The latter use case scenario involves the academic teachers or administration staff (e.g. dean office). Nowadays they usually communicate with the selected student using emails. Then the leader of the student's group is obligated to pass the information received to the rest of the group. Although emails are reliable and secure mean of communications, in the case of urgency this approach might be ineffective. SMS or USSD messages provide similar level of security and reliability but due to immediate delivery are the most appropriate for such situations. The use of proposed solution creates the possibility to inform all the interested students at once just by creating notification to the target messaging group.

Aforementioned examples only show the base system functionalities and application possibilities. Due to open and distributed architecture the proposed solution might be easily adopted to new application scenarios.

IV. SUMMARY

In the paper we presented a prototype Student Information Delivery Platform. Proposed system architecture consists of two joined independent modules:

- Interactive Lecture Room Timetable Delivery Subsystem which allows to create, manage and display interactive timetables at the entrances to the lecture rooms,
- Student Massive Messaging Subsystem (SMMS) which makes it possible to send notifications to predefined groups of students or academics. The system incorporates SMS, USSD and email messaging in order to suit various delivery time and reliability needs.

Joint use of the proposed subsystems allows instant notification of the users on unexpected changes to the timetables as well as facilitates communications between academics and student groups. Future system development plans include implementation of RESTful northbound interfaces in all the key components as well as implementation of interfaces enabling integration with already deployed campus systems.

International Conference on Wireless Sensor Networks

A FEW years ago, the applications of WSN were rather interesting example than a powerful technology. Nowadays, this technology attracts still more and more scientific audience. Theoretical works, where the WSN principles were investigated, grew into the interesting practical applications integrated by this time in a real life. Various application fields, from military to healthcare, are already covered by WSN. Hand in hand with WSN application coverage expansion, still new and new tasks bringing along the new interesting problems occur. Therefore such application practices stimulate the progress of WSN theory as well as unlock new application possibilities.

Wireless sensor networks, as the spatially distributed networks consisted of relatively simple components interconnected mutually, provide quite wide application potential to be utilized in military, industry, transport, agriculture, healthcare and many other branches. However, in the near future, even higher growth of WSN application coverage could be expected. This expansion is nevertheless conditioned by solving questions related to the communication protocols standardization, to the lack of effective energy sources enabling network nodes working time prolongation, as well as to the progress in the field of ultra-low-power microelectronic components industry. An integration of WSN within the public data networks as well as within the domains where confidential and private data are proceed (e.g. E-Health) brings about problems related to the ethical and legal questions too.

The WSN is one of actual affairs getting to the fore in the European Research Area since the issue of Future network technologies research and innovation is planned to be included in the new HORIZON2020 FP7 program.

It is therefore necessary to create an experience-sharing platform for scientific researchers and experts from research institutes and WSN occupied companies that employ benefits of this modern technology and to the exchange of skills, experiences and new ideas from the WSN problematic within the all participants of iNetSApp.

Topics

Original contributions, not currently under review to another journal or conference, are solicited in relevant areas including, but not limited to, the following:

Development of sensor nodes and networks

- Sensor Circuits and Sensor devices – HW
- Applications and Programming of Sensor Network – SW
- Architectures, Protocols and Algorithms of Sensor Network
- Modeling and Simulation of WSN behavior
- Operating systems

Problems dealt in the process of WSN development

- Distributed data processing
- Communication/Standardization of communication protocols
- Time synchronization of sensor network components
- Distribution and auto-localization of sensor network components
- WSN life-time/energy requirements/energy harvesting
- Reliability, Services, QoS and Fault Tolerance in Sensor Networks
- Security and Monitoring of Sensor Networks
- Legal and ethical aspects related to the integration of sensor networks

Applications of WSN

- Military
- Health-care
- Environment monitoring
- Transportation & Infrastructure
- Precision agriculture
- Industry application
- Security systems and Surveillance
- Home automation
- Entertainment – integration of WSN into the social networks
- Other interesting applications

***Abstract*— In this paper, the system presents an integrated wireless sensor network (WSN) to monitor the information from agriculture systems namely temperature, humidity, pondus hydrogenii (pH) value…etc. The purpose is to provide a faster and more convenient platform for the client to obtain information from an array of sensor nodes that has been set-up in an agricultural system. A WSN will collect the values of various parameters from the front-end sensors at the host end. At the client sides, one can use the internet to request for Web Services that will store this big data into distributed SQL databases which are already in our proposed cloud system. In addition, this work presents the concept of cloud computing and services. The benefits of this system include basic computing hardware and reasonable storage capacities making it suitable for any smart device which can monitor real-time farmland information anywhere. The customers can fully access our cloud service using devices that have internet capabilities.**

I. Introduction

WIRELESS sensor network (WSN) consists of a large number of sensor nodes that are interconnected to form a wide communication network. Usually, it can achieve small size, low cost, low power consumption, fewer network components and other features easily. In recent years, it has been readily implemented in agriculture, industry, environmental protection and other fields.

With the development of hardware limitations, and in pursuit of a better performance and enhancing greater computing capability, people turn to find other techniques to achieve these goals. Therefore, the concept of "Cloud" was born. In fact, as early as the Internet appeared, the "Cloud" has already existed silently providing for us some services.

In recent years, the "Cloud" concept has become more and more popular, especially on the business sector. There are also many types of cloud computing platforms such as Google, Amazon, IBM, and Microsoft…etc. However, the true essence of using "clouds" was not completely understood. "Cloud" was then not a specific technology but rather a concept.

II. Cloud Computing

"Cloud" refers to a network. In the beginning, engineers drew a network diagram in the form of a cloud to represent Wide Area Network. This had an undefined volume of interconnected computers and network routers [1]. So to the client, this "cloud" was just a means of interacting with other sides.

A. Distributed Computing

According to literal interpretation [2], the idea of distributed computing is to divide the whole work load into smaller units. Each work fragment will be given to a corresponding slave computer that will do the computing and then will send back the results to the master computer. This is shown in Fig. 2.

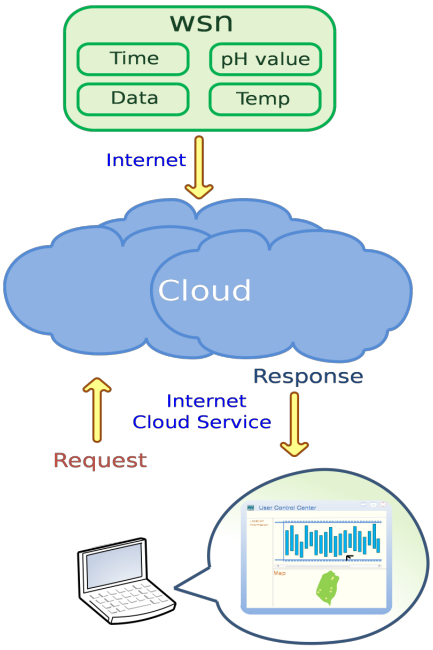

Fig. 1. Cloud concept

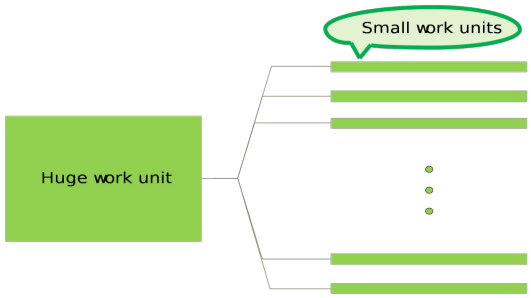

Fig. 2. Distributed computing

Through this technique, cloud computing can achieve a similar processing power to that of a "Super computer" with relatively lower cost and lesser fabrication complexity.

B. Virtualization Technology

Virtualization is a kind of software technology which can be applied to many fields. In fact, the concept of "Cloud" appeared very early [3], but due to lack of network bandwidth, insufficient storage space, and premature virtualization technology it was unstable and lacked flexibility.

However, with the development of virtualization technology, the development of clouds has been accelerated. In the past, our computing power was based on personal computers locally, but through virtualization technology we can now use cloud computing power which is centralized.

The proposed cloud system consists of a master server computer and four virtual slave server computers. The data are distributed onto the respective storage spaces of the four slave server computers which shall be used in the distributed computing process.

III. Database Design

A. Database Concept

Database refers to a particular subject or a theme arranged in a structured set of multiple and complex data in the computer. As a storage structure, the database can be broadly divided into: Hierarchical, Network, Relational, and Object-oriented. We used relational database in our project. Relational database is a database that has a collection of tables of data items which are formally described and organized based on the relational model. In this model, each table must identify a column or group of columns referred to as the "primary key" to uniquely identify each row. The rows of one table can relate to rows of another by establishing a "foreign key" which is a column or group of columns in one table that points to the primary key of another table.

B. Stored Procedure

The Stored Procedure (SP) could be divided into four instructions : Insert, Update, Delete, and Select in the database. These basic instructions can also control the data in the database and even combine more complex instructions so that the user can handle data more efficiently. In this project, we used T-SQL to write the database instructions. Every time one accesses a regular database, it has to check the syntax and this consumes a lot of time. So we implemented another technology that is "Stored procedure" which is written using T-SQL. Stored procedure will process the composition, verify the syntax by T-SQL, and then store. After that, one just needs to use it directly.

IV. Web Service Design

A. Web Service Concept

With XML (Extensible Markup Language), SOAP (Simple Object Access Protocol), WSDL (Web Service Description Language), UDDI (Universal Description, Discovery and Integration) appearing one by one, Web Service-oriented software, a new generation of distributed computing technology, and Web Services were born. Web Service through the open-type standard (e.g. XML, SOAP... etc.) of Web communication protocol alongside with the data provides services to other applications. Web Service consists of reusable components that can be published, discovered and invoked across the Web [4].

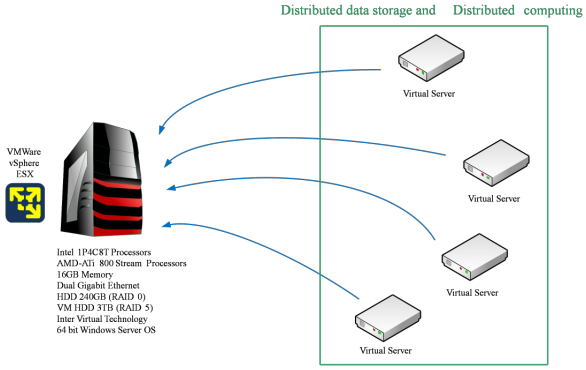

Fig. 3. Cloud system structure

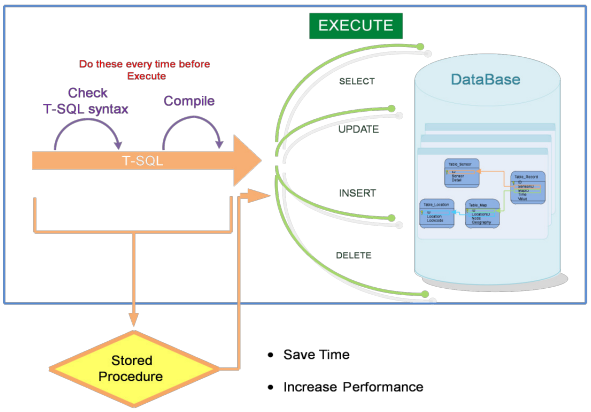

Fig. 4. Stored procedure's concept

Its basic function is to respond to the call from the client to the server. Its purpose is to let the application from different platforms intercommunicate. When using the program, one inputs a value onto it, and then the program will request the Web Service to compute. The project used C# to design the user interface; while the platform was built

using .NET that can do the integration and implement the application.

B. Related Technologies

XML is a language form and a kind of syntax which can easily be read by the user and that the computer program can easily identify. It emanated from the SGML (Standard Generalized Markup Language). XML was developed by the XML Working Group, an organization formerly known as SGML Editorial Review Board; and so, XML is reviewed by a group of SGML experts. XML does not replace HTML. HTML focuses on how the file appears in the browser; while XML focuses on how to represent them in a structured way.

SOAP, Simple Object Access Protocol, SOAP is a kind of protocol that defines the way XML data are delivered and the various transmission protocols, like HTTP, FTP, SMTP, and TCP. SOAP uses XML as the data transmission format, and combines with the aforementioned transmission protocols to send the message.

C. LINQ-to-SQL

LINQ is a kind of method to link different program languages. Without LINQ, it is hard to establish a communication link between the SQL database and the programming language. LINQ can do object-oriented programming; it can also make the T-SQL language easily readable in C#, where the basic language is different; and it can also automatically generate the corresponding data type.

V. User Control Center

The relationship between user control center and Web Service are divided into two directions: “data” and “Panorama Map”.

A. Data Curve

Due to the large amount of data coming from the front-end sensors of temperature, humidity, and pH value… etc., a virtual machine is therefore used as a storage medium whose contents shall later be extracted via the Web Service. The process is as follows: one will first get the display window size to the Web Service, then he will extract the quantity of data from the database. The cloud will then compute the result which will be fitted onto the screen. [5]

B. Panorama Map

Because the farm we can monitor can be of large scale covering entire Taiwan or even the whole world, we therefore made reference to the operation of Google map. At first, the program will send the start instruction to let the cloud side know the user side’s display window size, and then the cloud will compute the image result and relay it back to the user control center.

Seven parameters have been designed to operate the map, namely: user control center’s display window width and height, X and Y coordinates of present location map, X and Y coordinates of displacement, and the presented map hierarchy.

When the user zooms in or out of the map, the user control center will send the new map’s hierarchical parameters to the cloud to regain the map. As the map’s display is maximized, it will show the images of the farmland as well as the corresponding sensor information. When the sensor is clicked, the user will get its information and data.

C. Interface

The design of the data curve is divided into three parts, namely: initial, static and dynamic. Regardless of whether the user starts the user control center or changes the window size, the coding of the initial status will still redraw the screen. It will calculate the window size, split the X axis, and then use the amount of data it gets from the Web Service to calculate the initial screen size.

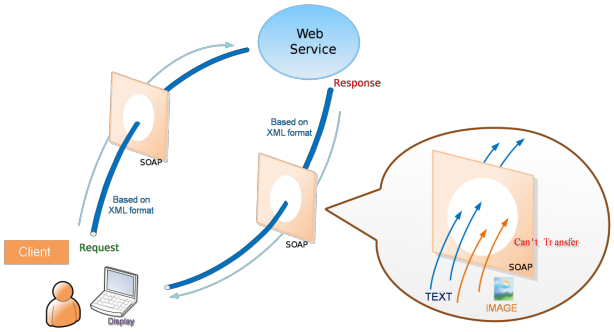

Fig. 5. Web Service concept

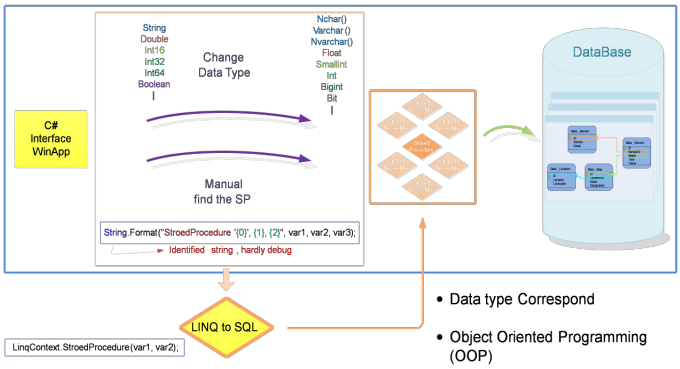

Fig. 6. LINQ-to-SQL concept

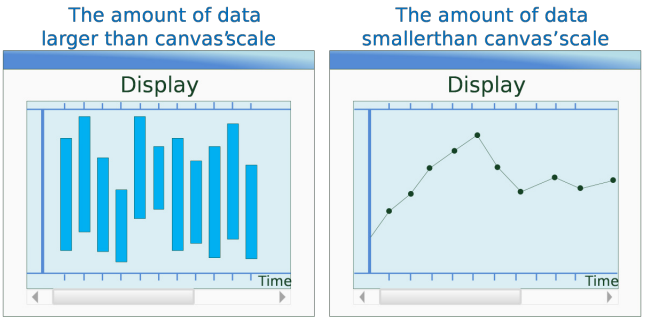

Fig. 7. Relation between data curve and data

The design of the relational database involves two concepts: one is that the data in the database should not be multiple repetitions, and the other is that two separated

tables should be established with a correct relation to ensure the consistency. A good database design depends on its characteristics. Because of the related characteristics, data duplication between tables can be minimized. This design results into saving the storage space and establishing a correct relation. Hence, one doesn't need to modify each data over and over again.

VI. Conclusion

The system proposed an internet database design by using the SQL database, LINQ-to-SQL technique, Web Service, virtualization technology and C# interface. By using this paper's method, the client's end can monitor the environmental condition of the agricultural place at any place. The major elements of this work are wireless network applications, C # interface, cloud computing system, database design, Web Service, and user control center.

Data packets were sent via a USB connection to the host-end which transmits the values of various environmental parameters coming from the front-end sensors. The number of WSN nodes can be more than 600,000 and each node can return the value for every one second. Therefore, the database will become enormous. The issue of quick access of information at the client end has been addressed by our system. C# interface will be designed to display the data curve which will aid in the decision making of the client with regard to getting better yield from his farm. Besides this, the sensor data will be uploaded to the cloud database allowing the client to use our Cloud Service as long as the user's display facility has internet connectivity.

Acknowledgment

The proponents of this work would like to acknowledge the National Science Council, Taiwan, ROC for funding this project (NSC 102-2221-E-033-066). The work would also like to extend its gratitude to Chip Implementation Center (CIC) for the technical support given.

***Abstract*—The extensive use of the Wireless Sensor Networks (WSNs) in main critical scenarios stresses the need to verify their dependability properties at design time to prevent wrong design choices and at runtime in order to make a WSN more robust against failures that may occur during its operation. In literature, several approaches have been proposed in order to evaluate the dependability of a WSN during its inception and its operating.**

In this paper we present a survey on these adopted techniques reporting aspects and characteristics of some research studies. Moreover, by means of a comparison grid, we analyze the current state-of-the-art of the approaches of WSN dependability assessment in order to identify the most performant and to discuss the ongoing challenges.

***Index Terms*—Wireless Sensor Networks, Dependability, Reliability, Fault-Tolerance**

I. Introduction

NOWADAYS Wireless Sensor Networks (WSNs) are usually involved for critical systems monitoring [1][2] and in smart environments [3], thus the recent scientific production on WSNs dependability assessment is grown .

Unexpected events, such as node crash and packet loss, may affect the dependability of the WSN and hence it is necessary evaluate its robustness from the early stages of the development process (*design phase*) onwards to minimize the chances of unexpected problems during use. It is also crucial to monitor a WSN at runtime (*operating phase*) and to detect undesired effects that cannot be analyzed before the WSN deployment.

The approaches adopted in literature to assess WSN dependability, at *design time* or *runtime*, can be categorized in four classes: *experimental*, *simulative*, *analytical* and *formal*.

The first allows to analyze dependability at runtime by means of experiments. Experimental methods are used to evaluate a real system and they require the deployment of a real WSN. They are useful in operating phase since by means of them we can perform experiments directly on the real system from which we collect data. Among the experimental approaches we consider the *Fault Injection* techniques[4] which allow to evaluate the dependability of a real WSN by injecting faults.

The simulative approaches make use of well-known simulators that can be adopted at design time; this kind of approach consists in modeling the WSN and making an estimate of the dependability. In a similar way analytical approaches are conceived; the difference is in considering mathematical models to check the WSN behavior during the design. Finally, formal approaches use specifications of correctness and they can be adopted to assess WSN dependability both at design time and at runtime. Formal approaches offer a new opportunity for studying the WSN dependability.

The aim of this paper is to revise experimental, simulative, analytical and formal approaches and tools currently used in the field of WSN dependability assessment, including related studies. We want to provide a survey on the main approaches adopted for the WSN dependability assessment evaluating the best choice to perform dependability assessment of WSNs. A comparison of related work is presented to summarize the state-of-art and reason about what is still missing and the ongoing challenges.

The rest of the paper is organized as follows. In Section II experimental approaches are presented; the Section III includes the simulative approaches. An analysis of analytical approaches is documented in Section IV and the formal approaches are discussed in Section V. Finally in Section VI we report a comparison of the discussed papers and the Section VII ends the paper with conclusions.

II. Experimental Approaches

Experimental approaches are used to measure the WSN dependability directly from a real system, during its operation. In the prototyping phase, it is possible to perform an accelerated testing, for example by forcing a fault (by means of *Fault Injection* (FI) [4], [5]); it is also possible to collect occurring failures directly from system (by means of *Field Failure Data Analysis (FFDA)* techniques [6]).

FI is defined as the dependability validation technique based on the observation of the system behavior under the presence of faults which are deliberately introduced into the system [7].

Typically FI is used to i) assess the dependability level of a target system, such as an operational systems, a system

This work has been partially supported by the "Se@me: Sustainable e-maritime @ssistance for Maritime Employees, Passengers and Yachtsmen" project, funded under the "POR Campania 2007/2013 " initiative of the Regione Campania - Italy.

TABLE I
FAULT INJECTION TOOLS

Tool	Technique	Fault Model
XCEPTION [8]	SWIFI with exception trigger	Transient faults
FERRARI [9]	SWIFI with interrupt, fork, trap	Transient and permanent faults
FIAT [10]	SWIFI with exception trigger	Bit-flip faults in the memory
NFTAPE [11]	SWIFI with exception trigger	Several types of faults (*arbitrary model*)
MESSALINE [12]	HWIFI with forcing and insertion	Faults of type *stuck-at-0*, *stuck-at-1*, *logical bridging*, *physical bridging*
AVR-INJECT [4]	SWIFI with exception trigger	Bit-flip faults in the memory area, code area and special registers

prototype, or an emulated execution environment (the last two options are used especially in the pre-deployment phase of the system), and ii) to shed some light on the design choice of a system, for instance, showing its potential dependability bottlenecks. FI tries to determine whether the response of a system matches its specifications in the presence of a defined space of faults.

The implementation of tools for injecting faults has been the focus of several studies. Table I reports a summary of well known tools for fault injection in WSN and in other types of systems. Beyond their inherent differences, they operate in a similar way: each of them performs a study of the fault-free target, obtaining a 'gold file'; then, it injects a fault (obtaining the 'fault file') and it compares the gold file with the fault file, to evaluate the system behavior in response to the fault. Among of the tools mentioned in the table I, there is the AVR-Inject Tool which has been conceived to operate with WSNs. Unfortunately the AVR-Inject tool cannot be used at design time since it needs a prototype of the system, an assembly code that runs on the sensors and thus it needs very detailed information in design phase. Cinque et al. in [13] perform a fault-injection campaign in order to analyze the dependability for three different WSN operating systems (TinyOS, MantisOS, LiteOS). They consider a fault model without taking in account some dependability metric.

Field Failure Data Analysis (FFDA) [14] of a system represents the set of fault forecasting techniques which are performed at runtime. By means of this analysis, the dependability attributes of an actual and deployed system are measured considering real conditions. A system which is in normal operation is observed and the natural occurring errors and failures are monitored and recorded in log files. The FFDA is not practical, not feasible for the WSNs since they do not provide log and they have to be lightweight [15].

Other experimental approaches are described in [16] and [17].

In [16] authors present a deployment of 27 Crossbow Mica2 motes that compose a WSN. They describe a Structure-Aware Self-Adaptive WSN system (SASA) designed in order to detect changes of the network due to unexpected collapses and to maintain the WSN integrity. Detection latency, system errors, network bandwidth and packet loss rate are measured; coverage and connection resiliency metrics are not considered. A large scale simulation is performed in order to evaluate the system scalability and reliability.

Pennington et al. [17] assert that, due to the high complexity of the WSN dynamics, it is difficult to predict problems that may occur after the deployment of the WSN. Therefore, in their paper they propose a Integrity-Checking framework which considers real inputs for the testing and validation process. No case study is shown for framework evaluation.

Experimental approaches for WSN dependability assessment allow to gain insight in the actual failure behavior of WSNs and to establish the reliability degree of the network. However, results are difficult to reproduce and for this reason research studies on WSNs have migrated towards simulative and analytical approaches.

III. SIMULATIVE APPROACHES

A simulative approach for assessing WSNs usually makes use of behavioral simulators, i.e., tools able to reproduce the expected behavior of a system by means of a code-based description. Behavioral simulators allow to reproduce the expected behavior of WSN nodes on the basis of the real application planned to be executed on nodes. However, it is not always possible to observe non-functional properties of WSNs by means of simulative approaches, since models need to be redefined and adapted to the specific network to simulate.

Typical simulative approaches to evaluate WSN fault/failure models are provided in [18] and [19].

In [18] authors address the problem of modeling and evaluating the reliability of the communication infrastructure of a WSN. Authors assume that failures can be categorized in node and network failures.

The first on-line model-based testing technique [19] has been conceived to identify the sensors that have the highest probability to be faulty. The effectiveness of the approach is evaluated in the presence of random noise using a system of light sensors; a fault classification taxonomy is introduced.

Some work like [20] and [21] provide code generation of wireless sensor network applications to perform behavioral simulation and performance analysis.

In [20], a framework for modeling, simulation and code generation of WSNs is presented. The framework is based on Simulink, Stateflow and Embedded Coder; it allows engineers to simulate and automatically generate code of sensor network applications based on MathWorks tools. By means of this tool, an application developer can configure the connectivity of the sensor nodes and can start simulation and functional verification of the application. This framework is able to generate the complete application code for several target operating systems (e.g. TinyOS and MantisOS) from the simulated model.

In [21] a model-driven development process (MDD) is presented to obtain a major effort of optimization for WSN applications. In this work a set of modeling languages is the starting point for code generation and performance analysis.

Finally, the network lifetime is analyzed in [22]; to calculate the lifetime of a WSN, the authors perform simulation by means of a Castalia-based approach [23] that models path-loss.

A. Simulators

Several simulators for WSNs have been proposed in literature, such as *NS-2*, *OMNet++*, *Prowler*, *TOSSIM*, *OPNET* and *Avrora*.

NS-2 [24] is an event-based simulation tool for WSN. It is amply adopted in academic research being open source and easy to use. The simulations are written with C++/C languages and they can be observed graphically by Network AniMator (NAM).

OMNeT++ [25] is a component-based discrete network simulator. Even this simulator is based on C++ language and it has graphical tools for simulation building and evaluating results in real time. The most recent simulation environment built on OMNeT++ is Castalia [23]. This framework was realized for Wireless Sensor Networks, Body Area Networks [26] and networks of low-power embedded devices and it allows to test distributed algorithms and protocols for WSN considering some features of a real WSN like wireless channel, power consumption and considering a real node behavior. Castalia can be used to simulate a wide set of wireless sensor platforms.

Prowler [27] is an event-driven WSN simulator conceived to operate in Matlab environment. Initially it was realized to simulate MICA motes but then it has been extended also for more general platforms. Advantages of Matlab environments are simple implementing of applications, friendly GUI interface and good visualization facilities. By means of this simulator, it is possible to perform deterministic simulation to test application code of a WSN application and to perform probabilistic simulation to observe the behavior of the sensor nodes.

TOSSIM [28], [29] is the simulator built for TinyOS applications. Actually it is an emulator rather than a simulator since it runs actual application code; it allows to simulate the hardware of a sensor but it does not provide information about WSN dependability. Moreover TOSSIM is provided of a visualization tool, TinyViz.

OPNET [30] is a discrete event, object oriented network simulator. This tool was developed initially for military purposes but its large use grew as much to be considered also for commercial use. OPNET is a powerful software that can be used for research purpose and also as a network design tool.

Finally Avrora [31] is a simulator that adopts an approach which is more oriented to the verification of behavioral properties or performance indicators, and not oriented to the observation of dependability properties. It is a low-level emulator of the AVR processor mainly used to test the behavior of WSNs application prior to their deployment. It executes the disassembled code instruction per instruction and emulates the hardware of the processor and the hardware of the node (memory, LEDs, sensors, radio channel, etc.).

IV. Analytical Approaches

The study of the performance and dependability of WSNs can be performed by means of analytical models [32]. Some of these models are based on a mathematical representation of the WSN characteristics and are solved by means of simulation.

In [33] authors introduce an approach for the automated generation of WSN dependability models, based on a variant of Petri nets.

An analytical model to predict the battery exhaustion and the lifetime of a WSN, *LEACH*, is discussed in [34].

In [35] the authors present a network state model used to forecast the energy consumption of a sensor.

AboElFotoh et al. [36] present a probabilistic technique to observe the WSN behavior and discuss about dependability of a WSN; they suppose that the main causes of the failures are related to the crashes, power failures and natural causes. The authors evaluate dependability on the basis of the number of packets received by the sink in a deterministic time (*decision interval*). The dependability is computed evaluating the delay of the expected message.

In [37] authors develop an analytical model to investigate the relation between energy saving and system performance and to observe the effects when sensor sleep/active mode vary. By means of this model, authors can obtain several performance metrics, such as the distribution of the data delivery delay. This work adopts analytical model specifically representing the sensor in sleep/active mode considering channel contention and routing issues. In this work authors model a WSN by means of Markovian techniques; they assess dependability using data delivery resiliency and power consumption metrics.

A linear programming model [38] is introduced to address the problem of "multi-hop lifetime aware routing". The authors propose a Garg-Konemann-based approach to obtain the minimum cost arborescence for reaching the sink node optimizing the lifetime of sensor nodes.

Finally in [39] the node aging problem is addressed. The authors try to solve this problem by associating a survivor function for each sensor node (using *Weibull* distribution). The aim of this work is to demonstrate that the node aging process has an important impact on the connectivity at the increasing of the hop distance. By means of a mathematical analysis and a simulation, they observe that nodes at first hop consume their energy because of the aggregation with children nodes. Hence, they assert that the consumption is related to the number of children nodes.

Each analyzed work, which applies a simulative or analytical approach, defined its own fault model making simple assumptions on network topology and on power consumption; results cannot be generalized since they are obtained by means of abstract simulations. Thus there is a lack of realistic fault

models and this is a limit of these approaches. Therefore it is necessary a further kind of approach.

V. Formal Approaches

Formal approaches offer a new opportunity for the dependability study of WSNs both before and after its deployment. They are based on formal verification that consists in checking of the correctness of a system taking in account specifications or properties, using formal methods. Until now there is no work that has proven how to use an unique formal approach to perform dependability assessment at design time and runtime.

The formal verification is performed by providing a proof on an abstract mathematical model of the system. Typically to model systems we can consider labeled transition systems, timed automata, finite state machines, Petri nets, process algebra, hybrid automata, formal semantics of programming languages such as axiomatic semantics, operational semantics and denotational semantics.

In this section we focus on main formal approaches proposed in literature such as *model checking* and *Event Calculus*. Then we discuss about papers in which formal methods have been applied for dependability assessment of WSNs.

A. Model Checking

One of the well known formal approaches is *model checking* [40]. This technique consists of a systematically exhaustive exploration of the mathematical model (this is possible for finite models, but also for some infinite models where infinite sets of states can be effectively represented finitely by using abstraction or taking advantage of symmetry). Usually this consists of exploring all states and transitions in the model, by using smart and domain-specific abstraction techniques to consider whole groups of states in a single operation and reduce computing time. Implementation techniques include state space enumeration, symbolic state space enumeration, abstract interpretation, symbolic simulation, abstraction refinement. The properties to be verified are often described in temporal logics, such as linear temporal logic (LTL) or computational tree logic (CTL) [41]. The great advantage of model checking is that it is often fully automatic; its primary disadvantage is that it does not in general scale to large systems; symbolic models are typically limited to a few hundred bits of state, while explicit state enumeration requires the state space being explored to be relatively small.

Typically model checking allows to verify if a defined property of a system is satisfied. Thus, the limit of this technique is related to the prediction of a sequence of events. In other words, by means of model checking, an user is able to control if, given an event, the correctness properties are satisfied but is not able to know what will be the behavior of the system after that given event (e.g. node crash or packet loss).

B. Event Calculus

Event Calculus was proposed for the first time in 1986 by Marek Sergot and Robert Kowalski [42] and then it was extended by Murray Shanahan and Rob Miller in the 1990s [43]. This language belongs to the family of logical languages and it is commonly used for representing and reasoning of the events and their effects [44]. *Fluent*, *event* and *predicate* are the basic concepts of Event Calculus [45]. For every timepoint, the value of fluents or the events that occur can be specified.

This language is also named *narrative-based*: in the Event Calculus, there is a single time line on which events occur and this event sequence represents the *narrative*.

The most important and used predicates of Event Calculus are: *Initiates*, *Terminates*, *HoldsAt* and *Happens*.

Since the normal and failing behavior of a WSN can be characterized in terms of an event flow (for instance, a node is turned on, a packet is sent, a packet is lost, a node stops to work due to crash or battery exhaustion, or it gets isolated from the rest of the network due to the failure of other nodes, etc.), Event Calculus, that is an event-based formal language, can be used to formally specify the occurrence of such events and the response of the WSN to them, to check if given correctness properties are verified. Moreover dependability metrics can be valuated by analyzing the *narrative* generated by a Event Calculus reasoner based on the specification of the target WSN.

Finally several techniques are considered to perform automated reasoning in Event Calculus, such as *satisfiability solving*, *first-order logic automated theorem proving*, *Answer Set Programming (ASP)* and logic programming in *Prolog*.

To check the proposed correctness properties defined in Event Calculus, the most common adopted reasoner is the *Discrete Event Calculus (DEC) Reasoner*. The DEC Reasoner [46], [47] uses satisfiability (SAT) solvers [48] and by means of this we are able to perform reasoning like deduction, abduction, post-diction, and model finding. It is documented in details in [49] in which its syntax is explained (e.g. the meaning of the symbols used in the formulas).

C. Formal approaches for WSN

Lifetime of WSN is defined and evaluated in [50] by means of a mathematical formalism. In this work a generic definition of sensor network lifetime is presented and it is conceived in such way to incorporate different application requirements, such as i) number of alive nodes, ii) time latency in the delivery process, iii) delivery ratio, iv) connectivity, v) coverage, and vi) availability.

Recently, different formal methods and tools have been applied for the modeling and analysis of WSNs, such as [51], [52] and [53].

In [51] authors apply a formal tool to wireless sensor networks, *MEDAL*. They propose a formal language to specify the WSN and a tool to simulate it. However, the formal specification has to be rewritten if the WSN under study changes.

In [52] authors propose a methodology for modeling, analysis and development of WSNs using a formal language (PAWSN) and a tool environment (TEPAWSN). They consider only power consumption as dependability metric that is

necessary but not sufficient to assess the WSN dependability (e.g. other problems of WSN such as the isolation problem of a node have been analyzed) and also they apply only simulation.

In [53] authors describe a model-driven performance engineering framework for WSNs (called Moppet). This framework uses the Event Calculus formalism to estimate the performance of WSN applications in terms of power consumption and lifetime of each sensor node; other dependability metrics like coverage, connection resiliency and data delivery resiliency are not considered. The features related to a particular WSN have to be set in the framework every time that a new experiment starts.

There are some papers ([54],[55],[56]) that have considered the formal method in real-time contexts.

In [54] authors model and study WSN algorithms using the Real-Time Maude formalism. Though authors adopt this formalism, they use NS-2 simulator to analyze the considered scenarios making the work very similar to simulative approaches.

The work presented in [55] describes a new formal model for the specification and the validation of WSN. Authors assert the use of rigorous formal method in specification and validation can help designers to limit the introduction of potentially faulty components during the construction of the system. They consider a WSN as a Reactive Multi-Agent System consisting of concurrent reactive agents. In this paper dependability metrics are not treated and calculated and authors just describe the structure of a Reactive Decisional Agent by means of a formal language. Also, no case studies are reported to validate their proposal.

Patrignani et al. in [56] consider policies to monitor wireless sensor network applications in a WSN middleware characterized by a Component and Policy Infrastructure (CaPI); by means of a formalization they are able to catch dangerous or undesired effects which may compromise the correct behavior of a WSN application. In this work it has been developed a prototype that operates on the basis of a application topology in terms of communicating nodes and a set of properties to satisfy. Even if authors confirm that one of the most important benefits of formal approach is that problems occurring at runtime can be detected, they model a static and not dynamic network configuration, focusing only on security (encryption and decryption messages) and resource usage problems and in their scenario they do not consider other dependability metrics (coverage, data delivery resiliency, ...).

In [57] a methodology to investigate the correctness of the design of a WSN from the point of view of its dependability is proposed. The methodology is based on the *event calculus* formalism and it is backed up by a support tool aimed to simplify its adoption by system designers. The tool allows to specify the target WSN in a user-friendly way and it is able to generate automatically the event calculus specifications used to check correctness properties and evaluate dependability metrics such as coverage and connection resiliency but not data delivery resiliency and power consumption.

TABLE II
APPROACH CLASSIFICATION

Approach	Assessment	
	Design time	Runtime
Experimental	×	✓
Simulative	✓	×
Analytical	✓	×
Formal	✓	✓

VI. DISCUSSION

All the analyzed work provides interesting methods and/or techniques which give a contribution for the dependability assessment in WSN. These methods have been grouped in four categories: experimental, simulative, analytical and formal.

In table II a classification of the presented approaches is shown. Experimental methods are used to evaluate a real system and therefore they need for a existent prototype; they are useful at runtime since through these methods do experiments directly on the real system from which they collect data. Simulative and analytical may be adopted in the design phase: they model a system and make an estimate of reliability before of the system release. Finally formal methods make use of correctness specifications and they can be used at design time and at runtime too by means of runtime verification techniques.

Moreover, in this section, it is shown and discussed a comparison of the related work presented in the previous sections in which it emerges a lack of a work that allows to perform WSN dependability assessment both at design and at runtime.

In the grid, shown in figure 1, on the rows there is the analyzed work (approaches, tools and models); on the columns there are the properties chosen to highlight the differences.

In particular we have considered the following features:

- *Experimental Approach* to determine if the related work is based on experiments;
- *Simulative Approach* to determine if the related work is based on simulations;
- *Analytical Approach* to determine if the related work is based on analytical models;
- *Formal Approach* to determine if the related work is based on some formal method (e.g. model checking, Event Calculus) and in particular if the work adopts an approach that provides *Separated specifications*: we want to verify if the related work applies a modular solution considering two logical sets of specifications: a general correctness specification, valid independently of the particular WSN under study, and a structural specification related to the properties of the target WSN (e.g., number of nodes, topology, channel quality, initial battery charge);
- *Design time* to determine if the related work performs dependability assessment at design time;
- *Runtime* to determine if the related work performs dependability assessment at runtime;
- *WSN Dependability metrics* to determine if the related work considers the following dependability metrics: coverage, connection resiliency, data delivery resiliency,

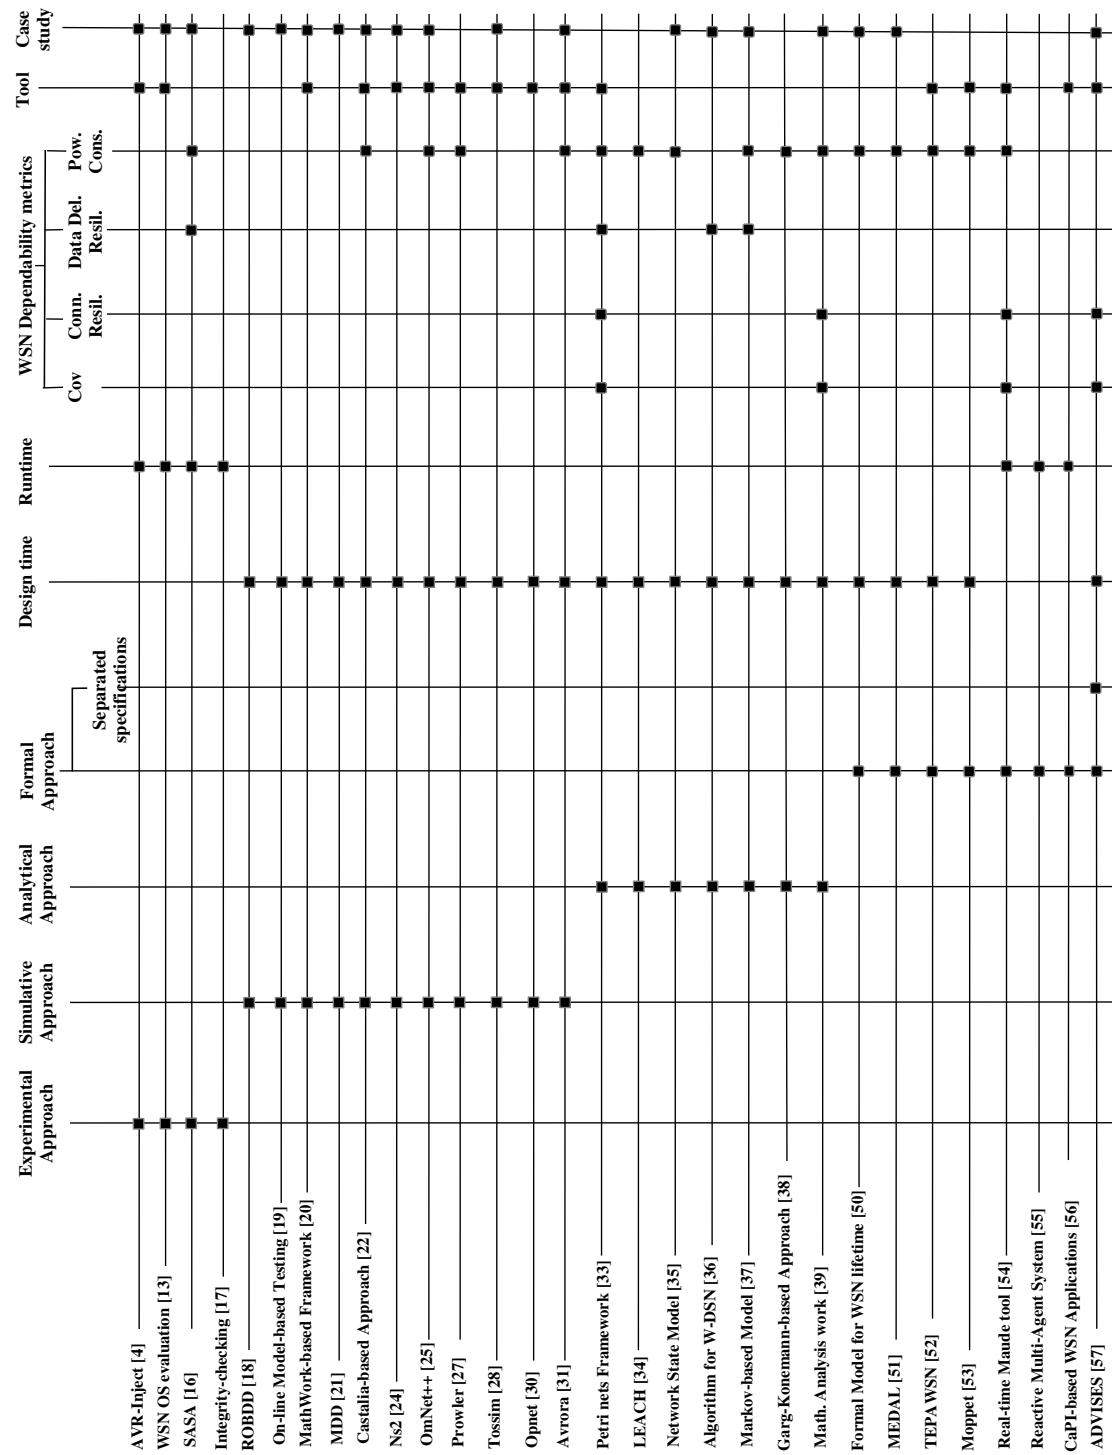

Fig. 1. Comparison of WSN dependability assessment studies

power consumption;
- *Tool* to determine if the related work proposes a novel tool to support designers;
- *Case study* to determine if the related work considers case studies in order to validate the proposed work.

From the survey of the literature it is possible to assert that among the most important dependability metrics, the power consumption is the only one that has been considered extensively, instead data delivery resiliency and connection resiliency are the least analyzed.

The majority of papers propose a tool and present results by means of a case study observing the behavior of the WSN under determined circumstances.

Therefore, looking the figure 1, there is no work that describes a framework conceived in order to perform WSN dependability assessment both at design and runtime measuring all the main dependability metrics. Many studies address the WSN dependability assessment at design time, few studies at runtime.

Moreover, we think that formal methods may be considered as a new and attractive solution for the assessment of dependability both at design time that at runtime by defining one specification for the system suitable for both purposes since the lack of a formal approach that can be applied for doing static and dynamic assessment of WSN dependability remains an open issue.

Thus, in the field of WSN research, a study of a framework that applies an approach to assess WSN dependability by means of a formal approach, before and after the deployment of a WSN, can be advantageous and innovative.

VII. Conclusions

In this paper, we have reported a survey on the approaches of WSN dependability assessment grouped in experimental, simulative, analytical and formal. What appears clear is that the path towards the production of an optimal approach to check the dependability level of WSN both at design and runtime is still long, and more research effort is needed to reach this compelling goal.

To achieve this goal, we think that applying formal techniques is a good approach since they could join the benefits of the experimental approaches (for dependability evaluation at runtime) and the simulative and analytical approaches (for dependability evaluation at design time). The idea of performing a complete check of the dependability degree on the WSN behavior, to enforce the fulfillment of correctness properties, seems a promising one to achieve more stable and dependable WSN-based systems in the future.

***Abstract*—This paper discusses factors influencing accuracy of estimating localization of radio networks terminals in indoor environment. It introduces parameters that can be useful to describe the quality of localization of radio landmarks. The paper presents a software for computer aided reference radio stations placement inside the buildings and shows the results of exemplary simulations carried out with the use of proposed algorithms.**

***Index Terms*—indoor positioning systems, Location Based Services, wireless local area networks, radiolocation**

I. Introduction

NOWADAYS many telecommunication systems use information about location of mobile terminal from GPS and GSM/UMTS systems to estimate user terminal location. But these systems have common defect, both do not work indoors. These limitation results from strong signal attenuation introduced by the outer walls of buildings and from the strong multipath propagation effects present in indoor areas. To overcome these problems there are created dedicated systems like sensor networks and used dedicated networks like WLAN, Bluetooth, ZigBee, RFID, UWB to work in a small area by having a lower signal strength which causes smaller signal interference in comparison to outdoor solutions. Many of these network systems are used in daily life to exchange information between terminals. But due to the growing interest in localization in indoor environment, a problem arises how to fast and correct locate reference landmarks, taking into consideration size of the area in which localization is possible, number of reference nodes and desired localization accuracy. If we place reference nodes correctly we can use these systems for example to help a blind or visually impaired person to move inside the building, or to help a disabled person to reach the medical room. Another important field of application of positioning systems includes navigation in industrial and manufacturing facilities [1].

This article discusses the factors influencing on location accuracy in indoor environment based on the RSS (Received Signal Strength). Then, it explains how to evaluate the quality of the reference station distribution based on the aforementioned factors. Next, it presents an algorithm which improves quality of placement of the reference nodes taking into consideration the aforementioned assessment methods. Then it deals with the results of the simulations in exemplary rooms with obstacles.

II. Factors Influencing Localization Accuracy

A. Lack of signals from minimum three reference radio stations

This is the most important factor that influences the possibility to estimate unknown position of the mobile terminal. When we have information about the distance from one reference station, we can only say that the terminal is somewhere around the circle with radius being equal to this distance. If we have information on the distances from two reference stations, we can limit our searching to two points resulting from intersection of two circles. To obtain unambiguous information about position of the terminal, information from at least three reference stations is required.

B. Adverse reference nodes geometry

Distance measurements between reference stations and localized terminal is not noiseless. The size of noise depend on the strength and types of signal used and environment surrounding reference station. All it caused a distance measurements error, that is shown as ring around the station, Fig. 1. As a result of imposition of three rings, we can indicate common areas where the terminal is likely to be localized in. This area is called the area of uncertainty, Fig. 1.

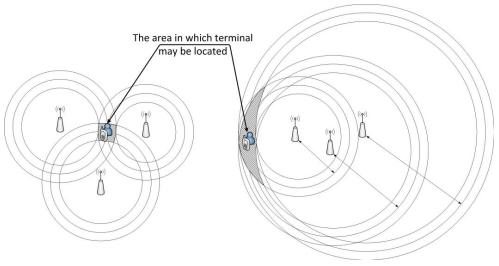

Fig. 1. Localization error for different geometry of reference nodes a) nodes located in an equilateral triangle b) nodes located on straight line.

The size of the area of uncertainty represents, in a sense, the error of localization. The uncertainty area is the smallest when the localized terminal is placed between the reference stations and the angles between adjacent stations are equal. On the contrary, the biggest area of uncertainty is created when the reference stations are placed along the line. This results in the highest error of unknown terminal localization.

978-83-60810-53-8/$25.00

C. Multipath propagation of radio signals

Multipath propagation results in imposition of several copies of the same signal reaching the receiver. The signal components travel along different paths and exhibit different power levels and phase shifts. This leads to the strong fluctuations of signal power, depending on the distance between the transmitter and the receiver [2], [3]. This factor has a particular importance in the localization methods based on the received signal strength and phase measurements [4], [5]. A graph shown in Fig. 2 presents the level of signal attenuation as a function of the distance between the antennas. Fluctuations of the signal power result from interfering of two waves: direct and reflected ones.

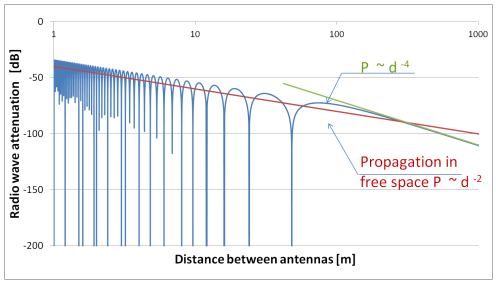

Fig. 2. Signal attenuation as a function of transmitter and receiver antennas separation

However, in a real indoor environment, the transmitting and receiving antennas are surrounded by walls and furnishing. In such conditions signals reflected from the obstacles reach the receiver, propagating along many different paths, thus having different phases. The number of interfering waves can be very high and difficult to estimate. In fact, there is no visible relationship between received signal strength and the distance, which makes difficult to determine the distance using the RSS method correctly. As a result, the calculated position shows significant errors. Another problem is the correct estimation of reflection coefficient of the radio wave for the obstacle. A huge coefficient variation dependent on the material which the obstacle is made of prevents from the accurate calculation of the radio wave reflected from the obstacle attenuation.

D. Radio signal attenuation in non line of sight case

If a line of sight (LOS) between localized object and reference station exists, we can assume that the measurement of signal strength is not affected by additional errors resulting from unspecified signal attenuation and delays due to reflections. In indoor environment it is often not possible to provide the LOS conditions in the entire room. In non line of sight case (NLOS), the signal reaches the receiver with additional attenuation resulting in the increase of the localization error.

E. Incorrect or inaccurate signal propagation model

Incorrectly chosen model of radio wave propagation, based on RSS method, can be a source of significant errors in terminal position calculation. The choice of appropriate propagation model should strictly depend on indoor environmental conditions. In practice, there is no ability to ensure that we choose the proper model, corresponding to temporary environmental conditions. For this purpose there are commonly used empirical models, based on a large number of measurements and statistical surveys.

III. Assessing the Distribution of Reference Stations

A. Evaluation of reference nodes geometry

To evaluate reference stations geometry in relation to the localized point we used two factors have been used: the first factor we propose is a simple formula determined on the trigonometric formulas. The second one is a modified factor HDOP (Horizontal Dilution Of Precision) used in GPS system to assess the layout geometry of satellites [6], [7], [8]. Fig. 3 shows the case where the terminal position is determined based on signals coming from four reference stations (according to [1]).

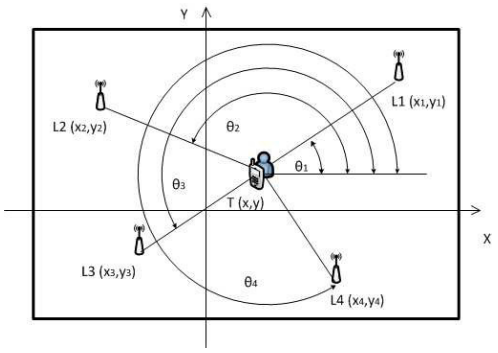

Fig. 3. Two dimensional localization schema.

In Fig. 3 the angle θ formed between the straight line passing through the localized terminal and a line parallel to the x axis are marked.
We assume that α is the angle between neighboring reference stations:

$$\alpha_1 = \theta_2 - \theta_1\,, \quad \alpha_2 = \theta_3 - \theta_2\,, \quad \alpha_3 = \theta_4 - \theta_3\,; \qquad (1)$$

The factor g(l) is obtained on the basis of trigonometric formulas:

$$g(l) = \frac{\sin^2\varphi_1 + \sin^2\varphi_2 + \sin^2\varphi_3 + \ldots + \sin^2\varphi_n}{n} \qquad (2)$$

where:

$$\varphi_n = \alpha_n - \left(\frac{2\pi}{n} - \frac{\pi}{2}\right) \qquad (3)$$

and:
α_n - the angle between the straight lines connecting the localized terminal with neighboring reference stations,
n - number of stations within the range of the terminal being localized.

The classification of the assumed geometry indexes is presented in Table I. This index measures the effect of the

TABLE I
EVALUATION OF GEOMETRY INDEX VALUES

Value of g(l) index	Evaluation of the geometry of the reference stations placement
0,5<g(l)≤1	Very good
0,35<g(l)≤0,5	Good
0,2<g(l)≤0,35	Sufficient
g(l)≤0,2	Bad

geometric configuration of the reference points on the position estimation [8].

The second factor that can be used to evaluate the distribution of radio stations is HDOP index, which is typically used to assess the potential localization error of GPS satellite navigation systems. HDOP factor for the three-dimensional case can be derived from matrix A:

$$\mathbf{A} = \begin{vmatrix} \frac{(x_1-x)}{R_1} & \frac{(y_1-y)}{R_1} & \frac{(z_1-z)}{R_1} & -1 \\ \frac{(x_2-x)}{R_2} & \frac{(y_2-y)}{R_2} & \frac{(z_2-z)}{R_2} & -1 \\ \frac{(x_3-x)}{R_3} & \frac{(y_3-y)}{R_3} & \frac{(z_3-z)}{R_3} & -1 \end{vmatrix} \tag{4}$$

where,

$$R_i = \sqrt{(x_i - x)^2 + (y_i - y)^2 + (z_i - z)^2} \tag{5}$$

and:
R_i - the distance between the coordinates (x_i, y_i, z_i) of the reference station and coordinates (x, y, z) of object to be localized. Introducing matrix Q:

$$\mathbf{Q} = (\mathbf{A}^T \mathbf{A})^{-1} \tag{6}$$

$$\mathbf{Q} = \begin{vmatrix} d_x^2 & d_{xy}^2 & d_{xz}^2 & d_{xt}^2 \\ d_{xy}^2 & d_y^2 & d_{yz}^2 & d_{yt}^2 \\ d_{xz}^2 & d_{yz}^2 & d_z^2 & d_{zt}^2 \\ d_{xt}^2 & d_{yt}^2 & d_{zt}^2 & d_t^2 \end{vmatrix} \tag{7}$$

the HDOP index for two dimensional case is determined.

$$HDOP = \sqrt{d_x^2 + d_y^2} \tag{8}$$

Based on the HDOP index, we can specify geometry index factor according to Table II [8].

