‘textual\_editor’ and ‘case\_tool’. After subsystem1 is designed, the REVIEW\_SS1\_DESIGN activity module is executed.

  REVIEW_SS1_DESIGN_USING_(PRODUCTS)

```

In the DESIGN\_SS2 activity, the ‘design\_eng2’ takes the requirement\_document as input and designs the ss2\_design\_document. The ss2\_design\_document is modified using the tools ‘textual\_editor’ and ‘case\_tool’. After the ss2 is designed, the REVIEW\_SS2\_DESIGN activity module is executed. The specification written for the DES\_SS2\_USING\_(PRODUCTS) activity is similar to the DES\_SS1\_USING\_(PRODUCTS) activity.

In the REVIEW\_SS1\_DESIGN activity, the ‘design\_rev1’ takes the requirement\_document and the ss1\_design\_document as input and reviews the design of ss1. The design of subsystem1 is reviewed using the tool ‘textual\_editor’. If subsystem1 passes the review, the

REVIEW\_SYSTEM\_USING\_(PRODUCTS) activity is called. If subsystem1 fails the review, the MODIFY\_SS1 activity module is executed.

**activity** REVIEW\_SS1\_DESIGN\_USING\_(PRODUCTS)

```

  MODIFY_SS1_USING_(PRODUCTS)

```

In the REVIEW\_SS2\_DESIGN activity, the ‘design\_rev2’ takes the requirement\_document and the ss2\_design\_document as input and reviews the design of ss2. The design of ss2 is reviewed using the tool ‘textual\_editor’. If ss2 passes the review, the REVIEW\_SYSTEM\_USING\_(PRODUCTS) activity is called. If ss2 fails the review, the MODIFY\_SS2 activity module is executed. Similarly we can write the specifications for REVIEW\_SS2\_DESIGN\_USING\_(PRODUCTS) activity, MODIFY\_SS1 activity, MODIFY\_SS2 activity, REVIEW\_SS\_DESIGN\_USING\_(PRODUCTS) activity, and MODIFY\_SYSTEM activity.

## IV. COMPARISON

A process modeling language can be compared through the following criteria: interface and style. Table 1 shows the comparison of several process modeling languages based on interface and styles along with the Descartes specification language used for process modeling.

Process modeling languages	Interface		Style			
	Graphical	Textual	Rule based	Object Modeling	State Transitions and petrinets	Programming language
APER-2		X		X		
CSPL		X				X
DPEL		X				X
Marvel		X	X			
MERLIN		X	X			
VRPML	X				X	
YAWN	X				X	
Descartes Specification Language		X	Formal Specification Style			

Table 1 Comparison of process modeling languages

The Descartes specification language could be used in both specification development and for describing a software process. With this advantage, the Descartes specification language has an edge over the other process modeling languages mentioned because, time and cost in training the personnel could be saved by using the Descartes specification language in both specification development and for describing a software process.

## V. SUMMARY AND FUTURE WORK

Managing a process manually will consume more time, cost more, and can result in low quality software. Thus, automation of a software process will save time and reduce extra work. This paper introduced the extended Descartes specification language for automating a software process. Extensions were made to the Descartes specification language for describing a software process. Extensions made to the Descartes specification language were identified to be helpful in modeling the basic elements of a software process.

The future research effort can focus on providing tool support for designing, modifying, analyzing, simulating, and verifying a process. Tool support would be more helpful for a user to organize the work and to keep track of what is going on in a

process. A tool could be provided for designing and modifying the specifications for a process. Simulating a process specification before it is executed could help in checking whether the process performs what is intended. At present, the Descartes specification language does not support simulation. Future research can concentrate on adding a simulation feature to the Descartes specification language. The tool support could be provided for simulation.

Email: marek.zgodka@gmail.com

**Abstract**—This article summarizes customer decision process focusing on information search. It explains the role and use communication channels that are used during information search, particularly the internet. It describes the internet and the role of search engines during information search. It explains the use of search engines and provides better understanding of ways in which search engines support customer decision process such as reduction of information search cost, higher involvement in the search process and increased ability to search for information. It also identifies some possible disadvantages like information irrelevancy or invisible web. Paper aims to identify the influence of search engines on information search phase of customer decision process.

### I. DECISION PROCESS

ONE of important issues in research on customer behaviour is observation, analysis and search of the values that influence customers during the purchasing decision process. In order to better understand the process, there have been distinguished phases of decision making process.

According to Engel J. F., Kollat D. T. and Blackwell R. D. decision making model consist of following phases: [1]

- A. Need Recognition
- B. Information Search
- C. Evaluation of Alternatives
- D. Purchase
- E. Post-Purchase Evaluation

When unsatisfied need is recognized, the customer begins searching for information. R. E. Rice, M. McCreadie and Chang S. L. define information as a "commodity or resource, and part of the communication process." [2] G. Stigler in 1961 said that knowledge is power and one should hardly have to tell academicians that information is a valuable resource. [3] Until then, conventional economics assumed unlimited access to information and ability to obtain information at no cost. Information search is a process during which consumers look for relevant information to make a reasoned decision. Consumers want to gain a better product and/or a better price and try to make the most optimal decision. They can seek for information on prices or characteristics of service/ product. Information search can be costly. The information itself can have its price, and consumers have to pay

to access it, or the process of search implies costs and time consumption.

First model of information search was presented in 1982 by G. Punj and R. Staelin. It was based on the assumption, that consumers are looking for the best and richest source of information, in order to make satisfactory purchase decision. They have examined five variables: knowledge and experience, need and efficiency of exploration, the market environment as an acceptable set size, customer satisfaction and cost-saving as a measure of the cost of exploration and search for information.[4] In 1991, N. Srinivasan and B. Ratchford extended the above model with perceived risks and perceived benefits of information search. [5]

J. R. Bettman stated that the process of information search is made up of internal and external search for information. He claimed that consumers usually first engage in internal search for information stored in memory. Main determinants of internal search scope are: the quantity of stored information, the suitability of information and the importance of decision. Only when information available in memory is insufficient to make a decision, consumers engage in external search for information.[6] Most of searches consists both, from internal and external information search. [7]

Progress of information and communication technologies has contributed to the development of information society. Historically, the processing and distribution of information consisted of, among others: mail, newspapers, radio, telephones. A special role in information society plays the Internet, that enabled the transfer of information to match the expectations and lifestyle of the recipient. As a result of these changes, massive numbers of readers and listeners are divided into smaller groups with common goals and interests.

### II. INTERNET

The Internet has become an important source of external information, as the information traditionally available in a variety of channels, became available in a single medium - Internet, thus influencing the decision-making process [8]. According to R. A. Peterson, S. Balasubramanian and B. J. Bronnenberg Internet offers the possibility to store large amounts of information in a number of virtual locations. It allows almost unlimited access to information from anywhere. Additionally, the Internet has the advantage of efficient and effective searching, organizing and sharing gath-

ered information [12]. Provides access to information named by R. Kraut, M. Patterson, V. Lundmark, S. Kiesler as "previously unavailable" [13]. N. Nie and L. Erbring defined Internet as a "huge public library" [14].

Compared to other media, the Internet has many advantages. On the Internet, there are multiple senders of information, so we can often compare data from several sources. It should be noted that Internet traffic is highly concentrated. Only 0.5 percent of Web pages is responsible for 80 percent of Internet traffic [15].

In communication via Internet (as opposed to traditional media), the consumer (user computer) takes the initiative in the selection of information that reaches him - he decides which information is needed. Thus, in the literature, Internet is often referred to as the "pull" medium, because of the unique way of sender - recipient communication (usually unavailable in other media). Information is pulled by customers, as opposed to traditional media (television, radio, press), where the consumer is only passive recipient of message [16].

Internet provides the ubiquity of information. It allows to get information from anywhere, anytime and reduces information asymmetry by removing the existing division between the sender and the recipient, because each side is both the sender and receiver of information [17]. Information retrieval is the result of consumer active search or navigation.

### III. SEARCH ENGINES

With the development of internet technology, the amount of information available on the Internet has grown to such an extent, that navigation to desired information became difficult. These difficulties has been solved by search engines, which spider the content of the global network, and then search for Internet resources relevant to our query. According to the PWN encyclopaedia definition, search engine is a web site that allows searching web pages containing the particular keywords. R. Prytherch described the search engine as a program produced by the publisher or data provider, enabling access to its information resources by author, title or keyword [18]. M. Busby defines it as kind of browser software, which searches the resources of the Internet, identifies the contents of web pages and stores it on computer's search engine [19].

Search engines offer some additional features that improves its search capabilities. In order to offer consumers the most relevant results, search engines take into account user behaviour on the Internet – i.e. queries entered into a search engine or web pages visited. On this basis, they are able to determine the interest of a consumer and choose the correct meaning of ambiguous words. Thanks to the computer's IP number, search engines can determine its approximate location. This allows search results geo-targeting, which means returning search results that located close to an Internet user. For the purpose of this article, we will define a search engine as a tool design to find information on entered query, that takes into account the location from which the query was asked, the personal preferences of consumers, and the time of query.

Internet search engine consists of:

A. software

called a robot, which follows links on the website, updates information and adds a new documents if found. Documents that change and are modified frequently or that are very important, are visited by robots more often. This does not affect the perceived by the search engine importance of the document, only the validity of the information presented.

B. Index

that stores the documents found by the robot. Index is a repository of all documents that search engine can search. During information search, search engines do not actually search the Internet resources but search engine's index.

C. User Interface

which is responsible for the exchange of information. It is a place where customer enters a query and gets a list of search results.

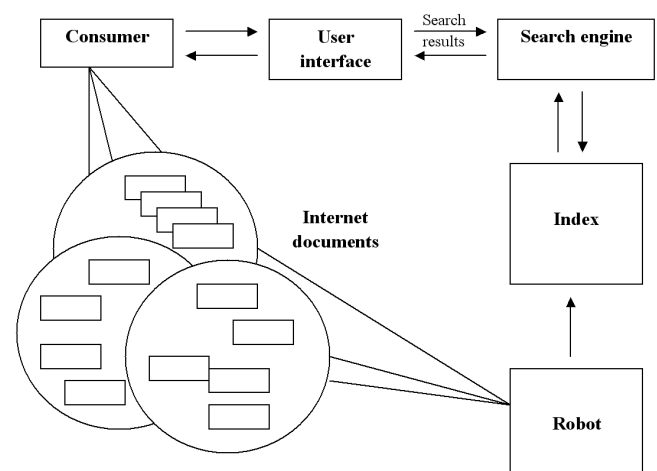

Fig. 1 Search engine architecture. Source: Own analysis

### IV. INFORMATION SEARCH ON THE INTERNET

With search engines, consumers can easily and precisely gain desired information. Use of search engine allows extremely easy and quick access to information on given topic. Internet users can find, compare and verify the information. Eric Schmidt, Google's director, described this situation as the democratization of information [21]. Through the Web, customers can very easily learn, compare and verify offers. Using so-called price search engines, they can easily compare prices and find a shop offering a selected product at the lowest price.

D.L. Hoffman i T.P. Novak distinguished two types of information search on the Internet [22]:

A. Specific information search

characterized by external motivation, focused on needs, consisting of direct search, leading to desired information.

B. General information search

characterized by internal motivation, constant involvement, consisting of indirect search and focusing on navigational choices.

## V. INFORMATION SEARCH WITH SEARCH ENGINE

Search engines enable to quickly find information on entered query, reducing the cost of information search. Yu Liang examined the long and short-term effects of reducing the information search cost. His research shows that in the short term, reduced cost of finding information will reduce the equilibrium price (The market price at which the supply of an item equals the quantity demanded). However, on the long-term basis, vendor will upgrade the product and as a result both the equilibrium price and vendors profit will increase. **Along with reduction of information search cost, consumers can look more and increase chances to find a product with better specifications.** Thus, the seller will be more motivated to offer a better product, that will have greater value for the buyer. As a result, product diversification will increase, what will reduce competition and prevent price drop to marginal cost. Reduction of information search cost will increase society welfare [25].

These advantages cause that over 85% of Internet users use search engines [26]. Typically, search engines apart from link to the website, provide some information important for the consumer. It may be the price, summarized description of a web site or phone number. This makes search engines both the source of information, as well as the way to reach more detailed information. Information access improvement by search engines depends on the importance of information obtained through the search results. Consumers use search engine to obtain the desired information. **The aim of search engine is to provide the most relevant answers to user's query.** Search engines build out their own web indexes, that collect increasing amounts of information and enhance algorithms to return the most relevant results. In a study conducted in 2000, 85% of British said that the quality of information returned by the search engine is important or very important. At the same time 31% of the examined group of respondents said that they often do not find the desired information on the web [27]. Search engine algorithms development is an ongoing process. Advances in technologies of data processing, content processing and information indexing improved information relevancy. In a study conducted in 2004, already 92% of Google users were satisfied with the results [28], what implies the constant search results improvement. **The process of information search on the web is characterized by the principle of "least effort". Users want to find information in quickest and easiest way, even at the expense of its quality** [29]. Most Internet users do not use advanced search functions, or specialized search engines, focusing on the general search engine, giving an average of two questions, consisting of two terms and only reading the first page of search results [30]. Consumers involvement in information search is associated with time spent on information access. Consumers engage in information search in order to maximize expected satisfaction with the chosen product. They compare different characteristics of products [31]. **Fast access (thanks to search engines) to desired information on the Internet may encourage the higher involvement in the search process** and offer possibility of accessing available information about the products.

Difference between search engine and web browser should be obvious. The purpose of a search engine like Google or NetSprint is to find a site for which we do not know the address. The web browser is a program to view and navigate the Web Site. We must have a browser to be able to use search engine. Nevertheless these two tools are often mistaken. In a survey conducted in six European Union countries in 2010, the question of what is a web browser, 68% of respondents said that it is a tool to access the Internet, while 40% answered that it is a search engine [32]. The above study shows that in Poland 57% of people do not distinguish between a search engine on the browser. So search engine can often replace some functionalities of web browser, giving the result of exact web site URL address and **being the first place where the consumer enters the address**, for example from a leaflet or a business card.

K. Wojcik among the determinants of consumer behaviour mentions capability of information search. The capability of information search is the consumer's own assessment of his personal capacity and motivation to perform actions associated with information search. The ability to information search is related to knowledge, experience and education of the consumer [33]. **Use of internet search engines may increase the ability to search for information** through a precise search results.

Consumers have a limited ability to process large amounts of information. Accordingly, in order to cope with information overload they make less careful choice, avoiding effort. It was confirmed by studies of K. Keller and R. Staelin [34]. They show that the quality of decisions made by consumers is deteriorating with increasing amounts of information. **Too much information on alternative choices not only does not facilitate consumer choice, but even reduces the effectiveness of this choice (information overload).** Search engines allow access to many information resources that are often not verified. This can lead to collection of large amounts of information, often difficult to process. Explained in this article disadvantages and advantages of search engines are presented in Fig. 2.

Strengths	Weaknesses
fast information access large information index reduction of information search cost increased information search ability	invisible web information irrelevancy
Opportunities	Threats
increasing information relevancy increasing information visibility	information overload

Fig. 2 Search engine influence on information search

Source: Own analysis

## VI. CONCLUSION

This article explains influence of search engine on customers decision process, particularly information search

phase. Some strengths, weaknesses, opportunities and threats have been described basing on literature, but they still require further investigation. Other possible topic that could be subject of investigation is the characteristics of different ways of search engines usage, or consumers awareness of the fact that search results hierarchy can be artificially influenced.

# 1<sup>st</sup> International Workshop on Interoperable Healthcare Systems—Challenges, Technologies, and Trends

ACCORDING to a 2009 report published by the World Health Organization, “Globally in 2006, expenditure on health was about 8.7% of gross domestic product, with the highest level in the Americas at 12.8% and the lowest in the South-East Asia Region at 3.4%. This translates to about US\$716 per capita on the average but there is tremendous variation ranging from a very low US\$31 per capita in the South-East Asia Region to a high of US\$2636 per capita in the Americas”.<sup>1</sup>

Spending on healthcare systems worldwide continues to surge in spite of the limited number of funding bodies besides governments. These systems have to include state of the art technologies and equipments to keep up the pace with the demands of a growing population and address the risks that diseases put on the welfare of this population. The rapid widespread of some diseases and scarcity of appropriate medical facilities in some countries are examples of challenges that healthcare stakeholders face daily. In addition the lack of a common healthcare systems interoperability framework undermines regularly the efforts put into offering better services that spread over multiple stakeholders. These systems are simply not meant to collaborate making any cross-system scenario tedious and error prone.

## AIMS AND TOPICS

This workshop aims at gathering researchers from the fields of IT and healthcare to think about the obstacles that hurdle the leveraging of interoperable IT healthcare applications. We target researchers from both industry and academia to join forces in this new area. We intend to discuss the recent and significant developments in the general area of healthcare systems. In particular, we hope to identify techniques from IT like service and ubiquitous computing that will have the greatest impact on making healthcare systems collaborate.

Specific possible topics include (but not limited to):

- Service computing for interoperable healthcare systems
- Agent computing for interoperable healthcare systems
- Pervasive computing for interoperable healthcare systems
- Standards for interoperable healthcare systems
- Methods for healthcare systems design
- Semantic technologies for healthcare systems
- Privacy and security in healthcare systems
- Mobile healthcare systems
- Context management for healthcare systems

- Protection of individual privacy for aggregate anonymous data
- Healthcare security and privacy policies
- Artificial intelligence technologies to support complex decision making in healthcare systems
- Case studies

## AUDIENCE

This workshop will be of particular interest to IT researchers who are working in the field of healthcare systems, those interested in developing open systems, in tracking and developing standards, and of general interest to anyone using IT for interoperable software development. We also believe that the Workshop's topic area will be of significant interest to the wider IT community and expect industry participation.

## FORMAT

The format of the workshop in terms of number of sessions, types of papers (long or short), keynote speakers, and last but not least panel discussions will be set upon completing paper review and author notification. The workshop format will be designed to foster discussion and developing action outcomes on key issues relating to developing interoperable healthcare systems.

## PROGRAM COMMITTEE

**Sohaib Majzoub**, AUD, U. A. E  
**Bassillio Dahlan**, AUD, U. A. E  
**Rabeb Mizouni**, Khalifa University, U. A. E.  
**Paul D. Yoo**, KUSTAR, U. A. E.  
**Hicham Elzabadani**, AUD, U. A. E  
**Lay-Ki Soon**, Soongsil University, Republic of Korea,  
**Elie Abi-Lahoud**, Bourgogne University, France  
**Ji Ruan**, Uni Sydney, Australia,  
**Nilmini Wickramasinghe**, RMIT, Australia  
**Mohy Mohyuddin**, King Abdullah International Medical Research Center, Saudi Arabia

## ORGANIZING COMMITTEE

**Zakaria Maamar**, Zayed University, Dubai, U. A. E., zakaria.maamar@zu.ac.ae, maamarz@gmail.com  
**Christian Guttmann**, Etisalat British Telecom Innovation Centre, Khalifa University, Abu Dhabi Campus, Abu Dhabi, U. A. E., christian.guttmann@kustar.ac.ae  
**Osama Elhassan**, TECOM Investment, Dubai, U. A. E.  
**Wathiq Mansoor**, American University in Dubai, Dubai, U. A. E., wmansoor@aud.edu

# The Intersection of Clinical Decision Support and Electronic Health Record: A Literature Review

Hajar Kashfi

Department of Applied Information Technology, Chalmers University of Technology  
SE-412 96 Gothenburg, Sweden, Email: hajar.kashfi@chalmers.se

**Abstract**—It is observed that clinical decision support (CDS) and electronic health records (EHR) should be integrated so that their contribution to improving the quality of health care is enhanced. In this paper, we present results from a review on the related literature. The aim of this review was to find out to what extent CDS developers have actually considered EHR integration in developing CDS. We have also investigated how various clinical standards are taken into account by CDS developers.

We observed that there are few CDS development projects where EHR integration is taken into account. Also, the number of studies where various clinical standards are taken into consideration in developing CDS is surprisingly low especially for *openEHR*, the EHR standard we aimed for. The reasons for low adoption of *openEHR* are issues such as complex and huge specifications, shortcomings in educational aspects, low empirical focus and low support for developers. It is concluded that there is a need for further investigation to discover the reasons why the rate of integration of EHRs and CDS is not at an optimum level and mostly to discover why CDS developers are not keen to adopt clinical standards.

## I. INTRODUCTION

**E**VEN though more than 50 years of research have been put into the clinical decision support (CDS) field, the adoption rate of these systems is still low [1], [2], [3], [4], [5], [6]. Various researchers have investigated the factors that should be considered by developers of such systems in order to result in higher adoption. One of these factors is the integration of CDS into the electronic health record (EHR) systems. Different benefits are associated with the integration of CDS into EHRs. For instance, integration facilitates real time access to the knowledge provided by CDS at point of care, it also eliminates tedious duplicate patient data entry since the pre-existing digital patient data in the EHR system can be utilized for the purpose of providing decision support [1], [7], [8].

The aim of this study is to answer this research question: *is integration of clinical decision support into electronic health record taken into consideration by developers of clinical decision support?* The related literature was reviewed not only to explore CDS developers' attitude towards integration of EHR and CDS, but also to discover the status of EHR standards in this field.

The structure of the paper is as follows. We start with the background information including the motivation for integration of CDS and EHRs in Section II. In Section III the literature review search strategy is given. The results of the review are presented in Section IV. Section V includes the discussion of the findings along with our reflection on the low adoption rate of the *openEHR* EHR standardization approach. Finally, we end with a conclusion and future directions of the study in Section VI.

## II. BACKGROUND

The idea of computerized medical records has been around as one of the key research areas in medical informatics for more than 20 years. Iakovidis defines EHR as “digitally stored health care information about an individual’s lifetime with the purpose of supporting continuity of care, education and research, and ensuring confidentiality at all times” [9]. EHRs include the whole range of patient-related data such as demographic information, medical history, medication, and allergies [10].

The main aim of EHRs is to make distributed and cooperating health information system and health networks a reality [10].

Several reasons have been identified for the low adoption rate of EHRs in small hospitals and office practices. This includes high implementation and maintenance costs, additional time and effort and finally the difficulty in choosing among available systems on the market due to a lack of standardization [1].

Improving the quality of health care is the ultimate goal of the EHR research domain, but it is in doubt whether EHRs have the ability to fulfill this goal [5]. EHRs need to be supported by other services in order to improve the quality of care [5], [11], [12], [13]. To reach the goal of improved health care quality, it is central to have CDS [5], [14], [3], [2], [6], [12], [15].

It has been observed that if there is no decision support service, the clinical knowledge needed for making a decision is not always available or applied [16]. Therefore, it is recommended that clinicians be automatically supported by

timely access to clinical decision support tools [7], [8]. The emphasis in the current application of EHRs is on timely access to patient data, patient tracking and providing decision support with the aim of improving quality of care [13]. In spite of this fact, the usage of decision support among EHR users is still quite low and there are still many EHR systems that do not include any CDS features [5]. Nonetheless, interest in applying CDS in various health care organizations to improve quality of health care has recently shown an increase [17], [18]. The CDS these organizations are looking for should provide support in patient specific assessments [17], [1].

#### A. Low Adoption of Clinical Decision Support

Results from several studies that deal with the question: *which factors should be considered in the design and development of CDS to result in an acceptable and effective CDS?* are summarized in [19]. These studies focus on developing such systems that lead to wider adoption of CDS and consequent improvement in quality of health care. According to these studies and those reviewed in this section, three of the main challenges in design and development of CDS are:

- human-related factors that are related to the way CDS systems are designed, evaluated and introduced to the users
- technical factors that are mainly related to knowledge representation and reasoning in CDS systems
- Integration to the EHR systems available in health organizations

#### B. Integration of Clinical Decision Support into Electronic Health Records

It is recommended that CDS be integrated into other information systems in the clinical domain and it has been demonstrated that an integrated system has better effects on the care process [20]. Different clinical applications such as computerized physician order entry (CPOE), electronic prescribing, e-prescribing (eRX) and personal health records (PHR) are valuable underlying platforms for CDS [16], [1]. Several studies discuss how delivery of decision support through EHRs can improve the quality of care [4], [3], [21], [22]. Moreover, integration of CDS into EHR systems has been advocated in several studies as being helpful to the wider adoption of CDS [2], [1], [5], [4], [23], [16], [24]. Overall, EHR is considered as leverage for CDS [6], [1].

Several studies have observed that manual data entry into CDS acts as a barrier for broad adoption of CDS. It is recommended that the CDS be provided at the point of care and without any additional effort to invoke it or utilize it [1], [17]. One sample scenario for an integrated CDS feature would be prompts or alerts that appear on the screen in order to inform the clinician about a drug-drug or drug-allergy interaction for one specific patient while reviewing/editing the patient's health record.

Manual data entry which is a time consuming task and a burden for clinicians can be removed by integrating CDS into EHR systems and utilizing the data which is already in an

electronic, computer-readable format. In this case, there is no need for duplicate data entry and the system can query related information from the EHR system [2], [1], [23], [25], [6]. Therefore, implementation of CDS is facilitated by EHRs. If there is no integration, data must be extracted from EHRs to be applied in the CDS. Moreover, if CDS is not integrated into EHRs, that part of the domain knowledge which is included in EHR is not applied properly [1].

#### C. Interoperability of EHR systems

EHR systems are being developed by various vendors, so they might be stored in different formats. This results in systems that are not interoperable, and makes sharing EHRs among different health organizations difficult. To overcome this problem, and to support secure and timely access to EHRs, national and international EHR standards are developed [26], [27]. *openEHR* [28] and *health level 7* (HL7) [29] are two of the well-known interoperability standards. A description of these two standards follows:

1) *openEHR*: *openEHR* is an open standard specification. The *openEHR* specification describes how health data, i.e. EHRs, are managed, stored, retrieved and exchanged [30]. Three main concepts defined in *openEHR* are (i) the two-level software architecture (ii) archetypes (iii) templates. The two-level architecture for clinical applications deals with separation of knowledge and information levels in order to overcome the problems caused by the ever-changing nature of clinical knowledge. This is realized by using *openEHR* archetypes. Archetypes and templates are used for data validation and sharing [28]. Beale et al. in [31] define archetype and template as follows:

- Archetype is “a computable expression of a domain content model in the form of structured constraint statements, based on a reference (information) model. *openEHR* archetypes are based on the *openEHR* reference model. Archetypes are all expressed in the same formalism. In general, they are defined for wide re-use, however, they can be specialized to include local particularities. They can accommodate any number of natural languages and terminologies.”
- Template is “a directly locally usable definition which composes archetypes into a larger structures often corresponding to a screen form, document, report or message. A template may add further local constraints on the archetypes it mentions, including removing or mandating optional sections, and may define default values.”

2) *Health Level 7*: HL7 is an EHR standard that focuses on communicating health data, i.e. EHRs, [10]. According to HL7 website<sup>1</sup>: “Health Level Seven International (HL7) is a not-for-profit, ANSI-accredited standards developing organization dedicated to providing a comprehensive framework and related standards for the exchange, integration, sharing, and retrieval of electronic health information that supports

<sup>1</sup><http://www.hl7.org/>

clinical practice and the management, delivery and evaluation of health services". In HL7 version 3 a comprehensive Reference Information Model (RIM) is introduced [10]. HL7 clinical document architecture (CDA) templates are analogous to *openEHR* archetypes [32].

3) *Other Standards in the Clinical Domain*: There are different approaches to support the interoperability among heterogeneous clinical systems. Other than EHR interoperability standards that concentrate on standardizing the clinical information model, the initiative has been taken to standardize other concepts in the clinical domain such as clinical guidelines and clinical terminologies to improve shareability and reusability of them among health institutions.

- **Communicating the Clinical Terminology** The language is not uniform in the clinical domain and clinicians may use different terms to refer to the same concepts. Therefore, there is a need to standardize the clinical terminology to enable communicating it [33]. SNOMED CT (Systematized Nomenclature of Medicine – Clinical Terms) is an advanced clinical terminology and coding system [33]. SNOMED CT concepts are usually referred to by an information model such as *openEHR* and HL7 [34].

ICD (International Classification of Diseases) is a coding system that is designed to "promote international comparability in the collection, processing, classification, and presentation of mortality statistics" [35]. This classification standard is suitable for statistical reporting rather than clinical documentation as is supported by SNOMED CT. There is a map between SNOMED CT terms and the equivalent ICD codes [34].

- **Sharing Clinical Guidelines** Developing clinical guidelines involves a lot of effort. Therefore, there have been initiatives to enable reusability and shareability of clinical guidelines among various health organizations. The first step to support reusability and shareability of clinical guidelines is to define a common format for representing them [36]. One well-known language for this purpose is the one developed by the InterMed Collaboratory named GLIF (the GuideLine Interchange Format) [36].

### III. METHODS AND MATERIALS

The search was conducted in the Scenedirect<sup>2</sup> database that includes the major journals in medical informatics. The search strategy is depicted in Figure 1 and explained in more details in the following.

- searching the combination of phrases "clinical decision support" and "electronic health record" returned 48 articles where 37 of them were selected for further studies.
- searching the combination of phrases "clinical decision support" and "medical health record" (excluding the papers that had the phrase "electronic health record") returned 50 articles where 37 of them were selected for further studies.

<sup>2</sup><http://sciencedirect.com>

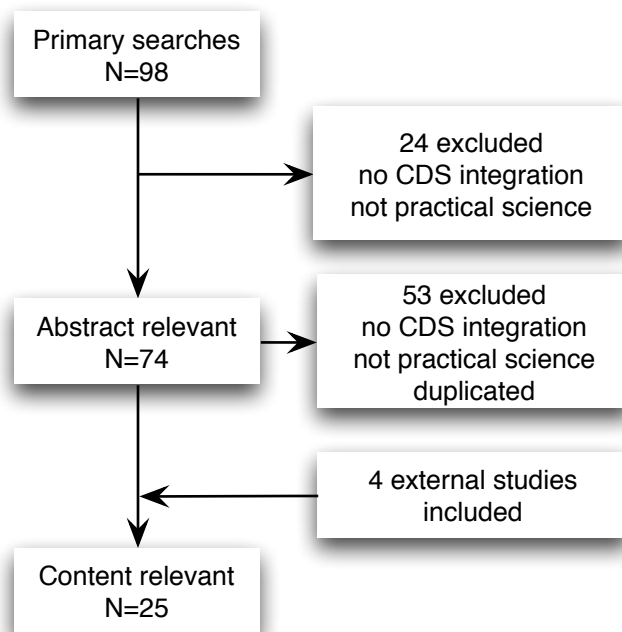

Fig. 1. Search process.

Of these 74 studies, only 21 turned out to be relevant to the review. In addition to these 21 studies, 4 more studies that the author had found were included in the review.

Inclusion criteria for the papers were positive answers to these questions based on their titles and abstracts:

- Is the study discussing development and/or evaluation of an EHR or a CDS system (i.e. practical science)?
- If Have the authors considered integration of CDS into EHRs or a related application (i.e. integration)?

Since, we were particularly interested in *openEHR*, further searches were carried out in ScienceDirect and PubMed<sup>3</sup> specifically on *openEHR* to find out if any development of an *openEHR*-based CDSS is documented in the literature:

- In ScienceDirect, searching the combination of phrases "clinical decision support" and *openEHR* resulted in 1 article that was reviewed before (the study by Greenes [1]).
- In PubMed, searching the combination of phrases "clinical decision support" and *openEHR* resulted in 2 articles by the author of this paper [37], [38] (these papers are not included in the review).

### IV. RESULTS

This section includes the preliminary findings from the literature review. Analysis of the findings are given in the next section.

The 25 selected articles were reviewed in order to find out whether they consider any of the clinical standards (i.e. EHR standards, guideline representation standards, and terminology

<sup>3</sup><http://pubmed.org>

TABLE I  
THE SUMMARY OF THE FINDINGS.

Who	Year	Integr- ation	Standards

Were et al. [62]	2010	✓	HL7	✗	✗

or vocabulary standards). The summary of the results is shown in Table I. The Integration column indicates if the integration of EHRs and CDS is taken into consideration in the study (✓) or not (✗), there are cases where the authors did not reveal any information in this regard (-). If any sorts of standards is applied in the study, the corresponding column is marked with ✓, and in cases where an international standard is used with the name of the standard e.g. HL7 for EHR, SNOMED CT for terminology.

As evident from Table I, there are various studies that have applied EHR standards (not including *openEHR*) in developing EHRs with CDS functionalities. HL7 is used in 7 studies, GLIF in 1, and SNOMED CT/ICT in 2 studies. There are also studies in which local representations or terminologies were used for representing clinical guidelines or clinical terms [60], [41]. Most of the CDS services were documented to be integrated into a CPOE system. The summary of findings is presented in Figure 2.

#### A. HL7 versus *openEHR*

While searching the combination of phrases “clinical decision support” and HL7 resulted in 41 papers<sup>4</sup>, we did not find any study that reports on implementation of a CDS applying *openEHR*<sup>5</sup>.

## V. DISCUSSION

Theory supports the benefits offered by integrating CDS into EHR, but this concept is still appreciated more in theory

<sup>4</sup>Not all of these studies are included in the review.

<sup>5</sup>The search was done in mid 2010. However, in a new search in 2011, we found more new studies related to *openEHR*. These studies are discussed more in the discussion section.

Fig. 2. Various standards reported in the reviewed studies. All of the EHR standards that were applied in studies were HL7. *openEHR* was not adopted in any of the studies.

than in practice. Only 25 related studies were discovered in this database while around 100 studies are documented in the literature that, based on their titles and abstracts, are about developing a CDSS. Nonetheless, the publication years of these 25 studies are an indication that in recent years, there has been an increase in consideration of EHR integration in development of CDS.

Moreover, it is observed that taking standards into consideration in any clinical application (and generally any information system) is very important [11]. In case of CDSSs, since such systems operate by utilizing both patient/organizational-specific data and clinical knowledge, it is important to consider the standards that support each of these areas [11]. This however is observed to still be in need of further improvements. Of these 25 studies, only 6 had considered EHR standardization, and 3 had considered terminology standards which are both surprisingly small numbers.

Finally, one can conclude that based on the literature, HL7 has a higher level of adoption than *openEHR* and that applying *openEHR* in development of clinical applications specially CDS is yet rare. This brings the question that regardless of the advances in theory why *openEHR* is suffering from a low adoption rate in practice. This issue is discussed more in the following section.

#### A. Low Adoption of *openEHR*

Below is a list of problems that we or others have faced using *openEHR*<sup>6</sup>. These issues are considered as barriers to higher adoption of *openEHR*<sup>7</sup>:

1) *Being huge and complex\**: *openEHR* is naturally complex, and this complexity is not unexpected since *openEHR* is considered to be a solution for a complicated problem (i.e. interoperable future-proof EHR) in a complex domain (i.e. the clinical domain). For instance the powerful archetype model allows expressing complex clinical concepts, therefore, an inexperienced archetype developer should expect to spend some time on learning the *openEHR* concepts. Additionally, getting a grip on the current specifications (more than 1000 pages), UML diagrams and code documentation is challenging. At the same time, it is notable that this complexity is intensified by

<sup>6</sup>In November 2010, there was a discussion on *openEHR* mailing list with the same topic. This shows that even people in the *openEHR* community have noticed that the adoption rate is low and some actions should be taken in order to improve it. Especially, it is noticeable that the amount of attention to *openEHR* is much less than HL7 in various domains i.e. government, academy and industry.

<sup>7</sup>Some of the issues presented here are the result of investigating the discussions in the *openEHR* mailing list, even though some others had been experienced in this study. Those issues are marked with an asterisk.

some other aspects such as improper educational support and limited internationalization.

2) *Shortcoming in educational aspects\**: Understanding a concept is the first step to be able to adopt it and this is even more valid for such complex concepts like those in *openEHR*. Unfortunately, no formal tutorial document exists for *openEHR*, formal training sessions are rare and even worse, not so many *openEHR* trainers exist around the world. Easy to understand tutorials are needed to help novice developers get a grip on *openEHR*.

3) *Low government and industry penetration*: Many of those who are interested in *openEHR*, in spending time on learning it or adopting it, are from the academic world (the main of which is University College London<sup>8</sup>). So far, there are very few companies that are adopting *openEHR* and to our knowledge these companies are considered to be a part of the core *openEHR* community. The main companies are Oceaninformatics<sup>9</sup>, Cambio<sup>10</sup>, and Zilics<sup>11</sup>. But what about “ordinary audience”? On the other hand, low support from the governmental agencies lead to low industry penetration. Considering the complication and the cost imposed by the *openEHR* approach, and also limited documentations and guidelines, applying *openEHR* is not still cost-efficient and yet commercial companies show a lot of hesitation to accept risks imposed by adopting this immature standard.

4) *Shortcoming in internationalization aspects*: In order to reach an international-wide adoption, it is suggested that establishing regional communities would be helpful; nevertheless, there are other concerns in this regard. *openEHR* community should consider issues such as supporting and providing guidelines for regional communities all around the world. It is also beneficial to publish *openEHR* specifications in various languages in order to speed up the process of learning for various people. Regional events such as educational sessions, gatherings and so on are also valuable to influence collaboration. As an example, in Sweden, there are around 4 groups of people<sup>12</sup> doing research on or adopting *openEHR*, but collaboration among them is at a very low level.

5) *Low empirical focus\**: *openEHR* should not just be about complex theoretical specifications and reference models, but also about implementation and practice. Semantic interoperability, two-level modeling and involving clinicians are interesting concepts, but so far these have been far from the practice. Currently, there are just a few empirical efforts on *openEHR*. Most of the focus of *openEHR* community has been on representation of domain concepts and theoretical aspects of the approach. Still, there is a huge need for supporting developers to make *openEHR* more practical.

6) *Limited tools and implementations\**: As mentioned above, developers needed to be supported in order to improve

adoption of *openEHR*. One way of delivering this support is by providing frameworks and application programming interfaces (API). At this time, the *openEHR* reference model implementation is still immature and lacks important parts like templates, persistence, and services.

#### B. Recent Advances in The *openEHR*-based CDS

When it comes to CDS, there are a few studies that deal with how *openEHR* offers opportunities for CDS. Most of these efforts however, seem to be more focused on integrating clinical guidelines into *openEHR* archetypes or utilizing archetypes for representing clinical guidelines [63], [25], [64] or to integrate reasoning and clinical archetypes (enhance archetypes by including knowledge representation capabilities to them) [65]. To our knowledge there is almost no study that has been focused on benefiting from the well-structured *openEHR*-based patient data for adopting data intensive reasoning methods in CDSSs or methods that rely on previous cases to carry out the reasoning process.

#### C. Why Are Clinical Standards Important for CDS?

According to the discussion in Section II, enough motivation exists to integrate CDS into EHRs. There is still a question whether integration of CDS into EHRs can be done without taking EHR related standards into account. If EHR standards are not considered in CDS development, all clinical data should be translated to a format understandable for the CDS system. This is not an efficient way for CDS and the EHR system to communicate. Moreover, there is an increasing interest in the medical informatics community to share clinical knowledge. This can also be supported if CDS is developed based on EHR standards. For instance, by enriching standard compatible EHRs with the reasoning knowledge, EHR sharing will also result in sharing and reusing the embedded knowledge. In cases where general domain knowledge including clinical guidelines are integrated into EHRs, the reusability and sharing of knowledge can be achieved as well.

## VI. CONCLUSION

Researchers in the area of CDS and also EHR have argued that by integrating CDS into EHRs, the improvement in the quality of health care would be higher than when the systems operate separately. The integration will be more efficient if the standards related to EHRs are considered in developing CDS. The possibility to share the domain knowledge, especially the reasoning knowledge, in decision making is another motivation for taking standards into account in developing CDS.

Nevertheless, a review of the related literature indicates that not all of CDS developers take integration into account, also there are very few of them who consider standards in developing CDS. Discovering the reasons for this however needs further investigation and has not been in the scope of this review.

## ACKNOWLEDGMENT

I would like to give thanks to Olof Torgersson who provided helpful suggestions to improve the paper.

**Abstract**—Rapid development of mobile technology and growing number of users open new possibilities in the context of using mobile devices in the healthcare. Despite that, the resources and computing power of these devices are still far less than desktop computers. Thus, one can take into account these limitations when designing applications for such devices. On the other hand, the increasing functionality of mobile devices makes them a real alternative for a traditional PC in certain areas. Nowadays, the mobility becomes one of the most required feature for the information system users. They require to be connected and have access to data all the time at any location. This is also true in the context of hospital environment where the medical staff must collect, update and retrieve various type of data. EMeH Platform is a solution that provides the possibility to create efficient distributed applications based on the SOA paradigm. It offers universal environment that allows to integrate PDAs, smartphones, tablets as well as specialized barcode scanners and RFID readers with the existing hospital information system. Layered and flexible design that reflect real usage scenarios, efficient and economic resource usage and consistent dynamically generated user interface makes EMeH Platform interesting extension to the traditional hospital information systems.

## I. INTRODUCTION

**H**EALTHCARE domain is one of the most dynamic and promising field of the IT appliance nowadays. As studies shows the IT infrastructure and software can increase the productivity and revenue of hospitals [1], [2], however, the medical personnel spend more time on data entry at the front of PC instead being with patients. The use of mobile devices in medical information systems creates the possibility of reducing this negative effect [3].

In the recent years the mobile devices became more universal and popular. The PDA, smartphone or tablets offer increasing functionality and power. There are also specialized mobile devices equipped with barcode scanners, RFID readers and GPS receivers. Currently, these devices, though still weaker than desktop PC, have enough power to become interesting alternative to them and can play the role of complex IT system terminals.

Implementing the entire functionality of a hospital information system (HIS) as mobile application is pointless due to the imposed limits of the devices, eg. entering of a long text is still inconvenient and time consuming. However, in some cases, the mobility becomes one of the most important feature. Barcode scanners and RFID readers can greatly accelerate the process of collecting data about medical equipment, drugs and patients. The tablets can be used by medical staff to present patient health record (Electronic Health Record, EHR) close to

his bed. Emergency situations are the next field where mobility becomes important and useful.

As mentioned previously, there are many possible mobile services that can enrich HIS. Typically they are realized as dedicated and separated applications, which makes the process of software development and management more difficult and expensive. The need to create many simple applications raises the idea of using service-oriented architecture (SOA) [4]. According to the SOA, applications will be replaced by web services used by the client's applications. To minimize the resource requirements imposed on mobile device, such a client application responsible for providing user interface should be implemented using thin-client paradigm.

In this paper we describe the EMeH Platform that allows to utilize various mobile devices in the healthcare environment. What is more important the EMeH Platform allows full integration with existing HIS system and follows newest trends in building distributed applications for network environment.

The paper is organized as follows. Section II briefly presents current trends on mobile device markets. The concept of the EMeH Platform is described in Section III. Detailed description of the client application is presented in Section IV, while Section V contains a description of the service environment. Related works are discussed in Section VI. Finally, concluding remarks are presented in Section VII.

## II. MOBILE PLATFORMS

In the recent years mobile devices market has dynamically developed. Therefore, a number of available mobile platforms and operating systems is considerable. Table I shows summary of the most popular mobile operating systems in the space of last two years.

Currently Google Android is the most popular operating system among all mobile platforms. It's market share has increased four-times last year, thereupon at the moment it has more users than the previous leader of ranking - Symbian operating system. Second mobile platform, which increased it's market share last year is Apple iOS. All other platforms have lost some of their popularity.

Regardless of the rapid development of the most recent platforms, there is a limited group of mobile devices, created precisely for specialized usage and amongst which vast majority are based on operating systems from Windows Mobile family. These devices, called mobile computers (e.g. handheld computers, wearable computers, vehicle-mounted mobile computers) can have various additional modules or peripherals

TABLE I  
TOP MOBILE PLATFORMS - GARTNER, MAY 2011 [5]

Mobile platform	Market Share 2010 / 2011 [%]	Trend
Android	9.6 / 36.0	+
Symbian	44.2 / 27.4	-
Apple iOS	15.3 / 16.8	+
RIM Blackberry	19.7 / 12.9	-
Windows Mobile/Phone 7	6.8 / 3.6	-
Other OS	4.4 / 3.3	-

such as barcode scanners, RFID readers or can be adjusted to heavy duty (rugged mobile computer).

This kind of specialized devices can be extensively applicable in modern healthcare systems, hence the client application for the EMeH Platform was created for this mobile platform above all. However, keeping in mind actual statistics, Android version of client application was implemented to reach wider group of users and devices as well.

### III. GENERAL CONCEPT

The EMeH Platform was built to verify the capabilities of modern mobile devices in terms of creating e-healthcare [6] platform. E-healthcare associated with mobile devices is commonly called in the literature as mobile healthcare—*m-healthcare* or *m-health* [7]. The EMeH Platform is composed of client application for mobile devices and web service environment, which runs medical applications as services. Platform architecture was based on the SOA paradigm, which can be described as a modular, scalable and interoperable approach for building systems architecture. Thanks to these features, the SOA is the appropriate approach for placing a variety of simple applications in distributed network as web services. Basic client application was built using thin-client architecture with adaptive user interface. Furthermore, an effort was made to apply SOA guidelines to mobile devices—special services located at client's side are also available for created application.

The SOA paradigm is a crucial idea, which affected the design of this *m-healthcare* system. Frequently the infrastructure of medical facilities is expanded and its elements have to cooperate with each other. Hence its necessary to create separated modules with diverse functionalities on various devices and to provide communication between them. The SOA favors modularity of systems and ensures easy scalability. In addition usage of common interface (such as REST [8]) for accessing services assures interoperability of created applications. Such an architecture enables creation of web services which will be available to many users on various devices. Moreover, it is easy to access these services, because users need to install only client applications on their devices. The web service environment was created as a runtime environment for web services to simplify design and deployment of applications.

The assumption that every module of the system can be a separate web service in the distributed network, enforces client-server architecture of interaction between mobile devices and applications. Thus, the EMeH Platform can be

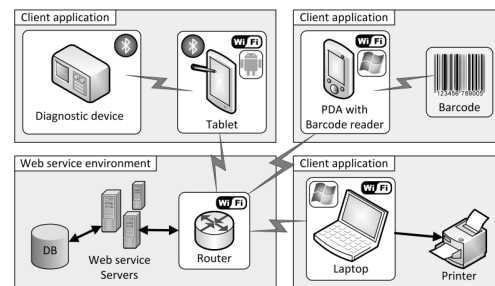

Fig. 1. General system idea

divided into two basic parts:

- *Client application* - created as a thin-client application working on mobile device,
- *Web service environment* - real medical applications consumed by client application and running in prepared runtime environment.

General idea of the system is presented in the Figure 1. To communicate with web service, every device needs only client application installed on the device. Main medium of communication between mobile device and web service is wireless network. However, it is possible to use Bluetooth technology or other ones to communicate with certain additional devices (at client's side) as well.

#### A. Client application

Client applications installed on mobile devices act similarly to web browsers, since they are thin clients. What makes difference between them is the fact, that web browsers connect to servers to browse web pages, whereas discussed client applications communicate with web services located on servers dedicated for purposes of medical institutions. Graphical user interface in the client application is generated based on data obtained from services. It determines web services' ability to control the activity of client application. Client application as a thin client makes it possible to consume various services simultaneously and the effect of such actions depends solely on service creator.

Additionally, client applications have the possibility to use services located at client's side - *local services*. This kind of service is created as an extra library and extends functionality of client application, therefore it can be called *plugin*. Plugins allow client application to use device specific peripherals such as barcode scanners, Bluetooth communication modules, RFID reader modules, etc. It is a significant mechanism of easy extending functionality with virtually no restrictions. Moreover, it provides extensions to client application without necessity to reinstall it. This gives web services the ability to command mobile device to do extra operations such as reading barcode after defined user action (e.g. pressing the button) or communicating with other devices using Bluetooth module.

Main tasks of client application running on mobile device are invocation of services by sending requests, processing of received responses from services and presentation of processed

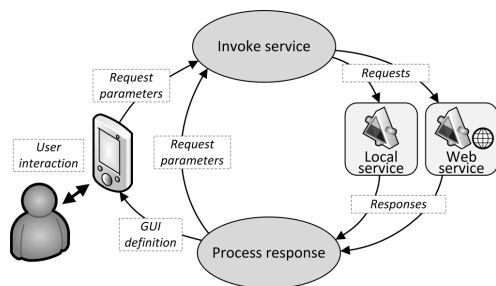

Fig. 2. Client-Service interaction flow

data to the user. It needs to be emphasized that client application does not interfere with content of presented data in any way, it only affects the way of displaying data on the screen.

The general application flow of client application is shown in the Figure 2. Every user action on mobile device triggers invocation of certain service, which in consequence can change the data displayed on device's screen. Description of mappings between user actions and service invocations is included in responses received by client application. In short, such behavior can be described as a feedback loop.

Invocation of service can be parameterized by additional parameters obtained from user interface or provided in preceding responses from services. User actions can be explained as any interaction with client application - for example it can be pressing the button, inserting text into textbox or even changing the orientation of the screen (rotating device). On the other hand, service invoked by client application, in general, returns commands in order to create or modify the graphical user interface, or to send request to some services. Summarizing, the information flow in client application is *event-driven* - it is triggered and controlled by actions performed by user.

### B. Services

Services are the part of system responsible for data processing. There are two kinds of services:

- Web services – installed in runtime environment for web services and located on servers, accessed by client applications using Wireless Local Area Network (WLAN). According to the SOA paradigm, medical applications for the EMeH Platform are designed as web services;
- Local services for mobile device – client application can utilize also services located directly on mobile device. This element expands the interpretation of the SOA paradigm through having services located not only on servers, but also as software (especially libraries) working at the client's side.

Figure 3 presents the distribution of services, which can be accessed by client application by sending requests. It shows clear division to local services and web services. Local services can do various operations on mobile device, inter alia scanning barcodes, communicating via Bluetooth module or using GPS receiver. Whereas web services are medical applications situated in runtime environment.

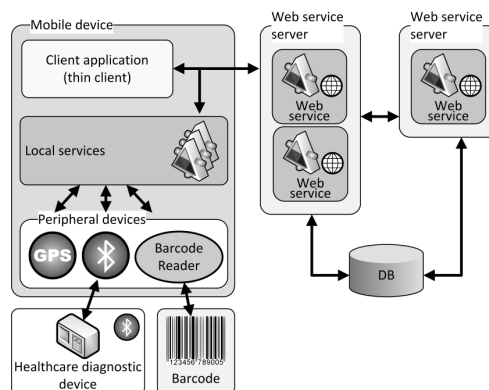

Fig. 3. Service types

In general, the network communication in general causes many security threats [9]. E-healthcare systems in many instances use confidential data (such as passwords, patient personal data, etc.), hence to protect against intrusive access of unauthorized parties, the system has to provide safe data transfer. To protect from unauthorized access, the EMeH Platform encrypts transferred data using HTTPS protocol with Secure Socket Layer (SSL) certificates. Besides in runtime environment there is a user session state management, which goal is to maintain information about user identity and activities.

## IV. CLIENT APPLICATION

In this section we describe architecture of the client application for the EMeH Platform in detail. Further, we discuss self-updating application model applied to the client application.

### A. Client architecture

As it was mentioned in the previous section, application running on mobile device is based on the thin client architecture. Thereupon, its work is focused on effective service invocation and proper presentation of received data. However, it's important to note that while processing responses from services application neither does not interfere, nor modifies the content of these responses, but only transforms them to graphical user interface.

There can be distinguished three basic layers of the client architecture: presentation layer, logic layer and communication layer. Each of them is described below.

#### Presentation layer

Client application was designed to work with various mobile devices to achieve interoperability in the EMeH Platform. These devices can differ in many ways, starting with screen parameters, such as screen resolution, aspect ratio or pixel density. Apart from screen differences, devices can run on diverse operating systems, what has an influence on methods of user interface generation. To obtain uniform way of defining user interface, client applications use common XML-based protocol of screen definitions. First client application

implementations were made for Windows Mobile and Google Android platforms, and both use the same protocol for user interface generation.

If the client application sends request to web service, then it expects response containing description of elements, which will be shown on the screen. Web service formats responses in such a way, that it does not rely on mobile device characteristics (screen parameters, operating system, etc.), thus screen definition protocol is platform independent by design. Therefore it is fundamental to transform every response to representation suitable for given device. These operations are performed by client's presentation layer.

Discussed transformation of the response and the whole user interface management itself involves some time overhead noticeable to the user. For that matter, we applied double buffering of user interface, which significantly improves screen content replacement time. It can be described shortly as two image buffers - first for current user interface content (visible to the user) and second not visible at the moment. When response from service is being processed, content of the first buffer is displayed on the screen. While in the background transformation of user interface is in progress. Eventually, when processing finishes, buffers are swapped - second buffer becomes the first one (is visible on the screen), and the first buffer goes into the background.

#### *Logic layer*

Logic layer is a part of the system where messages from services are processed to create user interface. Besides that logic layer manages events fired by user interaction with presentation layer.

Message processing means identifying type of response contained in the message and executing adequate operation depending on that type. There are three types of service responses:

- response demanding from client application to create new user interface and display completely new data on the screen (whole application window has to be recreated),
- response demanding update of certain element on the screen, i.e. change of any attribute of whichever element (for example text or color substitution on chosen label),
- response demanding client application to invoke some service with given parameters.

The message from service may contain several responses of different types - this allows to receive many screen modification or service invocation orders. Furthermore, messages can include additional data affecting client application behavior - *metadata*. Metadata can show message window, store temporary value on the device or even quit the application.

In addition to service response interpretation, logic layer has to acquire the information about events fired by user interactions (when and where was text entered, button pressed, screen touched etc.). It's essential, because process of sending request from client application to service is executed as a reaction to certain user action - as it was described in the Figure 2. To control how application should react for user

interaction (make decision which services should be called and with which parameters), the logic layer has to monitor every event fired in the presentation layer. It indicates that logic layer is responsible for interpreting user actions, formulating requests to services linked with this actions and transferring required information to communication layer, which connects directly to appropriate services.

#### *Communication layer*

Communication layer is responsible for invocation of services. As it was described in section III-B services are divided into two types: web services and local services.

Web services are basically applications deployed in runtime environment for web services, based on the SOA and having the common REST-style interface as an access method.

On the other hand local services are services located physically on mobile device. Local services are similar to *plugins* located e.g. in shared libraries, which can perform operations on client application requests. They can serve as e.g. library for device I/O operations or peripherals management - such as barcode scanners, RFID transceivers, GPS receivers, etc. To attach local service to the client application, one only has to add new entry to the application configuration file. Usage of local service does not require network connection (unless it uses it). Besides standard synchronous invocation of web services and local services, there is a possibility to invoke local services asynchronously, what allows continuous processing without waiting for response from service.

#### *B. Update mechanism*

To spare users and administrators contingent problems related to updating version of application on every single mobile device with the EMeH Platform, a mechanism called *Updater* was created. It is an implementation of self-updating application model, which utilizes a small update application (*Updater*) to alter main client application. Every client application before start uses this additional application to connect to specially exposed web service containing all versions descriptions to check whether there are any updates particular for it's device. If newer version of application or some local services (created for certain device) are available, they are automatically downloaded and installed on mobile device. It guarantees consistency between all client applications on every mobile device working within the EMeH Platform, compatibility with all web services and simple maintenance of versions in network with many different mobile devices.

## V. WEB SERVICE ENVIRONMENT

Runtime environment of web services was created to provide web services with the set of common functionalities. There are two general parts of the environment:

- web services, i.e. applications running in runtime environment,
- preprocessing modules, providing web services with essential system features, i.e. authentication etc.

Figure 4, discussed in detail below, presents these elements with regard to control flow among them (marked with arrows).

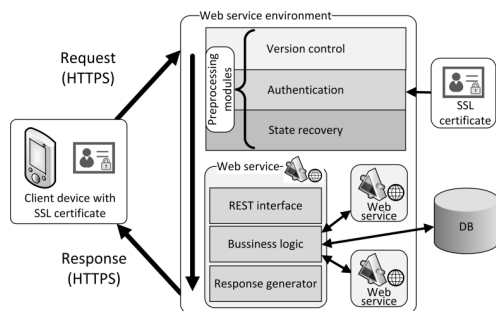

Fig. 4. Request processing flow

### A. Common preprocessing modules

In web service environment, the following preprocessing modules are implemented:

- module for controlling version of client application,
- user authentication module,
- state recovery module, used e.g. after mobile device failure

*Version control* module verifies version of application installed on mobile device that connects to the web service environment. It is important, because inconsistent versions of client-side application and web service-side environment can ensue unpredictable errors during communication. Every request sent from client to web services contains information about application version. If application version is not compatible with web service environment version, then client receives a response, which demands necessary updates to be made. Afterwards, the *updater* application (see: IV-B) on device downloads new version from the server and installs it automatically.

After verification of the client application version, the request is advanced to *authentication* module. SSL certificates are used to assure secure communication between client and services. These certificates, installed on both sides of connection, provide data encryption and identity verification for both client application, and web service environment. To positively pass authentication process, device certificate has to be compatible with corresponding certificate of web service environment.

*State recovery* module serves as mechanism of restoring interrupted user session. Whereas logging to the system, state recovery module checks whether previous user session was terminated properly. Negative result means that there exists high risk, that session was interrupted during users' work, hence module tries to recover it to the user. What is the most important, session is associated to a specific user - not to device which was used to send requests to web service environment. It gives possibility to quickly end up working on broken device and continue working on another, without losing any effects of work.

### B. Web service structure

Structure of web services working in runtime environment can be divided into three main parts:

- REST interface used for communication,
- business logic of application,
- response generator for client application.

Every web service deployed in web service environment can be accessed by clients via *REST interface*. REST is architecture style for stateless communication using HTTP protocol (or encrypted HTTPS) in the EMEH Platform. According to the REST principles, access to the service is enabled by methods of HTTP protocol: GET, POST, PUT and DELETE, meaning getting, creating, modifying and deleting data respectively. Messages exchanged between clients and web services have structure of XML documents as a result of platform independent protocol described in section IV-A.

*Business logic* is the only element of web service environment which provides certain functionalities directly to client applications. It defines specifications for client application: which events caused by the user of application will be linked to which services (web services as well as local services) and how the result will be presented i.e. which elements will be displayed on the screen. It is neither not dictated in any way, nor limited, and it depends solely on the author's concept—communication with other available services, databases, filesystem or server software is allowed. In other words, business logic module of web service has strict influence on how client-service interaction presented on Figure 2 will look like.

It is important, that all data prepared in business logic need to be passed to the *response generator* module, because it creates responses for mobile devices using platform independent protocol. This module is responsible for transformation of internal representation of data obtained from business logic of web service into format comprehensible for client applications and based on three types of responses discussed in section IV-A.

## VI. RELATED WORK

In the last decade m-healthcare systems have become a popular subject of scientific researches [10], [3], [11]. Wide spectrum of work constitutes systems for continuous monitoring of patients, what can be achieved by wearing special devices [12]. Those systems are based on so-called Body Area Networks [13]. This kind of network is dynamically developing sector of IT, in which mobile devices are used to e.g. monitor of vital signs [14] and report to a doctor every potential threat for patient's health [15].

Another issue, which is highlighted in the literature is using mobile devices in everyday work of medical staff [16]. Attempts were made to use RFID or barcode technologies to identify patients on hospital wards [17], [18], [19] or medicaments in hospital pharmacy [20]. Mobile devices with the GPS receivers were used to track elderly patients outside hospitals [21], [22]. Wireless access to basic functions of existing hospital information systems is also a big challenge

[23]. Mobile devices are used as terminals for collecting and viewing patient's medical documentation [24] or to prescribe medicines [25], [26].

The SOA assures interoperability [27] and ease of data exchange between separate medical systems [28]. In [29], [30] the SOA-based e-healthcare systems were presented, [31] contains description of the prototype SOA-based m-healthcare system for cellular phones, whereas [32], [33] show attempts to use REST interface in healthcare systems.

In the literature there were widely described thin-client architecture [34], [35] and automatic generation of user interface. There also appeared positions about adaptive user interface [36], context-aware user interface [37] and dynamical user interface [38], [35], however none of mentioned was related to medical applications.

## VII. CONCLUSIONS

This article presents a new m-healthcare platform, which utilizes modern mobile devices for e-healthcare applications. Among basic requirements for distributed system for mobile devices the most important are: modularity, accessibility, scalability and interoperability. Therefore platform was built using service oriented architecture and the access to services was assured by the RESTful interface, which enables stateless communication over HTTP protocol.

The EMeH Platform combines features of the systems mentioned in VI. It consists of client application and runtime environment for web services. Client application is a thin-client application with user interface generated dynamically of data received from services. Services can be divided into web services and local services. Web services are applications settled in runtime environment, which ensures common mechanisms for authentication, version control and user session recovery. On the other hand, local services are essentially plugins available on mobile devices. The idea of services located at client's side arises as an interpretation of the SOA paradigm in terms of a single mobile device. Local services are capable of interacting with e.g. mobile device's peripherals, such as Bluetooth, RFID or barcode modules, thus can be highly suitable for hospital information systems.

Great emphasis was put on ensuring interoperability of the created platform. To use the EMeH Platform on mobile device with other than Microsoft Windows Mobile or Google Android operating systems installed, it is needed to implement new client application for displaying user interfaces (defined by services) in new system specific manner. However, communication protocol and activity of services in web service environment is universal for every mobile platform due to the common RESTful interface of invoking services.

The EMeH Platform was implemented as a part of the *Hospital Information System Eskulap, Poznan University of Technology, Poland* [39]. In web service environment there are already some fully implemented applications, e.g. mobile dispensary in pharmacy or application for monitoring of patients on hospital wards, which currently are being performed acceptance tests in hospitals. On mobile devices there are

available client application versions for Microsoft Windows Mobile 5.0+ and Android 2.2+ operating systems.

In the future there will be more client applications implemented to extend the scope of the platform on additional operating systems, such as Apple iOS or Microsoft Windows Phone 7. Besides that, there will be created a new tool for graphical screen definition creation in web services. There will be also implemented more web services for the EMeH Platform, based on existing software of the Eskulap System. Reason is that many of existing applications for desktop computers could be easily extended by the access from mobile devices, such as: laboratory, medical imaging or ambulance service applications.

**Abstract**—The healthcare setting is multifaceted, comprised of many different components including private, governmental, and regulatory agencies. There is always a necessity of timely and reliable information exchange among these agencies especially on “Infectious Disease” information due to their criticality. The heterogeneity of the systems used by these agencies has led us into designing and developing an interoperable solution to exchange data effectively among several independent yet collaborating health authorities at both state and national levels. This research work articulates the efforts put into achieving an interoperable “Infectious Diseases Reporting System” that incorporates ontology-based semantic rules to align different infectious disease coding standards and to deploy Web services for collecting data from remote sources. This effort is a first step towards achieving a policy-based interoperable Infectious disease monitoring system which can be used across different yet collaborating regulatory agencies.

**Index Terms**—Interoperability, Semantics, Healthcare system.

## I. INTRODUCTION

**I**NFECTIONOUS diseases outbreaks demand a timely and proportional response to mitigate effects on public health. Management of these outbreaks is becoming a growing concern in public health, as it requires extreme actions and coordination between governing authorities at both state and national levels. Tracking and identifying emerging infectious diseases and epidemic outbreaks in particular poses critical challenges on public health researchers and practitioners. Dealing with large numbers of incoming reports and alerts requires an automated system which performs real time analysis on a centralized repository of collected clinical information. As such, intrinsically intensive information exchange should be exercised between healthcare facilities and this repository, which is normally operated by a regulator. Regulators use these collected information to identify, manage, and investigate infectious diseases outbreaks. Such data, when visually and adequately represented, support the education of healthcare providers within participating facilities and improves the outcome of disease outbreaks management.

## A. Challenges

Gathering information from various sources (i.e., healthcare facilities) in real-time is a challenge because of the diverse and heterogeneous nature that labels interfacing healthcare applications. Moreover, the capability of aligning and integrating healthcare data standards varies drastically from one coding system to another. There is a necessity here to design an advanced interoperable system that is empowered with a semantic layer to retrieve and map the information onto a unified standard to support alerting and surveillance. The design of such an interoperable system is complex and challenging due to the following factors:

1. Each healthcare facility has its own software to manage patient’s data e.g., Physician Practice Management System (PPMS) and Electronic Medical Records (EMR). Moreover, even standardized EMR systems might be interfaced differently and sub-systems such as Lab systems are isolated in terms of their used standards (i.e., proprietary standards) and thus raise extra integration challenges.

2. Each facility has its own policies and procedures for reporting patient data.

3. The network infrastructure and real time reporting may affect the data availability.

4. Last but not least, from a regulatory body point of view, since the infectious disease is a growing concern in public health, it is necessary to collaborate with other health authorities to exchange and manage the related information and alerts.

To address the aforementioned factors, a platform is needed to enable interoperable information exchange between independent healthcare systems.

## B. Proposed Solution

This research work presents the design and development of semantic information integration for Infectious Diseases Reporting system using Web services as a core component for information exchange with ontology-based rules. Ontology has been predominantly used to represent well-categorized concepts and to support mappings between models. The central ontology has been designed for the system and expressed in OWL [1][2] so as to semantically assign dis-

eases represented in various coding standards to a single unified entity.

The rest of the paper is organized as follows. Section 2 provides some background information and literature survey. Section 3 presents the architecture and implementation details. Section 4 discusses some design decisions and their impact on the implementation. Section 5 summarizes the research outcomes and outlines future work.

## II. LITERATURE SURVEY

In [3] Iqbal et al. propose an ontology based model for an Electronic Medical Record that targets Chronic Disease Management with focus on providing a coherent information structure to support other acute diseases and co-morbidities. However, this model is patient-centric as it comprises longitudinal information of the patient, but it lacks the capability of collecting data from heterogeneous system.

In [4] Sampalli et al. propose an ontology model for patient profiles. In this model, frequently occurring procedure/diagnosis terms are extracted from patient charts, converted into SNOMED CT (Systematized Nomenclature of Medicine-Clinical Terms) and then categorized using the ontology concepts. The categories include medical, physical, psychosocial, rehabilitation, and nutrition. However, since the rules associated with the ontology are applied on patient charts for recurrent medical terminologies, the degree of accuracy between the doctors' diagnosed term and the converted concept identifiers cannot be easily measured. Such a study can be helpful for statistical analysis but not on patient treatment.

In [5] Ngamnij Arch-int et al. describe a semantic bridge ontology that provides Web services with the same service information but different parameters – according to the proprietary database structures – to integrate or exchange data and obtain common semantic meanings.

Iqbal et al. and Sampalli et al. demonstrate the use of ontology based rules in conceptual categorization and the value-added of ontology to enhance the expressiveness of concept. In our work, we have used “criticality” in “Infectious Disease” as the key indicator of expressiveness based on the diagnosis code. Regarding Arch-int et al. the ontology rules are not used to create a conceptual model for the relationships of the data from the disparate systems.

## III. OUR INFECTIOUS DISEASES REPORTING SYSTEM

### A. Design

We have divided our system into the following modules: Interoperable Web Service, Ontology-based Infectious Disease, Semantic Bridge to communicate with other health authorities, and Business Intelligence and Reporting.

Our infection diseases reporting system is built upon a set of Web services that interface with existing systems to collect infectious diseases. The content of these systems is structured differently with different standards (e.g., ICD-10 [6] or ICD-9 [7]). It is worth noting that some local health-

care facilities send their disease codes as “descriptive text” to Web services. Thus we need an ontology bridge to map counterpart meanings of single concept (e.g., disease name “malaria”) that are defined by different standard codes into a uniform entity.

The regulatory body defines “criticality” of each infectious disease. Each infectious disease has several characteristics properties but we focused only on “Criticality. We utilized OWL to build the relationship between ICD-10 codes and ICD-9 [7] class as “union-of” relationship to streamline a unified infectious disease classification range: Highly Critical, Critical, etc. to establish an “infectious disease centric” ontology model on patient data. The collection of these ontology-based entities reflects our conceptual model. The role of “Ontology-based Infectious Disease” module is to build such a model in order to represent and reason about the “criticality” of infectious diseases.

For a single regulatory body, there is a necessity to communicate its captured infectious diseases incidents to other health authorities at state and national level. Therefore we provide a web service based mechanism to exchange collected incidents data. Each health authority defines its own web service WSDL (Web Services Description Language) description. Since the WSDL parameters for web service methods will be different for each health authority, although the information are same, it is necessary to build ontology based rule to get the semantic meaning of the appropriate parameters. The role of “Semantic Bridge” module is to bridge the internal artifact properties with the WSDL parameter names of external health authority's web services.

The “Business Intelligence and Reporting” module is built to provide the regulatory body a statistical research and education program.

The architecture of our infection diseases reporting system is built upon 5 layers (Fig. 1): Resource, Mediation, Application Layer, Business Intelligence and Reporting, and Semantic Bridge.

The Resource Layer hosts a Centralized Data Repository, which has Patient Profile information that is stored in an Object Relational Database.

The mediation layer hosts three components:

- *Interoperable Web service*

It is implemented in SOAP and facilitates the Infectious Diseases data retrieval that will be triggered by the facilities when a patient encounter of infectious disease occurs. The Web service converts the retrieved patient data into internal artifacts and passes the information through the Ontology Engine.

- *Ontology Engine*

It facilitates building the conceptual model of the “Criticality” of the disease based on the data retrieved in Web services by issuing SOQL query to the ontology rules on “Infectious Disease”. Fig. 2 shows the “Architecture of Ontology”.

gy engine for Semantic Bridge”. The “Cholera” disease is denoted in OWL as follows.

```

InfectiousDisease rdf:ID="Cholera">
  <CriticalityCondition rdf:resource="&xsd:string">
  HighlyCritical
  </CriticalityCondition>
  <DiseaseDescription rdf:resource="&xsd:string">
  Cholera is an infectious Disease
  </DiseaseDescription>
  <owl:unionOf rdf:parseType="Collection">
  <owl:Thing rdf:about="#CholeraCD10" />
  <owl:Thing rdf:about="#CholeraCD9" />
  </owl:unionOf>
    
```

• Alert system

It is implemented as an e-mail notification system that informs the regulatory body authority when a patient has some infectious diseases.

The Application Layer consists of Web interface screens for viewing Patient profile data and also for assigning proper coding to the reported Infectious Disease if it is submitted as a descriptive text without standard coding terminology. If the “descriptive text” contains medical terminology, there is an automated search of the ICD -10 with that medical term. If this search manages to fetch the appropriate code, it will stamp that internal artifact disease coding as “Automated text conversion”. We have built web portal on top of the ICD -10 to search for codes or description, which will help the medical coding experts to assign “descriptive text” proper coding and convert them to conceptual model.

The Business Intelligence and Reporting Layer retrieves the data stored in Centralized Data Repository and transforms them into Dimensional data model and stored in "Warehouse" Object Relational database. We have built "Reports".

The Semantic Bridge Layer allows to address the problem of semantic discrepancies of WSDL parameter names. We have built some common ontology rules on the parameter names between the internal artifact property names and WSDL parameter names. For instance, let us take an internal artifact property called “patient name” that is codified as “PatName” using a WSDL parameter and “PatientName” as another internal artifact property. These two parameters are semantically the same and hence, are described in OWL model as “same-as” relationship. This mapping is illustrated for other parameters in Table I.

TABLE I.  
WSDL PARAMETER NAMES WEB SERVICES ARE MAPPED TO INTERNAL ARTIFACT PROPERTY

Internal artifact property name	WSDL parameter name for the web service 1	WSDL parameter name for the web-service 2
PatientName	Name	PatName
MRNNo	MedicalRecordNumber	MRNNumber
Healthcard	HealthcardNo	HealthcardNumber
DateOfBirth	DOB	BirthDate
Gender	Sex	Gender
DiagnosisCode	ICD10Code	ICD9Code
DiagnosisStatus	Status	Status
PhysicianName	ClinicianName	Providername

The following “Patient Name” property in OWL

```

<Parameter rdf:ID="PatientName">
  <parameterFrom>InternalArtifact</parameterFrom>
  <parameterID>PatientName</parameterID >

  <owl:sameAs rdf:resource="#Name">
  <owl:sameAs rdf:resource="# PatName">

</ Parameter>
<Parameter rdf:ID="Name">
  <parameterFrom>Webservice1</parameterFrom>
  <parameterID>Name</parameterID>

</ Parameter>

<Parameter rdf:ID="PatName">
  <parameterFrom>Webservice2</parameterFrom>
  <parameterID>PatName</parameterID>