TABLE II
EVALUATION OF HDOP INDEX VALUES

Value of g(l) index	Evaluation of the geometry of the reference stations placement
<1	Measurements error or redundancy
1	Ideal
1-2	Very Good
2-5	Good
5-10	Medium
10-20	Sufficient
>20	Bad

B. Quality of radio signal in non line of sight case

To evaluate the quality of radio signals reaching the receiver, we additionally assumed the criterion of maximum acceptable additional signal attenuation due to the presence of obstacles between the localized terminal and a reference station. We assumed the following classification of radio propagation conditions:

- conditions are considered to be ideal when there is no additional attenuation in radio path caused by obstacles,
- conditions are very good, if the additional attenuation in radio path caused by obstacles does not exceed 2 dB, for each station,
- conditions are good, if the additional attenuation caused by an obstacle exceed 2dB is from 0% to 25% number of stations
- conditions are bad, if the additional attenuation caused by an obstacle is greater than 2 dB is from 25% to 50% number of stations,
- conditions are very bad, if the additional signal attenuation caused by obstacles is greater than 2 dB from more than 50% of the stations.

IV. ANALYSIS OF THE REFERENCE NODES PLACEMENT

A. Assumptions

The following assumptions regarding the assessment of reference radio stations placement have been taken into account in the article.

- In every part of room, radio signals from at least three reference radio stations should reach the receiver. It is also assumed that the number of stations within range should not exceed four. The increase of the number of stations does not necessarily improves the location accuracy but significantly increases the cost of network construction.
- The power levels of the received signals should exceed some minimum threshold level.
- Reference stations should be as far separated as possible, which allows to reduce the spatial density of the stations.
- Another important aspect is to provide direct visibility of reference stations (LOS) at each point in the room. Alternatively, signal attenuation due to the obstacles should not exceed the assumed maximum level.
- In the ideal case the angles between the reference stations in relation to the terminal position should be equal.

B. Simulation software

To examine the impact of the reference stations placement on the localization accuracy, a dedicated simulation software has been developed. The software allows evaluation of reference nodes placement for an assumed two-dimensional room layout using the criteria presented in Section III. Apart from the assessment of the reference nodes placement, the software allows to optimize the initial locations of the nodes in order to maximize the values of quality of placement coefficients. We implemented an iterative algorithm based on the idea

described in [9], [10]. Every placement of the reference nodes can be described with an overall system of a so-called "energy function". The energy of the system is computed as the sum of the energies assigned to test locations in the room. The test locations are randomly distributed within the area under investigation, and the energy assigned to a single location is a function of coefficients defined in Section III.

$$E = \sum_{n=1}^{N} \quad (a_1 Q_1 + a_2 Q_2 + a_3 Q_3 + \cdots + a_1 Q_1) \qquad (9)$$

where:
E - an overall system energy,
Q_k - value of quality factor,
a_k - weight quality factor,
N - number of all measurement points,
n - measuring point number,

The model of the system is based on resilience phenomenon, i.e. when the distance between the two neighboring reference nodes increases, the force repelling these nodes decreases. The goal of the algorithm is to minimize the overall system energy and to maximize coefficients describing the quality of the reference nodes placement. In every iteration, the software estimates reference nodes placement quality coefficients as well as system energy and forces repelling the neighboring nodes. Additionally, a random Brownian motion of the nodes is assumed to minimize the risk of stopping the optimization algorithm in some local minima. As a result, new positions of the reference stations are estimated.

$$V = \sum_{n=1}^{N} \quad (ad_n + b) + V_B) \qquad (10)$$

where:
N - number station in range
a, b - coefficient
d - distance between stations
V_B - Brown motion vector

The flow diagram of the reference nodes placement optimization algorithm implemented in the software is presented in Fig. 4.

In the simulations, to calculate signal attenuation and to estimate the distance between the antennas a Multi-Wall indoor radio propagation model [2], [3] was used. For distances d < 1m we assume free space signal propagation loss:

$$L(d < 1)_{dB} = 40 + 20 \log(d) \qquad (11)$$

For distances d > 1m we compute the propagation loss with the use of the Multi-Wall model:

$$L_{MWM}[dB] = 40 + 10 \cdot 4 \log(d) + \sum_{s=1}^{s=Sn} \quad (n_{ws} \cdot L_{ws}) \qquad (12)$$

where:
L - signal attenuation,

Fig. 4. Reference stations placement optimization algorithm.

d - distance between the antennas,
n - number of walls on the signal propagation path,
S - type of wall material is made,
Sn - number of wall types,
Lws - attenuation of a single wall,

C. Simulation results

Firstly, we try to see the relationship between placement of the reference stations and the size of the area where the terminal can receive signals from at least three of the beacon stations. For the simulations we assumed an example of 25 m x 25 m room layout and the following algorithm parameters: transmit power level is equal to 5 dBm and minimum received signal strength required at the receiver antenna equal to -85 dBm. Fig. 5 and Fig. 6 present results of the reference stations placement. Black rectangles denote obstacles and blue circles indicate reference stations. Areas where the quality requirements are not met are marked with crosses.
To assess localization conditions, we evaluate quality criteria for test points distributed in the area of the room layout. The test points are located randomly in the room and the number of points is determined by the program user. The higher the number of points, the greater the accuracy but also the longer the computation time. Fig. 7 shows sample results obtained for the scenario presented in Fig. 6, and the bars indicate percentage of the room area as a function of a number of visible reference stations.

To evaluate the performance of reference stations placement optimization algorithm, we performed a series of simulations for sample room layout and for various initial placements of

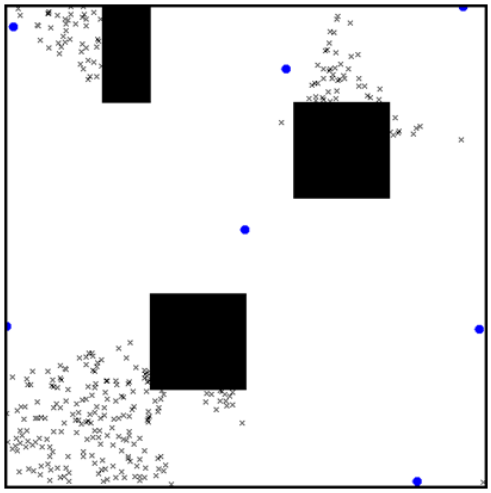

Fig. 5. Example placement of 7 reference stations in room No.1 25m x 25m.

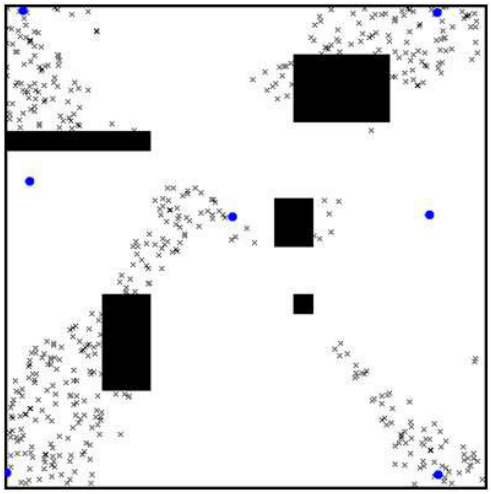

Fig. 6. Example placement of 7 reference stations in room No.2 25m x 25m.

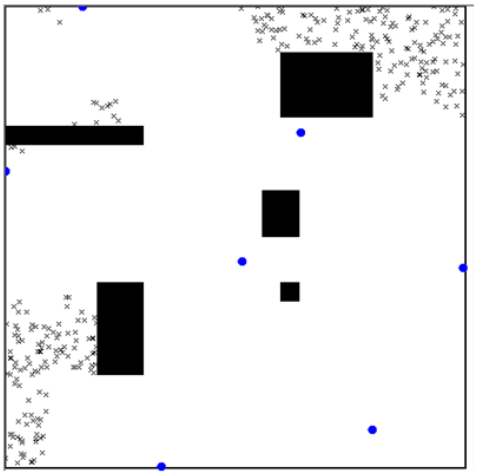

Fig. 9. The result of the reference stations placement optimization.

the stations. Fig. 8 and Fig. 9 show the initial conditions and optimization results for the same room layout as in Fig. 6.

V. Summary

In the paper, we described parameters that can be used to evaluate the quality of reference nodes placement and its influence on the network terminal positioning accuracy. We also presented a software for computer aided optimization of the reference stations of indoor positioning systems. The software implements an optimization algorithm based on resilience phenomenon and Brownian motion model. The results of simulations carried out for sample room layouts proved the suitability of the proposed approach to finding such locations of the reference stations that maximize positioning quality criteria. However, it must be noted that the resulting reference stations placement depends on the initial positions of the nodes. The goal of the further research is to evaluate results the optimization of reference stations placement for sample real

life scenarios. Measurement campaigns verifying simulation results are planned in a university campus buildings. The measurement data will be also used to further adjust the proposed algorithms.

***Abstract*—In recent years, smart-devices became very popular among people of all ages around the world. Very important is especially their usage in health applications. Special Body Area Network (BAN) for the stress monitoring is currently being developed within the authors' department. Android-based smartphone is employed as the main control unit of the sensor network built on the star architecture. Since the power consumption of the smart-phone as well as of the single sensor node is one of the key limitations of the network, special attention has to be given on it. In this article, energy requirements necessary for the data transmission among the network is analysed in detail. For this purpose, communication solution based on 2.4 GHz proprietary RF transceiver is implemented.**

I. Introduction

THESE fast moving, hurried times we live in bring along different health risks to the people's lives. In particular, the growing number of people suffering from stress, which induces high numbers of severe diseases such as cardiovascular disease, impaired immune system, asthma, peptic ulcer disease, indigestion, headaches, migraines and depression, is one of the typical problems of nowadays. Many people do not realize soon enough that their current stress level is harmful for their health. Therefore, it is necessary to have the stress issue under control and manage it somehow. For this reason, this paper presents the proposed system for monitoring the vital signs of a human body that are related to the stress issues. The system is based on the networking principles of Body Area Network (BAN). The sensor nodes around a human body that communicate in a coordinated fashion create BAN [1]. BAN requirements include low energy specifications and this fact is preferred for various applications including the field of e-Health [1], [2], [3]. Wearable sensor components enable monitoring anywhere, anytime and during wide range of activities (at home, at work, indoors, outdoors, during sports, etc.). Mostly, a comprehensive health image is obtained in comparison with the traditional diagnosing methods [3]. In addition, prompt disease identification typically leads to successful treatment even in case of serious illness [4]. Mostly, a central and most powerful network node is the coordinator of the network [1], [3]. The network coordinator for this application has been chosen to be a smartphone. The reason for this comes from smartphone features - embedded microprocessor, touch screen, capabilities to perform calls (emergency calls), send short text messages and connect to the internet [2].

This work was supported by Foundation Volkswagen Slovakia taking advantage of the Texas Instruments Sample Program.

Various such systems, using the smartphone assets, have been already introduced. In [6], a special body monitoring system for detection of the human body temperature by thermopile sensor, electrical activity of brainwaves by electrocardiogram and electrical activity of the heart by electroencephalogram have been introduced. Smartphone had been in this case used as the communication gateway interfacing the sensors' data with the remote monitoring server, in spite of its management and local-storage functions.

In [7], more complex telemedical system measuring ECG, heart rate, heart rate variability, pulse oximetry, plethysmography and fall detection was presented for the purpose of the patients' physiological parameters outside the clinical environment monitoring and recording. The smartphone was except the common features used for the data visualization and patient's localization matters in order to the emergency communication with a clinical server will be guaranteed on a certain level of quality.

An agent-based approach was presented in [8]. A multi-agent architecture for mobile health monitoring interacting doctor and patient beyond the episodes of visits is presented, involving a team of Java-based intelligent agents that collate patient's data through Bluetooth compliant monitoring device and recommend actions to patients and medical staff in a mobile environment. Agents at the smartphones are also able to monitor the patient's environment through an integrated VGA camera to track patient actions and relay images back to medical staff.

System in [9] is devoted to the monitoring of the athletes during their training process providing them information about the body response to fatigue. Different sensors are utilized within the system, including the photoplethysmographic (PPG) sensor for the heart beat-variability monitoring that is used for the arrhythmias or arterial stenosis and occlusions detection, and the earlobe sensor for the tissue impedance measurement that defining an amount of physical effort due to the ions'

978-83-60810-53-8/$25.00

concentration analysis. Whilst the smartphone was employed as the main control unit for the data collection and analysis, the system provide non-invasive method for the athletes monitoring without interfering their training.

Energy optimization through scheduled communication, Bluetooth parameter tuning and protocol optimization was stressed within the system in [10]. There was developed a Bluetooth-based body sensor network consisted of one smartphone as the network coordinator, multiple sensor nodes for the human body monitoring, and a wristwatch as the user interface. Since the Bluetooth is characterized by large power overhead, its duty cycle was minimised. The developed platform was supplied with a set of APIs for applications on the phone to manage the network, collect data from the sensors, and interact with users via the watch. Data from sensors, which had been most time in a sleep mode, were on account of the measurement request reported to the Internet server or to the phone which could perform its own analysis displayed afterwards through the wristwatch.

In [11], the design and implementation considerations of a smartphone-centred platform for low-cost continuous health monitoring based on commercial-off-the-shelf wireless wearable biosensors were introduced. The platform approach was implemented utilizing PPG biosensors and different smartphones to measure heart rate, breathing rate, oxygen saturation, and estimate obstructive sleep apnea.

The first part of the article describes radio frequency solutions and their comparison in order to better evaluate their power consumption requirements. Smartphone connectivity is investigated in the following part. The next section discusses the mere composition of the network, as well as the principles of communication and timing in the network. Efforts to reduce energy requirements are described in the last part. The proposed sensors are able to capture the temperature, humidity and heart-rate characteristics. Such, values are able to detect if a human is under the stress. Thus, by the analysis of these parameters, the level of human's stress can be found out.

II. Radio Frequency Solutions

An important task of the system design is to select the proper communication mean for the BAN. If one considers a selection of wireless connectivity for a smartphone, two major technologies come to mind. The first is IEEE 802.11.4 (WiFi), which is very powerful, but it is able to drain out the battery in a quite short time. The second option for smartphone wireless connection is IEEE 802.15.1 (Bluetooth). On the subject of the energy consumption, both standards require significant amount of energy and considerably reduce the smartphone's lifetime [12].

Except mentioned technologies, there are also other possibilities which are much more suitable for the BAN purposes, especially in the frame of power consumption. In [7], IEEE 802.15.4 ZigBee platform was implemented within the developed BAN due to the energy-saving reasons. However, though is ZigBee primarily appointed for the low-power, low-cost, multihop networks, it does not exactly meet demands of IEEE 802.15.6 standard for wireless communications supporting ultra-low power devices operating in or around the human body. Therefore, proprietary radio functioning on 2.4GHz ISM was chosen for the BAN purposes. This choice allows definition of the unique low-energy-consuming communication protocol which can be further modified according to the latest release of the BAN standard. Several embedded solutions are available on the market nowadays. The Table I briefly compares the current consumption of the selected transceivers for 2.4 GHz ISM band.

TABLE I
BAN Compliant Transceivers' Current Consumption Comparison in Different Power Modes for Proprietary 2.4GHz ISM Band Radio Modules

Power mode	Quasar RFM 70 [13]	Microchip MRF24J40MA [14]	Nordic NRF24E2 [15]	Microchip MRF89XAM9A [16]
RX mode	17.50 mA	19.00 mA	22.00 mA	3.00 mA
TX mode	14.57 mA	23.00 mA	27.00 mA	25.00 mA
Power down	3.00 μA	2.00 μA	-	1.05 μA
Standby	50.00 μA	-	30.00 μA	-

TABLE II
TI System-on-chip Current Consumption Comparison in Different Power Modes

Power mode	CC2511 [17]	CC2530 [18]	CC2543 [19]	CC2545 [20]
Active mode	3.97 mA	6.27 mA	4.50 mA	4.50 mA
RX mode	19.12 mA	24,80 mA	21.20 mA	20.80 mA
TX mode	21.50 mA	33,93 mA	27.70 mA	28.25 mA
Power mode 0	4.28 mA	-	3.80 mA	3.75 mA
Power mode 1	0.22 mA	0.25 mA	0.24 mA	0.24 mA
Power mode 2	0.75μA	1.50 μA	0.90 μA	0.90 μA
Power mode 3	0.65 μA	0.70 μA	0.40 μA	0.40 μA

Transceiver solution requires a microcontroller (MCU) to process the measured data and to initialize wireless communication. Furthermore, additional space on the PCB (printed circuit board) is required when taking advantage of the standalone transceiver interconnected with MCU via some interface. As the sensors ought to be as small as possible we decided to investigate system-on-chip (SoC) 2.4 GHz RF solutions as well. Whilst Texas Instruments (TI) is probably the best producer of such solutions in the sense of current consumption, selected SoC representatives from TI family were chosen for comparison in Table II.

Common features of these SoCs and transceivers include low-cost 2.4 GHz radio solution, ultra-low power requirements, suitability for portable applications and several advanced low-power operating modes in order to save the power. Since ultra-low power requirements are necessary for proposed application the power requirements parameter was key part of the communication subsystem selection. All values in the Table II are average values of the current consumption based on the datasheet information.

Along with the table, it is possible to conclude that the best power consumption requirements had the first SoC solution TI

CC2511. Therefore, the main MCU that is connected directly to the smartphone via USB, functioning as the communication gateway for the BAN, has been chosen the mentioned CC2511. This chip was, however, unsuitable for the sensor nodes since it lacks the most important communication interfaces - SPI and I^2C [17]. Thus, it was necessary to select another SoC solution that comprises these peripherals. The second best solution provided in the Table II was TI CC2545 that had all desired peripherals and features satisfying the sensors' claims [20].

III. Smartphone USB Connectivity Constraints

Universal Serial Bus (USB) was employed as the main communication interface as well as the power source for the communication gateway board - control node (Fig. 1 and Fig. 2) - since it provides bus-power. That is one of the key advantages, because the device obtains power from the bus and no extra cables are required. In the following subsections, the necessary basics of the USB interconnectivity management will be summarized.

A. USB Device Types

The device specifies its power consumption in 100 mA load units in the configuration descriptor [21]. The device cannot increase its power consumption above the declared amount of load units. Three classes of USB devices exist [22]:

- *Low-power bus powered devices (LPBPDs)* - draw all necessary power from the bus and cannot draw more than one load unit. This class of devices has to be designed to work in 4.40 V up to a maximum 5.25 V voltage range. Therefore, many devices require LDO regulators;
- *High-power bus powered devices (HPBPDs)* - all necessary power is drawn from the bus and cannot draw more than one unit load until it has been configured. After the configuration, the device may drain up to five load units (max. 500 mA) provided in the configuration descriptor. Such devices have to operate in 4.40 V - 5.25 V voltage range. When operating at a full unit load, the minimal voltage level is 4.75 V. Once again, a LDO regulator is needed for many devices;
- *Self-powered devices (SPDs)* - may draw up to one load unit from the bus and the rest of the necessary power may derive from an external source. One load unit allows reliable detection and enumeration of the devices without main/secondary power applied;

No USB device, whether bus powered or self-powered can drive the bus (in sense of the power). If the power is lost, the device has 10 seconds to remove power from the pull-up resistors on the USB data pins that are used for speed identification. Another very important consideration for implementation is the inrush current that has to be limited. The inrush current contributes to the capacitance of the device between the USB power and the USB ground [22]. The maximum decoupling capacitance stated in USB specifications is 10 μF. When the device disconnects, a large voltage peak may occur. Therefore, at least 1 μF decoupling capacitance has to be implemented for safe USB operation [21].

Fig. 1. Central unit - smartphone connection

B. USB Suspend Mode

Support for suspend mode is mandatory for all devices. During this mode, additional constrains apply. The maximum suspend current is proportional to the load unit. For one load unit the maximum suspend current is 500 μA [21]. This includes current from the pull-up resistors on the bus. Another consideration for many devices is the 3.3 V regulator. Regular voltage regulator has average quiescent currents around 600 μA [22]. For one unit load it is necessary to implement more efficient and sophisticated voltage regulators. In most cases, microcontroller clock has to be stopped or slowed down to fall within the 500 μA limit [22].

A USB device will enter suspend when there is no activity on the bus for greater than 3.0 ms. Then, the device has another 7 ms to shut down and draw no more than the designated suspend current [21]. In order to maintain connected, the device has to provide power to its pull up speed selection resistors also during suspend mode.

USB specification determines frame packet start as well as periodical sending of keepalive packets. This prevents an idle bus from entering suspend mode during the data absence. High speed bus has micro-frames sent every 125.0 μs, full speed bus sends frames each 1.0 ms and low speed bus sends the keepalive frames every 1 ms only in the absence of any low speed data [21].

IV. Characteristic of the Proposed BAN

Proposed network for the vital function monitoring senses three characteristics of human body, assuming that the stress can be determined with change of sweating, heart-rate and body temperature. Due to the reasons of energy-saving, temperature and humidity was being monitored each time period on temperature/humidity module (TH module), with the time period set to $1s$. If a significant change from the normal value was spotted, the control node/central unit (CU) sent the information to oximeter module (O module) for the need of heart rate measurement. In case that the stress was indicated also from heart rate, signal is sent to the smartphone and according to the stress rate, the smartphone application will choose form available methods and will offer suitable activity for stress dismantle.

Communication structure of the BAN modules was based on the star network architecture, where the central unit interconnecting whole BAN was set to be CU. More about the architecture of BAN was written in [2], [3]. The interfaces

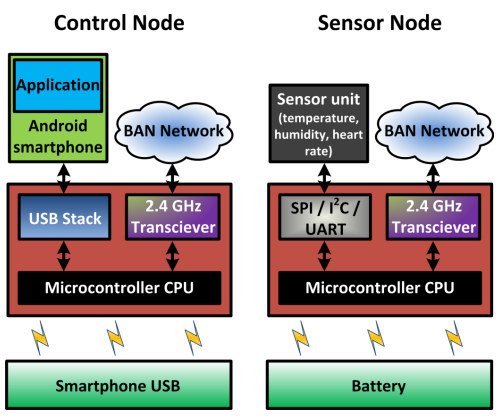

Fig. 2. BAN concept

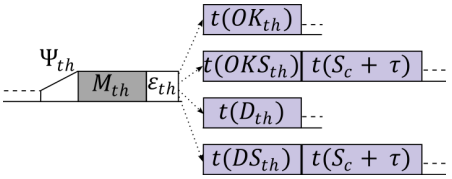

Fig. 3. Time diagram for temperature-humidity module

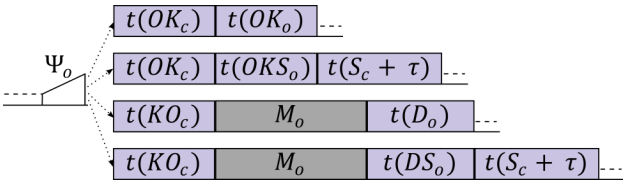

Fig. 4. Time diagram for oximeter module

utilized within the particular nodes are depicted in Fig. 2. The central unit was connected to the smartphone through USB.

For temperature and humidity monitoring, HIH-6131-021-001 sensor is used. The sensor goes into sleep mode when not taking a measurement and consuming only 1 μA of power. In full operation consumes 1 mA and the time of power-on to data ready is 60 ms [23]. Standard way of the pulse oximetry with emitting diode and photodetector is used for the heart-rate measures in a fingertip.

V. Timing and Communication Slots

Aforementioned modules communicate with each other in window slots (TDMA). CU which collects information from sensor modules, is responsible not only for measured data evaluation but also for synchronization of measuring modules.

Because the aim is to decrease the energy requirements, CU is active in communication slots for each module. Then it evaluates data, sends them to smartphone and goes into sleep mode for the next communication period.

In Fig. 3 time diagram for TH module is depicted. The module sleeps and wakes in the time Ψ_{th} [s] before measurement. Ψ_{th} depends on the wake-up-time of the selected core TI CC2545 necessary for getting from power mode 3 to active mode as well as on the assurance constant value. Ψ_{th} was set to $150\,\mu s$. Because the measurement is required before each communication slot, the RX/TX initialization is made at the same time as the measurement is made. Measurement of used temperature/humidity sensor HIH-6131-021-001 is ready after $M_{th} = 60\,ms$. The measurement is sent to core through SPI interface and the data are concerned for sending. Data processing and communication of the core with the sensor last for ε_{th} [s]. If data do not get over the change limit, the data are not sent, only information about good condition of module is sent in packet OK_{th}. Type of communication after data processing is visible in the Fig. 3 with respect to the Table IV. After last communication in corresponding communication period the module returns back to the sleep mode.

Measured data are processed in CU. If the values are in the scope where the stress was not identified, CU sends only OK_c packet to O module in corresponding time slot and the O module does not measure heart rate. Because measuring is energy-demanding, in this way it is assured that energy consumption is suppressed. Time flow of oximeter communication period is depicted in Fig. 4. O module does not measure before each communication slot, but it needs to wake up in the time Ψ_o before the packet arrives from the CU. $\Psi_o = 650\,\mu s$ depends on the ability of module to change from power mode 3 to active mode, on the time necessary for the activation of receiving as well as on the subsumption of the assurance constant.

Because the communication with each module is different, for communication purposes not the same packets are used. Form of the packet is visible in Table III, acceptable types of packet and length of data are mentioned in Table IV.

Because the communication under the communication rate $v_c = 1\,Mb/s$ is aimed to be accomplished within the system, the time for communication of worst case is when the packet size $PS = 7B$ (according to Table III and IV) is sent. The length of communication slot t_s is set as:

$$t_s = \frac{v_c}{PS} + \lambda \approx 60.5\,\mu s, \quad (1)$$

where λ is assurance constant for resynchronization and was set to $0.5\,\mu s$. λ assures, that also when the crystal inaccuracy

TABLE IV
BAN PACKET TYPES

Packet type	Data length	Description
D_{th}	4 B	Data from temperature/humidity module
D_o	1 B	Data from oximeter module
DS_{th}	4 B	Data with synchronization request from temperature/humidity module
DS_o	1 B	Data with synchronization request from oximeter module
OK_c	0 B[a]	Information packet from central unit for oximeter module that there is no need for measurement
KO_c	0 B[a]	Information packet from central unit for oximeter module that there is need for measurement
OK_o	0 B[a]	Acknowledgement from oximeter module about the packet OK_c from central unit
OKS_o	0 B[a]	Acknowledgement about the packet OK_c from central unit and synchronization request from oximeter module
OK_{th}	0 B[a]	Information packet from temperature and humidity module for central unit that everything is all right and the measurement does not change after treshold
OKS_{th}	0 B[a]	Information packet from temperature and humidity module for central unit that everything is all right, measurement does not change after treshold and there is need for synchronization
S_c	4 B	Synchronizing time from central unit

[a]Information packet differs only in packet header. There is no need to transfer data.

will occur, the communication in corresponding time slot will be possible.

Because the communication is performed between the nodes with two different cores CC2511 and CC2545, they oscillators have different crystal frequency (f_{CC2511}, f_{CC2545}) and accuracy (acc_{CC2511}, acc_{CC2545}) . Time of communication period is set to 1s, error of crystal for core CC2511 Δ_{2511} is set to:

$$\Delta_{2511} = \frac{1}{f_{CC2511}} - \frac{1}{f_{CC2511} + acc_{CC2511}} \approx 1.538x10^{-12}\,s \quad (2)$$

Error of core CC2545 Δ_{2545} is set to:

$$\Delta_{2545} = \frac{1}{f_{CC2545}} - \frac{1}{f_{CC2545} + acc_{CC2545}} \approx 1.875x10^{-12}\,s \quad (3)$$

set for $60.5\,\mu s$ and the number of synchronized periods p_s is set as:

$$p_s = \frac{\frac{\lambda}{2}}{\Delta_{2511} + \Delta_{2545}} = \frac{0.25x10^{-6}\,s}{3,413x10^{-12}\,s} \approx 73\,249 \quad (4)$$

It means that the synchronization is necessary after 73 249 cycles. As was mentioned, cycle for TH measure is long 1 second, so the synchronization is used 2 times a day.

When each of sensing modules need to synchronize, it sends the synchronization packet to CU. The type of synchronization packets are mentioned in Table IV.

VI. Energy saving in TH module

Low power consumption is one of major condition in many applications. Amount of required energy is very important in monitoring applications where an effort to achieve long operation time is emphasized. It is not only the problem of applications from BAN area, but also from many other monitoring applications in the field of wireless sensor network [24].

One of the possibility is to use sleep mode as was mentioned in previous part. For TH module, communication period lasts $1s$ and is visible in Fig. 3. TH module is active for time t_a:

$$t_a = \Psi_{th} + M_{th} + \varepsilon_{th} + t_s \approx 0.066\,s \quad (5)$$

and sleeps for $t_{sleep} = 0.934\,s$. Concerning the consumptions listed in Table II, average current I_{avg} for TH node was estimated as $2\,mA$. According to used battery CR2450 which capacity is $600\,mAh$, the TH module should operate more than 12 days.

VII. Conclusion

This paper presents the smartphone-based Body Area Network for monitoring of human vital signs regarding the stress situation. In particular, energy requirements are discussed. The results showed that the designed BAN is able to last up to 2 weeks without any intervention. On the other hand the smartphone in not capable of such long lifetime. Therefore, until now, the weakest link of the network is the smartphone and the coordinator module attached to it. This application is eligible for eHealth sector as well as general wellness to serve as front-line in cardiovascular disease detection. The future work is focused on implementation of the developed system into different application fields of modern life, primarily into the field of intelligent transportation systems aiming the problematic of the professional drivers' behaviour on the road with the comparison to their actual stress level.

***Abstract*—Traditional wireless sensor nodes are designed with low-power modules that offer limited computational performance and communication bandwidth and therefore, are generally applicable to low-sample rate intermittent monitoring applications. Nevertheless, high-sample rate monitoring applications can be realized by designing sensor nodes that can perform high-throughput in-sensor processing, while maintaining low-power characteristics. In this paper, a high-performance and low-power wireless hardware platform is presented. With its compact size and modular structure enabling there to be an integrated customized sensor layer, it can be used for a wide variety of applications. In addition, the flexibility provided through dynamically configurable interfaces and power management, helps optimizing performance and power consumption for different applications.**

***Keywords*—FPGA, wireless platform, high-throughput, low-power**

I. Introduction

With the advent of low-cost, low-power, and miniature size electronics, wireless sensor nodes have emerged as a low-cost alternative to fixed wired-based sensing solutions. These nodes are typically designed using a low-power micro-controller, a radio transceiver, and one or more sensors to measure a particular physical phenomenon. Based on the limited computational performance, communication bandwidth, and lifetime, these nodes have traditionally been applied to particular low-sample rate intermittent monitoring applications in different field [1]-[4]. However, their potential advantages have provided the motivation to explore them in relation to high-sample rate applications.

Given the limited bandwidth and high-power consumption of radio transceivers that are typically used in these nodes, the major challenge lies in transmitting a large amount of data generated by high-sample rate applications. In order to overcome this challenge, researchers have proposed in-sensor processing [5]-[8] in which, raw data is processed locally in a sensor node, and only results are transmitted wirelessly. Therefore, it reduces communication activity and the associated power consumption. However, it is observed that typical low-power micro-controllers integrated in sensor nodes, often lack high-throughput performance when complex mathematical and signal processing algorithms are involved. Therefore, to meet the demands of high computational performance, the prototype design reported in [5] employs a high-throughput micro-controller for in-sensor data processing, in addition to a low-power 8-bit micro-controller. In [6], a Field Programmable Gate Array (FPGA) based in-sensor processing solution is demonstrated in relation to an image processing application. In [7] and [8], FPGA-based commercial evaluation kits and micro-controller based wireless nodes were used to investigate their performance and energy consumption for high-sample rate applications. Based on the presented results in these articles, it can be concluded that high-throughput processing requirements can only be fulfilled through an FPGA, however, by accurately distributing the processing, communication and control specific tasks on a micro-controller and an FPGA, it is possible to optimize both the performance and power consumption for an application.

By analyzing the published literature relating to high-performance wireless nodes, it was found that there are only two such nodes, [9] and [10] that are able be used for high-throughput in-sensor processing. Both nodes are very similar in their design, as they are built on a similar layered structure and they integrate similar modules. For example, each has a sensor layer, a processing layer consisting of micro-controller and/or an FPGA, a communication layer to enable wireless communication and, in addition, to a power supply layer. On both nodes, the processing layer consists of an FPGA that can be used for in-sensor processing. However, both these FPGAs (Spartan-IIE, and Spartan-IIIE) were built on a technology that is now a decade old and therefore, does not offer the high-performance and low-power consumption that is the case with the modern FPGAs. Apart from that, inter module communication interfaces such as between FPGA and micro-controller, and between wireless transceiver and micro-controller are fixed in these nodes and therefore, cannot be re-configured for different applications without modifying the hardware design. Additionally, the compactness of these nodes is compromised because of the extra height, resulting from the interface connectors on both sides of a layer and also stacking of four layers on top of each other to form a complete working node.

To overcome the above mentioned problems, we have developed a high-performance, low-power and compact wireless embedded platform, the SENTIOF that is shown in Fig. 1. It integrates a micro-controller, an FPGA, an SRAM, a FLASH, and a radio transceiver on a single printed circuit board (PCB), while providing easy integration of a customized sensing layer,

978-83-60810-53-8/$25.00

in order to use it in different applications. The SENTIOF is designed with the following key characteristics.

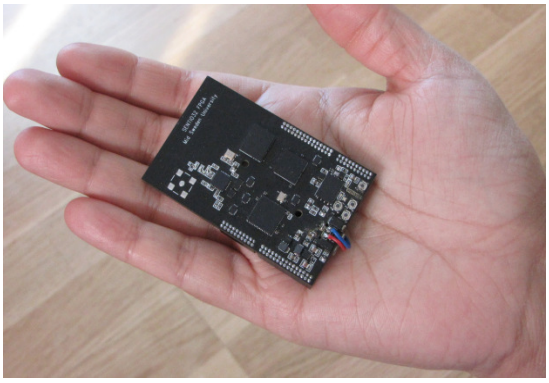

Figure 1. The SENTIOF platform

High-Performance In addition to sequential processing capabilities, there must be support for hardware acceleration in order to perform computationally intensive processing.

Low-power The integrated components should be operable at different clock frequencies so as to optimize the power consumption and performance. In addition, the platform must support a dynamic power management to switch-off unused components.

Sensor integration The platform must support easy integration of application dependent sensors. Therefore, in addition to different power supply voltages, a large number of input-output interfaces from a micro-controller and FPGA should be provided for this purpose.

Flexibility In addition to the easy integration of sensors either with a micro-controller, FPGA or both, the platform must support the easy realization of application dependent communication between the micro-controller and the FPGA.

Compact size The platform should have small dimensions so that it can be deployed in applications with space constraints.

The details regarding the design, performance and power consumption of the SENTIOF are the main focus of this paper. The remaining sections are organized as follows. Section II describes the hardware design aspects of the SETNIOF. Section III is devoted to software related details. In section IV, the performance and the power consumption analysis are presented, while concluding remarks are given section V.

II. Hardware Design

A simplified design of the SENTIOF, representing all major components and their interconnections is shown in Fig. 2. With the exception of power source, all other components are integrated in the SENTIOF platform, which is discussed in detail in the following.

A. Plateform Components

Based on the functional description of the integrated components, the SENTIOF can be divided into different logical units, such as processing, communication, memory, power management and sensor interface, and can be then described accordingly.

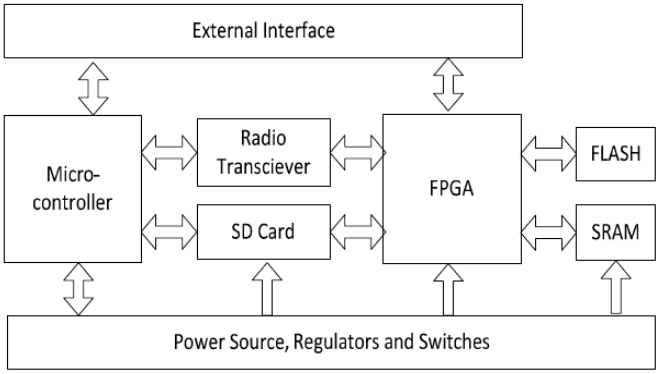

Figure 2. Architectural depiction of the SENTIOF

Processing Unit

In order to achieve a high-computational performance, two processing resources, a 32-bit micro-controller ATUC3B0512 [11], and a Spartan-6 FPGA XC6SLX16-2CPG196 [12], are integrated in the SENTIOF.

The micro-controller provides high computational capabilities by means of a compact single-cycle instruction set including DSP instructions and an operational clock frequency of up to 60 MHz. Additionally, it includes an extensive set of input-output (IO) interfaces and a number of low-power modes in order to optimize the power consumption for an application. The micro-controller can be used to process the application data, read the sensor's data, and/or communicate with the radio transceiver in order to transmit or receive data/results. In addition to its application dependent data processing, the micro-controller performs all the control specific operations such as power and FPGA configuration management and therefore, acts as a central control unit in the SENTIOF.

The micro-controller can be used as the main processing unit for a wide variety of monitoring applications. However, in order to achieve a high-throughput computational performance as required in many high-sample rate applications, the FPGA is integrated into the SENTIOF. Due to hardware parallelism, it is possible for multiple independent tasks to be realized using dedicated hardware logic in the FPGA, which thus be performed simultaneously at high speed. In addition, the re-configurability of the FPGA allows synthesizing different algorithms with optimized control and data paths, without modifying any real hardware. The selected FPGA is enriched with sufficient amount of basic logic cells, in addition to other resources such as block RAM, multiply-and-accumulator (MAC) units, and PLLs. A summary of these resources is given in Table I.

Radio transceiver

In order to enable wireless communication in the SENTIOF, an IEEE 802.15.4 compliant low-power radio transceiver, CC2520 [13] is integrated in the design. The

transceiver operates at the 2.4 GHz license free band and provides a maximum throughput of 250 kbps. In addition to 6 reconfigurable GPIOs for optional command and interrupt signals, the radio transceiver includes a SPI interface to communicate and exchange data either with the micro-controller or with the FPGA. The interface to both the micro-controller and the FPGA is achieved by means of multiplexer/de-multiplexer switches and is therefore, able to be configured dynamically. This additional flexibility can be exploited to optimize the performance and the power-consumption of the communication activity according to the requirements of an application.

TABLE I.
A SUMMARY OF LOGIC RESOURCES OF THE SPARTAN-6 FPGA XC6SLX16-2CPG196

Logic Cells	LUT size	Dis-tribu-ted RAM	Block RAM	MAC units	PLL	Number of IOs
14,579	6-input	136 kb	576 kb	32	2	106

Memory

High-sampling rate applications generally process a large amount of raw data, and generate both intermediate and finals results that must be stored in fast memories in order to achieve a high performance. Therefore, in addition to a 96 kB of SRAM in the micro-controller and 89 kB in the FPGA, a 4 MB of additional SRAM, CY62177DV30 [14] is integrated in the SENTIOF. The low-power SRAM, interfaced with the FPGA, provides a 16-bit wide data path for read and write operations that can be performed in 55 ns.

The FPGA requires re-configuration each time it is powered-on. Therefore, a high-speed and low-power FLASH based configuration memory, W25Q64BV [15][14] is used for this purpose. The selected FLASH memory provides a rapid access rate of 85 MHz and a quad serial peripheral interface (SPI), which enables the configuration of the FPGA in the minimum time. In addition to the configuration data of 4 Mb, the 64 Mb FLASH can be used to store application data.

For long term data storage, the SENTIOF is designed to support a micro-SD card. In a similar manner to that for the radio transceiver, the interface to the SD card can also be dynamically configured either to the micro-controller or to the FPGA, as it is interfaced to both these processing units through multiplexer/de-multiplexer switches.

Power

The SENTIOF is powered by means of a single DC power source, with output voltage between 3.6V and 6V. This DC voltage is fed to the SENTIOF and is then regulated and converted to four different levels as shown in Fig. 3. In relation to these four voltages, the 1.2V regulated voltage is used to power the FPGA's core while the 1.8V is used to power the radio transceiver and the core of the micro-controller. Apart from the radio transceiver, the cores of the FPGA and the micro-controller, all other components on the SENTIOF platform are powered with 3.3V. The boost convertor that can be adjusted to provide up to 6.5V, is included for external devices/sensors that may require a higher voltage than is provided by attached DC power source, i.e. typically a 3.6V. In addition to a DC power source, the SENTIOF can also be powered through a USB interface. This provides an added advantage of continuous long term power during an application development process.

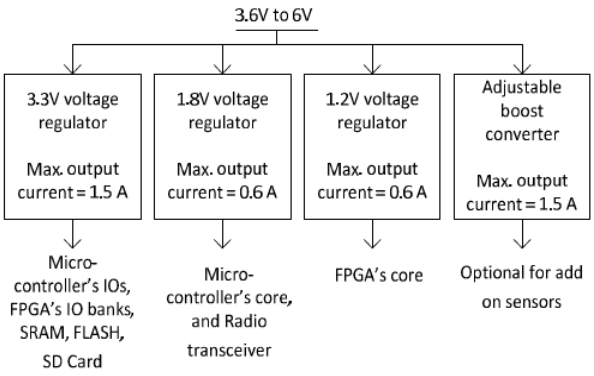

Figure 3. Power supply distribution in the SENTIOF

External Interface

The external interface provided through the 1.27 mm-pitch connectors serves three purposes. Firstly, it provides a large set of IOs, both from the micro-controller and the FPGA, in addition to all regulated power sources in order to integrate a customized sensor board with the SENTIOF. Secondly, the JTAG interfaces required to program/configure each of the micro-controller, the FPGA, and the FLASH memory from the computer are also made accessible through this external interface. Lastly, the application specific communication requirements between the micro-controller and the FPGA can also be fulfilled through this interface.

B. PCB Design

In order to ensure a high-performance and low-production cost, special consideration was given to the PCB design. This includes the separation of different ground planes, the minimization of trace length between the high-speed devices, limiting the design to a reduced number of layers, and avoiding micro and buried vias.

To minimize noise in relation to all the different types of components, four ground planes are used. A generic ground plane, GND, is used to connect ground plane of the DC power source to other planes through 0 Ohm resistors, as shown in Fig. 4. In these planes, the digital ground, DGND serves as a return path for all digital components including the FPGA, micro-controller, SRAM etc. The power ground, PGND is used to minimize the noise from other planes onto the power supply components. As there are no analog components mounted on the SENTIOF, the analog ground AGND is not used. However, it is provided to ensure that analog sensors can be reliably interfaced with the SENTIOF.

In relation to all the components mounted on the SENTIOF, it is the FPGA that has the highest pin count of 196 pins, which

are packed into 8x8 mm BGA package organized in 14 x 14 rows and columns. The 0.5 mm horizontal and vertical pin pitch resulting from this small footprint was a challenging factor, as it determined the routing and clearance rules in addition to the number of the routing layers. For example, if the manufacturer's guidelines regarding the PCB design of the FPGA [16] are strictly followed, then it requires a minimum of 7 PCB layers using micro-vias, while restricting the trace width and clearance to 0.075 mm. The production cost of the resulting PCB is then significantly higher in comparison to an equivalent PCB with a via diameter of more than 0.15 mm, and a trace width and clearance of 0.1 mm or more.

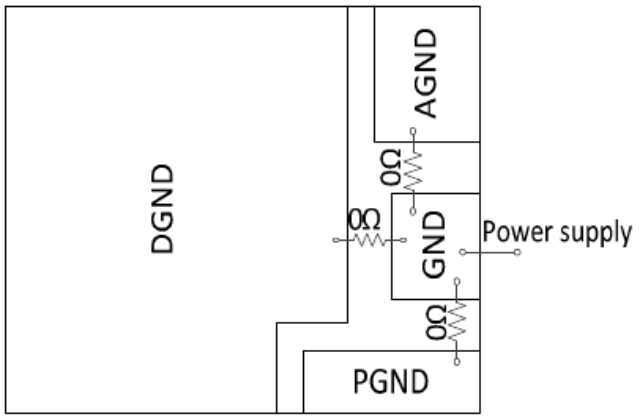

Figure 4. Ground planes used in the SENTIOF.

Therefore, to relax the production requirements, the via-in-pad option was used for the FPGA. This allowed to use larger pad size and, eventually, larger via hole diameter of 0.2 mm, a minimum trace width and clearance of 0.1 mm. In addition, it also helped to reduce the PCB design to 6 layers and without the necessity of buried vias.

Among other components, it was the radio transceiver that required the strictest observation of the manufacturer's guidelines, in order to ensure proper functionality. Therefore, the layout of the radio transceiver was completely matched with the reference layout. In addition to providing an interface for an external antenna, a PCB antenna is also incorporated for the radio transceiver.

C. Physical Structure

The size of the PCB is 65 x 40 mm, with 5 mm of interface height on one side that is used to attach a sensor module. A sensor module comprising of one or more sensors, is electrically connected with the SENTIOF platform through a rigid and strong header interface. In addition, two mounting holes are created in order to provide structural reinforcement of the platform and the sensor module, which may be required for certain applications.

III. Software Design

In order to use the SENTIOF for an application, supporting software must be developed for both the micro-controller and the FPGA. Currently, this is achieved using two different software development environments, the AVR32 Studio and the Xilinx ISE for the micro-controller and FPGA, respectively.

The integrated development environment for the micro-controller that can be obtained from Atmel's website free of charge and it integrates a software framework and a GNU tool chain allowing easy and rapid application development in C/C++. To further enhance the software development process of the micro-controller in relation to the SENTIOF, application programming interfaces (APIs) are developed for all control and data transfer specific operations including power management, radio communication and reading/writing to SD card.

The Xilinx ISE Design Suite integrates all the tools to support complete design development, starting from an RTL design specification to the generation of a programming file for the FPGA. It also includes a wide variety of IP cores that can be integrated into a design, thus resulting in rapid development. In relation to the SENTIOF, we have developed interface APIs for both the SRAM and the FLASH, which can be re-used in other designs. Similar APIs for the radio transceiver and the SD card interface will also be developed in the near future.

IV. Performance and Power Consumption Analysis

The SENTIOF was designed to achieve a high computational performance and low power consumption goals, and these were ensured at each development stage including architectural decisions, component selection, and PCB layout. Performance of both the micro-controller and the FPGA is dependent on an underlying application. Therefore, a measure of clock frequency, on which these two can be operated, is discussed for analysis purposes. However, the precisely measured power consumption for various activities is used for analysis in the this section.

D. Clock frequency

The micro-controller can either be clocked from an internal oscillator producing a clock frequency of about 115 kHz or from an external oscillator producing 16 MHz of clock frequency. The clock from the internal oscillator is often too slow for a computationally intensive application and therefore, may be used in either very low-speed applications or during sleep modes. However, to achieve different performance levels, the micro-controller can be operated at a wide frequency range, with an upper limit of 60 MHz. In such cases, the desired frequency can be synthesized from a 16 MHz external oscillator by using a built-in Phase Locked Loop (PLL) in the micro-controller.

During the SENTIOF design it was observed that the available oscillators with frequencies higher than 19 MHz, as is required in the FPGA, consume a significant amount of power that is undesirable in a low-power platform. Therefore, a global clock generation feature of the micro-controller was instead used to provide the clock for the FPGA. The frequency of this input clock can be further increased to 375 MHz using a PLL in the FPGA.

E. FPGA Configuration

In order to conserve power, it may be desirable to switch off the FPGA for idle time periods in an application. However, upon power-up, it must be reconfigured to resume its job. The (re)configuration for the FPGA integrated in the SENTIOF is accomplished by loading nearly 3.6 Mb of configuration data into the FPGA, from the associated FLASH memory. Depending upon the clock frequency and the bus width options that are selected to configure the FPGA, the actual configuration time can vary from one application to another.

The minimum configuration time of 15.16 ms was recorded by applying a maximum supported speed of 66 MHz and a maximum bus width option of 4 bits, also known as quad SPI.

F. Power Consumption

The power consumption in the SENTIOF can be optimized through dynamic power management, where all major components including the micro-controller, FPGA, SRAM, FLASH, and the radio transceiver can be switched to low-power modes at run time. This allows a reduction in the power consumption of each component to a minimum level, typically from tens of micro-watts to a few milli-watts depending upon the actual component. Therefore, to further minimize the power consumption during the idle state, the SENTIOF is designed to dynamically switch-off/on the FPGA, SRAM, FLASH, and SD card as they consume significant power in their low-power modes. To realize this power on/off mechanism, a very low-power metal-oxide semiconductor (MOS) transistor is used as a switch between the power supply and the power connection of the components. The transistor is then switched on/off through the micro-controller, which performs all control specific operations including power management. It should be noted that radio transceiver that typically consumes 1μW in low-power mode and, it is not enabled to be switched on/off using MOS transceiver, as the MOS transistor consumes almost the same amount of power as that of the radio transceiver in low-power mode and therefore, no significant power can be conserved by the power on/off method.

Depending on the application, the SENTIOF may be in active mode, where it performs data acquisition, processing, and/or result transmission, or it may be in sleep mode for certain time duration before it is operational again. The power consumption in these modes differs significantly and therefore, it is discussed with respect to these two modes in the following.

Sleep mode

In sleep state, with the exception of the micro-controller, other components including the FPGA, SRAM, FLASH, and the SD card are switched-off. The micro-controller however, is switched to a low-power mode known as DeepStop, in which it is not only able to keep track of the sleep duration by using real time counter (RTC), but is also capable of switching all components including itself to the active state.

In sleep mode, the average current drawn by the SENTIOF from a 3.6V supply source was measured to be 95 μA. During this mode, both the 1.8V and 3.3V voltage regulators which remained fully functional to ensure the required voltage levels to the micro-controller were responsible for nearly 70% of the reported current consumption.

Active mode

Unlike the sleep mode, the power consumption of the SENTIOF during its active mode is dependent on an frequencies and the time duration for which different components are active. Nevertheless, to provide a rough idea, the current consumption was measured for a number of application scenarios involving almost all the major components on the SENTIOF, and is summarized in Table II. Each reported value represents the total amount of current that was drawn by the SETNIOF for a corresponding scenario, from a 3.6V power source.

For application scenarios 1, 2, and 3 given in Table II, the micro-controller was in the active state performing a simple addition operation repeatedly. Apart from the 3.3V and 1.8V voltage regulators that are required to provide power to the mi-

TABLE II. THE AVERAGE CURRENT CONSUMPTION OF THE SENTIOF FOR DIFFERENT APPLICATION SCENARIOS

S. No.	Actions	Average Current (mA)
1.	The micro-controller is clocked at 16 MHz and is in active mode, where it performs an addition operation repeatedly.	5.54
2.	Same as of 1, except the clock frequency is 20 MHz.	7.49
3.	Same as of 1, except the clock frequency is 60 MHz.	21.34
4.	The micro-controller is clocked at 16 MHz and is in Frozen mode, in which it generates 20 MHz of clock frequency for the FPGA.	4.28
5.	Same as of 4 + both the FPGA and the Flash are ON, and the FPGA loads bit-stream from the FLASH at 66 MHz using quad SPI interface.	30.3
6.	Same as of 4 + FPGA is active and is running a design in which, a 100 MHz of clock is synthesized through internal PLL, and then is used to update a 27-bit counter.	22.31
7.	Same as of 6, except that the FPGA is in standby mode.	8.30
8.	Same as of 6 + the FPGA reads 16-bit data word from the SRAM repeatedly at a rate of 16.6 MHz.	34.58
9.	Same as of 6 + the FPGA writes 16-bit data word to the SRAM repeatedly at a rate of 16.6 MHz.	44.62
10.	Same as of 6 + the FPGA erases the FLASH memory.	48.17
11.	Same as of 6 + the FPGA reads data from the FLASH memory at a rate of 50 MHz.	29.90

13.	Same as of 2 + the micro-controller reads data from the SD card at a rate of 20 MHz.	20.64
14.	Same as of 2 + the micro-controller writes data to the SD card at a rate of 20 MHz.	24.37
15.	Same as of 1 + the radio transceiver operates in receive mode and received packets are transferred to the micro-controller.	31.34
16.	Same as of 1 + the data packets from the micro-controller are transmitted by the radio transceiver at rate of 250 kpbs using 5 dBm power.	39.15

cro-controller, all other modules were in the off state. The micro-controller was clocked through a 16 MHz external oscillator, and then synthesized to 20 MHz and 60 MHz through an internal PLL.

The average current drawn by the SENTIOF while configuring the FPGA from the associated FLASH is given in Scenario 5. Scenarios 8 and 9 list the current consumption when the FPGA performs read and write operations on the SRAM. Other important scenarios include 15 and 16, in which the radio transceiver is operated in receive and transmit modes, respectively.

V. Conclusion

In this paper, we presented a high-performance and low-power wireless hardware platform, SENTIOF that is capable of performing high-throughput in-sensor processing, as typically required for high-sample rate monitoring applications.

The SENTIOF integrates a micro-controller, an FPGA, an SRAM, a FLASH, and a radio transceiver on a single PCB in order to realize a high-performance compact wireless platform. This application independent platform allows for the integration of any kind of sensors through an application specific and customized sensor layer. In addition, the dynamic power management and reconfigurable architecture can be exploited to optimize performance and power consumption according to different applications.

The flexibility provided through dynamically configurable interfaces, customizable communication between the micro-controller and the FPGA, and dynamic power management can also be used to explore efficient architectures for different monitoring applications.

***Abstract*—The paper presents a prototype radio network aiding the visually impaired to navigate in indoor areas. The main purpose of the system is to provide accurate and reliable location information as well as to enable access to location related context information. The nodes of the network operate in two modes providing basis for both rough and precise user position estimation. The data transmitted by the nodes are used to get access to additional services, e.g. to retrieve position related context information.**

***Index Terms*—Context-aware services, indoor radio communication, location services, personal communication networks, pervasive computing, radio navigation, wireless sensor networks**

I. Introduction

THERE ARE about 285 million visually impaired people living around the world [1]. The inability to sense the surrounding environment strongly affects the possibility of utilizing public spaces, including urban areas, transportation systems and public buildings [2]. Recently, a number of electronic systems aiding the visually impaired in travel and mobility have been developed [3-8]. Most of these systems require accurate information on current user location. Obtaining precise information on user location can facilitate access to public services offered in large buildings (e.g. city halls, hospitals) by aiding to locate rooms or by giving a remote guidance on how to get to the target destination. Contemporary satellite navigation systems like GPS provide positioning services sufficient for successful navigation of pedestrians in typical outdoor scenarios and thus are often incorporated in electronic travel aids (ETA) for the visually impaired. However, the use of satellite positioning systems is limited to outdoor areas only. The GPS positioning accuracy also decreases in dense urban environments where multipath propagation and strong signal attenuation result in insufficient quality of satellite beacons. Therefore, there is a need to develop dedicated systems aiding the blind and the visually impaired in urban navigation. Most of electronic mobility aids offered on the market make use of local networks of reference stations that transmit infrared [3] or radio signals [4], [5], [6]. The transmitters are used to identify various points of interest (POI) like bus stops, entrances to public buildings, etc. One of the first indoor positioning systems that used radio beacons and Received Signal Strength Indicator (RSSI) measurements was the RADAR system developed by Microsoft Research in the beginning of the 21st century [9]. From that time the problem of indoor positioning and navigation has been widely addressed around the world [10-22]. Hence maintaining low deployment and maintenance costs is among the most important objectives of the research, majority of the solutions reported in the literature rely on radio signal strength measurements. Signal strength readouts can be incorporated to location services in at least two ways. First of all, radio wave indoor propagation models can be used to determine the possible location of the terminal. This approach requires detailed description of the propagation environment and thus is difficult to implement. Another approach involves the use of database search methods to calculate user position. Therefore, it is necessary to provide reference RSSI measurements (i.e. measurements taken in predefined locations) that are stored in the reference database, and which are then used by location estimation algorithms. In the paper, we present a wireless indoor positioning system developed as a part of a complex solution aiding the visually impaired in independent travel and mobility.

This work was partially supported by the National Centre for Research and Development of Poland under grant no. NR-02 0083-10 in years 2010-2013.