</ Parameter>
    
```

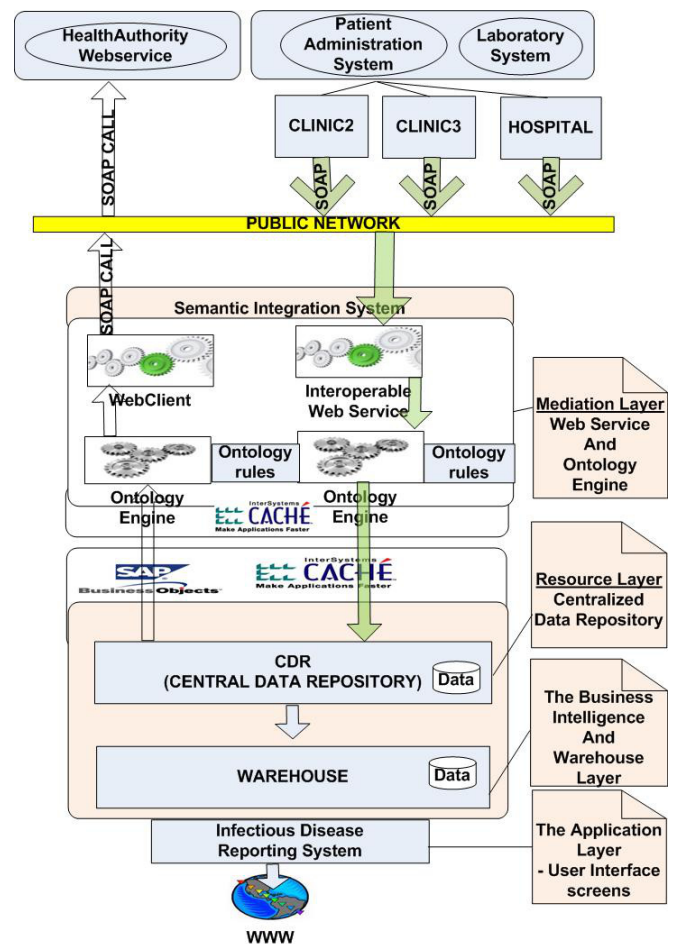

Fig 1 Architecture of Infectious Disease Reporting System

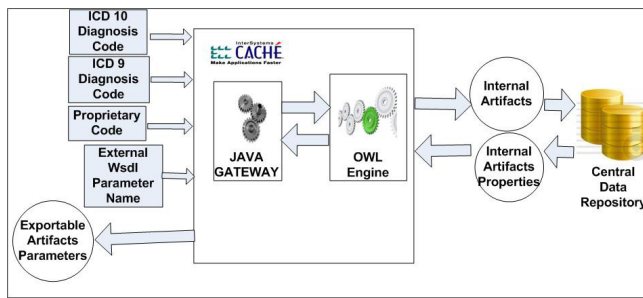

Fig 2 Architecture of Ontology Engine for Semantic Bridge

### B. Dataflow

When a patient is diagnosed with an infectious disease, the clinical system launches a Web service that will send the data to our system. These data will be managed by some ontology rules before they get stored in the Central Data Repository (CDR) as "Patient Profile". Moreover these data will be subject to some mining as follows.

1. The Healthcare facilities send the data of infectious disease to the Web service.
2. The Web service delivers the data to the semantic engine. It is implemented on Intersystem's cache having a "Java Gateway" and "OWL" engine. This engine converts the data into a conceptual model of internal artifacts.
3. The internal artifacts finally are stored in the "Central Data Repository".
4. The data are mined in the "warehouse repository" for statistical reports and charts generation.
5. To report the infectious disease to an external health authority Web service, the ontology relationships are established between the internal artifacts parameters and the external callable WSDL parameters. This will match the semantic meaning of the WSDL parameters and makes web service client as semantically integrated with the external WSDL parameters.

### C. Technologies Used and Delivered Components.

We have built the web service on top of Intersystem's Cache implementation. The infectious disease data collected is transformed into data mining for the statistics research, which is built on Business Objects. The web pages are built on "Cache Server Page". For the transformation of the data to the conceptual model with OWL for both Infectious Diseases and the Semantic wsdl parameters, the jena engine is implemented. Table II shows the technology components and their vendors list. Table III shows the components designed and delivered.

TABLE II.  
SUMMARY OF IMPLEMENTATION TECHNOLOGIES

Technologies	Brand
Database & Language	Intersystem's Cache [8]
Reports & Graphs	Business Objects [9]
OWL	Jena[10]

TABLE III.  
MAJOR COMPONENTS DESIGNED AND DELIVERED

Component	Description of the Component
Web service	This service exposes web method "ReportDisease" and collects for the data submitted from the external request from the Healthcare facility medical systems
User Interface screens	Web page for searching ICD 10 disease codes and description. Used by medical coding experts to assign proper coding
Semantic Bridge	To achieve semantic interoperability, we have used the ontology based rule on the internal artifact property name with the wsdl parameter names of the external web services
E-mail alerting system.	Automated e-mail system was built to notify the regulatory body for the infectious disease reporting.
Reporting system	We have built data warehouse for statistical research with ad-hoc reporting tool on Business Objects
Security	Security Layer on the Web pages with the authentication on Active Directory

## IV. DISCUSSION

The architecture presented in this paper lays down the basis for the development of an Interoperable medical application that targets multi-regulators "Infectious Disease Reporting System". The ontology developed in this study adds another layer of expressiveness whereas Web services secured the reach ability of the existing systems across different platforms. To achieve semantic integration, we have built a set of ontology rules on WSDL parameters with the internal artifacts parameters. The key limitation in this work is the inability to capture medical tests and results, which form together the fundamental support for confirming diagnosis of infectious disease. To achieve this goal, we have to expand the array of data to accommodate medical tests and their results by providing ontology vocabulary on the LOINC codes to convert them into conceptual model.

## V. CONCLUSION AND FUTURE WORK

This research work is driven by the immense needs and posed challenges for integrating different healthcare systems to monitor and manage public health indicators such as infectious diseases. As such, this work can be extended in many aspects such as putting forward a policy-based framework to allow injecting regulators rules. This direction should follow the approach specified by El-Hassan et al. [11] which allows specifying rules for accessing resources

(e.g., patients data) in both normal and emergency situations. Additionally, advances in web services that advocate collaboration between independent agents have to be incorporated. In this perspective, web services research presented by Khosravifar et al. [12] demonstrate a viable candidate for community-based web services that manage service-based interactions between equal parties.

# International Workshop on Ubiquitous Home Healthcare

**P**OPULATION aging is a phenomenon affecting many countries around the world. For example in Europe the life expectancy increased from 45 years in the early twentieth century, to 80 years now. Significantly longer life leads to age-related problems and diseases. In parallel, the cost of hospital care is increasing and additionally, a lack of the qualified caregivers is observed. Development of ubiquitous healthcare technologies can improve the quality of life of assisted citizens and can curtail growth in healthcare spending fueled by aging populations, and the prevalence of obesity, diabetes, cancer and chronic heart and lung diseases. In particular, information systems integrated with wearable, mobile devices and sensor networks at home can continuously assist persons while moving out or staying at home. Ubiquitous healthcare systems used as assisted living solutions will not only help to prevent, detect and monitor health conditions of a person but will also support of elderly, sick and disabled people in their independent living.

The goal of the UHH 2011 workshop is to gather researchers and engineers working in the field of ubiquitous healthcare to present and discuss new ideas, methods, and applications of assisted living IT technologies.

## TOPICS

The workshop welcomes all work related to ubiquitous healthcare, but with a focus on the following themes (this list is not exhaustive):

- Ubiquitous healthcare information systems,
- Information processing algorithms for UHH,
- Ubiquitous services for home and mobile applications,
- Human-system interaction in UHH,
- Data mining and knowledge discovery in ubiquitous healthcare,
- Integration of sensors and devices for UHH,
- Security of ubiquitous healthcare systems,
- Ensuring the Availability, Transparency, Seamlessness, Awareness, and Trustworthiness (A.T.S.A.T.) of home and mobile systems,
- Standardization in ubiquitous home healthcare,
- Applications of UHH for elderly, sick, and disabled people,
- Elderly care monitored dosage systems,
- Welfare technology for UHH.

The proposed papers should emphasize at least one of the following aspects:

- Assisted living,
- Home care,
- Self care,
- Mobile care.

## PROGRAM COMMITTEE

**Piotr Augustyniak**, AGH-UST, Institute of Automatics, Multidisciplinary School of Engineering In Biomedicine, Poland

**Adam Bujnowski**, Gdansk University of Technology, Department of Biomedical Engineering, Poland

**Jan Cornelis**, Vrije Universiteit Brussel, Department of Electronics and Informatics, Belgium

**Jens Hauelsen**, Faculty of Computer Science and Automation, Ilmenau University of Technology, Germany

**Zdzisław S. Hippe**, University of Information Technology and Management in Rzeszow, Faculty of Applied Informatics, Poland

**Eddie YK Ng**, Nanyang Tech. University, School of Mechanical & Aero. Engg., Singapore

**Nicolas Pallikarakis**, University of Patras, Biomedical Technology Unit - BITU, Greece

**Ewaryst Tkacz**, Silesian University of Technology, Institute of Electronics, Poland

**Stefan Wagner**, University of Aarhus, Aarhus School of Engineering, Denmark

**Krzysztof Zaremba**, Warsaw University of Technology, Faculty of Electronics and Information Technology, Poland

**Artur Poliński**, Gdansk University of Technology, Department of Biomedical Engineering, Poland

## ORGANIZING COMMITTEE

**Jacek Ruminski** (chairperson), Gdansk University of Technology, Department of Biomedical Engineering, [jwr@computer.org](mailto:jwr@computer.org)

**Abstract**—In the present study, a home monitoring healthcare system for elderly and chronic patients has been proposed. The system was developed for three types of users: assisted person, doctor and guardian. It analyzes the collected information (e.g. biomedical signals) and in case of detection of dangerous events informs physician and guardian. A mobile device has a key role in the system. It allows exchange and visualization of data to the users. This paper describes the design and implementation of a tablet in the home monitoring healthcare system, with specially developed data exchange protocol. Additionally special security features to protect data exchange were introduced. Software part of the system was made using modern technologies such as JavaFX for central unit and Android for mobile devices.

## I. INTRODUCTION

RECENTLY healthcare for elderly people has been an important research topic. The increase in life expectancy due to improvements in living standards, and medical treatments, has resulted in an aging population diseases in the last few years [1], [2]. Therefore, the modern health care system aims to enhance the safety and comfort of the patient's life while managing chronic diseases. This creates the need to develop home e-health system, which will integrate various wireless sensors for long-term monitoring and vital signs extraction of the patients. The rapid development of information and telecommunication technology has brought great revolutions in that field [3]. New features of mobile devices (smart-phones, tablets), create new opportunities to use them as devices for the management and presentation of medical data.

There are many promising systems implementing the selected function or the complex monitoring of the patient. One of the first approaches proposed a wearable patient monitoring system, which integrates current personal digital assistant (PDA) technology and wireless local area network (WLAN) technology [4], [5]. A wireless PDA-based monitor is used to continuously acquire the patient's vital signs, including heart rate and SpO<sub>2</sub>. The patient's bio-signals are transmitted in real-time, through the WLAN to a remote central management unit

In another approach a mobile phone was proposed as a client-side part that communicates with the central device by the GSM network [6], [7]. An alert management mechanism has been included in back-end healthcare center to enable various strategies for emergency alerts triggered by automatically recognized situations.

A Bluetooth-enabled in-home patient monitoring system, facilitating early detection of Alzheimer's disease was proposed in [9]. The location and hence the movement of a patient is tracked and reported to a local database, with the use of short-range Bluetooth communications. The collected data is then transmitted via the Internet to a decision engine (on a remote site). "Electronic Doctor's Bag" [8] is another approach to medical system with mobile communication. The main idea of this system is that a nurse instead of a doctor, carries the Electronic Doctor's Bag and visits a patient. Than an equivalent to face-to-face communication between the doctor and the patient is realized remotely.

Data security and optimization of wireless communication between devices of the system [10], [11] are very important aspects of the functioning of the patient in-home monitoring systems.

The purpose of this study is to develop a system of comprehensive and continuous monitoring of the patient at home. The functionality of the various parts of the system was optimized for a user. System that is adapted for continuous measurement of biomedical signals, depending on the patient's disease. System that analyzes the collected information and in the case of detection of dangerous events informs physician and guardian. The purpose of this study is to increase the amount of information that can be acquired from patient at home and exchanging them with doctors.

## II. SYSTEM STRUCTURE

Home monitoring of patients is a wide term and different applications are possible. Some users are highly immobilized others are free to move but suffer dementia. The platform design requires creating a multi-modular system. Proposed by us the Domestic system structure is presented in Fig 1. Our system consists of the following components:

This work was partly supported by European Regional Development Fund concerning the project: UDA-POIG.01.03.01-22-139/09-00 -"Home assistance for elders and disabled – DOMESTIC", Innovative Economy 2007-2013, National Cohesion Strategy.

### A. Users

- An assisted person (AP) – person supported with the system. Communicates with the Domestic system using HCI, various sensors and possibly an Android device.
- A physician - A person in charge of AP health. It should be either doctor or otherwise qualified person. Physician communicates with the system only by tablet.
- A guardian - A person who cares for the patient (eg family member, social service person), communicates with the system using tablet or other Android device.

Fig. 1 Domestic system structure (details are given in the text)

### B. HCI

The human-computer interface is one of the most important elements of the platform. The acceptance of the entire system depends highly on the way it can be used by older/immobilized users. Three elementary modes of the HCI are being designed: interface based on touch screen; visually guided interface; audio guided interface.

### C. Home station – central unit

Central computer around which whole system revolves. Home station is a Domestic device consisting of computer with Bluetooth adapter and HCI software. It should manage databases, synchronize with global database, collect and process sensor data, process and dispatch events, integrate data, manage communication, support mental training, etc.

### D. Set of sensors

Set of devices collecting data relevant to patients health state. Different categories of sensors are currently prepared to measure: heart pulse, temperature, body composition parameters, glucose concentration, blood pressure, electric heart activity, and posture activity. Another group of sensors consists of those related to monitor user environment parameters. This is especially important for older people deciding to live independently at home.

### E. Mobile device - tablet

A device with Android operating system, used by users of the system. It allows to communicate with Home station and access to functions such as real-time medical measurements or AP information. Features and details of such device are described in the next paragraph.

## III. MOBILE DEVICE

This work is focused on use of a mobile device for exchange and visualization of data in home monitoring. Portable device used in Domestic system must have Android operating system. This type of device is going to be used by all system users. In the case of the patient and guardian device can be either mobile or tablet, while in the case of a physician use of tablet is recommended (due to the improved readability of medical data presented). Special software was prepared for each user type, which enables, among other things, communication with the central unit and carrying out the appropriate function for the role.

In case of the AP it must fulfill three basic functions: communication with the AP (surveys), monitoring of the AP when not within range of the central unit and notification of some activities. Guardian using a mobile device will be alerted about the dangerous events occurring on the side of the patient and, additionally, when he is in the patient's home will be able to view basic data about the patient's condition (e.g., the last activity of the patient or test results).

Application that was prepared for a doctor is the most expanded. It has been prepared mainly to carry out visits in the patient's home. When the device is within the range of the patient's central station the device will automatically connect to it and update current basic information about the patient. Additionally, there is possibility to browse offline basic medical data, which are stored in the internal database. If the device is equipped with a GSM module, it will be served alerts notifications emitted from the patient central unit as well. During home visits physician has access to personal, electronic healthcare records, which contain the list of actual diseases and prescribed medications, information about recent events and a physician's personal notes about the patient. Additionally, physician can access the archived data or add new data if needed. An example of the patient chart with some test data is presented in Fig. 2. Another feature allows the physician to access the list of measurements which suits the patient's condition. After selecting a particular type of test, information specific to this measurement is presented, both in text and a graphics. The physician has the opportunity to view the entire history of examination, that are automatically downloaded from the central station. There is also a possibility to carry out test directly from the application. Monitoring of patient basic vital signs (ECG, pulse, blood pressure, temperature) which is an example of real time measurement, is shown in Fig. 3.

Interface design for medical applications is the result of consultation with prospective users of the system. It imposed the emphasis on maximizing the clarity of the information presented and intuitive interface. In addition, particular attention was paid to issues of communication and the security of transmitted data between the mobile device and a central unit. These issues are described more specifically in the following paragraphs.

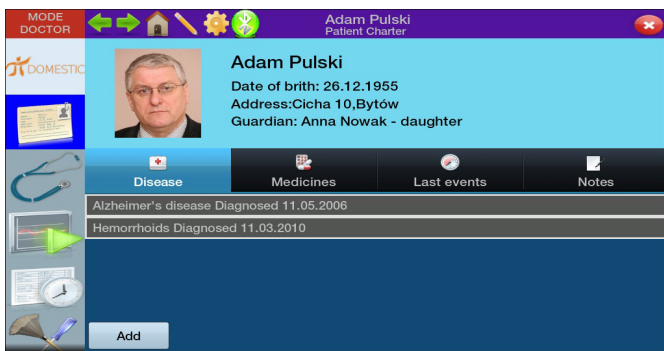

Fig. 2 Patient panel view

Fig. 3 Real time monitoring of patient vital signs

IV COMMUNICATION

When two of domestic devices get in detection range of each other and at least one of them is a server, communication begins. After connection is established devices start to exchange protocol defined communicates as shown in Fig. 4. At the beginning, message containing information about the sender device type (Initial request), is sent by a server device (e.g. medical tablet). In response, if client device recognized type of server it sends its own type (Initial response), otherwise error message is sent and the connection broken. Server then analyzes information it has been given, to recognize client device. If recognition was negative connection is broken and error message is sent, otherwise communication continues. What happens next depends on what devices are connected. In case of Home Station - Medical Tablet connection conversation will go as follows. Server device requests list of assisted persons associated with connected device (Request list of AP). Client responds by sending *ids* of users stored in its database (Send list of AP). Medical tablet presents received data to the physician and wait for him to take action. During this time, if the entire system is not set to be synchronized externally (e.g. through the internet), devices update each others databases (DB synchronization). Further steps are results of user actions. For each action server device sends a request (Request AP data) to which client responds accordingly (Send AP data).

V SECURITY

Bluetooth offers some security mechanisms to prevent unauthorized access to transmitted data and device functions. Two most important of them are pairing and data encryption.

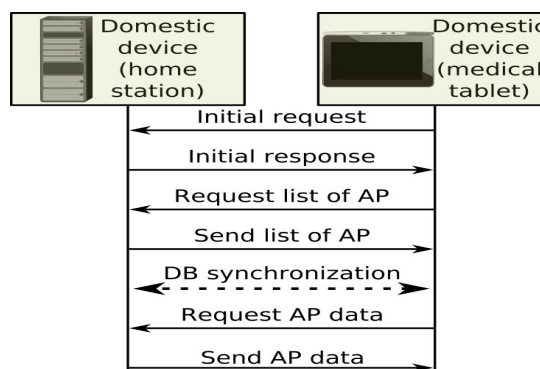

Fig. 4 Data exchange protocol (details are given in the text)

This security measures are not perfect however. To further increase safety of medical data, additional mechanisms were implemented: registering devices; additional data encryption; specially designed system structure. Domestic applications respond only to devices that has been specifically registered to work with them. Registration of device's Bluetooth address is done through applications user interface and not remotely to reduce possibility of registering unauthorized device as much as possible. To prevent data leakage in case of hijacking of Bluetooth connection, domestic applications encrypt all communicates before sending them through Bluetooth adapter (in addition to Bluetooths encryption). Domestic system structure is designed to enhance all security mechanisms mentioned above. Data storing devices such as home stations act as clients for purpose of establishing Bluetooth connections so it is impossible to scan them for services. Part of the data transmitted between domestic devices is in form of unique IDs. To interpret it a device must have access to the Domestic database, otherwise it would only get meaningless strings of characters.

VI DISCUSSION

This paper has presented a comprehensive system of home monitoring of elderly and chronic patients. Previously these types of systems were designed primarily for one group of users. Our system assumes the existence of three types of active members: an assisted person, a guardian and a physician. In the design phase of the system main purpose was to achieve maximum benefit for its individual members. In the case of th AP the goal was to ensure the maximum possible convenience of the system that will, at the same time, provide the highest possible level of control over his condition. For a doctor, it is necessary to provide a solution that will allow the correct interpretation of medical data. We used a tablet with Android system and our software, which is prepared to acquire, process and manage medical data and communicate with other devices, using readable and easy to use graphical user interface. In case of a guardian it was important to obtain basic information about patient condition and alert messages via a GSM network

It is usually necessary to monitor and record multiple physiological parameters of patient with chronic disease as the base data to analyze and track patient's condition and to

provide medical treatment. Currently, the majority of the proposed systems of this type is characterized by large size or limited working area, which reduces the desire to use it and quality of everyday life of the patient. We offer a complete system with modular structure, which allows to choose a set of wireless sensors individually for each patient depending on his condition. It provides integration of multiple physiological parameters extracted from all devices. The main component of the system is the central unit, which communicates directly with other devices, systems and processes and stores all data related to patient. The system has three main strengths: good expandability, highly flexible architecture, simple to design hardware and software.

The software of central unit was developed in Java/JavaFX environment. It offers rich graphical user interface creation combined with all the advantages of Java language. This allows the creation of visually pleasing, cross platform applications with minimal effort. On top of that JavaFX is meant to be able to run on many mobile devices, in browsers and possibly even on TV sets. A trait that might prove useful during development of further Domestic devices.

For Domestic mobile devices Android OS was chosen. This is one of the most popular systems (next to the Apple OS's) used in mobile devices, characterized by the following advantages. Open source platform based on Java, with multi-tasking and wide hardware support. A large variety of available devices, including wide range of tablets with the version of Android 3.0 which is suited to this type of devices. Personal mobile devices with Android system are powerful and flexible in use. It reduces both the time and cost needed for system development.

Both Wi-Fi and Bluetooth provide enough range and transfer rate to fulfill Domestic goals. Advantages Bluetooth has over Wi-Fi are security and ease of use. Bluetooth has two level password protection and getting access to one point of Bluetooth network does not grant access to any other part of it, as opposed to Wi-Fi networks. It is also easier, both software and hardware wise, to establish Bluetooth connection. Another possible choice is ZigBee, however it is inconvenient to send large amounts of data over ZigBee, besides hardly any popular mobile device has built-in ZigBee module, which make it practically useless in out system.

## VII CONCLUSION

The concept of full care service is to prevent interference with patients daily life and still be able to provide long-term

health monitoring services. Achieving this goal is attempted by: flexibility and modularity of the system that makes its presence less noticeable; easy-to-use, intuitive interfaces that are enhancing every day usage of the system; deployment of devices that are well suited for their functions, open and accessible which reduces both development and installation time; usage of modern technologies that allow less devices do more. All of that makes Domestic system as close to provide full care services as close as possible.

Email: paolo.ciampolini@unipr.it

**Abstract**—In this paper, a novel multi-sensor wearable device, called MuSA, is introduced. MuSA aims at integrating in the CARDEA ambient-assisted-living framework: on the one hand, MuSA provides CARDEA with useful ambient-intelligence features, such as localization and identification; on the other hand, it may borrow from the environmental control system many infrastructural and communication components, resulting in a less expensive implementation. MuSA exploits on-board sensors and signal processing units for fall detection, heartbeat and breathing rates detection. At this level too, sharing of part of the circuitry enables power and cost savings. Ubiquitous computing paradigm is followed, carrying out all of the signal processing and decision processes at the wearable node: this makes communication toward supervision levels much less demanding and independent on the actual physical features of the sensors themselves. Test have been carried out, confirming that the low-cost approach which has been followed still allows for adequate quality of responses. Field test is starting, to evaluate psychological and ergonomic aspect as well.

### INTRODUCTION

POPULATION ageing is putting to severe proof current health- and social-care models: the relative number of people experiencing frailty and disability conditions due to old age is increasing, so that conventional caregiving schemes are becoming hardly sustainable. In particular, institutionalization is frequently exploited to provide care to lone elderly. This practice, however, implies high costs (besides potentially threatening quality of life), and cannot be easily scaled to the increasing number of older people needing assistance: hence, home care and home assisted living strategies are an essential component of present and future care policies. Tools based on information and communication technologies may play an enabling role, allowing for the implementation of many assistive functions in the home environment, aimed at autonomy and independent life. To this purpose, basic needs to be accounted for are related to ambient safety and security, as well as personal and health monitoring. In this paper, an integrated approach to such issues is described. The CARDEA system [1] encompasses within the same framework many functions which are customarily carried out by independent entities: CARDEA relies on standard IP

communication techniques (even at the field level) and is inherently based on distributed intelligence techniques. On-board processing is extensively exploited by ambient sensors and wearable sensors, aiming at reducing communication overheads, increasing reliability and reducing costs. An open and flexible architecture is implemented, allowing for reconfigurability and interoperability. Remote access and control of every device is enabled through web-based tools.

In the following section, the CARDEA framework is introduced, emphasizing the adoption of distributed-intelligence ambient control modules. Then, MuSA wearable wireless sensor platform is described. Conclusions and ongoing work are eventually discussed in last section.

### CARDEA

CARDEA[1] is a powerful and versatile Ambient Assisted Living (AAL) system, developed at University of Parma.

Fig. 1 CARDEA system view

The system is inherently based on standard IP communication, and has a hierarchical structure, easily scalable from the single apartment to large residential complexes. An intelligent module, called FEIM (Field Ethernet Interface Module) has been designed and

implemented to cope with a wide variety of sensor devices: FEIM module allows for connecting low-cost sensors, even if not conceived for network connectivity.

FEIM is based on an embedded microcomputer, and can be programmed to control analog and digital multiple field devices (up to 25 per module). Local processing power is also exploited to implement low-level decision strategies (light or appliance control, for instance) or safety-critical tasks (alarm messaging) making them independent on actual availability of network connection. FEIMs communicate among them on a peer-to-peer basis, requiring no external supervision, allowing for establishing operating rules involving different device clusters.

Fig. 2 FEIM module

Also, dynamic reconfiguration is exploited to implement fault-tolerant policies and graceful degradation strategies, by accounting for redundant configurations and module hot-swapping. At a higher hierarchical level, supervisor processes, running on any networked machine, are exploited for the implementation of more complex operating rules and to deal with user's interfaces and external network gateways. CARDEA includes a number of user interfaces, easily accessible and suitable for elderly people and people with disabilities [2]. It also features a web-extension module, which enables full control and monitoring functions from any remote location, by means of dynamic web applications [3].

A wireless sensor network (WSN) contribute to the system architecture as well, dealing with mobile devices. Here, we shall refer to a WSN based on the IEEE-082.15.4 (ZigBee) standard protocol, exploited for the implementation of wearable sensors described in the following.

#### CARDEA-MUSA

Wearable devices are exploited to monitor personal activities and vital signs. They are conceived to provide continuous monitoring, so they need to be small and lightweight, and minimally intrusive. Also, battery power should last as long as possible, this calling for accurate management of the

power budget. Finally, being such devices exploited for security and health purposes, high reliability, as well as ease of use and reconfigurability [4], are mandatory. Of course, inexpensiveness is needed to allow for large-scale deployment.

CARDEA MuSA (MULTi Sensor Assistant) is a wearable multisensor platform, specifically designed with assistive purposes, compliant with ZigBee/IEEE802.15.4 standard protocol. MuSA is designed to be worn at belt or at chest: it is quite small (78x48x20 mm), and lightweight (about 70 grams, Li-Ion battery included). Different functions can be implemented on the same platform: basic configuration of MuSA includes a call button, automatic fall detection and an indoor localization function. The latter function can be exploited in large residential complexes, allowing CARDEA to make caregivers aware of the actual position of a person needing assistance, or to detect wandering behaviors of cognitive-impaired people [5]. CARDEA MuSA can be extended with further functions, hosted by the same hardware platform: a basic ECG system is implemented, used to evaluate heart rate. A breath rate detector is included as well, based on chest expansion measurement. All of the signal acquisition and processing is carried out by MuSA on-board circuitry: detection of abnormal behaviors or deviation of vital signs from their "normal" range is carried out by MuSA. Radio communication is hence kept at a bare minimum (alarm messages and network management), saving battery energy.

MuSA board is based on CC2531 system-on-chip [6] by Texas Instruments. Two basic building blocks can be identified: a IEEE 802.15.4 radio transceiver, and a microcontroller taking care of ZigBee stack management. The same microcontroller is exploited for digital signal processing. The board also include sensors and analog front-end circuitry needed to acquire vital signs.

Fig. 3 MuSA wearable device

MuSA is fully integrated in the CARDEA framework: a network of ZigBee fixed-position nodes is deployed into the environment, and managed by CARDEA. Such nodes exchange information with MuSA mobile devices, and make them available to CARDEA, either by exploiting a FEIM interface channel (i.e., similarly to environmental sensors) or directly at the supervision level, communicating with supervising processes through a TCP/IP socket. Then, all of

the communication features of CARDEA (web-based remote management, phone or SMS messaging, etc.) are straightforwardly available to MuSA, with no need of replicating such features in a stand-alone MuSA base-station.

#### A. Fall-Detection

The fear of falling is a major issue, threatening elderly self-confidence and independence. Falls are one of the first causes of death or serious injury in older adults [7]: the use of automatic fall detection systems could both speed up the assistance of the people in need and give a security feeling to the person using it. Perspectively, behavioral analysis of people's motion (gait quality, for instance, based on the same accelerometric patterns exploited for fall detection) can be exploited for possibly preventing fall conditions.

There are several ways to fall: the fall movement can be quite different, depending heavily on the actual situation. In [8] a fall classification attempt is presented; the author identifies three different kinds of most common falls for an older adult: fall during sleep, from the seated position and from standing up to lying on the floor. Whereas the first two can be somehow monitored by means of bed- or chair-occupancy sensors managed by CARDEA, the last one (also being the most frequent kind) calls for smarter automatic detectors [9]. Fall detectors may exploit artificial vision algorithm, environmental sensors and wearable sensors. Wearable sensors provides a fair trade-off among cost, performance and intrusiveness: the adoption of a wearable device, moreover, also provides CARDEA with identity information, enabling management of personalized settings and behaviors.

At the heart of fall detector, the low-power LIS331DLH [10] triaxial MEMS accelerometer manufactured by ST Microelectronics is used for algorithm implementation.

Basic fall detection algorithms exploit threshold comparison [11]: since falls are often associated to acceleration peaks, current acceleration (the Euclidean norm of the acceleration vector, actually) is checked against a given threshold, which depends on personal physical features (height, weight, ...). However, tuning such a threshold is critical, with respect to false-positive and false-negative conditions: many daily-living activities may result indeed in accelerations comparable with those involved in a fall (stumbling, sitting down or standing up, bending down, ...). Hence, a more reliable detection strategy is needed: to this purpose, MuSA correlates acceleration pattern with postural information. Body orientation can be easily inferred by exploiting further sensors such as gyros or protractors, introducing however additional costs, size and power constraints. We therefore exploited digital signal processing to extract relative orientation information from the same stream of accelerometric data. The MEMS accelerometer, in fact, is subject to the gravity acceleration  $G$ , which can be regarded as a "static" component of the sensed acceleration. Static acceleration can be extracted from the sensor output stream by proper filtering, thus providing a reference that

can be used to calculate the angle shift between subsequent estimations [20].

A differential approach is followed, which makes the algorithm independent on the actual sensor-wearing fashion. Whenever an acceleration peak exceeding the threshold is observed, a comparison between the orientation before and after the peak occurrence is carried out.

The algorithm is illustrated in Fig. 4: acceleration components ( $A_x, A_y, A_z$ ) are acquired from the MEMS every 16 ms. Then, the acceleration norm is computed, and acceleration components are stored for subsequent processing. When the norm exceeds the given threshold, comparison of static accelerations starts, looking for the tilt angle computed just before and after the acceleration peak.

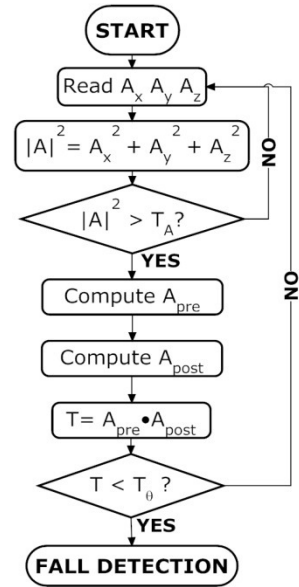

Fig. 4 Fall detection algorithm flowchart

$A_{pre}$  is static acceleration (i.e., steady state) component, averaged on a 1 sec time interval prior to the acceleration trigger, while  $A_{post}$  refers to the same average component, computed after the trigger. Averaging allows for noise reduction, and the dot product between pre- and post-peak average accelerations can be computed:

$$T = A_{pre} \cdot A_{post} = \sum_i A_{pre_i} A_{post_i} \quad (1)$$

Since the intensity of  $A$  in both cases should be equal to  $G$ , the tilt angle  $\theta$  can be readily worked out:

$$T = |A_{pre}| |A_{post}| \cos \theta = G^2 \cos \theta \quad (2)$$

and compared with a suitable threshold, in order to infer an actual fall.

So doing, data coming from a single accelerometer provide both acceleration and (relative) tilt-angle estimate.

The algorithm reliability has been verified through some tests, following the methodology introduced in [12]. We tested MuSA on a set of twelve volunteers (20-30 years old, 51-78 kg weight, 163-192 cm height), who were asked to

simulate different kind of falls from the standing position (backwards to sitting position, backwards to lying position, forward to knees, laterally to right side, laterally to the left side). Then, the volunteers were asked to perform daily living activities, suitable for being mistaken for falls (recovering standing position from previously described falls, sit down on a chair, stand up from a chair, sit down on a stool, stand up from a stool). Every test was repeated five times by each volunteer, summing up to 840 records in the database.

By considering the number of True Positives (TPs) and the number of False Negatives (FNs) we may evaluate the sensor sensitivity, i.e., the ability of recognizing actual falls:

$$\text{Sensitivity} = \frac{TPs}{TPs+FNs} \quad (3)$$

For the given test set, a 99 % sensitivity figure was achieved. Similarly, taking True Negatives (TNs) and False Positives (FPs), we may evaluate sensor effectiveness in discriminating misleading events:

$$\text{Specificity} = \frac{TNs}{TNs+FPs} \quad (4)$$

A 97.8 % specificity figure was estimated on the given set.

The algorithm, although relying on limited computational power available, is hence quite accurate; data processing and interpretation is carried out by MuSA on-board processor, which hence can be seen by CARDEA as a simple binary sensor, signaling falls by means of a Boolean variable.

A low-power operating mode has also been implemented, exploiting LIS331DLH features to reduce MEMS sampling frequencies. In fact, acceleration threshold and orientation can be monitored by the MEMS device itself, relieving the microprocessor from continuously checking the data stream. The CPU is awoken by the accelerometer (through an interrupt line) whenever an over-threshold acceleration is detected. In normal conditions, CPU activity is hence limited to coarse sampling of accelerometer registers (acceleration and orientation). This allows for better exploitation of sleep modes, at the expense of a less detailed recording of motion data: by tuning time intervals, we were able to attain a 50% reduction in the processor power consumption, with a negligible degradation in sensitivity and specificity.

### B. Heartbeat Detection

CARDEA MuSA is also capable of estimating the heartbeat rate. This can be exploited to promptly notify abnormal heart rhythms (i.e., arrhythmias, tachycardia or bradycardia), or, when combined with motion data, to provide a more accurate picture of the energy expenditure. A simple electrocardiogram (ECG) section is exploited to this purpose. Diagnostic systems usually rely on a variable number of body electrodes, placed at specific configuration patterns (leads) [13]: of course, ECG definition and accuracy increases with the number of electrodes and leads acquired,

providing more physiological insight. MuSA, however, aims at continuous monitoring and is not conceived as a diagnostic tool: then, in order to limit sensor intrusiveness and to cope with circuit size and power consumption, we adopted a simple, two-electrode scheme [14], which enables, depending on the actual body placement of electrodes, exploitation of three fundamental Einthoven leads. On-board circuitry include an analog front-end, consisting of an instrumentation amplifier and a low-pass analog filter (106 Hz cutoff frequency). Digital processing is then carried out by the CC2531 CPU: just after first A/D conversion, digital filtering of mains (50 Hz) frequency noise is carried out. Then the input signal is numerically derived, in order to emphasize Q-wave peaks, the frequency of which is subsequently identified by means of a threshold comparator.

Fig. 5 MuSA embedded ECG subsystem

In order to deal with individual diversity, the algorithm thresholds are automatically calibrated, on the basis of the signal acquired in the early monitoring stages.

TABLE I.  
HEARTBEAT RATE ESTIMATION

	Average relative error
Einthoven I lead	4,1955%
Einthoven II lead	2,8221%
Einthoven III lead	2,0008%

The estimated heartbeat rate is then checked against (user-defined) normal range boundaries: should such boundaries be exceeded, an alarm is issued to CARDEA, which, in turn, activates messaging strategies aimed at relatives, medical doctors, neighbors, caregivers, etc., according to the current profile. Since the estimate on moving subject can be quite noisy, the alarm is issued on average estimation. Such an approach is compatible with available computing resources and accurate enough for the given purpose: by computing heartbeat frequency on-board, no ECG tracing needs to be transmitted on the radio-link, thus greatly reducing radio power consumption.

Tests have been conducted on a set of volunteers, under different activity conditions, and exploiting different Einthoven leads: estimated frequencies were then compared with those extracted from a reference instrument. Results are summarized in Table I above, and demonstrate the achievement of fairly reliable detection in all cases.

### C. Breathing Rate Detection

Estimation of breathing rate exploits a piezoelectric sensor (Measurement Specialties LDT0-028K) inserted into the elastic chest strap. The sensor detects variations in the strap strain due to inhaling and exhaling movements, and produce a charge variation at the piezo-polymeric film. The signal is hence acquired through a charge preamplifier, having a narrow, low-frequency bandwidth (0.007 Hz - 16 Hz), so to filter out components due to movements different from breathing.

Fig. 6 MuSA embedded breathing-rate estimation subsystem

Similarly to the ECG section, after a further analog amplification stage, the signal (shown in Fig. 6) is acquired by the TI-CC2531 chip, which looks for amplitude peaks. In this case too, the time-domain sensor signal (an example of which is shown in Fig. 4) does not need to be transmitted to CARDEA: MuSA compares breathing frequencies worked out with the assigned “normal” range, and issues anomaly warnings when needed. By exploiting CARDEA cooperation, careful partition of tasks between the wearable device and the environmental infrastructure was made possible, allowing for effective management of the available power and computational budgets. At the base station side, most functions (alarm dispatching and notifications) can be borrowed from environmental control modules, thus resulting in an inexpensive and versatile device. Moreover,

data coming from MuSA can be correlated with environmental information sources, to increase, through data fusion, the overall reliability of the monitoring system. Finally, sharing the same CARDEA information space, makes MuSA outcomes readily available on the web, thanks to the CARDEA<sub>web</sub> extension.

### CONCLUSIONS AND ONGOING WORK

The concept of multi-sensor, multi-functional wearable platform is being currently expanded, accounting for further functionalities: in particular, MuSA prototypes are being developed including body temperature and microphonic sensors. Body temperature is acquired through a low-cost NTC thermistor, embedded in the chest strap as well. Analog signal treatment is carried out through an instrumentation amplifier (TI-INA330, [6]), whereas digital processing is carried out, as usual, by the CC2531 chip. First tests show that such a low-cost approach still allows for accuracy in the 0.1 °C, which is adequate for long-term monitoring purposes.

Including a microphone will also allow MuSA user to communicate verbally with remote caregivers, when seeking for assistance or in case of fall. Integration with CARDEA avoids the need of accounting for a bi-directional voice-channel: incoming voice message can be managed by the environmental control system, thus not requiring to embed speakers or audio amplifiers into MuSA. A tiny MEMS microphone (Analog Devices ADMP401- 4-5) easily fits the MuSA board. Sampling and digital encoding of the audio stream is carried out by the digital processor, which subsequently send it over the radio link.

CARDEA-MuSA is currently undertaking a field-test campaign, being deployed at some assisted-living facilities already running long-term CARDEA trials [3]. Besides technical performance and reliability, assessed by lab test, this will allow to check its ergonomic and psychological impact on elderly users and on their caregivers, allowing for optimizing the service and to evaluate potential benefit of the adoption of wearable multifunctional devices in actual care policies.

**Abstract**—Monitoring system for detection of person and his/her activity in the bathroom is described in the paper. It also detects and monitors person taking bath. The system consists of sensors measuring humidity, air and water temperature, spilled water, and state of bathtub. The bathtub state detector (BSD) allows controlling water level and its temperature. It also monitors of person’s activity when being in bathtub. It is an essential part of the system. The BSD distinguishes between four cases: 1. the bathtub filled only with water, 2. the bathtub filled with water and occupied by person, 3. the bathtub filled with water and occupied by active (moving) person, and 4. empty bathtub. Presence and activity of the person is recognized by means of multifrequency impedance measurements.

**Keywords:** Bath monitoring, intelligent sensors, bio-impedance

### I. INTRODUCTION

HYGIENE is an important factor that may affects a health status of the human. Regular usage of the bath plays significant role in maintaining good health state and in preserving conditions of life. However, utilization of the bathtub may involve dangerous situations especially for persons living alone. Thus, it is important to monitor a process of the bathroom utilization in the case of the elders.

Tasks realized by such a system may be divided in two categories. First, is to provide a comfortable conditions, e.g. temperature of air and water used while another one is to recognize dangerous situations, including risk of sudden death, especially when temperature of the bath water is too high [6]. Thus, in the study we concentrated on two basic problems. One is a control system of the bathroom environment such as temperature and humidity of the air, water flames on the floor and the water temperature and its level when the bathtub was filling and/or filled. Another problem was to develop a monitoring system for person having a bath. It could be achieved by measuring signals generated by a human body, e.g. electrocardiogram (ECG) or generating and measuring signals which parameters would be affected by the human body. Moreover, the developed system had to be relatively cheap and had to preserve privacy demands. Additionally, the device had to be “invisible” (did not demand any control or adjust) for the person being monitored. Electrical impedance measurements has fulfilled above demands. In order to improve quality of the data a four-electrode technique was examined both theoretically and experimentally.

### II. METHODS

#### A. The system structure

A global structure of the system is based on a star topology. Thus, it is a sensor-actuator network. A central element of the network, called the central system, is a kind of computer equipped with communication interfaces. It receives all the information from the sensors and so called auxiliary systems. It can interact either with the supervised person, or installed actuators (valves, switches etc.) according to the information extracted from the data collected. The central system communicates with the external world by means of alerts broadcasted to relatives, caregivers, supervisors or physicians using different media (e.g. GSM, Internet, etc.). A simplified structure of the system is shown in Fig. 1.

The internal structure, decision rules and performance of the system must be adaptable to different demands. That is why it has a modular structure allowing its reconfiguration. The term “dedicated systems” in Fig. 1 stands for devices performing complete signal processing and taking decision. Thus, it contains an autonomic computation/processing unit. It is also equipped with own set of sensors and actuators.

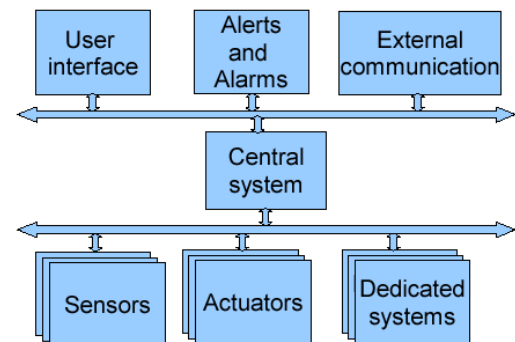

Fig 1: A simplified structure of the monitoring system

The dedicated systems communicate with the central one. These systems govern all resources and also collect data from the sensors directly connected to each and control the actuators.

#### B. Dedicated systems

The dedicated systems controlling events in the bathroom (Fig. 2) are described in the following paragraphs of section. One of them is devoted to control air conditions in the bathroom. Another one is dedicated to detect a presence of the water on a floor. Next one allows controlling of temperature

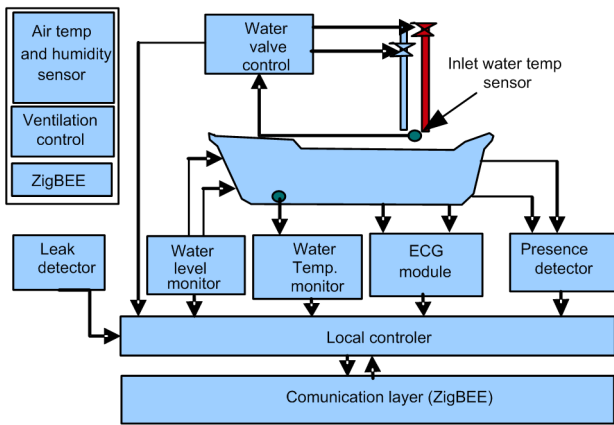

Fig. 2. A block diagram of the bathroom dedicated systems (devices)

and level of the water in a bathtub. And the last one presented in the paper enables detection of human body presence in the bathtub. Together, all of them, together with a central system, form the system for monitoring events and conditions of the bathroom when it is being utilized.

#### i. Air conditions device

The bathroom is a space with specific air conditions. Usually, it is the warmest chamber in a house or in a flat. Moreover, because of using hot and evaporating water, a humidity of the air is higher than in other chambers.

High humidity and temperature of the air, aside being uncomfortable for elders, may create perfect conditions for growing and developing of moulds which in turn, also may be dangerous for the health. Thus this space requires special care in order to maintain the appropriate conditions. Mechanical ventilation is a typical method to keep a proper humidity level. However, it must be controlled as excessive ventilation may lead to significant decrease of temperature in the bathroom. Thus, temperature controller and mechanical ventilation system to maintain low level of the humidity has been designed. It is built around the microcontroller PIC24F equipped with ZigBee module, temperature and humidity sensors (Fig. 3). Basing on measured data appropriate procedure controls the fan performance. It also allows reporting value of humidity and temperature of the air to the central system via ZigBee. Basing on their values adequate efficiency of the ventilation system is adjusted.

In order to achieve compatibility of the ventilation controller with the central system and other devices it has been equipped with ZigBee and the communication protocol [6]. At the moment, the bathroom air-conditions are controlled by means of mechanical ventilation. However, it can be extended to a more sophisticated system by including other actuators (e.g. heating device) or sensors.

#### ii. Water level and temperature monitor

Water filling control module consists of electrically controlled valves for cool and warm water with water temperature measurement and two-level detector (Fig. 4). The valves are controlled by means of the microcontroller (PIC24F16) equipped with sensors. It enables analogue

Fig 3: A block diagram of bathroom conditions controller

temperature measurement and water level detection. Water level is determined by measuring electrical impedance between electrodes. A reference electrode is placed close to the sink-hole and two other electrodes are located at two places indicating a low level and a high level of the water. Output data are transferred to microcontroller and by means of ZigBee module are available for the local controller or the central system.

Similar, the temperature of the water in the bathtub can be measured during process of taking bath. If the temperature will be too low an alert suggesting end of the bath can be raised.

Fig. 4. A block diagram of system controlling the process of bathtub filling with water by measuring its level and temperature

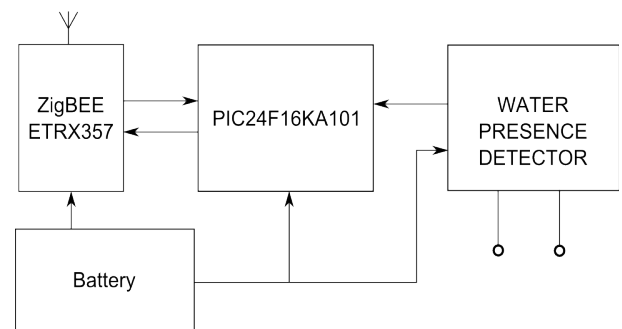

Fig. 5. A block diagram of the leak detector

It is also possible to stop the filling process (using actuators controlled by this system). As the microcontroller is connected to the ZigBee communication module the central system may also control (supervise) temperature of the water in the bathtub. Moreover, it controls the process of

filling the bathtub with water basing on information obtained from the system detecting presence of person in the bathtub. It prevents the water from overflowing the bathtub.

### iii. Water leak detector

Next device already examined is a water leak-detector (Fig. 5). It is a portable and battery-operated device and it detects water presence on the floor. As it is a portable device it may be also utilized in other chambers exposed to water, e.g. kitchen. It consists of a microcontroller (PIC24F16KA101), water presence detector, ZigBee communication module and battery power supply. We have utilized low power microcontroller using advanced sleep modes to maintain long live time of the battery. Thus, we can use single lithium battery (Minmax ER14505M) for a very long period (at least one year).

### iv. Monitoring system of a human body presence in the bathtub

Human body consists of electrically dispersive materials. I.e. its electrical properties, e.g. complex permittivity, depend on frequency of electrical field. The dispersion of electrical permittivity occurs in a few frequency ranges named respectively  $\alpha$ ,  $\beta$ , and  $\gamma$  dispersion. The  $\alpha$ -dispersion appears at relatively low frequency range. On the other hand, water exhibits invariable properties in this frequency range. This suggests a simple method of human presence detection based on electrical impedance measurements. However, there were some problems to be solved before utilizing this technique. Determination of an optimal electrodes position, providing adequate sensitivity of the method independently on body position and localization in the bathtub, was one of them. A Finite Element Method was used for performing simulations. It allowed selecting adequate shape, size and localization of electrodes in the bathtub. An example of 2D model is presented in Fig. 6. As a result a four-electrode technique was selected for experiments. Thus, also the developed measuring system utilized a four electrode technique (Fig. 7). It was built around the AD5933 integrated circuit devoted to measuring impedance.

Fig. 6. Sensitivity plot for the selected geometry

However, originally this integrated circuit utilized a two electrode technique. The two-electrode technique is very susceptible to electrode impedance arising from polarization phenomenon. Thus it was necessary to equip the AD5933 with additional circuits (converter V/I, instrumentation amplifier and high-pass filters see Fig. 7) what allowing its utilization in four-electrode technique. The circuit performing

Fig 7. Block diagram of patient detection module enhanced with ECG measurement unit

measurements of electrical impedance was enhanced with unit devoted to electrocardiographic signal measurements. Since the person taking the bath is immersed in the water almost all the time it is possible to measure ECG signals of the person. In typical application signal is processed and only HR parameter is reported to the central system. However, in case of arrhythmia or other situations recognized as dangerous, collected ECG waveforms can be transferred for further analysis. We decided to attach the measuring electrodes at the both sides of the bathtub while the reference one was put at the bottom of the bathtub. They were combined with a bath-tub carpet. It simplified system service and allowed removing of the carpet for cleaning or exchange. In such way almost any bathtub may be adopted for such measurements. At first stage of the study a separate set of electrodes was used for both types of measurements, i.e. electrocardiographic and impedance. However, it was assumed that the final solution would utilize the same set of electrodes for measuring simultaneously both signals. Up to now, we have achieved results from separate electrode matrices. To perform experimental tests we have used a FriendlyARM mini2440 embedded board.

Fig 8. Prototype of the impedance measuring circuit with the host embedded computer

It consisted of main board with CPU S3C2440A, ARM920T (Samsung) with 64MB of 32-bit SRAM, Solid State 256MB NAND Flash hard disk. Additionally board was equipped with 640x480px graphic display and resistive touch-screen. The board was working under GNU/Linux operating system. Therefore using of IIC bus was native. We utilized a custom board with the AD5933 circuit (Analog Devices) and the developed analogue front-end (See Fig. 8). An application for communication to the AD5933 impedance

analyzer has been created. Additionally a graphic front-end using the QT libraries has been created in order to communicate with the application and to present the results.

A reliability of ECG measurement would be affected by many factors. At first we needed to know if the person is in the water. As it was already mentioned, detection of the person presence in the bathtub was done by the electrical impedance measurements. The impedance spectroscopy measurements were performed for a set of selected frequencies (200 Hz – 100 kHz).

### III. RESULTS

#### A. Theoretical model

The Finite Element model of the bath and electrodes was simulated using Matlab package. At first we have calculated spatial sensitivity distribution. Values of the sensitivity shown in Fig. 9 are both positive and negative. Thus, it is necessary to answer if, and how it will affect the

Fig. 9. Sensitivity plot for the selected geometry

measurements. A different localization of human body in respect to position of electrode matrix has been simulated. A dispersive property of human body has been assumed. In general, the model of the dispersive object immersed in non-dispersive media (tap water) has been examined assuming different localization of the object. In such case the dependence of impedance on frequency takes form of semicircle (Fig. 10). Position of the center and the radius of the semicircle depend on distance between the body and surface of the electrode matrix.

The bigger is the distance the smaller radius of impedance plot and in fact the lower value of impedance. This may be explained by the fact that increasing the distance between the body and the matrix of electrodes reduces amount of measurement current flowing through the body. Thus, the body impedance is paralleled by impedance of water. The higher volume of water localized between the body and electrodes the smaller value of impedance. It appears that the impedance of bathtub filled only with water for low frequency, was lower than that of the body.

Increasing volume of the body in comparison to volume of the water leads to wider dispersion (Fig. 11). In this experiment the distance between the electrodes and the body remained constant. The volume of the body was being increased by expanding it laterally and toward upper limits of the model.

Fig. 10. Influence of the height of the dispersive object above electrode level on spectroscopic measurement (result of simulations)

Fig. 11. Influence of the size of the object on the measured impedance values

It was achieved by substitution of water by body tissue in the model.

#### B. Phantom measurements

We have also performed experiments with a body immersed in the bathtub. Measurements have been performed using a developed model of the measurement system. Before attempting measurements in the bathtub a phantom studies were performed. We used a plastic tank filled with ordinary tap water. At the bottom of the tank a set of Ag electrodes was placed. After calibration we have immersed different objects (hand, leg, etc.) into tank and performed measurements with frequency range 200 Hz to 100 kHz.

Data have been collected using specially developed software (Fig. 12). Results of such measurements are presented in Figs. 13 and 14. However, when immersing the hand or leg in the tank led to quite big current leaks to surroundings at high frequency. So, we decided to reduce the range of current frequency to 80 kHz. It also resulted from low accuracy of measurement system for higher range of frequency. Nevertheless, a character of the measured impedance plot is similar to that obtained from simulation study.

Another presentation of impedance data is shown in Fig. 14. The curves were obtained for the following conditions: f1 – small part of biological tissue around electrodes, w1, w2 – bathtub filled only with water, b1, b2 – the human body directly on electrode matrix, b3 – the human body at distance (a few centimeters) from the electrode matrix.

Finally, measurement of ECG was performed with person sitting in the bathtub filled with a tap water. A three

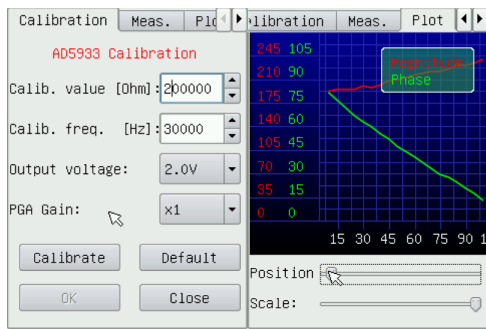

Fig. 12. An example of screen-shot from the embedded application

Fig 13. Real measurements of the measured impedance over frequency range from 200 Hz to 80 kHz: b – body directly on electrodes, b1 – body about 1cm above electrodes, w – water only.

Fig 14. Dependence of impedance modulus and phase on frequency (details in the text)

electrode technique was employed. The result of measurement is presented in Figs. 15 and 16. Impedance was

measured only for one frequency of current equal to 10 kHz.

It appeared that person sitting on electrodes used for measuring impedance drastically increased its value

Fig. 15. Impedance measured at 10 kHz and ECG using separate matrices of electrodes

Fig. 16. Example of the ECG recording

in comparison to that obtained from theoretical studies by means of FEM method. However, the measured value was smaller, as expected, than that obtained in phantom studies. It was mainly due to much bigger object (bathtub vs. tank). As it is seen in Fig. 15 the recorded ECG contains a large component of very low frequency. Also, power frequency interference is very high. However, it is possible to monitor heart rate as QRS waveform is easily distinguished from other components of the signal.

#### IV. DISCUSSION

Home automation and so called intelligent buildings are regarded as an expensive toy for rich society. This is caused by cost of such installations. However, some parts of such installation becoming installed, besides the price – for example alarm systems. Similarly when considering protection and safety of elders some installations can be regarded as affordable. We are presenting such example of intelligent supervision of the bath.

Quality of the signals obtained during experiments suggests that further improvement has to be done yet. Nevertheless, it is shown that it is possible to detect the presence of the person in the bathtub and moreover it is possible to evaluate heart rate of that person. Thus, dangerous situations may be recognized, e.g. arrhythmia, additional excitations, etc.

This information is sent to caregiver and appropriate decision has to be taken.

However, to make the system a more reliable (to reduce a number of possible false alarms) another form (additional) of monitoring person's state when taking a bath is also considered.

#### V. CONCLUSIONS

We have showed that it is possible to detect presence of the person in the bathtub and to measure heart rate. However, quality of the recorded signals still has to be improved. Additionally it is possible to estimate person's activity by means of the impedance spectroscopy.

When the impedance measurements are stable it is possible to record ECG signal properly. Usage of readily available embedded platform reduces cost of development and reduces time of development. Additionally, popular operating system with well documented libraries allows easy development of modern applications.

**Abstract**—During the last thirty years low-coherence measurement methods have gained popularity because of their unique advantages. Low-coherence interferometry, low-coherence reflectometry and low-coherence optical tomography offer resolution and dynamic range of measurement at the range of classical optical techniques. Moreover, they enable measurements of the absolute value of the optical path differences, which is still an unsolved problem in high-coherence interferometry. Furthermore, the use of the spectral signal processing makes this method immune for any change of the optical system transmission.

In this article the low-coherence method of a hematocrit measurement has been presented. Elaborated measurement method has many advantages: relatively simple configuration, potentially low cost and high resolution. Investigation of this method confirms its ability to determine the hematocrit value with appropriate measurement accuracy. Furthermore, results of experimental works have shown that the application of the fiberoptic low-coherent interferometry can become an effective base of method of the *in-vivo* hematocrit measurement in the future.

### I. INTRODUCTION

BLOOD analysis is frequently performed for medical diagnosis. One of the important analytes is the blood hematocrit (HCT), defined as the ratio of packed red blood cells volume to whole blood volume. The normal ranges of the hematocrit are 39-50% for male and 35-45% for female respectively. The high level of the hematocrit indicates risk factors for heart and cerebral infarction due to hemoconcentration. Dehydration or cerebral can be also origins of the HCT high level. Therefore, the hematocrit value as well as blood pressure should be controlled during the daily life as the indices of various physiological conditions in order to reduce the cardiovascular disease risk factor. It should be noted that the continuous monitoring of the HCT is also needed to perform appropriate dialysis and blood infusion.

The blood hematocrit is routinely determined in the clinic by analysis of blood samples. There are several methods of measurement of the HCT and hemoglobin. Unfortunately, almost all of them require either blood sampling or catheterization. Repeatable blood sampling during continuous monitoring of the hematocrit value is associated with an increasing

risk of infection (e.g. HIV or hepatitis). Moreover, such way of examination and loss of even small volume of blood required for the HCT measurement can be harmful to the patients (especially for neonates, small children and old people). Therefore, there is a need of non-invasive method of the hematocrit measurement, because recently used methods are based on the *in-vitro* measurement.

There is a great interest in optical measurement that would permit simultaneous analysis of multiple components (analytes) in whole blood without the need for conventional sample processing, such as centrifuging and adding reagents. There are few optical methods of the hematocrit measurement. Schmitt et al. [1] uses the dual-wavelength near IR-photoplethysmography. Intensity sensitivity detector working with dual wavelength has been described by Oshima et al. [2]. Xu et al. applied optical coherence tomography for investigating the HCT value [3]. Enejder et al. [4] used Raman spectroscopy and partial least squares (PLS) data analysis for simultaneous measurement of concentrations of multiple analytes in whole blood, including the hematocrit and hemoglobin. There are also works in which authors tried to find correlation between oxygen saturation of whole blood and hematocrit value [5, 6]. However, all of them investigated the HCT value *in-vitro* by using sample of blood. Recently, only one method of non-invasive hematocrit measurement by the use of spectral domain low coherence interferometry has been demonstrated by Iftimia et al. [7]. Unfortunately, until now it is possible to make such a measurement only insight the eye, which is uncomfortable for the patient and difficult because of the eye movement. The light beam interrogating the eye must be stabilized on a fixed location on a specific retinal vessel to collect reproducible depth-reflectivity profiles in the blood. This is possible only by employing the eye motion stabilization technique. The eye motion stabilization can generally be accomplished invasively with suction cups or retrobulbar injections, inaccurately with fixation, more precisely at slower speeds with a passive image processing approach, or at high speeds with active tracking. Fixation requires patient cooperation and is difficult in patients with poor vision. Therefore, at the present state of art *in-vivo* measurement of the HCT is more complex and expensive than laboratory analysis of collected blood samples.

The purpose of our study is to develop an accurate and stable low-coherence optical hematocrit measurement

This work was supported by the European Regional Development Fund in frame of the project: UDA-POIG.01.03.01-22-139/09-02 -“Home assistance for elders and disabled – DOMESTIC”, Innovative Economy 2007-2013, National Cohesion Strategy.

method. The preliminary stage of research, which is subject of this paper, includes analysis and selection of sufficient configuration of the low-coherence system for the HCT determination, setting up the low-coherence measurement system and *in-vitro* confirmation whether proposed method has sufficient accuracy to be the base of system which, if manufactured successfully, could have impact to development of the systems for *in-vivo* monitoring of the hematocrit.

## II. LOW-COHERENCE MEASUREMENT METHOD

The low-coherence interferometric measurement system consists of a broadband source, a sensing interferometer and an optical processor (see Fig. 1).

Fig. 1. Basic low-coherence interferometry setup.

The light from the broadband source is transmitted to the sensing interferometer by the coupler and a fiber optic link. At the sensing interferometer the amplitude of light is divided into two components and an optical path difference (OPD), which depends on the instantaneous value of the measurand (mainly its dimension or refractive index), is introduced between them. The sensing interferometer is designed in such a way that a defined relationship exists between the optical path difference and the measurand. The signal from the sensing interferometer is transmitted back by the fiber to the optical processor. The optical processor consists of a second optical system, the output of which is a function of OPD generated at the sensing interferometer. The sensing interferometer is located inside the measurand field whilst the optical processor is placed in a controlled environment far from the field. The optical processor is either a second interferometer (when the phase processing of the measured signal is used) or a spectrometer (when the spectral processing of the measured signal is used). The measurement system with the phase processing of the measured signal has very high measurement sensitivity and resolution, much higher than that of the system with spectral processing. However, the system with spectral processing of the measured signal has two important advantages. It does not need movable mechanical elements for precise adjustment as well as it is immune to any change of the optical system transmission. This is possible because in such a system the information about the measurand is encoded in the spectra of the measurement signal. Optical intensity at the output of such an interferometer can be expressed as [10]:

$$I_{out} = \langle EE^* \rangle \quad (1)$$

where:  $E = E_1 + E_2$ ,  $E_1$  and  $E_2$  – amplitudes of the electric vector of the light wave reflected from the first and the

second reflective surfaces inside the sensing interferometer respectively; brackets  $\langle \rangle$  denote time averages, asterisk \* denote the complex conjugation.

When the spectral signal processing is used, the recorded signal can be expressed as [11]:

$$I_{out}(\nu) = S(\nu) \left[ 1 + V_0 \cos(\Delta\phi(\nu)) \right] \quad (2)$$

where:  $S(\nu)$  – spectral distribution of the light source;  $V_0$  – visibility of the measured signal,  $\Delta\phi(\nu)$  – the phase difference between interfering beams.

The phase difference between interfering beams can be calculated from a following equation [8]:

$$\phi(\nu) = \frac{2\pi \nu \delta}{c} \quad (3)$$

where:  $\delta$  – optical path difference,  $c$  – velocity of the light in vacuum.

If the light source exhibits a Gaussian spectrum, the normalized spectra pattern is predicted to be a cosine function modified by the Gaussian visibility profile. In the spectral domain signal processing the modulation frequency of the measurement signal gives information about the measurand (Equation (2)), as shown in Fig. 2.

Fig. 2. Calculated measured signal from interferometer with spectral signal processing for different phase differences between interfering beams. ( $\Delta\phi$  – phase difference).

It can be noted that for  $\Delta\phi = 0$  there is no spectral modulation. If the phase difference between the interfering beams varies from zero, the function takes the form of the cosine curve. The spacing of adjacent transmission peaks is proportional to the inverse of the optical path difference ( $1/\delta$ ) [12].

In this processing, it is necessary to use special measurement equipment and advanced mathematical processing of the measurement signal. However, as it was mentioned earlier, low-coherence measurement system based on the spectral signal processing has significant advantages – there is no need of precise mechanical scanning and no need of use of movable adjusting components. Moreover, the system using the spectral signal processing and Fabry-Perot sensing interferometer is not sensitive for any change of a transmission of the optical system. This is possible because in the system information about the measurand is encoded in the spectra of the measured signal. Therefore such a setup is the most convenient for the low-coherence hematocrit measurement.

### III. EXPERIMENTAL

#### A. Measurement setup

The scheme of the developed low-coherence fiber-optic set-up for hematocrit measurement is shown in Fig.3. The optical spectrum analyzer (Ando AQ6319 or Anritsu MS9740A) was implemented as the optical processor. The superluminescent diode with Gaussian spectral intensity distribution was used as a low-coherence source. The optimal choice of optical source parameters is a very important problem in low-coherence measurement system because they affect the metrological parameters of such a system. Therefore, not only the central wavelength ( $\lambda$ ) and optical spectral bandwidth full width at half maximum ( $\Delta\lambda$ ), but the shape of spectral characteristic as well, should be selected very carefully. In presented research work the selection of optical parameters of the source was made to increase visibility of the measured signal. During laboratory tests conducted for a few sources having different parameters, the best results were obtained for superluminescent diode Superlum Broadlighter S1300-G-I-20 having following optical parameters:  $\lambda_0 = 1290$  nm,  $\Delta\lambda = 50$  nm.

Fig. 3. The experimental setup.

As a sensing interferometer authors implemented a low-finesse fiber-optic Fabry-Perot interferometer, shown in Fig. 4. The theoretical investigation had shown that the use of a single mode optical fiber would be the most convenient. Hence, the Fabry-Perot interferometer was built using the standard single mode telecommunication optical fibers, a fiber coupler, the measurand field and a mirror. The interferometer consists of optic-fiber with uncoated end, which has a reflectance of 0.04. The second reflectance surface is made by the silver mirror with reflectance of 0.99. This configuration provided high visibility value of measured signal.

When the measurand field is filled by the investigated liquid, the reflective surfaces of the Fabry-Perot are made by two boundaries: fiber/liquid and liquid/mirror respectively. In such a setup each change of refractive index of the investigated liquid results in change of the optical path difference of interfering beams and the phase difference of those beams due to Equations 2 and 3.

#### B. Object of investigation

In order to find out whether proposed method has sufficient accuracy to be base of system for *in-vivo* monitoring of the hematocrit in the future, serie of *in-vitro* measurements

Fig. 4. The experimental setup.

was carried out. During experimental work authors used the whole human blood for tests. Set of 2 ml blood samples with various hematocrit levels were provided by the Gdansk Blood Donor Centre. Such approach has significant advantage, because we were able to use wide representative group of volunteers. It should be noted that samples were get from rather healthy volunteers and therefore our measurement range of the hematocrit measurement was limited to the value of 30 to 50%. However, this range was wide enough to find out the relationship between the HCT and measured optical signal and if resolution of the measurement is sufficient, as well. At this stage we were not measuring blood samples having very extreme HCT values which refers to very sick patients. This will be the object of the future research work. Detailed information the HCT distribution in investigated samples is given in Table 1.

HCT range	Number of samples
32,2 ÷ 33,8	12
34,0 ÷ 35,8	9
36,1 ÷ 37,9	12
38,0 ÷ 39,8	10
40,0 ÷ 41,5	13
42,1 ÷ 43,9	14
44,1 ÷ 45,8	19
46,2 ÷ 47,6	6
48,0 ÷ 49,0	4

Moreover, the hematocrit level of each blood sample was obtained by clinical diagnostics with accuracy  $\pm 0.1$  at the Gdansk Blood Donor Centre as reference measurements, as well. Our investigation, as well as clinically research, showed that obtained HCT level of blood probes were stabled for 72 hours. During all part of our measurement

process the temperature of blood probes were restricted controlled.

#### IV. RESULTS AND DISCUSSION

With the use of elaborated low-coherence system with Fabry-Perot interferometer, the hematocrit value of numerous blood sample was measured. Experimental investigation gave a series of recorded spectra. In Fig. 5 measured reference signal from sensor without any liquid is presented. Measured signals of the blood sample with  $HCT = 35.2\%$  and with  $HCT = 49.2\%$  are shown in Fig. 6a and 6b respectively.

Fig. 5. The reference signal.

a)

b)

Fig. 6. Measured signal of the blood sample with a)  $HCT=35.2\%$ , b)  $HCT=49.2\%$ .

It should be noted (Fig.5, Fig.6) that by the use a dedicated sensing interferometer, designed in our laboratory, it was possible to get visibility of the measured signal  $V=0.98$ , which is really hard to achieve in really optoelectronic low-coherence system.

As there are shown in Fig. 6a and 6b, the change of the hematocrit value changes the refractive index of the blood sample and optical path difference between interfering beams as well. It occurs in phase changes (Equation 2 and 3) and can be detected by the analysis of the measured signal modulation or by counting number of fringes in the measured signal. The change in the number of fringes in the measured signal due to HCT level is shown in Fig. 7. Additionally, the deviation of the number fringes during HCT level measurement is presented in Fig. 8

Fig. 7. Number of fringes in the spectra of measured signal vs. HCT level.

Fig.8. Number of fringes in the spectra of measured signal vs. HCT level.

Mathematical processing of the measured signals provided information about measurand from the spectrum of signal is shown in Fig. 9.

The result of experimental works shows, that can be seen in Fig. 7, that low-coherence method of hematocrit measurement with Fabry-Perot interferometer configuration has proper accuracy to measure the hematocrit value. The method was elaborated in the HCT range extending from 30% to 50%. The output signal was analysed by measurement the change of fringe numbers of the spectra pattern. The change of the number of fringes of investigated spectral pattern equal to 8 was achieved in investigated range, thus obtained sensitivity of the hematocrit measurement can be

Fig. 9. Experimental results - change of number of signal spectra fringes vs. hematocrit value: dots – measured value, dash line – regression line. ( $R^2$  - determination coefficient of statistical model of HCT vs. number of fringes relationship)

estimated as 0.4 [a.u./%]. Time required for single measurement was in range of 0.8-1.2 s. Experimental configuration had very high the value of visibility of the measured signal (usually 0.98), what always leads to decrease of the value of signal-to-noise ratio of the measured signal. Furthermore, it had very high determination coefficient of statistical model of HCT vs. number of fringes relationship ( $R^2=0.978$ ) as well.

## V. CONCLUSIONS

In this paper the low-coherence method of the hematocrit measurement with spectral signal processing has been presented. Elaborated measurement system which used this method has numerous advantages: relatively simple configuration, potentially low cost, high resolution, dielectric construction. Furthermore, it had optical sensor head (Fabry-Perot interferometer) of small size and very low thermal inertia. What is more important, by utilizing spectral signal processing those sensors exhibit immunity of any changes of optical transmission in measurement system.

The results of experimental works showed that implemented experimental set-up provided good quality of the measured optical signals by offering great value of visibility of the measured signal, exhibits immunity for changes of the optical signal polarization and got simple configuration.

The investigation of this method confirms its ability for the hematocrit control with appropriate measurement accuracy. The presented preliminary results can be the base for building sensor ready for practical applications and in the opinion of authors it will be possible to build the low-coherence optical *in-vivo* hematocrit sensor in the future. In the further stage of the research, developed system will be applied for the *in-vivo* measurements carried out through the skin. The best place on the human body for measurement as well as method of preparation patient skin surface will be determined. As during the *in-vivo* measurements results would be probably influenced not only by refractive index of the blood but also by change of Fabry-Perot cavity dimensions caused by a human pulse, we predict that phase-sensitive detection synchronised with the human pulse should be applied.

**Abstract**—Health monitoring at home could be an important element of care and support environment for older people. Diversity of diseases and different needs of users require universal design of a home platform. We present our work on a sensor-based multimodal platform that is trained to recognize the activities elderly person on their home. Two specific problems were investigated: configuration and functionality of central workstation as a module for data acquisition and analysis and second problem is devoted to user’s home environment monitoring.

## I. INTRODUCTION

HEALTH personalization and support for older and immobilized people is actually very important target of many national and international initiatives (e.g. Framework Program 7, Hong Kong “Care for the Elderly 2007 - Active Mind”). Different research areas are connected with those initiatives including “Wearable Sensors (WS)” [1], “Body Area Sensors (BAS)” [2], “Wireless Sensor Networks (WSN)” [3] and telemedicine methods [4]. As a result of this research different sensors and integrated solutions were proposed, usually dedicated for a particular goal. Designing a home platform for support of older or immobilized people different categories of existing and possible components should be considered from particular sensors to central computer stations.

In case of systems with integrated sensors many solutions were proposed like Crossbow IRIS [5], Sun SPOT [6], eWatch [7], Smart-Its [8] or other [9]. Many motes are currently under constructions, however they are usually equipped with embedded sensors (e.g. temperature, light, and location), expending slots (e.g. sandwich model) and communication modules (Bluetooth or based on IEEE 802.15). Dedicated, medical extensions are often proposed like results of CodeBlue project [10], MobiHealth project [11] or UbiMon (Ubiquitous Monitoring Environment for Wearable and Implantable Sensors) project [12]. Typical so-

lutions used for such extensions (or standalone systems) are universal medical diagnostic devices, including ECG, pulse oxymeter, blood pressure/pulse monitors, etc.

Communication interfaces allow data acquisition (especially at home) from motes to a one central station (or a middleware). The central station may be used to process data to assess user state based on many parameters and inform a user relatives or healthcare professional (a nurse, general practitioner) about the patient condition. The central station is often required to limit data processing at sensor node and to build an integrated view on the patient (including ontology based context models [13]).

Recent advances in sensor technology, cellular networks and information technology allow to improve the well-being of the elderly by assisting them in their everyday activities, monitoring their health status and environment conditions. There is more and more projects concerning the “smart” or “intelligent” homes with prototyping information-sensor systems recognizing habitant activities and abnormalities of them [14][15][16][17]. It is possible to develop systems that recognize an individual’s everyday activities and automatically detect changes in the behavioral patterns of people at home that indicate declining health [18].

Human-computer interface (HCI) for older citizens or immobilized people/patients is also very important aspect of the home-based system. Specially designed user-interfaces and interaction devices are often required.

The main goal of this paper is to present a design of the multimodal, integrated platform for communication, training and health and environment monitoring at home. Communication includes technical and functional methods of a user communication with his/her environment as well as processing of alerts from a home/user sensor network. The training is mainly related to promote mental activity of a group of patients in danger (e.g. patients with dementia). Home monitoring is devoted to collect patient-related data and home environment data (e.g. fire detection). The very important aspect of the presented platform, is designing of a central computer station to collect data, process events/alerts, supply a proper human-computer interface, etc. In section II

This work was partly supported by European Regional Development Fund concerning the project: UDA-POIG.01.03.01-22-139/09-00 -“Home assistance for elders and disabled – DOMESTIC”, Innovative Economy 2007-2013, National Cohesion Strategy.

and III the design of the proposed system is presented. Next results of first module implementations are shown, including human-computer interface for immobilized patient and a module for home environment monitoring.

## II. PLATFORM STRUCTURE

The aim of our work is to create a smart system that will be adaptable to individuals, will be able to recognize their activities and will help their well being by raising alarms when a potential departure from routine or desirable behavior is detected (for example, the individual did not eat lunch or appears to not take their medication at prescribed times).

Home monitoring of people/patients is a wide term and different applications are possible. Some users are highly immobilized (only basic head/eyes communications) others are free to move but suffer dementia. The platform design requires creating a multi-modular system. The most important features of the platform are human-computer interface (or human-platform interface), middleware (e.g. used for data processing) and sensor/communication nodes.

### A. Central Workstation

The role of central workstation combines the middleware functionality and HCI (described later). The following functionalities are requested from the central workstation:

- database management,
- sensor data collection and processing,
- events dispatching and processing (e.g. “take a pill” and “no activity alarm”),
- data integration, classification, rules induction and other activity related to create overall person/patient model including his/her environment,
- communication management (e.g. which interface should be used to send a particular message),
- access control and support for other security mechanisms,
- support for mental training (actually discussed with psychologists/neurologists),
- Human Computer Interface.

TV-set connected to personal computer can be used as central workstation – Fig. 1. Of course it is possible to use standard computer monitor or touchable monitors.

The human-computer interface is one of the most important elements of the platform. The user acceptance of the entire system depends highly on the method how the system can be used by older/immobilized users. Three elementary modes of the HCI were designed:

- interface based on touch screen,
- visually guided interface,
- audio guided interface.

All interfaces require a new design of the graphical user interface. This includes to prepare a platform front end (with selection of services divided into three groups: emergency,

medical, and personal activity), GUI of each service and virtual devices (e.g. keyboard, remote control).

Fig. 1 TV set as a Central Workstation – example of Graphic User Interface also portable tablet with proper software is presented

Visually guided interface is especially designed for this category of patients, which are unable to move. Even in this group there are different subcategories that should be taken into account (patient can use only eyes; patient can move his/her head; patient can move head and a hand, etc.).

We assumed that the platform should also use existing internet services, however, redesigned for the older/immobilized people.