II. System architecture

The architecture of the proposed indoor positioning system consists of a local localization server, a local database server and an optional global localization server. A wide range of portable user devices (PDAs, smartphones, notebooks, etc.) operating in different wireless networks may be used as system terminals. The terminals should have the capability to measure strength of the signals transmitted by system reference stations mounted inside a building. Thus, a dedicated software or hardware is necessary to make use of the measurement data, especially to pass the results to the local positioning server. The tasks of the local positioning server are: to keep information about the layout of the area it serves (e.g. an office building), to make the use of local database engine to store reference measurement data, and to compute the probable user location based on the RSSI measurement values reported by the terminal. Moreover, the local server is also responsible for communication with the global localization server, if available. The global localization server can be also

used to deliver new positioning algorithms. The architecture of the proposed system is shown in Fig. 1. All the components of the system communicate using XML/JSON and SOAP-based Web Services.

III. Wireless Positioning Techniques

A variety of techniques can be employed to estimate the position of a wireless network terminal. In majority of systems measurements of signal parameters transmitted by system reference stations are used. Then, the position of the terminal is estimated based on calculation of distances of the terminal to at least some of the reference nodes. The most commonly used signal properties include propagation time, angle of arrival, and received signal strength [10].

A. Proximity Detection

The most straightforward method to estimate the position of a radio terminal is to determine whether it is within the coverage of some reference station. The accuracy of positioning with this approach strongly depends on the range of reference transmitters. However, when reference stations transmit signals with relatively low power, the position of the user terminal may be well approximated by the known location of the reference transmitter. This approach is called proximity detection. Practical implementation of this positioning technique involves installation of many reference nodes, often called radio tags. However, due to simple tag's construction the overall system installation cost might remain low. This technique offers good accuracy, however it strongly depends on the number of installed reference tags. The idea of positioning system using proximity detection is shown in Fig. 2.

B. Database Search-based Indoor Positioning

Distance estimation techniques involving radio wave propagation modeling are widely used in positioning systems. However, due very high complexity of indoor radio wave propagation environment, applicability of these methods is limited to outdoor areas. In typical indoor scenarios, strong multipath propagation effects make it impossible to unambiguously relate measured signal parameter value to a distance from the transmitter. Even along short propagation paths, signal parameters may exhibit very strong variability. Another factor limiting performance of positioning methods is time variability of indoor radio channel characteristics. For example, depending of the time of the day, the offices may either be crowded or almost empty what may result in significant changes of the reported values. Therefore, there is a need to search for new positioning methods for indoor applications. One of the approaches that is adequate for indoor systems assumes the use of correlation analysis of reported signal parameter values with some reference data recorded at predefined locations. As database search methods rely on evaluation of similarity of measured signal characteristics at actual location to the reference datasets, these methods are not so prone to multipath and shadowing effects as the methods based on radio wave propagation modeling. Despite of the fact that database correlation methods may be based on analysis of any available signal parameters, most of practical implementations involve received signal strength measurements. The advantage of the use of RSSI is that most of contemporary radio receivers provide possibility to monitor RSSI level and a wide range of devices can be used with a positioning system without a need to implement any hardware modifications. The use of database search methods makes it also possible to reduce the influence of RSSI time variability by the use of normalization to the value read from a given reference signal source.

C. Proposed Positioning Technique

The proposed implementation of a wireless indoor positioning system involves received signal strength (RSSI) measurements to estimate terminal position. It makes use of the advantages of both aforementioned approaches, i.e. proximity detection and database search methods. Hence proximity detection is most effective and accurate when area served by a single reference tag is relatively small, the tags should be equipped with radio transmitters supporting low transmit power modes. On the other hand, database search method accuracy increases with the number of sources of reference signals. In that case, the nodes should be capable to transmit reference signals over relatively large areas. Moreover, the coverage areas of neighboring transmitters should overlap. It is worth mentioning, that position information returned in the form of absolute geographical coordinates of the user is not the most expected output from indoor navigation and positioning systems. Geographical coordinates are more suitable for outdoor positioning, mainly due to easy integration with GIS systems. Moreover, in indoor applications accurate and

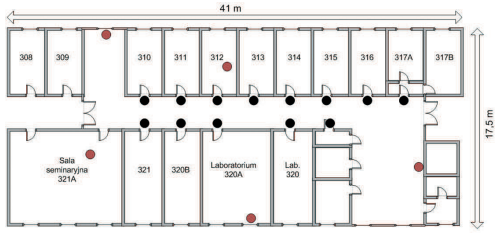

Fig. 3. Test site with reference points (black dots) and reference tags (red dots) used in the second experiment.

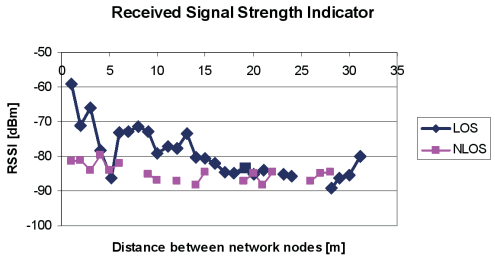

Fig. 4. RSSI as a function of distance from the transmitter.

reliable altitude estimation is required. Although in outdoor scenarios the use of absolute altitude above ground or sea level as altitude descriptor is the most convenient, in indoor scenarios floor index should be considered as the natural way of expressing in-building altitude of travelling people. Therefore, the proposed indoor positioning system makes use of area-based context-related positioning. Area-based positioning systems provide end users with context information related to the current zone of the building. The system output data set includes but is not limited to:

- floor index or name (if applicable),
- zone within a building (e.g. “north wing”),
- room or office number or its name (e.g. “kitchen” or “auditory no. 416”),
- additional site-related information (like name of current lecture in an auditory room).

Moreover, the proposed system returns absolute coordinates of the user terminal to ensure backward compatibility.

IV. Experiment Results

The prototype system was built with the use of Texas Instrument’s CC1110 radio transceivers operating in 868 MHz unlicensed band and transmitting with output power ranging from -30 dBm to +10 dBm. The reference nodes and the user terminal were equipped with omnidirectional antennas having +2.2 dBi gain. The receiver sensitivity was -110 dBm. The reference nodes were mounted in an office building as shown in Fig. 3. All network nodes were utilizing SimpliciTI protocol to communicate with each other. The test premises consisted of about 41 meters long and 3.5 meters wide corridor with doors leading to several offices and laboratories. In order to evaluate the positioning accuracy of the implemented methods a number of experiments have been conducted. The goal of the first experiment was to estimate the size of the zones covered by the reference nodes when packets are being sent with the lowest available transmit power, i.e. -30 dBm. During the experiment one of the tags has been placed in the building entrance area while the second one served as data receiver. Measurements of Received Signal Strength Indicator (RSSI) have been recorded along 36 meter long path. The experiment was repeated twice in order to examine system behavior in Line-of-Sight (LOS) and Non-Line-of-Sight (NLOS) conditions. The results of the first phase of experiments have been summarized in Fig. 4. As the result of the experiment the maximum radius of the zone covered by a single reference tag was estimated to be about 25 meters for LOS, and about 10 meters for NLOS conditions. In practical system application, node proximity will be detected only when the RSSI values exceed predefined threshold values. It must be also noted that the use of miniaturized radio tag modules equipped with ceramic antennas will result in significant decrease of the coverage area of a single tag. The goal of the next experiment was to evaluate door identification accuracy with the use of database search methods. Reference Points of Interests (POI) have been distributed at the entrance doors to the rooms as shown in Fig. 3. The database search algorithms has been used to determine the user position on the basis of RSSI measurements from five reference tags distributed in the test premises. Results of the experiment have been summarized in Table I and Fig. 5.

TABLE I
Summary of Experiment Results

Indicator	Result
Average positioning error (25 %)	0 m
Average positioning error (50 %)	2.38 m
Average positioning error (75 %)	3.23 m
Average positioning error (100 %)	4.47 m

As presented in Table I database search method resulted in mean positioning error of 4.47 meters and 2.38 meters for 50 % of cases. It is worth to mention that for 29.76 % of analyzed test cases user position was determined correctly (therefore 25 % error rate counts 0) and for another 15.48 %

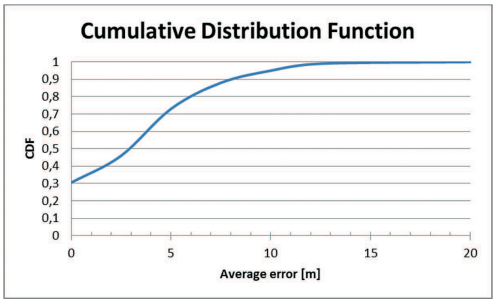

Fig. 5. Cumulative Distribution Function of positioning error from conducted experiment.

of cases user position was estimated at neighboring door. Cumulative Distribution Function is presented in Fig. 5. It can be noticed that maximum positioning error in conducted experiment reached 20 meters (for a single case) and for 90 % of cases positioning error was lower than 8 meters.

V. System user interface

Indoor positioning system presented in the article is a part of a complex solution designed for aiding the blind and the visually impaired in independent mobility and travel. Therefore, described positioning system shares components like reference tags or user terminals with the remaining part of the system. The use of Text-To-Speech enabled smartphone as a mobile electronic aid makes it possible to provide the visually impaired users with voice messages presenting position related information e.g. description of rooms the user is passing by. Moreover, an interactive plan showing part of the building where user was localized is simultaneously displayed on the screen of the mobile phone. This function makes the system suitable for a wider group of target users. Displaying additional context-related information may be helpful in effective navigation in large and unknown buildings.

VI. Conclusion

In this paper indoor positioning system for short range radio communications network has been proposed. The system is a part of complex solution designed for aiding navigation of visually impaired in independent travel and mobility. The positioning system combines proximity sensing and database search methods. The experiments conducted in a large office building resulted in average positioning error not exceeding 4.47 meters. Positioning results are returned as contextual information regarding the area where the user was localized. The use of smartphone as a user terminal makes it possible to present the results to the users in the form of voice messages. Future development works assume incorporation of multi-system positioning. As the result, the positioning methods implemented in the system will benefit from the use of data from generally available radio networks, like public Wi-Fi or mobile cellular telephony networks.

Information Technology for Management, Business & Society

IT4MBS is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the disciplines of information technology and information systems. The IT4BMS area emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This area takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems.

Events that constitute IT4BMS are:

- **ABICT'13 –** 4th International Workshop on Advances in Business ICT
- **Agent Day'13**
- **AITM'13 –** 11th Conference on Advanced Information Technologies for Management
- **IT4L'13** – 2nd Workshop on Information Technologies for Logistics
- **KAM'13 –** 19th Conference on Knowledge Acquisition and Management
- **MMT'13 –** 3rd Workshop on Modeling Multi-commodity Trade: Towards Smart Systems
- **TAMoCo'13** – Techniques and Applications for Mobile Commerce

4th International Workshop on Advances in Business ICT

ABICT focuses on Advances in Business ICT approached from a multidisciplinary perspective. It will provide an international forum for scientists/experts from academia and industry to discuss and exchange current results, applications, new ideas of ongoing research and experience on all aspects of Business Intelligence. ABICT will be also an opportunity to demonstrate different ideas and tools for developing and supporting organizational creativity, as well as advances in decision support systems.

We kindly invite contributions originating from any area of computer science, information technology and computational solutions for different applications areas, data integration and organizational implementation of ABICT, as well as practical ABICT solutions.

Topics

Topics include (but are not limited to):

- Advanced Technologies of Data Processing, Content Processing and Information Indexing
- Business Applications of Social Networks
- Business Data Mining and Knowledge Discovery
- Business Intelligence, Business Analytics
- Business Rules
- Business-oriented Time Series Data Mining, Analysis, and Processing
- Data Warehousing
- Information Forensics and Security, Information Management, Risk Assessment and Analysis
- Information Systems in Enterprise Management
- Information Technologies in Enterprise Logistics
- Information Technologies in Enterprise Management, Information Systems,
- Service Oriented Architectures (SOA)
- Knowledge Management
- Recommender Systems
- Semantic Web and Ontologies in Business ICT
- Virtual Enterprise
- Web-Based Data Management Systems
- Web 2.0 and Web 3.0 in fusing Business Intelligence systems and Decision Support Systems
- Knowledge Management for better Decision Support, Collaboration and Competitiveness
- Creativity Support Tools
- Customer Relationship Management, social Customer Relationship Management

A Hierarchical Approach for Configuring Business Processes

Mateusz Baran, Krzysztof Kluza,
Grzegorz J. Nalepa, Antoni Ligęza
AGH University of Science and Technology
al. A. Mickiewicza 30, 30-059 Krakow, Poland
E-mail: {matb,kluza,gjn,ligeza}@agh.edu.pl

***Abstract*—Business Process models in the case of real life systems are often very complex. Hierarchization allows for managing model complexity by "hiding" process details into sub-levels. This helps to avoid inconsistencies and fosters reuse of similar parts of models. Configuration, in turn, gives the opportunity to keep different models in one configurable model. In the paper, we propose an approach for configuring Business Processes that relies on hierarchization for more expressive power and simplicity. Our goal is achieved by allowing arbitrary n-to-m relationships between tasks in the merged processes. The approach preserves similar abstraction level of subprocesses in a hierarchy and allows a user to grasp the high-level flow of the merged processes.**

***Index Terms*—BPMN, Business Processes, Business Process Hierarchization, Business Process Configuration**

I. Introduction

ENTERPRISES take advantage of using Business Processes (BP) in their everyday practice. These processes define the way the company works by describing control flow between tasks. Design and development of such processes, especially more and more complex ones, require advanced methods and tools, e.g. [1], [2], [3].

Business Process Model and Notation (BPMN) [4] is a visual language used to model Business Processes. It is a set of graphical elements denoting such constructs as activities, splits and joins, events etc. (see Figure 1). These elements can be connected using control flow and provide a visual description of process logic [5]. Thus, a visual model is easier to understand than textual description and helps to manage software complexity [6].

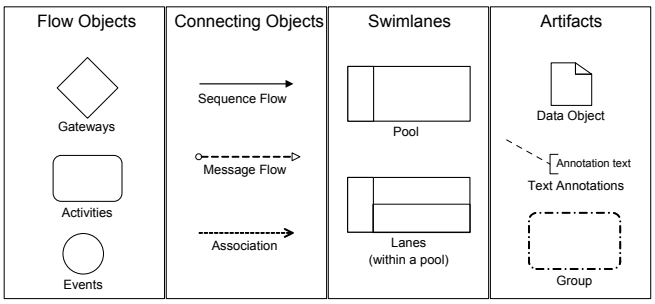

Figure 1. BPMN core objects

Although the BPMN notation is very rich when considering the number of elements and possible constructs, apart from the notation rules, some style directions for modelers are often used [7]. To deal with the actual BP complexity, analysts use various modularization techniques. Mostly, they benefit from their experience and modularize processes manually during the design because these techniques are not standardized. Modularization issue is important in the case of understandability of models [8]. Thus, guidelines for analysts, such as [9], emphasize the role of using a limited number of elements and decomposing a process model.

In the case of large collection of processes [10], especially modeled by different analysts, processes can be modularized in different ways on distinct granularity level [8]. Moreover, the processes in the collection can be similar [11], but this similarity is lost when the models are kept separately.

Automatic hierarchization and configuration, which is the subject of this paper, can help in preventing these problems. Hierarchization provides different abstraction levels and, properly developed, can ensure the same way of modularization for all the processes. Configuration gives the opportunity of unification of processes and enables to keep different models in one configurable model.

The rest of this paper is organized as follows: Section II presents motivation for our research. Section III and IV describe related works in the hierarchizaton and configuration areas. In Section V, we present our configuration BP approach which takes advantage of hierarchization. We evaluated the proposed approach based on the issue tracker case study. The paper is summarized in Section VI.

II. Motivation

Modern business applications require advanced modeling solutions to deal with the model complexity. Thus, several challenges in Business Process modeling can be distinguished:

- the *granularity modularization* challenge – how to model different processes similarly, especially in respect of abstraction layers [12].
- the *similarity capturing* challenge – it is not easy to grasp similarities in the collection of only partially similar models [13], especially if they are modularized differently.
- the *collection storing* challenge – how to store a large collection of models in some optimized way [14].

978-83-60810-53-8/$25.00

In our research, we deal with these challenges using automatic hierarchization that allows us to preserve similar abstraction level of subprocesses in a hierarchy. To address two other challenges, we propose a new BP configuration technique, that allows us to express similarities between different BP models in a simple, but comprehensive way. Our configuration is based on the hierarchical model prepared previously.

The aim of this paper is to present our approach for configuring Business Processes based on hierarchization. We present the automatic hierarchization algorithm that takes advantage of task taxonomy and the algorithm for configuration.

The proposed approach has several advantages. Thanks to the use of hierarchization, the obtained model structure incorporates similar activities, and the configuration step can be simplified. Thus, the configurable process diagram is easy to comprehend. Contrary to the existing configuration methods, in our approach we can bind not only one task with another, but also groups of tasks which were considered in hierarchization step. Such configuration technique address the abovementioned problems by managing both process model complexity and diversity.

III. Hierarchization Issues in Business Process Models

La Rosa et al. [15] distinguished 3 abstract syntax modifications that are related to modularization for managing process model complexity. These are:

1) vertical modularization – a pattern for decomposing a model into vertical modules, i.e. subprocesses, according to a hierarchical structure
2) horizontal modularization – a pattern for partitioning a model into peer modules, i.e. breaking down a model into smaller and more easily manageable parts, especially assigned to different users in order to facilitate collaboration.
3) orthogonal modularization – a pattern for decomposing a model along the crosscutting concerns of the modeling domain, such as security or privacy, which are scattered across several model elements or modules.

Our approach is consistent with the vertical and horizontal patterns. Although we decompose a model into subprocesses, in fact we use some additional information to decompose it, such as task assignment or task categories, which is an example of the second pattern instance. The last one, orthogonal pattern, requires to extend the notation, as in [16]; thus, it is not our case.

It is important to notice that such decomposition has several advantages:

- increases their understandability by "hiding" process details into sub-levels [8],
- decreases redundancy, helps avoid inconsistencies and fosters reuse by referring to a subprocess from several places [17], [18], [13], [19],
- decreases the error possibility [20],
- increases maintainability of such processes [9].

IV. Business Process Configuration

Business Process configuration is a tool for expressing similarities between different Business Process models. There are mechanisms for managing and comparing processes in large repositories [21], [22], refactoring of such repositories [14] as well as automatic extraction methods for cloned fragments in such process model repositories [14], [17]. However, our case differs from the existing approaches because we do not base on any directly visible similarity, but on previously defined taxonomy of states or roles in the processes etc. Moreover, our hierarchization algorithm forces the generation of similar models as a result.

There are a few methods of extraction of configurable processes. They focus on different goals. Analyzing digest configurable Business Process reveals high-level workflow that might not be apparent in particular models. The structure is partially lost in the process so this does not concern our approach.

The method of interest in this article are models merged into configurable model [23]. They allow the analyst to see several processes as special cases of one configurable model. The model emphasizes similarities preserving all the details.

Configurable Business Processes are also a good alternative to current reference model bases such as SAP. Instead of presenting the analyst a few example models, a more general, configurable solution can be delivered. It makes producing final models faster and less error-prone [24].

There is an active research field in the area of configurable Business Processes. In [25], Rosemann et al. describe an approach focused on hand-made diagrams for the purpose of reference modeling. La Rosa et al. [24] extend it with roles and objects.

Variant-rich process models were explored in PESOA project [26], [27]. They enable process designer to specify a few variants of a task.

Our approach is a specialized version of solution proposed by La Rosa in [28]. Hierarchization algorithm produces models of very specific structure and this fact is exploited in our approach.

V. Hierarchization-based Business Process Configuration Approach

We propose an approach for configuring Business Processes that relies on hierarchization for more expressive power and simplicity. The first goal is achieved by allowing arbitrary n-to-m relationships between tasks in merged processes. Taxonomy of tasks provides level of flexibility which many of current state-of-the-art solutions are lacking [25], [28].

Simplicity is the effect of constructing a very specific type of models during hierarchization. These models do not require general configuration algorithms that often produce complicated, hard to analyze diagrams. Sufficient configuration algorithm is described in Section V-C.

General flow of data in the whole approach is depicted in Figure 2.

Figure 2. General flow of data in proposed approach

A. Case Study

To present our configuration approach, we chose 3 different BPMN models of bug tracking systems: Django[1], JIRA[2] and the model of the issue tracking approach in VersionOne[3].

A bug tracking system is a software application which helps in tracking and documenting the reported software bugs (or other software issues in a more general case). Such systems are often integrated with other software project management applications, such as in VersionOne, because they are valuable for the company.

Thus, apart from popularity, we selected such a case study because these kinds of processes have similar users assigned to similar kinds of tasks, the processes of different bug trackers present the existing variability, and such an example can be easily used to present our algorithm in a comprehensive way.

B. Automatic Hierarchization Algorithm

The hierarchization algorithm is given a BPMN model, a set of high-level BPMN tasks and an assignment of BPMN model's tasks to the high-level tasks. Using this information it constructs two-level hierarchical diagram. The lower level contains one diagram for each high-level task. Higher level diagram contains high level tasks (with lower-level diagram as subprocesses). This is done in such way to maximize simplicity and preserve semantics of original model.

Hierarchization is performed in several steps.

1) **Introduction of high-level expanded subprocesses**
In the first step, expanded subprocesses are introduced. Tasks are assigned to them according to given specification. Gateways are placed outside of all subprocesses unless all their incoming and outgoing flows lead to tasks of the same process. Intra-subprocess flows are kept. Inter-subprocess flows are replaced by:
   a) flow from source element to end event (in subprocess),
   b) OR-gateway right after subprocess (one per subprocess),
   c) flow from introduced gateway to target of initial flow with condition 'subprocess ended in event introduced in 1a'.

   This step is depicted in Figure 3. After this step is performed, assumption 1 of configuration algorithm (Section V-C) is fulfilled.

[1]See: https://code.djangoproject.com/
[2]See: http://www.atlassian.com/software/jira/
[3]See: http://www.versionone.com/

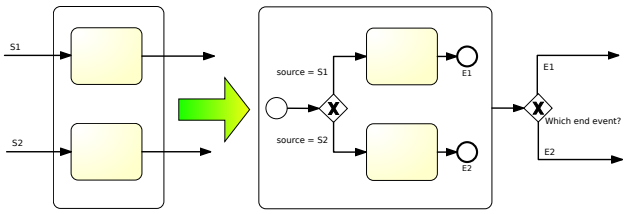

Figure 3. First step of hierarchization algorithm

2) **Gateway simplification**
The previous step introduced new gateways. The original diagram may contain unnecessary gateways too. Creating configurable diagram in proposed approach requires a very specific structure of high-level model. It can be achieved through gateway simplification.
The process of gateway simplification is depicted in Figure 4. In a simplified model one gateway G is placed after every subprocess $S(G)$ (unless it has only one outgoing flow which does not end in a gateway). Gateway G has outgoing flows to all subprocesses and end events reachable in original model from $S(G)$. Conditions labeling these flows are determined as follows.
Let $flow_N(G,T)$ and $flow_O(G,T)$ be the flows in the new and old graphs respectively from gateway G to target item T. Let $C_N(G,T)$ and $C_O(G,T)$ be the conditions on flow $flow_N(G,T)$ and $flow_O(G,T)$ respectively. Let $P(G,T)$ be the set of all paths in old graph (all gateways appear at most once) from G to P. Let $L(G)$ be the set of loops in gateway graph reachable from gateway G. Then the following hold:

$all((G_1, G_2, \ldots, G_k), T)$ holds iff $C_O(G_k, T)$ and
for all $i \in \{1, 2, \ldots, k-1\}$ holds $C_O(G_i, G_{i+1})$
$C_N(G,T)$ holds iff exists $p \in P(G,T)$ such that $all(p,T)$

Presented procedure works as long as graph of gateways is acyclic. Cycles need additional compensation for the fact that infinite looping is possible. We propose a solution where a new task "loop infinitely" is added and connected by flow from all gateways that allow looping. Condition on the new flow may be defined by analogy to the previous case:

$all((G_1, G_2, \ldots, G_k))$ holds iff $C_O(G_k, G_1)$ and
for all $i \in \{1, 2, \ldots, k-1\}$ holds $C_O(G_i, G_{i+1})$
$C_N(G,T)$ holds iff exists $p \in L(G)$ such that $all(p)$

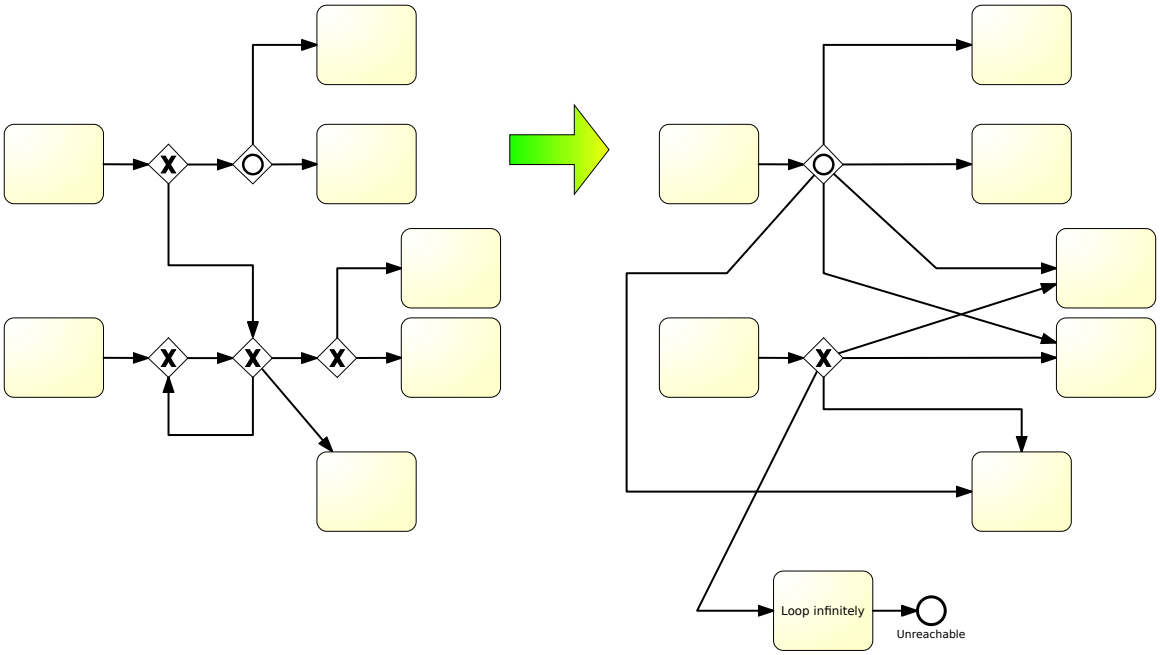

Figure 4. Second step of hierarchization algorithm (gateway simplification)

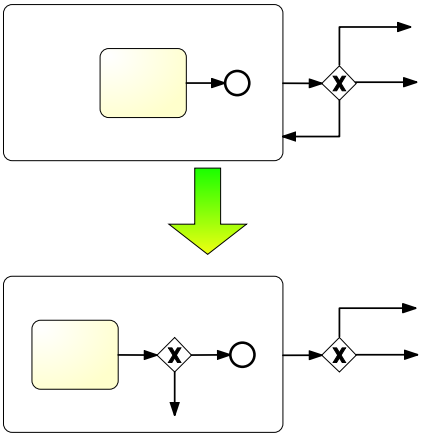

Figure 5. The idea of third step of hierarchization

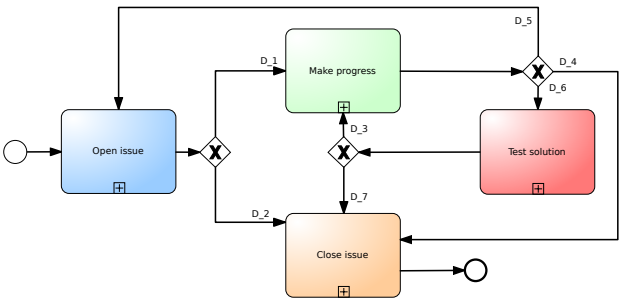

Figure 6. High-level diagram of Django issue tracking

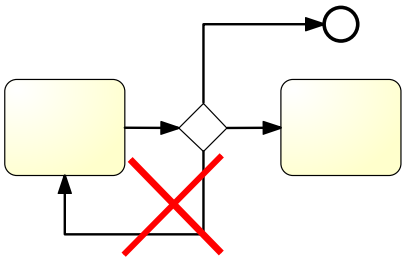

Figure 7. Possible flows to and from a gateway

Figure 4 shows a graph of gateways before and after simplification. Simplification assures that requirements 2 and 3 from Section V-C are fulfilled.

3) **Removal of recurring flows**
Last step of hierarchization is elimination of recurring flows. By this a flow from a gateway to activity preceding this gateway is meant (see Figure 5).
Before each end event in the subprocess that can result in recurring flow a new XOR gateway is placed. It has two output flows: one to end event and one to task or gateway a recurring flow would lead to (see Figure 5). The condition on the latter flow is created according to condition on original recurring flow.
This step of hierarchization algorithm makes requirement 4 of configuration process fulfilled. The result of hierarchization of Django issue tracking process can be seen in Figure 6.

C. Process Configuration

Let us be given N BPMN models such that:

1) all of them share the same set of tasks,
2) flows outgoing from tasks or start event end in a different task, end event or an (XOR or OR) gateway (Figure 7),
3) flows outgoing from gateways always end in tasks or an end event,
4) no flow outgoing from a gateway leads to a task that has a flow to this gateway.

Then the configurable model that entails all the given models can be defined as follows:

1) configurable diagram has one start event, all the specified tasks and all the end events from N given models,
2) for all tasks and start event (let i be the current item):
   a) If all diagrams have flow outgoing from i that ends in (the same) task or the only end event then the same flow exists in merged diagram.
   b) If in at least one model the flow f ends in a gateway, the merged model has a configurable gateway after i. It is a configurable type gateway if there are diagrams with two different types of gateways (or one without gateway).
   c) If and only if any input diagram gateway after i has a flow to an item, the configurable gateway has a flow to this item too. The flows are labeled with model number and condition from that model.

D. Approach Evaluation

As we tested our approach on the three issue tracking systems, the results we got are optimistic. The obtained model is simple and comprehensible. Figure 9 compares initial and hierarchical versions of Django system. The three hierarchized models, simplified by the algorithm, can be simultaneously compared on high level and on the subprocess level. The final high level configurable model is presented in Figure 8.

One of the drawbacks of our approach is that conditions on control flows outgoing from gateways may become complex after hierarchization. However, it is not an obstacle in understanding of high level flow in the process, which is the goal of the approach.

VI. Conclusion and Future Work

The research presented in this paper addresses three challenges in Business Process modeling, which we distinguished in Section II. These are granularity modularization, similarity capturing and collection storing challenges.

In the paper, we proposed automatic hierarchization algorithm that takes advantage of task taxonomy and allows us to preserve similar abstraction level of subprocesses in a hierarchy. A Business Process configuration technique, based on the hierarchization result is presented as well. It allows for expressing similarities between different BP models in a simple but comprehensive way. Thanks to this, a user can grasp the high-level flow of the merged processes.

In comparison to other approaches, our hierarchization algorithm supports arbitrary n-to-m relationships between tasks in the merged processes.

To get a proof of concept of our approach, we narrowed our attention to the subset of BPMN, similarly expressive to EPC. Thanks to the use of the taxonomy shared by the three models and the hierarchization algorithm, the configuration approach is straightforward.

In future work, we consider to extend the approach in several ways, e.g. to allow more BPMN elements or multi-level diagrams [1], and to integrate it with Business Rules [29], especially in the XTT2 representation [30], [31], in order to use control flow as inference flow [32] and to allow for automatic verification of models [33], [34], [35]. Moreover, automatic generation of taxonomy using some process metrics [11], [36] is also considered, as well as automatic assignment of tasks to subprocesses based on Natural Language Processing.

***Abstract*—Taking an existing large-scale simulation model of the German toll system we identify the typical workload by profiling the runtime behavior. Crucial performance hot spots are identified and related to the real-world application to analyze and evaluate the observed efficiency. In a benchmark approach we compare the observed performance to different simulation frameworks.**

I. Introduction

As technology advances, systems and processes with higher complexity, interconnectedness and heterogeneity can be developed. Simultaneously, user requirements are constantly increasing: Software evolution is a fact of life. Modeling and simulation techniques are applied to design, analyze, evaluate, validate, and optimize such systems. The article analyzes the performance of a large-scale Discrete Event Simulation (DES, [1]) simulation model of the German toll system implemented in MSArchitect [2] – similar to and larger than existing simulation models [3, 4].

The next section gives an overview of the automatic German toll system, the corresponding simulation model and typical simulation results. Section III introduces the simulation framework architecture and performance measurement techniques. Section IV analyzes and evaluates the simulation performance of several DES kernels using small test models. Section V analyses the performance within the application domain followed by a summary in section VI.

II. Executable model of the German toll system

For the application domain we use an existing simulation model of the German toll system [5–7], a large-scale autonomous toll system [8] operated by Toll Collect GmbH. The tolls for heavy-goods vehicles (HGVs) driving on federal motorways – a total of 4.36 bn € in 2012 [9] – is collected by the toll system, more than 90% fully automatic using the more than 750 000 on-board units (OBUs) deployed in the HGVs. The simulation model includes all subsystems necessary for the automatic tolling processes (fig. 1) and for delivering updates to the OBU software, geo and tariff data as well as a model of the user interaction [10].

From the process perspective the simulation model covers business and system processes differing at least 7 orders of magnitude in time: All major technical processes with durations of one second and longer are included in the model aiming to predict the dynamic system behavior of fleet-wide

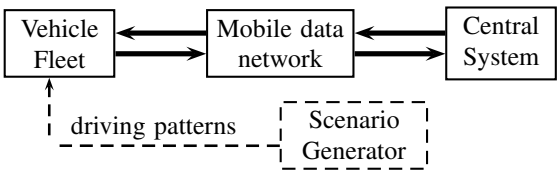

Fig. 1. High-Level simulation model of the Toll Collect system (upper half) and the model for the user interaction (scenario generator, lower half).

updates (taking weeks to months). In fact, the model includes some processes with higher temporal resolution (down to 50 ms for the connection handling by the firewalls). Using the Pearson correlation as metric to compare the simulation results with the observed update rates between 04/2012 and 01/2013 we find the correlation to be above (better than) 0,994.

Even on the application level the user interaction (precalculated driving patterns) creates a large number of events to be processed by the simulation logic. On average each OBU will be powered-on for 16% of the time and process tolls for 32 000 km annually ([11], one toll event per 4.2 km on average [12]) spread across 1 300 power cycles (including three times as many periods of loss of access to the mobile data network). Of course, many more events are created from within the application logic, e.g. to forward tolls to the central systems or to run error recovery protocols in the case of network unavailability.

III. Simulator architecture and performance measurement

This section describes the architecture of the simulator and different possibilities to measure and evaluate simulation performance. MSArchitect distinguishes between atomic models and composite models (as most actor-oriented DES/PDES tools) to capture the behavior and structure of systems and processes. Atomics interact with the simulation kernel and contain the whole behavioral description, including event consumption and creation, time advance of events, and manipulation of data entities. They are typically written in C++ (all common programming languages work as well) and compiled into binary code for execution. The composite models provide the structural composition of models, but do not themselves contribute to the execution semantics. Combining both modeling types results in a hierarchical model tree with atomic models as leafs and composite models as nodes, as shown in fig. 2.

978-83-60810-53-8/$25.00

TABLE I
TECHNICAL REPRESENTATION LAYERS USED IN MSARCHITECT

Technical layer	Vocabulary	Performance factors
DES Composition	interconnection of ports, states and, parameters	model hierarchy, summable model structure, data exchange via ports, forks and merges, sharing of states, port multiplicities
DES Atomic Interface	ports, states, parameters, lifecycle methods, inheritance, model/data types	data type conversion, reuse of data objects, memory organization
Code	C++ types, variables, instructions, method calls, control/data-flow, inheritance	kernel event scheduling, C++ type resolution, utilization of external code, memory allocation, caching, code granularity/distribution
Machine	Object code, register, memory, instructions (arithmetic, jump, call)	CPU capabilities (instruction set, latencies, cache), memory, code structure

The definition of atomic models and composite models relies on a well-defined application programming interface (API) to the simulation kernel: Typically consisting of ports (communication interfaces), states, parameters and methods [13].

Based on the simulation kernel API definition and the possibilities for model description four technical representation layers can be differentiated in MSArchitect (tab. I, in principle applicable to all DES tools) with different factors impacting the performance on each layer. The *DES Composition Layer* describes the interconnection of models within a composite model and allows analyzing structural dependencies and properties [13]. On this layer, much of the performance depends on the application level behavior and its implementation as abstract simulation model. Starting with the *DES Atomic Interface Layer* the performance becomes independent of the application domain and is determined by the simulation toolset ([14], which describes the interface of atomic models as well as restrictions on features available for the functional description). The *Code Layer* contains the functional implementation of all atomics in the form of lifecycle methods and custom code sections. The *Machine Layer* contains preprocessed and compiled code for model execution and references to external runtime libraries to be executed on a given CPU architecture.

The layers define the information available for profiling the runtime behavior, collected either by the simulation kernel, simulation logs or (external) performance profiling tools. This analysis repeats the kernel benchmarks presented in [7] and expands the performance analysis to the application level taking the example of a real-world simulation in section V.

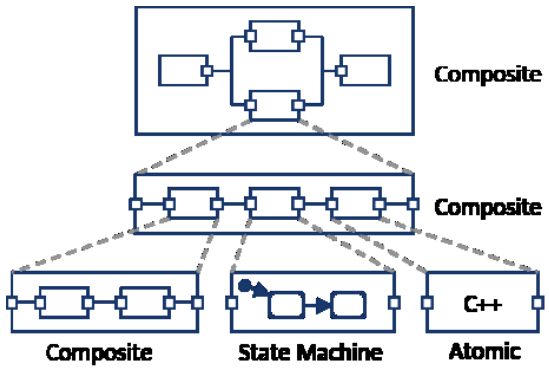

Fig. 2. Model hierarchy: Composite models and Atomics.

IV. BENCHMARK OF SIMULATION KERNEL PERFORMANCE

In this section we perform a kernel benchmark using the five test models introduced in [7]. With regards to the technical representation layers in tab. I the test models are defined on the *DES Composition Layer* and the *DES Atomic Interface Layer*. We included the most important performance influencing factors in our tests: The Future Event List (FEL) management, memory and data type management, pseudo-random number generator performance, and arithmetic operations performance [15].

Each test model is simulated with a set of simulation parameters using different system design tools. We selected six system design tools for evaluation: Ptolemy II, Omnet++, AnyLogic, MLDesigner, SimEvents and MSArchitect. All tools were run in serial mode on an Intel Core i7 X990 at 3.47 GHz with 24 GiByte RAM using either Windows 7 Enterprise (64 bit) or openSuse 11.4 (32 bit, kernel 2.6.37.6).

Fig. 3 gives the results of the event processing performance of the Runtime Scaling test. The tests show that neither the event processing performance nor the memory consumption is affected by increasing the simulation runtime and only OMNeT++ is sensitive to the additional hierarchy levels. However, from the test results it is already obvious that the different tools vary in event processing performance by an order of magnitude: MSArchitect provides the highest speed. MLDesigner, AnyLogic, and OMNeT++ provide 25% of the speed (compared to [7] the MSArchitect performance improved by more than 30%). Ptolemy II is twenty times slower. Looking at the memory usage during the simulation the difference between the tools is again more than an order

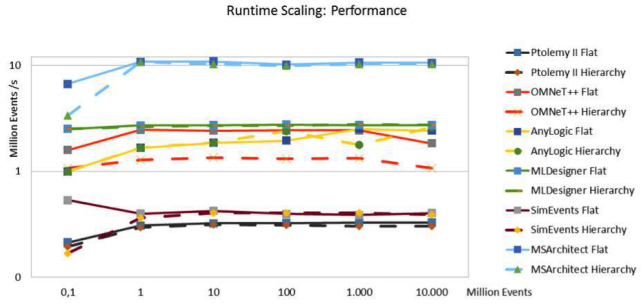

Fig. 3. Runtime performance (top) and memory usage (bottom) scaling of different DES tools.

of magnitude – the slowest tool using the most memory and the fastest tool using the least.

Repeating the FEL Size Scaling test we observe – as expected – a systematic performance reduction with increasing FEL size, due to the increasing overhead for FEL management. With increasing FEL size three of the five tools develop drastic performance degradation coinciding with a rapid grow of memory consumption. In absolute numbers, MSArchitect has the best test performance and the lowest memory usage until FEL size 10^6. Subsequently the memory usage of MLDesigner is lower since MSArchitect runs in 64 bit mode only. However, in our tests MLDesigner stopped to work for FEL sizes above $15 \cdot 10^7$. We tested MSArchitect successfully with a FEL size of 10^8.

The comparison of the DES tools using the FEL Adaption, Data Type Management and Random Number Generation tests yield the same findings as presented previously ([7], with some improvements in MSArchitects' RNG performance): Both, MSArchitect and OMNeT++ show the best performance in some categories. MSArchitect is the fastest simulation kernel in most categories and requires least memory for data handling.

V. Profiling of the simulation model

To evaluate the application-level simulation performance of our model of the German toll system, we use both the kernel logging capabilities of MSArchitect and an external profiling application (Intel VTune). Kernel logging allows to count the number of calls of atomic models as well as the total number of samples (corresponding to a processor cycle). The external profiler allows measuring the time and space complexity as well as chip-level details on the instruction execution.

To profile the simulation model we take the simulation scenario used to verify the simulation model of ther automatic German toll system against real-world data (see section II) using pre-calculated user interaction. The simulation model reads and parses the driving patterns (containing the events for power cycles, tolling and network unavailability) and feeds the events into the simulation model. The simulation model in turn creates many more events (e.g. for scheduling timeouts) to be processed by the simulation kernel. Using a single CPU core the simulation run encompassing a fleet of 700 000 OBUs and a simulated time period of 45 weeks takes less than 10 hours to compute.

As mentioned above, in a first step we apply the kernel logging capabilities of MSArchitect resulting in a file with profiling information at the end of the simulation run. Tab. II shows an excerpt of the file, containing the top-10 (out of 65) atomic blocks by runtime.

First of all, the atomic block "AccessSessionStateSwitch" is striking, consuming a large amount of time with a high number of calls. The block is responsible for switching OBU data structures in response to its state to one of the output ports. As the block switches between 34 states, 539 samples per call are acceptable. Nevertheless the number of calls could be reduced for performance improvement by changing the model architecture – especially once the model is ported to the parallel DES core.

TABLE II
KERNEL LOGGING RESULTS: TOP 10 ATOMIC BLOCKS BY RUNTIME.

Atomic Block	Calls [M]	Samples [G]	Time [%]	Samples per Call
AccessSessionStateSwitch	19 980	10 760	10,89	539
ExternDStxt	0,0007	9 565	9,68	13 665 M
StaHandling	482	6 503	6,58	13 483
EinzelbuchungsHandling	4 660	6 442	6,52	1 382
IpAutomat	7 323	5 749	5,82	785
Delay (Standard)	8 874	5 522	5,59	622
CheckComponentState	7 363	3 859	3,91	524
NetzverlustHandling	3 020	3 479	3,52	1 152
AccessSessionStateWrite	5 841	3 215	3,26	551
MfbSwitch	5 525	3 196	3,24	579

The next conspicuous atomic block is "ExternDStxt", reading the pre-generated files provided by the scenario generator model as ASCII file. The block consumes 9,681% of the runtime for 13 665 M samples/call and is rarely executed (twice per simulated day). In order to reduce the load, scenarios should be computed on the fly. The atomic block "StaHandling" is responsible for generating and controlling status requests, which may result in update processes. The block consumes 6,581% of simulation time. We see potential for improvements in changing the implementation (e.g. conversion of formulas to save operations, replacing divisions by multiplications with reciprocal and using of compare functions from standard libraries).

With 4 660 M calls "EinzelbuchungsHandling" is a frequently executed atomic block. After analyzing the implementation we find 1 382 samples/call acceptable. The block depends on the random number generator and would benefit from faster random number generation algorithms. The atomic block "SimOutObuVersions" cyclically writes the software, region, and tariff version of all OBUs to an output file. In our scenario we simulate 50 weeks and write data every 30 minutes, resulting in 16801 calls. 89 M samples/call seems to be quite costly and offers room for improvement.

In summary the simulation of the scenario took 98 811 263 M calls. Of these, the model components consumed 84,51% and the simulation kernel (logical processor) 15,49%.

In the second step we apply the Intel VTune [16] profiler, which operates at functional level resp. Code Layer (see table III). The external profiler catches the activities of both the simulation kernel and the simulation model (denoted as "K" or "M" in tab. III).

Most of the CPU time is consumed by kernel functions responsible for data transport. These functions are grouped by component (resp. namespace msa.sim.core, denoted as "K" in the first column of tab. III), as Port.send, EventManager.enqueueEvent, LogicalProccesor.mainLoopFast, and EventManager.dequeueEvent. In sum the functions consume 61,1% of the CPU time. Conspicuous is the relative high last level cache miss rate of function EventManager.enqueueEvent with 3,2% and the needed instructions per call of function LogicalProcessor.mainLoopFast with 2 379. However, the

TABLE III
VTUNE PROFILING RESULTS FOR SIMULATION KERNEL (K) AND MODEL (M): TOP 10 FUNCTIONS BY RUNTIME

Shown are the CPU instructions retired (IR), estimated call count (eCC), instructions per call (IPC) and last level cache miss rate (MR).

	Function	Time [%]	IR [G]	eCC [M]	IPC	MR [%]
K	Port.send	9,0	44	689	65	0,4
K	EventManager.enqueueEvent	7,7	21	92	237	3,2
K	LogicalProcessor.mainLoopFast	7,0	17	7	2 379	0,3
K	EventManager.dequeueEvent	6,3	104	2 517	41	1,1
K	big._mul<unsigned int>	5,0	103	2 611	40	0,3
M	StaHandling.Dice	4,8	12	11	1 097	0,1
K	EventManager.scheduleEvent	3,5	53	1 286	42	0,2
K	Any.extractToken	3,0	70	1 805	39	1,7
K	Pin.popFrontToken	2,8	49	1 234	40	0,2
K	EventManager.bucketOf	2,7	17	327	55	0,0

number of calls depends on the dispatch of data within atomic model components, which are grouped in form of user libraries. In our model we have two user libraries: GPRSSimulation (GPRSSimulation.Components.Atomics, denoted as "M" in the first column of tab. III) and Standard (msa.Standard.Control). The latter is a support library included in MSArchitect. Combined they are responsible for 20,1% of CPU time consumption. Performance critical and starting point for improvement is function StaHandling.Dice with 1 097 instructions per call and a CPU time consumption of 4,80%.

Both, kernel logging and profiling showed that most of the resources are utilized by functions responsible for data input/output and functions responsible for transmission and processing of tolling information. Relating the resource utilization of model components to real-word applications we could recognize a weak correlation: The application-level performance is determined by the real-world behavior of the simulated system.

VI. SUMMARY

Extending [7] we have shown how to analyze the performance of DES simulations: Generic benchmark test-cases allow a simple and direct comparison of different simulation tools. Not surprisingly the tools differ vastly as to their time and memory consumption. However, the benchmark results cannot be transferred to the application domain: The workload generated by a given simulation model determines in large part its performance. Taking an existing simulation model of a large-scale technical system we performed an in-depth performance analysis for one simulation tool using both the performance analysis methods provided by the simulation kernel and an external profiler with access to the CPU hardware profiling support.

Both profilers immediately identify the same bottleneck: Reading the ASCII-formatted pre-calculated driving patterns from disk. Consequently the simulation model is now integrated with the scenario generator. This in turn will allow implementing an optimization algorithm to fit the driving patterns to the observed system behavior – a feature that we expect to drastically improve the accuracy of the simulation results for the short-term behavior [10].

The hardware profiler catches both the application-level methods as well as the atomics provided by the simulation kernel (with or without access to its source code). Looking e.g. at the cache miss rate we find some simulation kernel routines and several application-level methods with a considerable probability of needing access to the main memory. We take this as starting point for future improvements.

MSArchitect, the simulation kernel used in the application benchmark, is currently extended to allow the automatic model reduction and (semi-) automatic parallelization of simulation runs. The single-core benchmark performed here will be the baseline to measure the improvements against.

***Abstract*—An original approach to digital moving trend based filters (MTF) design, based on Bode plots analysis is proposed, aimed at seasonal time series decomposition and prediction. A number of polynomials of different range are discussed to be used in the MTF as the LS approximation formula. The Bode plots of the MTF are shown, and the best filter is selected. Results of a seasonal time series decomposition and prediction with the best MTF is presented and compared to the classical MTF calculations (involving the linear LS approximation).**

I. Introduction

The nonstationary time series filtering with moving trends is the well known approach to a nonparametric long term trend extraction from the series, aimed at further processing of stationary residuals and the series prediction [1], [2]. The classical moving trend filter (MTF) is based on rolling approximation of the series with the least-square (LS) linear approximation in a moving window [1]. The window width affects the extracted trend smoothness and cyclic components separation effectiveness. However typically, it is adjusted by a trial method, to reach the appropriately smooth nonparametric trend. This paper shows that much better smoothing properties and cyclic component extraction may be reached by using in MTF a higher order polynomial approximations and by specification of the required filter properties in frequency domain. Hence, the MTF design is proposed by analysis of Bode plots [4] of a number of the filter variants. The MTFs designed in this way were successfully applied to analysis of hydrogeological data [5] and to financial time series prediction [6]. Smoothing and prediction of a step change and a cyclic signal with the studied MTF was shown to illustrate their properties.

II. Moving Trend Based Filters – Formal Basis And Properties

Nonstationary time series $y(t)$ may be viewed as the sum of an aperiodic trend function $f(t)$, a cyclic component $C(t)$ of time period T, and a higher frequency zero-average noise $z(t)$ [3], [7]:

$$y(t)=f(t)+C(t)+z(t) \tag{1}$$

The periodic component can be written in the form of the harmonic series [4]:

$$C(t)=\sum_{k=1}^{K} A_k \sin\left(\omega_T i_k (t-\tau_k)\right),\ \omega_T=\frac{2\pi}{T} \tag{2}$$

where i_k , k=1,..., K denote the set of harmonics indices of the consecutive components k=1,...K (e.g. i_k=1, 2, 10), A_k – the amplitude of i_k-th harmonic, τ_k is the delay of the k-th component.

The nonparametric trend $f(t)$ may be calculated for each time step t_n by a low-pass digital filter designed in such a way to remove the ω_T and higher frequency components from the original series $y(t)$. The cyclic component $C(t)$ can be extracted from the filtering residuals by the Least Square (LS) approximation with the regression model of the form (2), and then, the regression residuals $z(t)$ may be viewed as a high-frequency stochastic process and treated with ARMA approach [2] (if its homoscedasticity can be assumed) or with GARCH models in case of its heteroscedasticity [3].

One of the techniques recommended to calculate the nonparametric trend $f(t_n)$ is a rolling approximation of the series $y(t_n)$ with the LS linear approximation in a window containing M samples, and then averaging of the approximates $y_F(i,t_n)$ obtained for each t_n [1]. It is referred to as moving trend based smoothing/filtering, which may be further used to h-samples ahead prediction of the series main component $f(t_n+h)$ by its extrapolation with a h-samples increment $\Delta_h f$ averaged with harmonic weights [1]:

$$\begin{gathered} f(t_{n+h})=f(t_n)+\Delta_h f, \\ \Delta_h f=\sum_{i=1}^{n-h} C_i\left(f(t_{i+h})-f(t_i)\right) \\ C_0=0, C_i=C_{i-1}+\frac{1}{(n-h)(n-h-i+1)} \end{gathered} \tag{3}$$

Hereby we propose a generalization of the moving trend smoothing algorithm, by employing higher order approximating polynomials, with appropriately designed properties. Let us consider the polynomial of the form (4) in the time interval of M samples, with the time counted from $-M$+1 to 0:

978-83-60810-53-8/$25.00

$$y_F(t_i) \stackrel{def.}{=} b_0 + b_1 t_i + b_2 t_i^2 + b_3 t_i^3 + b_4 t_i^4, \quad t_i = \{-M+1, \ldots, -1, 0\} \tag{4}$$

The derivatives of y_{F0} at the interval end ($t_i = 0$) can be easily shaped by fixing selected coefficients b_k at zero values, which implies different profiles of the LS approximates y_F, as shown in figure 1.

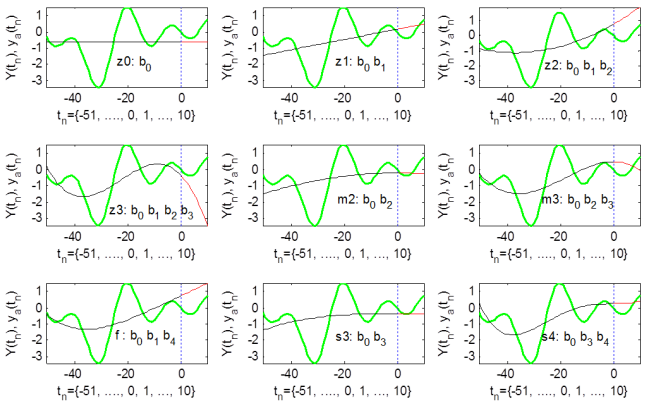

Fig 1. Properties of the approximating polynomials (4) considered to be used in the moving trend based filters; filter codes z0, z1, ..., s3, s4 used in sequel and corresponding nonzero coefficients are listed; vertical dotted line shows the interval end; shadow line: $y(t_n)=\sin(0.5\omega_T t_n)- \sin(\omega_T t_n)+ \sin(2\omega_T t_n)- \sin(3\omega_T t_n)$, $T=M=52$

In the moving trend algorithms the series splits into three sections. The first (starting *s*) section begins at the first (oldest) sample and finishes with the (*M*-1)-th one, the filtering window width enlarges from *M* to 2*M*-2, and the number L_n of the approximates $y_F(i,t_n)$ to be averaged increases from 1 to the *M*-1. The second (central *c*) section ranges from the *M*-th to *n*–*M*+1 samples, the filtering window width is 2*M*-1 (constant), and the number of approximates is *M*. The third (final *f*) section contains the samples from *n*–*M*+2 to *n* (the newest one), the window width reduces from 2*M*-2 to *M*, and the number of approximates $y_F(i,t_n)$ to be averaged decreases from *M*-1 to 1.

The calculations in the sections $\{s, c, f\}$ may be expressed in the FIR filtering form [3], [5]:

for $i = 1,\ldots,M-1$:

$$\begin{aligned} f(t_i) &= \sum_{k=1}^{i+M-1} g_s(i,k)\cdot y(t_{i+M-k}) \\ &= \sum_{k=1}^{n} G_s(k,i)\cdot y(t_{n-k+1}), \\ G_s(k,i) &\stackrel{def.}{=} [g_s(i,k), 0_{(n-i-M+1)}]^T, \end{aligned} \tag{5}$$

for $i = M,\ldots,n-M+1$:

$$\begin{aligned} f(t_i) &= \sum_{k=1}^{2M-1} g_c(k)\cdot y(t_{i+M-k}) \\ &= \sum_{k=1}^{n} G_c(k,i)\cdot y(t_{n-k+1}), \\ G_c(k,i) &\stackrel{def.}{=} [0_{(i-M+1)}, g_c, 0_{(n-i-M)}]^T, \end{aligned} \tag{6}$$

and for the final section, $i = n-M+2,\ldots,n$; $j \stackrel{def.}{=} i-n+M-1 = 1,\ldots,M-1$:

$$\begin{aligned} f(t_i) &= \sum_{k=1}^{2M-j-1} g_f(j,k)\cdot y(t_{i+M-j-k}) \\ &= \sum_{k=1}^{n} G_f(k,i)\cdot y(t_{n-k+1}), \\ G_f(k,i) &\stackrel{def.}{=} [0_{(i-M)}, g_f(j,k)]^T \end{aligned} \tag{7}$$

where g_s, g_c, g_f denote the impulse response vectors of filters in the sections ***s***, ***c***, ***f***, written also as the columns G_s, G_c and G_f of the unified smoothing filter matrix $G_{nx(n-1)}$, and the proper filter vector $G(k,n)$.