The General Purpose Input Output (GPIO) interface was used to connect different sensors for user’s home environment monitoring. Currently, a thermistor-based temperature measurement sensor and an optoelectronic-based movement detector, water leakage and current load detectors were implemented. Humidity, fire and gas detectors are under construction.

The Siemens TC65T module was used as a main controller for home environment monitoring multi-sensor. The module combines GPIO and GSM communication interface. Using Java 2 Micro Edition a set of Midlets was prepared to process GPIO events and communicate with the environment. The module is used as one of the external communication interfaces. Communication between sensors and central station is realized using ZigBEE standard.

The central workstation was build using Java 2 Enterprise Edition, Apache Web server and MySQL database management system. Events from the sensor modules are stored in MySQL tables and can be processed and visualized using dynamically constructed web page. The external access to information services is limited by access lists and is secured by SSL. Additionally, a set of J2ME Midlets was prepared for mobile phones to remotely manage the selected sensor module. Midlets allow to set alarm limits (e.g. smallest and highest acceptable temperatures) which are used to decide about alert generation to a privileged user (e.g. relative, guardian). The module accepts also SMS requests (from the configurable phone numbers) for sending current status data (request-response model).

Fig. 2 Floor plan with sensor placement

### B. Sensors

To allow digital devices to be treated as ‘everyday stuff’ we need to open up access to the supporting infrastructure that connects devices and provide users with a simple model that allows them to manage the introduction and arrangement of new interactive devices.

Multimodal platform will use different sensors (or multi sensors) to collect information about person/patient state and his/her environment. Different categories of sensors are currently prepared to measure: heart pulse, temperature, body composition parameters (weight, fat content, etc.), glucose concentration, blood pressure, electric heart activity (ECG), and posture activity (accelerometer). Additionally special multi-sensors are considered to design for a particular group of patients (disease-oriented). Placement of sensors is shown on Fig.2. Appropriate database structure is designed to collect information from each sensor. The one-to-many relationship is used between mother table (directory of sensors) and sensor tables. Each sensor has its own data table (tables). Particular data event is marked using timestamp so it is easy to analyze a set of measurements from many sensors during given period of time. The platform can be easily scaled with a new sensor (multisensory) using plug-in methodology (common interface, XML configuration file, a new data table).

Another group of sensors consists of those related to monitor user environment parameters. This is especially important for older people deciding to live alone without

permanent, personal help. Taking into account the privacy of those persons, different sensors can be required to observe fire and gas dangers, humidity/temperature conditions at home activity of the person, emergency calls (e.g. symptoms of heart attack, ischemia, etc.).

### III. SENSORS CONFIGURATION

An exemplary flat plan is shown on Fig.2. Living spaces is consisting of two bedrooms, two bathrooms, kitchen, living room and laundry/utility room. In addition, there will be a shared basement with a home entertainment area with centralized computing services. Different wireless sensors are placed in the habitation area – indicated green on the Fig.2. There are:

- CM – current load meter and switch,
- IB – intelligent bed, with medical diagnostic devices,
- LD – light detector,
- MD – movement detector, sensors that can detect movement over whole flat (indicated blue line),
- TD – room temperature detector,
- TFD – temperature and fire detector,
- UD – urine detector,
- WG – weight meter,
- WL – water leak detector,
- WM – water meter.

Entertainment/main station devices used for acquire and analyze sensors data and for personal rehabilitation and activate purposes:

- TV set – which can be also a central station of the multimodal platform controlled by special designed remote control,

- PC – personal computer – and also central station of the multimodal platform.

System will include human position tracking through ultrasonic sensors or RF technology.

Activities in a smart environment include physical activities as well as interactions (with objects) can be monitored. For example, activities may include walking, resting on a couch and using the coffee machine, refrigerator, etc. An important rule is that these activities are not instantaneous, but have distinct start and end times. In addition, well-defined time relations exist between the events constituting an activity. These temporal relations are important in the determination of the monitored user's indoor activities and can be used for knowledge and pattern discovery in day-to-day activities.

#### A. Current consumption measurement

Electrical current consumption monitoring can be achieved by means of monitoring of the AC current drawn by the load. This can be achieved assuming that the amplitude of the power network voltage is constant during measurement period. This simplifies significantly measuring circuit. AC current is monitored by means of the current transformer. Current induced in the transformer is converted into voltage, amplified and rectified. This signal is converted to constant value by means of filtration. Voltage that is proportional to amplitude of the current can be directly measured but instead it is integrated and value of the signal is measured with specified and constant acquisition period. This allows to detect even very short current peaks. Results of measurement is stored in internal memory of the microcontroller and transmitted to central system by means of the ZigBEE network. However, we have designed and developed two different power meters. One that is working on a simple principle of AC current monitoring and second more precise – that utilizes readily available integrated circuit (ADE7753 from Analog Devices) for power consumption measurement. The block diagram of first circuit is shown on Fig. 3.

Fig. 3 Energy meter 1 block diagram

The circuit is detecting AC current by means of the current transformer. Signal is then amplified, rectified and filtered by means of low-pass filter. DC value of voltage is then equivalent to the momentary current drawn by the load – and assuming constant amplitude of the AC voltage – to the power delivered to the load. Momentary values are then integrated to avoid losing of the short power peaks that might occur. After read-out, the integrator is zeroed and is scoring the energy until the next read-out. Cyclic read-outs are collected and transmitted to the host system by means of the wireless connection using the ZigBEE standard.

Another project utilizes the integrated power meter. The idea of operation is very similar, but now we can measure energy more accurately. The simplified block diagram of the circuit is shown on Fig. 4a) where the photograph of the prototype is shown on Fig. 4b).

Fig. 4 Energy meter 2 a) block diagram; b) the prototype

#### B. Intelligent wall-socket

We also have developed the electronic circuit for electric wall socket - Fig. 5. The main task of the circuit is detection of the electrical current flowing to the load and possibility of remote power off of the socket e.g. in the case that supervised person leave the place leaving e.g. iron switched on. The power consumption is measured also by means of the current monitoring. The power delivery is controlled by means of triac with zero-crossing switch on ability. The communication with the system is also realized by means of ZigBEE

#### C. Intelligent wall-switch

Intelligent wall-switch (Fig. 6) circuit was developed to support classical wall-switch by option of the light measurement and detection of the switch state. Information about current state of the switch and ambient light intensity

is available by means of the ZigBEE communication standard.

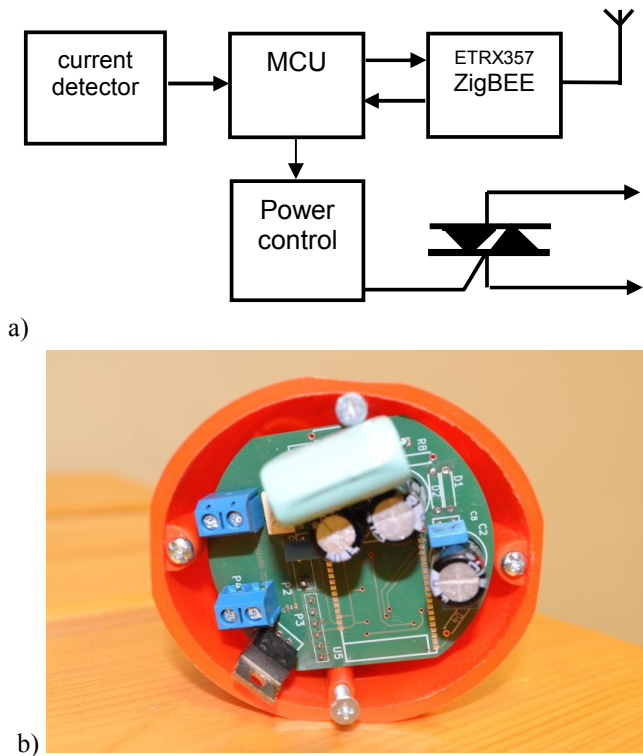

Fig. 5 Wall socket module a) block diagram; b) the prototype – CM (current meter)

Additionally it is possible to detect, whether the ambient light comes from (AC power supply or daylight).

Fig. 6 An intelligent wall switch a) block diagram; b) the prototype

#### D. Water consumption measurement

We have developed two different water measurement meters working based on two different principles. First circuit is scoring pulses from mechanical water consumption meter. It requires no modification from the casual water meter as most of modern devices have rotating indicator. Thus, we are scoring the revolutions of the meter internal rotor by means of reflection of the IR light. Block diagram of the module is shown on Fig. 7a) where the working prototype is shown on Fig 7b).

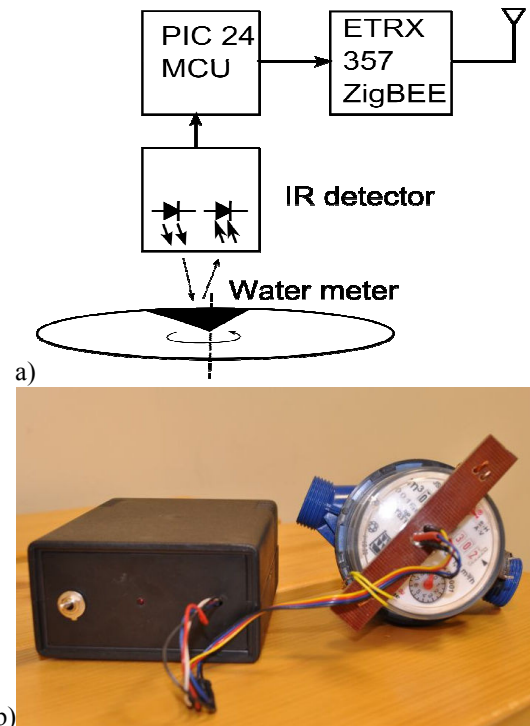

Fig. 7 Automatic detection of water leaking – WD, a) block diagram; b) the prototype

Unfortunately we are not always allowed to gain access to the water flow meter, for many reasons, but happily we are not interested in accurate water measurement, rather water flow information. Thus we developed also a water flow sensor, that can report binary information about state of the water in the pipe – is it flowing or not. Water flowing in the pipe makes the noise that can be picked up by means of the microphone. The amplified acoustic signal is then filtered and processed by means of the microcontroller. The microcontroller (Atmega8 by Atmel) is also communicating with the central system by means of the ZigBEE standard. The block diagram of the detector is shown on Fig.8a where on Fig. 8b) the working prototype can be seen.

#### E. Water leak detector

The water leak detector is a module that detects water leakage on the floor. Device is build on the basis of the ZigBEE module, microcontroller and resistance meter that is detecting unit.

Fig. 8 Water flow sonic detector diagram and prototype

Device is battery powered and thus it can be placed anywhere, where is a risk of water leakage. The block diagram of the device is shown on Fig. 9a) where on Fig. 9b) the prototype is shown.

Fig. 9 Water leakage detector a) the block diagram; b) the prototype

#### F. Sound detector module

Sound detection module is a device that can be placed anywhere in the room. Its task is to detect and classify all surrounding sounds and perform its classification. The classification is performed within device by means of the embedded digital signal microcontroller (dsPIC30f6014 from Microchip). The device can distinguish between groan, fall, door closing and several others. Recognized sound is

classified and reported to the central system, which will take adequate action. The block diagram of the device is shown on Fig. 10a) where the photo of the prototype can be found on Fig. 10b).

Fig. 10 Ambient sound detection module a) block diagram; b) working prototype

#### IV. ALERTS

Alerts are messages generated by the person aided, sensor network nodes, medical devices or the central station (as a result of processing of measurement data) to inform the people supported (internal alerts) and individuals (relatives, guardians, doctors – external alerts) of the occurrence of a particular situation. Alerts are divided into internal and external alerts. Table 1 presents the mutual relationship between the types of alerts and typical actors of the support system. Particular situations have been classified into the following priorities:

0 (emergency) - critical situation concerning the danger to life or of injury / incident (including a call for rescue of persons assisted), etc. This level is an "emergency" that requires call the appropriate emergency services.

1 (alarm) - alarm situation concerning the health status of the monitored person or his environment (including the request for assistance from the assisted person). Requires immediate action from a relative / guardian / physician. It does not require an automatic emergency call.

2 (warning) - the situation of concern regarding activities assisted person (broken diet, problems with taking medications, applying procedures, rehabilitation, etc.). This requires rapid intervention relative / guardian.

3 (system error) - the situation of concern associated with

TABLE I.  
THE MUTUAL RELATIONSHIP BETWEEN THE TYPES OF ALERTS AND TYPICAL ACTORS OF THE SUPPORT SYSTEM

Alert priority/alert recipient	Emergency teams	GP/ Personal doctor	Nurse/social service	Relatives/guardians	Neighbors	Assisted person
0 (emergency)	X	X	X	X	X	X
1 (alarm)		X	X	X	X	X
2 (warning)			X	X		X
3 (system error)				X		X
4 (serious problem)			X	X	X	X
5 (problem)						X

the technical problems with the support system - required the intervention of a relative / guardian and, possibly, maintenance of the system

4 (serious problem) - the occurrence of a failure in the home environment, or request for help / information generated by the person aided - for a person aided and relative / guardian

5 (problem) - the occurrence of a failure in the home environment (or a simple remainder) - for a person assisted.

Alert system was implemented in Java and Java FX. Concurrent processing (java.io.concurrent package, e.g. PriorityBlockingQueue) has been used to map N-sources to M-alerts and K-recipients. Each source (e.g. water consumption sensor, ECG sensor, etc.) is related to an observable producer, which delivers XM-based message to the central station. The central station processes particular or combined messages to identify the priority of the situation and send the alert to the consumers. Consumers distribute alerts to particular recipients. It is assumed that at least four communication channels can be used:

- visual and audio messages for the assisted person;
- audio or/and visual messages for neighbors (environment of the assisted person home),
- messages transmitted by GSM module (SMS, audio messages, data alerts),
- messages transmitted by the secondary data channel (e.g. analog phone modem, internet connection, etc.).

When the situation occurs the message is received by central station (internal alert) and is processed to prepare appropriate response. One possible response is audio/visual information to the assisted person (locally) or external recipient (processed message in the dedicated software). In Fig.11 the examples of windows are presented for different priorities of the alerts. All alerts are recorded in the database as well as responses.

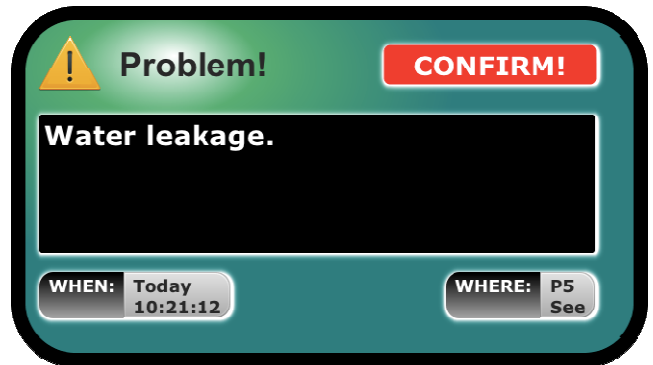

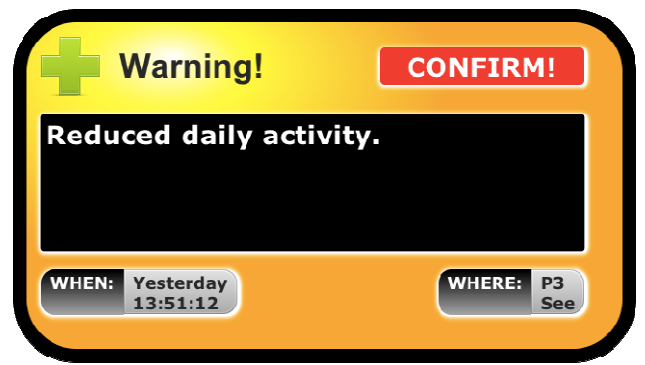

Fig. 11 Examples of windows for different priorities of the alerts

A user can get precise localization of the alert source (button “WHERE”) and should confirm the message (the information is stored together with the recipient role). When the “CONFIRM” button is pressed the user can get additionally information (which depends on the alert message), for example in case of “water leakage” the contact data to the appropriate service can appear.

V.CONCLUSION

The design of multimodal platform for communication, training and patient monitoring at home was presented.

In our work we want to solve three aspects. First, we want to support social connections between elder parents and their adult children or colleagues and friends preventing against digital and social exclusion. These persistent connections will convey activity in the respective homes as well as trends over time. Second, we hope to support "everyday cognition" by augmenting those aspects of memory that decline with age and planning capabilities of elder residents. Third, we also plan to sense and identify potential crisis situations so that appropriate outside services can be contacted as needed.

The presented multimodal platform infrastructure is an excellent chance to obtain general information about a user while at home, and a wearable computer can gather data wherever the user may go outside. The home can contain a large amount of computation and infrastructure for sensing at a distance, while a wearable has the advantage of immediate and intimate contact with the user. The data gathered on the wearable might then be filtered and released to the environmental infrastructure as appropriate. On the other

hand, the wearable may draw on the house's data resources to cache important information for the mobile user when away from the house. Thus, an automated wireless collaboration between the platforms seems appropriate, with the user placing limits on the type and level of information transferred between his personal and environmental infrastructure. We will develop such infrastructure interactions and explore some of the technical and social benefits.

The very important aspect (especially for older people on retirement) of the system is the cost. We assumed to build implementations of all platform elements using no expensive solutions. The already implemented modules are using free software and relatively inexpensive hardware elements.

One possibility is to optimize the GUI of applications and design special virtual keyboards (with limited set of key). Different options of HCI are required for different group of patients. The new audio commands processing subsystem is required (modified version of the general purpose system present in Microsoft Vista/7). Finally the combination of visually and audio guided interfaces could be more comfortable for many patients.

Dedicated multi sensors for special group of patients are still under designing. The final goal is the possibility to collect a platform from building blocks according to the given patient needs. That is why the proper system design is so important.

Another open problem is respecting people/patients privacy and creates a highly secure system in a house and in external communications. Some previous works were published [19][20] but this is still an open subject. The system is still under development and up to now we don't have a evaluation results of usage the system by older people. In laboratory condition system works reliably but still with limited functionality. We will plan to evaluate prototyping system in situ in the nursing home and in the home of older person.

**Abstract**— In this paper we describe a wearable ubiquitous healthcare monitoring system that integrates electrocardiogram (ECG device) and an accelerometer sensor with a mobile device in a Bluetooth-based body surface network (BSN). Our research focused on the right connection of the hardware units, combination of the detection of QRS complexes, calculation of heart rate (HR) and the detection of human falls. The main aim of this research was the early detection of abnormal situations (high/low HR, a fall) and the heart rate variability analysis. The human falls are very risky events that occur not only in the elderly people's daily living but also by epileptics and asthmatics. For these people independent living is strictly forbidden. A wearable sensor based monitoring system can inhibit serious injuries and allow those people live an independent life. Additionally, an SMS messaging module was integrated with the monitoring system. After detecting a non-standard situation a short notice is sent. The implementation of the QRS complex detection algorithm, that was based on the Tompkins formula, was tested on the records from the MIT-BIH database.

### I. INTRODUCTION

RECENT advances in biomedical engineering, wireless network and computer technologies have enabled the possibility of remote patient monitoring. Based on these technologies, it is possible to improve patient care, chronic disease management, and promote lifelong health and well-being for the ageing population.

The aim of this paper is to provide an overview of the authors experience in constructing and implementing wearable sensor network for home monitoring. Our project and research are based on a wearable ubiquitous healthcare monitoring system that integrates 12-leads ECG signal transmitter (ASPEKT 500), an accelerometer sensor and a mobile device in a Bluetooth-based body surface network (BSN).

### II. HARDWARE UNITS

ASPEKT 500 is a digital unit designated for wireless ECG signal transmission to PC or mobile device (fig. 1). It is manufactured by Aspel [8]. The transmitter allows a free patients movement up to 10 m from receiver. Small dimensions and weight make the examination more comfortable for a patient.

Fig. 1 ASPEKT 500 - Wireless ECG signal transmitter [8]

ASPEKT 500 - Wireless ECG signal transmitter is equipped with ten electrode cable. In order to receive 12-leads (Einthoven, Goldberger, Wilson) we need to connect electrodes as shown in the fig. 2.

Fig. 2 Electrodes location on the patient [8]

ECG data is sampled at 500 Hz frequency. Battery operated time is about 12 hours.

### III. METHODS

The most important aim in the monitoring system is the detection of the QRS complexes in real-time. This gives us the opportunity to calculate the heart rate and observe the heart rate variability. The data processing is crucial to extract the correct part of the signal, the QRS complex. The ECG waveform contains also P, T, sometimes U waves and a lot of noise (60 Hz power line noise, EMG, motion artifacts) [3].

One of the most popular and often cited QRS detection algorithms that works in the time domain is the Pan and Tompkins algorithm that was proposed in 1985 [1, 2, 3]. The QRS detection algorithm is based on analysis of the slope, amplitude and width of the QRS complex which refers to the depolarization of the right and left ventricles. Figure 3 shows a block diagram of the Pan-Tompkins algorithm which will be hereafter described.

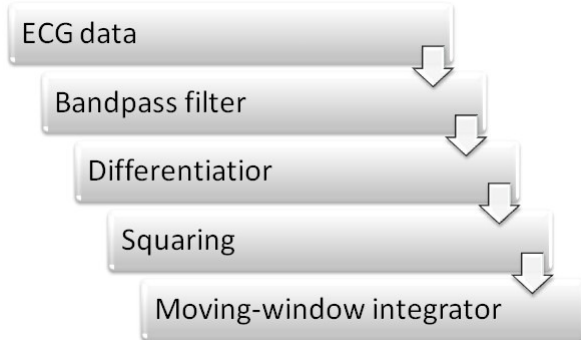

Fig. 3 Diagram of the Pan-Tompkins algorithm [1, 2].

The bandpass filter contains of a lowpass filter and a highpass filter. The lowpass filter has a cutoff frequency of 17 Hz and the highpass filter has a cutoff frequency of 5 Hz. After filtering the signal is differentiated. The derivative operator suppresses the low-frequency elements (P and T waves) and picks the high frequencies out (QRS complex). This operation gives us information about the QRS complex slope. The next step is squaring operation which makes all values positive. This enables us to analyze each channel. The squaring operation also emphasis the higher frequencies and makes the QRS complex interpretation easier. After the squaring operation multiple peaks are observed within the QRS complex. To eliminate this the moving-window integration filter is being performed. To detect QRS complexes an adaptive thresholding is applied. New peak is marked when a local maximum is find during before defined period. After the QRS detection algorithm the heart rate is calculated.

One of the project goals is to detect a fall. Fall detection could be achieved by analyzing the accelerometer data. The most common method of detecting a fall is calculating the absolute sum of ACC signal in different direction as shown in fig. 4.

$$FALL = \sqrt{ACC_X^2 + ACC_Y^2 + ACC_Z^2}$$

Fig. 4 FALL parameter

Thresholding FALL value is used to alert a fall.

#### IV. SYSTEM ARCHITECTURE

The monitoring system prototype has been build and analyzing software has been implemented in order to check if it is possible to monitor human activity remotely. The wireless ECG recorder transmits data to mobile device via wireless network based on Bluetooth technology. Data is analyzed by

implemented software and forwarded using general packet radio service to Internet database, where medical data is accessible to a doctor. Fig. 5 presents the system design.

Fig. 5 Monitoring system design.

Implemented software is organized into 4 modules: ECG signal analysis, Fall detection, Heart Rate Variability and Database (fig. 6).

Fig. 6 Monitoring system architecture.

The most important module of the monitoring system is the ECG data analysis module which analysis the incoming signal data from the ECG recorder. The ECG data analysis module executes the Pan and Tompkins algorithm that was described in section III. The output of this module is transmitted to the Heart rate variability module. This part of the system calculates the HRV and sends the results to the Database via GPRS.

Fall detection module is responsible for analyzing data from accelerometer and calculating FALL factor described in section III. If the fall is detected the alarm module is switched on. The alarm module is a combination of two methods. The first one is a signal bell which can be switched off during 10 seconds. If isn't accomplished a text message is send to a trusted friend.

#### V. TESTS AND RESULTS

One of the most important stages in the implementation of the monitoring system is its verification. Tested has been the

QRS detection algorithm using ECG signals from the MIT-BIH arrhythmia database [5] and fall detection algorithm. Fig. 7 presents four cases of QRS detection possibilities.

QRS detection	Absence of QRS complex	QRS complex occurs
Detected	FP (false positive)	TP(true positive)
Undetected	TN (true negative)	FN (false negative)

Fig. 7 QRS complex detection possibilities.

The effectiveness of the application was performed by calculating the four cases mentioned in fig. 7 for every file from the database. The MIT-BIH database contains signals with different abnormalities (very noisy signal, high P wave, high T wave, arrhythmias and noise that is similar to QRS complex).

The most common used equation to demonstrate the effectiveness of the QRS detection algorithm is the sensitivity which equals TP times all QRS complexes (FN+TP). Fig. 8 presents results for selected files.

Signal nr.	Total QRS complex	TP	Sensitivity
100	2273	2273	100 [%]
101	1865	1863	99,8 [%]
105	2572	2541	98,6 [%]
113	1795	1711	95,2 [%]
117	1535	1498	97,4 [%]

Fig.8 Results for the MIT-BIH database files.

The proposed method of detecting falls did not give satisfactory results in performed tests. It often provided with false positive detections especially during making rapid movements or stops. Further research is needed in order to elaborate more accurate algorithm.

## VI. CONCLUSION AND FUTURE WORKS

The achieved results are satisfactory for our monitoring purposes. However, more tests are needed on a representative group to assess system performance. In the future works we plan to develop more advanced algorithms of detecting non-standard situations and improve fall detection algorithm.

The proposed healthcare monitoring system can help to monitor health conditions (heart rate, heart rate variability) and support elderly, sick and disabled people in their independent living.

**Abstract**—In this paper the simple and robust method of measuring the pulse rate is presented. Elaborated algorithm allows for efficient pulse rate registration directly from face image captured from webcam. The desired signal was obtained by proper channel selection and principal component analysis. A developed non-contact method of heart rate monitoring is shown in the paper. The proposed technique may have a great value in monitoring person at home after adequate enhancements are introduced.

## I. INTRODUCTION

HOME health care is nowadays growing and changing discipline. The remote monitoring of vital signs includes not only the high accuracy diagnostic devices but also simple ones and accessible for everyone. One of the most frequent examinations performed in health care monitoring is cardiac pulse measurement. There are many different methods of contact measurement of a heart rate among which the golden standard is an electrocardiography (ECG). However, recording electric potential generated by the heart requires appropriate application of the electrodes what may be too complicated and annoying in home conditions. Other methods of measuring cardiac pulse involve thermal imaging [1], Doppler phenomenon both optical [2] and ultrasonic [3] or piezoelectric measurements [4]. Photoplethysmography (PPG) is another method that is being used in detecting pulse rate [5]. It utilizes changes of the optical properties of a selected skin area involved by pulsating blood contents. The typical implementation of PPG uses dedicated light sources, e. g. near-infrared light. Changes of the light intensity reflected from the skin correspond to a volume of tissue blood perfusion. Moreover, it has been proved that pulse measurement from human face is also possible using daylight as the illumination source [6]. *Poh et al.* has developed a robust method for computation of the heart rate from digital color video recordings of the human face [7]. The method is based

on blind source separation of the color channels into independent components.

A principal component analysis is used in our procedure. It is applied to video channels and in effect it reduces computational complexity in comparison to independent component analysis. We also show that it is possible to determine a pulse rate based on small rectangular region of the face image and only on two color channels. It is important when considering computational efficiency of the home health care monitoring system and its operation in real time.

## II. METHODS

### A. Experimental setup and measurement procedure

The experimental setup consisted of web and thermographic cameras, and synchronized recorder of ECG (Fig. 1).

Fig. 1 Experimental setup

The measurements were performed indoors and the only light source was sunlight. The 30 seconds long video sequences were recorded by means of a Logitech Webcam 9000 Pro. The resolution of the videos was 640x480 pixels and the frame rate was 20 fps. Sequences of images were saved in AVI format without compression. While the video

was being recorded the ECG signal was collected using the AsCARD electrocardiograph (AsCARD MrGrey v.201, Aspel). The sampling rate of ECG signal was 400 Hz.

Together 10 white volunteers, 2 women and 8 men, of different age (20 - 64 years), were examined. During the measurements they were sitting still and distant 1 m in front of the camera. Experiments were performed in room naturally lighted at midday (Fig. 1).

### B. ROI's selection

The analysis was performed for two different ROI's (regions of interest) sizes. First, the rectangle containing the face region was selected at the first frame of video recording (Fig. 2a). Coordinates of the selected face region remained the same for the whole sequence of images. The second ROI was a rectangular-shaped part of the forehead area. It was defined basing on pupils' coordinates and distance calculated between them (Fig. 2b). It was expected that it would be possible to find a part of forehead to be visible "uniformly". To prove this assumption thermographic images were taken for all examined persons. Thermograms were recorded by the FLIR ThermoCam SC3000 thermal camera having temperature resolution equal 0.1°K.

Fig.2 Definition of ROI's for two approaches utilized in the paper, a) the whole face as a ROI, b) selected part of the forehead as a ROI

### C. Image decomposition

The ROI's were decomposed into three RGB channels. Analyses were performed for a different channels combination: RGB, RG, GB, RB.

### D. Methods of analysis

The Independent Component Analysis (ICA) is a statistical and computational technique used to separate independent signals from a set of observations that consist of linear mixtures of the underlying sources [8]. The ICA model assumes that the observed signals  $\mathbf{y}(t)$  are linear mixtures of the unknown sources  $\mathbf{x}(t)$ :

$$\mathbf{y}(t) = \mathbf{A}\mathbf{x}(t) \quad (1)$$

where the mixing matrix  $\mathbf{A}$  is also unknown. To estimate both  $\mathbf{A}$  and  $\mathbf{x}(t)$  we assume that the components of vector  $\mathbf{x}$  are statistically independent and nongaussian. After estimating  $\mathbf{A}$  matrix its inverse  $\mathbf{W}$  (demixing matrix) can be computed. Then the independent components can be obtained:

$$\mathbf{x}(t) = \mathbf{W}\mathbf{y}(t) \quad (2)$$

To evaluate the demixing matrix many algorithms have been proposed. In the present study the FastICA algorithm was used [9].

The Principal Component Analysis, (PCA), is sometimes called the Karhunen-Loeve Transformation, which is a technique commonly used for data reduction in statistical pattern recognition and signal processing. The PCA is a transformation that identifies patterns in data, and expresses the data in such way that it highlights the similarities and differences. That makes PCA a powerful tool for analyzing data [10].

The basic idea in PCA is to find the components  $s_1, s_2, \dots, s_N$  so that they explain the maximum amount of variance possible by  $N$  linearly transformed components. The principal components are then given by  $s_i = w_i^T \cdot x$ . The computation of the  $w_i$  can be accomplished by using the covariance matrix  $E\{xx^T\} = C$ . The vectors  $w_i$  are the eigenvectors of  $C$  that corresponds to the  $N$  largest eigenvalues of  $C$ .

These components should be ordered in such way that the first component,  $s_1$ , points in the direction where the inputs have the highest variance. The second component is orthogonal to the first and points in the direction of highest variance when the first projection has been subtracted, and so forth.

Suppose we have two zero mean random vectors,  $\mathbf{X}$  and  $\mathbf{Y}$ , that gives  $E[\mathbf{X}] = 0$  and  $E[\mathbf{Y}] = 0$ . Let  $\mathbf{u}$  denote a unit vector, onto which the  $\mathbf{X}$  is to be projected. This projection is defined by the inner product of the vectors  $\mathbf{X}$  and  $\mathbf{U}$ , as shown by

$$\mathbf{Y} = \mathbf{U}^T \mathbf{X} \quad (2)$$

where  $\mathbf{U}$  is an orthonormal matrix. The principal components are columns of  $\mathbf{U}$  and they are found by seeking the directions of maximum data variance, under the orthogonality constraint. Columns of  $\mathbf{U}$  are eigenvectors of the covariance matrix ordered with decreasing variance [11].

### E. Algorithm

For every ROI's channel, pixels values were added separately for each frame. The signals obtained this way were filtered using a FIR bandpass filter (0.5–3.7 Hz, 32-

point Hamming window, designed with MATLAB FDATool). Next, independent and principal component analyses were performed. The ICA was performed using FastICA algorithm implemented in MATLAB. Principal components were obtained with the use of MATLAB *processpca* function.

### III. RESULTS

The images of examined volunteers were processed so as to find regions of interest to further analysis (Fig. 3).

Fig. 3 Selection of the analyzed region: a) whole face ROI, b) forehead ROI

The uniformity of ROI localized on the forehead was analyzed using thermal images. The mean pixel value and the variance  $\sigma^2$  were calculated for face and forehead ROI. Examples of obtained images with calculated  $\bar{x}$  and  $\sigma^2$  are shown in Fig. 4. The images support the assumption that it is possible to select almost uniform part of face to be analyzed.

Video sequences were processed in order to obtain a desired time - dependent signals. A sum of pixels values was calculated for each channel throughout the ROI (Fig. 5). Obtained signals were bandpass filtered (0.5–3.7 Hz).

Independent component analysis and principal component analysis were conducted for different sets of data (Fig. 6 - 7). Firstly, analyses were performed for the ROI containing whole face area, and then a rectangular shape ROI selected on the forehead center was analyzed. Signals from three channels R, G and B were an input to ICA and PCA.

Fig. 4 Temperature distribution of the face for selected persons examined in the study

Fig. 5 Sum of pixels values of video sequence for whole face ROI; R, G and B stands for RGB channels

The result of PCA was compared with that obtained by ICA (Fig. 8). Time of calculation for ICA performed on the face ROI was equal to 223 ms, while for forehead ROI 94 ms. The time of calculation when using PCA for the same data set was respectively 1.4 ms and 1.2 ms.

To check whether obtained “pulse” signal changes are related to the heart rate the results obtained from PCA were compared with an ECG signal that was measured during video recordings (Fig. 9).

Fig. 6 Bandpass filtered result of independent component analysis for three RGB channels, ROI – the whole face

Fig. 7 Bandpass filtered result of principal component analysis for three RGB channels, whole face ROI

In Table I mean heart rates of four selected patients are presented. Results obtained from webcam measurements are compared to that obtained from ECG (R-R interval). Mean heart rate was calculated using two methods: one based on the interval between positive slope zero-crossings of the 2<sup>nd</sup> or 3<sup>rd</sup> PC and the second using maximum of the power spectral density function. Results obtained with the use of the second method are the same for face and forehead ROI in all cases.

Fig. 8 Comparison of results obtained for ICA and PCA for the same data set

Fig. 9 Third principal component for two different ROI's: face and forehead, compared to ECG signal; it can be noticed that components of registered video signals are changing with heart rate

TABLE I.  
HEART RATES OF FOUR SELECTED PATIENTS

Mean heart rate [bpm](measurement time = 30s)				
Patient Id	Web camera			ECG
	zero crossing		fft	
	face ROI	forehead ROI		
1.	87.56	100.67	91.41	87.89
2.	59.32	59.18	58.01	58.59
3.	94.84	104.35	98.44	99.61
4.	60.07	76.85	59.76	58.66

When analyzing signals from only two channels, detection of a pulse rate was most effective when RG combination was considered (Fig. 10 - 11). However, compared to the analysis using three channels the “pulse” component (2<sup>nd</sup> PC) was more distorted, especially when forehead ROI was analyzed (Fig. 11). Spectra of principal components containing pulse signals are presented in Fig. 12. Pulse component extracted from R and G channels apart from 1 Hz component contains also frequencies from 0.3 – 1 Hz range.

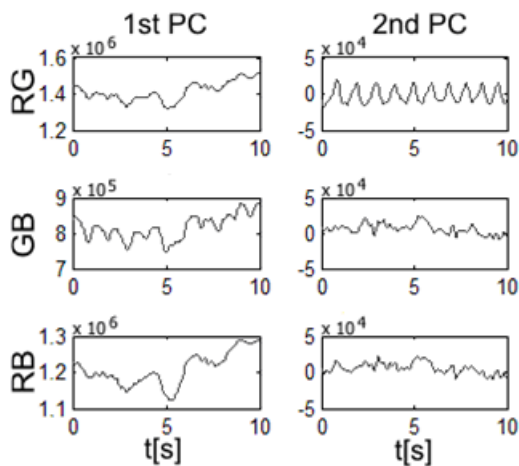

Fig. 10 Principal components for different channel combination: RG, GB, RB; face ROI

#### IV. DISCUSSION

Using the methods detailed in Section III, we estimated pulse rate based on webcam recordings. To reduce both complexity and number of calculations a smaller ROI was selected (the rectangular region of the forehead) as well as fewer color channels and less complex method of analysis was chosen.

The results obtained from independent and principal component analysis' show that those two methods extract the “pulse” component with similar accuracy. However, comparison of time of calculation and other studies [12]

Fig. 11 Principal components for different channel combination: RG, GB, RB; forehead ROI

allows for the conclusion that PCA is less computationally complex so it is reasonable to choose that method to reduce time and complexity of analysis. The obtained results show that when only pulse rate is considered there is no need to use the more computationally complex ICA method. The accuracy of extraction of cardiac pulse signal by PCA is comparable to that obtained by ICA and is sufficient for our purposes. Moreover, the time of calculation obtained for PCA suggests possibility of using this approach in real-time applications.

Selected forehead rectangular area is a region of the face with a temperature relatively constant for healthy male and female of different age. As shown in Fig. 4 the selected part of the forehead area, in contrast to other parts of the face, e.g. nose, has almost the same temperature for examined subjects. Furthermore, assuming that the examined object is kept still it does not contain any “moving” elements, like blinking eyes or moving lips. Based on the analysis performed on the forehead ROI it was possible to determine the pulse rate with sufficient accuracy for the selected group of patients. The results indicate that the selected forehead ROI is representative for the whole face region.

As it is shown in Fig. 10 and Fig. 11 the selected R and G channels contained most of the information about color changes corresponding to the blood volume pulse. So it was possible to reduce the number of analyzed signals from three to two. Decrease in ROI's size or number of channels increases the level of noise (Fig. 12). However, taking into account that these measurements are destined for daily monitoring of vital signs not for clinical purposes, the high accuracy is not the most important factor.

To improve the accuracy of the presented algorithm it is important to provide proper experiment conditions. The object of research needs to be motionless, so the examination have to be performed in the sitting or supine position. The proper lightening conditions are also very important because when analyzed face images are under- or overexposed information about color changes may be lost.

Fig. 12 Spectral density of two different ROI's (face and forehead) and two different channel combination (RGB and RG)

## V. CONCLUSIONS

A simple processing of image data and then applying PCA allows extracting the changeable component containing information of the heart rate. The presented algorithm seems to be quite effective and easy to use in the daily monitoring of home care patients. However, a further study has to be performed on moving persons and the same with more than one camera.

*Abstract*—Pulse pressure velocity measurements (PPV) may be a source of useful information on artery state. A 2007 guideline of the European Society of Hypertension recommends assessing arterial stiffness in patients with arterial hypertension, by measuring the PPV. Mechanical changes in the cardiovascular tree involved in the blood ejection have been measured at the thorax level and on the wrist using impedance techniques, in combination with a one channel electrocardiographic signal. Performing impedance measurements on the wrist is a very challenging task because of the very low conductivity changes in combination with the relatively high value of the basal impedance. This is especially a problem, when the dimensions of the measuring probe are required to be adequate for integration into a whole day wearable sensor. In this study, it has been shown that such measurements are indeed possible, and that they may deliver very useful information on pulse pressure velocity when compared to the classical approach based on the measurement of the PPV delay in relation to the ECG signal. However, it has been found that a significant discrepancy may exist between results obtained using the classical approach and the impedance measurement technique proposed here.

**Keywords:** Pressure pulse velocity, impedance technique, body sensors

### I. INTRODUCTION

**P**ULSE pressure wave velocity (PWV) measurements allow evaluation of arterial stiffness. The pressure wave following the ejection of blood by the heart is gradually conveyed to the periphery. Close to the heart the wave velocity is of the order of 5 m/s and gradually increases towards the periphery and then again decreases in very small arteries. However, only the mean value of the wave velocity over a given segment is considered, while the vessel wall characteristics are highly site dependent. On the other hand, pulse wave velocity assessment has the advantage that no blood pressure information (measured invasively) is required. Several studies have shown that wave velocity measurements allow assessment of the haemodynamic profile of a patient as a function of age and pathophysiological conditions [1], [2]. The European

Society of Hypertension recommends in its guidelines evaluation of this parameter in patients with arterial hypertension. It is also suggested that carotid-femoral pulse wave velocities greater than 12 m/s are an indicator of organ damage [1].

In general, apart from geometric non-uniformity, the changing elastic properties and viscous components make the structure of the artery much more complicated. E.g. for the aorta, stiffness is increasing with the distance away from the heart, which is accompanied by increased damping properties due to differential compositions of the wall.

Different approaches for PWV measurement may be applied [1], [6], while in most of them the pulse pressure is measured at two distant points separated by a known distance, and the propagation delay between the two signals is estimated. This time delay is determined between two “corresponding” points on the pressure wave. Measurements should be performed at stable conditions, as the propagation of the pressure wave depends on many factors, including the pressure itself. The difference between results obtained by applying two different approaches in estimation of the PPV is examined in this paper. A first approach is based on the time delay between the R wave and a selected point of the pulse, while the second one is based on the measurement of the time delay between two impedance signals, one measured on the thorax and another at the wrist.

### II. METHODS

Impedance measurements have been already applied in evaluation of blood flow in artery and venous system. However, the most widespread method, called impedance plethysmography, is based on occlusion of venous return in selected part of a limb (a segment) and measurement of impedance change following the change of segment volume [11]. Pairs of measurement electrodes are localized distantly when comparing to limb diameter in this application. It is in contradiction to the presented application. On the other hand, it is known phenomenon that configuration of electrode matrix (a probe) influences a shape of the recorded signal [11].

This work was partially supported by the European Regional Development Fund in frame of the project: UDA-POIG.01.03.01-22-139/09-02 -“Home assistance for elders and disabled – DOMESTIC”, Innovative Economy 2007-2013, National Cohesion Strategy.