Similarly, the prediction formula (3) may be written in the following convolution form:

$$\begin{aligned} f(t_{n+h}) &= \sum_{k=1}^{n} P_h(k)\cdot y(t_{n-k+1}), \\ P_h(k) &\stackrel{def.}{=} \\ G_f(k, M-1) &+ \sum_{i=1}^{n-h} C_i\cdot(G(k,i+h) - G(k,i)), \\ G &\stackrel{def.}{=} [G_s, G_c, G_f] \end{aligned} \tag{8}$$

Notice that P_h are strongly affected by properties of the proper (the worst) filter $G_f(k,M-1)=G(k,n)$.

By making the Fourier Transform of the filters g_s, g_c, g_f and P_h involving different approximating polynomial types {z0....s4} with different *M* (see fig. 1), one may examine their properties in frequency domain, and select a filtering variant (type, *M*) suitable for smoothing and/or prediction demands, usually related to ω_T viewed as the cut-off frequency of the designed low-pass filters. The Bode plots of the examined filters are shown in figures 2-6. We have stated that the approximation window width *M* affects directly g_s, g_f and P_h delays, but it is of almost no effect on a shape of all the filters gain. Hence *M* may be taken as the lowest value producing gains close to 1 for $\omega<\omega_T$, near zero for $\omega=\omega_T$ and close to 0 for $\omega>\omega_T$.

Figure 2 shows the central smoothing filters are much better than 1st order recursive ones.

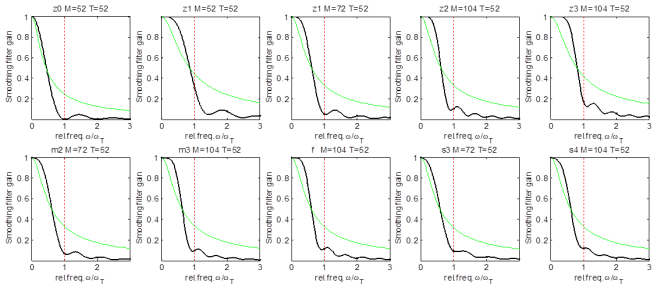

Fig 2. Gain diagrams (vs. ω/ω_T) for the best smoothing filter (central section); vertical point lines show ω_T, shadow solid lines – gain diagram for the 1st order recursive filter of the same half-gain frequency.

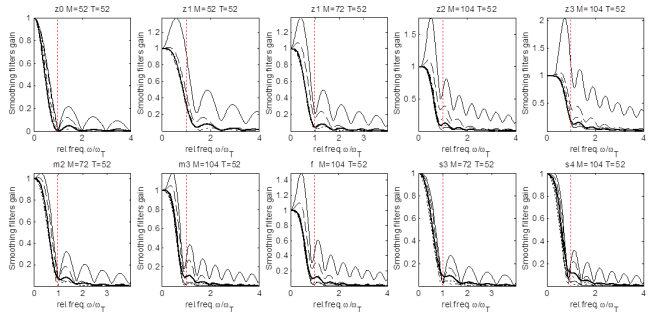

Fig 3. Gain diagrams (vs. ω/ω_T) for the smoothing filters: central section - bold lines $h<-M$, the final section for h=0 solid lines (proper filter), h=-20 dotted lines, h=-40 point-dotted lines.

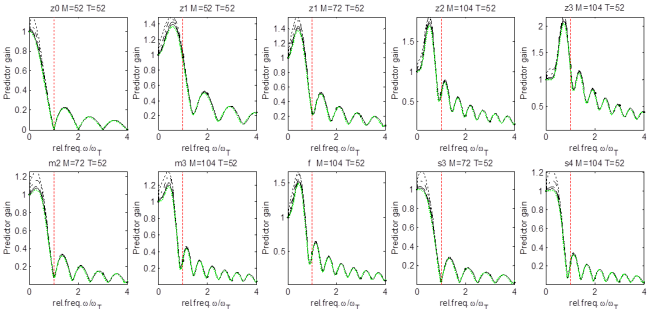

Fig 4. Gain diagrams for the moving trend based predictors: shadow bold line – final filter h=0; h=5 solid lines, h=10 dotted lines, h=26 point-dotted lines, h=T=52 point lines.

Gain properties of all the smoothing filters in the central section (fig. 2) are similar. When assuming M=1.38*T=72, the classical filter z1 seems to be the best due to the pass- and attenuation band properties as well as cut-off frequency gain, although z3 pass-band and attenuation of z0 look better. However a view on figures 3 and 4 gives evidence that only z0, s3 and s4 might be accepted from the perspective of final section smoothing (fig. 3) and prediction (fig. 4) properties. In particular, very bad pass and attenuation properties (excessive gain) of the classical filter z1 are clearly seen. Having in mind numerical problems (ill-conditioning) which can be met in s4 for larger M, one may take that the filter s3 with M=72 (1.38T) is the best choice (its pass-band is noticeably better than that of z0). The same conclusion may be drawn on a basis of delay properties shown in figures 5 and 6. In the pass-band a close to uniform and small delay is required (minimum delay distortion of the trend). It is satisfied only by z0 filters, but s4 delay distortion is acceptable and significantly lower than for the classical filter z1. The delay of predictors is larger than that of the final filter (h=0) by prediction horizon (see fig. 7). It means that the MTF prediction (eq. 3) does not differ essentially from Zero Order Hold of the $f(t_n)$.

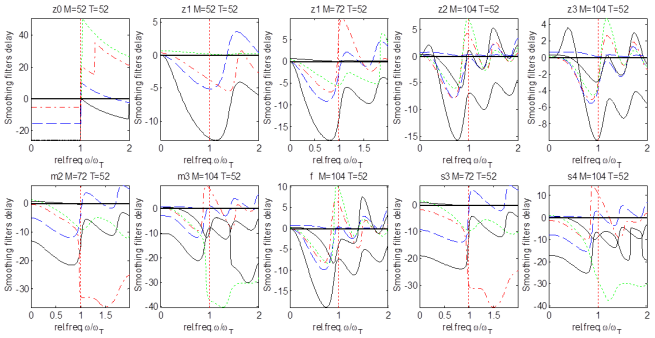

Fig 5. Delay of the final section smoothing filters: h=0 solid lines, h= -20 dotted lines, h=-40 point-dotted lines, h=-60 point lines, h=-70 solid lines close to the zero-delay, bold-line 0 delay of central section filter.

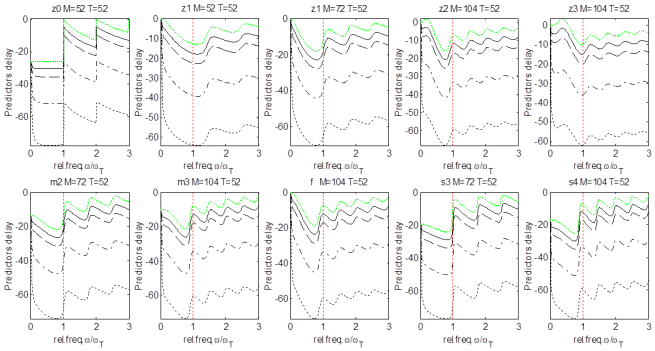

Fig 6. Predictors delay: h=0 shadow point lines, h= 5 solid lined, h=10 dotted lines, h=26 point-dotted lines, h=T=52 point lines.

The frequency properties presented above are visible in time domain responses – see figures 8, 9. Step change distortions shown in figure 8 are the larger, the greater irregularities of the pass-band gain and delay.

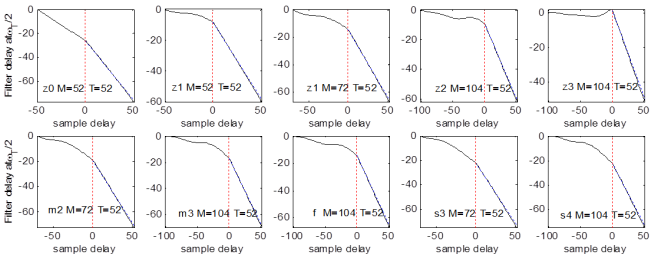

Fig 7. Delay of smoothing filters and predictors for $\omega_T/2$ versus the sample delay.

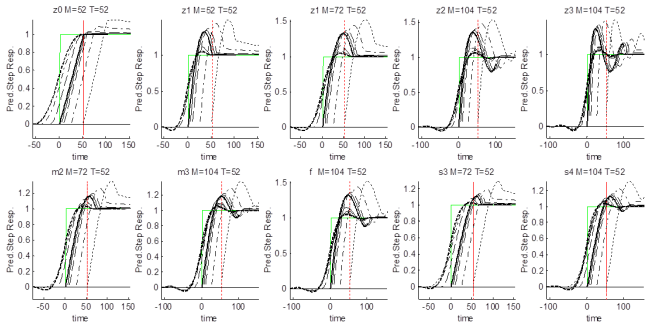

Fig 8. Signal step-wise change smoothing and prediction: shadow bold line – signal; bold dotted line – central segment filter response (h<-M); dotted point line smoothing with h=-40, h=-20 dotted line; bold line final filter response (h=0); prediction with h=5 solid lines, h=10 dotted lines, h=26 point-dotted lines, h=52 point lines.

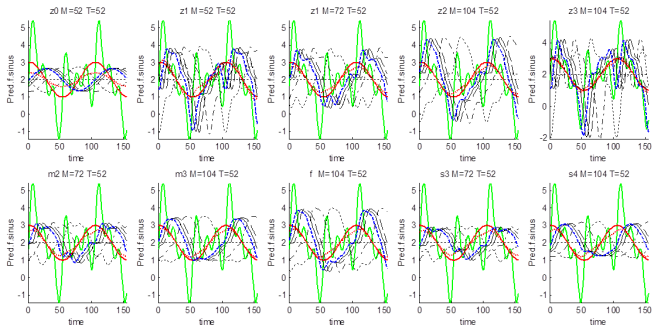

Fig 9. Periodic signal processing with the studied filters: shadow bold line – the signal $y(t_n)$ (see fig.1); bold line – the main harmonic of y, ω=0.5ω_Γ (to be extracted), bold point lines – the main harmonic reconstruction by the central filter response (h=-M), the main harmonic reconstruction with the final filter – bold dotted lines, and prediction with h=5 solid lines, h=10 dotted lines, h=26 point-dotted lines, h=52 point lines.

Figure 9 illustrates effects of filtering and prediction of a periodic signal (used also as the example in fig. 1). The harmonic of ω=ω_Γ/2 has to be extracted (reconstructed), but the signal contains strong components in the filters attenuation band. Hence the attenuation gain profile is of significant effect on the extracted signal shape. The best reconstruction is reached with z0 filters. The classical (z2) filters produce highly distorted responses, both in smoothing and prediction cases, while s3 and s4 yield acceptable results. All predictions are similar in shape to the proper filter response (h=0) and additionally delayed by the prediction horizon – see fig. 7 (i.e. they do not differ noticeably from ZOH predictions).

The extracted signal distortion in the starting and final sections is significant, hence separation of the filtering residuals into periodic $C(t)$ and stochastic $z(t)$ components, by fitting the regression model (2), should be performed with the central section data only. Then the periodic component $C(t)$ should extrapolated on the full data interval and subtracted from the filtering residuals to get $z(t)$.

III. Conclusion

The classical moving trend smoothing algorithm (based on linear approximates) is of low efficiency, when applied to series prediction. Much better smoothing and prediction properties may be reached by employing the 3.th order polynomial (s3) including only a constant and 3.th order monomial (only b_0, b_3 are to be tuned by LS method). The approximation window width M may be easily adjusted by examination the Gain Plots of the moving trend based filters in frequency domain. The recommended filter s3 enables for very effective separation of the series onto low frequency (ω<ω_Γ) and high frequency (ω≥ω_Γ) components, by taking the approximation window width M=1.38*T.

Smoothing (reconstruction of low frequency components) is the most effective (with no delay) in the central segment of the series. In the final section the low frequency signal distortion is significant, mainly due to varying delay of the consecutive final segment filters, which decreases prediction quality. The distortion produced by the recommended filter s3 is much weaker than that of the classical moving trend smoothing.

The periodic component $C(t)$ may be extracted from the filtering residuals by a regression method applied to residuals in the central section of the processed series.

***Abstract*—Data reflecting social and business relations has often form of network of connections between entities (called social network). In such network important and influential users can be identified as well as groups of strongly connected users. Finding such groups and observing their evolution becomes an increasingly important research problem. One of the significant problems is to develop method incorporating not only information about connections between entities but also information obtained from text written by the users. Method presented in this paper combine social network analysis and text mining in order to understand groups evolution.**

I. Introduction

NOWADAYS, elements of our everyday life move increasingly to the virtual reality: we write blogs or comment on someone else's posts, participate in discussions on forums, we exchange our opinions on fanpages of telecommunications companies and banks whose products we use. Everywhere we leave traces of our activity, which can be analyzed and ably combined with each other. Trading companies and banks might be interested in finding active or influential people in their environment and to offer them a new product in hope that it will be proposed by them to many others. Identification on time disgruntled people on banks or telecommunications companies fanpages will allow to respond quickly and prevent the spread of discontent.

The data about different types of dependencies can be modeled as a network of relationships and its structure can be analyzed using Social Network Analysis methods (e.g. for finding important nodes). Such a network, however, is not homogeneous and one can distinguish groups of people, for example, who more often exchange opinions. Such groups frequently are formed around important individuals and, for various reasons, the groups continue to exist or not, grow, shrink or can be joined with other groups. To understand causes of such events, which significantly affect the behavior of groups, it is important to include information that we can extract from the content of opinions or comments that are left behind. If the group talk about the same topics, does it affect its longer duration? Or, perhaps has a variety of discussed topics stronger impact on the duration of groups? How the themes of discussion are changing in a group? Is a small group with a strong leader more durable than a large one with few strong individuals?

Such knowledge derived from open sources can be combined, for example, with information about the history of bank transfers or loans as well as data about phone calls. Methods and algorithms proposed in the paper have been tested on one of the largest and highly dynamic polish blogosphere: salon24.pl, in which the main topic of discussion are political issues. However, they can be applied to other social media such as, for example, Twitter.

II. Related work

A. Blogosphere and Social network analysis

Internet social media (e.g. blogs, forums, media sharing systems, microblogging, social networking, wikis) has revolutionized the Internet and the way of communication between people. Among them, blogs play a special role in creating opinions and information propagation. Author gives opinions on some themes or describes interesting events and readers comment on these posts. Posts can be categorized by tags. A very important element of blogs is the possibility of adding comments, which allows discussions. Basic interactions between bloggers are writing comments in relation to posts or other comments. The relationships between bloggers are very dynamic and temporal: lifetime of a post is very short [1].

Based on blogs, posts and comments, we can build network, which can be analysed by Social Network Analysis (SNA) methods [2]. The SNA approach provides measures (SNA centrality measures) which make it possible to determine the most important or influential nodes (bloggers) in the network. Around such bloggers, the groups are forming, sharing similar interests.

B. Groups in social networks

Groups (or communities) are sets of nodes that are relatively densely connected to each other but sparsely connected to other nodes in network [3]. Many methods of finding groups exist in literature - one of the most popular ones is the CPM method (Clique Percolation Method) [4], which allows to extract overlapping groups i.e. groups that can have shared nodes with other groups.

Considering the dynamic nature of various social media, a growing interest in developing algorithms for extracting communities that take into account the dynamic aspect of the network has been observed.

978-83-60810-53-8/$25.00

A method of tracking groups over time was proposed in [5]. First, a division into time steps is carried out. At each step, the graph is created and groups are extracted. Groups from consecutive time steps are matched using the Jaccard index (value of this measure above predefined threshold means a continuation for analysed group). Palla et al. in [6] identified basic events that may occur in the life cycle of the group: growth, merging, birth, construction, splitting and death.

For further analysis, different characteristics, describing the communities and their transformation in time [7], are calculated, which concerns the comparison of the strength of internal relations of group members with their external connections with nodes outside the group, density of connections in the group or stability of the membership in time.

C. Methods of text mining

Text classification is one of major goals of Text Mining [8]. It involves extracting similar documents, inferring text topic and searching documents based on topic criteria.

Most text mining methods focus on text preprocessing (eg. stop words removal, words stemming and lemmatization) and converting input into structural representation [9]. Each word is represented as a separate entity assigned with a weight of the word importance, and thus it also allows to easily extract keywords. Algorithm TF-IDF (Term Frequency - Inverted Document Frequency) is one of the most popular weighting method [9]. It is based on the assumption that the importance of a word is proportional to number of occurrences of this word in a document, and inversely proportional to number of documents in which the word occurred. However, using only keywords to classify texts fails to find connection between semantically convergent documents that utilize different vocabularies, and more complex methods need to be applied such as Topic Modeling [10].

Topic Modeling [11] is a statistical technique that uncovers abstract "topics" that occur in a collection of documents. "Topic" is a set of words that tend to co-occur in multiple documents, and, therefore, they are assumed to have similar semantics. Main benefit of this model is that instead of using words from pattern to search for similar documents, words from topic are used, and therefore similar texts can be discovered even if they use different vocabulary.

Entirely different approach to uncovering documents semantics involves human input and it is called tagging [12]. Tags can be assigned either by author or by community in a process called crowdsourcing [13]. Number of tags assigned to a document may be large, and, therefore, it is imperative that a proper grouping and selection mechanism is implemented.

D. Text mining in the context of social network analysis

Existing research utilizing both SNA and Text Mining are mainly focused on very narrow cases. Aggarwal and Wang in [14] provided broad overview of text mining methods useful for social networks analysis. Tuulos and Tirri in [15] analysed IRC (Internet Relay Chat) communication network to discover and verify chat channels topics. Agrawal et al. in [16] used text mining methods to split social group into protagonists and antagonists. Caverlee and Webb in [17] used automatic classification methods based on keywords extraction and Topic Modeling to confirm personal information provided by Myspace users.

III. Analysis topics of groups and their impact on group behaviour

In this section we provide the concept of methods used to further analysis. The social network from whole data range is divided into series of time slots and each time slot contains static snapshot of network from defined period of time. In every time slot we extract groups and then find their dynamics in time. Irrespectively, we also discover topics in texts of comments and posts. Afterwards, we try to match topics for groups based on topics of comments and posts written by members of groups between themselves. Next, we analyse relations between topics of groups and behaviour of groups.

A. Groups in dynamic social network

Groups in each time slot were detected using the CPM [4] method (directed version of CPM from CFinder [1]). Groups from neighbouring time slots can be matched in order to find continuation of groups from different time. For this purpose, the SGCI (Stable Group Changes Identification) [18] method was employed. The algorihm consists of four main steps: identification of short-lived groups in each separated time slot; identification of group continuation (using modified Jaccard measure), separation of the stable groups (lasting for a certain time interval) and the identification of types of group changes (transition between the states of the stable group). The SGCI method identifies following event types:

- **split**, occurs when group divides into several groups in next time slot,
- **deletion**, similar to split, but it happens when small group detaches from significantly bigger one,
- **merge**, when several groups in the previous time slot join together and create larger group,
- **addition**, similar to merge, but it takes place when small group attaches to significantly bigger group,
- **split_merge**, when for the predecessor group the event is split and for the succesor group of given transition the event is merge in the same time,
- **decay**, the total disintegration of the group - the group does not exist in the next time slot,
- **constancy** means simple transition without significant change of the group size,
- **change_size** - simple transition with the change of the group size.

More detailed description of this method is provided in [18].

B. Finding topics of groups

For texts of posts and comments we employed methods of text mining in order to discover topics. Topics were extracted using 3 different methods:

[1] http://www.cfinder.org/

- TF-IDF keywords - words with the highest TF-IDF scores,
- Topic Modeling - topics extracted with LDA algorithm,
- Tags provided by post authors.

Keywords set for Topic Model is assumed to be a set of the most significant words for topics inferenced for messages.

We compared these methods between themselves using *similarity* measure:

$$similarity(S_1, S_2) = \frac{|S_1 \cup S_2|}{\min(|S_1|, |S_2|)}$$

where: S – keywords set, $|S|$ – number of elements in S.

For each group we can also assign set of topics discussed by its members. The topics are inferred based on posts and comments written by members of groups. We focused mostly on topic modelling as this method provides the highest level of abstraction from presented methods. Only topics that were present in more than 5% messages for groups were taken into consideration.

We defined *topic exploitation* for given topic and group as a ratio between number of group messages on certain topic and all messages for this group:

$$topicExploitation_k = \frac{|T_k|}{\sum_{i=1}^{n} |T_i|}$$

where: T_k – set of messages (posts and comments) for which topic with number k was inferenced, n – number of all topics, $|T_x|$ – amount of elements in T_x.

C. Topics changes in groups

To describe topics changes during transition between groups, we introduced following metrics:

- *Change in topic exploitation* for m-th group after transition t from time slot n to $n+1$ is calculated as:

  $$c_{m,n,t} = \sum_i \sum_k [g_{m,n,i} - g_{k,n+1,i} \cdot f(m,n,k,t)]$$

  where: i is a number of topic, $g_{m,n,i}$ is the topic exploitation of i-th Topic for m-th group in n-th time slot, f is function returning 1 if k-th group in slot $n+1$ is a continuation of m-th group from slot n and this transition has event type t.
- *Maximal positive change of single topic* (how much a topic gained) for m-th group after transition t from time slot n to $n+1$ is defined as:

  $$mpc_{m,n,t} = \max_i \sum_k [\epsilon(g_{m,n,i} - g_{k,n+1,i} \cdot f(m,n,k,t))]$$

  where: ϵ is a function returning the argument when the argument is **negative**, otherwise 0; other symbols were explained for *Change in topic exploitation* measure.
- *Maximal negative change of single topic* (how much a topic lost) for m-th group after transition from time slot n to $n+1$ was calculated as:

  $$mnc_{m,n,t} = \max_i \sum_k [\theta(g_{m,n,i} - g_{k,n+1,i} \cdot f(m,n,k,t))]$$

  where: θ is a function returning the argument when the argument is **positive**, otherwise 0; other symbols were explained for *Change in topic exploitation* measure.

Using above metrics we can analyse influence of different evolution types on topics change. Therefore, for each evolution type the average values of above defined measures for all groups are evaluated and we refer to them as *Average overall change in topic exploitation*, *Average maximal positive change of single topic* and *Average maximal negative change of single topic* respectively.

For above metrics, evolution events were taken into consideration only if there were at least 10 such events in selected time period.

D. Migrations of users depending on topics

To analyse difference in topics between given user and given group, we defined *topic divergence*, which has the following form:

$$m_t = t_{group} - t_{user} = \sum_{i=1}^{n} |(topic_{i,user} - topic_{i,group})|$$

where: n is a number of all topics in model (350), t_{group} is set of weights of each topic for given group, $topic_{i,group}$ – weight of i-th topic for given group, t_{user} is set of weights of each topic for given user, $topic_{i,user}$ is weight of i-th topic for given user.

It's worth noting that minimal value of m_t is 0.0 when user and a group has identical weight for every topic and maximal value is 2.0 when they are totally different. Maximum value of 2.0 is connected with the fact that group might cover topic X in 100% and user might cover topic Y in 100%, and therefore difference between group and user on topic X is 100% and on topic Y is also 100% which adds up to 200%.

Using this measure, we are trying to investigate relations between *topic divergence* and migrations of users (leaving and joining to groups). For this purpose the following measures are utilized:

- *Probability of leaving the group*. We assumed that potentially any member can leave the group. This value is calculated as:

  $$P_l(m) = \frac{|leavers_m \cap candidates_m|}{|candidates_m|}$$

  where: $leavers_m$ are users that in fact left any group and had the value of *topic divergence* measure equals m; $candidates_m$ are members of groups that have *topic divergence* = m.
- *Probability of joining the group*. When considering topic measure we assumed that candidates for joining are all users that were active in previous time slot. This value is calculated as:

  $$P_j(m) = \frac{|joiners_m \cap candidates_m|}{|candidates_m|}$$

  where: $joiners_m$ are users that in fact joined any group and had the value of *topic divergence* measure equals m;

$candidates_m$ – users active in previous time slot with *topic divergence* = m.

While calculating joiners and leavers sets we considered all group continuations to be a single group. The reason for that is to prevent *deletion* event to distort results - if a group splits into multiple small groups and we are assuming that anyone from the group can leave, then we will get very high accuracy from each event when huge group changes into small group.

It is worth noting that only both values - probability and histogram with migrations can provide us with complete information. Probability alone strongly depends on test case - if only 1 user had measure value = X and this user migrates then probability of migration for measure=X will be 100%, even if 100 different users migrated but they all had measure value=Y just as rest 10000 users, and thus probability for measure value=Y will be 1%. Without histogram we could not tell if any of those cases are marginal.

Analogically histogram itself can tell us only for which value there are the most migrations.

IV. Description of experiments

A. Data set

The analysed data about blogs was retrieved from the portal www.salon24.pl, which is dedicated especially to political discussions, but also subjects from other domains may be brought up. The data consists of 26 722 users (11 084 of them have their own blog), 285 532 posts and 4 173 457 comments within the period 1.01.2008 - 31.03.2012. Presented results were conducted on whole dataset - from 1.01.2008 to 31.03.2012. The analyzed period was divided into time slots, each lasting 7 days and neighboring slots overlap each other by 1 days. In the examined period there are 259 time slots. In each slot we used the comments model, introduced in [19] - the users are nodes and relations between them are built in the following way: from user who wrote the comment to the user who was commented on or if the user whose comment was commented on is not explicitly referenced in the comment (by using @ and name of author of comment) the target of the relation is the author of post.

B. Number of groups

The number of communities, with given size, for different value of *k* (parameter for CPM algorithm) is presented in table I. The *k* parameter determines the minimum group size (e.g. *k* equals 3 means that groups should consist of 3 or more members). The larger value of *k*, the smaller size of the biggest group. As we can notice, small groups outnumber other ones for each *k*. Furthermore, for *k* equals 6 the quantity of groups is much lower than for other values of *k* parameter.

C. Evolution events

Table II contains number of different evolution events in dataset for different values of *k*. We can observe for *k* equal 4 or 5 that the most popular events are *addition* and *deletion*, but for *k* equal 6, the most frequent events are *merge* and *split* (events similar to *addition* and *deletion*). The reason is that

TABLE I
NUMBERS OF GROUPS WITH DEFINED SIZE.

size	k=4	k=5	k=6
< 5	1596	0	0
5 – 6	384	2372	0
6 – 7	207	632	584
7 – 8	113	255	149
8 – 9	88	139	86
9 – 10	50	63	39
10 – 50	289	332	199
50 – 100	25	54	30
100 – 200	59	96	6
> 200	172	17	0

for *k* equal 4 or 5, there is a lot of small groups and there are also very huge groups (which not happens for *k* equal 6). In further analysis, we focus on groups extracted for parameter *k* equal 5 from the CPM method.

TABLE II
NUMBERS OF EVOLUTION EVENTS.

type	k=4	k=5	k=6
change_size	699	470	195
constancy	257	100	42
merge	428	439	434
split	323	409	397
addition	1091	2070	197
deletion	1115	2040	188

D. Convergence of different message topic extraction methods

This experiment covered comparison of different messages topic inference methods: TF-IDF keywords, topic modelling and tags provided by users.

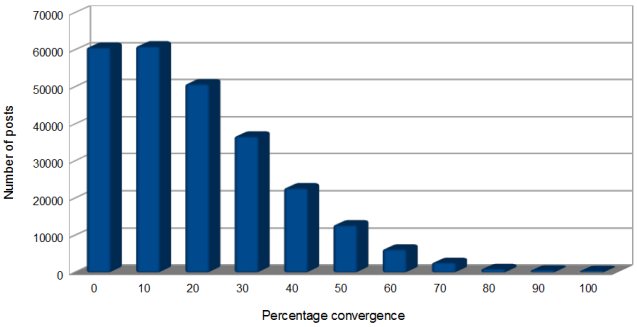

Fig. 1. Convergence level of TF-IDF keywords and most significant Topic Model words for inferenced topics

Fig. 1 presents comparison between TF-IDF keywords and Topic Modelling. As it can be seen, for about 20% of documents there was not even a single matching word. Convergence rate above 50% was achieved by merely 6000 posts which is around 5% of all input data.

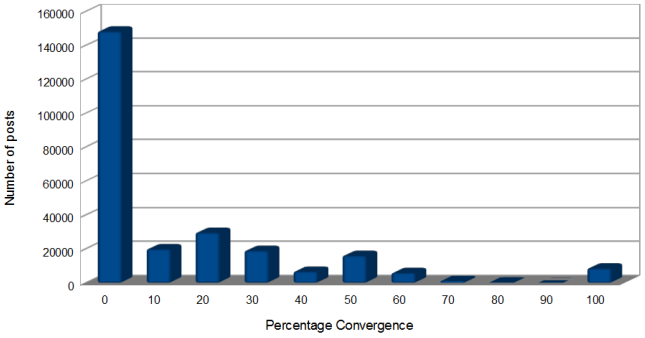

Fig. 2. Convergence level of TF-IDF keywords and user provided Tags

In fig. 2 TF-IDF keywords are compared with user tags. One can see that for huge part of documents achieved convergence rate was 0%. There are also local maxima at 20, 30, 50 and 100% and their origin is connected with number of tags user provides, which in most cases is between 1 and 5 (when matched 1/5, 1/4, 1/3, 1/2 and 1/1 of keywords).

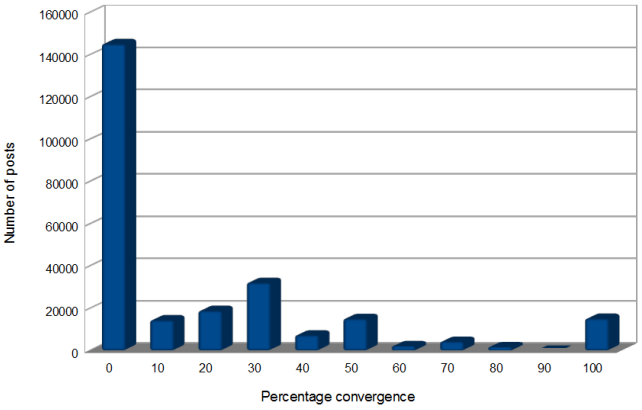

Fig. 3. Convergence level of user provided Tags and most significant Topic Model words for inferenced topics

Fig. 3 displays user tags in comparison with topic modelling. This histogram shows that, similarly to fig. 2, very huge part of tested posts don't have even a single word in common. We can also notice similar maxima due to the same reasons.

According to presented data, convergence rate seems to be very low, and therefore it would be imperative to check which of presented methods gives correct results. However, in depth analysis of our results uncovered that in fact all three methods are properly describing posts semantic. The problem is with vocabulary that is being used to describe it. The reason for different vocabulary is connected with level of generalisation that is utilised by presented methods:

- keywords provides very specific and detailed description of given document,
- tags provides general summary of the document and are far less specific, but error-prone of misspelling (they are provided by post authors),
- topics provides very general and abstract idea behind the document.

For these reasons, we are focusing more on topic modelling.

E. Topics coverage by groups

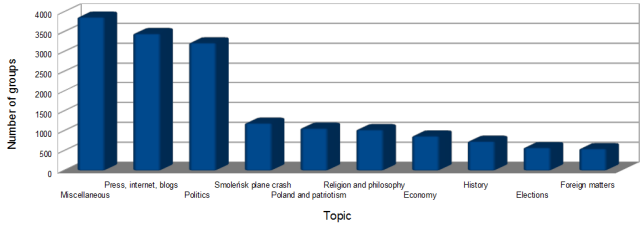

Fig. 4. Number of groups exploiting given topic

Figure 4 shows number of groups that exploit given topic in more than 5% of total group members messages. This figure presents ten most popular topics. We can notice that most popular topic is *Miscellaneous* which is very general and in fact is a mix of many themes.

F. Influence of group size on covered topics

In this experiment we aimed to check if there is a correlation between groups size and topics this groups covers.

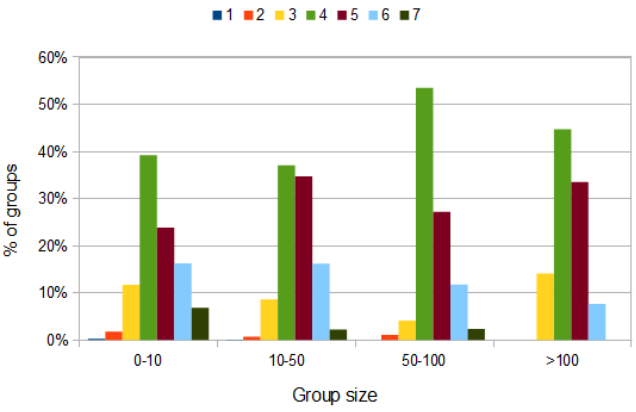

Fig. 5. Number of topics covered by groups with certain size, k=5

Fig. 5 shows number of Topics covered by groups with certain sizes. Considering 5% threshold of topic importance we used to remove noise. Maximum value any group could achieve was twenty topics, however no group covered more than seven topics and most groups cover four or five topics. In fig. 5 we can observe that three to seven topics are in groups of any size, but there are some small and medium-size groups that discuss only about one or two topics, which not happens in large groups.

Fig. 6 presents that for some topics *topic exploitation* is very similar regardless of group size (e.g. *Press, internet, blogging* topic), but there are some specific topics that are discussed to a greater extent among members in small group (e.g. topic related with science) or among members in larger ones (e.g. politics).

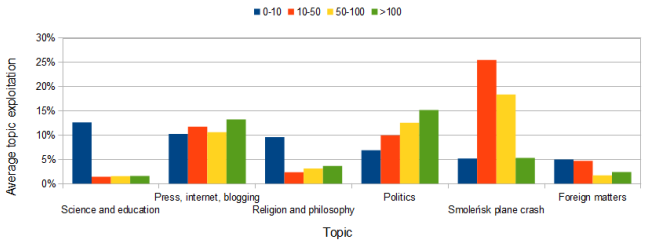

Fig. 6. Percentage topics exploitation for groups with certain size, k=5

G. Influence of duration time on covered topics

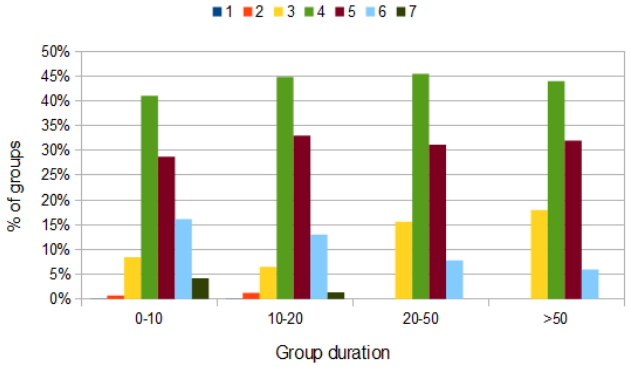

Fig. 7. Number of topics covered by groups with duration time, k=5

We can notice some regularities on fig. 7 :

- only very short living groups covers one and two topics,
- as previously, most groups cover four and five topics.

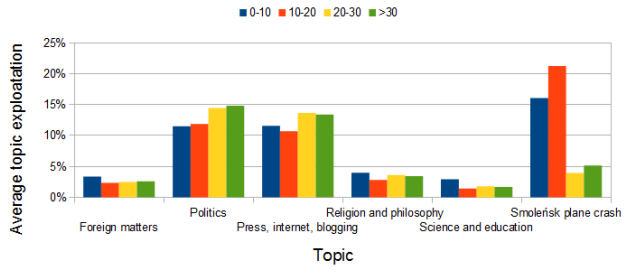

Fig. 8. Percentage topics exploitation for groups with certain duration time, k=5

In fig. 8 one can see that most topics achieved similar scores, with an exception - Polish Air Force Tu-154 crash was, to a large degree, discussed by short-term groups.

H. Connection between topics change and groups evolution

This experiment aimed to verify if there is any apparent connection between group evolution type and change in topics coverage for this group. Experiment was based on three measures (described earlier in section III-C):

- average overall change in topics coverage after evolution,
- average maximal positive change of single topic,
- average maximal negative change of single topic.

Evolution events were taken into consideration only if there were at least ten such events in selected time period. Presented results were collected for groups with $k = 5$ and for periods of length 360 days. There are two evolution types that are not present on the chart - *split_merge* that did not occur and *decay* that was omitted. *Decay* event means that group ceased to exist, and therefore we cannot calculate how topics of this group changed, because there is no continuation of the group.

Average overall change in topics. Figure 9 presents some regularities:

- *addition* event has clearly the highest overall topic change,
- *split* and *change_size* are connected with the lowest topic change,
- *merge* and *deletion* are in between,
- quite surprisingly *constancy* seems to vary between periods, even though one could expect that it will be connected with very small topic change.

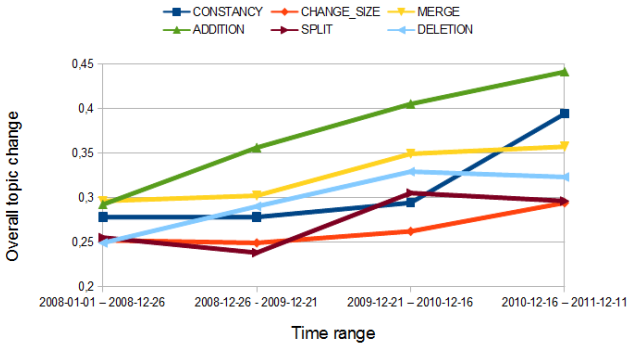

Fig. 9. Average overall change in topics coverage for every evolution event type - period 360 days

Average maximal positive change of single topic. Figure 10 presents that:

- *addition* has lowest average maximum single topic change. It means that on average after *addition* even topic that gained the most, gained very little.
- *deletion* and *split* caused highest positive change.
- *merge* and change_size were in between.

Average maximal negative change of single topic. Figure 11 shows that:

- *addition* is connected with highest drop for a single topic. It means that after *addition* there is a topic that significantly loses popularity.
- *change_size*, *split*, *deletion* and *merge* has very low average drop in topic popularity - even topics that lose popularity after such events lose very little.

Summary for different types of topic change. *Addition* is connected with: highest overall change in topics, highest negative change and lowest positive change. Therefore, we can deduce that when multiple small groups are forming a single

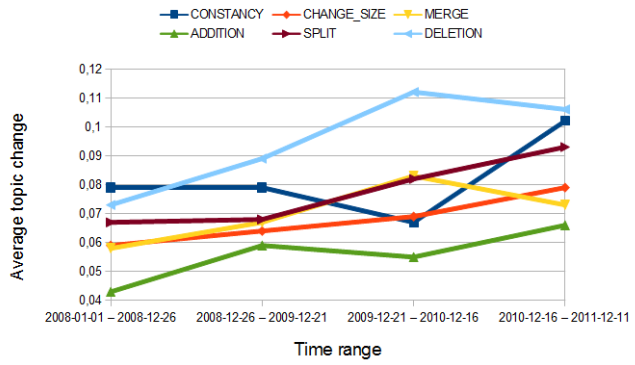

Fig. 10. Average maximal positive change of single topic - period 360 days

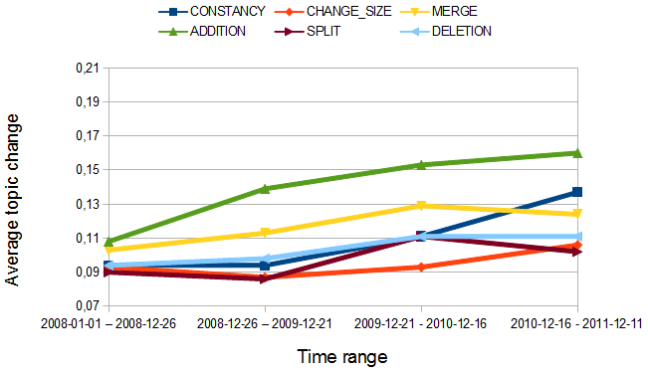

Fig. 11. Average maximal negative change of single topic - period 360 days

large group it is usually connected with significant drop of popularity of the main topic of each of the groups, and small rise in popularity of different topics - presumably of main topics of other groups.

Deletion and *split* cause small overall topic change, small negative change and large positive change. It means that splitting a group causes a rise of popularity of a single topic at the expense of all the others.

Change_size has very small changes in topics. We could expect that *constancy* behave the same way, however it does not.

Merge event causes medium rise of single topic popularity at the expense of all the others, meaning that joining groups are very similar and after join the leading topic emerges.

I. Migrations between groups

This experiment was conducted to check if migration of users between groups could be predicted using information about topic preferences of users and groups.

Important: currently analysed user does not have to be a member of the group. In fact, when calculating probability of joining a group we consider only users that are not yet members.

As a measure connected with users and groups topics we used *topic divergence* between user and group (details in section III-D).

Based on this measure, we tested their influence on:

- probability of leaving the group (candidates for leaving group are all members of group),
- probability of joining the group (candidates for joining are all users that were active in the previous time slot).

While calculating joiners and leavers sets we considered all group continuations to be a single group. The reason for that is to prevent *deletion* event to distort results - if a group splits into multiple small groups and we are assuming that anyone from the group can leave, then we will get very high accuracy from each event when huge group changes into many small groups.

Joining groups. Figure 12 shows that there is high probability of joining for users that are high convergent with the group, however, when we look at figure 13, we can notice that some of them (most convergent users with groups) are marginal cases (very few migrations). Moreover, we can notice that probability of joining groups is rather constant regardless the value of *topic divergence*, except the smallest values of this measure.

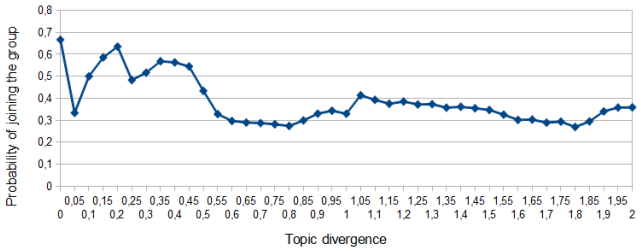

Fig. 12. Probability of user joining a group based on topic divergence.

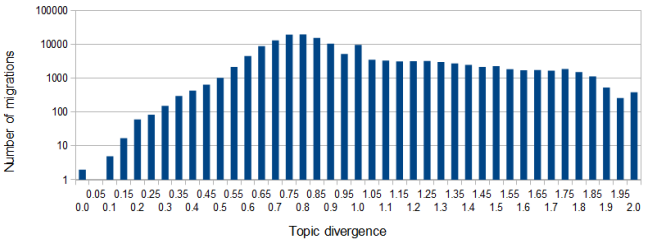

Fig. 13. Number of users that did join the group based on topic divergence.

Most migrations occur between 50% and 100% divergence and we can also see a rise in probability there, due to more cases. There is an interesting local extreme in figure 13 around 100% divergence. It would seem that there is a large portion of joiners that in previous time slot wrote all their posts and comments on one topic, or more likely wrote only a single post or comment, and then joined the group where this topic was not relevant. It is worth noting that our candidates were only a fraction of real joiners. It seems that about half joiners were people that were inactive in previous time slot (151 819 joiners were inactive user and 154 977 real joiners were from the candidate set).

Leaving groups. As can be deduced from figure 14, for low divergence values probability of leaving is low and is rising along with divergence up until 50% divergence and, further, the probability of leaving is rather constant. Alhough, it drops down for very high divergence, however, figure 15 tells us that it is a marginal case.

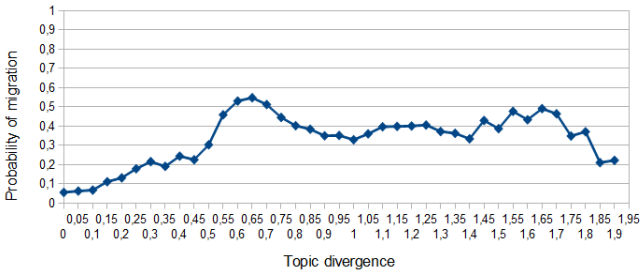

Fig. 14. Probability of user leaving a group based on topic divergence.

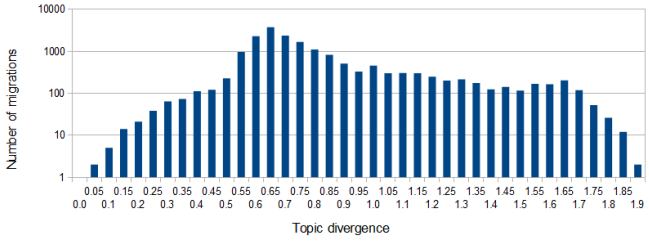

Fig. 15. Number of users that did leave the group based on topic divergence.

V. Conclusion

In this paper the analysis of topics for communities detected in real-world data from blogosphere is presented. We conducted experiments concerning relations between discussed topics by members of groups and some aspects of groups such as their duration time or their size. Furthermore, we also analysed influence of group evolution events on changes of topics and investigated the impact of topic divergence on users behaviour such as joining or leaving group.

Presented results seem promising and they reveal new insights into behaviour of groups and individuals. Analysis of topics discussed inside communities can be useful tool enabling better understanding of processes inside social network.

In future we are planning to use information about topics to improve our method of prediction of group behaviour [20]. Moreover, we intend to carry out similar experiments (related to analysis of topics in communities) on other datasets - we want to use also blogs in English language and datasets from different kinds of social media e.g. microblogs. Another interesting direction of further research is the analysis of key persons in groups in terms of topics they discuss and such analysis could lead to enhance our method of defining user roles and finding most influential people [21].

***Abstract*—Attribute-Relationship Diagrams (ARD) aim at capturing relations, especially dependency relation, between the specified attributes. This paper describes work-in-progress research concerning process and rules integration, which takes advantage of the ARD method and allows for generating executable models. The paper examines the possibility of generating the rule-oriented BPMN model and enriching process models with rules from the ARD diagram.**

***Index Terms*—BPMN, Business Processes, Business Rules**

I. Introduction

BUSINESS Process (BP) models constitute a graphical representation of processes in an organization. Such a process is composed of related tasks that produce a specific service or product for a particular customer [1]. When it comes to practical modeling, Business Process Model and Notation (BPMN) [2], [3] constitutes a standard for this purpose.

The current version of the BPMN notation allows for modeling many aspects of business; nonetheless, it is not suitable for modeling some aspects of the enterprise, especially decision rules or constraints [4]. Recently, the Business Rules (BR) approach has been proposed as a new way of capturing the functional requirements and modeling system logic in a designer-friendly fashion. Moreover, the BR approach is a solution originated from Rule-Based Systems, that are a mature and well established technology. As processes and rules are related to each other, BR are often, but not limited to, used for the specification of task logic in process models.

BR can be acquired based on some data using machine learning techniques [5] or generated from natural language specification [6]; however, they often have to be modeled manually based on the knowledge collected from the domain experts, as usually their knowledge is not written down anywhere. Similarly, processes are designed manually as well. However, the simplified process models can be generated using process mining tools [7] or acquired from natural language description using NLP techniques [8]. Other method of acquiring BPMN models is to transform the existing process models in other languages to the BPMN notation. From a researcher's point of view, this can be a challenge in the case that languages are of different paradigm or presents a different aspect of the system, e.g. UML use-case diagrams [9].

The paper is supported by the HiBuProBuRul Project funded from NCN (National Science Centre) resources for science (no. DEC-2011/03/N/ST6/00909).

In this paper, we present work-in-progress research which is a part of our research concerning process and rules integration [10], [11], [12]. We examine the possibility of generation of the rule-oriented BPMN model as well as the possibility of enriching BP processes with rules from the ARD diagram.

As the ARD method allows a domain expert for gradual identification of the properties of a system being designed, we argue that having the system properties identified and described in terms of attributes, it is possible to generate executable BPMN model with the corresponding BR tasks as well as enrich the BP model with such BR tasks. Such an approach would allow for generating business processes and rule schemas for logic task specification at the same time. The generated rule prototypes comply with the XTT rule representation [13], [14], [15], [16] from the Semantic Knowledge Engineering approach [17].

The paper is organized as follows. In Section II we present the motivation for our research. Section III provides a short overview of the related approaches. Section IV presents the details of the ARD method. In Section V, we give an overview of the proposed method for process model generation and enriching the BP model with BR tasks based on a design example. The hybrid execution environment is presented in Section VI. Section VII summarizes the paper.

II. Motivation

The complexity of software has been constantly increasing for the last decades. To deal with this growth, new design methods and advanced modeling solutions are required [18]. For this purpose, modern applications use business processes and business rules as business logic specification [19].

According to the BPMN 2.0 specification [2], the notation is not suitable for modeling such concepts as rules. Therefore, this reveals the challenges in modeling and executing processes with rules. It is so because processes and rules are developed or modeled separately and are not well matched.

Our research aims at developing the integrated method for modeling BP with BR to provide a consistent method for modeling business systems. Such a method will allow for modeling processes with rules in a straightforward way, and then for executing such a developed model.

The main contribution of this paper is a presentation of the possibility of generation of the rule-oriented BPMN model, which can be used for enriching the BP models with BR tasks.

III. Related work

Several approaches can be considered as related to the method presented in this paper. As our method proposes automatic generation of a BPMN model, the approach can be compared with such approaches as: process mining [7], generating processes from text in natural language (based on NLP methods) [8], or finally transforming process from other notations to BPMN, especially from the notations that are not process-oriented, e.g. the UML use case diagrams [20].

The process mining methods [7] allow for very flexible process models generation, and in some cases this technique does not require any human activity. However, the result of the method is a very general process that is not suitable for direct execution. In order to be an executable BPMN model, it has to be significantly enhanced and refactored. In the case of our method, it is not as much flexible as process mining technique, but it produces a BPMN model which is executable and provides support for Business Rule tasks.

Generating processes from text description provided in natural language [8] can have practical results and allows for generating a high quality BPMN model. High quality models can also be obtained through translation from other representations, such as the UML use case diagrams [21], [22]. Unfortunately, a method based on the natural language description has to be supported by an advanced NLP system, thus practical applications of this method is very complex. Translation from other representations, in turn, requires process models designed using such representations, which often do not exist. In our approach, a process model is generated based on the carefully prepared ARD diagram. Although this requires the ARD diagram, it is very simple model and in some cases it can be obtained from text description using some mining technique to acquire attributes. This requires additional research yet. However, there has been trials of mining such attributes from text in natural language [23].

There are also other approaches, such as generating business process models from Bill Of Materials (BOM) [24], Product Based Workflow Design (PBWD) [25], [26], based on Product Data Model (PDM), or Decision Dependency Design (D3) [27], [28]. These are more similar to the method proposed in this paper. However, in the case of our approach, apart from the fact that it generates an executable BPMN model, it supports the rule prototypes generation for Business Rule tasks, what makes the BPMN model data consistent with the rule engine requirements for data. Therefore, we claim that our approach is partially rule-based [29].

It is important to mention that the presented approach can be used either for generating a new rule-oriented BPMN model or for enriching the existing process model with rules based on the corresponding ARD diagram.

Although the work presented in this paper is work-in-progress research, the method overview presented in the paper reveals significant differences from the techniques mentioned above, especially in the case of method simplicity and support for rules in process models.

IV. Attribute Relationship Diagrams

Attribute Relationship Diagram (ARD) [30] constitute a method which allows a user (especially a domain expert) for gradual identification of the system properties during design.

The goal of this method is to capture functional dependencies between attributes. The attributes are expressed in terms of Attributive Logic [31], [17], [32] and denote particular system properties identified by the domain expert. The identified dependencies form a directed graph in which properties are represented as nodes and dependencies are represented as transitions. In the following definitions, we present more formal description of ARD.

A typical atomic formula (or fact) takes the following form

$$a(p) = d$$

where a is an attribute, p is a property and d is the current value of a for p. More complex descriptions take usually the form of conjunctions of such atoms and are omnipresent in the AI literature [33].

An **attribute** $a_i \in A$ is a function (or partial function) of the form:

$$a_i \colon P \to \mathbb{D}_i$$

where

- P is a set of property symbols,
- A is a set of attribute names,
- $\mathbb{D}$ is a set of attribute values (the domains).

An example of an attribute can be the `carAge`, which denotes the age of a car, and the attribute value is within the domain $\mathbb{D}_{carAge} = [0, \inf]$.

A **generalized attribute** $a_j \in A$ is a function (or partial function) of the form:

$$a_j \colon P \to 2^{\mathbb{D}_j}$$

where $2^{\mathbb{D}_j}$ is the family of all the subsets of $\mathbb{D}_{\mathbb{j}}$.

An example of a generalized attribute can be the `ownedInsurances`, which is a set of the customer insurances, and the attribute value is a subset of the domain $\mathbb{D}_{ownedInsurances}$, which consists of the possible insurances that a particular customer can posses.

In the case of abstraction level, the ARD attributes and generalized attributes can be described either as conceptual or physical ones.

A **conceptual attribute** $c \in C$ is an attribute describing some general, abstract aspect of the system.
Conceptual attribute names are capitalized, e.g.: `BaseRate`. During the design process, conceptual attributes are being *finalized* into, possibly multiple, physical attributes.

A **physical attribute** $a \in A$ is an attribute describing a specific well-defined, atomic aspect of the system.
Names of physical attributes are not capitalized, e.g. `payment`. A physical attribute origins from one or more (indirectly) conceptual attributes and can not be further *finalized*.

A **simple property** $p_s \in P$ is a property described by a single attribute.

A **complex property** $p_c \in P$ is a property described by multiple attributes.

A **dependency** $d \in D$ is an ordered pair of properties (f, t), where $f \in P$ is the **independent property** and $t \in P$ is the **dependent property** that depends on f. For simplicity $d = (f, t) \in D$ will be presented as: $dep(f, t)$.

An **ARD diagram** R is a pair (P, D), where P is a set of properties, and D is a set of dependencies, and between two properties only a single dependency is allowed.

To illustrate the ARD concepts, an exemplary ARD diagram with properties and the dependency between them is presented in Figure 1. The diagram should be interpreted in the following way: `payment` depends somehow on `carCapacity` and `baseCharge`.

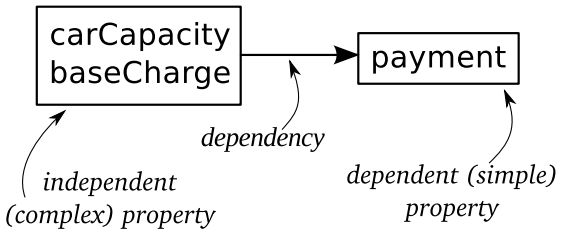

Figure 1. An example of the ARD diagram

The core aspects of the ARD method are diagram transformations, which regard properties and serve as a tool for diagram specification and development. Transformations are required to specify additional dependencies or introduce new attributes for the system. For the transformation of the diagram R_1 into the diagram R_2, the R_2 is more specific than the R_1.

Finalization *final* is a function of the form:

$$final : p_1 \rightarrow p_2$$

that transforms a simple property $p_1 \in P$ described by a conceptual attribute into a property $p_2 \in P$, where the attribute describing p_1 is substituted by one or more conceptual or physical attributes describing p_2, which are more detailed than the attribute describing a property p_1.

In Figure 2, an exemplary finalization transformation is presented. It shows that the simple property `BaseRate` (described by a single conceptual attribute) is finalized into a new complex property described by two physical attributes `carCapacity` and `baseCharge`.

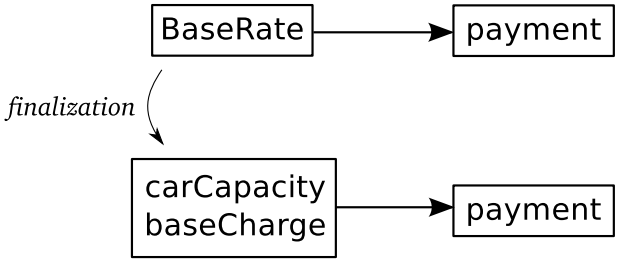

Figure 2. An example of the ARD finalization transformation

Split *split* is a function of the form:

$$split : p_c \rightarrow \{p^1, p^2, \ldots, p^n\}$$

where a complex property p_c is replaced by n properties, each of them described by one or more attributes originally describing p_c. Since p_c may depend on some other properties $p_o^1 \ldots p_o^n$, dependencies between these properties and $p^1 \ldots p^n$ have to be stated.

To illustrate this transformation, Figure 3 shows the complex property described by two physical attributes (`carCapacity` and `baseCharge`), which is split into two simple properties described by these attributes.

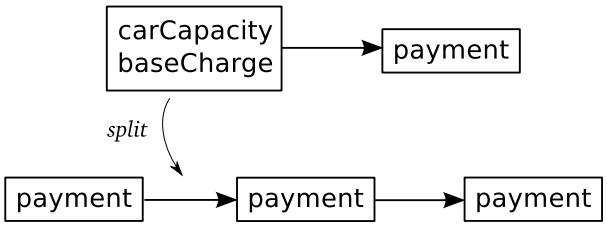

Figure 3. An example of the ARD split transformation

Upon splitting and finalization, the ARD model is more and more specific (see Figure 4). The consecutive levels of ARD forms a hierarchy of progressively detailed diagrams, which constitutes Transformation Process History (TPH) [34]. The implementation of this hierarchical model is provided through storing the lowest available, most detailed diagram level at any time, and additional information needed to recreate all of the higher levels. Such model captures information about changes made to properties at consecutive diagram levels.

A. Polish Liability Insurance Case Study

Let us now present an illustrative example of the Polish Liability Insurance (PLLI) case study. The example was developed as a benchmark case for the Semantic Knowledge Engineering (SKE) approach for rule-based systems [17]. Based on this simple case study, we will then present how ARD can be used for BPMN model generation.

In the PLLI case study, the price for the liability insurance for protecting against third party claims is to be calculated.

The price is calculated based on various reasons, which can be obtained from the domain expert. The main factors in calculating the liability insurance premium are data about the vehicle, such as the car engine capacity, the car age, etc. Additionally, the impact on the insurance price have such data as the driver's age, the period of holding the license, the number of accidents in the last year, etc. Moreover, in the calculation, the insurance premium can be increased or decreased because of number of payment installments, other insurances, continuity of insurance or the number of cars insured. All these pieces of data can be specified using the ARD method and presented using the ARD diagram (see Figure 5). As specification of ARD is an iterative process, the corresponding TPH diagram, presenting split and finalization transformations, can be easily depicted, as shown in Figure 6.

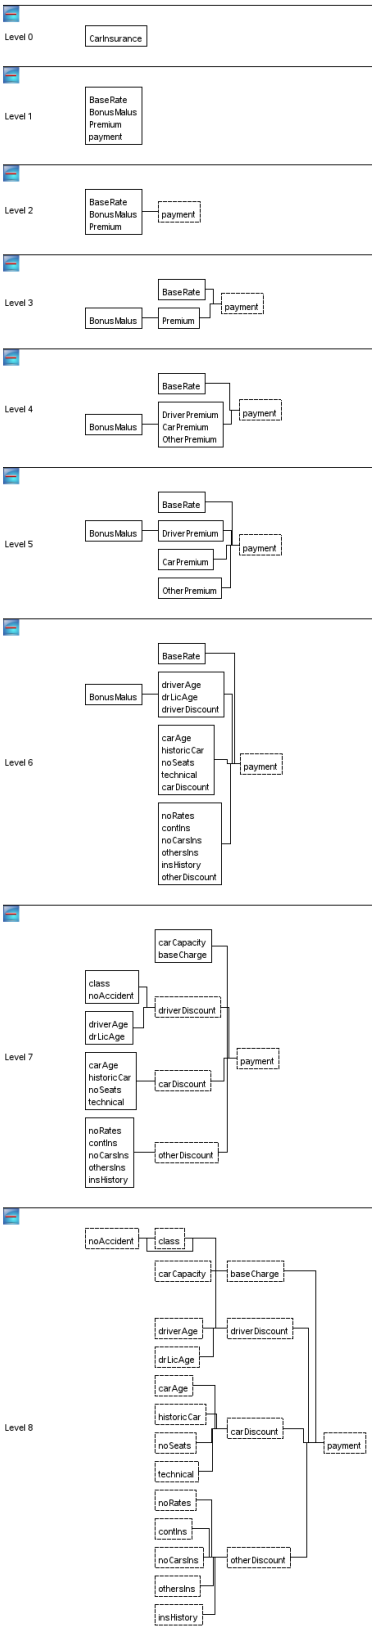

Figure 4. The ARD levels for the PLLI case study

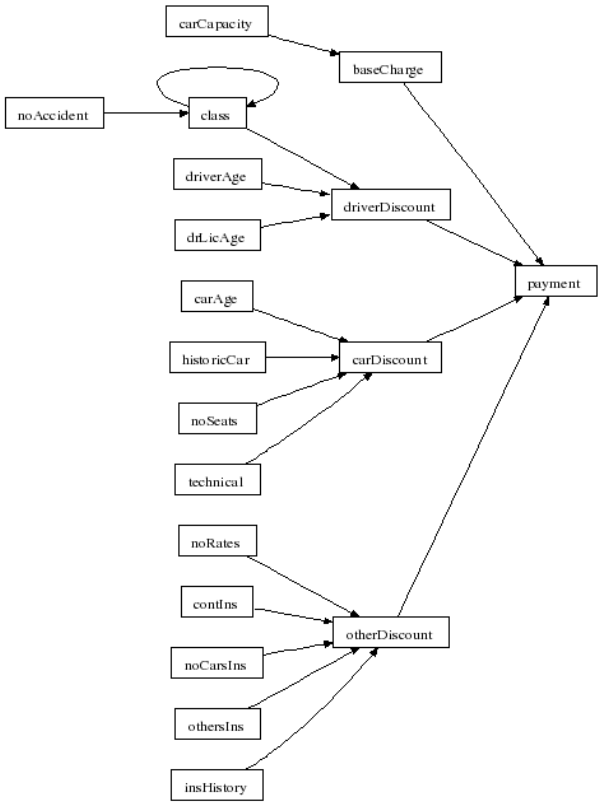

Figure 5. A complete ARD model for the PPLI example

B. Advantages of ARD

There are several advantages of using the ARD method to specify the system. Firstly, this method describes the system in an attribute-oriented way, and thus it is easy to comprehend and generates a simple model.

ARD can be used even if there are not many pieces of information available. It is so because this method does not require anything apart from the specification of dependencies between attributes. It is important to mention that we do not specify the detail semantics of the dependency relationship; thus it is only claimed that one property depends on other property. Although this limitation of ARD can be seen as a drawback, the main focus of this method is on simplicity.

The ARD method can also be extended, e.g. there can be used some mining technique to acquire attributes and dependencies among them. However, this requires additional research tasks yet. There has been trials of mining such attributes from text in natural language [23].

Applying ARD as a design process allows a domain expert to identify attributes of the modeled system and refine them gradually, as well as generates rule prototypes based on the identified attributes. Thanks to storing the history of transformations, it is possible to refactor such a system [35].

In the following section, we give a short overview of the proposed method of process model generation and enriching the BP model with BR tasks based on a design example.

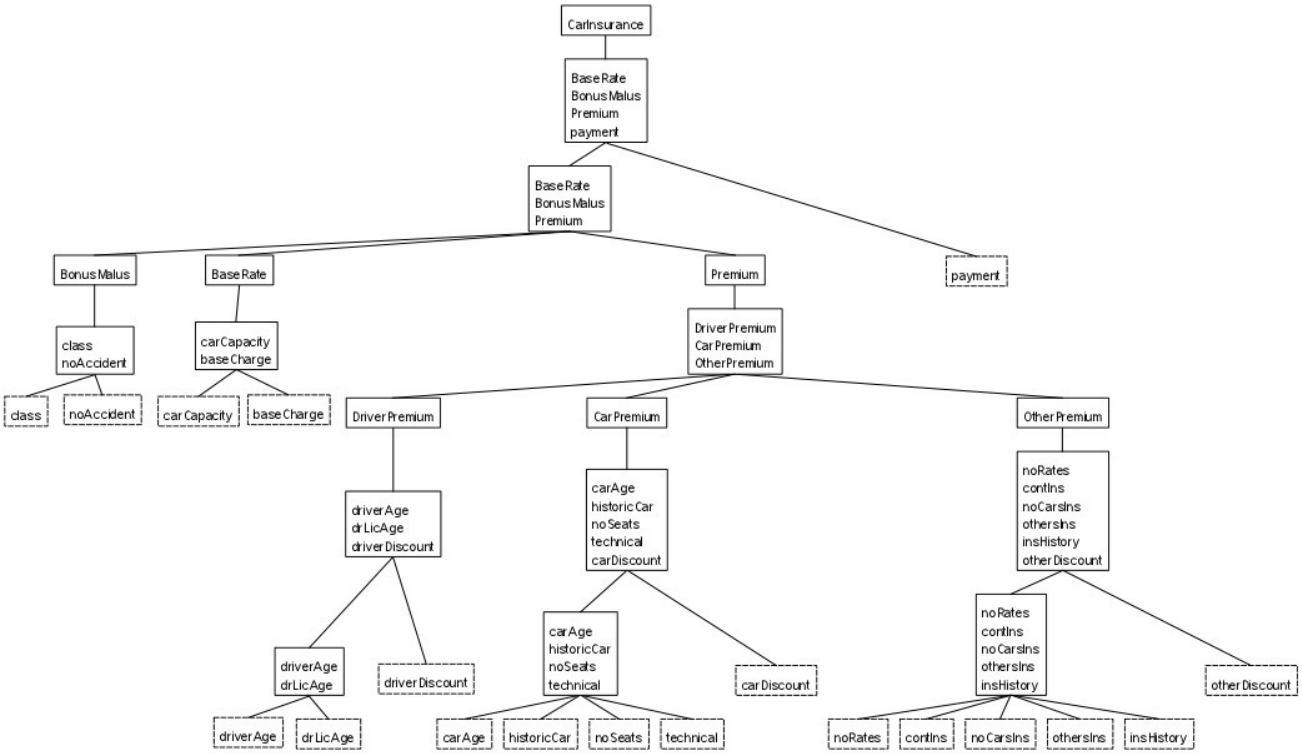

Figure 6. An example of the TPH diagram, corresponding to the ARD diagram presented in Figure 5

V. Rule-oriented BPMN Model Generation

In the proposed rule-oriented approach for BPMN model generation, we consider:

1) **Generating the whole BPMN model based on ARD**, presented in the previous section. Such an approach requires specific input and generates particular output:

   Input: Attribute-Relationship Diagram (ARD), and additionally Transformation Process History (TPH).
   The input is the most detailed ARD+ diagram, that has all of the physical attributes identified (in fact, this can also be applied to higher level diagrams, generating rules for some parts of the system being designed).

   Output: A rule-oriented BPMN process model.
   The output is a process model in the BPMN notation with User tasks, BR tasks and additional elements of the control flow objects. BR tasks contain rule prototypes in a very general format:

   ```
   rule:
   condition attributes | decision attributes
   ```

   Goal: The goal of this approach is to automatically build a rule-oriented BPMN process model on the basis of the ARD diagram (optionally supported by the TPH diagram). The algorithm will generate both User Tasks with form attributes for entering particular pieces of information and Business Rule Tasks with prototypes of decision tables.

   Sketch of the algorithm:

   1. Generate BR tasks from ARD based on the modified version of the algorithm for generating the XTT2 representation from ARD (detailed description of this part is presented below).
   2. Generate proper User tasks which acquire necessary information from the user.
   3. Generate proper User/Mail tasks to communicate process results to the user.
   4. Complete the diagram using control flow with additional flow objects, such as start and end events, and gateways.

2) **Enriching the existing BPMN model with BR tasks based on ARD** (either developed parallely to BP model or generated based on the process description).

   Input: BPMN process model, Attribute-Relationship Diagram (ARD) corresponding to the BPMN model, and additionally Transformation Process History (TPH).

   Output: A rule-oriented BPMN process model.

   Goal: The goal of this approach is to automatically enrich a BPMN process model with rule tasks on the basis of the ARD diagram (optionally supported by the TPH diagram). The algorithm will support refactoring of the process model to rule-oriented way by proposing new BR tasks for the process model.

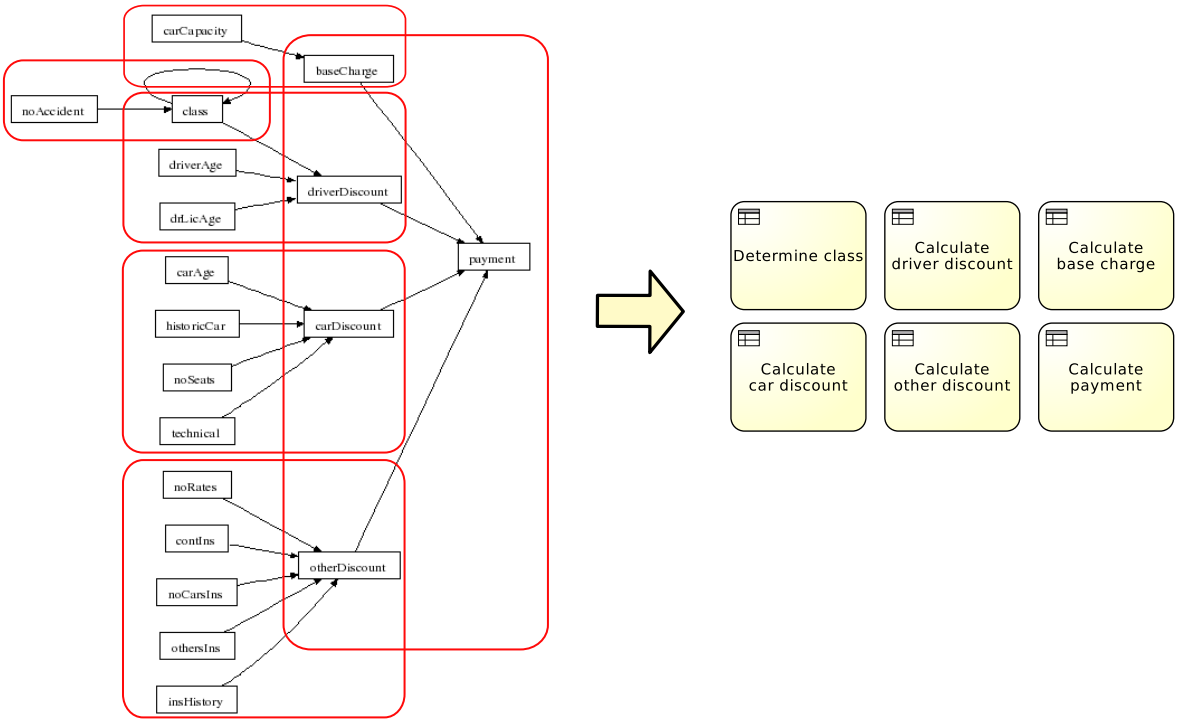

Figure 7. BR tasks generated from the ARD diagram

In the aforementioned cases, the most important aspect is to generate Business Rule tasks with rule prototypes for a process model. This can be done using the modified version of the algorithm for generating the XTT2 representation from ARD (described in [36], [34]). The result of application of this algorithm is presented in Figure 7. A draft of the algorithm for generating Business Rule tasks with rule prototypes for a process model is as follows:

1) Prepare data:
   a) Choose a dependency $d \in D : dep(f,t), f \neq t$, where D is a set of dependencies in the ARD diagram.
   b) Select all independent properties (other than f) that t depends on. Let $F_t = \{f_t^i : dep(f_t^i, t), f_t^i \neq f\}$. Remove the considered dependencies from the set: $D := D \setminus \{d_{f_t^i,t}\}$.
   c) Select all dependent properties (other than t) that depend only on f. Let $T_f = \{t_f^i : dep(f, t_f^i), t_f^i \neq t, \nexists f_x : (dep(f_x, t_f^i), f_x \neq f)\}$. Remove the considered dependencies from the set: $D := D \setminus \{d_{f,t_f^i}\}$.
2) Create BR tasks based on F_t and T_f:
   a) if $F_t = \emptyset, T_f = \emptyset$, create a BR task determining the value of the t attribute and associate the task with the following decision table schema: $f \mid t$.
   b) if $F_t \neq \emptyset, T_f = \emptyset$, create a BR task determining the value of the t attribute and associate it with the following decision table schema: f, f_t^1, f_t^2, ... $\mid t$.
   c) if $F_t = \emptyset, T_f \neq \emptyset$, create a BR task determining the value of the $T_f \cup \{t\}$) attributes and associate it with the decision table schema: $f \mid t$, t_f^1, t_f^2, ...
   d) if $F_t \neq \emptyset, T_f \neq \emptyset$, create two BR tasks determining the value of the T_f and t attributes and associate them with the following decision table schemas respectively: f, f_t^1, f_t^2, ... $\mid t$ and $f \mid t_f^1$, t_f^2, ...
3) Go to step 1 if there are any dependencies left ($D \neq \emptyset$).

The result of application of the BR task generation for the Polish Liability Insurance case is presented in Figure 7. Next, User tasks which acquire necessary information from the user and User/Mail tasks to communicate process results to the user have to be generated (see Figure 8 and 9).

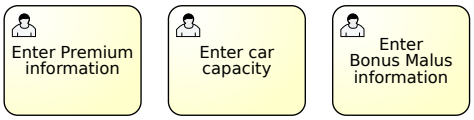

Figure 8. User tasks generated from the ARD diagram

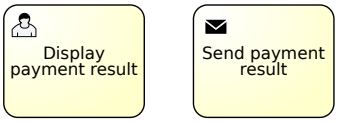

Figure 9. User/Mail tasks generated from the ARD diagram

Finally, the model have to be completed using control flow with additional flow objects, such as start and end events, and gateways. The resulting diagram can be observed in the Activiti-based environment presented in Figure 10.

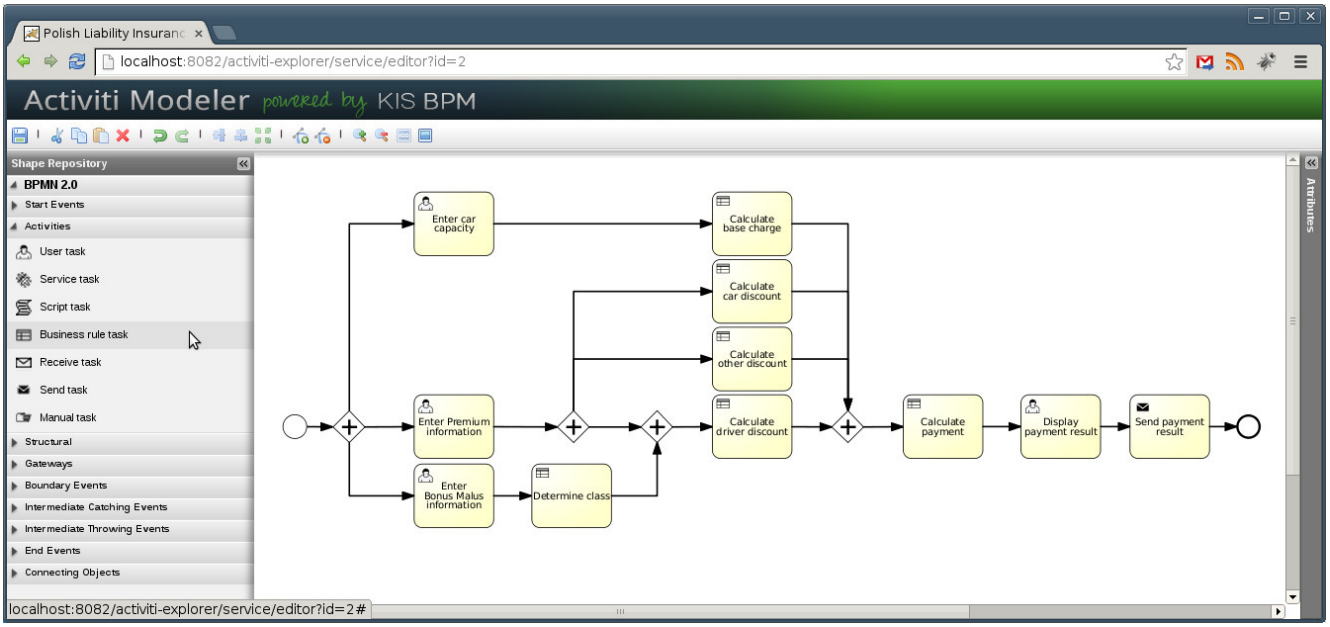

Figure 10. A prototype Activiti-based environment for modeling and executing processes with rules

VI. Hybrid Execution Environment

As a BPMN model generated from ARD constitutes an executable specification of a process, it can be executed in the process runtime environment. However, for complete execution of the model, i.e. execution of the Business Rule task logic, a process engine, such as jBPM [37] or Activiti [38], has to delegate rule execution to the business rule engine. As decision table schemas are generated automatically, the created decision tables have to be complemented with rules. Decision table can be filled in with rules using a dedicated editor [13] or a dedicated plugin for the process modeler [11]. Then, our prototype hybrid execution environment [12], [39], can serve as a specific execution example for this approach.

VII. Concluding Remarks

The aim of this paper is to examine the possibility of generating the rule-oriented BPMN model and enriching process models with rules based on the ARD diagram. We give an overview of the method for process model generation and present a first draft of the algorithm for automatic generation of rule-oriented BPMN process models from Attribute Relationship Diagram. In the algorithm, BR tasks with corresponding decision table schemas are generated and the resulting model can be executed in the hybrid execution environment.

The presented approach can be used either to generate the whole BPMN model based on the existing ARD diagram or to enrich the existing BPMN model with BR tasks based on ARD developed parallely to BP model or generated based on the process description. As the generated rule schemas are complementary to the process model, the solution addresses the two mentioned challenges: separation between processes and rules in the modeling phase and the problem of the execution of such separated data, which usually requires some additional integration or configuration in the execution environment.

As this paper presents a work-in-progress research, our future work will consist in refining and formalizing the presented approach. Then, we plan to extend the approach with new patterns and some optimization elements. We consider also enriching the ARD diagram with selected relations from the similar methods [24], [25], [27], [28], [26] and integrate the method with automatic verification features [40], [41].

***Abstract*—The paper describes some possible time structures for describing and analyzing economic phenomena. Since a simple linear time structure is not enough for this task, use of more complex structures are proposed.**

I. Introduction

INTRODUCING the notion of time allows to perform inference about changing domains, including the economic one. It also allows a computer to simulate human inference, because people infer about time and change [3]. In particular, such notions as change, causality or actions are described in the context of time, therefore the proper representation of time, and proper temporal reasoning is so important in the field of e.g. artificial intelligence [9, 10].

In artificial intelligence domain, which is concerned about knowledge, the temporal aspects of this knowledge are particularly important, because they are connected with both representation and inference. For an intelligent system to simulate intelligent behavior, to adapt to changes in the environment, or to verify its beliefs it has to be able to acquire new knowledge, and to maintain knowledge in an up-to-date form. Knowledge changes due to two main reasons. The first reason is the passing of time, the second one is new information on objects in the knowledge, having temporal characteristics [2, 11].

In order to represent properly temporal phenomena (or temporal knowledge about them) it is necessary to establish – prior to choosing the temporal formalism – a proper time structure. It is so because time structure determines the representation. For example, if one chooses dense time, it is not possible to represent knowledge in the situation calculus, because it is for only discrete phenomena [8]. In turn, the structure of time depends on the characteristics of the domain to be modeled. As Kania writes [5] p. 62, determining the structure of time is necessary to properly operate on time values, to operate on database etc.

The structure of time has to depend on a phenomena being investigated and should enable the best way to model it.

II. Time Structures to Describe Economic Phenomena – Basic Assumptions

We are convinced that for a temporal analysis of enterprise's environment it should be assumed that time is: discrete, branching into the future, finite in the past, but infinite in the future. We have chosen this structure because of several reasons:

a) Discrete time – there are several elements of the environment that change in a continuous manner, but some of the elements (e.g. barriers to entry) change discretely. From a practical point of view, it is not possible to provide information to the temporal intelligent system continuously. Changes have to be registered discretely. Moreover, assuming continuous time would be linked with introducing a second order axiomatization [1] p. 36.

b) Time branching into the future – the enterprise's environment is nondeterministic. Linear time assumes deterministic domain, while time branching into the future assumes a nondeterministic one. Also, introducing time branching into the future, when present actions may develop into several future ones, would allow to deepen the analysis of the environment, allowing e.g. for „what-if" analyses. It is not the only possible structure. For example, if we take into account the differences of temporal aspects of different markets we may think of a parallel time structure, which enables e.g. analyzing different markets simultaneously. Also a right linear time structure (time branching into the past) could be adopted – in order to determine, which changes in the past on the markets are responsible for the present situation of an enterprise. Using nonlinear time structures for analyzing economic environment is surely an interesting research area.

c) Time unbounded in the future – this assumption seems obvious: in a given moment, an enterprise is not able to define for how long it will be operating, therefore it is not possible to determine a moment in time, when the analysis will not be needed any more. However, as managerial practice shows, a time horizon longer than 5 years is not needed. For example, investment plans for more than 5 years are practically unreal. But it should be pointed out here, that a time point named „now" is different every day, moving into the future, and so moves the time horizon, even striving for infinity. Also obvious is assuming time bounded in the past: nor an enter-

978-83-60810-53-8/$25.00

prise, nor a temporal intelligent systems operate from „always". Moreover, an analysis getting far into the past would not be useful, because the environment is changing and turbulent. It should be assumed a certain „past time horizon of analysis", therefore bounding time in the past is justified.

Formally speaking, a time structure for modeling economic realm is a structure fulfilling the following conditions::

a) $\forall t_1, t_2 \in T$
   - $t_1 < t_2 \Rightarrow \exists t_3: (t_1 < t_3) \wedge \neg(\exists t_4: t_1 < t_4 \wedge t_4 < t_3)$,
   - $t_2 < t_1 \Rightarrow \exists t_3: (t_3 < t_1) \wedge \neg(\exists t_4: t_3 < t_4 \wedge t_4 < t_1)$,

b) $\forall t_1, t_2, t_3 \in T\ (t_2 < t_1 \wedge t_3 < t_1) \Rightarrow (t_2 < t_3) \vee (t_2 = t_3) \vee (t_3 < t_2)$

c) $\neg(\forall t_1 \exists t_2: t_2 < t_1)$.

It is a general assumption, but in specific situations the model may be broadened, because – as it has been already pointed out – the time structure has to be adjusted to the phenomenon being analyzed. In the next section different time structures are presented and discussed.

III. A SET OF TIME STRUCTURES

The most commonly adopted model is the one of linear time, which can be graphically depicted as a straight line, while formally a time structure T is linear, if [6] p. 20:

$$\forall t_1, t_2 \in T: (t_1 < t_2) \vee (t_1 = t_2) \vee (t_2 < t_1).$$

The models of nonlinear time are: time branching into the future, time branching into the past, time branching in both directions (parallel time), cyclic time. A motivation for adopting the branching time structure is as follows: many different pasts („routes") may have led to the present time, and from „now" may arise many different „routes" into the future. The formal definitions are: ([6] p. 21 and next):

A time structure T is branching into the future (left-linear), if

$\forall t_1, t_2, t_3 \in T\ (t_2 < t_1 \wedge t_3 < t_1) \Rightarrow (t_2 < t_3) \vee (t_2 = t_3) \vee (t_3 < t_2)$.

A time structure T is branching into the past (right-linear) if

$\forall t_1, t_2, t_3 \in T\ (t_1 < t_2 \wedge t_1 < t_3) \Rightarrow (t_2 < t_3) \vee (t_2 = t_3) \vee (t_3 < t_2)$.

A time structure T is parallel, if it is left- and right-linear, that is branching into both directions.

One more structure, discussed rarely in the literature, but interesting, is a cyclic time structure. A metric point time structure T is an ordered tuple $\langle T, C, <, <^*, \delta, S\rangle$, where: T – set of time points, C – set of distances between points, $<$ - a global order over T, $<^*$ - local order over T, δ – metrics over T, S – length of a semicircle.

For each time point $x \in T$ there exists exactly one point $x^* \in T$ that $\delta(x, x^*) = S$. These two points divide the time circle into two semicircles. The characteristics of a cyclic time structure are as follows (after [4], p. 30):

- completeness: $\forall x, y\ (x < y)$,
- local antisymmetry: $\forall x, y\ (x <^* y \rightarrow \neg(y <^* x))$,
- local linearity: $\forall x, y\ ((x \neq y\ \&\ x \neq y^*) \rightarrow (x <^* y \vee y <^* x))$,
- local transivity: $\forall x, y, z\ ((\delta(x, y) + \delta(y, z) < S) \rightarrow (x <^* y\ \&\ y <^* z \rightarrow x <^* z))$,
- coherence: $\forall x, y, z\ ((\delta(x, y) + \delta(y, z) < S) \rightarrow (x <^* y\ \&\ y <^* z \rightarrow \delta(x, y) + \delta(y, z) = \delta(x, z)))$.

One may imagine such situations, in which classic time structures would be not enough. Consider a situation, when two enterprises join (perform a fusion), operate as one enterprise for a certain period of time, and divide again into two enterprises, but cooperating together (so it is justified to analyze them together, but not on one time axis). In this case we deal subsequently with time structures: right-linear one, linear one, and left-linear one. Formally this situation may be written as:

- $(t_1, t_2, t_3 < t_F) \Rightarrow (\forall t_1, t_2, t_3 \in T: (t_1 < t_2 \wedge t_1 < t_3) \Rightarrow (t_2 < t_3) \vee (t_2 = t_3) \vee (t_3 < t_2))$,
- $((t_1, t_2 > t_F) \wedge (t_1, t_2 < t_P)) \Rightarrow (\forall t_1, t_2 \in T: (t_1 < t_2) \vee (t_1 = t_2) \vee (t_2 < t_1))$,
- $(t_1, t_2, t_3 > t_P) \Rightarrow (\forall t_1, t_2, t_3 \in T\ (t_2 < t_1 \wedge t_3 < t_1) \Rightarrow (t_2 < t_3) \vee (t_2 = t_3) \vee (t_3 < t_2))$,

where: t_F – the moment of fusion, t_P – the moment in which enterprise divides again.

This structure has the following properties:

- transivity: $\forall x, y\ (x < y\ \&\ y < z \rightarrow x < z)$,
- anti-reflexivity: $\forall x\ \neg(x < x)$,
- antisymmetry: $\forall x, y\ (x < y \rightarrow \neg(x < y))$,
- discreteness: $\forall x, y\ (x < y\ \rightarrow \exists z(x < z\ \&\ \neg\exists u(x < u\ \&\ u < z)))$

  $\forall x, y\ (x < y\ \rightarrow \exists z(z < y\ \&\ \neg\exists u(u < u\ \&\ u < y)))$.

Of course, different structures may be combined together in different ways, according to the analytical needs. It seems that the easiest is combining branching structures with linear one. The combinations similar to the one shown above may be numerous, one can imagine e.g. chains composed of branching and linear time structures. On the other hand, combining the cyclic time structure with branching and/or linear ones seems difficult, or even impossible, because the cyclic structure is a closed one.

It is necessary to discuss, how many time structures can arise from basic ones? Before we answer this question, we have to make some assumptions:

- for simplicity, we consider only a basic structure $\langle T, <\rangle$, other axioms of this structure are omitted;

- we assume representation in 1st order predicate calculus; in the calculus generally the linearity axiom is manipulated, therefore we deal with a finite set: linearity axiom, left-linearity axiom, right-linearity axiom;

- we omit the question of time metrics, because this does not affect the linear or non-linear property of time structure.

Having the above assumptions, we may say that the set of possible time structures arising from combining basic time structures is a combination with repetitions of those struc-

tures. As it is commonly known, the number of *k*-element combinations with repetitions of a *n*-element set is given by a formula:

$$C_n^k = \frac{(k+n-1)!}{k!\,(n-1)!}$$

Where

k – number of sequence elements,

n – number of set elements.

In the considered case, k = 1, 2, 3 or 4, and n = 4 (linear structure, left-linear structure, right-linear structure, parallel structure).

Therefore, the set of possible time structures is computed as:

$$S = 1 + \frac{(2+4-1)!}{2!\,(4-1)!} + \frac{(3+4-1)!}{3!\,(4-1)!} + \frac{(4+4-1)!}{4!\,(4-1)!} = 66$$

It should be noted here that in case of using multiple time structures for economic realm description and in case of using a temporal intelligent system, we have to deal with a heterogenic time structure in the knowledge base of the system. Thus, we face a problem of unifying the structure. Is it necessary for performing reasoning by an intelligent system? This problem is similar to the one of the heterogeneous knowledge in a temporal intelligent system, described in detail in [7], but it is beyond the scope of this paper.

IV. Concluding Remarks

In the paper the motivation for temporal representation of economic knowledge has been presented, the possible time structures have been pointed out, and the possible combinations of them for economic realm description have been shown. The main conclusion stresses out the variety of possibilities given by only 4 time structures, combined in different ways. Leaving linear time axiomatization, in order to take into account richer structures, will enable to better depict the economic realm, e.g. for building a knowledge base of a temporal intelligent system.

The problem of time structures heterogeneity in a temporal knowledge base arises while using more than one structure. It has to be discussed and checked, whether to perform reasoning in a temporal intelligent system it is necessary to unify these structures, and if so, how it should be done. This will be the topic of future research studies.

40-287 Katowice, Poland
Email: celina.olszak@ue.katowice.pl

Abstract—**The main purpose of this paper is to assess the level of Business Intelligence (BI) maturity in organizations. The research questions I ask in this study are: (1) what possibilities offer BI systems for different organizations, (2) how to measure and evaluate the BI maturity in organizations? The study was based on: (1) a critical analysis of literature, (2) a observation of different BI initiatives undertaken in various organizations, as well as on (3) semi-structured interviews conducted in polish organizations in 2012. Some interviews, conducted in 20 polish enterprises, were held with executives, senior members of staff, and ICT specialists. The reminder of my paper is organized as follows. Firstly, the idea of BI is described. Next, the issue of BI maturity models is recognized. Finally, Garter's Maturity Model for Business Intelligence and Performance Management is used to assess the level of BI in surveyed organizations.**

I. Introduction

ALTHOUGH Business Intelligence (BI) has been developing for over 20 years, many organizations are not able to make from it the effective tool for decision making or creating the competitive advantage [1], [2]. One of the reason of this fact is that they do not know a theoretical foundation how to diagnose (measure) BI using in organizations. So, the systematic and deliberate study on possibilities that offer BI for organizations and the ways of its assessment is crucial. The research questions I ask in this study are: (1) what possibilities offer BI systems for different organizations, (2) how to measure and evaluate the BI maturity in organizations? The study was based on: (1) a critical analysis of literature, (2) a observation of different BI initiatives undertaken in various organizations, as well as on (3) semi-structured interviews conducted in polish organizations in 2012. Some interviews, conducted in 20 polish enterprises, were held with over 80 responders: executives, senior members of staff, and ICT specialists They represented the service sector: telecommunications (T)-4, consulting (C)-4, banking (B)-4, insurance (I)-4, marketing agencies (MA)-4.

The reminder of my paper is organized as follows. Firstly, the idea of BI is described. Next, the issue of BI maturity models is recognized. Finally, Garter's Model for Business Intelligence and Performance Management is used to assess the level of BI maturity in surveyed organizations.

The paper provides valuable information on the possibilities that offer BI systems for organizations and the ways of their evaluation. It is dedicated for decision-makers, managers and ICT specialists interested in using BI systems in organizations. The study makes useful contribution to the literature and theorists on the idea of BI, BI using in organizations, and the ways of its assessment.

II. Background and Related Works On Business Intelligence

A. The issue of Business Intelligence

From a historical perspective, Business Intelligence (BI) is a popularized, umbrella term introduced by Howard Dresner of the Gartner Group in 1989 to describe a set of concepts and methods to improve business decision making by using fact-based support systems [3]. BI involves collecting, storing and presenting data, and managing knowledge by means of employing different analytic tools. Intelligent data analysis is usually obtained by OLAP (On-Line Analytical Processing), data mining and data warehouses techniques [4].

With the passing of time, the term BI has been understood much more broadly, namely, as a connecting factor of different components of decision support infrastructure [5], and providing comprehensive information for policy makers [6]. Hence, many definitions of BI focus on the capability of an enterprise to improve business efficiency and to achieve higher business goals. It is said that BI provides a means to obtain crucial information to improve strategic decisions and, therefore, plays an important role in current decision support systems [7]. The term Business Intelligence (BI) is often used as a broad category of technologies, applications, and processes for gathering, storing, accessing, and analyzing data to help users make better decisions [8]. More generally, BI can be understood as a process providing better insight in a company and its chain of actions.

According to many authors there are distinguished 3 ages in the development of BI: BI 1.0, BI 2.0, BI 3.0.

The first age of BI, called BI 1.0. falls on seventies and eighties of XX century. It is closely related with the management information systems (MIS), executive information systems (EIS), and decision support systems (DSS). Generally, the first applications from this age were dedicated on

978-83-60810-53-8/$25.00

mainframes. They were able to process the simple tasks for operational and tactical management. They were characterized by production the simple reporting and represented simple, static applications. Individual reports were written by expert programmers. BI 1.0 was focused on "delivery to the consumer" and market leaders include: SAS, IBM [9].

The second age of BI (1990-2005) - BI 2.0 is the type of enterprise scale BI we see today. It means a concept and methodologies for improvement of business decisions using facts and information from supporting systems [33]. It is characterized by end-user friendlier client-based BI tools and centralized. Data warehouse configured to deliver preformatted information to specialists analysts and users within management. So, the role of BI 2.0 and its impact on organizations (compared to BI 1.0) has been changed. From simple, static analytical applications, BI 2.0 has evolved into solutions that can be used in strategic planning, predictive modeling, forecasting, monitoring operations, and studying the profitability of products [1],[10]. BI 2.0 is focused on "creation and delivery for consumers" and market leaders include: Business Objects, Cognos, Hyperion, Microsoft, Teradata, Oracle.

BI 3.0. presents a new era in the evolution of BI. Thanks to web and mobile technologies it appears intelligent business network for every one. There is a growing acceptance of the idea that analysis is a collaborative (not only singular) and social effort. It focuses on a collaborative workgroups (which are self-regulated) and on information outcomes within the confines of core business interaction with customers, employees, regulators etc. There is common sense that BI 3.0 should go beyond reliance on structured data available in internal sources but should use also external, mostly unstructured data in various formats (social media posts, free form web content, images, and video files) [11]. BI 3.0 is concentrated on "creation, delivery and management for consumers" [9]. According to Scott [12] there are 5 core attributes that support BI 3.0 philosophy: proactive, real-time, integrated with business processes, operational (available to line workers), and extended to reach beyond the boundaries of the organizations to improve information delivery and decision support functionality for all. It is indicated also that there is no reason to depreciate in BI 3.0 the functions (known from BI 2.0) like: reporting, OLAP, data mining. They have still their strong position. BI 3.0 philosophy is to raise the added value of BI tools' architecture by anchoring collaborative style of information search and analysis with intuitive and self-service user interface that delivers timely and highly relevant insights to anyone who is properly authorized and needs them [11].

According to Chatter [13] there are 3 prerequisites for software tools to be recognized as a BI 3.0 tools: be social, relevant (automatically delivers relevant insights that users really need according to their situation and user profile), and fully self-service (intuitiveness).

The analysis of different articles, papers and reports show that BI is mainly identified with:

- tools, technologies, and software products. BI is used to collect, integrate, analyze and make data available [14]. It includes: data warehouse, data mining and OLAP (On-line Analytical Processing). Data warehouse is a key technology, integrating heterogenic data from different information sources for analytical purposes [7]. Hence, it is assumed that the main tasks to be faced by BI include: intelligent exploration, integration, aggregation and a multidimensional analysis of data originating from various information resources [15];
- knowledge management. BI is the capability of the organization to explain, plan, predict, solve problems and learn in order to increase organizational knowledge [16]. BI is assumed to be solution that is responsible for transcription of data into information and knowledge [10];
- decision support systems. BI is considered as a new generation of decision supports systems. They differ from previous management information systems in, first of all, their wider thematic range, multivariate analysis, semi-structured data originating from different sources and multidimensional data presentation [17], [16], [6], [18];
- dashboards. Dashboards are the becoming the preferred method for delivering and displaying BI to users. They are more visual and intuitive, and typically provide linkages that enable immediate action to be taken [5];
- new working culture with information - BI constitutes an important upturn in techniques of working with information [4]. It means specific philosophy and methodology that would refer to working with information and knowledge, open communication and knowledge sharing [10]. The BI users must know more than just technology - business and soft skills are needed too;
- process. The process constitutes of activities to gather, select, aggregate, analyze, and distribute information [19]. Some of these activities are the responsibility of the BI staff, while others are the joint responsibility of the BI staff and the business units [8];
- analytics and advanced analyses. The term "analytics", introduced by Davenport and Harris[20], means "the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, fact-based management to drive decisions and actions. Analytics are a subset of what has come to be called BI: a set of technologies and processes that use data to understand and analyze business performance";
- Competitive Business Intelligence (CI). Another subset of BI is CI. Its goal is to provide a balanced picture of the environment to the decision makers [15]. CI is the analytical process that transforms scattered information about competitors and customers into relevant, accurate

and usable strategic knowledge on market evolution, business opportunities and threats.

B. Business Intelligence in organizations

According to Goodhue, Wixom and Watson [8] there are three targets that organizations can aim for when implementing BI:

- single or a few applications. They are used in selected departments (marketing, sale, controlling etc.) to support effective marketing campaigns, to analyze profitability different products and to monitor the behaviors of customers;
- BI infrastructure. "The organizations create an infrastructure for BI by clearing up and defining their data, establishing efficient process to move data from source systems to a highly extensible data warehouse, implementing a variety of BI tools and applications, and investing in BI user training";
- organizational transformation. BI systems are used in order to introduce new business model oriented on change management, knowledge management and customer relationship management. BI aims to run company differently. In this case, some investments in huge corporate data warehouse are needed.

Many case studies confirm that BI may be utilized in an organization for [11], [21], [22];

- increasing the effectiveness of strategic, tactic and operational planning including first of all: (a) modelling different variants in the development of an organization; (b) informing about the realization of enterprise's strategy, mission, goals and tasks; (c) providing information on trends, results of introduced changes and realization of plans; (d) identifying problems and 'bottlenecks' to be tackled; (e) providing analyses of "the best" and "the worst" products, employees, regions; (f) providing analyses of deviations from the realization of plans for particular organizational units or individuals; (g) and providing information on the enterprise's environment;
- creating or improving relations with customers, mainly: (a) providing sales representatives with adequate knowledge about customers so that they could promptly meet their customers' needs; (b) following the level of customers' satisfaction together with efficiency of business practices; (c) and identifying market trends;
- analysing and improving business processes and operational efficiency of an organization particularly by means of: (a) providing knowledge and experience emerged while developing and launching new products onto the market; (b) providing knowledge on particular business processes; (c) exchanging of knowledge among research teams and corporate departments.

The most spectacular results, from using BI, have been observed while running promotional campaigns, anticipating sales and customer behaviors, creating loyalty policies and investigating anomalies and frauds [23]. The studies show that BI may also generates a wide variety of organizational benefits [8]. Some BI benefits are tangible and easy to measure (e.g., the reduction of software and hardware licenses and fees). Other benefits, such as improved quality and timeliness of information or improvement of business process and the enabling of new ways of doing business, are much more difficult to quantify, but they may generate a competitive advantage or open up new markets for the company. According to Howson [24], who examined 513 organizations, to the most significant measures of success of BI projects belong: improved business performance, better access to data, support of key stakeholders, user perception that it is mission critical, return on investment, percentage of active users, costs savings, defined users.

C. Business Intelligence maturity models

The effective development of BI in the organization should be based on scientific theories. It seems that theory of maturity models gives the good foundation [25]. The term of maturity describes a "state of being complete, perfect or ready. To reach this a desired state of maturity, an evolutionary transformation path from an initial to a target stage needs to be progressed" [26]. Maturity models are used to guide this transformation process. They help define and categorize the state of an organizational capability [27]. Maturity model for BI helps organization to answer for these questions: where in the organization is most of the reporting and business analysis done today?, who is using business reports, analysis and success indicators?, what drives BI in the organization?, which strategies for developing BI are in use today?, and what business value does BI bring? [28].

A high number of maturity models for BI has been proposed [26], [29], [27], [30].

One of the most popular is Gartner's Maturity Model for Business Intelligence and Performance Management. It describes a roadmap for organizations to find out where they are in their usage of BI. It provides a path for progress by which they can benefit from BI initiatives. The model recognizes five levels of maturity: unaware, tactical, focused, strategic, and pervasive. The assessment includes three key areas: people, processes, metrics and technology [28], [29], [30]. The first level is often described as "information anarchy". It means that data are incomplete, incorrect, inconsistent and organization does not have defined metrics. The uses of reporting tools are limited. The second level of BI maturity means that the organization starts to invest into BI. Metrics are usually used on the department level only. Most of the data, tools, and applications are in "silos". Users are often not skilled enough in order to take advantage of the BI system. At the third BI maturity level the organization achieves its first success and obtains some business benefits from BI, but it still applies to a limited part of the organization. Management dashboards are often requested at this level. At the strategic level, organizations have a clear business strategy for BI development. The application of BI is

TABLE I.
OVERVIEW OF BI MATURITY MODELS

Name of the model	Description
TDWI's Business Intelligence Model –Eckerson's Model Eckerson [30]	This model focuses mainly on the technical aspect for maturity assessment. It constitutes of 6 maturity levels and uses a metaphor of human evolution: prenatal, infant, child, teenager, adult and sage
Gartner's Maturity Model for BI and PM [31]	The model is a mean to assess the maturity of an organization's efforts in BI and PM and how mature these need to become to reach the business goals. The model recognizes 5 maturity levels: unaware, tactical, focused, strategic, pervasive
AMR Research's Business Intelligence/ Performance Management [29]	The model is described by 4 maturity levels: reacting (where have we been?), anticipating (where are we now?), collaborating (where are we going?), and orchestrating (are we all on the same page?). It is used to assess the organization in the area BI and PM
Business Information Maturity Model [28]	The model is characterized by 3 maturity levels. The first level answers the question „ what business users want to access", the second "why the information is needed", the third "how information put into business use"
Model of Analytical Competition [1]	The model describes the path that an organization can follow from having virtually no analytical capabilities to being a serious analytical competitor. It includes 5 stages of analytical competition: analytically impaired, localized analytics, analytical aspirations, analytical companies, and analytical competitors
Information Evolution Model, SAS [32]	The model supports organization in assessing how they use information to drive business, e.g., to outline how information is managed and utilizes as a corporate asset. It is characterized by 5 maturity levels: operate, consolidate, integrate, optimize, innovate
Model Business Intelligence Maturity Hierarchy [33]	The model was developed in knowledge management and constitutes of 4 maturity levels: data, information, knowledge and wisdom
Infrastructure Optimization Maturity Model [28]	The model enables a move from reactive to proactive service management. It aids in assessing different areas comprising the company infrastructure. The model is described by 4 maturity levels: basic, standardized, rationalized (advanced), and dynamic
Lauder of Business Intelligence (LOBI) [28]	The model describes levels of maturity in effectiveness and efficiency of decision making. IT, processes and people are assessed from the perspective of 6 levels: facts, data, information, knowledge, understanding, enabled intuition
Hawlett Package Business Maturity Model	The model aims at describing the path forward as companies work toward closer alignment of business an IT organizations. It includes 5 maturity levels: operation, improvement, alignment, empowerment, and transformation
Watson's Model [27]	The model is based on the stages of growth concept, a theory describing the observation that many things change over time in sequential, predictable ways. The maturity levels include: initiation, growth, and maturity
Teradata's BI and DW MM [26]	Maturity concept is process-centric, stressing the impact of BI on the business processes The model has 5 maturity levels: reporting (what happened?), analyzing (why did it happen?), predicting (what will happen?), operationalizing (what is happing?), and activating (make it happen).

often extended to customers and suppliers. It supports the tactical and strategic decision making. Sponsors come from the highest management. At the last BI maturity level, BI pays pervasive role for all areas of the business and corporate culture. BI provides flexibility for adapting to the fast business changes and information demand. The users have access to information and analysis needed for creating a business value and influence business performance. The usage of BI is available to customers, suppliers, and other business partners.

Moving from one maturity level to another requires changes in all of the characteristics that make up these stages (e.g., changes in management vision, founding, data management) [8].

III. RESEARCH METHODOLOGY

The aim of the survey was to assess the BI using in 20 purposefully selected organizations, and to determine the factors that allow the firms to achieve high competences in BI, and consequently various business benefits [2]. The research was of qualitative nature and used as a research tech-

TABLE II.
TYPES OF ASKED QUESTIONS AND ANSWERS

No	Asked questions during interviews	Answers (number of organizations)
1	How do you define BI?	Tools to manage information (9), data warehouse (5), analytical applications (4), new way of doing business (2)
2	What do you use BI for (reporting, ad-hoc reporting, analyzing, alerting, predictive modeling, operationalizing, optimization, activating, etc.) ?	Reporting (15), ad-hoc reporting (9), analyzing (12), alerting (2), predictive modeling (2), optimization (3), activating (2)
3	Does your organization have a defined BI strategy?	Comprehensive BI strategy (5), partly defined BI strategy (12), none (3)
4	Does your organization have defined business processes?	Defined basic processes (9), defined core business processes (6), not defined (5)
5	Does your organization/department have defined metrics?	Metrics for selected departments (13), metrics for the whole organization (4), none metrics (3)
6	Assess the quality of data used in your organization (complete, correct, consistent; high/medium/poor quality data, etc.)	High quality data (6), medium quality data (11), rather poor quality data (3)
7	Are you skilled enough in order to take advantage of BI systems?	Skilled enough (7), not skilled enough (8), poor skilled (5)
8	Do you use management dashboards?	Used management dashboards in limited scope (14), used management dashboards in whole organization (4), not used (2)
9	Is your BI (un)limited to the part/department of organization?	BI limited to the part of organization (15), unlimited (5)
10	Are you motivated to use BI (how)?	Users motivated by training (8), motivated by bonuses (6), not motivated (6)
11	Do you use BI for analyzing customers, suppliers, competitors and other business partners?	BI for analyzing customers (17), suppliers (14), competitors (5), other stakeholders (4)
12	Who is the sponsorship of BI in your organization?	CIO (3), senior management (6), business analyst (4), ICT specialists (7)
13	What kind of BI software do you use?	Regional data warehouse (9), centralized data warehouse (5), operational data bases (6)
14	Describe some successes/failures from using BI	Success: acquiring new customers (14), acquiring new suppliers (11), increase of sale (8), fraud detection (6), launching new channels of sale (3), launching new products (3). Failures: not trust in BI (4), gap between BI/ business (12), users do not recognize their own data after it is processed (7), decision-making skills absent (6), BI is expensive (5)
15	Indicate some benefits from using BI	Better access to data (13), better decisions (12), improvement of business process (9), improved business performance (8), costs saving (7), transparency of information (5), new way of doing business (2)

nique of an in-depth interview. Types of core interviews questions relevant to this paper are reflected in table 1.

The survey was conducted in 2012 among purposefully selected firms (in Poland) that are considered to be advanced in BI. They represented the service sector: telecommunications (T)-4, consulting (C)-4, banking (B)-4, insurance (I)-4, marketing agencies (MA)-4. Interviews were held with executives, senior members of staff and ICT specialists. Interviewees were selected on their involvement in BI or on their ability to offer an insight based on experience in BI and related decision support systems. Gartner's Maturity Model for Business Intelligence and Performance Management (described in the previous section), for the assessment of the BI-maturity level in selected organizations, was used.

IV. FINDINGS

My research confirmed that BI identified in the literature was also experienced in selected organizations. Table 2 presents the answers for asked questions. The BI maturity in surveyed organizations (mapping onto Gartner's Maturity Model for Business Intelligence and Performance Management) and factors that allow them to achieve the various business benefits with BI, are indicated in table 3.

V. DISCUSSION

The collected and processed data were mapped onto Gartner's Maturity Model for Business Intelligence and Performance Management. The obtained results allow to state that among 20 surveyed organizations two organizations fall into the category of "pervasive" level. These were telecommunication company and marketing agency. Their analytical and BI competences are aimed at business benefits, like: acquiring new customers, launching new products and new channels of sale.

BI competences are treated by these organizations as their core competences that help them to compete on the market. Organizations achieve significant economic benefits and use BI for marketing analyses (sales profitability, profit margins, meeting sales targets, time of orders), customer analyses (time of maintaining contacts with customers, customer

TABLE III.
OVERVIEW OF BI- MATURITY LEVELS IN SURVEYED ORGANIZATIONS

Level	People	Process	Metrics and technology	Scope of benefits
Unaware	Users do not know their own data requirements or how to use them	Users do not know business processes; data are poor quality	Lack of appropriate hardware and software; the metrics are not defined; the use of reporting is limited	Almost none
Tactical 2I, 2C, 1MA	The users take the first BI initiatives; low support from senior executives	Identification of basic business processes	Regional data warehouses are built; analyzing trends and past data; first interactive reporting tools; metrics are usually used on the department level only	Low benefits limited to small group of users; better access to data and static reporting
Success factors: support from senior management, appropriate BI tools, quality of data, defined business processes and metrics				
Focused 2T, 1MA, 2C, 2I, 2B	Users try to optimize the efficiency of individual departments by BI	Standardization of business processes and building best practices in BI	Management dashboards are used; a centralized data warehouse is built; ad-hoc reporting, query drilldown	Benefits limited to departments and business units; improvement of internal business processes and decision making on operational level
Success factors: developing corporate culture based on facts, stating clearly BI strategy, implementing training system on BI				
Strategic 1MA, 1T, 2B	Users have high BI capabilities, but often not aligned with right role	Business process management based on facts	High-quality data; have BI strategy; using more complex prediction and modeling tools; data mining	Benefits for the whole organization; integrated analysis for finance, logistics, production; improvement of decision making on all levels of management
Success factors: support from CEO, motivation of users for collecting, analyzing and using information				
Pervasive 1T, 1MA	Users have capabilities and time to use BI; skill training in BI; users are encouraged to collect, process analyze and share information; CEO passion and broad-based management commitment	Broadly supported, process-oriented culture based on facts, learning and sharing of knowledge	Enterprise-wide BI architecture largely implemented; customized reports; business and BI are aligned and cooperative	Benefits for the whole environment; competing in BI; new ways of doing business
Success factors: strong support of CEO, effective HRM and all user's trust in BI				

profitability, modeling customers' behavior and reactions, customer satisfaction), monitoring of competitors and current trends in the marketplace. The common analytical approach is used by the whole organization where broadly supported fact-based and learning culture is cultivated. The interviewees confirmed that the factors that help those organizations to stay at that high maturity level in BI, include strong support of CEO and all user's trust in BI.

An interesting group was made up of organizations classified at the fourth BI maturity level. Four organizations (1MA, 1T, 2B) in my study fit into the strategic level. They do not compete through BI, but they have high competences in using different BI analyses, like: financial analyses (reviewing of costs and revenues, calculation and comparative analyses of corporate income statements, analyses of corporate balance sheet and profitability), customer profitability, customer segmentation, improving marketing effectiveness. It seems that there is a very little to be done in order to use BI for making significant changes in running a business. Therefore, shifting these organizations from "strategic" to "pervasive" level requires more support from CEO and his/her real passion. The interviewees indicated the greater need for motivation of users for collecting, analyzing and using information.