### A. Theoretical backgrounds

Sensitivity of impedance measurements to conductivity changes localized in examined segment can be evaluated by relation  $S = \nabla \phi_n \cdot \nabla \varphi_n$ , where  $\phi_n$  and  $\varphi_n$  are normalized potential distributions associated with unit current flowing respectively between “current” and “voltage” electrodes. The latter one is a hypothetical one. The impedance change involved by conductivity changes is described by the following relationship [3]

$$\Delta Z = - \int_V \Delta \sigma(x, y, z) \nabla \phi_n \cdot \nabla \varphi_n dv \quad (1)$$

where  $\Delta \sigma(x, y, z)$  - spatially distributed change of conductivity. The relationship (1) allows calculation of impedance change ( $\Delta Z$ ) associated with conductivity change ( $\Delta \sigma$ ) undergone in the subject. A geometry, conductivity distribution and the electrode matrix configuration are reflected in spatial distribution of potentials ( $\phi_n, \varphi_n$ ).

According to the relationship (1) a value of the measured impedance change depends on a volume of the conductivity change. Thus, it is important to estimate how volume changes of an artery reflect pulse pressure propagation along it.

The wave propagation velocity, based on theoretical model in [4], [5], is described by the relationship

$$c^2 = \frac{Eh}{2\rho(1-\mu^2)r_0} \left[ 1 - \frac{2}{ar_0} \frac{J_1(ar_0)}{J_0(ar_0)} \right] \quad (2)$$

where  $c$  is the pulse pressure velocity,  $E$  the modulus of elasticity,  $\mu$  the Poisson's ratio,  $J_0(ar_0)$  and  $J_1(ar_0)$  Bessel functions of the first kind, and  $a^2 = -j\omega\rho/\eta$ , where  $\rho$ ,  $\omega$  and  $\eta$  denote the blood density, circular frequency, and blood viscosity, respectively.

For inviscid fluids,  $\eta = 0$ ,  $a \rightarrow \infty$  the second term in square brackets in eq. 1 becomes zero

$$\frac{2}{ar_0} \frac{J_1(ar_0)}{J_0(ar_0)} = 0. \quad (3)$$

As a result the following relationship is obtained:

$$c^2 = \frac{Eh}{2\rho(1-\mu^2)r_0}. \quad (4)$$

Setting  $\mu = 0$ , (3) reduces to the well-known Moens-Korteweg equation:

$$c_0^2 = \frac{Eh}{2\rho r_0}. \quad (5)$$

The above relationship has been obtained assuming that [4]:

1. The wall material is homogeneous, elastic, isotropic, and follows Hooke's law.
2. The relative variations of the dimensions are small.
3. Variation of length is not possible.

4. There exists only a radial motion; so there is no rotation (in other words rotational symmetry is assumed).
5. The thickness  $h$  of the wall tube is small, as compared with the inner radius  $r_0$ , at the mean pressure in the tube.

However, in the actual measurements the above assumptions are not fulfilled exactly. In spite of this, it is generally accepted that pulse velocity measurement is essential in evaluation of cardiovascular state [6]. The relationship (2) can be rewritten in the following form [7]

$$c = \frac{c_0}{(X - jY)(1 - j\omega W)} \quad (6)$$

where viscous effects of the blood on phase velocity, ( $c$ ), are taken into account by  $X - jY$  term and the second term in the denominator of equation (6) takes into account the effects of wall viscosity as well as a complex Poisson ratio.

### B. Measurement technique

The pressure wave or its function has been measured at the thorax and wrist using two different sensors, both being based on the impedance technique. The thorax sensor is described elsewhere [8]. Fig. 1 shows the electronic circuit of the wrist sensor, which consists of a current source built around two operational amplifiers, that delivers a current of 0.1 mA<sub>pp</sub> at 20 kHz. The high output impedance of the current source ensures a constant current for changes of load impedance up to 10 kΩ. These specifications have been realized by means of an active feedback design.

The voltage arising from the current flowing between electrodes  $I_1$  and  $I_2$  is measured by means of voltage electrodes  $V_1$  and  $V_2$ , and amplified 50X. In the next stage, a programmable amplifier allows to select four levels of amplification, such as to ensure a maximum SNR ratio.

Fig. 1. Schematic diagram of measurement circuit,  $I(\omega)$  – current source,  $K$ ,  $G$ ,  $K_Z$ ,  $K_{\Delta Z}$  – gain of respective stage of bandpass amplifier, mark  $\times$  stands for synchronous demodulator

The amplified signal is then passed to a synchronous demodulator, built around another operational amplifier. The maximum input amplitude is determined by the linear range of the synchronous demodulator.

After demodulation the signal is split between two channels, acting as low-pass and pass-band filters, respectively. The former delivers a signal proportional to the value of the basal impedance  $Z$ , depending on the average electrical and the geometrical properties of the wrist. The amplifier marked  $K_Z$  in Fig. 1, is a low pass filter with a corner frequency equal to 2 Hz. The time-dependent signal,  $\Delta Z$ , reflects the changes of blood volume in the measured segment of the body, and in

general is synchronous with the blood induced conductivity changes in the wrist segment of the hand. The amplifier  $K_{\Delta Z}$ , instead acts as a pass-band filter with middle frequency equal to 11 Hz, a low corner frequency below 0.3 Hz, and high corner frequency equal to 20 Hz. For the middle frequency, this two-stage amplifier has a constant gain equal to 200.

C. Model and realization of the sensor's probe

It was assumed that the sensor should be in the form of a watch with the four electrodes mounted on the watch strap. To allow calculation of the sensitivity function for different sensor configurations, a FEM model of the limb segment was built.

Fig. 2. Schematic representation of a cross-section of the wrist. Construction of the four electrode sensor (current injecting electrodes marked red, voltage measuring electrodes marked green); r.a. indicates the radial artery, while u.a. stands for ulnar artery.

This model was in the form of a cylinder of finite length with four circumferential electrodes. Two of them (marked by letter I) were used for current injection, while the other two (marked V) serve as voltage measurement electrodes. Several variants, differing in geometry, were examined both theoretically and experimentally.

First, a sensor consisting of classical circumferential electrodes was examined for equally spaced electrodes. Then, the voltage electrodes were moved closer to the current electrodes, so that these are no longer equally spaced, but with the external dimensions preserved. This latter sensor configuration is shown in Fig. 2.

D. Signal analysis

The recorded signals were analyzed manually after being collected and imported into Microsoft Excel. Time relations between the impedance signals were calculated and assessed according to the definitions specified in Fig. 3. Although only one time course of the impedance signal is illustrated in Fig. 3, the same parameters were calculated for the impedance signals recorded on the upper thorax and the wrist. The effect of the arm position is known to influence both the arterial and venous pressure [9], [10], and was closer examined in our experiments.

Fig. 3. Definition of time parameters and amplitude of the signal:  $t_n$ , the time delay between R wave in the ECG and the beginning of impedance signal  $\Delta Z_e$ ,  $t_x$ , the time delay between the R wave and the maximum of impedance signal  $\Delta Z_e$ , and  $t_r$ , the rise time of the signal.

Pressure waves were recorded for the arm hanging freely down the body, kept at the heart level, and raised straight above the head.

III. RESULTS

It can be assumed, from relationship (2) that the pulse velocity is larger than 5m/s for the considered arteries (starting from the ascending aorta and finishing at the ulnar or the radial arteries). Moreover, assuming that heart rate is 1 Hz (in fact it is a little bit higher) a wavelength of generated pressure wave of frequency 1 Hz is around 5 m. Higher harmonics are of course respectively shorter.

Sensitivity values were calculated for a circumferential electrode configuration applied to a cylinder of radius R and height  $\pm 10 R$ .

Fig. 4. Local sensitivity function (a) for conductivity changes at 0.5R (filled triangles), 0.9R (crosses) and 0.99R (filled squares), where R is the radius of the cylinder and b) total sensitivity,  $S_e$ , calculated as the sum (integral) of sensitivity S along coordinate "z" for different value of r. An anisotropic model, with anisotropy ratio equal to 2, was assumed.

Anisotropy of the conductivity was assumed, i.e. the ratio  $\sigma_l/\sigma_t = 2, 4, \text{ etc.}$ , with  $\sigma_l$  and  $\sigma_t$  the longitudinal and transfer conductivity, respectively. The voltage electrodes were placed at  $\pm R$ , with the current electrodes positioned at  $\pm 1.3 R$ . Sensitivity values for a conductivity changes localized at  $0.5 R, 0.9 R$  and  $R$  respectively are shown in Fig. 4a. The integral sensitivity (calculated as a sum of sensitivity for a certain depth) is also dependant on artery localization in the segment (Fig. 4b).

The developed sensor was found to allow measurement of impedance changes less than  $15 \text{ m}\Omega$  in magnitude, with the channel bandwidth of the impedance measurements limited to  $20 \text{ Hz}$ , while the basal impedance value ranged from  $10 \Omega$  up to  $60 \Omega$ . However, the impedance measured between "current" electrodes belonged to range  $(200 \pm 20\,000) \Omega$  and strongly depended on types of electrodes used.

Fig. 5. (a) Noise of the  $\Delta Z$  channel recorded on a resistance of  $1 \text{ k}\Omega$ , (b) resulting power density.

The noise level of the sensor was estimated by means of measurements recorded on a  $1 \text{ k}\Omega$  resistor (Fig. 4). The signals recorded using the thorax and wrist sensors are presented in Fig. 6 and 7, respectively. All signals have been acquired for standing person with the hand hanging freely down the body.

Fig. 6. Recorded signals of electrical heart activity and impedance changes on the upper part of the thorax and the wrist. The signals are marked in more detail in the following figures

Fig. 7. One cycle of the signals presented in Fig. 6.  $\Delta Z_n$  denotes the impedance change recorded on the upper part of thorax, while  $\Delta Z_w$  is the impedance change recorded at the wrist. The hand was kept hanging down.

All signals presented in Fig. 8 have been obtained with the wrist kept at the level of the heart. Parameters of the signal measured on the thorax are changed slightly in comparison to previous one.

Fig. 8. One cycle of recorded signals with the hand kept at the level of the heart,  $\Delta Z_n$  denotes the impedance change recorded on the upper part of thorax, while  $\Delta Z_w$  is the impedance change recorded at the wrist.

The most significant and noticeable changes are observed for the signal recorded at the "wrist," rather than for the "cardiac" signal recorded on the thorax. However, when raising the hand above the head, both impedance signals show changes (Fig. 9). An enhanced wave coinciding with the QRS complex of the ECG has appeared, probably reflecting the activity of the atria.

Differences in time delay were evaluated for different positions of the arm, i.e. freely hanging along the body, kept at the level of heart, and held straight above the head. Time delays were calculated between the ECG and impedance signals measured on the wrist (Fig. 10), as well as between the impedance signals measured on the thorax and at the wrist (Fig. 11).

Fig. 9. One cycle of recorded signals with the hand kept above the head,  $\Delta Z_n$  denotes the impedance change recorded on the upper part of thorax, while  $\Delta Z_w$  is the impedance change recorded at the wrist.

Fig. 10. Time delay between the R wave of the recorded ECG starting point of  $\Delta Z_w$  signal, for three positions of the arm: (1) arm hanging freely down the body, (2) arm kept at the level of the heart, and (3) arm hold straight above head. Indicated in bold is the trend line.

Fig. 11. Time delay between the starting the point of the impedance signal measured on the thorax, and the starting point of  $\Delta Z_w$  as measured at the wrist, for three positions of the arm: (1) arm hanging freely down the body, (2) arm kept at the level of the heart, and (3) arm hold straight above head.

The distance between the heart and the wrist is relatively short so that different measurement methods may yield large discrepancies. The differences observed between the two methods were indeed quite large, often separated by almost a factor 2.

#### IV. DISCUSSION

Recently, the measurement of large artery stiffness, as a factor indicating the development of cardiovascular complications, has become one of the most essential parameters in patients with cardiovascular diseases such as arterial hypertension [1]. It is assumed that the measurement of pulse pressure velocity can contribute useful information on the state of the cardiovascular system.

Typically, impedance plethysmography has been applied to relatively big segments, e.g. lower or upper limb, with the electrode separation assumed bigger than the radius of the segment being measured. In the current application, however, the distance between the electrodes is less than or comparable with the radius of the segment (the distance between current electrodes was equal to 4 cm), which results in significantly higher sensitivities for superficial than deep conductivity changes. With both arteries taken into account, the radial and the ulnar being superficial, this could be considered as rather advantageous effect. However, the sensitivity function of the probe becomes bipolar, especially for regions close to the surface, as seen in Fig. 4a. This effect can decrease the total sensitivity for superficially located arteries (Fig. 4b). In order to minimize the region of negative sensitivity, voltage and current electrodes were

brought close together. The effect can be eliminated completely when a two-electrode technique is utilized. Unfortunately, as two-electrode techniques are known to be very susceptible to motion artefacts they cannot be used in the current application. The proposed measurement probe consists of pairs of electrodes, each containing of a voltage and current electrode positioned closely to each other. The separation between electrode pairs instead should be as large as possible, such as to ensure that larger magnitude impedance signals are recorded.

Further studies are needed to investigate the origin of the recorded signals when utilizing electrical impedance measurements. As the pulse is travelling along the artery, the shape of the recorded signal is influenced by many factors, also by measurement procedures and equipment used. However, assuming the pressure wave velocity of 5 m/s, and a distance between the voltage electrodes equal to 6-8 cm, the time pulse propagation between electrodes is less than 8 milliseconds. So, in a first approximation this effect may be neglected, and the signal source can be assumed arising from a uniform change of volume within the artery. This uniform radial expansion of artery results from response to transmural pressure (difference between pressure inside and outside the artery). It follows from a comparison of the maximal distance between electrodes, equal to  $\sim 8$  cm, with wavelength of the dominating harmonics of pulse wave in vascular tree. In fact, instead of distance between electrodes the length of the artery participating in measurement should be considered. This length can be evaluated using the data presented in Fig. 4. As it is shown this length depends on the artery localization (depth) in the segment. In spite of this, it can be assumed that the impedance measurements reflect changes of the local artery diameter.

According to the relationships (2) and (6) pulse wave velocity is determined both, by the properties of fluid (blood) and vessels. Analysis of these relationships allows the following conclusions: for a large artery, and consequently a large value of the term  $|a|r_0$ , the phase velocity,  $c$ , approaches the phase velocity in an inviscid fluid. On the other hand, for very small values of  $|a|r_0$  the phase velocity becomes very small. Thus, when estimating the artery's properties from the phase velocity measurements certain precautions must be taken. Moreover, some properties of artery's wall depend also on pressure. Thus, its value should be included in estimation procedure.

The recorded signals are also affected by conditions of measurement (Figs. 7-9). Position of the hand, in relation to the heart level, influences essentially shape of impedance signals, both recorded on the thorax and the wrist. However, this does not change significantly time relations between recorded signals. However, noticed a change in time delay between R wave and  $\Delta Z_n$  also can be considered as a "natural" response of cardiovascular system. Note, that slopes of regression lines presented in Figs. 10 and 11 are different. It seems that further experiments should also include other measurement method allowing precise determination of ejection time from left ventricle.

The proposed measurement method generally is known as impedance plethysmography, and is sensitive to conductivity changes undergoing within the electrical field created by the current flowing between the current electrodes, as well as to the geometrical relation between the voltage and current electrodes, and the shape of the examined body segment [11].

It must be underlined that this type of measurements also is susceptible to artefacts arising from wrist movements. This was also the reason to divide the probe into two parts, each located closely to the corresponding artery. Unfortunately, muscles and tendons are also in close proximity to the arteries.

It is observed from the results that the difference between the velocity estimated from measuring the time delay between the R wave of the ECG signal and the pulse pressure at the wrist, and that estimated from the time delay between the two impedance signals, is almost 100 %. In the former method, the time of isovolumetric contraction of the chambers is included. Taking into account that this time is comparable with the time of pulse propagation along the arm, this explains largely the measurement discrepancy. This effect may be amplified in persons having vessels affected by arteriosclerosis, as such vessels demonstrate a higher pulse propagation speed. Heart insufficiency may further increase the time of isovolumetric contraction, and also cause larger measurement variances.

Taking into account the effect of different arm positions on the recorded signal, it seems that supplementary information obtained by means of an accelerometer would be useful.

Despite providing a more precise estimation of the pulse velocity propagation along the arteries in arm, the proposed method also has its drawbacks. As the magnitudes of the conductivity changes are very low, the very high gain required to recover a reasonable and interpretable signal, makes the measurement system susceptible to interferences and artefacts. The total gain used in the proposed system such as to obtain the presented signals, ranged from 2000 up to 5000. Additional artefacts may also arise from changes in geometry of the wrist and tissues involved in operating and moving hand.

## V. CONCLUSIONS

It has been shown that measuring the propagation of pulse pressure along the arm is possible using an impedance technique. Moreover, it has been shown that the conventional method, based on the simultaneous measurement of ECG and pulse, contains a large time delay component arising from the isovolumetric ventricle contraction. However, it should be underlined that the presented impedance technique may also be susceptible to measurement artefacts as a consequence of the high amplification required to obtain appropriate signal levels that allow proper parameterization and interpretation.

**Abstract**—The paper presents an analysis of correlation between heart rate (HR) and blood pressure (BP). The actual data were obtained from three female and one male. The systolic and diastolic blood pressure was measured with the invasive method in the radial artery. The correlation coefficient indicates only linear dependence, so the inverse of HR was also taken into account. Since the measurements can be corrupted by noise the moving average filtering and trend analysis for all data was done. The results of the correlation analysis of this filtered data were similar to results obtained for raw data. The observed correlation coefficient between HR and BP (systolic and diastolic) for whole available data seems a random number. However the short-term correlation is relatively large (about 0.5), but rather unpredictable, since even sign of the correlation coefficient is changing.

## I. INTRODUCTION

OUR goal is to monitor value of blood pressure (BP) in elder people at their homes. Such measurements are made using non-invasive technique. However, such measurements are made rarely and a time interval between two successive measurements is relatively large. Thus, some serious events may be overlooked. It would be very useful and desirable to develop a method allowing continuous monitoring of BP. Such method may use information gained non-invasively, e.g. about heart rate (HR) or length of the RR interval. We would like to know if knowledge of one of these parameters allows us to estimate value of BP. We are not interested in cohort correlation between HR (or length of RR interval) and BP, rather we are interested in such correlation for individuals. We are not interesting in the relation between variability of HR and BP also. However, such models have been already proposed [1], [2]. There is a publication [3], which reports that resting HR is associated to clinic BP over the whole range of BP values and has been observed at any age. Moreover, the correlation is positive and is stronger for systolic than diastolic values of BP. The strong positive correlation between BP and HR was also reported in [4]. There is also report that exercise-induced increase in systolic BP was positively correlated with resting systolic BP, whereas the correlation of exercise-induced HR

increase with resting HR was negative [5]. The correlation between BP and HR is also reported in [6], for men and women. However, the dependence was much stronger for men than for women. We would like to verify all of these studies for applicability of using HR to predict BP values in our project devoted to home assistance for elders and disabled.

## II. MATERIALS AND METHODS

The data were obtained from monitoring of four persons: three female at age of 47, 52 and 70 and one male at age 86. Physiological data recordings were performed using the S5 DATEX/OHMEDA system for monitoring critically ill patients. Digital data were transferred by the serial port to Computer Information System developed in Department of Hyperbaric Medicine and Sea Rescue. The measurements included diastolic and systolic values of pressure. The arterial BP (measured invasively in the radial artery), central venous pressure (measured invasively in a close proximity of the right atrium of the heart) and non-invasive BP (measured from pressure oscillations of the cuff placed on the upper arm) were recorded. HR, arterial BP and central venous pressure were measured, on average, each 30 seconds, while the non-invasive BP was measured, also on average, each 30 minutes.

The correlation coefficient for HR and arterial pressure (systolic (SBP) and diastolic (DBP)) measured using invasive method was calculated. Since the correlation coefficient describes only linear dependence the calculations were repeated for inverse of HR and arterial pressure. The relation between HR and  $1/HR$  is nonlinear, thus we can observe correlation in one case and no correlation in another one.

Patients were monitored only for few days. To obtain more reliable results the invasive BP measurements were correlated with HR, since the number of samples was about 60 times larger in comparison to non-invasive BP measurements. Invasive arterial BP measurements were chosen, since their values were similar to non-invasive measurements.

Three different approaches were tested. First one was based on correlation between raw data. Since the measurements could be corrupted by noise (for example patient movements or rounding of HR and BP values to the nearest integer by measurement system) the signals were also correlated after performing a filtration procedure. A moving aver-

This work was partly supported by European Regional Development Fund concerning the project: UDAPOIG. 01.03.01-22-139/09-00 "Home assistance for elders and disabled – DOMESTIC", Innovative Economy 2007-2013, National Cohesion Strategy.

age (MA) with equal weights, thus a very simple low pass filter was used. The filter lengths were 3, 4, and 5 samples and did not introduce too much smoothing. Another approach was based on least squares approximation. The increase and decrease of BP value was considered. As an indicator of such changes the parameter  $a$  from the linear least square fitting of HR and BP ( $y=ax+b$ ) could be used. It indicated trend of signals. The fitting was done for each signal separately, and the correlation analysis was performed for  $a$  coefficients. The  $a$  coefficients were calculated for 3, 4, 5, 6, 8, and 10 successive samples. It prevented from missing short-term changes, since such short-time changes might be interested in many applications. This procedure was repeated for all successive samples similarly as in the case of MA filtration.

The HR and BP were measured regularly each 30 seconds, however in some cases the measurements were done more often, while in some cases less often. Such changes could indicate medical intervention. So the samples were divided into groups of continuous measurements done each 30 seconds. However, each group could have different length (different number of samples). We decided to make analysis taking into account groups, which length was not less than 50 samples. To check if the size of the groups was influencing the correlation coefficient, the second analysis was done for groups, which length was not less than 100 samples. The correlation coefficient  $r$  and  $p$ -value (the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero) were calculated for each group of measurement samples for all patients.

### III. RESULTS

All figures show example results of analysis for groups of samples of length not less than 100 samples. Fig. 1 shows SBP dependence on HR. The correlation coefficient was equal to 0.901 ( $p<0.001$ ). Fig. 2 shows results of MA filtration (DBP versus HR). The correlation coefficient was equal to  $-0.708$  ( $p<0.001$ ). Fig. 3 shows coefficients  $a$  for SBP dependence on coefficients  $a$  for HR. The correlation coefficient was equal to 0.669 ( $p<0.001$ ). The change of the correlation coefficient with time for SBP dependence on HR after MA filtration is shown in Fig. 4. Corresponding values of  $p$  for the correlation coefficients presented in Fig. 4 have a large distribution (Fig. 5). However, it appears that the lower value of  $p$  the higher correlation between data (Fig. 6). First 46 correlation coefficients in Fig. 6 have  $p<0.01$ , while first 48  $p<0.05$ . However, correlation is both positive and negative.

IV. DISCUSSION

Different types of analyses were performed in the study. The properties of raw data, filtered (using MA filter of different length) were analyzed. The trend analysis for different number of samples used in calculation of coefficient “ $a$ ” was also performed. It follows from our study that correlation coefficient is not constant. The value of coefficient is accidental and different for data sequences analyzed. However, it has been found that if there is correlation between HR and BP, then such correlation with opposite sign is between  $1/HR$  and BP. It follows from the fact, that a function  $f(x)=1/x$  is nonlinear, but for relatively small interval far from 0 it can be well approximated by straight line. The obtained results show that the correlation coefficient is a good measure of dependence between HR and BP. All observed dependences were linear or no dependence was observed. No nonlinear dependence was observed.

Assuming that the sequence of data contained at least 100 samples the 20 to 60 correlation coefficients were obtained for each patient and for each type of test performed. This number was larger for shorter sequences (as sequences containing at least 50 samples were also examined). Only the correlation coefficients with  $p < 0.05$  were considered for further analysis. Because of a relatively large number of coefficients their average value was also calculated. Moreover, average value of the absolute values of the correlation coefficients and their variances for each patient and each type of study were calculated. The relative numbers of the significant ( $p < 0.05$ ) correlation coefficients were also calculated in each study. The comparison between results for SBP and DBP and for series of at least 50 and 100 samples were conducted.

First, the average of the correlation coefficients and average of their absolute values for all patients were calculated. These values were calculated using the average patient’s value. The variance between patients has also been considered and the resulting remarks from this examination are presented in the following paragraph.

The average correlation coefficient for HR and BP was about 0.2, but the difference between maximum and minimum value was even about 0.6. As can be seen in Fig. 4 there is very large variation in the correlation coefficients’ for each patient. The results for DBP had smaller variation than for SBP. It is interesting that taking into account absolute value of the correlation coefficients the average value is much higher and depends on type of data (correlated parameters). Observe that correlation coefficients having low absolute value have not been significant (Figs. 4 - 6). Absolute values of correlation coefficients were calculated for SBP versus HR and DBP versus HR basing on raw data. Then, the average values were evaluated and they were, respectively, 0.45 and 0.4. This value increased to 0.5 for SBP after applying MA filtration and remained almost constant independently on the filter length. It was in opposition to correlation between HR and DBP where the result was dependent on filter length and changed from 0.45 to 0.48. Trend analysis has shown an increase in the average of the absolute values of the correlation coefficients with number of samples

taken into account for the calculation of the  $a$  coefficient (from 0.30 to 0.40 for SBP and DBP). A little larger variance in the absolute values of the correlation coefficients was observed for SBP.

In the following analysis the variance of the correlation coefficients for each patient is considered. It shows how the correlation was changing with time of data collecting from patients. The variance of the correlation coefficient for SBP and DBP was similar (a little bit lower for DBP). The lowest variance was obtained for trend analysis, while the largest one for MA filtering. The variance was increasing with the length of the filter (for MA) and number of samples taken into account for the calculation of the  $a$  coefficient.

The ratio of significant ( $p < 0.05$ ) to not significant correlation coefficients depended on the type of analysis (raw data, MA filtered, and trend analysis). The values for DBP were about 10% higher than for SBP. The larger number of significant values was obtained for MA analysis and the ratio grew along with the filter length (from 0.66 to 0.71 for SBP and from 0.73 to 0.77 for DBP). A smaller number of significant values was obtained for trend analysis. However, an observed dependence was not monotonic (values from 0.43 to 0.56 for SBP and 0.48 to 0.60 for DBP). Moreover, there was large interpersonal dependence – the ratio changes even from 0.2 to 0.7 for the same method but different persons for SBP. For DBP the variances were smaller.

Influence of the number of samples utilized in the correlation analysis on results obtained is discussed in the following paragraph. Two types of data were compared – containing 50 and more samples to these ones having at least 100 samples. There was no dependence of average value of the correlation coefficient on the length of the data sequence taken into account. In some patients the correlation coefficient was decreasing and in some cases increasing. It was more stable for DBP, while for SBP very large changes for 2 patients were observed. It can be explained if we look at the Fig. 4. It follows from this figure, that one can expect that average value of the correlation coefficient is a random number. However, comparison of the average of the absolute values of the correlation coefficients showed that in most cases this value was decreasing for longer sequences (similarly for SBP and DBP, 10 % on average and it is not dependent on the method of analysis – raw data, MA filtering, trend analysis). Similar results were obtained for variance analysis, but the decrease was even larger – about 20 %. As it can be expected the number of significant correlation coefficients ( $p < 0.05$ ) increases in general with increasing sequence length. Similar results for SBP and DBP, like in the previous

cases, not dependent on the method of analysis – raw data, MA filtering, trend analysis, were observed. The average increase was 10 %.

Finally, the correlation coefficients between HR and SBP or DBP measured invasively for all data and for each patient were calculated. All the correlation coefficients were significant ( $p < 0.05$ ). The correlation coefficients for HR and SBP were equal to 0.30, 0.31, -0.10, and -0.24 for subsequent patients, while for HR and DBP they were respectively -0.02, 0.14, -0.29, and -0.10. The number of measurements for each patient varied from 8451 to 21248 for each parameter. It suggests that a long-term correlation is rather a random number, as can be expected from Fig. 4.

A medicine taken by the patients and interventions of medical doctors could change cardiovascular relationships, thus also our results. Unfortunately, there was no included any information on any medical treatment or interventions in the data. Maybe the low correlation was observed after drug administration, so taking into account such data may allow predicting BP values for HR. However, it should be remembered that elderly people are taking medicines regularly even non-prescribed by physician.

## V. CONCLUSION

The observed correlation coefficient between HR and BP (systolic and diastolic) for whole available data seems a random number. However, the short-term correlation is relatively large (about 0.5), but rather unpredictable, since even sign of the correlation coefficient is changing.

**Abstract**—This paper is a review and a comparison of some preconditioners based on incomplete factorizations of matrices — for matrices describing Markov chains. Three preconditioners are considered: ILU(0), ILU3, IWZ(0). Two of them (ILU(0), ILU3) are based on the LU factorization, the latter (IWZ(0))— on the WZ factorization. The preconditioners are investigated in respect of their usability for decreasing number of iterations in a projection method, namely GMRES( $m$ ). To choose the best preconditioner for such methods, authors introduce a measure called *iteration speed-up* ( $p$ ) and some of its relatives, as well as they define a function giving an average number of restarts needed to achieve a given accuracy for matrices from a some set ( $I_s$ ). These measures are studied for two different cases of matrices describing Markov chains to compare influence of the examined incomplete preconditioners for GMRES( $m$ ).

$O(n^2)$  for  $n$  iterations), which is a big disadvantage for huge systems coming from Markov chains. On the other hand, GMRES( $m$ ) (that is, the GMRES method restarted after  $m$  iterations) requires at most  $O(m \cdot n)$  additional space for computations, regardless of the number  $k$  of restarts (because after every restart the working space can be reused), but the achieved accuracy can be comparable (for an appropriate  $m$ , of course, which is often not easy to choose) to the accuracy achieved with GMRES after the same total number of iterations — that is  $k \cdot m$  — but in the latter case the space needed is  $O(k \cdot m \cdot n)$ . So, we investigate a restarted version, GMRES( $m$ ), as a potentially more economical method for huge systems.

## I. INTRODUCTION AND MOTIVATION

**W**HILE modelling probabilities stationary distributions (independent of time) with Markov chains, we obtain a following linear equation system:

$$\mathbf{Q}^T \mathbf{x} = \mathbf{0}, \quad \mathbf{x} \geq \mathbf{0}, \quad \mathbf{x}^T \mathbf{e} = 1, \quad (1)$$

where  $\mathbf{Q}$  is a transition rate matrix,  $\mathbf{x}$  is an unknown vector of states' probabilities and  $\mathbf{e} = (1, 1, \dots, 1)^T$ . The matrix  $\mathbf{Q}$  is a singular square one of size  $n \times n$ , of rank  $n - 1$ , with a weakly dominant diagonal, usually a sparse, large and ill-conditioned one. These traits of  $\mathbf{Q}$  cause the need to treat the system (1) specially.

One of the most popular methods to solve the system 1 is the GMRES method [13]. The full GMRES algorithm (that is: GMRES( $n$ ),  $n$  being the size of the system) is guaranteed to converge in at most  $n$  steps when we used full precision arithmetic (that means: no restarts are needed), but it is not very useful for large systems of equations, because a good approximate solution is often computed quite early, after very few iterations.

Moreover, the traditional GMRES (without restarts) requires quite a lot of space (additional  $O(n)$  for every iteration, so

The very concept of the preconditioning is almost as old as iterative methods [8]. One of the most famous preconditioning techniques is the incomplete factorization of the original matrix  $\mathbf{Q}$ . The idea of the incomplete factorization was presented by Buleev [3], [4] and Varga [15]. The papers that popularized the incomplete factorizations were [9], [10].

There is a need for preconditioners that are fast, stable, scalable, easy to parallelize and that generate a small fill-in. In [1], [2] preconditioners for Krylov subspace methods for solving large singular linear systems arising from Markov modeling are considered.

The incomplete LU (ILU) factorization process computes a sparse lower triangular matrix  $\mathbf{L}$  and a sparse upper triangular matrix  $\mathbf{U}$ . Here we discuss the ILU(0) factorization, the simplest form of the ILU preconditioners. ILU(0) consists in taking the zero pattern as the original matrix  $\mathbf{Q}$ . Using ILU(0) for solving Markov chains was shown in [14].

ILU3 is another kind of incomplete factorization based on the LU factorization. Here, the factors are nonzero only on their three central diagonals — for the matrix  $\mathbf{L}$  it is the main diagonal and the one directly below, and for the matrix  $\mathbf{U}$  it is the main diagonal and the one directly above. This factorization was not used to Markov chains so we wanted to test it.

The incomplete WZ factorization is originally described in some previous works [5]. In [6] we discussed its performance for GMRES. This work is a step forward in the investigation

This work was partially supported within the project N N516 479640 of the Ministry of Science and Higher Education of the Polish Republic (MNiSW) *Modele dynamiki transmisji, sterowania zatkanieniem i jakością usług w Internecie*.

of such incomplete preconditioners and compares some kinds of IWZ and ILU.

We are concerned in the influence of the preconditioner's structure on the GMRES( $m$ ) method, so we are considering three incomplete factorization methods, namely ILU(0), ILU3 i IWZ(0). These methods differ with the structure of the factors and the number of nonzeros. In factorizations IWZ(0) and ILU(0) the number of nonzeros is exactly the same as in the original matrix  $\mathbf{Q}$  but factors ( $\mathbf{L}$  and  $\mathbf{U}$  in ILU(0),  $\mathbf{W}$  and  $\mathbf{Z}$  in IWZ(0)) have different structures. The ILU3 factorization has usually less nonzero elements than the original matrix  $\mathbf{Q}$  and the structure of the factors is similar to ILU(0). ILU3 is less accurate than ILU(0) and IWZ(0), so we can expect worse results.

We consider an impact of the incomplete factorization preconditioners on the GMRES( $m$ ) method for the numerical solution of Markov chains. We study the relationship between the number of iterations, the convergence rate of the GMRES( $m$ ) method and properties of the matrix  $\mathbf{Q}$  and the structure of preconditioners. For better understanding of the behavior of the GMRES( $m$ ) convergence and its preconditioners we introduce some measures — the iteration speed-up among others (see Section IV-A).

The research was carried out for two cases. The first case are matrices that have not got any particular structure and we assume that the matrix row and column ordering is given and cannot be changed. The second case are matrices of a Markov chain known from the literature as the epidemic model and these matrices have got a structure. For all those (sparse) matrices we introduced another measure — matrix density.

The rest of the paper is organized as follows. Section II recalls briefly the incomplete preconditioning. Section III presents two test cases. Section IV describes conducted numerical experiments. Section V contains some conclusions.

## II. INCOMPLETE PRECONDITIONERS

The convergence rate of iterative methods depends on properties of the coefficient matrix of the linear system. If the matrix  $\mathbf{Q}$  is ill-conditioned, this can make the convergence of iterative methods slow. One way to prevent such problems is to transform the system (1) into an equivalent system (that is, having the same solution), but with better numerical properties. Such a transformation can be done by preconditioning, that is by converting the system (1) into:

$$\mathbf{M}^{-1}\mathbf{Q}^T\mathbf{x} = \mathbf{0}, \quad \sum_{i=1}^n x_i = 1, \quad \mathbf{x} \geq \mathbf{0}, \quad (2)$$

where the nonsingular matrix  $\mathbf{M}$  (known as a preconditioner) approximates the matrix  $\mathbf{Q}^T$  in a manner. The system (2) has the same solutions as (1) but it is (hopefully) better conditioned.

The matrix  $\mathbf{M}$  should have the following properties:

- its use should entail low memory requirements;
- its inverse should be cheaply applicable;
- the transformed problem (2) should converge faster (in shorter computational time) than the original problem.

Of course, there is a clear conflict among these three requirements, especially for the construction of general purpose preconditioners.

Generally, computing and using a good preconditioner is an expensive task consisting of finding the matrix  $\mathbf{M}$  and its inverse. If the preconditioning is to be used, that cost should be refunded by a reduced number of iterations needed to acquire a required accuracy — or by using the same preconditioner for various linear systems.

The preconditioner matrix is usually built on the base of the original coefficients of the matrix  $\mathbf{Q}$ .

### A. ILU(0) preconditioner

The incomplete LU factorization (denoted ILU) is based on the well known LU factorization, where a lower triangular matrix (with ones on the diagonal)  $\tilde{\mathbf{L}}$  and an upper triangular matrix  $\tilde{\mathbf{U}}$  are found and where the preconditioner matrix  $\mathbf{M} = \tilde{\mathbf{L}}\tilde{\mathbf{U}}$  is a kind of approximation for the matrix  $\mathbf{Q}^T$ .

There are many variants of ILU, the most straightforward being ILU(0) [14]. In ILU(0) the computations are conducted as in the traditional (complete) LU factorization (that is, the Gaussian elimination), but any new nonzero element ( $l_{ij}$  and  $u_{ij}$ ) arising in the process is dropped if it appears in the place of a zero element in the original matrix  $\mathbf{Q}^T$ . Hence, the factors together have the same number of nonzeros as the original matrix  $\mathbf{Q}^T$ . Thereby, the most important problem of the factorization of sparse matrices — the fill-in (which consists in appearing nonzero elements in new matrices on the places of zero elements in the original matrix, what makes dense the output factors and renders impossible their packed storage) — is eliminated. At the expense of accuracy, of course.

After ILU(0) we have:

$$\mathbf{Q}^T = \tilde{\mathbf{L}}\tilde{\mathbf{U}} + \mathbf{R}_{LU}, \quad (3)$$

where  $\tilde{\mathbf{L}}$  and  $\tilde{\mathbf{U}}$  are (respectively) the lower triangular matrix and the upper triangular matrix and the remainder matrix  $\mathbf{R}_{LU}$  is hoped to be small in a sense.

Let  $\mathbf{M} = \tilde{\mathbf{L}}\tilde{\mathbf{U}}$ , then  $\mathbf{M}^{-1} = \tilde{\mathbf{U}}^{-1}\tilde{\mathbf{L}}^{-1}$  and the equation (2) takes the shape:

$$\tilde{\mathbf{U}}^{-1}\tilde{\mathbf{L}}^{-1}\mathbf{Q}^T\mathbf{x} = \mathbf{0}, \quad \sum_{i=1}^n x_i = 1, \quad \mathbf{x} \geq \mathbf{0}. \quad (4)$$

Let  $\mathbf{S}_{LU} = \tilde{\mathbf{U}}^{-1}\tilde{\mathbf{L}}^{-1}\mathbf{Q}^T$ . Now, the equation (4) takes the shape:

$$\mathbf{S}_{LU}\mathbf{x} = \mathbf{0}, \quad \sum_{i=1}^n x_i = 1, \quad \mathbf{x} \geq \mathbf{0}. \quad (5)$$

The following Octave code was used to generate the ILU(0) factors used in this article. For a given matrix  $\mathbf{Q}$  two triangular matrices are constructed. The matrix ( $\mathbf{L}$ ) is lower triangular (the main diagonal of  $\mathbf{L}$  is filled with ones only) and the matrix ( $\mathbf{U}$ ) — upper triangular. The time complexity is  $O(n^3)$ .