The survey has shown that up to 9 organizations (2T, 1MA, 2C, 2I, 2B) use BI on the department level. Although they would be much more common in a random sample, and perhaps the largest group. BI in these organizations has not been playing a strategic role and benefits from it are limited. BI is used to perform ad hoc reporting and to answer questions related to departments' ongoing operations, up-to-date financial standing, sales and co-operation with suppliers and customers. BI and management are often not aligned. The observation and interviews with senior executives allow to state that the lack of appropriate knowledge about possibilities of BI among staff results in a relatively low use of it. Therefore, the main tasks for organizations include first of all: developing corporate culture based on facts and learning,

stating clearly BI strategy and implementing training system on BI.

I found in my study that 5 organizations (2I, 2C, 1MA) are at the position of "tactical" maturity level. They use a traditional approach to management, focused more on the performing the basic tasks of departments than on business processes. The knowledge about BI in these organizations is rather low and identified mainly with regional data warehouses or databases. Only basic business processes are recognized and basic metrics are used. The interviewees indicated that many users have some problems with recognizing their own data after processing. The users have rather low experience with other types of management information systems. Their intellectual resources are not adequate in order to develop complex BI infrastructure and to use it for improvement of business processes and decision-making.

To conclude the discussion on the use of BI in surveyed organizations, I wonder why organizations in a similar segment, with similar financial resources and comparable BI infrastructure, derive from BI such diverse benefits (e.g. in the studied case, telecommunications companies and advertising agencies). Seeking the answer to this question it should be noted that the organizations, that have been classified into the category of BI "pervasive" level, were highly determined to collect, process, analyze, and share information. Corporate culture based on facts and learning helped them to use chances offered by BI. The most important factors that decided on the success of BI initiatives refer not to the technology, but to the strong believe of all users in BI.

VI. Conclusions

The main conclusion of this study is that BI systems may be a trigger for making more effective decisions, improving business processes and business performance, as well as doing new business. Observation and conducted discussions with interviews let to state, that the factors that allow organizations to achieve business benefits with BI, include first of all: management leadership and support, corporate culture, expressed by effective information resources management, clearly stated strategy and objectives, and use of appropriate BI technologies. Additionally, the important factors were: clearly defined business processes, business performance measurement, incentive system to encourage collecting, analyzing information and knowledge sharing, appropriate resources (financial, intellectual), training and education on BI and knowledge management.

The research has made a theoretical contribution to our understanding of BI issue. The outcomes extend current theory on BI and provide useful information, which hopefully will help the organizations to understand the consequences of the different ways of BI using, as well as, to determine the factors on which they should give particular attention while building different BI applications.

***Abstract*—With the new technological advances and strong move towards Future Internet and Internet as a Platform a new environment is emerging. This environment is generative, social, strongly interactive and collaborative, so users play a fundamental role in it. Business applications are simplifying, webifying and getting more user-centric. In this environment, context and context-awareness plays a fundamental role, as context gives meaning and accurately describes the situation of an user. This paper introduces the basis for a new research methodology that aims to address and visualize the topic of context and context-awareness from a holistic point of view, by means of text mining and text clustering.**

I. Introduction

THE concepts of context and context awareness have been studied for more than 20 years in the field of artificial intelligence, computer and cognitive science. However, it has been still identified by Gartner, alongside cloud computing, business impact of social computing, and pattern based strategy, as being one of the broad trends that will change IT and the economy in the next 10 years [1].

Moreover these IT and economical changes are reflecting themselves also onto business applications. Applications are simplifying, are becoming mobile, are moving to the cloud, are getting more social and user focused [2].

For instance smart phones although almost anywhere present nowadays, they present also a lot of downsides, i.e. they ring in movie theaters, conferences, meetings, air flights, they are the cause of car accidents. Theaters and even restaurants in some places have employed cell-phone jamming to limit cell-phone disruptions. This could be considered partly a social problem, but is also a technological problem. Through better applications, people can be helped to make better and safer use of their smart phones.

Hence we are faced with a series of new challenges in the context of developing future business apps. They need to:

- be highly adaptive;
- provide UIs that are user specific;
- provide means for users to modify them by themselves according to their needs, goals, context, while still keeping the underlying infrastructure in place;
- be interactive;
- be distributed, at the same time cloud computing ready;
- support both desktop and mobile environments, while providing a similar experience, finally
- developed with business users, and vendors and for customers, while hiding as much as possible all technical requirements.

To understand what is required to tackle these challenges a holistic and unified approach is needed. In this setting, the purpose of this paper is to introduces the basis of a new research methodology that aims to address and visualize the topic of context and context awareness from a holistic point of view, by means of text mining and text clustering.

It is worth emphasizing, that in this paper we do not explicitly introduce the term *"context"*. In fact, we aim at identifying and categorizing different uses of this term according to the existing literature.

II. Context and Context Awareness – Related Work in General

Over time, there have been written a large number of surveys on the topic of context and context-awareness addressing different directions of research. By far the most known and most cited (according to Google Scholar[1]: 3213 times) survey is the work by Dey and Abowd [3]. They argue that context is important for interactive applications and for applications where the context of users is changing rapidly. They discuss what a context-aware application means and give a definition for the term *context*.

Context and context-awareness in mobile computing is one of the oldest directions [4] of research when it comes to context-aware applications. This is because information such as user's location, nearby people and devices, time of day and user activity can be used to improve, for instance, latency time or boost up communication signal by using bandwidth from nearby devices and so forth.

Context modeling is part of any endeavor that tackles context-aware systems. Strang and Popien [5] address the problem of modeling of *context* in the context of ubiquitous computing paradigm (paradigm for which context is a driver). Several approaches are studied and discussed. Bolchini et al. [6] deal also with the problem of context modeling from a data-oriented perspective. A general framework for classifying context modeling approaches has been defined.

[1]http://scholar.google.com/scholar?cites=7671228831233541198&as_sdt=2005&sciodt=0,5&hl=en

978-83-60810-53-8/$25.00

Context-awareness has become lately of importance also for the development of web service-based systems [7]. These systems are more and more knowledge-based [8], e.g. using business rules and processes for a specification [9]–[11].

Although the issue of context has been well studied in the field of mobile systems and pervasive computing, the interest in the business-oriented community has been only recently growing. In fact with business applications becoming more social and user focused, cloud-based, massively distributed and mobile, both of these areas seem to finally meet. Therefore, studying the impact of context in business applications is of great conceptual and practical importance.

III. Research Methodology

To be able to investigate and to get a better understanding about the role of context and context awareness in relationship with business applications we used a particular research method which we are going to present in this section.

We are going to emphasize through out this section, that there is a huge amount of work that tackles the problem of context and context awareness in different fields and from different aspects. However, there is no unified view on the matter, nor – to the best of our knowledge – there is any approach that provides a holistic view on the subject. Therefore we propose a research methodology which takes advantage of the existing techniques for text clustering and text mining to get a broader view on the research that has been done on the side of context and context awareness.

The motivation to use text mining and clustering techniques is very simple. Too many papers that need to be organized, make the task almost impossible to fulfill. Moreover such an approach will provide an automatic way to extract related terms, topics and directions of research.

We present our methodology in a form of a simple workflow, modeled as a business process model, designed using the BPMN [12] notation and depicted in Figure 1. The model presents the steps that we took in our research approach and the ordering of those steps.

We have compiled a bibliography file which so far contains 94 carefully selected bibliographic entries that spans over a period of more than 20 years, starting 1991-2013. The quality of the papers is also an important factor. There are two ways to weight and asses the quality of the papers. One way is objective as it is given by the number of citation a paper has. We have extracted the number of citation, where this number existed, for a paper from digital libraries websites: CiteSeer[2], Google Scholar[3], ACM Digital Library[4], IEEE Xplore Digital library[5]. In the cases where there is no available citation number, we can not know for sure if a paper has been cited or not, therefore it is up to the researcher to read and asses the quality of a paper. This approach one could say that is rather subjective. Table I depicts only a small excerpt of this bibliography file, due to space limitation. However the entire file is available to download as a bibtex file or consult online at the following address: `http://geist.agh.edu.pl/pub:research:context_aware`.

The steps for compiling this bibliographic collections are depicted in Figure 1. We start by searching via Google for context related keywords i.e. *context*, *context-awareness*, *context-aware surveys*. A survey is a better entry point as it provides a wider view on a subject. These are just entry search terms. The more you search and read, the more terms can be further used. Besides the "random" search, we followed (searched) also concrete references that were indicated in the initial papers that we retrieved and read.

The next step in the process (See Figure 1) is to add bibliographic entries. We used for the clustering algorithms the abstract of each paper, if there was one. In consequence a bibliographic entry, if there is one, needs to have an abstract. Some of the papers also contained keywords. We have also used when available the keywords associated. These were combined with the abstract.

We used JabRef[6] to compile our bibliography. JabRef offers the functionality of an export layout, which we are using to export the bibliographic information into Carrot2[7] input format. Carrot2 as stated on the project website is an "Open Source Search Results Clustering Engine. It can automatically organize small collections of documents (search results but not only) into thematic categories". The reason for using Carrot2 over other tools (such as Lemur[8], Terrier[9]) is its *simplicity*. It was very simple to write an export layout from JabRef to Carrot2 XML input format. The export layout is also available online at the previosly given address. And also the results are by default given also in several visual formats.

Although Carrot2 provides several search algorithms we used Lingo and K-Means algorithms as they provided the best results. Unfortunately the free version of Carrot2 does not provide options to addresses issues such as synonyms in order to improve the results. Arthur and Vassilvitskii state in [13] that the K-Means method is a well known geometric clustering algorithm based on work by Lloyd [14]. Though the K-Means term has been first used by MacQueen [15]. According to [13] given a set of n data points, the algorithm uses a local search approach to partition the points into k clusters. Lingo [16] as described by the authors is able to capture thematic threads in a search result, that is discover groups of related documents and describe the subject of these groups in a way meaningful to a human.

Figures 2 and 3 depict the results of running the K-Means and respectively Lingo algorithms over our bibliographic collection. The results are visualized in a Foam representation. Results are similar but not the same. We can easily visualize directions of research and words related with the context concept. Having similar results it helps to verify the output of

4	Towards a better understanding of context and context-awareness	1999	3213

the clustering algorithms. Having differences helps to identify what each algorithm has missed with respect to the other.

The authors of [17] already identified that context is of fundamental importance for cognitive psychology, and computer science. Furthermore it states that in computer science the notion of context has been addressed in several areas such as: artificial intelligence, software development, databases, data integration, machine learning and knowledge representation. Since all these directions have been also identified by our research approach we argue that results are satisfactory in terms of how adequately the mining and clustering algorithms have performed.

In addition based on the information depicted in Figures 2 and 3, context has been used to address many of the future business apps challenges we have enumerated in Section I: adaptation, mobile computing, flexibility, user, modeling, task management, distributed systems, business process models.

IV. CONCLUSION

Context, context-awareness studied for a long time already, it still part of future development trends. Now, because of the changes (i.e. move to the cloud, social computing and so forth), that both IT and economy are witnessing, context is required to tackle the challenges that these changes bring in.

We propose a new research methodology in order to tackle the large number of publications that have been published over time, starting 1991 to present in order to get a more holistic view on the subject of context and context-awareness, by employing text mining and text clustering techniques.

This paper presents results of research that is work in progress. In our future work we will continue to investigate the results and ideas that can be extracted from using the text mining and text clustering based research methodology that we have introduced here. We will investigate semantic wikis, e.g. [18], [19], as systems that can be made context-aware and user-centric [20].

However, our ultimate goal is to provide a holistic design and deployment approach for context-aware user-centric business applications through a (1) unified modeling and methodological approach for context aware applications, and (2) unified execution framework of context aware applications.

Rapid Application Prototyping for Functional Languages

Martin Podloucký
Department of Software Engineering,
Faculty of Information Technology,
Czech Technical University,
Prague, Czech Republic
Email: martin.podloucky@fit.cvut.cz

***Abstract*—This work addresses the problem of automated graphical user interface generation for functional programs in relation to rapid application prototyping. First an analysis of current state in the field of automated GUI generation is performed. Based on the analysis, the concept of *functionally structured user interface* (FSUI) is introduced. Meta-data system for code annotation is then specified for the Clojure programming language and a transformation from this system to FSUI data model is implemented. Finally, a graphical layer for displaying the actual interface is implemented in Clojure.**

I. Goal

THE focus of this work is to investigate the idea of automated GUI generation for functional programs for application in software prototyping. The main goals are:

1) Analyse the current state in the field of automated GUI generation.
2) Based on the analysis, explore possible approaches to GUI generation for functional languages.
3) Design and implement an automated GUI generator for functional programs.
4) The generator should create the GUI from annotated source code of the program.
5) Both the generator and the GUI should be implemented in functional language.

II. Paper structure

Firstly, the basic concepts, such as application prototyping and functional programming along with the motivation for this work, are explained in section III. Then, the Clojure programming language is introduced in section IV. Analysis of current state in the field of GUI generation is performed in section V. Some possible approaches to a solution of the stated problem, based on results of the analysis, are described in section VI. Finally, the concept of functionally structured user interface is presented in section VII.

III. Introduction

Software engineering industry is evolving and expanding rapidly, constantly searching for better techniques and technologies allowing software to be created faster with lower cost and better resulting quality [1]. Great desire for innovations can be observed in the field of business applications where the cost of the development is a key factor [2]. In this domain, the advantageous fact is that business applications have many common characteristics. They are based on similar principles, work with similar data and they have to deal with alike limitations [2]. This situation creates a good opportunity to use techniques such as prototyping [3] and generative programming [4].

A. Prototyping and generative programming

Application prototyping focuses on creating incomplete versions of the software being developed [3]. The purpose of such prototypes may be to explore possible solutions or to provide a piece of working software to the customer for evaluation in early stages of development [3]. There are several approaches to prototyping [5]: some prototypes are developed only to be discarded after they served their purpose. Such approach is called *throwaway prototyping* or sometimes *rapid prototyping*. Another approach is to incrementally evolve the prototype to fully functional product. This approach is often called *evolutionary prototyping*.

The main concern of either approach is being able to create prototypes as fast as possible [3]. Some techniques that can be used to shorten the prototype development time may be those of generative programming [4] and model driven development [6]. When significant parts of prototypes can be generated from conceptual models or from annotated source code, developers may focus more on implementing application logic rather then, for instance, implementing graphical user interface.

Graphical user interface (GUI) seems like a good candidate for a functionality to be generated out of annotated source code. GUIs used in prototypes do not need to meet too strict requirements on user friendliness since their aim is primarily to be suitable for presentation to the customer or for quick testing of basic functionality of the demanded software [3]. Furthermore, generating the GUI from source code may help to shorten the development time since there is minimum additional and external information needed to generate the GUI. According to [7] the source code already contains enough information to create properly working GUI.

978-83-60810-53-8/$25.00

B. Functional languages

The family of Lisp languages such as Common Lisp [8], Scheme [9], Clojure [10] and others are hereby taken as functional languages. This work is focused on generating GUI from source code written in such a functional language. There are several reasons for choosing functional languages rather than imperative ones as focus of this work.

1) Code in functional languages has simpler structure then a code written imperatively [11], [12]. Since thorough analysis of source code is needed this decision simplifies algorithms used in GUI generation.
2) Functional languages are growing in popularity even for writing business applications [13].
3) There is a number of similar tools for object-oriented languages such as Java or Smalltalk (discussed in section V). It is interesting to investigate which of its functionalities and approaches could be used in the functional world.

IV. The Clojure language

Clojure is a relatively new functional language based on Lisp [10]. It was created by Rich Hickey whose goal was to create mainstream functional language which can compete and complement present mainstream object oriented languages [10]. Basic features and characteristics of Clojure according to Rich Hickey [10] are

Functional programming
: The philosophy behind Clojure is that most parts of most programs should be functional, and that programs that are more functional are more robust compared to programs written imperatively. Clojure provides the common functional tools, however, doesn't force the program to be referentially transparent.

Lisp
: Clojure is a member of the Lisp family of languages, extending the code-as-data system beyond parenthesized lists (s-expressions) to vectors and maps.

Dynamic Development
: Programming in Clojure is interactive. It is not a language abstraction, but an environment, where almost all of the language constructs are reified, and thus can be examined and changed.

Hosted on the JVM
: Clojure is designed to be a hosted language, sharing the Java virtual machine (JVM) type system, garbage collector, threads etc. It compiles all functions to JVM bytecode. Clojure has simple syntax to reference and create Java classes therefore it can easily interoperate with Java and its libraries.

Runtime Polymorphism
: Clojure supports polymorphism at 3 levels. First, almost all of the core infrastructure data structures in the Clojure runtime are defined by Java interfaces. Second, Clojure supports the generation of implementations of Java interfaces. The final and primary language construct for polymorphism is the Clojure multimethod.

Concurrent Programming
: Since the core data structures are immutable, they can be shared readily between threads. However, it is often necessary to have state change in a program. Clojure allows state to change but provides mechanism to ensure that, when it does so, it remains consistent, while alleviating developers from having to avoid conflicts manually using locks etc. This is achieved by using the software transactional memory system (STM) [14].

Clojure is chosen here to represent a Lisp-like functional language. This work therefore focuses on generating GUI from source code written in Clojure. Clojure was chosen as a representative language for several reasons

1) Clojure can easily interoperate with Java and so the GUI can be created using standard Java GUI libraries such as Swing [15].
2) Clojure has very robust mechanism for state manipulation which allows to write the code for the GUI in Clojure itself.
3) Clojure is more suitable for writing business applications than other commonly used Lisps [13]. Therefore, it makes more sense to create rapid prototypes with graphical interfaces especially in Clojure.

V. Current methods for GUI generation

This section analyses current state in the field of automatic GUI generation. The author of this work did not find any current implementation of automated GUI generation for functional languages. Several implementations exist for object oriented languages such as Java, C# or Smalltalk. There is also work [7] which explores automated GUI derivation from programs written in term rewriting systems [16]. Let's first focus on object oriented frameworks.

Most of the object oriented GUI generators share a similar paradigm which is based on annotating domain data model using some kind of meta-data. This annotated model is then used as an input to the generator which then generates not only a graphical interface but often also application logic, database scheme and other components. This is essentially the whole application. In some cases a static generator isn't even necessary and the application's GUI accesses the annotated classes dynamically using reflection. Reflection is an ability of a programming language to change properties and behaviour of objects at runtime.

A. OpenXava

OpenXava [17] was hereby chosen as the main representative of the formerly described approach to object oriented GUI generation and a business application generation. This framework is capable of generating web applications in Java programming language with GUI based on AJAX technology. Input for the generator is a domain data model written in Java, annotated with combination of JPA annotations and

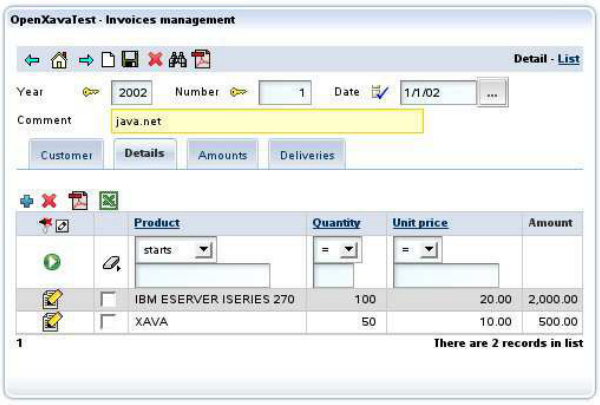

Fig. 1. Example of graphical user interface generated using OpenXava (taken from [17]).

OpenXava's own annotations. The output is a complete web application which uses Hibernate or JPA to store its data. An example of generated GUI is shown in figure 1.

OpenXava is a powerful technology which allows total separation of development of application's business logic and its user interface. Its advantages and disadvantages are more or less common to all hereby mentioned OO frameworks:

1) Independence of particular UI technology. It is possible to implement generators that produce code for different GUI libraries ranging from desktop UI to web or mobile interfaces.
2) Developers are freed from time consuming changes of the graphical interface when the model changes or when migrating to another platform.

However, the formerly described technology has some disadvantages as well:

1) Source code of the data model is often overloaded with meta-data which complicates orientation in the code and potential changes.
2) The user interface should better be derived from user behaviour and adapt to his intuition and habits rather than following the logic of the code underneath the UI [18].

B. Other OO frameworks

The OpenXava framework was used here as a representative of many others that function on similar principles. Some of them are listed along with their brief characteristics and differences.

NakedObjects [19]
: is a framework based on .NET platform. It works with domain model as well, however, the model is now written in languages for CLR – Common Language Runtime. In contrast to the OpenXava, NakedObjects uses reflection instead of code annotations and the resulting UI is created dynamically.

RomaFramework [20]
: works with domain model in Java. Besides code annotations, it makes it possible to use separated XML files to provide meta-data. Both annotation and XML approaches can be used together which can significantly reduce the amount of annotations in source code.

Magritte [21]
: is targeted at dynamic web application written in Smalltalk. Domain classes are annotated with so called description objects which add additional information using naming conventions. Such information is then used to generate GUI, database schemas etc.

There are other OO frameworks based on paradigm described above such as Tynamo [22] (previously named Trails [23]), JMatter [24], Apache Isis [25] and others. The nature of all frameworks mentioned so far is very close to the term of model driven software development (MDSD) [6] where the whole application is generated from some kind of model. As shown above, for decorating the model with additional UI information, a rich annotation language is often required. Even though, according to [7] a source code already contains enough UI information even without using expressive annotations. This idea is demonstrated in [7] by writing a small application computing an average of entered numbers. The application is written in term rewriting language [16]. Generating GUIs using this approach for functional languages is discussed in the next section.

VI. Possible approaches

Several possible approaches for generation of graphical interfaces from functional code were investigated during this work. Here are the main criteria according to which the final solution was assessed.

Practicality
: Useful and practical solution are favourized. For instance, code heavily burdened with vast amount of annotations is not considered practical since it corrupts readability and maintainability. These factors are key in prototyping since prototypes should be developed rapidly [3].

Separation
: The generated GUI should be separated from the application logic so that those two parts can be developed independently.

Generator extendability
: The solution should be extendable enough to allow creation of generators for other platforms such as mobile platforms or web.

A. IO oriented approach

The input/output (IO) oriented approach is based on the idea in [7]. It is hereby named IO oriented since its primary focus is on inputs entered by the user and outputs returned by the program in response. Term rewriting is in its nature close enough to the functional paradigm and thus the technique

described in [7] can be easily adapted for Clojure. The original tree rewriting program is shown in figure 2 and its Clojure implementation is shown by listing 1. This solution, however, has some serious disadvantages.

Listing 1 Program for computing an average rewritten to Clojure.

```
(defn add-number [average size]
  (do
    (label "Add:Result"
           (str "Average of " size " = " average))
    (action
      "Add:Add"
      (add-number
        (/ (+ (* average size) (number 0))
           (inc size))
        (inc size))
      "Add:Finish"
      (alert "Done" "Completed"))))

(defn compute []
  (add-number (number 0)
              (number 1 1 100)))
```

1) The code in Clojure is difficult to read since the GUI directives are heavily intertwined with the code for application logic. This violates our practicality requirement.
2) The GUI is tightly coupled with the application. It is not even possible to run the application without some kind of GUI. Moreover, the GUI directives cannot be easily removed from the program. Even the computational nature of the program has to take the GUI into consideration. This goes against the requirement of separation.
3) Another problem, which is more technical in nature, is interrupting the program. When the program is expecting some input from the user, it is blocking other possible actions such as termination.

Problems described above arise from the very nature of the idea used in [7] thus they cannot be easily overcome.

B. Action oriented approach

All problems described above have essentially the same cause. That is that functions contain directives for graphical interface inside their bodies. From certain point of view we can say that functions are actions that a user can execute. Such an action expects some inputs, produce some output, and as a an implicit side effect, it enables or disables some other actions. This information can be explicitly captured be annotating those functions before or inside their bodies.

The only GUI directive used inside bodies of functions would be a directive for enabling or disabling actions. The GUI generator could, by some kind of source code analysis, identify actions that belong together in the sense of their inputs. Graphical representation such as buttons and input fields belonging to those actions could then be grouped into graphical forms and windows.

According to the solution eventually presented in this article the above approach goes in the right direction. Even though, it is still rejected because serious difficulties are connected to it. The main issue is that the graph representing how actions are enabled and disabled through the flow of the program may heavily depend on the input of the program since we do not impose any restrictions on how the function should determine which actions will be enabled or disabled. Thus, constructing such a graph is in general an undecidable problem (explained in [26]). On the other hand, imposing restrictions that would make this problem decidable would seriously limit expressiveness of the functional language (further details in [26]).

VII. Functionally structured user interface

The above approaches to generating GUI from source code are not very useful still. The IO oriented approach has serious disadvantages and the action oriented approach forces us to overcome undecidability issues. This pushes us to look at the problem from another point of view. An interesting idea is to make the GUI less static and adjust its behaviour according to how functional programs actually work.

The question is how is the functional program essentially different from object oriented program from the user's point of view. By user is hereby meant the end user of the graphical interface of the program. One way to look at this is that when using graphical interface of OO program, the user creates and manipulates objects as primary entities. Functional program, on the other hand, is more about using functions as primary entities. These functions only then create, manipulate and transform objects. Thus, to reflect the different nature of functional programs, the GUI should be somehow function or operation (here we say *action*) centric. This is how we arrive at the term *functionally structured user interface* (FSUI).

A. FSUI specification

The main idea of the FSUI concept is that the UI has the same structure for all Clojure functional programs. Only the description of actions and their inputs and outputs is generated. GUI directives for enabling and disabling actions are not annotations. Instead, they are executable functions which then call the FSUI throw registered callbacks. Thus then, the program may be executed without any generated GUI just from a command line. In such a case, no callbacks are registered for the directives and so those directives do nothing.

Design of the graphical FSUI is shown in figure 3. The graphical FSUI is based on interaction of three basic kinds of components – *actions*, *invokers* and *value holders*.

Actions

An *action* represents a function from the source code of the underlying program. Each action is represented as a button on the left side of the UI. The program starts with some initial actions which can then enable or disable other actions by executing GUI directives inside the body of the function. These are the only directives that are placed inside function

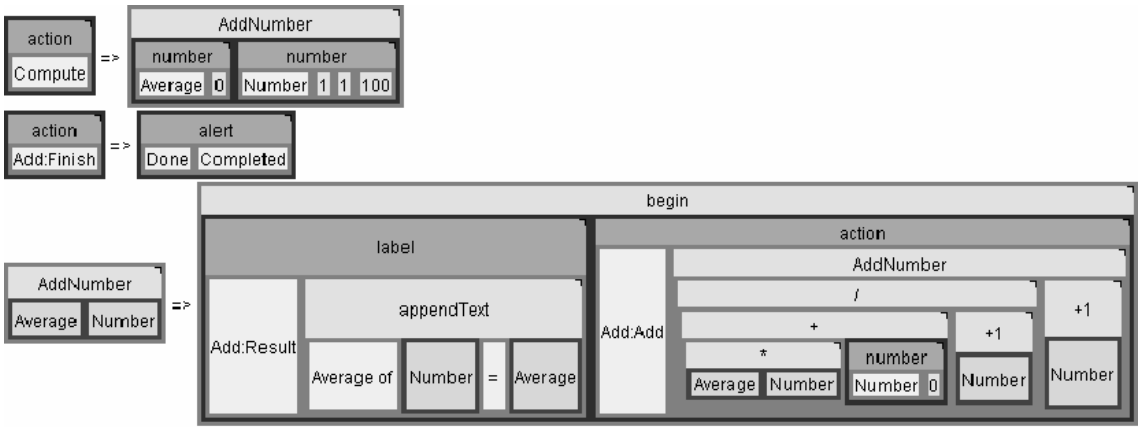

Fig. 2. Program computing an average written in tree rewriting scheme (taken from [7]).

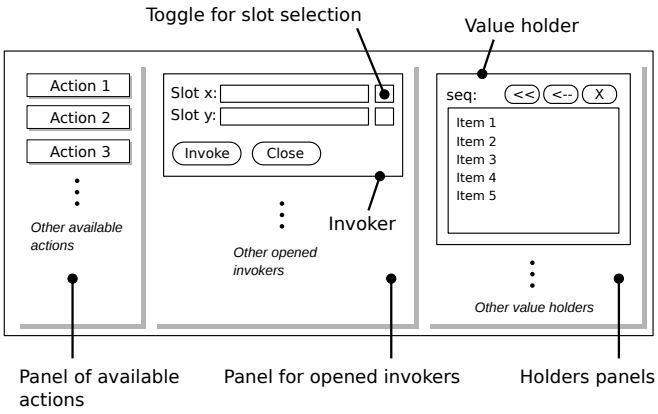

Fig. 3. Design of functionally structured user interface.

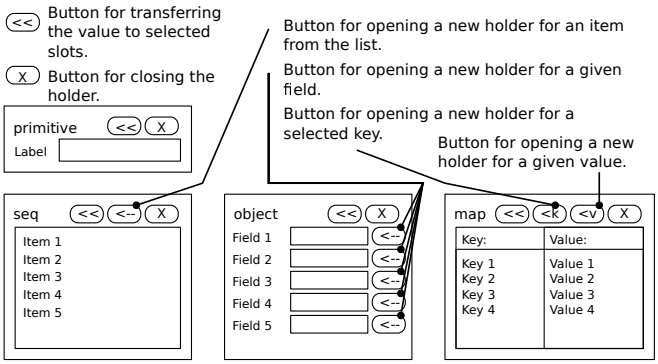

Fig. 4. Four types of holders for corresponding value types.

implementations. The key concept here is that actions do not execute functions right ahead. Instead, they open so called *invokers*.

Invokers

Invoker is a component used to collect inputs for particular action. The user can enter those inputs using *slots* (see figure 3). Slots are represented in the FSUI by text fields. Each slot declares its type so that the user cannot enter invalid values (more about the type system later in this section). The invokers panel in the middle of the UI can contain as many opened invokers as the user wishes. The actual invocation of the represented function is done by clicking on Invoke button. The same function can be executed multiple times since the invoker stays opened until the user closes it. When the function returns a value this value is inserted into so called *value holder*.

Value holders

Value holder displays a graphical component according to the type of value returned by the executed function. There are four types of holders at this time (see figure 4). These types are taken from the type system described later in this section.

Value from a holder can be transferred to a slot with compatible type. The fundamental idea here is that all values in holders are immutable thus they can be changed only by invoking a function on them. This preserves the immutability principle from the functional programming paradigm and makes the UI actually more function oriented than object oriented.

The flow of the program is controlled solely by enabling and disabling actions in the source code. Since all values are immutable, and the user has to execute a function even to create a non-primitive value, the programmer has a great control over what the user can and cannot do at a given moment.

The FSUI is implemented in Clojure in Swing GUI toolkit [15] with help of Seesaw library [27]. This library makes it easier to write GUIs in functional style.

B. The type system

Although the user is limited to create non-primitive values only using functions, he has considerable freedom in what

functions to execute and what values to pass them as arguments. To prevent errors and misunderstandings in the GUI, a function should clearly declare values of what types are expected as input and what is the type of the returned output. As the Clojure language is not statically typed, a type system for annotating functions had to be developed.

These requirements were imposed on the type system

1) The types system should be simple enough so that the user can understand it and be able to relatively easily determine which value can be passed to which function.
2) There is absolutely no need for type inference. All the type information is explicitly written in function annotations.
3) Primitive types as well as composed ones should be implemented. Lists, maps and objects are for now the basic composed types in FSUI. Objects are just heterogeneous key-value structures grouping different kinds of values together.

The type system meeting the above requirements was developed based on [28]. It is used for annotating function bodies in a way that each function is prepended with a type signature. Type signature is a list of type forms specifying value types. The first form in the list specifies the type of the return value and the following forms specify types of the arguments. The grammar for the type signature is shown in listing 2.

Listing 2 Structure of type signature.

```
<signature> ::= (<form> <form-list>)
<form-list> ::= <form> | <form> <form-list>

<form>      ::= <prim> |
                (seq <form>) |
                (map <form> <form>) |
                (object <name>)
<prim>      ::= :bool | :int | :float | :ratio |
                :number | :string | :file
<name>      ::= arbitrary symbol starting
                with a lower case letter
```

C. The generator

As it was previously mentioned, the GUI itself is dynamic which means that the code for the GUI itself doesn't have to be generated. The GUI needs only a description of actions and their respective inputs and outputs. This description is saved in Clojure data structure which is the output of the generator. Input for the generator is annotated source code in Clojure. The generator and the dynamic GUI are both implemented purely in Clojure.

VIII. Discussion

The solution developed in my master thesis [26] and described here contributes a new approach to the field of application prototypes development in functional languages hereby represented by Clojure. The main attributes of this solution, compared to object oriented approaches analysed in section V, are:

1) The UI generation is done using actual source code instead of domain data model.
2) The generator of the FSUI was developed to use more lightweight annotations then the OO solutions usually use.
3) The generated UI is uniform for all generated prototypes.
4) The type system was implemented with simplicity in mind so that the user can understand the GUI quickly.
5) Output of the generation was designed to simplify implementing the FSUI on other platforms.

Possible shortcomings of the whole FSUI and ideas for future development may be:

1) The FSUI is not flexible enough to support specific needs of particular prototypes. More control over the resulting UI layout could be integrated into source code annotations. Specific locations for invokers and value holders may be specified or actions could be nested and produce menu hierarchies.
2) The type system is not flexible enough either since it does not yet support recursive types.
3) This solution is built on top of Lisp-like languages which are dynamically typed. If statically typed languages such as Haskell are used, there will be no need for separate type system and the code annotations could reduce even further.

IX. Conclusion

Focus of this work was on the problem of automated GUI generation for functional languages in relation to application prototyping. Its result is, on the one hand, an analysis of current state in automated GUI generation in object oriented languages, on the other hand, a design and implementation of functionally structured user interface concept using Clojure and Java programming languages.

***Abstract*—This work presents the analysis of evaluation concerning the articles that are send to publication in academic journals, basing on additional parameters not resulting from essential value of the research work. Currently, majority of article verification algorithms is oriented on the selection of such works that are potentially more strongly influencing the international position of journal. For that purpose, editorial offices, and also reviewers, apply multi-criterion parametric evaluations and accepted parameters have often very subjective character. Presented work makes an attempt to identify used criterion functions i.e. defining evaluation parameters. These parameters were divided onto categories and there was proposed their preliminary verification basing on statistical analysis of already published articles in individual journals. Each parameter has attributed weight function, which allows to defined its impact on the total evaluation of article, and also adaptation of formula to any academic journal. Weight functions will be determined with usage of neural networks or genetic algorithms, aiming to their individual adaptation to particular journal.**

I. Introduction

PREVIOUS investigations over the evaluation of academic journals, cause the continuous improvement of algorithms by which the articles published in these journals are verified. This results from endless aspiration of journals to obtain maximum of points in created rankings (Philadelphia List, Impact Factor, quoting indicators etc.) [2-4].

New appearing methods of the evaluation of journals and modifications of already existing, cause that the essential evaluation of the article can be unsettled in the interest of the parametric evaluation forced by publisher[8-16].

In effect, innovative publications can be inadequately evaluated or not published due to their wrong preparation. Introduced and described below coefficients of scientific articles parametrization are supposed for the task to determine an influence of these subjective parameters on the evaluation of articles in individual journals. Furthermore, there were presented series of factors which, if they will be taken into consideration during writing of scientific articles , have a chance to increase probability of obtaining positive review and in effect the acceptance of publication in renowned journals. In the further process of research works, there is planned realization of automatic information system, which role will be verification of the working version of article, before sending it to the journal and the definition of the probability of obtaining high parametric evaluation. Described parametric evaluation will determine the coefficient EPQ – Estimated Paper Quality. This coefficient will be helpful for scientists who concentrate mainly over essential, and less over the editorial part of their scientific article. The low value of EPQ should induce the author to analyze and supplement his publication before sending article to editorial office of chosen earlier journals.

II. Evaluation of journals

Academic journals are subjected to continuous verification through evaluation of published articles influence on environment of scientists. There exist many parameters evaluating the parametric quality of the journal, here are some of them [20-26]:

- Impact Factor (IF)
- Relative Citation Rates (RCR) / Journal to Field Impact Score (JFIS)
- Article Influence (AI)
- SCImago Journal Rank (SJR)
- Source-Normalized Impact per Paper (SNIP).

Each of them characterizes different factors which influence final evaluation of journals. Different journal evaluation criteria cause the inhomogeneity in resultant rankings. Furthermore, algorithms of evaluation are subjected to continuous changes aiming to the most reliable definition of publications quality. From this reason, the aim of publishing companies, instead of valuing scientific publications having less 'popular' character (though substantially equally good whether even much better), can be wish of achievement of as highest parametric coefficients evaluating other of their publications.

The most popular is Impact Factor (IF) (1). It counts all quoting from particular calendar year, and it divides them by amount of "cited" publications from last two years (C)

978-83-60810-53-8/$25.00

$$IF = \frac{B}{C} \quad (1)$$

Other indicators, although they also reflect the parametric quality rating of journal, are not so popular.

It can be accepted that, as higher evaluation of given journal in the ranking, the article published in it, has a chance to obtain greater range, and consequently receiving greater quantity of quotations. It seems that there exists the conformity of business among the journal and author of the article, however this concerns only wishes of obtaining as maximum quotations quantity at other publishers through the large number of scientists.

Wanting to check our chances for the publication in given journal, often we set incorrect question - *will this journal publish my article?*

To show existing dependences and conflicts of interests between author and editor, one ought to set himself the question:

How my article will help the journal to obtain better position in the ranking (more points in the parametric evaluation of journals)?

The answer is dependent on many factors (the general diagram of dependence among publication publishers and authors is presented on Fig. 1), which can subjectively influence the evaluation of article, aside from its essential value.

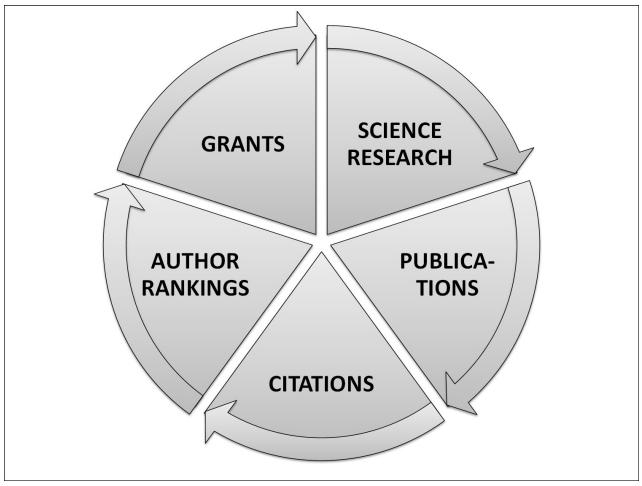

Fig 1. The influence of research work elements on financing and publishing of research

A. The evaluation of Authors

Authors are also subjected to parametric evaluation, targeting the verification of their achievements through the creation of ranking reflecting their contribution to the development of given field. One of main parameters applied in relation to authors of publication is proposed in year 2005 the Hirsch index (h-index) [1]. As easily can be envisaged, such evaluation can be sensitive on manipulation on the side of several cooperating with themselves authors, who mutually will quote their works (aside from their essential contribution into researches). The parametric evaluation of publication issues from the category of scientific research. Scientific researches require financings, and one of the popular sources of learning financing are exploratory grants. To obtain the financing there is expected that the scientist will carry out planned investigations and their effect will have visible influence on given exploratory field. How is measured such influence?

Most readable measure are publications and their quotations. From this reason, scientists who have a suitably high Hirsch index, are treated as trustworthy to commit to them public money on carried researches. Readable dependencies appear between the financing of research, with quantity of publication, and with their quotations which put themselves greater chance for future financial resources.

III. Parametric evaluation of the Article

Every article, except the essential value, can be described by a group of parameters defining its quality from the interest of journal point of view. Here appears mentioned conflict of interests between publishing houses, and authors [17].

In the evaluation of article, the essential value can be estimated by additional parameters defining the range of carried researches, e.g. the article containing theoretical models can classified lower than articles containing, except the theory, also simulation models. As the best will be evaluated articles containing the experimental verification carried researches. Separately, enough high classification can have articles containing rich and complex reviews of the literature from the given field, because this type of articles are quoted often many times. This results from the specific approach of scientists to carried researches and wishes of using elaborated earlier literature review - which often requires a lot of time, and belongs to „little attractive" researches.

Thereby, that at the evaluation of articles value nobody can foresee how often he will be quoted in the future. In the simplification it can be assumed, that in the initial phase of article analysis, each has an evaluation for the essential value on the same level. Since the quantity of elaborated article future quotations cannot be influenced, it can be influenced whom the author quotes in his own publication. This way the quantity of "gained' quotations from the journal's point of view, can be controlled . The issue here is the period of time in which journals are subjected to evaluation in rankings. For the calculation of Impact Factor, there are taken into consideration last 2 years, what means that the auto quotation of other articles which appeared in the same publishing house within a period of last 2 years, have a positive influence on IF indicator increase. Therefore, the publishing house will be willingly promoting art-

icles which already show quotations from their own journal, what is a method to obtaining higher place in the ranking. However, if there exists a group of journals given by the common institution, then cross quotations of other journals belonging to the same publisher are also added value. Here arises a threat regarding the reliability of published articles, because one can apply the mechanism which would permit ranking speculations between journals. Following the paragraphs of this article contain the case study describing such situations.

IV. EPQ - the coefficient of the parametric evaluation of article

To show series of factors participating in the evaluation of given article, there was proposed the EPQ coefficient (Estimated Paper Quality). It can be presented as weighted mean of individual parameters, with suitably assorted weights functions. The value of parameters is standardized so that it contains itself in range from 0 to 1. This type of method descends from Churchman and Ackoff (1954) researches, under the name SAW (Simple Additive Weighting) [18-19]. SAW is one of more popular solutions in MADM type (Multi-Attribute Decision Making) problems of the which undoubtedly is a problem described in work. Elaborated process of EPQ calculation is similar to above methods, however there appear differences in designating of individual parameters. Differences are caused by different way of P_i parameters values determination.

$$EPQ = \frac{1}{n}\sum_{i=1}^{n} P_i * w_i \qquad (2)$$

where P_i is appropriate parameter of evaluation, with following index n appointed , and w_i is weight for given parameter. Below in the table (cf. Table I) there is presented list of parameters together with their asserted values and ranges. All parameters P_i are situated in the same range: $P \in [0,1]$.

V. The example of the EPQ calculation

The definition of the exact value EPQ does not decide about "the success" and the publication of the given magazine article. This will permit however finishing up and improvement of the editorial part which could not take into account mentioned above factors influencing decision of editors and reviewers. Elaborated in such way system using the informatics network , will permit quick definition of the article modification. Outwardly, it will enable based on obtained result EPQ to propose the alternative academic journal which parameters answer to the result. There was calculated the value EPQ for example of publication based on the *Matlab* software.

VI. SEO, Hirsch index and Impact Factor

A. The similarity of the Hirsch Index and Impact Factor to Page Rank, and threats resulting from Black Hat SEO methods?

The growth of the Hirsch index and IF is strictly dependent on the quantity of given author publication quotations. This model can be compared to the published ranking of websites (*PR - Page Rank*) used in Google search engine [5-7]. The similarity refers to the quantity of quotations which correspond to quantities of returnable links indicating given page of data sources.

There are known general methods of influencing the algorithm of search engine in this way, so that the indicated page will be higher in the SERP ranking (Search Engine Results Page). This methods are divided on so called white and black. White Hat SEO - means the positioning of the website in compliance with official guidelines of search engines, what should result in better page adaptation to Webcrawler's and engines of search engines requirements. Good preparation of the website facilitates quick indexing of it in the search engine base of data, however increasing number of valuable references to page (gained naturally and resulting from its popularity and uniqueness) permits its positioning and obtaining of high place in the SERP ranking. As valuable references are acknowledged links from pages about high PR which are often visited by users (e.g. thematic, community websites). There also exists Black Hat SEO which is characterized using all possible gaps in the search engine, for the purpose of raising the ranking of given website. Such effects are achieved through the manipulation with the quantity of returnable links and their "artificial" addition through generating large quantity of pages with links. So many of manipulation methods is the necessity of continuous algorithms change of search and qualitative selection of websites.

From obvious reasons, exact parameters of the algorithm are not revealed for the purpose of their protection before the manipulation. There can be only estimated general dependencies and on their base there can be created algorithms improving the position of website in ranking of searches. Methods of rankings creating e.g. PR and IF, and also H- index, cause the risk of appearing methods taken from SEO, which in the artificial way will manipulate results of mentioned above rankings. Probably there is no possibility of obtaining 100% reliable and objective ranking not burdened with the above risk.

From this reason, the essential evaluation of publication can be shaken, in the interest of the parametric evaluation. This can cause the reverse to intended effect i.e. these rankings will promote less ambitious scientific discoveries, but artificially will overvalue indexes across the elaboration of their manipulation method. Below there is presented case study, which in the mental experiment could result with

TABLE I.
DEFINING PARAMETERS FOR CALCULATION THE EPQ INDICATOR

No.	Parameter P_i	Meaning of value substituted to P_i	Formula on P_i	Range	Initial weight w_i	Range of weight
1	P_1	H – authors Hirsch index	$P_1=(1-\frac{1}{1-H})*(w_1)$	H=[0:inf]	1	[0:1]
2	P_2	I – the quantity of authors indexed publications	$P_2=(1-\frac{1}{1-I})*(w_2)$	I=[0:inf]	1	[0:1]
3	P_3	C – quantity of authors indexed quotations	$P_3=(1-\frac{1}{1+C})*(w_3)$	C=[0:inf]	1	[0:1]
4	P_4	S - degree/ the scientific title of the author (none/engineer/MSc/the doctor/assistant professor/professor)	$P_4=(1-\frac{1}{1+20*S})*(w_4)$	S=[0:5]	1	[0:1]
CONTENT RATING OF ARTICLE						
5	P_5	Gaussian distribution calculated basing on the quantity of all quotations contained by author in the article, where: d - height of the Gaussian curve top, x - quantity of all quotations contained by author in the article, σ - standard deviation of Gaussian distribution, μ - expected value, equal average quantity of quotations devolving on one article in the given journal, a - quotations devolving on one article (k) in the given journal.	$P_5=(d*e^{\frac{-(x-\mu)^2}{2\sigma^2}})*(w_5)$ $\sigma=\sqrt{\frac{1}{k-1}\sum_{i=1}^{k}(x_i-\mu)^2}$ $\mu=\frac{1}{k}\sum_{i=1}^{k}a_i$	d=[1] x=[0:inf] σ=[0:inf] μ=[0:inf] a=[0:inf] k=[0:inf]	1	[0:1]
6	P_6	A - the quantity of quotations coming from archival numbers of the same journal to which the publication is submitted	$P_6=(1-\frac{1}{1-A})*(w_6)$	A=[0:inf]	1	[0:1]
7	P_7	B - the quantity of quotations coming from archival numbers of remaining journals belonging to the same publishing house to which publication is submitted	$P_7=(1-\frac{1}{1+B})*(w_7)$	B=[0:inf]	1	[0:1]
8	P_8	The indicator of the publication originality. O - the quantity of similar articles earlier published by the author. D - the sum of "duplicates", measured by the coefficient of similarity of genuine text and small pictures between previous articles of the author, and with his current publication	$P_8=(\frac{1}{1+O})*(w_8)$ $O=\sum_{i=1}^{n}D_i$	O=[0:inf] D=[0:inf]	1	[0:1]
9	P_9	R_d - the quantity of quoted publications of the current editor of journal to which publication is submitted	$P_9=(1-\frac{1}{1+R_d})*(w_9)$	R_d=[0:inf]	1	[0:1]
10	P_{10}	R_c - the quantity of quoted publications of current reviewer of journal to which publication is submitted	$P_{10}=(1-\frac{1}{1+R_c})*(w_{10})$	R_c=[0:inf]	1	[0:1]
OTHER PARAMETERS						
11	P_{11}	J - the quantity of authors publications quoted by current editor or reviewer of the journal to which publication is submitted	$P_{11}=(1-\frac{1}{1+J})*(w_{11})$	[0:inf]	1	[0:1]
12	P_{12}	K - the quantity of authors common publication articles and current editor or reviewer of journal to which publication is submitted	$P_{12}=(1-\frac{1}{1+K})*(w_{12})$	[0:inf]	1	[0:1]
13	P_{13}	Z - quantity of elements from the range carried researches (the form of survey): review, theory, model, simulation, experiment, lack/other.	$P_{13}=(1-\frac{1}{1+20+Z})*(w_{13})$	[0:5]	1	[0:1]

"artificial" increasing of IF for the journal, or with 'artificial" increasing of the H-index for given scientist.

B. *How to create Journal with IF=100 (Case Study I)?*

In the after-mentioned mental experiment we establish that one publishing house can belong to several academic journals having similar character, or there was undertaken cooperation between publishing houses for the purpose of one common journal strong promotion. The first journal

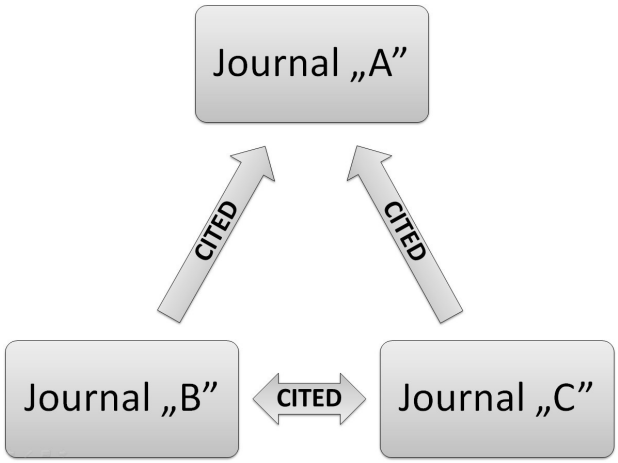

Fig 2. The diagram of quotations hinterland building for promoted journal.

„A" will be promoted, however remaining „B", „C" will constitute the hinterland with place for journal "A" quotations.

In this case arises classical system of hinterland with links (in our case - with quotations), known among computer scientists dealing with the positioning of websites (so called SEO - Search Engine Optimization). The example of building of quotations hinterland is presented on "Fig. 2". On the assumption that the journal "A" will have few articles in one publishing-cycle , then remaining journals can force writing for them authors, to quote several articles from journal "A". So extortionate ranking of promoted journal can have other advantages.

VII. The methodology of designating weights

Particularly essential from the usage of EPQ indicator point of view, is the possibility of weights definition w_i in way compatible to parametric evaluations applied by the given journal. The large number of academic journals causes different approach to the parametric evaluation of accepted to editorial office and the review of article. Basing on the data from previous years, considering all publications printed within the framework of one publishing-title , we are able to determine weights of individual parameters individually for the given journal.

For that purpose we will use neural networks with the feedback which will learn to recognize the influence of given parameter on the positive acceptance of article to the publication. In case of the analysis, already printed publications, we will subordinate the quantity of published articles from the value of individual parameters. The more articles will have e.g. the high parameter P6, the greater influence on the printing of publication has the quantity of archival articles quotations laded from the same journal.

VIII. Application realizing EPQ designating

For the purpose of individual parameters designation, we will use the access to individual databases, among others: SCOPUS, WEB OF KNOWLEDGE, and others. Application in the first instance will collect data: ref. of author, quotations, journal, publication, and then made the evaluation of parametric sent publication. Based on this evaluation, it can propose suggestions ref. introductions of changes in the article, or present proposal of the alternative journal to which the parametric evaluation was in order better. The system architecture may be built based on the client-server methodology what is presented on Fig. 3.

IX. The architectural schema

On the after mentioned Fig. 3 there is presented the general architectural schema of the system.

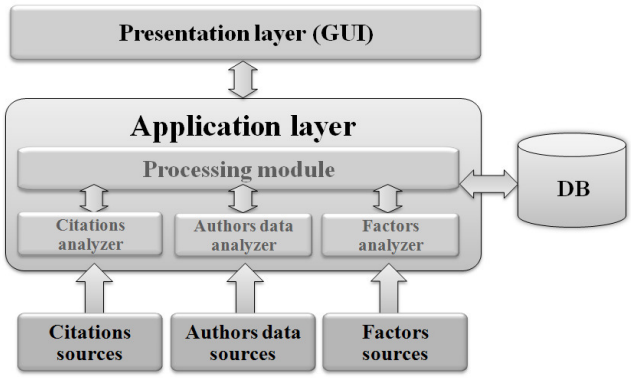

Fig 3. The architecture of proposed information system designating the EPQ coefficient.

In presented architecture system we distinguish:

1. *Presentation layer* - layer of the application responsible for the presentation of results and communication with user, receiving data from user (proposed article, survey for the author)
2. *Application layer* - layer responsible for the resumption of data and processing of results, consists of:
   - *citations analyzer* (module processing the quotation categorizing and counting quotations of authors works.

- *authors data analyzer* (module processing data of authors (also reviewers and editors), checking relations of author with journals across quotations as well as categorizing his achievement)
- *factors analyzer* (module being supposed for the task to process available data sources information of used in the algorithm coefficients for journals and authors)

1. *DB* - layer of database recording source data and results of calculations with application layer, permitting caching of data sources in the situation when data don't need to be refreshed at every operation of weight-coefficients calculation weight- coefficients.
2. *Sources* - layer of gaining data from chosen sources dividing into sources of quotations gaining ("citations sources"), given authors ("authors the date sources") and coefficients used in the algorithm of EPQ count ("factors sources").

The system architecture in case of further development can be calibrated because the module of processing may receive partial results of calculations (weights of component parameters) from individual modules which can be find on separate instances of servers. Every module of gaining data can have the separate database in which will store received results of the data sources indexing In case of presentation layer, the system can communicate with software of the *thin client* type in case of approach users (authors of articles) and with the software of the *fat client* type in case of the administrator who can control work of the processing module (settings control).

III. Conclusion

As this is the elaboration of the preliminary concept of articles parametric evaluation across proposing of the EPQ parameter , only verification on figures will permit the definition of its real effectiveness in the classification of articles to individual academic journals. Methodology is based on foundations that the substantially good article can be worse evaluated, due to remaining factors on which reviewers and editors of journals pay attention. Elaborated system, targets proper verifying and correction of article before delivering to publishing houses. This will permit to carry essential research on equally high level, and to regard of subjective 'expectations' from the side of publishing house in relation to the author. So improved article has greater chances for printing in the renowned journal, what can positively rebound on future publications of many authors.

***Abstract*—Most companies have a large number of projects that they would like to do for various reasons. However, usually there is never enough time and money available to complete all of them. Selecting a portfolio from available project proposals is crucial for the success of each company. This paper proposes a practical framework for modelling projects portfolio selection problem with fuzzy parameters resulting from uncertainty associated with decision makers' judgment. A fuzzy multi-attribute decision-making approach is adopted. A two-step evaluation model that combines fuzzy AHP (*Analytic Hierarchy Process*) and fuzzy TOPSIS (*Technique for Order Preference by Similarity Ideal Solution*) methods is used to rank potential projects. The proposed approach is illustrated by an empirical study of a real case from steel industry involving five criteria and ten projects.**

I. Introduction

DECISIONS on investment projects have a direct impact on a company's success. They are, however, particularly difficult, because of the ubiquitous uncertainty associated with any business activity. This causes that the project portfolios selection (PPS) becomes an increasingly complex decision task, which in turn motivates managers to utilise modern techniques and tools to optimise capital allocation.

At present, there are a lot of methods that can be applied to solve PPS problems, including Economic Analysis, Decision Theory, Optimisation and Multi-criteria methodologies. In order to deal with both financial and non-financial project attributes, the multi-criteria decision making (MCDM) analysis is a preferred approach. The goal of the multi-criteria decision making analysis is to "provide a set of attributes aggregation methodologies that enable the development of models considering the decision makers' (DMs') preferential system and judgement policy" [7]. In general, MCDM methods may be divided into two groups: multi-objective decision making (MODM) and multi-attribute decision making (MADM). The latter have been used to solve problems with discrete decision choices and a predetermined or limited number of alternative choices. A comparative study on various MCDM methods is presented, e.g., in [1] and [8].

In this paper, an MADM approach to project portfolio selection is applied. The classical approach is expanded to deal with uncertainty expressed in the form of fuzzy numbers. There is a range of scientific publications which develop very sophisticated methods for describing uncertainty. Meanwhile, according to the survey of Hubbard [9], modern enterprises still asses and mitigate risk using old fashioned methods which have not evolved much for several decades. This paper attempts to fill out the gap between the theory and practise. A practical framework to deal with the PPS problem is developed. The reminder of this paper is organised as follows. Section II briefly describes problems with modelling uncertainty in PPS. Section III presents methodology used to solve the PPS problem. The proposed framework is described in Section IV. Numerical example is shown in Section V. The paper ends with concluding remarks.

II. Risk and uncertainty in project portfolio selection

There is no universally accepted definition of business risk and uncertainty, but in the PPS context they may be understood as potential problems with availability and certainty of information, and also imprecise choices. To deal with uncertainty in PPS, it must be first noted that PPS usually consists of two stages. In the first stage, projects are selected on the basis of the threshold criteria which are determined by decision-makers. In order that a project can pass to the next stage, it must strictly fulfil these criteria. The selected projects are input for an MADM method, which usually first calculates the weights of criteria, and then determines the ranking of potential projects. Each part of an MADM method is associated with different type of uncertainty. The main source of uncertainty in determination of criteria weights is imprecision of expert judgements. Due to cognitive biases, decisions may be deviated from a standard of rationality or good judgement. To take into account these systematic errors, fuzzy numbers are used instead of crisp numbers.

In this paper, fuzzy criteria weights are obtained using a fuzzy AHP method. Some researchers believe that classical Saaty's AHP method has some weaknesses which are connected with uncertainty. In [18] authors points out that mapping experts judgement to crisp numbers and cognitive biases generates uncertainty which is not taken into account by the classical AHP method and may have huge impact on the results. To deal with this problem, some researches fuzzified AHP (e.g., [4] has considered trapezoidal fuzzy intervals for comparison ratios in AHP and [5] has proposed approach for triangular case).

Some criticise the fuzzy AHP and argue that it does not give much different results then the crisp version. However, it is important to note that the main criticism is based on assumption that comparison ratios are based on expert consensus. In practise, comparison ratios are usually averages of expert

978-83-60810-53-8/$25.00

ratios. As long as there are no agreement between experts, everyone of them interprets linguistic variables in different ways. In this situation, expert verbal possibilities should better be translated into fuzzy than crisp numbers.

The second aspect of representing model uncertainty by fuzzy numbers concerns the type of fuzzy numbers that should be used. Generally, there are two approaches to fuzzification of comparison ratios – fuzzy numbers [19], [21] and fuzzy intervals [13]. The empirical study shows [3] that membership functions of numerical equivalents of linguistic terms are similar to fuzzy numbers, which are not distributed equidistantly along the possibility scale and which vary considerably in symmetry and vagueness.

Usually, after the first stage, the calculated criteria weights are defuzzified. In the proposed approach, fuzzy weights are passed to the second stage. This guaranties that uncertain judgements of decision-makers are taken into account also during the second phase of PPS.

The second phase of PPS determines the ranking of potential projects based on the weights obtained in the first stage. In this phase, uncertainty concerns attributes of alternatives. The attributes are divided into two groups: objective (numerical) and subjective (linguistic). A majority of authors argue that only subjective criteria should be described in terms of fuzzy numbers. In the proposed approach it is assumed that quantification of financial attributes of investment projects should be modelled as mixture of possibility and probability distribution.

III. Methodology

The proposed methodology of selecting an efficient portfolio of investment projects consists of the following steps. First, multiple criteria that are considered in the decision-making process are identified. Then, criteria weights are calculated according to the fuzzy AHP methodology. After constructing the relationship of a criteria decision matrix, the fuzzy TOPSIS approach is used to achieve the final ranking results.

The AHP method ([16]) is a flexible MCDM tool for complex problems where both qualitative and quantitative aspects need to be considered ([2]). The AHP integrates different measures into a single overall score for ranking alternatives. By reducing complex decisions to a series of simple, pairwise comparison judgements, then synthesising the results, the AHP not only helps the analysts to arrive at the best decision, but also provides a clear rationale for the choices made [5]. The fuzzy AHP [5] is the fuzzy extension of AHP to deal with the fuzziness of the data involved in the decision making process. Fuzzy AHP enables decision makers to specify preferences in the form of natural language expressions about the importance of each performance attribute.

TOPSIS [10] is another popular approach to MCDM. The main idea is that the best alternative should have the shortest distance from the (positive) ideal solution and the farthest distance from the negative ideal solution. The TOPSIS method has also been extended in different ways to deal with fuzzy numbers. The simplest one is to change fuzzy MCDM into a crisp one by using defuzzification. This approach, however, can lead to the loss of information. Another approach is to define a crisp Euclidean distance between fuzzy numbers. An approach based on α-cuts can also be found in the literature [20].

IV. Proposed framework for project portfolio selection

Based on the methodology described in Section III, a new approach to project portfolio selection problem is proposed. It consists of four stages described in the following subsections.

A. Identification of available investment projects and criteria

First, a committee of decision-makers who come from different managerial levels is formed. They identify m potential investment projects $A_1,\ldots,A_m$ and n criteria $C_1, \ldots, C_n$ that each project must fulfil. To properly assess a project, many factors should be considered [14], [15]. McKown and Mohamed [12] presents multi-criteria project selection where uncertainty of profitability parameters is described by fuzzy numbers. They point out that the selection of investment projects should consist of two kinds of parameters – financial (e.g., net present value) and non-financial (e.g., social, environmental, strategic an organisational). The method proposed in this paper allows to aggregate financial and non-financial indicators. First, the criteria are divided into two groups – objective and subjective. Objective criteria are described by fuzzy numbers which usually result from fuzzy modelling or aggregation of historical data. Subjective criteria are qualitative criteria with values that are specified by decision makers in the form of linguistic variables. Here, linguistic variables are transformed into fuzzy numbers (triangular or trapezoidal). This simplifies further ranking of projects.

B. Calculation of synthetic importance weights

Obviously, the problem of calculating the importance weights of the criteria is a typical multi-variable and multi-objective optimisation problem. To calculate importance weights of the criteria the fuzzy AHP is used. To make a pairwise comparison, a linguistic scale is developed. Table I provides summary of translation developed based on [3]. The final scores of criteria are also represented by fuzzy numbers.

C. Development of performance ratings for projects

The performance ratings of objective and subjective parameters are calculated. At the end of this stage the threshold selection is made. Only those projects which have passed the threshold selection are taken into account in the next stage of the PPS.

D. Calculating hierarchy of projects using fuzzy TOPSIS

The hierarchy of projects is established. Then, the overall ranking of projects is calculated. The ranking allows a decision-maker to select the most appropriate investment option.

V. NUMERICAL EXAMPLE

The proposed approach was applied for PPS in steel industry. There are five criteria $C1, \ldots, C5$ – financial, market, technology and environment, staff and compliance with the company's strategic objective. Each of them is divided into subcriteria. The objective ones are NPV, IRR, Pay-back period, the rest is subjective. There is also the third level of subcriteria for the $C2$ criterion. They are called attributes.

To calculate weights of criteria, a team of decision makers make pairwise comparison. The results of this comparison are presented in Tables II, III and IV. Then, using the fuzzy AHP global priorities are obtained (Table V). The priorities are presented in terms of fuzzy numbers. It can be noticed that the higher hierarchy of the criteria is, the wider fuzzy number are. For example, fuzzy weight $C2.3.1$ range between 0 to nearly 0.3. This illustrates the well-known phenomenon of accumulation of uncertainty. That is why in next step the consistency degree should be used (e.g., fuzzy preference

TABLE V
IMPORTANCE WEIGHTS OF INDIVIDUAL REQUIREMENTS

C2.2	(0.018,0.061,0.204)	C2.3.3	(0.002,0.015,0.127)
C2.3	(0.011,0.063,0.31)		

TABLE VI
FINAL RANKING OF PROJECTS

Project	Rank	Project	Rank	Project	Rank
P9	0.7154	P3	0.6817	P5	0.6770
P10	0.7101	P7	0.6789	P6	0.6714
P1	0.7095	P8	0.6782	P2	0.6615
P4	0.7011				

programming).

In the next step, evaluation matrix is created. Matrix consists of 15 criteria and 10 projects ($P1, \ldots, P10$). The objective criteria are characterised by fuzzy intervals. The level of subjective criteria are specified by experts. The subjective criteria are translated into triangular fuzzy numbers.

In the presented example, there are two kinds of subjective attributes – some of them describe patterns, and some of them judgements. Market size criterion $C2.1$ and prospects for market growth criterion $C2.2$ belong to first group. They describe the belief of decision maker that market for project i will behave in accordance with some pattern. For example, pattern *stable* means the dynamic of the market growth which may be described by the fuzzy number $(-1.02, 0, 1.02)$.

The second group that is subjective criteria represents judgements of experts. Therefore, they are treated as ordinal fuzzy variables. Since all of subjective criteria are ordinal (variable with order), thus fuzzy ordinal rank transformation is used. After translation of linguistic variables – the fuzzy TOPSIS is applied. The obtained final ranking of projects is presented in Table VI.

VI. CONCLUSION

The evaluation and selection of industrial projects is one of the most important aspects of PPS. This paper proposed a combined fuzzy MADM approach based on fuzzy AHP and fuzzy TOPSIS techniques. A real world case study from steel industry was presented to explain approach. The paper introduced fuzzy decision making concept, when some data is burden with uncertainty. It is argued that if a fuzzy MADM problem is defuzzified into crisp one to early, then the advantage of modeling uncertainty becomes negligible. The rational approach is to defuzzify imprecise values at the very end of methods. Based on this argument, we perform deffuzzification at the very end of MADM method during calculate weight of criteria.

More research is needed to examine projects interaction and dependency. Further research is also required with respect to the subjective criteria of project selection. The problem of quantifying the qualitative factors remains a difficult and sometimes controversial tasks.

***Abstract*—The paper addresses tools that support knowledge-based management. These tools are referred as Business Intelligence. Competitive Intelligence is also discussed. They transport data into comprehensive information about company processes and real-world impact on their progress. Basic principles of these applications are also described. The paper presents the results of the questionnaire survey conducted among SMEs in the Czech-Polish border area. The questions are focused on the use of these tools and intensions in cloud exploitation. The results and the lack of show a considerable interest in the use of Business Intelligence applications awareness of business managers with regard to Cloud computing possibilities.**

I. Introduction

GLOBAL economic models are undergoing profound changes which include e.g. global competition, global transfers and changes in the way of work in many industries or the pressure on the qualification of the workforce. In developed countries, this causes a gradual shift to an economy of intangible assets and relationships [1]. These changes are underpinned by the key role of information and communication technologies (ICT) providing modern infrastructure, which allows implementing most of the changes. Simultaneously, ICT provides tools to increase performance, competitiveness and innovation in virtually all areas of the economy.

Managers currently have access to a considerable amount of data available from a variety of sources. To make decisions, they need an efficient tool that would help them process data to obtain necessary information. Such tools are Business Intelligence (BI) applications that specifically aim to provide decision support to managers. These tools allow them to analyses the situation in their own company, provide access to information from external company environment and based on the processed data, provide the managers with early warning of existing threats and highlight new business opportunities [2].

At the same time, the range of Competitive Intelligence (CI) tools and methods is expanding. The CI tools and methods introduce into management sophisticated methods of work for contextual search in external information sources through the Internet [3].

New opportunities for managers are also brought about by the new Cloud Computing (CI) technologies provided by ICT companies as a service. While part of company managers is aware of the existence of CI, the majority are still distrustful of it or have no idea what the term means.

II. Increasing the Entrepreneurial Potential of Using ICT in the Czech-Polish Border Area

Since 2012, the Department of Applied Informatics, VSB-TU Ostrava has been conducting a research "Application software for decision support in small enterprises in the Czech-Polish border area". This research is conducted jointly by the Department of Economic Informatics, University of Economics in Katowice.

The survey results also confirmed that the adoption of ICT present an adaptive challenge, not a technical problem. It provides the SMEs with several advantages, especially at the tactical and operational level of management.

- At the level of operational management: an increase in the quality of data management, communication, decision making, data exchange, improving cash-flow control, gradual transition to work with digital documents, shortening the response time to queries (improving customer relations, company profile).
- At the tactical level: rapid response to changes, promotion of teamwork, more flexible scheduling, flexible processing of offers, better integration of business processes, and overall improvement in efficiency and effectiveness.

Although information is today recognized as an important means of creating added value, there is a lack consistency between ICT and business. The basis to solve these problems can be found in the balance between the global and information strategies of the company. These strategies must be prepared on the same basis and with the same weight (attention). The truth is that most SMEs typically do not pay attention to the information strategy – creating IS and ICT development plan in the company in the long term. They are focused on current issues in the struggle to keep the company on the market.

A company information strategy mainly aims to strengthen the link between IS and ICT development in the company and its global strategy in order to subsequently increase its competitiveness and support the development of new forms of business.

When preparing the IS strategy in the longer term, it is necessary to consider four aspects of the IS: achieving the intended objective (effectiveness), efficiency, reliability and continuity of its development.

978-83-60810-53-8/$25.00

III. Methodology, Data, Results and Discussion

Part of the survey focuses on segmenting entities by type of the applications used and by their relationship to the type of ICT service provision. A sub-aim is to familiarize the respondents with a range of options currently offered to purchase, operate and maintain ICT and to determine the level of awareness of companies about the possibility to use cloud computing. Previous results in these areas confirm very similar approaches in the border area concerned.

The survey also includes a questionnaire survey carried out in electronic form on both Czech and Polish sides of the region. The outcome of the project was 160 replies from both Czech (100 responses) and Polish (60 responses) companies. The return rate of the questionnaire on the Czech side was 18.4% (105 responses of 572 questionnaire views). The return rate of the questionnaire on the Polish side was 16.5% (75 responses of 455 questionnaire views). Average time to fill out a questionnaire was about 11 minutes.

The questionnaire is divided into eight interconnected parts: **A, B** (present and future use of ICT tools), **D** (data sources to support decision-making processes), **M** (modules used within IS), **E** (what are your preferences in software procurement), **F** (software functions important to select ICT), **G** (way of ICT maintenance) and **I** (company identification).

The part concerning the applications used is divided into four groups:

A1, B1 – Application for personal IT – office software; antivirus; compression software.

A2, B2 – IT support for key processes in your organization (production, storage, logistics, billing, human resources, inventory, accounting, purchase and sale, etc.).

A3, B3 – Information technology at the tactical management level (MIS – an economic software, using data provided by systems at the operational management level).

A4, B4 - Comprehensive BI solution.

For these four types of applications, intensity of use in the present is examined (variables **A1-A4)**, as well as the assumption of utilizing these applications in the future (variables **B1-B4).**

The first part of the analysis is focused on distributing the relative frequencies of using ICT tools in SMEs in the Czech-Polish border area in the second half of 2012 in %. The results are shown in Table 1.

In the Czech border area, the first level is used the most (L1) – Simple Office ICT tools with 97%, followed by the second level supporting the management of the sub-processes (L2) in 93% of the SMEs. The third level - Comprehensive ICT tools of MIS System (L3) are used only in 62% of companies and BI ICT (L4) are supported in 42% of SMEs. In the Polish border area, ICT tools of L1/L2/L3/L4 levels are used in 97% / 93% / 56% / 28% of SMEs. The first two levels are comparable between regions, but the use of integrated MIS and BI are in the Czech border area significantly higher by about 6% and 14%.

In terms of future development in ICT tools used in both border areas, the use of Simple Office ICT tools assumes the same level, but in the case of ICT tools for the sub-process analysis in SMEs there is stagnation in the Polish region and a slightly increase of 3% is expected in Czech SMEs. On the other hand, it is beneficial planned to increase of ICT using for L3 (a comprehensive MIS) by 10.2% and 5.6% in the Czech and Polish SMEs, respectively. This trend is also detected for of BI tools (by 18.4% in the Czech SMEs and only by 8.3% in the Polish SMEs).

The above results show a considerable interest in and expansion of the use of BI applications.

Another issue of interest includes part E of the questionnaire "What are your preferences in software procurement?". This section offers the respondents four answers, as shown in Figure 2. Out of 96% of valid responses on the Czech side and 56% of valid responses on the Polish side, the evaluation was carried out for the entire region, as well as separately for the Czech and Polish sides.

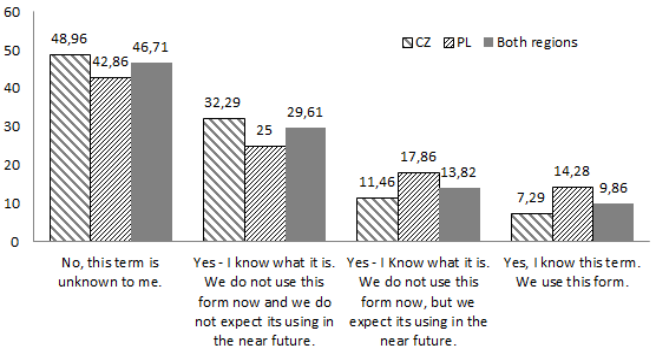

Fig. 2 Empirical distribution of the knowledge of the cloud technologies

The questionnaires about confirmed the expected lack of awareness of managers of what Cloud Computing (CC) is to offer. The correlation between the company size and the

knowledge of the term CC is a weak, blat statistically significant.

IV. Business Intelligence Tools And Competitive Intelligence, Cloud Computing

BI is system of tools, design solutions and organizational measures to enable the organizational management based on knowledge. These tools have been increasingly applied in companies worldwide. They are specifically aimed at supporting the needs of managers. They form a part of the overall company IS that works with selected or modified data, and that uses these modifications to become the bearer of comprehensive information characterizing the relevant processes in the company. Primarily, they are used to identify and locate specific phenomena in the company, and subsequently to perform their in-depth analysis. An area of BI consists of a number of separate components, with its own architecture and methodology [4].

Many case studies confirm that BI may be utilized in an organization for:

- Increasing the effectiveness of strategic, tactic and operational planning including: modelling different variants in the development of an organization; informing about the realization of enterprise's strategy, mission, goals and tasks; trends, results of introduced changes and realization of plans; identifying problems to be tackled; providing analyses of products, employees, regions; providing analyses of deviations from the realization of plans for particular organizational units or individuals;
- Creating or improving relations with customers, mainly: adequate knowledge about customers for sales representatives so that they could promptly meet their customers' needs and identifying market trends;
- Analyzing and improving business processes and operational efficiency of an organization.
- Providing knowledge and experience which emerged while developing and launching new products onto the market; providing knowledge on particular business processes. [5].

The BI applications use the "OLAP" (On-Line Analytical Processing) technology and Data Mining for advanced analyses. Data Mining allows searching of correlations in large volumes of data, which were not known in advance. The ultimate goal is to provide readable, well-organized, analyzable and readily available information from the maximum number of corporate databases and external sources, which can be utilized in the management [6].

CI represents a set of following activities: definition, collection, analysis and distribution of information and knowledge about clients, competitors and other aspects of the external environment surrounding the organization. These activities are carried out in order to reduce the risk of threats from external business environment, mapping potential opportunities and reaching competitive position.

If we ask ourselves the question what difference there is between CI and BI, the correct answer is that the difference is not very significant. The basis for this assertion is the understanding of the meaning of "intelligence" as the ability to use knowledge assets in action. In our case, these actions relate to the strategic management of an organization.

Thus, the CI only represents another development step, introducing into management sophisticated working methods in connection with the development of advanced technologies for contextual search in external information sources throughout the Internet.

CC is sharing HW and SW means via networks, changing the traditional IT processes and business models. It allows a more efficient use of computing and other data center sources and service providers and brings users to meet their requirements for the speed of the deployment of services, their quality and availability at a transparent price [4]. As already stated above, CC is based on virtualization. Storage, servers, applications and desktops are separated from the actual physical information infrastructure of the business. Virtualization enables greater efficiency and flexibility of IT while reducing IT costs. CC also brings benefits and risks. Benefits of CC:

- The applications or services are provided from centralized data centers through a network, thereby eliminating the software management on each PC.
- Users are not required to know the technology, nor manage its operation on their own. Access to applications and data located on a server is facilitated through a web browser (SaaS - Software as a Service).
- HW can also be provided as a service (IaaS - Infrastructure as a Service). The same applies to the computing platform (PaaS - Platform as a Service).
- Dynamically scalable resources and elasticity.
- Reducing financial costs; the provider supplies the product to multiple users (multitenancy).
- CC changes ICT to a service. Computing power becomes a commodity that we buy and scale as needed.

Limiting factors of CC:

- A possible risk of failing to maintain permanent operation of IT via the Internet – reliability.
- Increased costs for the transfer of large volumes of data.
- Concerns about the security of sensitive data and data in general.
- Lack of control over one's own data, valuable data located off the company.
- Problems with managing permissions and roles with growing company portfolio of CC applications.

A very important contribution of CC for the customer is the transfer of risk and responsibility to the service provider. The supplier is responsible for implementation, audit, security, monitoring, necessary capacity plan, maintenance and support, as well as for availability management.

By using the CC, one can solve the problem of SMEs - lack of availability of many ICT due to their prices and the required infrastructure. In the current economic situation,

CC offers SMEs a viable solution to secure access to the necessary technologies [7].

Currently, CC services offer on-line provision of virtually all software products that can be virtualized into the cloud.

Users no longer have to worry about the management of applications, servers and computer networks and can focus on selecting the range and quality of services purchased from the provider, measuring their use and the prices they pay.

V. Conclusion

A company's global strategy is currently an active strategy. Its quality is dependent on the support of the existing IS. If the IS/IT are well designed and used, they may affect the company's competitiveness. The goal is an interconnection between the development of the information system and the global strategies of a company or an institution [8].

The ICT has become a necessary tool for enterprises, public administration and citizens in most countries. Good strategic management of companies and institutions is conditional upon continuous IS management and maintaining its integrity.

In EU-25, there are approximately 23 million SMEs, representing 99% of all EU companies and providing jobs to approximately 75 million people [9].

The significant role of SMEs is certainly beyond any doubt. It is the ability to respond quickly to changing conditions or absorb free labor that is seen as irreplaceable. SMEs struggle to gain access to capital. This problem persists despite the fact that commercial banks in recent years show a growing interest in these otherwise risky clients that mostly want relatively small loans. The above suggests that capital-intensive investment in ICT is often not a priority for the management of these companies [10].

Changes in company strategy and processes require changes in hardware, software, data storage sites and telecommunication equipment. The quality of business processes is often dependent on the capabilities and features provided by company IS.

Sufficient amount of information nowadays becomes the key factor for success in all fields of human activity. However, obtaining information as such is not enough; they must meet certain parameters. Valuable, meaningful piece of information is one which is provided at the right time and the right place, which it is relevant, correct, complete, and meeting many other requirements.

Projections suggest that in the next decade, we should expect a very rapid development in conventional as well as unconventional approaches to IT and information processing. Possible results are not attractive only in terms of technology, but they can significantly contribute to cost savings and increased productivity in all areas of business and management [11].

Acknowledgment

The results in the paper are based on findings of a research Fund of microprojects Euroregion Silesia, project CZ.3.22/3.3.04/12.02994 (BENEFIT 7) and the European Social Fund within the project CZ.1.07/2.3.00/20.0296.

Implementation of the Big Data concept in organizations – possibilities, impediments and challenges

Janusz Wielki
Opole University of Technology
ul. Waryńskiego 4, 45-047 Opole,
Poland
Email: Janusz@Wielki.pl

***Abstract*—This paper is devoted to the analysis of the Big Data phenomenon. It is composed of seven parts. In the first, the growing role of data and information and their rapid increase in the new socio-economical reality, are discussed. Next, the notion of Big Data is defined and the main sources of growth of data are characterized. In the following part of the paper the most significant possibilities linked with Big Data are presented and discussed. The next part is devoted to the characterization of tools, techniques and the most useful data in the context of Big Data initiatives. In the following part of the paper the success factors of Big Data initiatives are analyzed, followed by an analysis of the most important problems and challenges connected with Big Data. In the final part of the paper, the most significant conclusions and suggestions are offered.**

I. Introduction

INCREASING amounts of data are streaming into contemporary organizations as a result of the rapidly growing quantity of data being generated not only by the organizations themselves but also in the organizations' business environments by both their stakeholders and other entities operating there. Thus, it is in this context that such expressions as "a data-centric world" have become more and more common [1].

The above mentioned processes are significant elements of the socio-economical changes taking place worldwide, where the extremely dynamic development of increasingly powerful and pervasive information technology has an important role to play. Advancements in this field have been a significant catalyst for the transformation of the contemporary economy and the emergence of an "interconnected economy". This new type of economy, in the resource dimension, is a knowledge-based economy, where the most meaningful form of capital is intellectual capital [2]. Under these conditions, from an organization's point of view, the ability to collect the right data and information and to transform it effectively into useful knowledge becomes an increasingly important issue.

Recently, the field of information technology has begun to enter into a new era, as a result of the intensification of the progress being made there. It is an era where processing power and data storage have become virtually free, while networks and cloud-based solutions provide users with global access and pervasive services. As a result of these processes, Big Data sets are being generated which have grown exponentially in size [3]. In 2012, about 2.5 exabytes of data were created every day, with this amount doubling about every forty months [4]. Generally, 90% of the global data in existence has been created over the last two years [5].

As a result, the amount of data and information available for organizations for analysis is exploding [4]. This provides organizations with completely new operating possibilities, while simultaneously generating numerous new challenges. In this context the term "Big Data" has emerged and is being used more and more commonly in the business world.

II. Big Data and the Most Important Sources of the Growth of Data

The term Big Data is not universally understood and applied, leading to various approaches to analyzing it. According to the Leadership Council for Information Advantage, this term is not precise "(…) it's a characterization of the never-ending accumulation of all kinds of data, most of it unstructured. It describes data sets that are growing exponentially and that are too large, too raw or too unstructured for analysis using relational database techniques" [6]. On the other hand, NewVantage Partners describes Big Data as "a term used to describe data sets so large, so complex or that require such rapid processing (sometimes called the Volume/Variety/Velocity problem), that they become difficult or impossible to work with using standard database management or analytical tools" [8]. It is important to underline that Big Data not only relates to the storage and consumption of original content but also to the data connected with this consumption [9].

Generally, there have been some significant trends that have caused a considerable increase in data generation [7]. The first trend, the growth in traditional transactional databases is chiefly connected with the fact that organizations are collecting data with greater granularity and frequency. This is due to various reasons such as the increasing level of competition, increasing turbulence in the business environment and the growing expectations of customers. All of these factors require organizations to react rapidly and with maximum flexibility to the changes taking place and then adjust to them. In order to be able to do this, they are forced to conduct more and more detailed analysis concerning marketplaces, competition and the behavior of consumers [7].

The second trend, the increase of multimedia content, is connected with the rapid increase in the use of multimedia in the various industries of the contemporary economy, such as the health care sector where over 95 % of the clinical data

978-83-60810-53-8/$25.00

generated is in video format. Generally, multimedia data already accounts for over half of Internet backbone traffic and it is predicted that this share will grow to 70% by the end of 2013 [7].

The next trend which has caused a growth in the amount of data being generated is the development of the phenomenon called "The Internet of Things", where the number of physical objects or devices that communicate with each other without any human interference is increasing at a fast pace. They link with each other in a wired or wireless manner, often using IP protocols. As they are equipped with various sensors or actuators they collect and send huge amounts of data [10]. By 2015 the amount of data generated from the 'Internet of Things' will grow exponentially as the number of connected nodes deployed in the world is expected to grow at a rate of over 30% per year [7].

Social media is the next extremely significant source of the increase of data. Facebook users alone generate huge amounts of data. In 2011 the 600 million active users of this social platform spent over 9.3 billion hours a month on the site, with the average Facebook user generating 90 pieces of content (photos, notes, blog posts, links, or news stories) [7]. A year later the number of Facebook users reached 1 billion. Research conducted at the beginning of 2012 showed that if only messages are considered, users receive an average of nearly twelve messages a month, and send nine [11]. In the case of YouTube, every minute 24 hours of video is uploaded, while over the same timeframe Twitter users send 98000 tweets [7], [12]. In addition, smart phones are playing an increasingly important role in social networks. Although the penetration of social networks is increasing for both PCs and smartphones, it is significantly higher for smartphones. If frequent users are considered in the case of PC's it is 11% p.a. while in the case of smartphones it is 28% p.a [7]. This has caused a rapid increase in mobile data traffic which doubled between the third quarter of 2011 and the third quarter of 2012. It is predicted that mobile data traffic will grow twelve fold by 2018 [13].

III. Opportunities and Benefits Connected With Big Data Utilization

The development of the Big Data phenomenon and its associated tools and techniques, is not something which has been separated from the wider processes which have been taking place in organizations over recent years. In fact, it is becoming more and more common in organizations concerned with the field of analytics and has significantly expanded the possibilities available within the scope of business intelligence (BI) tools.

Given their role in providing organizations with numerous possibilities and opportunities in the sphere of analytics, business intelligence systems are well suited for aggregating and analyzing structured data [14]. But there are, however, some types of analyses that BI can not handle. These mainly relate to situations where data sets become increasingly diverse, more granular, real-time and iterative.

Such types of unstructured, high volume, fast-changing data, pose problems when trying to apply traditional approaches based on relational database models. As a result, it has become apparent that there is growing demand for a new class of technologies and analytical methods [6].

There are many diverse benefits arising from the utilization of Big Data, depending on the sector of the economy, as has been confirmed by the results of research conducted by the McKinsey Global Institute. These results show the transformational potential of Big Data in such diverse domains as health care, public sector administration, retail, manufacturing and personal location data [7]. According to the results of a survey conducted in summer 2012 by NewVantage Partners, among C-level executives and function heads from many of America's leading companies, there are seven basic groups of benefits connected with Big Data initiatives. Better, fact-based decision making (22%) and an improved customer experience (22%) are the most important of these benefits, coupled with the overall message that the expectation is to make better decisions faster. The other groups of benefits include: increased sales (15%), new product innovations (11%), reduced risk (11%), more efficient operations (10%) and higher quality products and services (10%) [15].

Organizations use Big Data platforms to give them answers to important questions in seconds rather than months. Thus, the key value of Big Data is to accelerate the time-to-answer period, allowing an increase in the pace of decision-making at both the operational and tactical levels [14], [15]. An extremely important new element, in the context of decision-making, connected with the Big Data phenomenon, is the possibility for constant business experimentation to guide decisions and test new products, business models, and customer-oriented innovations. Such an approach even allows, in some cases, for decision making in real-time. There are many examples of companies using this in practice. For example multifunctional teams in Capital One perform over 65,000 tests each year. They experiment with combinations of market segments and new products. The online grocer FreshDirect adjusts, on a daily basis or even more frequently, prices and promotions based on online data feeds. Tesco is another example. This company gathers transaction data on its millions of customers through a loyalty card program and uses it to analyze new business opportunities. For example, it looks at how to create the most effective promotions for specific customer segments and how to inform them about decisions concerning pricing, promotions, and shelf allocation [17]. Walmart is another example. This company created the Big Data platform (The Online Marketing Platform) which is used, among other things, to run many parallel experiments to test new data models [16]. Also such dot-com giants as Amazon, eBay and Google have been using testing in order to drive their performance [17].

According to the McKinsey Global Institute, five key ways in which Big Data creates value for organizations can be distinguished [7]:

- creating transparency by integrating data and making it more easily accessible to all relevant stakeholders,
- enabling experimentation to discover needs, expose variability, and improve performance,

- segmenting populations in order to customize actions,
- replacing or supporting human decision making with automated algorithms,
- innovating new business models, products and services.

Generally, the results of the research conducted in February 2012 among 607 executives from around the world by the Economist Intelligence Unit confirm the value of Big Data utilization by companies. The surveyed executives claim that Big Data initiatives have improved the performance of their organizations over the past three years by around 26%. Simultaneously they expect that such initiatives will improve performance by an average of 41% over the next three years [18]. In addition, it is worth noticing that according to the results of the research of Brynjolfsson et al., firms where decision making is based on data and business analytics have 5-6% higher output and productivity. Decision making based on data and business analytics also impacts on other performance measures such as asset utilization, equity return and market value [18].

As in the case of BI initiatives Big Data systems have been used for two purposes - human decision support and decision automation. According to the results of the above mentioned research conducted by the Economist Intelligence Unit, Big Data is used, on average, for decision support 58% of the time and for decision automation around 29% of the time, based on the level of risk connected with the decision [14].

IV. Tools, Techniques and the Most Useful Data in the Context of Big Data Initiatives

The effective implementation of Big Data initiatives requires an undertaking of appropriate organizational actions, including ensuring organizations are provided with all the necessary resources to enable analysis of the ever-growing data sets to which they have access. In this context, the application of proper techniques and technologies is one of the key issues. In practice, organizations use many various techniques and technologies to aggregate, manipulate, analyze, and visualize Big Data. They come from various fields such as statistics, computer science, applied mathematics, and economics. Some of them have been developed intentionally and some of them have been adapted for this purpose. Examples of techniques utilized for the analysis of Big Data are: A/B testing, data fusion and data integration, data mining, machine learning, predictive modeling, sentiment analysis, spatial analysis, simulation or time series analysis. Examples of technologies used to aggregate, manipulate, manage, and analyze of Big Data are: Big Table, Cassandra, Google File System, Hadoop, Hbase, MapReduce, stream processing, visualization (tag cloud, clustergram, history flow, spatial information flow) [7].

Increasingly, there are a number of new analytical toolkits for the analysis of Big Data. Examples of such solutions are [19]:

- Alterian, TweetReach (network intelligence tools for real-time analysis of the reactions and responses to changes of industry players),
- NM Incite, Social Mention, SocMetrics, Traackr, Tweepi (sentiment analysis tools for estimating the buzz around a product or service, influencer intelligence tools for identifying key influencers and targeting for marketing or insights),
- Attensity, Autonomy (live testing tools for getting direct feedback from users on new products or ideas, data mining tools for text-analytics to estimate market size).

In addition, a very important element of Big Data initiatives is properly trained people. In this context, a specific type of worker is indicated, known as data scientists, who are properly trained to work with Big Data. In practice, it means that they should be people who know how to discover the answers to an organization's key questions from huge collections of unstructured data. These people should be a hybrid of analyst, data hacker, communicator and trusted advisor [20]. In addition to analytical abilities and substantial and creative IT skills, they should be close to the products and processes inside the organization [21]. As the acquisition of in-depth domain knowledge from data scientists typically takes years [14], most organizations build platforms to close the gap between the people who make decisions and data scientists, such as that created by Walmart - the Social Genome Platform. It facilitates cooperation among buyers, merchandisers, product managers and other people who have worked in retail for years and data scientists [22].

In addition to proper techniques, tools and people, the basic resource required for Big Data initiatives is appropriate data. As was mentioned earlier, a lot of data from various sources is currently flowing into contemporary organizations but not all Big Data sets are equally valuable,. Business activity data such as sales, purchases, costs etc. is definitely the most important source of data. Office documentation is the second key source of data, closely followed by social media. In certain sectors such as healthcare, pharmaceutical, and biotechnology, data sets from social media are more important that those from office documentation. The other important types of data sets include: point-of-sale data, Website clickstream data, RFID/logistics data, geospatial data, telecommunications data, telemetry data [18].

V. Success Factors of Big Data Initiatives

Through an analysis of implemented Big Data initiatives, various success factors can be determined, each with their own set of recommendations.Marchand and Peppard have identified five important guidelines for the success of a Big Data project. They include [24]:

1. Placing people at the heart of the Big Data initiative.
2. Emphasizing information utilization as the way to unlock value from information technology.

3. Equipping IT project teams with cognitive and behavioral scientists.
4. Focusing on learning.
5. Worrying more about solving business problems than about deploying technology.

Based on their experiences gained from cooperation with companies from data rich industries, Barton and Court, on the other hand, came to the conclusion that full exploitation of data and analytics requires three capabilities [25]:

1. Choosing the right data. In this context two aspects are important: creative sourcing of internal and external data and upgrading IT architecture and infrastructure for easy data merging.
2. Emphasizing information utilization as the way to unlock value from information technology. In this context two aspects are important: focusing on the biggest drivers of performance and building models that balance complexity with ease of use.
3. Equipping IT project teams with cognitive and behavioral scientists. In this context two aspects are important: creating simple, understandable tools for people on the front lines and updating business processes and developing capabilities to enable tools utilization.

According to Barth et al., organizations that benefit from Big Data base their activities on three fundamental issues [21]:

1. Paying attention to data flow as opposed to stocks.
2. Relying on data scientists and product and process developers rather than data analysts.
3. Moving analytics away from the IT function, into core business, with operational and production functions.

VI. The most significant obstacles and challenges connected with Big Data eferences

As with other IT-related initiatives, Big Data also has its own set of problems and challenges. The Economic Intelligence Unit research mentioned earlier indicates some of the impediments to the effective utilization of Big Data for decision-making [14]. "Organizational silos" were the most significant barrier (55,7%), which result from the fact that data connected with particular organizational functions (i.e. sales, distribution etc.) are collected in "function silos" rather than pooled for the benefit of the entire company. The second (50,6%), although no less important, issue is the lack of appropriately skilled people (data scientists) prepared to analyze data. The third aspect (43,7%) is the excessively long time it takes organizations to analyze huge data sets. As was mentioned earlier, organizations expect to be able to analyze and act on data in real time. The fourth barrier (41,7%) is the difficulties concerned with the analysis of ever increasing amounts of unstructured data. Finally, the inability of senior management to view Big Data in a sufficiently strategic way (34,9%) is the fifth key impediment [14].

McAfee and Brynjolfsson indicate five management challenges which prevent organizations from reaping the full benefits of Big Data utilization. They are: leadership, talent management, technology, decision making, company culture.

When considering leadership, having more or better data does not guarantee success. The leaders still have to have a vision of the organization's development, set clear goals, understand the market, etc. Big Data changes the way organizations make many of their decisions. Talent management is connected with the necessity of providing the organization with the right people (such as data scientists) who are prepared to work with huge sets of data. The next challenge relates to the problem of assuring the data scientists have the proper tools to handle the Big Data. Although the technology alone is not enough to succeed in Big Data initiatives, it is a necessary part of it. The next challenge is connected with the problem of ensuring there are mechanisms in place to guarantee that the information and the relevant decision-makers are in the same location. It is important to make sure that the people who understand the problems are able to use the right data and to work with people who have the necessary problem solving skills.

The final challenge is connected with changes related to organizational culture. The key issue in this context is to make decisions as data-driven as possible, instead of basing them on hunches and instinct [4]. It is worth mentioning that the significance of such cultural transformation is also mentioned in other research e.g. that concerning sectoral Big Data projects [23].

In addition, the numerous challenges connected with data and legal rights should be noted. They relate to such issues as copyright, database rights, confidentiality, trade marks, contract law, competition law [1]. There is another important challenge also connected with legal aspects. It relates to the transparency in data collection practices. A further important risk is around the utilization of Big Data to increase the automation of decision-making. There is one more important danger which is underlined in the context of Big Data. It is connected with the fact that Big Data might not be providing the whole picture for a particular situation. There are several reasons for this i.e. biases in data collection, exclusions or gaps in data signals or the constant need for context in conclusions [26].

At the same time, existing pre-Big Data challenges and threats are still developing, such as the problem of securing collected data and information. These issues chiefly relate to the problem of how to protect competitively sensitive data and data that should be kept private by organizations (e.g. various types of consumer data) [7]. As a result, the problems connected with the broadly defined security of the IT infrastructure of organizations and protection against various attacks becomes an even more important issue than previously [27]. The increasing dependence, as a result of the Big Data phenomenon, of organizations on the efficient and reliable functioning of their IT infrastructure, means that securing it has become even more important.

VII. Conclusions

The rapidly growing amount of data which organizations have at their disposal and the opportunities connected with its practical utilization are increasingly changing the processes relating to making decisions at various organizational

levels. Thus, Big Data offers huge potential to positively impact on the functioning of organizations generally and gives them a competitive advantage. Companies are now trying to utilize to an even greater degree the opportunities and chances that are emerging.

But if initiatives aimed at the practical usage of Big Data sets are to be successful at giving an organization a competitive advantage and be of value, it is not enough to just collect and own the appropriate data sets. In fact, this is only the starting point of every Big Data initiative. Further essential elements are suitable analytical models, tools, skilled people, and organizational capabilities. Lack of all of these necessary components can lead to a situation whereby instead of expected benefits there is only disappointment and a belief that Big Data initiatives are only the next wave in a long line of management fads.

Generally, although Big Data solutions have a huge potential for both commercial organizations and governments, there is uncertainty concerning the speed with which they can be utilized in a secure and useful way [3].

Agent Day 2013

DURING the last decade agent systems have been constantly developed and many approaches were successful in such areas as transport, decision support, distributed monitoring and control systems, computation. Such immanent features of the agents like autonomy or task-orientation assured the result. These (and others) features of the agent systems may be further extended to produce new paradigms for constructing scalable computing systems with focus on grid computing, cloud computing, resilient control and monitoring systems, SCADA and many more.

It is also worth noticing, that hardware available several years ago, such as computing clusters, are nowadays outperformed by simple desktop sets or even portable computers. Even environment appliances such as gaming consoles or GPUs may be used to perform complex computations in parallel, much faster than even multi-core CPUs. Such a plethora of possibilities calls for promotion and dissemination of results and ideas connected or inspired by agent-based systems or their features.

Topics

For the "Agent Day" Session we would like to give guidance in the subject, as the following topics, that do not exhaust all the possibilities:

- multi-agent management, scheduling, load-balancing
- multi-agent computation and simulation
- stochastic and structural modeling of complex systems
- distributed and grid computing
- software reuse in complex systems
- GPU and gaming consoles for computing
- nature-inspired, evolutionary and memetic computing
- scalability, extendability, resilience in complex systems
- mobile robotics
- data-intensive computing
- various application of multi-agent systems

***Abstract*—Context-aware mobile systems have gained a remarkable popularity in recent years. Mobile devices are equipped with a variety of sensors and become computationally powerful, which allows for real-time fusion and processing of data gathered by them. However, most of existing frameworks for context-aware systems, are usually dedicated to static, centralized architectures, and those that were designed for mobile devices, focus mainly on limited resources in terms of CPU and memory, which in nowadays world is no longer a big issue. Mobile platforms require from the context modelling language and inference engine to be simple and lightweight, but on the other hand – to be powerful enough to allow not only solving simple context identification tasks but also more complex reasoning. These, with combination of a large number of sensors and CPU power available on mobile devices result in high energy consumption of a system. The original contribution of this paper is a proposal of an intelligent middleware for mobile context-aware frameworks, that is able to learn sensor usage habits, and minimize energy consumption of the system.**

I. Introduction

RESEARCH in the area of pervasive computing and ambient intelligence aims to make use of context information to allow devices or applications behave in a context-aware, thus "intelligent" way. Dey [1] defines context as *"any information that can be used to characterize the situation of an entity*. The *information* in Dey's definition may be: (1) location of the user (spatial context), (2) presence or absence of other devices and users nearby, or collaboration with other users (social context), (3) time (temporal context), (4) user *behavior* or *activity*, and possibly (5) any other environmental data gathered by microphones, light sensors, etc.

The variety of sensors available on nowadays mobile devices allow for complex contex-based reasoning, but at the same time requires a lot of resources and energy.

Although there are many frameworks and middlewares developed for context-aware systems [2], [3], [4], they do not provide full support for all of the challenges that we believe are crucial for mobile computing (e.g. smartphones or tablets), with respect to the context modelling and context-based reasoning. Those are:

Energy efficiency – most of the sensors, when turned on all the time, decrease the mobile device battery level very fast. This reflects on usability of the system and ecological aspects regarding energy saving.

Data privacy – most of the users do not want to send information about their location, activities, and other private data to external servers. Hence, the context reasoning should be performed by the mobile device itself.

Resource limitations – although mobile phones and tablets are becoming computationally powerful, the context aware system has to consume as low CPU and memory resources as possible in order to be transparent to the user and other applications.

System responsiveness – in mobile environment context changes very fast. Hence, no delays are admissible in processing contextual data.

Context data distribution – in mobile pervasive environments many devices produces huge amount of contextual information, hence the quality measures should be developed and distribution methods designed to fit characteristics of such unstable and dynamic network [5].

All of these require from the modelling language and inference engine to be simple and lightweight. On the other hand, the model should be powerful enough to allow not only solving simple context identification tasks but also more advanced context processing and reasoning.

This gives motivation for developing a solution that will allow for using advanced reasoning and modelling techniques, with as low energy cost as possible. The original contribution of the paper is a proposal of an intelligent middleware for mobile context aware frameworks, that is able to learn sensor usage habits, and minimize energy consumption of the system.

The rest of the article is organized as follows: In Section II an existing context aware systems and frameworks are presented, and the motivation of the paper is given. The architecture that can be used in combination with our approach is presented in Section III. The Section IV discusses the learning algorithm used for intelligent middleware and Section V presents an evaluation of the algorithm. Finally, summary and directions for future work are given in Section VI.

II. State of the art and motivation

In recent years, a lot of development was devoted to build applications that use mobile devices to monitor and analyse various user contexts. The availability of application distribution platforms for common mobile operating systems, e.g. Google Play for Android stimulated the popularity and adoption of such solutions. However, most of them focus only on a very narrow application area of context awareness. Most of them are end user applications, and not more generic

978-83-60810-53-8/$25.00

frameworks. Some selected representative cases are briefly described below.

A. Context aware systems

The SocialCircuits platform [6] uses mobile phones to measure social ties between individuals, and uses long- and short-term surveys to measure the shifts in individual habits, opinions, health, and friendships influenced by these ties.

Jung [7] focused on discovering social relationships (e.g., family, friends, colleagues and so on) between people. He proposed an interactive approach to build meaningful social networks by interacting with human experts, and applied the proposed system to discover the social networks between mobile users by collecting a dataset from about two millions of users. Given a certain social relation (e.g., isFatherOf), the system can evaluate a set of conditions (which are represented as propositional axioms) asserted from the human experts, and show them a social network resulted from data mining tools.

Sociometric badge [8] has been designed to identify human activity patterns, analyse conversational prosody features and wirelessly communicate with radio base-stations and mobile phones. Sensor data from the badges has been used in various organizational contexts to automatically predict employee's self-assessment of job satisfaction and quality of interactions.

Eagle and Pentland [9] used mobile phone Bluetooth transceivers, phone communication logs and cellular tower identifiers to identify the social network structure, recognize social patterns in daily user activity, infer relationships, identify socially significant locations and model organizational rhythms.

Beside research projects, there exist also a variety of application that are used for gathering information about context from mobile devices, like SDCF [10], AWARE [1], JCAF [11], SCOUT [12], ContextDriod [13], Gimbal [2]. These are mostly concerned with low-level context data acquisition from sensors, suitable for further context identification. On the other hand, they do not provide support nor methodology for creating complex and fully customizable context-aware systems and do not provide any mechanisms for limiting energy consumption of the system.

What is more, all of the approaches described above use their own dedicated methods for gathering and maintaining context. These methods are mostly not applicable for reuse, or their functionality is limited to simple context matching. Some of the systems do not provide any support for context modelling nor context reasoning, limiting their functionality only to identifying and collecting contextual information.

B. Context aware frameworks

To solve the issue of reusability of the system, a lot of frameworks were designed. These frameworks are based on many different architecture paradigms which pros and cons in terms of energy efficiency, responsiveness, and privacy were presented in this Section.

[1]http://www.awareframework.com
[2]https://www.gimbal.com/

The system described in [14] uses *direct sensor access* architecture which is usually not very energy efficient, however it preserver privacy issues, since no communication with external servers is usually needed, and the interpretation of the sensor data as well as reasoning is performed directly on the host device

The CoBrA system [15] was build on *centralized context server* architecture. This approach is especially useful when a context-aware system is composed of many mobile devices with limited resources. The server relieves mobile agents from performing reasoning tasks. On the other hand, one has to consider privacy issues connected with sending private contextual data to remote server, quality of service issues, etc. This approach is also characterized with rather low responsiveness that stems from a possible lack of network connection or communication delays.

Service oriented architecture with combination of *distributed architecture* was used in SOCAM [16] system. In context-aware applications this architecture is used mainly in pervasive environment, where variety of context information from many different sources has to be processed. This architecture usually does not preserves privacy nor energy efficiency issues since usually it assumes communication over the web between each of its elements. Although SOCAM provides architecture for distributed mobile systems, it mostly solves problems of a low memory and CPU power of mobile agents, which nowadays is no longer a big issue for most of the mobile devices like smart-phones or tablets. On the other hand, energy efficiency issue is still a big problem, which was not addressed by none of the solutions described in this Section.

This gives motivation for developing an architecture that will allow for advanced context-based reasoning and modelling, but at the same time allow for minimizing energy usage costs of sensors that are needed in such reasoning. An overview of the proposed system is presented in following Section.

III. Intelligent middleware approach

The proposed solution incorporates an idea of a mobile device as an autonomous context-aware entity, equipped with intelligent middleware layer and context-based inference layer. The intelligent middleware act as a proxy between context sources and inference layer. It is able to learn sensor usage patterns and thus adjusting sampling rates to significantly improve energy consumption of the system (See Section IV).

The architecture of a system that may use intelligent middleware approach should consist of three main elements:

1) sensors layer – responsible for gathering data from sensors and performing initial preprocessing of them,
2) inference layer – responsible for context based reasoning and knowledge management, and
3) intelligent middleware layer – acting as an intelligent proxy between sensors layer and the inference layer.

The *Sensor Layer* gathers data directly from mobile device sensors. Due to the different possible sensor types (GPS, Accelerometer, Bluetooth), different methods for interpreting

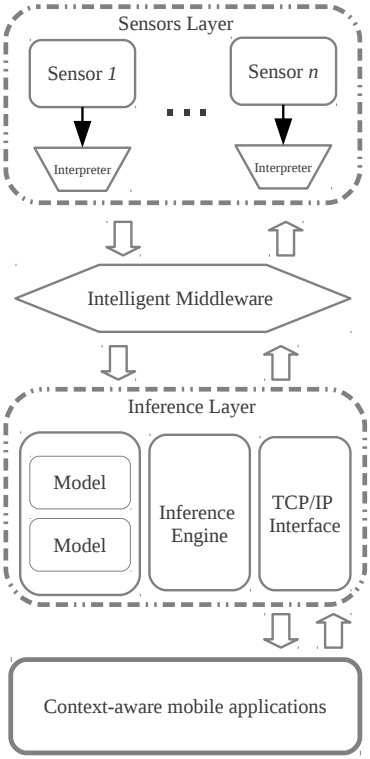

Figure 1. Architecture of the mobile context aware framework

these data are required. Hence, each sensor has its own interpreter module that is responsible for initial preprocessing of the raw data. Data preprocessing is triggered by the intelligent middleware.

The *Inference Layer* is responsible for performing reasoning, based on the model (knowledge base) and the working memory elements (facts). The inference engine may be a rule engine, first-order logic reasoner, probabilistic inference module, or any other custom approach. However, we argue, that to allow more complex reasoning tasks than just simple context classification, the best choice is lightweight rule engine [17].

The *Intelligent Middleware* is responsible for exchanging information between sensors layer and inference layer. The working memory is shared between all models stored within the inference layer, acting as a *knowledge cache*. Therefore, it minimizes the number of required requests to the sensors layer, improving power efficiency of the entire system.

The idea of separating Intelligent Middleware from inference layer is that it is able to learn sensors usage habits, and in consequence adapt itself to the individual device characteristics. It automatically generates a model of usage habits from historical data and based on that model data it adjusts the sampling rates for the sensors appropriately. It improves power efficiency of the system, since sampling rates are not fixed, but leaned from the usage patterns. On the other hand it may help in increasing responsiveness of the system, since the learned model allows predicting not only future sensor activity, but also context-aware application needs. Hence, it is possible to get the desired context in advance, before the application actually requests it. It can be especially useful in cases when context cannot be obtained by the middleware directly from the sensor layer, but has to be for example downloaded over the internet. However in this paper we focus only on the power efficiency advantage of the usage of the intelligent middleware approach.

The following sections describes in details the learning algorithm used, and provide an evaluation on a simple use case scenario.

IV. Learning algorithm

Input data. The algorithm takes as an input a vector of m percepts. Each percept is described by a pair (X_i, Y_i) interpreted respectively as time of percept and sensor activity state. Such a notation results in two vectors X, Y of size m such that $\forall_{i<m} 0 \leq X_i \leq 24 \wedge (Y_i = -1 \vee Y_i = 1)$. Time equals numbers of hours passed since last midnight and percept is:

$$Y_i = \{^{-1\ for\ inactive\ state}_{1\ for\ active\ state}$$

Learning objective. Sensor activity depends largely on its stochastic and inaccessible environment. Being so, it is impossible to predict it with absolute certainty, however, often some part of its variance can be explained by time of a day. The algorithm proposed aims to exploit that possibility by finding a function determining probability of sensor usage given time of a day $F(t) = P(X = 1|t)$. Problems of learning conditional probability are often addressed in Machine Learning by using logistic regression. The following paragraphs define necessary concepts and present the problem in terms of logistic regression with accordingly chosen parameters.

Hypotheses set. Finding objective function $F(t)$ is achieved by searching a hypotheses set H. Each function h in hypotheses set has to have the following properties:

1) be continuous,
2) be defined in range $< 0; 24 >$,
3) $h(0) = h(24)$,
4) return values in range $< 0; 1 >$ (probability).

To perform search it is necessary to represent each function in H in a general form parametrized by some vector w of length $2n+1$, such that every combination of parameters in w will yield in a proper hypothesis $h = H_w$. Such representation allows to transition from searching a set of functions to searching a linear space $\mathbb{R}^{2n+1}$.

A representation that has the first three of required properties is given below:

$$S(\omega, t) = \omega_0 + \sum_{i=0}^{n-1} \left(\omega_{2i+1} \cos\left(\frac{i * t * 12}{\Pi} \right) \right) + \sum_{i=0}^{n-1} \left(\omega_{2i+2} \sin\left(\frac{i * t * 12}{\Pi} \right) \right)$$

It may be understood as a sum of some first terms of Trigonometric Fourier Series parametrized by vector ω. Using only low frequency components is desirable because they are

most likely to describe habits of usage that usually occurs in long sequences of same actions. The only requirement left, that is – unbound return values, can be addressed by composing function $S(\omega, t)$ with sigmoid function:

$$\theta(x) = \frac{1}{1 + e^{-x}}$$

The resulting and correct hypotheses set parametrized by vector w is given by formula:

$$H_\omega(t) = \theta(S(\omega, t))$$

Interpreting hypothesis as probability

Assumed interpretation that $P(y = 1|x) = h(x)$ implies that $P(y = -1|x) = 1 - h(x)$. Because $h(x) = \theta(s(\omega, t))$, and the properties of θ: $\theta(-s) = 1 - \theta(s)$, the resulting probability formula is drawn:

$$P(y|x) = \theta(y * S(\omega, t))$$

This formula is based on the assumption made earlier, that y takes 1 for active and -1 for inactive state.

Learning input data Out of all possible functions in the hypotheses set one has to be chosen in terms of its lowest cost. In order to perform such a selection a cost measure has to be defined. The suggested measure is a combined probability of all the observations in a learning set. The higher the combined probability the better a hypothesis describes the user habit that gave rise to such sensor readings. Derivation of final formula to be optimized: $\max_\omega \prod_{i=0}^{m-1} P(Y_i|X_i)$ Maximizing an expression is equivalent to maximizing its logarithm:

$$\max_\omega \ln \prod_{i=0}^{m-1} \theta(Y_i * S(\omega, X_i))$$

$$\max_\omega \frac{1}{m} \ln \prod_{i=0}^{m-1} \theta(Y_i * S(\omega, X_i))$$

$$\min_\omega -\frac{1}{m} \ln \prod_{i=0}^{m-1} \theta(Y_i * S(\omega, X_i))$$

$$\min_\omega -\frac{1}{m} \sum_{i=0}^{m-1} ln(\frac{1}{\theta(Y_i * S(\omega, X_i))})$$

Formula in such a form is then subject to optimization. The optimization algorithm used in this case was gradient descend with initial ω coefficients set all to 0. Fast convergence to unique value is always achieved thanks to minimized formula being always convex.