```

function [L,U]=ilu0(Q)
[n,n]=size(Q); U=Q; L=zeros(n);
for i=1:n, L(i,i)=1.0; end;
for k=2:n,
    for i=1:k-1,
        if Q(k,i) != 0,
            L(k,i)=U(k,i)/U(i,i);
            for j=i+1:n,
                U(k,j)=U(k,j)-L(k,i)*U(i,j);
            end;
        end;
    end;
for i=1:n,
    if Q(k,i)==0, U(k,i)=0; end;
end;
for i=2:n,
    for j=1:n,
        if i>j, U(i,j)=0; end;
    end;
end;
end;

```

### B. ILU3 preconditioner

ILU3 is an incomplete LU factorization conducted quite similarly to ILU(0), but the structure of output matrices  $L$  and  $U$  have nothing to do with the structure of the input matrix  $Q^T$ . The output matrices simply consist of diagonals: the main one and its lower neighbor diagonal ( $L$ ) or the main one and its upper neighbor diagonal ( $U$ ).

As for now, this factorization was not used in solving Markov chains. However, it is quite fast ( $O(n)$ ) and easy to use in parallel. The code is shown below.

```

function [L,U]=ilu3(Q)
[n,n]=size(Q); U=Q; L=zeros(n);
for i=1:n, L(i,i)=1.0; end;
for k=2:n,
    i=k-1;
    L(k,i)=U(k,i)/U(i,i);
    U(k,k)=U(k,k)-L(k,i)*U(i,k);
    if (k<n),
        U(k,k+1)=U(k,k+1)-L(k,i)*U(i,k+1);
    end;
end;
for j=1:n,
    for i=1:n,
        if (i>j), U(i,j)=0; end;
        if (i+2<=j), U(i,j)=0; end;
    end;
end;
end;

```

### C. IWZ(0) preconditioner

The incomplete WZ (denoted IWZ) factorization is originally described in a previous works [5]; here we only recall it. The WZ factorization (on which IWZ is based) consists in decomposition of the given matrix ( $Q^T$  in the paper) into a product of two matrices:  $W$  and  $Z$  (Fig. 1).

The incomplete WZ factorization (IWZ) is based on the WZ factorization described above, where we find matrices  $\tilde{W}$  and

Fig. 1. The form of the output matrices in the WZ factorization (left:  $W$ ; right:  $Z$ )

$\tilde{Z}$  (of the form of the matrices  $W$  and  $Z$  shown in Fig. 1) and the product  $\tilde{W}\tilde{Z}$  is a kind of approximation for the matrix  $Q^T$ .

In IWZ(0) the computations are conducted as in the complete WZ factorization, but any new nonzero elements ( $w_{ij}$  and  $z_{ij}$ ) arising in the process are dropped if they appear in the place of a zero element in the original matrix  $Q^T$ . Hence, the factors together have the same number of nonzeros as the original matrix  $Q^T$ . It is worth noting that we got the inverse of  $\tilde{W}$  very easily, because [16]:

$$\tilde{W}^{-1} = (-1) \cdot (\tilde{W} - I) + I \quad (6)$$

$$\text{(just like } W^{-1} = (-1) \cdot (W - I) + I). \quad (7)$$

After IWZ(0) we have:

$$Q^T = \tilde{W}\tilde{Z} + R_{WZ}, \quad (8)$$

where  $\tilde{W}$  and  $\tilde{Z}$  are (respectively) matrices of the form of  $W$  and  $Z$  from Fig. 1 and the remainder matrix  $R_{WZ}$  is supposed to be small in a sense.

The time complexity is  $O(n^3)$  — just like for ILU(0).

Here is an Octave code that shows the sequence of operations that must be followed and that provides some feel for the applicability of the algorithm. This (and previous, that is for ILU(0) and ILU3) code is not meant to represent production versions of the algorithms.

```

function [W,Z]=iwz0(Q)
[n,n]=size(Q); Z=Q; W=zeros(n);
for i=1:n, W(i,i)=1.0; end;
for k=1:n/2-1,
    k2=n-k+1;
    det=Z(k,k)*Z(k2,k2)-Z(k2,k)*Z(k,k2);
    for i=k+1:k2-1,
        if Q(i,k)!=0,
            W(i,k)=(Z(k2,k)*Z(i,k2)-Z(k2,k2)*Z(i,k))/det;
        end;
        if Q(i,k2)!=0,
            W(i,k2)=(Z(k,k2)*Z(i,k)-Z(k,k)*Z(i,k2))/det;
        end;
    end;
    for j=k+1:k2-1,
        if Q(i,j)!=0,
            Z(i,j)=Z(i,j)+W(i,k)*Z(k,j)+W(i,k2)*Z(k2,j);
        end;
    end;

```

TABLE I

            | ((i<j)&(i>n-j+1)),
                Z(i,j)=0; end;
        end;
    end;
end;
end;

```

### III. TEST CASES

Here we shortly present two cases which were used to investigate the influence of our preconditioners (ILU(0), ILU3 and IWZ(0)) on the convergence of GMRES( $m$ ). We assume that the investigated matrix cannot be a subject for any reordering.

#### A. Case I

The matrices of the Case I were created randomly, with given some parameters as  $n$  (the number of rows) and  $nz$  (the number of nonzeros) as well as the range of the elements outside the diagonal. For every nonzero element, its indices (that is the number of its row and the number of its column) were randomly (uniformly) chosen as well as its value. Then, the diagonal elements were computed (from:  $q_{ii} = -\sum_{j \neq i} q_{ij}$ ) to get a correct transition rate matrix.

In Table I the essential characteristics of the matrices are presented ( $n$  is the number of rows and columns of the matrix,  $nz$  is the number of nonzeros in the matrix,  $d = nz/n$ ).

For these matrices we can observe, that the matrices might have the same size and a different value of  $d$ . The matrices were divided into two groups, the first group include matrices with  $d > 8$  (Group A), the second group include matrices with  $d \leq 8$  (Group B).

The structure of the matrix with ID=3 is shown in Fig. 2. We can see that the matrices from Case I have no particular structure. It is worth noting that IWZ(0) and ILU(0) for them have not such a structure either, because their structures are based on structures of  $\mathbf{Q}$ . And ILU3 preconditioner is just a tri-diagonal — as usual.

#### B. Case II

The matrix of Case II was generated from a standard two-dimensional Markovian model [7], [11]. This particular example has been taken from [11], [12]. The states of the chain are described with two numbers  $(u, v)$ ,  $u = 0, \dots, N_x$ ,

Fig. 2. The structure of the matrix with ID=3 of Case I

Fig. 3. The structure of the matrix of Case II

$v = 0, \dots, N_y$  (here  $N_x = 64$ ,  $N_y = 16$ ). The matrix describing the two-dimensional Markov chain has a structure shown in Fig. 3.

It is worth noting that for the matrix of Case II, the investigated preconditioners are also structured. It is so because ILU(0) and IWZ(0) inherit their structures after the original matrix (Fig. 3). But ILU3 is here somewhat a special case, because here it reduces to the Jacobi preconditioner (that is  $\mathbf{L} = \mathbf{I}$  and  $\mathbf{U} = \text{diag}(q_{ii})$ ).

### IV. EXPERIMENTAL RESULTS

The main goal of the numerical experiments was to test the incomplete factorization preconditioners in respect of their usability for the GMRES( $m$ ) method for matrices arising from Markov chains. The experiment was performed on a Pentium IV 2.8GHz computer with 1GB RAM under the Debian GNU/Linux operating system. We used a high-level programming language, namely Octave (a GNU equivalent of MATLAB).

A vector  $\mathbf{x}^{(0)} = (x_i^{(0)})$  with  $x_i^{(0)} = \frac{1}{i}$  was chosen as an initial vector. As a measure of accuracy of the solution we chose the 2-norm of the residual:

$$\varepsilon^{(k)}(\mathbf{Q}) = \|\mathbf{0} - \mathbf{Q}^T \mathbf{x}^{(k)}\|_2 = \|\mathbf{Q}^T \mathbf{x}^{(k)}\|_2. \quad (9)$$

TABLE II

NUMBER OF ITERATIONS NEED TO ACHIEVE A GIVEN ACCURACY  $\varepsilon^{(k)} < 10^{-16}$  FOR THE SELECTED VALUES OF THE PARAMETER  $m$  FOR CASE I (MATRICES FROM GROUP A ARE PRINTED NORMALLY, THOSE FROM GROUP B ARE DISTINGUISHED WITH A BOLD FONT)

$m$	method	matrix ID					
		1	<b>2</b>	3	<b>4</b>	5	<b>6</b>
$m = 1$	GMRES( $m$ )	45	<b>87</b>	44	<b>185</b>	42	<b>271</b>

	IWZ(0)G-( $m$ )	2	<b>3</b>	2	<b>4</b>	1	<b>4</b>
	ILU(0)G-( $m$ )	3	<b>4</b>	3	<b>5</b>	3	<b>4</b>
	ILU3G-( $m$ )	3	<b>7</b>	3	<b>8</b>	3	<b>9</b>

Above (and throughout the whole paper), as  $k$ , we consider the number of external iterations of GMRES( $m$ ), that is the number of restarts.

The accuracy has been studied experimentally for the matrices of Case I and Case II. We studied both the number of iterations needed to achieve a given accuracy, and the convergence rate. The stop condition used here is that the 2-norm of the residual (that is  $\varepsilon^{(k)}(\mathbf{Q}) = \|\mathbf{Q}^T \mathbf{x}^{(k)}\|_2$ ) is less than  $10^{-16}$  (such a chosen value is quite real if we are to find probabilities of unlikely but important events — as a packet loss or a channel jamming — precisely). To improve the readability we did not use  $\varepsilon^{(k)}(\mathbf{Q})$  in the results presentation, but rather:

$$\text{acc}(\mathbf{Q}, i) = -\log_{10} \varepsilon^{(i)}(\mathbf{Q}). \quad (10)$$

#### A. Number of iterations

Table II shows numbers of iterations (external iterations, that is restarts) used to achieve a given accuracy for selected parameters  $m$  for four methods: GMRES( $m$ ) alone (denoted GMRES( $m$ )) and GMRES( $m$ ) preconditioned with IWZ(0) (denoted IWZ(0)GMRES and ( $m$ )IWZ(0)G-( $m$ )), ILU(0) (denoted ILU(0)GMRES( $m$ ) and ILU(0)G-( $m$ )) and ILU3 (denoted ILU3GMRES( $m$ ) and ILU3G-( $m$ )).

For a deeper analysis of the influence of the preconditioners on the method, we consider some more measures.

Let  $I(M, \mathbf{A}, \varepsilon)$  denote a number of restarts (that is external iterations) needed to achieve the 2-norm of the residual less than  $\varepsilon$  for a given matrix  $\mathbf{A}$  with a given method  $M$ . In other words,  $I(M, \mathbf{A}, \varepsilon)$  is a minimal  $k$  for which defined in (9)  $\varepsilon^{(k)}(\mathbf{A}) < \varepsilon$ .

Let us define  $p(PM, \mathbf{A}, \varepsilon)$ , which shows the relationship between the number of iterations needed to achieve a given accuracy  $\varepsilon$  with a method  $M$  with no preconditioner and the same method  $M$  with a preconditioner  $P$  — both for the same matrix  $\mathbf{A}$ . We call it *iteration speed-up* and define as follows:

$$p(PM, \mathbf{A}, \varepsilon) = \frac{I(M, \mathbf{A}, \varepsilon)}{I(PM, \mathbf{A}, \varepsilon)}. \quad (11)$$

Now, let  $Is(M, Z, \varepsilon)$  be an average number of restarts needed to achieve a given accuracy for matrices from a set  $Z$ :

$$Is(M, Z, \varepsilon) = \text{avg}_{\mathbf{A} \in Z} I(M, \mathbf{A}, \varepsilon). \quad (12)$$

Next, we define  $ps(PM, Z, \varepsilon)$  which shows the relationship between the average number of iterations needed to achieve a given accuracy  $\varepsilon$  with a method  $M$  with no preconditioner and the same method  $M$  with a preconditioner  $P$  — for a set  $Z$  of matrices.

$$ps(PM, Z, \varepsilon) = \frac{Is(M, Z, \varepsilon)}{Is(PM, Z, \varepsilon)}. \quad (13)$$

At last, we are going to define some more characteristics with  $p$  defined above (11). They will be the maximal and minimal  $p$  for a given matrix  $\mathbf{A}$  solved with a preconditioned GMRES( $m$ ) (for  $m \in \{1, \dots, m_0\}$ ; with a preconditioner  $P$ ) as well as  $m$  giving that  $p$ :

$$p_{\max}(PGMRES(m), m_0, \mathbf{A}, \varepsilon) = \max_{1 \leq i \leq m_0} p(PGMRES(i), \mathbf{A}, \varepsilon), \quad (14)$$

$$p_{\min}(PGMRES(m), m_0, \mathbf{A}, \varepsilon) = \min_{1 \leq i \leq m_0} p(PGMRES(i), \mathbf{A}, \varepsilon), \quad (15)$$

$$m_{\max}(PGMRES(m), m_0, \mathbf{A}, \varepsilon) = \arg \max_{1 \leq i \leq m_0} p(PGMRES(i), \mathbf{A}, \varepsilon), \quad (16)$$

$$m_{\min}(PGMRES(m), m_0, \mathbf{A}, \varepsilon) = \arg \min_{1 \leq i \leq m_0} p(PGMRES(i), \mathbf{A}, \varepsilon). \quad (17)$$

Whenever we omit the parameter  $\varepsilon$  (as in  $p(\text{ILU}(0)\text{GMRES}(m), \mathbf{Q})$  where we mean iteration speed-up of the GMRES method restarted after  $m$  inner iterations preconditioned with the ILU(0) factorization — and similar), we assume  $\varepsilon = 10^{-16}$ .

Fig. 4 shows  $ps(PGMRES(m), \mathbf{A})$  and  $ps(PGMRES(m), \mathbf{B})$  — that is the relationship between the parameter  $m$  and the average number of restarts (external iterations) needed to achieve the given accuracy for  $P$  being preconditioners: ILU(0), ILU3, IWZ(0). The average number of iterations is counted for two groups of matrices: Group A with  $d > 8$  (the matrices 1, 3, 5) and Group B with  $d \leq 8$  (the matrices 2, 4, 6).

Some conclusions that can be drawn from Table II and Fig. 4 are following.

- With the increase of the parameter  $m$  the average number of iterations needed to achieve the assumed accuracy of the method GMRES( $m$ ), IWZ(0)GMRES( $m$ ), ILU3GMRES( $m$ ) and ILU(0)GMRES( $m$ ) decreases.
- Regardless of the size of the matrix, the number of iterations needed to achieve a given accuracy is practically the same and depends on the value of  $d = nz/n$  (see Group A versus Group B).
- In the methods IWZ(0)GMRES( $m$ ), ILU(0)GMRES( $m$ ) and ILU3GMRES( $m$ ) the number of outer iterations (that is, restarts) needed to achieve the given convergence is

Fig. 4. The relationship between the parameter  $m$  and the average number of restarts (external iterations) needed to achieve the accuracy  $10^{-16}$  for the matrices of Group A ( $d > 8$ ) and Group B ( $d \leq 8$ ) for Case I with preconditioners IWZ(0) (top); ILU(0) (middle); ILU3 (bottom)

less than in the GMRES( $m$ ) method, regardless of the parameter  $m$  and the parameter  $d$ .

- The value of the iteration speed-up ( $p$ ) for the matrices of Group A is not less than for those of Group B.
- For the matrices of Group B, the growth of  $p(\text{ILU}(0)\text{GMRES}(m), \mathbf{Q})$  and  $p(\text{IWZ}(0)\text{GMRES}(m), \mathbf{Q})$  is more uniform than for the matrix of Group A.

Table III shows the minimal and maximal values of  $p$  (that is  $p_{\min}$  and  $p_{\max}$  from (14) and (15)) and the values of the parameter  $m$  for which those values of  $p$  are reached ( $m_{\min}$  and  $m_{\max}$  from (16) and (17)) — in Case I.

Table IV provides values  $p(\text{ILU}(0)\text{GMRES}(m), \mathbf{Q})$ ,

TABLE III  
MAXIMAL AND MINIMAL VALUES OF THE CHARACTERISTICS  $p$  AND THE RESPECTIVE VALUES OF  $m$  FOR MATRICES OF CASE I

precond.	value	matrix ID					
		1	2	3	4	5	6
IWZ(0)	$p_{\max}$	3.21	3.00	4.00	5.61	4.20	<b>7.97</b>
	$m_{\max}$	9	8	1	2	1	1
	$p_{\min}$	2.00	2.50	2.00	3.50	2.00	3.75
	$m_{\min}$	8	2	7	10	6	9
ILU(0)	$p_{\max}$	3.21	3.11	3.67	5.69	3.82	<b>8.21</b>
	$m_{\max}$	1	1	1	1	1	1
	$p_{\min}$	1.33	2.00	1.33	2.80	1.00	3.20
	$m_{\min}$	10	10	10	10	10	9
ILU3	$p_{\max}$	1.45	1.32	1.83	2.33	2.00	<b>3.23</b>
	$m_{\max}$	1	1	1	2	1	1
	$p_{\min}$	1.18	1.11	1.25	1.67	1.00	1.60
	$m_{\min}$	3	8	7	9	10	9

TABLE IV  
VALUES OF  $p(\text{ILU}(0)\text{GMRES}(m), \mathbf{Q})$ ,  $p(\text{IWZ}(0)\text{GMRES}(m), \mathbf{Q})$ ,  $p(\text{ILU3GMRES}(m), \mathbf{Q})$  FOR THE MATRIX  $\mathbf{Q}$  OF CASE II FOR DIFFERENT VALUES  $m$

$m$	$p(\text{IWZ}(0)\text{G}-(m))$	$p(\text{ILU}(0)\text{G}-(m))$	$p(\text{ILU3G}-(m))$
5	<b>5.07</b>	<b>7.89</b>	<b>0.45</b>
14	5.00	5.00	0.25
25	4.50	3.00	0.16
29	3.50	2.33	0.15
33	3.00	2.00	0.19
41	2.00	1.33	0.17
49	1.50	1.00	0.14
61	1.50	1.50	0.16

$p(\text{IWZ}(0)\text{GMRES}(m), \mathbf{Q})$ ,  $p(\text{ILU3GMRES}(m), \mathbf{Q})$  for the matrix from Case II. In that table we omit  $\mathbf{Q}$  because there is only one such a matrix.

From Tables III and IV it can be concluded the following.

- With the growth of parameter  $m$  (where  $m$  changes from 1 to 10) the value of  $p$  for IWZ(0) and for ILU(0) decreases in both cases.
- IWZ(0) and ILU(0) improve (that is: decreases) the number of restarts for both cases — even 8 times.
- The ILU3 preconditioner in Case I always reduces the number of restarts. However, in Case II it always spoils the performance.
- IWZ(0) and ILU(0) behave similarly for both cases.

### B. Convergence rate of GMRES( $m$ )

1) *Case I:* Fig. 5 presents the relationship between the number of iterations and the achieved accuracy  $\text{acc}(\mathbf{Q}, i)$  (see (10)) for the matrices with ID 3 and 4 (from Group A and B, respectively) for the methods GMRES( $m$ ), IWZ(0)GMRES( $m$ ), ILU(0)GMRES( $m$ ) and ILU3GMRES( $m$ ) for two selected values of parameter  $m$ . The values of  $m$  were chosen after the analysis of Table III and Fig. 4. The maximal iteration speed-up is for  $m = 1$  (regardless of the preconditioner) and the minimal iteration speed-up is usually for  $m = 10$ .

Fig. 5 shows that the higher value of the parameter  $m$ , the more rapidly convergent is the method GMRES( $m$ ). Analogously, the higher value of the parameter  $m$  means that IWZ(0)GMRES( $m$ ), ILU(0)GMRES( $m$ ) and

ILU3GMRES( $m$ ) methods are faster convergent regardless of the matrix.

The convergence curve  $acc(\mathbf{Q}, i)$  as a function of  $i$  is almost of the same shape for any particular parameter  $m$  for the GMRES( $m$ ) method and the IWZ(0)GMRES( $m$ ), ILU(0)GMRES( $m$ ) and ILU3GMRES( $m$ ) methods — only for the preconditioned GMRES( $m$ ) methods the curve is shifted upwards. It means that these methods are faster convergent than the GMRES( $m$ ) method.

The best preconditioner for GMRES( $m$ ), regardless of the parameter  $m$  and of the properties of the matrix, is IWZ(0).

For the the matrix of ID 3 from Group A and  $m = 10$  (Fig. 5, higher middle) all the investigated preconditioners give similar results.

2) *Case II*: Fig. 6 shows the relationship between the number of iterations and the accuracy  $acc(\mathbf{Q}, i)$  (10) for the GMRES( $m$ ) method and the IWZ(0)GMRES( $m$ ), ILU(0)GMRES( $m$ ), ILU3GMRES( $m$ ) methods for  $m = 5$  and  $m = 49$ . The values of  $m$  was based on Table IV — the maximal iteration speed-up (regardless of the preconditioner) is usually for  $m = 5$  and minimal — for  $m = 49$ .

Fig. 6 and Table IV show the following conclusions.

- The preconditioner ILU3 is completely not fitted for Case II, worsening the accuracy of the method GMRES( $m$ ). As we noticed in the end of Section III-B, ILU3 reduces to the Jacobi preconditioner for such banded matrices as in Case II and it causes such a poor accuracy, because the Jacobi preconditioner is rather little effective.
- The best preconditioner is ILU(0). However, as  $m$  grows, the iteration speed-up declines.

For the matrix of Case II it is not always the case, that IWZ(0) improves the convergence rate, because that matrix has a banded structure. ILU(0), being diagonally arranged, seems to be more consistent with the matrix's structure than IWZ(0) — the structure of the latter “crosses” the structure of the original matrix and thus spoils it.

## V. CONCLUSION

Those numerical experiments helped us understand the effect of incomplete preconditioners on the convergence of preconditioned Krylov subspace methods — like GMRES( $m$ ).

Using IWZ(0) and ILU(0) improves the convergence of the GMRES( $m$ ) method (that is, decreases the number of the iterations needed to achieve the required accuracy — even 8 times) used to solve sparse linear equation systems connected to Markov chains.

Both preconditioners — IWZ(0) and ILU(0) — work similarly in terms of the iteration speed-up for the described method and matrices. However, ILU3 appears to be completely useless in the presented cases.

The rate of the convergence of the projection method GMRES( $m$ ) as well as the preconditioned one does not depend on the size of the matrix  $\mathbf{Q}$ .

The speed of convergence in terms of numbers of iterations (restarts) of GMRES( $m$ ) depends on the structure of the matrix. There were tested matrices for two different cases and

Fig. 5. The plot of the achieved accuracy  $acc(\mathbf{Q}, i)$  as a function of  $i$  for various matrices and values of  $m$ : matrix ID = 3 of Group A,  $m = 1$  (top); matrix ID = 3 of Group A,  $m = 10$  (higher middle); matrix ID = 4 of Group B,  $m = 1$  (lower middle); matrix ID = 4 of Group B,  $m = 10$  (bottom)

Fig. 6. The plot of the achieved accuracy  $acc(\mathbf{Q}, i)$  as a function of  $i$  for the matrix of Case II for various values of the parameter  $m$ :  $m = 5$  (top);  $m = 49$  (bottom)

they were characterized by the fact that the matrices from case I had no structure, the matrix from case II had a really clear structure.

The matrices of Case I were further distinguished by their density, given by  $d = nz/n$ . And the set of the matrices which had a low value of the parameter  $d$  ( $d < 8$ ) gave slower convergence and they require additional techniques to improve the rate of the convergence. This technique could be some

more complicated preconditioning.

**Abstract**—We profile GLPK, an open source linear programming solver, and show empirically that the form of matrix multiplication used in interior point methods takes a significant portion of the total execution time when solving some of the Netlib and other LP data sets. Then, we discuss the drawbacks of the matrix multiplication algorithm used in GLPK in terms of cache utilization and use blocking to develop two cache-aware implementations. We apply OpenMP to develop parallel implementations with load balancing. The best implementation achieved a median speedup of 21.9 when executed on a 12-core AMD Opteron.

**Keywords:** sparse matrix multiplication, cache optimization, interior point methods, multicore systems.

## I. INTRODUCTION

**D**URING recent years, processor designers have moved away from uniprocessor systems to multicore systems. This shift is mainly due to manufactures inability to continue enhancing the performance of single-core processors [1]. Increasing clock speeds requires higher voltage and causes, consequently, too much heat to dissipate. On the other hand, using deeper pipelines and other advanced architectural techniques have yielded decreasing improvements. In addition, and due to the speed gap between main memory and the processing cores, there has been more demand for an efficient cache system to allow exploiting the collective processing power [2]. As a result, multicore programmers need not only to provide a parallel implementation of the application, but they also have to take cache utilization into consideration for efficient utilization of the multicore system. Techniques to reduce cache and TLB misses depend on the application memory access pattern, for example, tiling/blocking [3] is the most popular method for applications with poor exploitation of temporal locality.

A Linear Programming (LP) solver is one of many compute-intensive applications that could benefit from the high multicore performance. It works as a decision maker that chooses values of many variables to achieve a goal (maximum profit, best resource allocation, etc.) while satisfying a set of constraints that are specified as mathematical equalities and inequalities [5]. If we have  $m$  constraints and  $n$  variables, the LP-problem in standard form can be written as:

$$\text{minimize } z = c^T x, \text{ subject to } Ax = b, x \geq 0,$$

where  $x$  is an  $n$ -dimensional column vector,  $c^T$  is an  $n$ -dimensional row vector,  $A$  is a  $m \times n$  matrix, and  $b$  is an  $m$ -dimensional column vector.

Solving LP problems in an efficient way is crucial for industrial and scientific fields, especially since an application might need to solve large problems and/or a long sequence of problems. For example, Miriam Regina, a network gas flow simulator developed by Miriam AS [4], solves thousands of LP problems to make a single allocation of gas flow in the network. On the other hand, it needs to solve bigger LP instances for the simulation to cover large networks that span the national boundaries.

The motivation for investigating matrix multiplication in interior point methods (IPM) [5, 6] is that it takes a large fraction of the total computation time when solving some of the data sets. In addition, it is a special form of multiplication of the form  $ADA^T$ , where  $A$  is a sparse matrix,  $D$  is a diagonal matrix, and  $A^T$  is the transpose of  $A$ . Moreover, sparse multiplication is a form of irregular computation that is much more challenging to accelerate than dense multiplication. On the other side, the structure of the multiplication result is constant through all IPM iterations, a fact that may be used to enhance its computation performance.

In this paper, we profile serial GLPK [7], an open source LP solver, and present empirical results showing that matrix multiplication takes a relatively long time to compute for some Netlib and miscellaneous problems [8, 9]. We also analyse memory access patterns of sparse multiplication and develop cache-aware algorithms that reduce the rate of cache and TLB misses. Moreover, a parallel version is also provided while trying to exploit the cache hierarchy of the multicore system.

The paper is organized as follows: Section II gives a brief overview of the AMD Opteron compute node used. Then, compute-intensive parts of the LP solver are introduced in section III. Section IV explains GLPK implementation of sparse matrix multiplication while section V describes techniques to enhance cache utilization. We present related work in section VI and conclude with experimental results and future work.

## II. MULTI-CORE HARDWARE

Introduced in 2009, the 64-bit Istanbul processor is the first 6-core AMD Opteron<sup>®</sup> processor and is available for 2-, 4-, and 8-socket systems, with clock speeds ranging from 2.0 to 2.8 GHz [10].

Fig. 1 shows a simplified block diagram. The processor has six cores, three levels of cache, a crossbar connecting the cores, the System Request Interface, the Memory controller, and three HyperTransport 3.0 links. The memory controller supports DDR2 memory with a bandwidth of up to 12.8 GB/s. In addition, the HyperTransport 3.0 links provide an aggregate bandwidth of 57.6 GB/s and are used to allow communication between different Istanbul processors. Each core has two levels of cache, a 512 KB L2 cache, 64 KB data cache and 64 KB instruction cache. However, all cores share a 6 MB L3 cache.

AMD Opteron multiprocessor systems are based on the cache coherent Non-Uniform Memory Access (ccNUMA) architecture. Each processor is connected directly to its own dedicated memory banks and it uses HT links to communicate with I/O busses and the other processor(s). Fig. 2 shows a block diagram of a 2-socket system.

## III. GLPK AND IPM COMPUTATIONAL KERNELS

The GLPK (GNU Linear Programming Kit) package is a set of ANSI C routines contained into a callable library and intended for solving large-scale linear programming, mixed integer programming, and other related problems [7]. GLPK has routines for solving LP problems using either simplex or one of the primal-dual interior point methods (IPMs), namely the Mehrotra's predictor-corrector method [6]. This method, as well as other primal-dual interior point methods, keeps repeating a set of matrix operations, until it converges to an optimal solution. Every iteration of the algorithm includes the following computations [11]:

- 1) Sparse matrix-matrix multiplication of the form  $S = PAD(PA)^T$ , where  $P$  is a permutation matrix stored

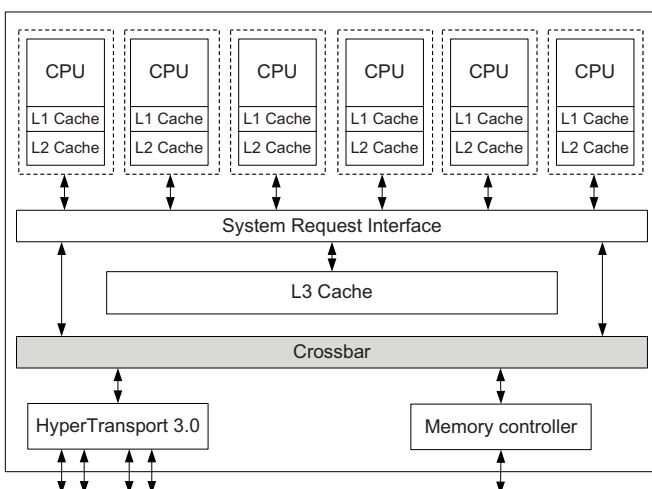

Fig. 1. Simplified block diagram of an AMD Opteron Istanbul processor.

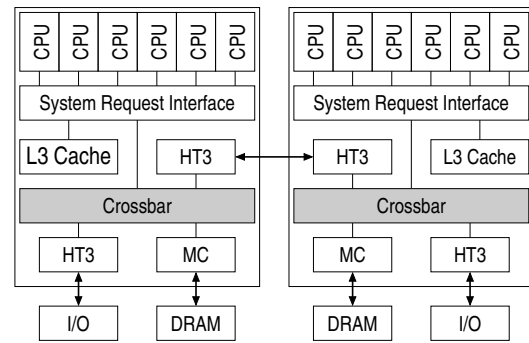

Fig. 2. Block diagram of a 2-socket system

as a single dimensional array,  $A$  is the sparse working constraint matrix stored using the CRS format,  $D$  is a diagonal matrix stored using a single dimensional array, and  $(PA)^T$  is the transpose of matrix  $PA$ . The output matrix  $S$  is a symmetric positive definite matrix.

- 2) Cholesky factorization of a symmetric sparse matrix  $S$ , the result of step 1, into  $LL^T$  where  $L$  is the lower factor matrix and  $L^T$  is the transpose of  $L$ .
- 3) Backward/forward solving using Cholesky factors.

### A. Compressed row storage CRS

Since most practical problems are very sparse, GLPK uses compressed row storage (CRS) to store the constraint matrix and other matrices used in the IPM algorithm. CRS is a general storage format that makes no assumptions about the sparsity structure of the matrix [12]. As shown in Table I, CRS uses three contiguous arrays to store a sparse matrix  $A$ :  $A_{\text{val}}$  stores all nonzero elements row by row,  $A_{\text{ind}}$  holds the column indices of the nonzeros, and  $A_{\text{ptr}}$  holds the offset of each row into  $A_{\text{val}}$ . CRS is usually used to access the matrix row by row, while another format called compressed column storage (CCS) is used when a column by column access is needed. Similar to CRS, CSS uses three arrays to store the matrix, however, it stores the nonzeros column by column and  $A_{\text{ptr}}$  have pointers to the start of columns in  $A_{\text{val}}$ .

### B. Time analysis of IPM computational kernels

Time analysis of serial IPM-based GLPK has been performed when solving big data sets taken from Netlib and the BPMPD website [9]. Size, number of nonzeros, and sparsity, fraction of nonzero elements of the matrix, of each data set

TABLE I  
A MATRIX  $A$  AND ITS CRS STORAGE

$$A = \begin{bmatrix} 0 & 3 & 0 & 0 & 1 \\ 4 & 1 & 0 & 0 & 0 \\ 0 & 5 & 9 & 2 & 0 \\ 6 & 0 & 0 & 5 & 3 \\ 0 & 0 & 5 & 9 & 0 \end{bmatrix}$$

$A_{\text{val}}$	3	1	4	1	5	9	2	6	5	3	5	9
$A_{\text{ind}}$	2	5	1	2	2	3	4	1	4	5	3	4
$A_{\text{ptr}}$	1	3	5	8	11	13	(nonzero count + 1)					

are shown in Table II. Results of time analysis are presented in Table III and they show that Cholesky factorization and sparse matrix multiplication of the form  $ADA^T$  are the two most computationally expensive tasks of the solver. However, a few of the data sets, namely BPMPD, CZPROB, and NEMSEMM1, show that a considerable amount of time is spent executing other parts of the code. These results show the importance of accelerating Cholesky factorization and sparse multiplication in order to enhance the performance of IPM based LP solvers.

IV. ORIGINAL IMPLEMENTATION OF GLPK MATRIX MULTIPLICATION AND CACHE PROBLEMS

As mentioned earlier, the sparse matrix product  $S$  in IPM has the form  $S = PAD(PA)^T$ . This product is computed in two phases: symbolic and numeric. The symbolic phase is performed once and is used to determine the nonzero structure of  $S$  for use in the numeric phase.

The numeric phase, which is implemented based on Gustavson’s algorithm [15], is executed every iteration to determine the numeric values of  $s_{i,j \geq i}$  of  $S$ . Algorithm 1 shows the pseudocode of the GLPK serial implementation of  $S = PAD(PA)^T$  where  $A$  is an  $m \times n$  matrix and  $P$  is stored in a permutation vector  $\pi$ . The matrix product is computed row by row (line 1) and the permutation is applied at lines 2 and 5. If row  $k$  of  $S$  has  $n_{nz}$  nonzeros, then its computation requires multiplying row  $i$  ( $i_p$  after permutation) of  $A$  by  $D$  and by other  $n_{nz}$  rows of  $A$ . Since rows have different sparsity, row  $i_p$  is decompressed into a vector  $w$  (line 3) as illustrated in Algorithm 2. Each nonzero in row  $i$  of  $S$  is finally obtained by performing a dot product between  $Dw$  and a row of  $A$  (line 6).

The GLPK implementation of  $S = PAD(PA)^T$  suffers from the following problems with regard to cache utilization:

- Because of the sparsity of  $A$ , a small fraction of the values in  $D$  and  $w$  need to be read for the computation of each nonzero of  $S$ . However, these values are scattered irregularly over large vectors,  $D$  and  $w$ , that don’t have room in L1 and L2 cache. Such irregular access pattern will cause a high cache miss rate.

**Algorithm 1** Serial implementation of  $S = PAD(PA)^T$ , using  $A_\alpha$  for row  $\alpha$  of  $A$ .

```

1: for  $i = 1 \rightarrow m$  do
2:    $i_p = \pi(i)$ 
3:    $w = (A_{i_p})^T$  {see Algorithm 2}
4:   for  $j = i \rightarrow m$  and  $s_{ij} \neq 0$  do
5:      $j_p = \pi(j)$ 
6:      $s_{ij} = A_{j_p} Dw$ 
7:   end for
8: end for
    
```

- Although the rows of  $A$  have small number of values that are stored contiguously, the permutations makes it difficult to benefit from data locality and might cause much TLB misses for matrices with high number of nonzeros [13].

V. CACHE-AWARE MATRIX MULTIPLICATION

Trying to exploit cache and avoid the problems mentioned in the previous section, we use 1D and 2D partitioning and develop techniques to avoid the overhead of accessing zero blocks and zero block rows. Both extensions of the original algorithm avoid the negative effect of permutation by performing it during the blocking phase, i.e. the rows are permuted in memory before they are split into several blocks. This allows more uniform access to rows of partitions during multiplication. The new algorithms are explained in the following subsections.

A. 1D partitioning of the matrix  $A$

The method is based on a vertical partitioning of  $PA$  into blocks  $A^{(1)}, A^{(2)}, \dots, A^{(v)}$ , where  $v$  is the number of vertical partitions. Moreover, partitioning is made once since  $A$  is

**Algorithm 2** Decompression of a row of matrix  $A$  into  $w$ .

```

1: for  $k = A_{\text{ptr}}(i_p) \rightarrow A_{\text{ptr}}(i_p + 1)$  do
2:    $l = A_{\text{ind}}(k)$ 
3:    $w(l) = A_{\text{val}}(k)$ 
4: end for
    
```

constant and only  $D$  changes through the IPM iterations. In addition, each of the blocks is stored in memory as an independent matrix using CRS. Algorithm 3 shows the pseudocode of the 1D algorithm.  $D$  and  $w$  are accessed in smaller chunks  $D^{(1)}, D^{(2)}, \dots, D^{(v)}$  and  $w'$  whose size depends on the width of  $A$ -partitions. The goal is to have  $D^{(\cdot)}$ 's and  $w'$  that can fit into L1/L2 cache and be reused through loop iterations at line 5.

One of the drawbacks of 1D partitioning is that many of the partitioned rows have no elements (zero rows) which waste cycles on loading and comparing  $A_{ptr}$  values. Fig. 3A shows an example of a vertical partitioning where 60% of the blocked rows have no elements. In fact, the percentage of zero rows is much higher in real problems as the matrices are much more sparse than the one shown in Fig. 3A. Another drawback is the extra storage of ptr array of each partition.

To avoid wasting time on zero partition rows, a higher level of compressed storage is used to efficiently access the nonzero rows of partitions. The matrix, as shown in Fig. 3A, is treated as an  $m \times v$  matrix and a new second level of CRS structure (only ptr and ind) is added and used to access nonzero partition rows. This adds more to storage requirements, but has a good effect on performance. The added  $Parts_{ptr}$  and  $Parts_{ind}$  are shown Fig. 3B, and the associated multiplication algorithm is shown in Algorithm 4.

### B. 2D partitioning of the matrix $A$

Data blocking is a well known technique to utilize data spatial locality [20] and it is well suited for dense matrix multiplication. We try to apply the same technique to sparse matrix multiplication by dividing matrix  $A$  into  $M \times N$  blocks and consequently matrix  $S$  into  $M \times M$  blocks all stored using CRS. Computation of an  $S$  block is achieved by multiplying two rows of  $A$  blocks as shown in Algorithm 5. Blocks have different sparsity and many  $A$  and  $S$  blocks may have no elements (zero blocks). Different sparsity of different blocks is a reason why blocking is not as efficient as when dealing with dense matrices. However, trying to exploit the existence of zero blocks we add extra information to  $S$  blocks as shown in the following:

- Each block of  $S$  has an array that stores the indices of nonzero rows.

---

**Algorithm 3** Vertically partitioned implementation of  $S = PAD(PA)^T$ , using  $A_{\alpha}^{(p)}$  for row  $\alpha$  of partition  $A^{(p)}$ .

---

**Require:**  $A \leftarrow PA$  {performed when partitioning}

```

1: for  $i = 1 \rightarrow m$  do
2:   for partition  $p = 1 \rightarrow v$  do
3:      $w' = (A_i^{(p)})^T$ 
4:     for  $j = i \rightarrow \text{mand}_{s_{ij}} \neq 0$  do
5:        $s_{ij} += A_j^{(p)} D^{(p)} w'$ 
6:     end for
7:   end for
8: end for
```

---

**Algorithm 4** Extension of Algorithm 3 with second level CRS

**Require:**  $A \leftarrow PA$  {performed when partitioning}

```

1: for  $i = 1 \rightarrow m$  do
2:   for  $t = Parts_{ptr}(i) \rightarrow Parts_{ptr}(i+1)$  do
3:     partition  $p = Parts_{ind}(t)$ 
4:      $w' = (A_i^{(p)})^T$ 
5:     for  $j = i \rightarrow \text{mand}_{s_{ij}} \neq 0$  do
6:        $s_{ij} += A_j^{(p)} D^{(p)} w'$ 
7:     end for
8:   end for
9: end for
```

---

**Algorithm 5** 2D partitioning of matrix  $A$

```

1: for  $I = 1 \rightarrow M$  do
2:   for  $J = 1 \rightarrow M$  do
3:     for  $K = 1 \rightarrow N$  do
4:        $S_{I,J} += A_{I,K} A_{J,K}$ 
5:     end for
6:   end for
7: end for
```

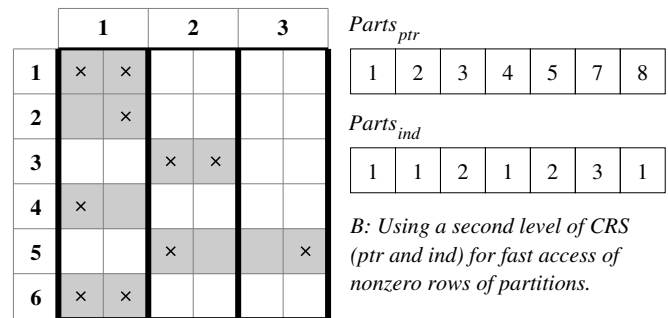

---

- Each block of  $S$  has an array of indices of participating pairs of  $A$  blocks.

The goal of the first point is to allow utilization of the already known  $S$  matrix structure. However, the second point aims at avoiding accessing  $A$  blocks that don't participate into computation of an  $S$  block. Two pairs of  $A$  blocks participate in the computation if their product produces one or more nonzeros, which is simply determined by checking if they have at least one common index of nonzero columns. We determine participating blocks just after the symbolic phase and use it through all IPM iterations. Suppose that matrix  $A$  has  $M \times N$  blocks then  $S$  has  $M \times M$  blocks as shown in Algorithm 5.

### C. Parallel computation of $S$ and load balancing

Parallelization of original GLPK implementation and our implementations of the sparse matrix multiplication have been achieved with OpenMP, mainly for loop parallelization. The original GLPK implementation is parallelized by parallelizing the for loop shown at line 1 in Algorithm 1, causing each core

A: Blocking  $A$  into 3 vertical partitions

B: Using a second level of CRS (ptr and ind) for fast access of nonzero rows of partitions.

Listing 1. Parallel block based matrix multiplication

```

#pragma omp parallel for
for row = 1 to M
  for col = 1 to M
    ...
A. Parallel 2D algorithm without load balancing

shares = assign_shares(num_cores, num_nonzeros[]);
#pragma omp parallel for
for i = 1 to num_cores
  for row = shares[i].from to shares[i].to
    for col = 1 to M
      ...
B. Parallel 2D algorithm with load balancing

```

to compute a chunk of  $S$  rows. Similarly, 1D partitioning of  $A$  also uses the same principle as the outer loop iterates over rows of  $S$ . Finally, multiplication based on 2D partitioning of  $A$  is parallelized by parallelizing the for loop shown at line 1 of Algorithm 5, causing each core to compute a chunk of rows of  $S$  blocks.

Due to different levels of sparsity within the same matrix in general, and as will be seen in the performance results section, our parallel implementation suffers from load imbalance. To address this, we divide  $S$  into a number of shares that equals the number of cores, and assign one core to each share. An ideal share would be any share whose number of nonzeros equals the number of nonzeros in  $S$  divided by the number of cores. Therefore, we try to assign shares such that they differ as less as possible from an ideal share. To force a core to compute one share, we add an outer loop over shares and apply the `omp parallel for` construct to the new added loop as shown in Listing 1.

A share is composed of a number of consecutive  $S$  rows in the original and 1D algorithms, but it is made of a number of consecutive rows of blocks in the 2D algorithm, making it harder to determine shares that are close to an ideal share. For the 2D algorithm, we try to determine shares that are bigger than an ideal share within a specified tolerance. If  $t$  denotes tolerance and  $d$  denotes number of nonzeros in an ideal share, then a share can have up to  $(1+t)d$  nonzeros. In our implementation, we start trying a 5% tolerance and decide all the shares except the last one. If the size of the last share doesn't satisfy the tolerance constraint, we keep increasing the tolerance by 5% and repeat the algorithm until all shares respect the tolerance constraint.

## VI. RELATED WORK

Our implementations, although not intended for general sparse matrix multiplication, are based on the classical Gustavson algorithm [15] using compressed row storage of matrices. That algorithm is also used in Csparse [19] and Matlab [21] and is proven to be optimal with respect to number

of operations and storage space of general sparse matrices.

Algorithms for sparse multiplication are developed with focus on optimizing number of operations and storage requirements, however they only perform better than Gustavson's algorithm when working on certain class of matrices. For example, Park et al. [17] built an efficient algorithm that is based on a compact storage of banded and triangular matrices. On the other hand, Buluç et al. [16] introduced what they called the doubly compressed sparse column (DCSC) which uses less space than compressed column storage (CSC) for storing hypersparse matrices, matrices where number of nonzeros is less than the dimension of the matrix. Such matrices may be the result of a 2D partitioning of sparse matrices for parallel processing.

To our knowledge, Sulatycke et al. are the only researchers who presented sparse matrix algorithms that take efficiency of caches into consideration [14]. Their cache aware algorithms are based on interchanging loops of a standard multiplication algorithm. Moreover, they presented a parallel version that is based on static and dynamic splitting of matrix rows among several threads. However, their experiments were conducted on up to 1000 x 1000 10% sparse matrices, which are much smaller and less sparse than those tested in this paper.

Most recent research about sparse matrix multiplication have been performed by Buluç et al. In [16], they discussed the scalability limitations of matrix multiplication on thousands of processors. Moreover, they developed a sequential hypersparse matrix multiplication algorithm using the DCSC sparse storage to overcome the presented limitations. Parallel implementation was simulated by dividing input matrices using 2D blocking decomposition, excluding other costs like updates and parallelization overheads. Based on their work in [22], load imbalance, hiding communication costs, and additions of submatrices, are the main challenges of parallelizing sparse multiplication. In addition, they have also analysed the scalability of using 1D and 2D block decomposition to divide the work among the processors and show analytically and experimentally that the 2D based algorithms are more scalable than those based on 1D blocking.

## VII. PERFORMANCE RESULTS AND CONCLUSION

### A. Cache aware matrix multiplication

Our experiments are performed on a 2 x 6 cores AMD Opteron (Istanbul 2431) compute node. All code including GLPK 4.43 is compiled with GCC 4.4.3, with optimization level 3 (-O3). Moreover, execution time of only the first IPM iteration has been measured when solving each of the data sets because iterations caused by solving one data set take the same amount of execution time. Table IV reports the execution time of original GLPK implementation and the new two implementations of the serial matrix multiplication, executed on a single core. Speedup is calculated taking the original implementation as a baseline. The following can be concluded:

- 1) The new 1D and 2D algorithms execute faster than the original one for all data sets. However, FIT2D is

accelerated much more than other data sets. This can be explained by the unique nonzero structure of its  $PA$  as shown in Fig. 4. The figure is created by placing a dot in the location of each nonzero element, i.e. the horizontal thin bar in the figure represents a group of adjacent dense rows in the matrix. The nonzero structure of this matrix is special because most rows have two values while the last few rows are dense. The original implementation is slow because it accesses most of the  $D$  values when one of the dense rows in the bottom of  $PA$  is involved, causing much L1 and L2 cache misses. However, the 1D and 2D implementations utilize the cache and improve locality of access as explained in section V.

- 2) Different data sets are accelerated by different values due to the difference in sparsity. Moreover, the distribution of nonzeros is different among different data sets.
- 3) 2D avoids accessing nonzero blocks and blocks whose multiplication doesn't result in any nonzeros, while 1D avoids accessing nonzero rows of partitions. 2D cause more performance when nonzeros are concentrated in chunks causing a lot of nonparticipating blocks to be avoided.

### B. Size of partitions/blocks

Table V shows sizes of partitions/blocks that cause optimal speedup for both implementations and for different data sets. The results show that the optimal dimensioning of block-/partitions are more related to the distribution of nonzeros than to the sparsity of data sets. If we fix partition size in the 1D implementation to 100 and the block size in the 2D implementation to  $100 \times 100$ , the speedup of NSCT2 and BAS1LP is reduced by 16% and 14% respectively. However, the speedup of 2D partitioning for CZPROB, NEMSEMM1, NSCT2, BPMPD, OLIVIER, and BAS1LP is reduced by an average of 8%.

### C. Parallel sparse matrix multiplication

The performance of the parallel matrix multiplication for original implementation and our implementations before and after load balancing is shown in Figs. 5-9. The results show the high importance of the load balancing. In addition, they show that problems that have longer serial execution time scale better than those which have relatively lower execution time.

TABLE IV  
SERIAL TIMINGS OF ORIGINAL AND NEW IMPLEMENTATIONS

Problem name	Orig. [s]	1D [s]		Speedup	
		1	3	1	3
FIT2D	2.455	0.0261	0.0227	94.1	108.0
CZPROB	0.004	0.0006	0.0007	6.6	5.7
NEMSEMM1	0.279	0.0783	0.0684	3.6	4.1

BAS1LP	0.992	0.7724	0.5933	1.3	1.7

Fig. 4. Nonzero structure of FIT2D after permutation.

Although both implementations show a comparable speedup when executed serially, the later has better speedup when both are executed in parallel. The median speedup of the 1D and 2D implementations is 12.0 and 21.9. Table VI shows the speedup achieved when executing the implementations on 10 cores with the execution time of the original serial algorithm as a baseline. We chose to show the results on 10 cores since some data sets show bad performance when executed on 11 and 12 cores.

To have a more clear view, we show the parallel performance of NEMSEMM1 as an example, in Fig. 10. The figure shows that speedup doesn't increase smoothly with increasing number of cores. This behaviour is due to two main reasons. First, a strange varying OpenMP overhead is observed. It is measured as the difference between the matrix multiplication time and the execution time of the thread that takes most time to finish computing its share. Second, because nonzeros can be concentrated in a small part(s) of the matrix, using nonzeros to divide the shares among threads doesn't always guarantee that load balancing will be improved. For example, in the 2D algorithm, one thread might be responsible for computing many very sparse blocks, while a second one might be responsible for computing a much lower number of dense blocks. The overhead caused by these two reasons can have a relatively big effect on performance as shown when using 11 and 12 cores.

## VIII. CONCLUSION AND FUTURE WORK

An efficient LP solver is crucial for many scientific and industrial applications. However, most research has been fo-

used on an efficient Cholesky factorization since it is the most expensive computation in interior point methods. We showed that, similar to Cholesky factorization, sparse matrix multiplication in IPM-based solvers use a relatively high percentage of the total execution time when solving some big data sets, and proposed two cache-aware implementations of the sparse multiplication algorithm used in GLPK. Moreover, we used OpenMP to parallelize the multiplication and developed

a simple, but efficient technique for load balancing.

Due to many zero rows of very sparse blocks, CRS and CCS are not optimal wrt. space for storing very sparse blocks, but we had to use them for two reasons,

- Block sparsity varies a lot even in the same data set

Fig. 9. Parallel 2D with load balancing.

Fig. 10. NEMSEMM1 with load balancing. Original serial execution time is used as a baseline.

- Our algorithms requires very fast access to rows/columns.

It might be possible to use different storage and computation mechanisms for blocks based on their sparsity. One approach to accomplish this is to use 2D partitioning but using larger blocks, and then choose the appropriate storage mechanism and block multiplication procedure based on the sparsity level. In case of dense (or close to dense blocks), another level of blocking can be performed to better utilize the cache.

Since blocking is our main technique of exploiting cache, it is interesting to try our algorithms on other multicore systems that have different cache systems.

**Abstract**—Recent changes in computational sciences force reevaluation of the role of dense matrix multiplication. Among others, this resulted in a proposal to consider generalized matrix multiplication, based on the theory of algebraic semirings. The aim of this note is to outline an initial object oriented model of the generalized matrix-multiply-add operation.

## I. INTRODUCTION

THE DENSE matrix multiplication appears in many computational problems. Its arithmetic complexity ( $O(n^3)$ ) and inherent data dependencies pose a challenge for reducing its *run-time* complexity. There exist three basic approaches to decrease the execution time of dense matrix multiplication.

(1) Reducing the number of (time consuming) scalar multiplications, while increasing the number of (much faster) additions; see, discussion and references in [1]. These approaches had very good theoretical arithmetical complexity, and worked well when implemented on computers with a single processor and main memory. However, due to complex data access patterns they became difficult to efficiently implement on computers with hierarchical memory. Furthermore, recursive matrix multiplication requires extra memory; e.g. Cray's implementation of Strassen's algorithm required extra space of  $2.34 * N^2$  for matrices of size  $N \times N$ .

(2) Parallelization of matrix multiplication, which is based on one of four classes of schedules ([2]): (i) Broadcast-Compute-Shift; (ii) All-Shift-Compute (or Systolic); (iii) Broadcast-Compute-Roll; and (iv) Compute-Roll-All (or Orbital). The latter is characterized by regularity and locality of data movement, maximal data reuse without data replication, recurrent ability to involve into computing all matrix data at once (retina I/O), etc.

(3) Combination of these approaches, where irregularity of data movement is exaggerated through the complexity of the underlying hardware. Interestingly, work on recursive (and recursive-parallel) matrix multiplication seems to be subsiding, as the last known to us paper comes from 2006 [3].

Note that, in sparse matrix algebra the main goal was to save memory; achieved via indexing structures storing information about non-zero elements (resulting in complex data access patterns; [4]). However, nowadays the basic element becomes a dense block while regularity of data access compensates for the multiplications by zero [5].

Generalized matrix multiplication appears in the Algebraic Path Problem (APP), examples of which include: finding the most reliable path, finding the critical path, finding the maximum capacity path, etc. Here, a generalized is based on the algebraic theory of semirings (see [6] and references collected there). Note that, standard linear algebra (with its matrix multiplication) is an example of an algebraic (matrix) semiring. Application of algebraic semirings to “unify through generalization” a large class of computational problems, should be viewed in the context of recent changes in CPU architectures: (1) popularity of fused multiply-add (FMA) units, which take three scalar operands and produce a result of  $c \leftarrow a \cdot b + c$  in a single clock cycle, (2) increase of the number of cores-per-processor (e.g. recent announcement of 10-core processors from Intel), and (3) success of GPU processors (e.g. the Fermi architecture from Nvidia and the Cypress architecture from AMD) that combine multiple FMA units (e.g. the Fermi architecture delivers in a single cycle 512 single-precision, or 256 double-precision FMA results).

Finally, the work reported in [4] illustrates a important aspect of highly optimized codes that deal with complex matrix structures. While the code generator, is approximately 6,000 lines long, the generated code is more than 100,000 lines. Therefore, when thinking about fast matrix multiplication, one needs to consider also the programming cost required to develop and later update codes based on complex data structures and movements.

## II. ALGEBRAIC SEMIRINGS IN SCIENTIFIC CALCULATIONS

Since 1970's, a number of problems have been combined into the *Algebraic Path Problem* (APP; see [7]). The APP includes problems from linear algebra, graph theory, optimization, etc. while their solution draws from theory of semirings.

A closed semiring  $(S, \oplus, \otimes, *, \bar{0}, \bar{1})$  is an algebraic structure defined for a set  $S$ , with two binary operations: addition  $\oplus : S \times S \rightarrow S$  and multiplication  $\otimes : S \times S \rightarrow S$ , a unary operation called *closure*  $*$  :  $S \rightarrow S$ , and two constants  $\bar{0}$  and  $\bar{1}$  in  $S$ . Here, we are particularly interested in the case when the elements of the set  $S$  are matrices. Thus, following [7], we introduce a matrix semiring  $(S^{n \times n}, \oplus, \otimes, \star, \bar{0}, \bar{1})$  as a set of  $n \times n$  matrices  $S^{n \times n}$  over a closed scalar semiring  $(S, \oplus, \otimes, *, \bar{0}, \bar{1})$  with two binary operations, matrix addition

## 1) Matrix Inversion Problem:

$$(\alpha) a(i, j) = a(i, j) + \sum_{k=0}^{N-1} a(i, k) \times a(k, j);$$

$$(\omega) c = a \times b + c;$$

## 2) All-Pairs Shortest Paths Problem:

$$(\alpha) a(i, j) = \min\{a(i, j), \min_{k=0}^{N-1}[a(i, k) + a(k, j)]\};$$

$$(\omega) c = \min(c, a + b);$$

## 3) Minimum Spanning Tree Problem:

$$(\alpha) a(i, j) = \min\{a(i, j), \min_{k=0}^{N-1}[\max(a(i, k), a(k, j))]\};$$

$$(\omega) c = \min[c, \max(a, b)].$$

Fig. 1. Matrix and scalar semiring operations for sample APP problems

$\oplus : S^{n \times n} \times S^{n \times n} \rightarrow S^{n \times n}$  and matrix multiplication  
 $\otimes : S^{n \times n} \times S^{n \times n} \rightarrow S^{n \times n}$ , a unary operation called *closure of a matrix*  $\star : S^{n \times n} \rightarrow S^{n \times n}$ , the zero  $n \times n$  matrix  $\bar{0}$  whose all elements equal to  $\bar{0}$ , and the  $n \times n$  identity matrix  $\bar{I}$  whose all main diagonal elements equal to  $\bar{1}$  and  $\bar{0}$  otherwise. Here, matrix addition and multiplication are defined as usually in linear algebra. Note that, special cases matrices that are non-square, symmetric, structural, etc., while not usually considered in the theory of semirings, are also handled by the above provided definition.

The existing blocked algorithms for solving the APP, are rich in generalized block MMA operations, which are their most compute intensive parts [8]. In the generalized block MMA, addition and multiplication originate from any semiring (possibly different than the standard numerical algebra). In Figure 1 we present the relation between the scalar multiply-add operation ( $\omega$ ), and the corresponding MMA kernel ( $\alpha$ ), for different semirings for three sample APP applications; here,  $N$  is the size of the matrix block (see, also [8]).

Overall, the generalized MMA is one of key operations for the APP problems, including MMA-based numerical linear algebra algorithms, which include block-formulations of linear algebraic problems (as conceptualized in the level 3 BLAS operations [9], and applied in the LAPACK library [10]).

## III. MATRIX OPERATIONS AND COMPUTER HARDWARE

In 1970's it was realized that many matrix algorithms consist of similar building blocks (e.g. a vector update, or a dot-product). As a result, Cray computers provided optimized vector operations:  $y \leftarrow y + \alpha x$ , while IBM supercomputers featured optimized dot products. This resulted also in creation of libraries of routines for scientific computing (e.g. the *scilib* library on the Cray's, and the *ESSL* library on the IBM's). Separately, the first hardware implementation of the fused multiply-add (FMA) operation was delivered in the IBM RS/6000 workstations [11]. Following this path, most current processors from IBM, Intel, AMD, NVidia, and others, include scalar floating-point FMA [12]. Observe that, the basic arithmetic operations: add and multiply, are performed by the FMA unit by making  $a = 1.0$  (or  $b = 1.0$ ) for addition, or  $c = 0.0$  for multiplication. Therefore, the two fundamental constants, 0.0 and 1.0, have to be available in the hardware. Therefore, processors that perform the FMA implement in hardware the scalar (+,  $\times$ ) semiring.

Obviously, the FMAs speed-up ( $\sim 2\times$ ) the solution of scientific, engineering, and multimedia algorithms based on the linear algebra (matrix) transforms [13]. On the other hand, lack of hardware support penalizes APP solvers from other semirings. For instance, in [8] authors have showed that the "penalty" for lack of a generalized FMA unit in the Cell/B.E. processor may be up to 400%. Obviously, this can be seen from the "positive side." Having hardware unit fully supporting operations listed in Figure 1 would speed up solution of APP problems by up to 4 times. Interestingly, we have just found that the AMD Cypress GPU processor supports the (min, max)-operation through a single call with 2 clock cycles per result. Therefore, the Minimum Spanning Tree problem (see, Figure 1) could be solved substantially more efficiently than previously realized. Furthermore, this could mean that the AMD hardware has build-in elements corresponding to  $-\infty$  and  $\infty$ . This, in turn, could constitute an important step towards hardware support of generalized scalar FMA operations needed to realize many APP kernels(see, also [8]).

In the 1990's three designs for parallel computers have been tried: (1) array processors, (2) shared memory parallel computers, and (3) distributed memory parallel computers. After a number of "trials-and-errors," combined with progress in miniaturization, we witness the first two approaches joined within a processor and such processors combined into large machines. Specifically, while vendors like IBM, Intel and AMD develop multi-core processors with slowly increasing number of cores, the Nvidia and the AMD develop array processors on the chip. However, all these designs lead to processors consisting of thousands of FMA units.

## IV. PROPOSED GENERALIZED MULTPLY-AND-ADD

Based on these considerations, in [14] we have defined a generic generalized matrix-multiply-add operation (MMA),

$$C \leftarrow \text{MMA}[\otimes, \oplus](A, B, C) : C \leftarrow A \otimes B \oplus C,$$

where the  $[\otimes, \oplus]$  operations originate from different matrix semirings. Note that, like in the scalar FMAs, generalized matrix *addition* and *multiplication*, can be implemented by making an  $n \times n$  matrix  $A$  (or  $B$ ) =  $\bar{0}$  for addition, or a matrix  $C = \bar{I}$  for multiplication (see, Section II).

Obviously, the generalized MMA resembles the `_GEMM` operation from the level 3 BLAS. Therefore, in [14] it was shown that, except for the triangular solve, BLAS 3 operations can be expressed in terms of the generalized MMA (in the linear algebra semiring). Note also that the proposed approach supports the idea that, in future computer hardware, data manipulation will be easiest to complete through matrix multiplication. Specifically, since the MMA represents a linear transformation of a vector space, it can be used for reordering of matrix rows/columns, matrix rotation, transposition, etc. Furthermore, operations like global reduction and broadcast can be easily obtained via matrix multiplication (see, [2]).

In summary, the proposal put forward in [14] covers three important aspects: a) it subsumes the level 3 BLAS, b) it generalizes the MMA, to encompass most of APP kernels,

and c) allows for new way of writing APP kernels, optimized for computers consisting of large number of processors with thousands of generalized FMA cores each, and simplified to support code maintainability.

## V. STATE-OF-THE-ART IN OBJECT ORIENTED BLAS

While our work extends and generalizes dense matrix multiplication, its object oriented (OO) realization should be conceptually related to OO numerical linear algebra, including the OO BLAS. Here, we briefly introduce selected OO realizations of numerical linear algebra in general, and BLAS in particular: MTL, uBLAS, TNT, Armadillo, and Eigen.

The uBLAS project ([15]) was focused on design of a C++ library that provided BLAS functionality. An additional goal of uBLAS was to evaluate if the abstraction penalty, resulting from object orientation, is acceptable. The uBLAS was guided by: (i) Blitz++ [16], POOMA [17], and MTL [18]. Data found on the Web indicates that the project was completed around 2002 and later subsumed into the BOOST [19] library.

The TNT project ([20]) is a collection of interfaces and C++ reference implementations that includes, among others, operations on multidimensional arrays and sparse matrices. The library, while not updated since 2004, can still be downloaded from the project Web site.

The MTL project remained active until around 2008-09, when the last paper/presentation concerning the MTL 4 was reported. Interestingly, this project provided not only an open source library, but also a paid one (more optimized).

There are two projects that are vigorously pursued today: Armadillo ([21]; last release on June 29, 2011) and Eigen ([22]; last release on May 30, 2011). Both support an extensive set of matrix operations. While Eigen seems to be focused on vector processor optimizations, Armadillo “links” with vendor optimized matrix libraries: MKL and ACML.

## VI. INITIAL OBJECT ORIENTED MODEL

Following the ideas described above, in Figure 2 we depict our proposed OO model for the generalized matrix multiplication. Here, we see the interface to be made available to the user. It will allow to instantiate needed matrices and develop code with generalized matrix operations: matrix addition, matrix multiplication, and the MMA. We also define the abstract class *scalar\_Semiring* needed to define operations of the *scalar* semiring (operations on elements of matrices).

The main class is the *Matrix* class. It describes how the matrix operations defined in the interface class are realized. Among others, it contains the MMA function, which is used to actually realize the matrix operations. The implementation of the MMA function is to be provided by the user, or by the hardware vendor (in a way similar to the vendor-optimized implementation of BLAS kernels).

Finally, we depict a sample specialization of the *scalar\_Semiring* class (for the Shortest Path Problem; see, Figure 1), with elements from the  $R_+$ ,  $\bar{0} = 1$ ,  $\bar{1} = \infty$ ,  $\oplus = \min$ , while  $\otimes = +$ . Based on this specific scalar semiring (and, possibly, a generalized FMA unit), the appropriate MMA operation is implemented in the *Matrix* class.

## VII. SAMPLE REALIZATION

Let us now recall that one of our goals is to simplify code development (in a way that the BLAS simplified it 30+ years ago). Therefore, code should be as simple as possible, with details of the implementation hidden. With this in mind, let us start from defining the interfaces. The *Matrix\_interface* defines operations available to the user to write her codes (for simplicity, our description is limited to square matrices).

```
interface Matrix_interface {
    Init(n); //initialisation of square matrix nxn
    Matrix matrix0(n)
        { /*generalized 0 matrix*/ }
    Matrix matrix11(n)
        { /*generalized identity matrix*/ }
    Matrix operator +
        { /*generalized matrix addition A+B*/ }
    Matrix operator *
        { /*generalized matrix product A*B*/ }
    Matrix Column_Permutation (A,i,j)
        { /*generalized permutation of column i
            and j in matrix A*/ }
    Matrix Row_Permutation (A,i,j)
        { /*generalized permutation of column i and
            j in matrix A*/ }
};
```

Here, user can create matrix objects, zero and identity matrices (for a given semiring). Furthermore, we define generalized matrix operators and two permutation matrices. This interface can be extended to include other user-defined operations. Next, we define the *scalar\_Semiring* class.

```
abstract class scalar_Semiring {
public:
    //T — type of element;
    zero, one:T;
    +: c=a+b;
    *: c=a*b;
};
```

It specifies generalized operations *addition* and *multiplication* as well as elements  $\bar{0}$  and  $\bar{1}$ . It has to be provided by the user, to “select” the semiring.

With the two interfaces in place, we can define the core class *Matrix*, which is **not** made visible to the user (is internal to the realization of the generalized MMA). It inherits the *scalar\_Semiring* interface, and implements the *Matrix\_interface* interface.

```
class Matrix inherit scalar_Semiring
    implement Matrix_interface {
T: type of element; /*double, single, ... */
n: int;
// Methods
Init(n); //initialisation of square matrix nxn
Matrix matrix_0(n) { /*generalized 0 matrix*/ }
Matrix matrix_1_1(n) { /*generalized identity matrix*/ }
Matrix matrix_IP(i,j,n)
    { /*generalized identity matrix with interchanged
        columns i and j*/ }
Matrix A+B { return MMA(A,M1: matrix_1_1(n),B) }
Matrix A*B { return MMA(A,B,M0: matrix_0(n)) }
Matrix Column_Permutation (A,i,j){
    P=matrix_IP(i,j,n);
    O=matrix_0(n);
    return MMA(P,A,O) }
Matrix Row_Permutation (A,i,j){
    P=matrix_IP(i,j,n);
    O=matrix_0(n);
    return MMA(A,P,O) }
...
private MMA(A,B,C: Matrix(n)) {
```

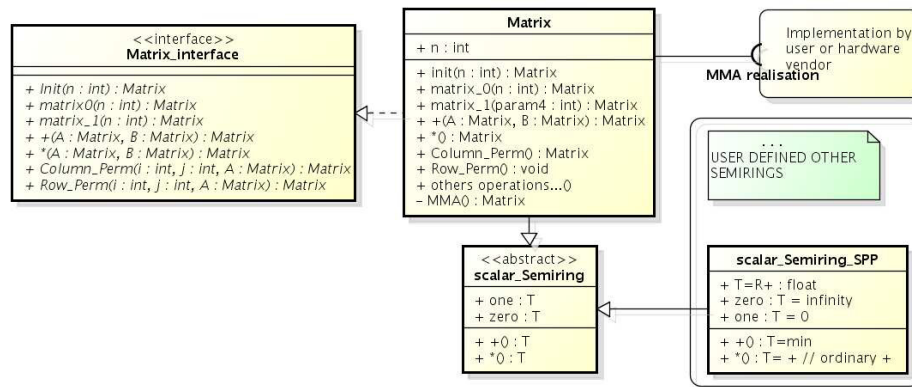

Fig. 2. General schema of the proposed object oriented model of generalized matrix multiplication

```

return vendor/user specific realization of
MMA = C+A*B where+ and * are from
class scalar_Semiring }
}

```

The key part of this class is the private function MMA. This is the actual ( user/vendor specific) realization of the MMA operation. As a result, user can perform operations:  $A \oplus B$ ,  $A \otimes B$ , or  $C \oplus A \otimes B$ , written in the code as  $A + B$ ,  $A * B$ , or  $C + A * B$  without any knowledge of their actual hardware/software realization. Observe also, that matrix column permutation, and row permutation have been defined in operations *Column\_Permutation* and *Row\_Permutation*, which are implemented through a call to the MMA function with appropriate matrices (see, also [14]).

Finally, in the next snippet we show the class *scalar\_Semiring* rewritten for the Shortest Path Problem (see, Figure1). After defining this class the user can simply apply the generalized MMA operation within the solver.

```

/*T = R+ PLUS infinity , + = min , * = + ,
ZERO = infinity , ONE = 0; */

```

```

class scalar_Semiring {
    zero="infinity";
    one=0;
    a+b = min(a,b);
    a*b = a+b;
}

```

## VIII. CONCLUDING REMARKS

The aim of this paper was to propose the object model for the generalized matrix multiplication. The proposed approach is not language specific and presented at a very high level. Next, we will proceed with its more detailed realization in most important languages used in scientific computing.

**Abstract**—We consider the 3D time dependent Stokes equation on a finite time interval and on a uniform rectangular mesh, written in terms of velocity and pressure.

For this problem, a parallel algorithm, based on a recently proposed direction splitting approach, is applied. Here, the pressure equation is derived from a perturbed form of the continuity equation, where the incompressibility constraint is penalized in a negative norm induced by the direction splitting. The scheme used in the algorithm is composed of: (a) pressure prediction, (b) velocity update, (c) penalty step, and (d) pressure correction. In order to achieve good parallel performance, the solution of the Poisson problem for the pressure correction is replaced by a solution to a sequence of one-dimensional second order elliptic boundary value problems (in each spatial direction). The efficiency and scalability of the proposed approach are tested on two distinct parallel computers and the experimental results are analyzed.

## I. INTRODUCTION

**T**HE OBJECTIVE of this note is to analyze the parallel performance of a novel fractional time stepping technique, based on a direction splitting strategy, developed to solve the incompressible Navier-Stokes equations.

Computational fluid dynamics (CFD) has undergone tremendous development as a discipline. This has been made possible by progresses in many fronts, including numerical algorithms for the Navier-Stokes equations, grid generation and adaptation, turbulence modeling, flow visualization, as well as the dramatic increase of computer CPU and network speeds.

Finding an approximate solution of the Navier-Stokes equations can be done by a large range of numerical methods. Among these, finite element methods are used mostly by mathematicians, while spectral methods and finite volume methods are favored by engineers and physicists. One reason for this difference in computational practices is that an advantage of finite volume methods over finite element ones lies primarily in ease of their physical interpretation and in simpler implementation. Currently, nearly all production-class flow solvers are based on second-order numerical methods, either finite volume [9], [10], [23], [25], finite difference [33], or finite element [4], [11], [12], [18], [20]. They are capable of delivering,

within a few hours, design-quality Reynolds Averaged Navier-Stokes results with several million cells (degrees of freedom) on various Beowulf-style cluster computers.

The efficient solution of the discretized Navier-Stokes equations necessitates rapidly convergent iterative methods. The two main approaches available here are: (i) preconditioned Krylov subspace methods [30], and (ii) multigrid methods [35], [36], [38]. These two approaches can be combined by using one or more multigrid cycles as preconditioners for the Krylov-type methods. Most of recent papers on the iterative solution of the discretized Navier-Stokes equations are devoted to block preconditioners [3], [7], [21], [31]. Here, more recent contributions include the preconditioning based on the augmented Lagrangian approach [3], and the least-squares commutator preconditioner generalized to the stabilized finite element discretizations of the Oseen problem [8]. Other relevant work includes the development of ILU-type preconditioners for saddle-point problems [28], and SIMPLE-type block preconditioners [29].