V. Evaluation

We implemented a prototype of an intelligent middleware, that learns user habits based on the usage of device sensors (in this case a GPS sensor). We assumed that the GPS sensor is active if the speed of the device exceeds some fixed threshold, otherwise the sensor was assumed to be inactive. This reflects to the cases where someone was moving or not.

The learning and evaluation process is presented in Figure 2. We first performed an acquisition of the GPS sensor data and save it to SQLite database. We collected samples from 5 consecutive days, which later were preprocessed offline to be ready for the learning algorithm. The main aim of the preprocessing phase was to decide weather the GPS sensor was active or not, depending on the speed threshold. After the learning process was finished, we moved learned model back again to the mobile device and based on that, we were adjusting sampling rates of the sensors.

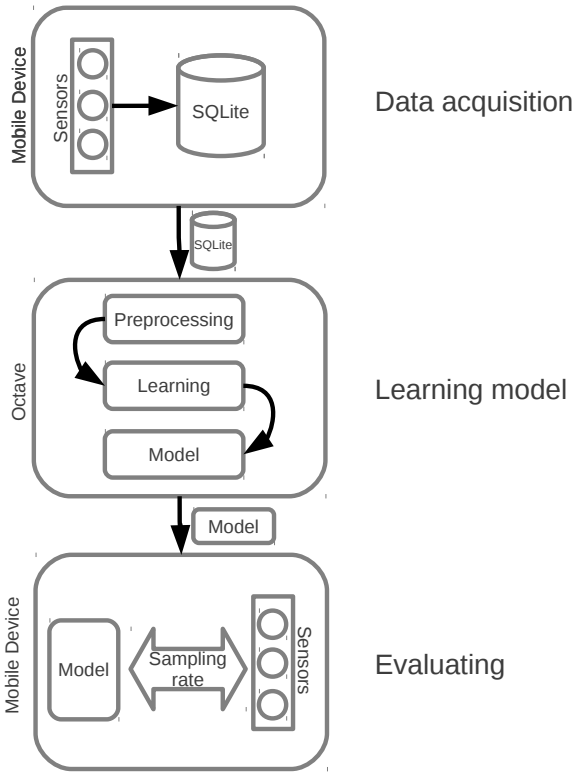

Figure 2. Learning and evaluation process of the intelligent middleware approach.

In the following Sections more details about implementation and evaluation results is presented.

A. Implementation

The prototype of the learning algorithm was written in Octave, and the evaluation of the learned model was performed on a Samsung Galaxy S II smartphone with Android 4.2 Jelly Bean installed.

The Octave learning phase was performed according to the learning algorithm described in Section IV. Fragment of a gradient descent source code responsible for learning parameters of the model is presented below.

```
for i=1:max_iterations,
  derivatives = zeros(nparams,1);
  for j=1:nsamples,
    product = -Y(j)*(X(j,:)*weights);
    error(i) += log(1+exp(product))/nsamples;
    sigm = sigmoid(product);
    for k=1:nparams,
       derivatives(k)=derivatives(k) +
```

```
            sigm*(Y(j)*X(j,k));
    end
  end
  derivatives = -derivatives / nsamples;
  weights -= learning_rate*derivatives;
end
```

During the evaluation phase, we used an Android device with a model of the sensor usage habits generated by the Octave algorithm. The algorithm that was adjusting sampling rates based on the learned model, performed following steps:

- Sample GPS sensor with a rate predicted by the intelligent middleware algorithm.
- When any movement is discovered, start sampling with the highest possible rate called `baseFreq` (we fixed this to be 1 second).
- After some fixed period of time called `continuityThreshold` (10 seconds in our approach), if no sensor activity was discovered, return to sampling rate predicted by the intelligent middleware algorithm.

The source code fragment responsible for this is presented below:

```
if(timeFromLastActivity < continuityThreshold){
   newFreq = baseFreq;
} else{
  float probability =
    middleware.getProbability(clockTime);
  int multiplier =
    (1.0f - probability) * scaleFactor + 1.0f;
  newFreq = baseFreq * multiplier;
}
if(newFreq != refreshFrequency)
  rescheduleUpdatesFromProviders(newFreq);
```

B. Results

We made experiments on two identical devices carried by the same person. One device was equipped with and intelligent middleware algorithm implemented and the other does not. Both devices were fully charged at the beginning of the experiment and was not recharged during it. We decided to use speed threshold equal to 5 km/h. With lower thresholds, the difference between intelligent middleware approach and the other one was hardly visible, because of the errors in GPS sensor readings which results in fake "active" states. As depicted in Figure 3, the intelligent middleware approach allowed for 50% battery saving than in case of the device without the algorithm implemented.

Figure 3 presents a proportion of the time that both devices worked on the battery. The right plot shows the time that the device without the intelligent middleware implemented worked, and the left plot presents a work time of the device with the intelligent middleware implemented.

The distance error which we define as a difference between the GPS samples generated in our approach and referenced samples generated by the approach without learning algorithm, is presented in Figure 4. The average distance error of the presented data equals 0.053 km. The high error in several

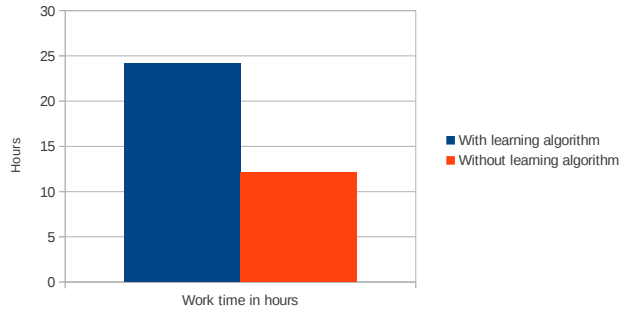

Figure 3. Difference in power consumption for device with and without learning algorithm implemented, with speed threshold set to 5km/h.

places on the plot is a result of noisy readings of GPS sensor rather than an algorithm fault.

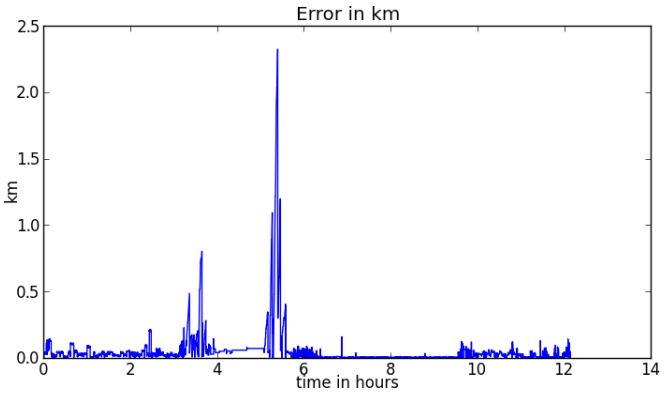

Figure 4. Error between position designated by the intelligent middleware approach and the reference data.

VI. Summary and Future Work

In this paper we presented a prototype of an intelligent middleware approach that is able to learn sensor usage habits and adjust sensor sampling rates to minimize energy consumption of the context-aware system. The middleware was presented as a part of a context reasoning platform tailored to the needs of such intelligent distributed mobile computing devices. We argue that most of the existing solutions are not fully applicable to mobile architectures, and does not fulfil energy efficiency needs of context-aware distributed systems. The presented approach was designed to solve that issue, however we believe that it is suitable for predicting not only future sensor activity, but also context-aware application needs. Hence, it is possible to get the desired context in advance, before the application actually requests it. It can be especially useful in cases when context cannot be obtained by the middleware directly from the sensor layer, but has to be for example downloaded over the internet.

We used a logistic regression algorithm to learn sensor usage model form historical data. This allowed for adjusting sampling rates of the sensors according to usage probability.

Evaluation on a real device showed that we can gain up to 50% of energy saving using this algorithm.

As a future work the implementation of the algorithm for an Android device is planned to allow real-time online learning and full evaluation of the intelligent middleware approach, not only for a GPS, but also other sensor like accelerometer, gyroscope, etc.

It is also planned to implement the learning algorithm that uses Markov chains, and compare it to existing implementation. We plan to design and develop an architecture dedicated for mobile context aware applications equipped with an intelligent middleware layer and rule based inference layer provided by the HeaRT [18] inference engine, which is a lightweight rule-based engine that uses XTT2 [19] notation for knowledge representation. This will allow for lightweight reasoning [20] and also verification of context models [21]. We plan to incorporate and evalueate the middleware in the context-aware system for monitoring threats in urban environment proposed in [22]. We also believe that it would be valuable to compare challenges and problems in mobile context-aware computing with an area connected with research about wireless sensor networks [23]. This two fields of science can possibly benefit from exchanging solutions and ideas especially regarding energy efficiency and resource limitations issues.

***Abstract*—ParaMoise is a novel organisational model that permits to specify parallel and concurrent systems' organisation and reorganisation. Workflows, locks and multiple organisation managers are the entities that differentiate this model from it antecedent, the $\mathcal{M}$oise$^+$ framework. All these entities must be efficiently designed and implemented to ensure the practical usage of the theoretically formulated model. The main challenge here is the distributed synchronisation of workflows and locks, that will maximise the performance of the system. This paper presents and analyses different workflows and locks management approaches that can be used to achieve this goal: from basic centralised or middleware based solutions, towards truly decentralised coordination mechanisms.**

I. Introduction

ORGANISATIONAL models are used in Multi-Agent Systems (MAS) to facilitate the teamwork between agents. They define the coordination and cooperation mechanisms between agents, resulting in a model that can be reused in various systems and environments, without need to create a custom solution for each of them. Additionally, a model of organisation enables to explicitly represent the social aspects of a MAS, which can be useful for both agents and external observers of the MAS.

Multiple organisational models were introduced [1]–[3], each of them with its own properties and assumptions about MAS architecture. The cited frameworks are notable, as they are general purpose and can fit into multiple domains that benefit from the MAS paradigm.

In this study, we further extend the MOISE [1] organisational model, which relies on a three dimensional description of the Organisation Specification (OS). The OS consists of a Structural Specification (SS) that describes roles together with their hierarchy and possible interactions, groups, and links between roles and groups, a Functional Specification (FS) that describes the schemas, further divided into goals, which are in turn grouped into missions, and a Deontic Specification (DS) that binds the SS and FS by a set of deontic modalities, which enforce or allow agents playing specific roles to commit to missions.

Moreover, MOISE clearly divides the general description of the organisation (OS) from the instantiation of that description, called Organisational Entity (OE). An OE consists of an OS, a set of agents, and the elements that create a valid instance of the OS using this set of agents, e.g. functions that determine the current assignment of agents to roles, groups, and missions, the set of currently existing groups, the set of applied deontic modalities.

The next step in the development of organisational models is considering the benefit and the cost of running an explicit organisation infrastructure in a system. The rationale for running an organisation is to facilitate reaching the desired states by the system. In case of a dynamic environment, it is likely that the organisation may decrease its efficiency due to changes in its environment. As a result, the *reorganisation* may be necessary to adapt the system [4]. The urge for the reorganisation can be especially important for large scale distributed systems, that may trigger reorganisation not only because of external environmental changes, but also due to internal events in MAS. Additionally, the concept of *artifact*, a general and abstract representation of object that can be perceived and used by agents, may be applied to represent organisation [5].

The state-of-the-art development in the field of modelling is ParaMoise [6], that enhances its predecessors by introducing novel concepts coming from the distributed and parallel computing field: workflows, locks, alternative or redundant execution paths, transactions, and failure handling mechanisms, as well as multiple managers of organisation. In effect, the resulting model offers more possibilities to execute parallel and concurrently, without removing or diminishing any of the properties of the antecedent models. The final goal of this development is improving the distribution properties of a MAS, which shall result in an increased performance and reliability, which are essential for dynamic, large scale systems.

However, ParaMoise is a theoretical approach, which application and performance will depend on a proper design and implementation of the proposed mechanisms. In this work, we aim to address this issue by discussing possible alternative designs. In this context, our contributions are the proposals of various design and implementation possibilities for the ParaMoise model divided into two groups:

978-83-60810-53-8/$25.00

a) Centralised: classical tools such as databases that supports transactions, which can be possibly seen as artifacts by MAS.

b) Decentralised: artifacts distributed among agents. In this context we consider that the responsible Organisation Manager (OrgManager) could host the organisational artifacts, which can be also delegated to a new auxiliary Organisation Carrier (OrgCarrier) role that sole purpose is to host the organisational artifacts. We also present the possible solutions for preventing deadlocks that can occur in case of multiple locks, followed by some further refinements of organisation to minimise the resulting synchronisation overheads. Finally, we highlight the impact of using distributed algorithms, as they give agents the possibility to choose the organisational artifact type according to their needs.

The rest of the article is organised as follows. Section II provides a state-of-the-art on ParaMoise, artifacts and distributed synchronisation. Section III presents a centralised solution approach that fulfils the basic requirements for the implementation, while section IV discusses the organisation distributions possibilities. Finally, section V describes the advantages of distributed artifacts and section VI concludes the paper.

II. State of the Art

This section is divided into three parts. Section II-A describes in more details the ParaMoise model, then section II-B presents the artifact-based approaches that are important in the discussed design concepts, and finally section II-C describes the basic algorithms that can be used for the distributed concurrency control.

A. ParaMoise

This section describes the main concepts introduced in the ParaMoise [6] organisational model. ParaMoise is a novel organisational model based on the MOISE [1] and $\mathcal{M}$oise$^+$ [7] models. One of the assumptions of Moise models is the full *autonomy* of agents, i.e. the agents decide by themselves what to do and when, given their current deontic situation, which in turn defines possible rewards or penalties for some performed actions. As a result, the system does not need any central scheduler that will assign tasks to agents, contrary to other state-of-the-art solutions such as GPGP/STÆM [3].

The ParaMoise model is based on the state-of-the-art definitions of organisational models [7], [8], and defines an OE as a tuple [6]: $\langle OS, \mathcal{A}, \mathcal{GI}, \mathcal{SI}, \mathcal{O}, sg, ar, am\rangle$, where OS is the organisational specification; $\mathcal{A}$ is the set of agents; $\mathcal{GI}$ is the set of group instances; $\mathcal{SI}$ is the set of social schemes; $\mathcal{O}$ is the set of current deontic modalities; $sg : \mathcal{GI} \rightarrow \mathbb{P}(\mathcal{GI})$ maps each group to its subgroups; $ar : \mathcal{A} \nrightarrow \mathbb{P}(\mathcal{R} \times \mathcal{GI})$ maps agents to the roles they are playing in the groups; $am : \mathcal{A} \nrightarrow \mathbb{P}(\mathcal{M} \times \mathcal{SI})$ maps agents to the missions they are committed to in the social schemes.

The first major contribution of the ParaMoise model is the *Workflow Specification* (WFS), which is a way to present goals and dependencies between them as a workflow. WFS is defined as [6]: $\langle \mathcal{G}, \mathcal{E}, \mathcal{M}, mo, nm, alt, fh\rangle$, where $\mathcal{G}$ is the set of global goals; $\mathcal{E}$ is the set of precedence relations; $\mathcal{M}$ is the set of mission labels; $mo : \mathcal{M} \rightarrow \mathbb{P}(\mathcal{G})$ is the function that specifies the mission set of goals ; $nm : \mathcal{M} \nrightarrow \mathbb{N} \times \mathbb{N}$ specifies the boundaries (min,max) of number of agents committed to the mission in well formed WFS; $alt : \mathcal{E} \rightarrow \mathbb{P}(\mathcal{E})$ is the function specifies the precedence relations alternatives; $fh : \mathcal{G}_p \nrightarrow \mathbb{N}$ specifies the failure handling mechanism for a primitive goal in terms of maximum number of allowed repetitions. An example of WFS is presented in Figure 1.

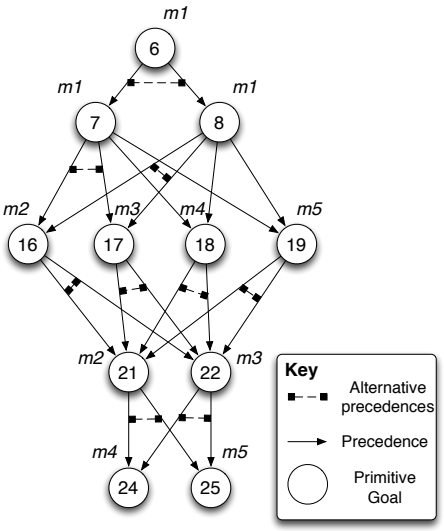

Fig. 1. An example of ParaMoise WFS.

An instantiation of a WFS by some agents is referred to as a *Workflow* (WF). The latter is defined as a tuple [6] $\langle WFS, es, gs, exe, gf\rangle$, where WFS is the workflow specification, $es : \mathcal{E} \rightarrow \{active, inactive, discarded\}$ is the function that maps edges to their activity status label; $gs : \mathcal{G}_p \rightarrow \{waiting, possible, executing, suspended, achieved, discarded\}$ is the function that specifies statuses of primitive goals; $exe : \mathcal{G}_p \nrightarrow \mathbb{P}(\mathcal{A})$ is the function that specifies the set of agents executing a goal; $gf : \mathcal{G}_p \rightarrow \mathbb{N}$ specifies numbers of repetitions of primitive goals. The status of the goals in the system changes according to the state transition diagram presented in Figure 2. The final example of a workflow usage is presented in Figure 3, which presents the capability of tracking the execution status.

The WFS and WF enable more parallelism, since they permit to represent an arbitrary structure of dependencies between goals. They are combined with *locks* to ensure mutual exclusion during reorganisation. The locks are defined as $\langle ROE, type\rangle$, where ROE is the reduced organisational entity (the elements of the OE on which the lock applies) and $type \in \{read, write\}$ specifies the type of the lock. Before a reorganisation, a lock must be created for all modified (write lock) or accessed (read lock) elements of the organisation. To minimise the scope of locks, they can be applied to a subset of

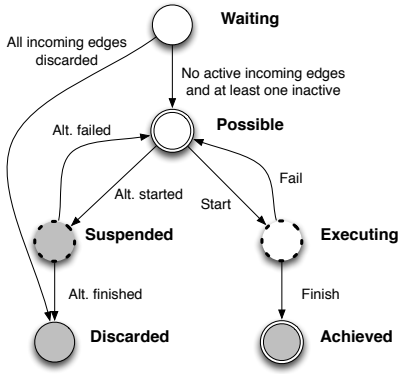

Fig. 2. State transition diagram of goals status in ParaMoise model [6].

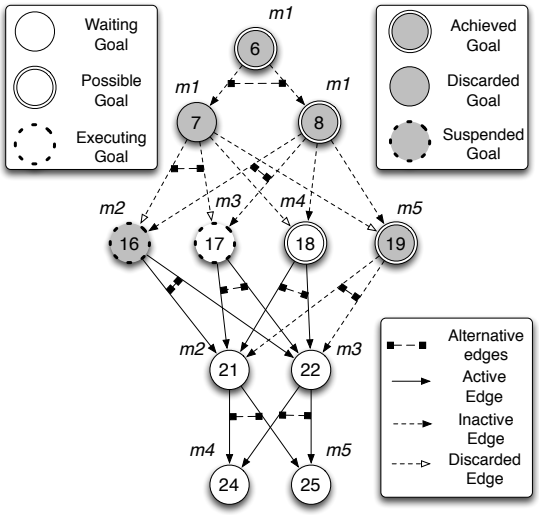

Fig. 3. An example of WF during execution

a set, or for a subdomain of a function. ParaMoise also introduces multiple managers of the organisation (OrgManagers), which fulfil the requirement for an effectively concurrent system.

An efficient access to the workflows and locks is crucial to achieve a high performance of concurrent and parallel execution and reorganisation in a system that applies ParaMoise. Therefore, it is important to find a design appropriate for a considered scenario. In this article we present two approaches: a basic centralised one, applicable for small scale systems, which is interesting as it underlines the basic requirements of the implementation of the model, and the decentralised approach with various possible design choices and their anticipated consequences.

The essential requirements for any implementation of the organisational model are:

1) the existence of all elements of the defined organisation,
2) the accessibility of all the existing elements by the agents with appropriate permissions,
3) the execution of workflow that ensures their correct state transitions,
4) the effective lock and reorganisation mechanisms.

The concept of artifacts can directly meet these requirements.

B. Artifact-Based Frameworks

ORA4MAS (Organisational Artifacts for Multi-Agent Systems) [5] is an approach that describes organisational entities as *artifacts*, based on the Agents and Artifacts (A&A) framework [9]. Artifacts are abstraction of interactive objects that can be perceived and used by agents. An artifact is defined by observable *properties* that represent its state, *operations* that determine its functionality, *links* that describe its relations with other artifacts, *events* that can be emitted in certain conditions, and corresponding *manual* that instructs the agents how to use artifacts. In this context we can see the artifacts as tools that can be used to achieve the goals of agents. ORA4MAS describes the theoretical foundations for using artifacts as the basis of reorganisation, but neglects some system designs aspects. It is a centralised solution based on the paradigms of the A&A framework.

Another drawback of ORA4MAS is the absence of reorganisation. It is partially covered by the JaCaMo [8] framework, which uses a central artifact to perform reorganisation by a single OrgManager that requires halting the whole organisation.

In this context, ParaMoise offers parallel and concurrent reorganisation at runtime, performed by multiple OrgManagers. In the same way ParaMoise enhances standard execution mechanisms, enabling arbitrary precedences between goals, novel possibilities of alternative goals, and a failure handling mechanism. However, the ParaMoise model does not propose any exact design and implementation, but only mentions the usage of artifacts as a perspective. This work proposes to answer to this need. In the remainder of the paper we discuss alternative scenarios, arguing that using well-known and established solutions results in an abundance of choices in which artifacts are one of the basic concepts, being an interface between agents and organisation support systems.

C. Decentralised Synchronisation

Decentralised synchronisation problems are crucial for distributed computing and distributed systems. In contrast to easier case of centralised systems synchronisation, they must be solved taking into account such properties as lack of the global knowledge or communication delays. As a result, a number of solutions to the problem were proposed to solve some main issues for ParaMoise: mutual exclusion (locks) and transactions [10].

1) Mutual Exclusion: Exemplary mutual exclusion algorithms are the Ricart and Agrawala algorithm [11] and token-based algorithms. We focus here on the basic algorithms, despite further refinements were proposed (e.g. Maekawa [12] or Sigma [13]) as they underline the common characteristics of this type of algorithms.

The Ricart and Agrawala algorithm requires communications between all agents, that have the possibility to access the critical section. As a result, the cost of synchronisation is $2(n-1)$, where n is the number of agents. Additionally, in the basic forms, the failure of any of the agents disturbs the proper work of the algorithm. These limitations prohibit usage of such algorithms in a large groups of agents. On the other hand, the algorithm is fair and in optimistic case leads to a fast resolution of the problem.

The token-based algorithms [10] ensure mutual exclusion by using a unique token for a critical section. These can be applicable for a set of distinct critical sections or resources. The token can be passed according to various strategies, e.g. continuously moving in the ring or using more sophisticated hierarchical structures.

2) Transactions: Another aspect of concurrency control is proper transaction handling, which is required for an effective WF management. Three main approaches can be distinguished [10].

Two phase locking (2PL) [14] is based on the standard lock mechanism. The locks are created in the two phases: in the first phase the locks are consecutively acquired according to the needs of a transaction and then in the following phase they are released.

The optimistic concurrency control [15] assumes that violations of mutual exclusion are rare, and it is possible to repair the potential damages done by such violation. As a consequence, there must exist an efficient repair mechanism and the collisions cannot be destructive. This is most effective in the case of relatively rare occurrence of conflicting write operations in a system [16].

The pessimistic timestamp ordering [10] is the last approach presented here. It associates the demands to access elements being part of a critical section with additional read and write timestamps. During the evaluation of the incoming transactions, the timestamps are used to check if the incoming transactions conflict with the ongoing ones. The approach is safer than the optimistic concurrency control, as it avoids the potential problems instead of resolving them.

III. Centralised Design

The centralised solution for synchronisation can be achieved with classical tools used for mutual exclusion and transactions. A central entity is responsible for keeping all the information about the state of the organisation. In case any agent needs to acquire knowledge about any part of the organisation, e.g. the agent's roles, obligations or known agents, it can query this entity.

The concurrent access control is performed centrally and in result does not pose a major challenge. A system of role-based access can effectively enforce that only the entitled agents can access specific elements of the organisation. The transaction mechanism can be straightforwardly applied to the execution of workflows, ensuring the correct state transitions of goals. Finally, lock creation and checking is done by a single entity that can prohibit any forbidden overlaps.

As a result, we can see this entity as a database which stores all elements of the organisation and grants access to them only to the roles that have the required permission. The workflows are stored inside the database and their status can be changed using the mechanism of transactions. The database routines ensure that the created lock does not overlap with other locks.

For an agent in the system, the database is seen as an artifact that stores the information about the organisation with well-defined interfaces to perform organisational actions. It can return information about the organisation or be exploited as a synchronisation tool used for efficient teamwork, as it holds the workflow state. Finally, the artifact has interfaces that enable OrgManagers to change the shape of the organisation by modifying the current state of the organisation in a safe way.

IV. Decentralised Design

This section presents the variety of possible design choices for the ParaMoise model and discusses their properties. Firstly, it describes the basic decentralisation capabilities and concepts in section IV-A, which introduces the decentralised artifacts described in section IV-B. Artifacts management problems and the corresponding organisational challenges are presented in section IV-C, while the solving of possible deadlock problems is discussed in section IV-D.

A. Decentralised Middleware

The most straightforward way to decentralise the system is to use an existing solution to distribute the centralised middleware, e.g. a database. This involves correct replication schema together with synchronisation of replicas. From the MAS design perspective these problems of distributed computing are out of the scope of this paper, as logically there is still one entity that is distributed, possibly with multiple equivalent interfaces. Therefore, the following paragraphs describes the applicability of decentralised synchronisation algorithms for the ParaMoise model. Following the structure of Section II-C, we describe two main issues: Mutual Exclusion and Transactions.

1) Mutual Exclusion: Solving the mutual exclusion problem is an essential design decision for ParaMoise, as it effectively determines the locks mechanism, its performance and properties. The Ricart and Agrawala algorithm is applicable for the ParaMoise model. The need for broadcast communication may rise scalability issues, however proper division schemas may result in more applicable solutions, which are discussed further in Section IV-D. The other discussed solution, token-based algorithms, seems to have limited applicability in the ParaMoise model. The lock in ParaMoise could have an arbitrary form, which makes the token impractical. There could be either a large number of tokens that could create significant overhead, or in the opposite case a small amount of token responsible for major organisational elements would decrease the possible number of concurrent reorganisations. Additionally, gathering multiple

tokens to perform reorganisation may lead to increased waiting time and deadlocks.

2) Transactions: The transactions mechanism is necessary to properly modify the status of goals during progress of WF, which is the core issue for the efficiency of the parallel and concurrent execution in a ParaMoise system. A WF is also used to express all the schemas in the organisation, including reorganisation processes. 2PL conceptually fits the ParaMoise locks and could be directly applied. In the case of using optimistic concurrency control for reorganisation, there is a need to ensure that the occurrence of a conflict will not result in breaking the consistency, by applying an effective rollback mechanism. The property of allowing the conflicts to happen is not acceptable in MAS organisations, as achieving some of the goals by agents can be impossible to undo, making the rollback impossible. Additionally, the changes of reorganisation shall be directly mapped into the behaviour of agents, which could lead to an inconsistent state in an organisation. Pessimistic timestamp ordering is applicable thanks to its more cautious nature. As it ensures that the organisation will be unique at any moment in time, it is applicable for usage in ParaMoise. The specifics of the solution require a mechanism for comparing the timestamps, which could be directly performed by an artifact created for each WF. We discuss more generally the usage of decentralised artifacts in the following section.

B. Decentralised Artifacts

The next step toward decentralised system is a logical distribution of artifacts among the distributed system. In this way, the agents are no longer using the monolithic organisational artifact, but they access a set of distinct artifacts. An example of such a division may be a system that stores the definition of each role as a separate artifact.

The logical division can lead to practical consequences: as the elements of the organisation are separated among artifacts, locks are distributed among the artifacts, therefore decreasing the complexity of checking for possible conflicts. Additionally, this approach eliminates performance bottleneck, and decreases the risk of single point of failure. On the other hand, larger reorganisations can require interactions with several artifacts, increasing therefore the complexity of the operation, leading to the possibility of deadlocks, and in case of lack of redundancy failure of any of the artifacts can lead to breaking down the whole organisation.

C. Role-Based Synchronisation

The concept of decentralised artifacts can be further advanced by merging it with the concept of roles. Agents of specific roles would be responsible for maintaing organisational artifacts. The responsibility may hold for the whole system, or for a specific group. A natural choice for the role responsible for artifacts is the OrgManager, however this solution would add another functionality to this role. As OrgManagers are already responsible for coordinating organisation and executing reorganisation, we propose a new role in the structural specification: Organisation Carrier (OrgCarrier).

The OrgCarrier responsibility is to maintain the organisational artifacts. To keep the control over parts of the organisation, OrgManagers have authority over OrgCarriers, i.e. the latter should follow the orders of the former. We present the novel structural specification in Figure 4. The authority link of the OrgManager pointing to the root role *soc* is transitively propagated to the OrgCarrier role. However, this is the only connection of OrgCarrier, since none of *Org* roles, except OrgManager, has knowledge about the OrgCarrier. This structure can fulfil its goals, being transparent for the rest of the system.

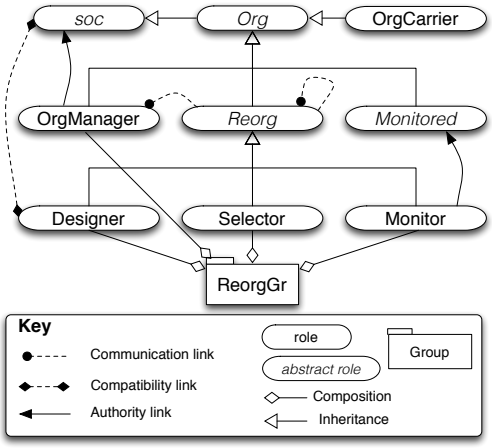

Fig. 4. Organization group structure with OrgCarrier role.

D. Resolving Deadlocks

As previously mentioned, introducing multiple locks distributed among artifacts leads to the possibility of deadlocks. An example leading to a deadlock is an attempt to create locks on two organisational elements by two OrgManagers. If they actions are synchronised, but they create locks in reverse order, a deadlock occurs. Such behaviour may be simply overcome by adding a timeout for each of the locks, however this may lead to poor system performance (waiting for timeout) or aborting lock for a valid operation that lasts longer than expected [16].

Another approach to solve the problem of deadlock could be the coordination between OrgManagers, using an algorithm such as Ricart and Agrawala. Each OrgManager broadcasts the description of the lock it wants to create together with a timestamp. Other OrgManagers must reply that they allow to create the lock. In case of conflict, the OrgManager that detects it takes a decision based on the timestamps. The lock with earlier timestamp has priority. Tie braking may be implemented, e.g. favouring the lowest agent ID number. The inherent drawback of this solution is its scalability: each agent must receive and send a message coming from the initiator of the procedure. Additionally, unreliable channels or agents that occur in dynamic systems may break this schema,

with the probability of failure growing with the number of OrgManagers.

The organisational model properties can be used to mitigate such negative behaviours. The responsibility of a subset of OrgManagers can be restricted to specific elements of the organisation. As an example, OrgManagers could form groups associated with a role. Additionally, to ensure that major reorganisation spanning across multiple roles can be executed, there must exist a subset of OrgManagers responsible for the whole organisation. As a result, each lock concerning an element of the organisation must be checked by the subset of agents (i.e. in a group) that contain the OrgManagers responsible for this element as well as the globally responsible OrgManagers. The effectivity of such solution is based on the assumption that the major reorganisations are relatively rare. Additionally, the division of elements of the organisation must be done with a granularity that ensures correct system behaviours.

V. Discussion

A. Advantages of Artifact Driven Organisation

Representing organisations with artifacts has an additional added value: agents are controlling the artifacts, thus they have the power to alter even the organisation implementation. For example, agents may initially choose to use the centralised monolithic artifact while the system is of small scale. However, together with the growth of the system agents may decide that this solution has reached its limits and shall be changed to better scale with the new situation. Then, by correct mapping of the existing organisation to new artifacts agents can replicate the existing OE and start to use the new type of artifacts.

Agents can learn how to use different organisational artifacts, what are their strong and weak points in terms of performance, reliability, recoverability, etc. Moreover, this solution can be used to perform updates, maintenance or archive the organisational artifacts. In case one type of artifacts starts to present erroneous behaviour, agents have possibility to choose another one.

VI. Conclusion

The ParaMoise model can be used using various designs and implementations. From the discussed alternatives, we see the Ricart and Agrawala family of algorithms, 2PL, and pessimistic timestamp ordering as the most fitting low-level primitives. We consider that artifacts could play a major role as interfaces between agents and systems that agents use. Artifacts are easy to distribute, can embed specific access control and synchronisation mechanisms, and they enhance the autonomy of agents. The paper also introduces the OrgCarrier role that can facilitate the management of the organisation. The properties of decentralised algorithms may require additional structure of the OrgManagers, for example by adding managers responsibility zones.

The future work includes experimental testing of the discussed solutions as well as implementing ParaMoise as a general purpose framework. We intend to use ParaMoise in a system optimising and managing Cloud Computing infrastructures, which could validate the approach. In this context, the optimisation of an organisation model to achieve the system objectives is a prospective research direction.

***Abstract*—Petri net modeling has well-known algorithms, so it is easy to develop computer tools to build, edit, and analyse these networks. These tools are designed to be able to add extensions giving additional functionality, such as an extension for evaluation networks.**

Evaluation networks are not as popular as Petri Net modeling, but they turns out that, in modeling of some of the problems, evaluation networks makes analysis of them very clear and intuitive. Unfortunately there are no mathematical tools and computer programmes for evaluation networks use. Fortunately, under certain assumptions, an evaluation network can be converted into a Petri net. This article presents an idea of how to convert an existing Petri net computer programme to draw evaluation nets and convert them into Petri nets in order to use existing tools for Petri net analysis.

Evaluation nets are well suited for modeling negotiation protocols between two parties represented by servers or software agents. This article provides an example of such a protocol presented in three versions: a sequence diagram UML, Petri net and Evaluation nets.

I. Introduction

PETRI net is one of the few languages for modeling distributed systems. It was invented in the 1960s by the German mathematician Carl Adam Petri, and described in his doctoral dissertation [1]. Petri nets are used to model concurrent systems [2], the discrete [3] synchronisation process [4], etc. They are used in computer science, and in other fields such as biology, medicine and chemistry [5].

Modeling Petri nets may be performed by a number of computer programmes, such as WoPeD [6], YASPER [7], CPN Tools [8] or PIPE2 [9]. They allow for graphical editing, interactive visualisation, and analysis of automatic Petri net.

A new areas of Petri net application arose, so various extensions were created. As a result, there are coloured Petri nets [10], timed Petri nets [11], stochastic Petri nets [12], etc.

Among these extensions are evaluation nets (*E*-Nets), the first use of which was associated with an analysis of the operation of information systems. *E*-Nets were invented by Garry J. Nutt and Jerre D. Noe, and described in Nutt's dissertation [13]. *E*-Nets are very poorly distributed. Teaching materials for the *E*-Nets are not widely available, and nor are computer programms for it. Unfortunately, *E*-Nets were not developed particularly dynamically for many years.

E-Nets are well-suited for modeling communication between systems [14]. However, the lack of programmes that work with *E*-Nets makes use of them very difficult, and the implementation of such programmes from scratch increases the cost of the study.

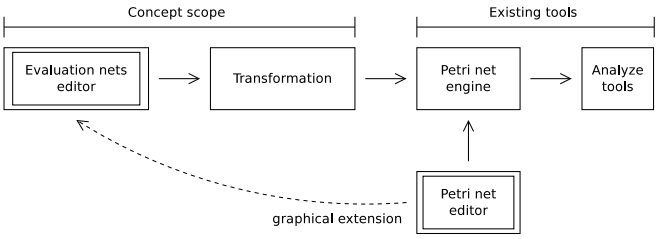

Fig. 1. Petri net editor is extended to support elements of evaluation nets. Then, when you call the analyser, evaluation nets will have been transformed to Petri net and as such referred to the process analyser.

The main motivations for writing an article on this theme are:

1) Evaluation networks are useful for designing algorithms for negotiations, such as between agents, servers, etc., yet their universal notation is very readable for humans.
2) The project of an algorithm may be verified by including the performance simulation of the evaluation nets. But there is no such network simulator.
3) Some elements of *E*-Nets can easily be presented in Petri net, so existing Petri net simulators can be used.

Our concept uses an opportunity to convert *E*-Nets (some restrictions were imposed) to Petri nets, and uses existing Petri net analysers for analysis by a visual extension of an existing Petri net editor, which draws evaluation nets on the screen and sends the ready Petri net to the analyser (Fig. 1).

The terms *E*-Nets and evaluation nets usually are used interchangeably, but for the record, in the rest of this article the names will be applied differently. The term "*E*-Nets" will be used for the original evaluation nets [15] and the variation created for this concept will be referred to as "evaluation nets."

The formalism of Petri Net were well described in [16] i [17]. That concept is based on those descriptions of Petri Net and it's extensions (Table I).

II. Evaluation nets

An *E*-net is a connected set of locations over the set of allowable transition schema. The formalism of original *E*-nets was described in [18] and [15].

978-83-60810-53-8/$25.00

In oryginal *E*-nets location may be connected with only one input and one output transition. Location in *E*-Nets can have no token (empty) or one token (full). For example in `F-TRANSITION` (Fig. 6) firing is not possible when the c location is full.

Since their creation, *E*-Nets have evolved. Some extensions were presented in [19]. These extensions were used in [14].

A lot of *E*-Nets structures can be transformed to Petri nets with coloured tokens [10] and an inhibitor arc [20] extension.

Token can have attributes. Attributes are in *Resolution procedure* and *transition procedure*. If attributes determine *E*-Nets, then conversion to Petri nets may be impossible. Therefore, for the simulation, we have to use external procedures to process the data in the token's attributes and to decide about the firing transition.

Unfortunately the usage of many external procedures in the cases of resolution locations and transition procedures seems to make the proposed model complex. The Petri net tools for analysis are not able to solve or make easiest the usage and the efficiency of proposed model. However, in some cases, it's enough to replace those procedures by simple conflict structures.

If we want to create an automatic converter from *E*-Nets to Petri nets, then we must impose additional restrictions on *E*-Nets. In this article we describe our variation of *E*-Nets. Some extensions are graphical only and these improve readability, but some extensions change the *E*-Net flow:

1) multi-connections between locations and transitions were Enabled, but this may produce conflict structures (similarly to with Petri nets),
2) if a conflict structure contains resolution locations then the order of firing is determined by the execution of these *resolution procedures*,
3) coloured token — a token with enumerated value (for example: colour) as an attribute,
4) transition schema — may use token colour instead of 0 and 1 values (something like switch-cache transition),
5) resolution location — can return a coloured token, return value cannot be determined from other tokens but can be randomised,
6) outer request location — a special kind of resolution location, represents request coming from outside the evaluation net (indicated by a rectangle with a double line),
7) transition with sender — transitions which are able to send tokens (represented by a horizontal arrow labeled with the corresponding message name), always after firing.

All these differences between evaluation nets and Petri nets, our extensions and transitions are described in Table I.

III. Transforming evaluation nets into Petri nets

In [18], there were described 5 primitives. Primitives are basic (trivial) constructions of evaluation nets (Fig. 6). All more complex evaluation nets are built by joining and extending of those primitives. *E*-Nets primitives may be replaced by their equivalents from Petri net (Fig. 7). Thus, we can acquire an evaluation net converted into a Petri net.

All original *E*-Nets primitives from Fig. 6 can be transformed with inhibitor arcs, colour tokens and conflict structures determined by e.g. controlled transitions (Fig. 7). `T-`, `F-` and `J-TRANSITION` may be transformed without any extensions but additional places, transitions and tokens are required.

Transformation of `X-` or `Y-TRANSITION` must be made by a lot of additional elements because we must emulate complex *transition schema* and all possible states of *resolution location*. With coloured Petri nets the number of additional elements may be reduced to 3 and 7 additional transitions for `X-` and `Y-TRANSITION`. Also added a lot of new connections. (Table II).

Transformation of a triangular location is trivial (use standard connection). The transformation of transition with sender is more difficult (Fig. 5).

Other transformation issues are described in Table I.

Following such transformation, Evaluation Nets can be transformed to Petri net analysis (Fig. 1).

A. Example

It turns out that evaluation networks are well-suited for modeling protocol negotiations between the two parties, such as that shown in Fig. 2. This protocol is based on the CNP [26] and is part of Complex Negotiations [27]. The specified protocol defines two participants: initiator and participant. If the initiator wants to start negotiations, it sends a message to the participant CFP (call for proposal). If the participant is interested in negotiations, the initiator receives the offer. Otherwise, the initiator sends the message *refuse* to end the negotiations as a failure. When Initiator is offered, decide whether a) accept the offer (accept), thus ending the negotiations successfully, b) reject the offer and end the negotiations a failure or c) rejects the offer but made a counteroffer and waits for a response from the participant.

Thanks to evaluation networks it is possible to design a computer system using the previously described negotiation protocol. Fig. 4 shows an evaluation net divided into two subnets, one belonging to the initiator, the second to the participant. Subnets do not have direct connections with each other (using arcs), but they exchange messages.

Initially, both participants are in a state of inactivity (`Idle`). Then the initiator is ordered to enter into negotiations, and as a result a token appears in l_1. This causes firing of a_1, which in addition to placing a token in l_4 sends a message called `CFP` (call for proposal). Initiator goes to l_4 (`Wait`) and waits for a response $\mathtt{S}_i$ from the participant. If the answer does not appear within the required time, the wait can be interrupted by a request l_3 (`Timer`). This is support for an emergency situation, which ends the Initiator net evaluation of the state of l_8 (`fail`).

In the meantime, the message `CFP` is received by l_{10} (located in the participant) which results in the appearance of the token and firing of a_5. Then the participant's evaluation

TABLE I
THE DIFFERENCES AND TRANSFORMATION METHOD BETWEEN EVALUATION NETS AND PETRI NET

Evaluation nets item	**Petri net equivalent**	**Original *E*-Nets limitations**	**Limitations of our evaluation nets variation**	**Original Petri net limitations**	**Useful Petri net variations**	**Transformation**
token	token	simple token or attributed token	first attribute is reserved for colour	simple token	colored token [10], object token [21]	When we use only coloured attribute value then we can use coloured token. Otherwise we must use object token.
location connections	place connections	connected to at least one transition	similarly to Petri net	no limitations	-	No conflicts.
token in location	token in place	no tokens (empty) or one single token (full) or one attributed token (full)	no tokens (empty) or one coloured token (full) with other attributes or not	no limitations of token count	inhibitor arcs [20], capacities of places [22]	Use inhibitor arcs of places.
transition schema	enabling rules, firing rules	schema values in tuple: 0 or 1 or "*e*" (only in right hand side of a schema), enabled transition cannot be disabled, it must fired (no conflicts)	may be use colour value instead to 0 or 1, conflict resolving determined by execution finish of resolution procedure or randomise function, transition can be disabled	input places must contains one or more token, output places not constrained enabling rules	inhibitor arcs [20], reset arcs [23], capacities of places [22]	Can be emulated by additional transitions, inhibitor arcs and loop connections (connect place with transition and transition with place). In output connections we can use capacities of places or inhibitor arcs. Reset arc may be used to reduce elements and improve readability of net.
transition procedure	-	-	not use	-	object token [21]	We can use outer procedures but existing Petri nets analysers may be unusable. However we can use tools for object tokens [8].
resolution location	conflict structure	returns token (single or attrubuted) or not	may return coloured token, return value cannot be dependent from previous events, returned value may be randomised or coming from outside of the evaluation net	firing is not deterministic	for decision of firing: Controlled Petri nets [24], Timed Petri nets [11], Stochastic Petri nets [12], Labeled Petri nets [25], etc.	Resolution location has resolution procedure. Resolution procedure running in enabling phase and result of it determine decision of firing. Automatic transformation to Petri nets without using external procedures is very difficult. For verifying the use cases we can use Timed Petri nets. For time benchmarking we can use Stochastic Petri nets.
triangular location [15]	connection	two interlinked triangular locations replaces long unreadable connection	-	-	-	It is only graphical notation. We can make extension for Petri net editor for supporting invisible connection and corresponding label.
transition with sender [14]	connection	-	it is sender triangular location and transition in one and when it fired then it sends coloured token from corresponding input location	-	-	Similarly to "triangular location." This item has been introduced for the improve readability of evaluation nets. Token was sent without depending of *transition schema*.

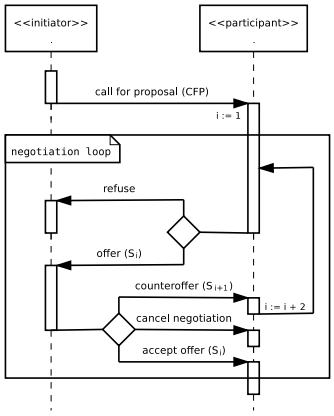

Fig. 2. Negotiation protocol in sequence diagram.

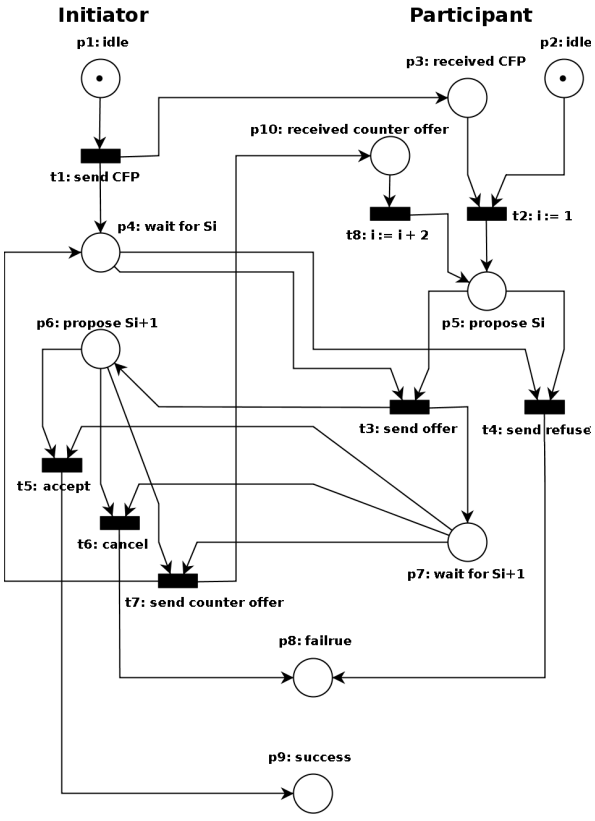

Fig. 3. Negotiation protocol in Petri net.

net goes to l_{12} (`Wait`) and expects him to make a decision (request l_{13}). As a result of the decision, a coloured token appears in l_{13} and the colour represents the `offer` (submission of proposals initiator) or `refuse` (breaking off of negotiations). The coloured token is processed by a_6, which decides whether to proceed according to evaluation net state l_{15} (`Wait`) or l_{17} (`fail`). Then the token is placed in the message S_i. The participant is in state l_{15} and is expecting a message from the initiator to be received by l_{14}. If the message does not appear

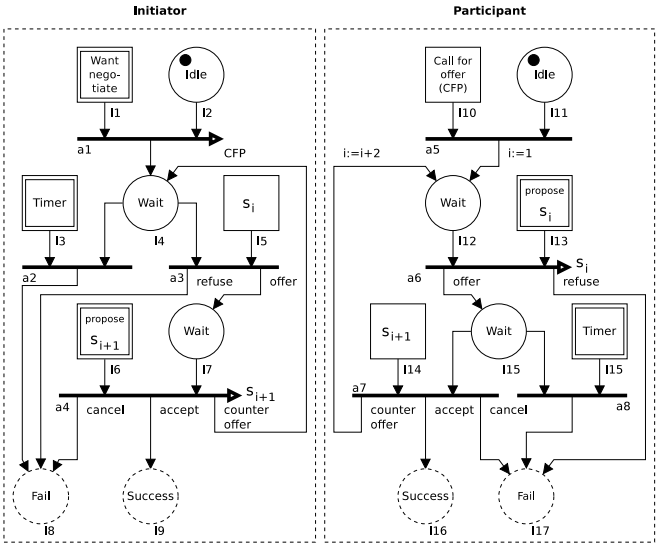

Fig. 4. Negotiation protocol in evaluation nets (our variation). S_i token can have *offer* or *refuse* enumeration value. S_{i+1} token can have *cancel*, *accept* and *counter offer* enumeration value. $i := 1$ and $i := i + 2$ have no effect on the evaluation net flow.

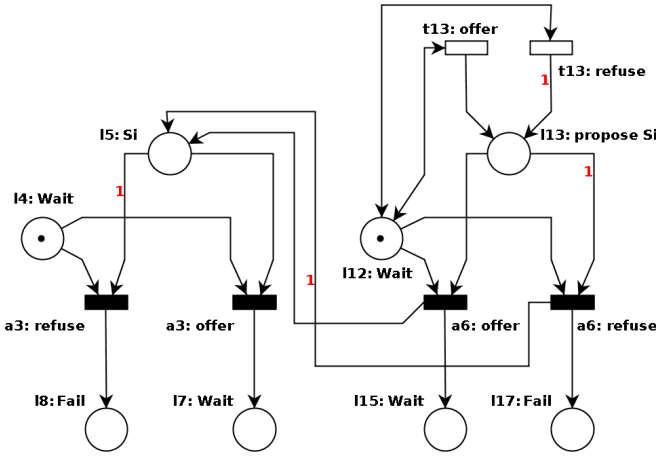

Fig. 5. Equivalent of l_4, l_5, l_7, l_8, l_{12}, l_{13}, l_{16}, l_{17}, a_3 and a_6 from Fig. 4 in coloured Petri nets. Inhibitor arcs are skipped.

T-TRANSITION	4/0	1/3	4	4/16	8	1/1
Switch: Fig. 5	8/0	2/2	2	8/12	-	2/0

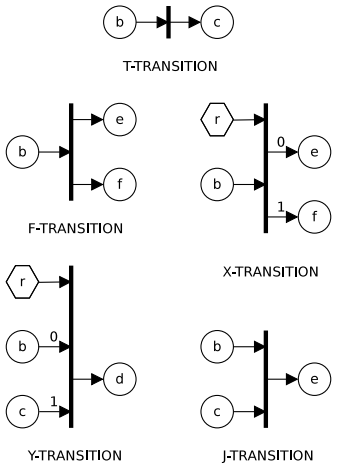

Fig. 6. Primitive *E*-Nets from [18].

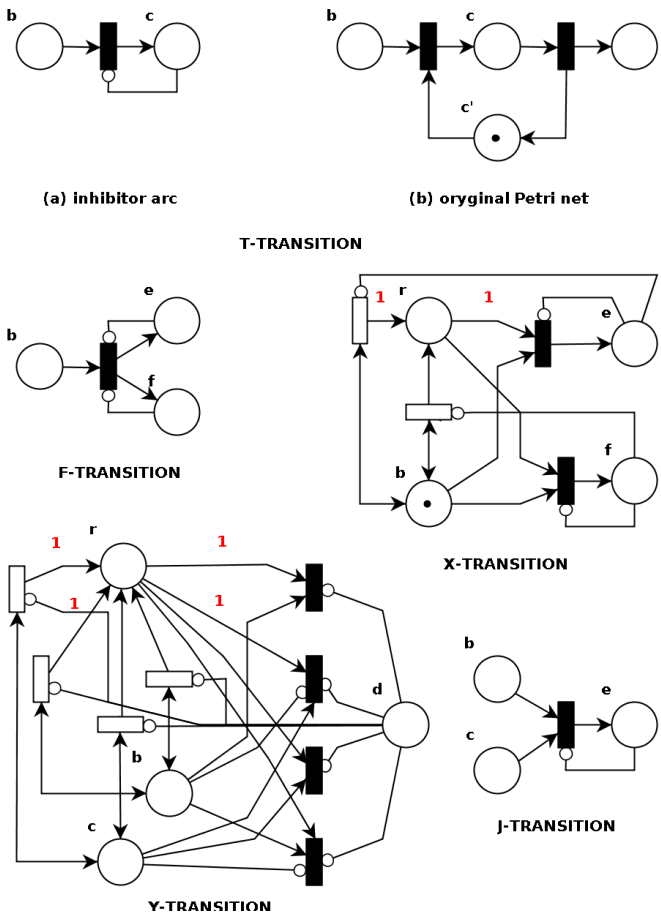

Fig. 7. *E*-Nets primitives from Fig. 6 transformed to Petri nets with extension: coloured, controlled and inhibitor arc. Additionally `T-TRANSITION` was transformed in two versions: (a) Petri net with extensions and (b) original Petri nets (b).

within a given time, the emergency procedure similar to that associated with l_3 will start in the initiator.

After receiving the message, initiator $\mathtt{S}_i$ is processed by a_3, which acts in a similar way to a_6. If the message contains the `refuse` attribute, the network is referred to the state of l_8 (`fail`), but when the message contains the attribute `offer`, the evaluation net goes into standby l_7 to make a decision by the initiator (decision will appear in the l_6).

Next, the attributed token is processed by a_4 and by a_7, which receives it through error $\mathtt{S}_{i+1}$ passed through a_4 and l_{14}.

We have tried to show the same example in Figure 3 using a controlled Petri net. This chart was prepared by hand. We tried to maintain maximum readability and so have omitted the emergency 'time out' in waiting for a message from the other side. We also abandoned the isolated, separate subnet Petri net for initiator and participant (such as in the evaluation net) to increase the number of transitions and arcs.

However, we provided standby. Cost reduction readability in this case was small because the whole Petri net is simple. Attributed tokens and resolution locations could be replaced with controlled transitions. In the former case, the initiator and participant received from their evaluation nets a request for attributed tokens. In this case, the initiator and participant will request a specific, enabled fired controlled transition.

Thus, this example shows that the use of an evaluation net instead of a Petri net makes sense visually. However, the lack of tools for analysis means that the evaluation drawings of the usefulness of the net are slightly larger than usual. This condition can be adjusted by using the described concept, which, however, entails the generation of a significant amount of additional elements. Only a portion of the changes resulting from the transformation in Fig. 5 is shown in Fig. 4.

IV. Conclusion

Evaluation nets are useful for some communication protocols e.g. the negotiation protocol from Fig. 2. However, they are not so popular, and tools for making and analysing them do not exist. Fortunately, evaluation nets with some restrictions can be transformed into Petri net.

The Petri net has many tools including mathematical tools, analysers and graphic editors. It is possible to extend the existing editor to support evaluation nets, transform them into Petri net and then use Petri net analysis tools.

Moreover, it is impossible to transform all things. The *transition procedure* and *resolution procedure* are programming instructions that operate on the attributes of tokens.

For this reason, we must either abandon them and possibly replace the *resolution procedure* function that returns a random result, or take the code of these procedures outside the Petri net and give them control over the firing transitions. In this article, we focused on the first solution. In the future, we want to focus on the other. There is a third solution, which is based on Petri net generating source code [28]. Maybe then it would be able to make a converter that is 100% compatible with the evaluation nets.

Another problem is that transformation adds a lot of new elements. Additional elements may require some modifications to analysers, but this exists only for the analyser and not for the user. For example, without a special filter on the analyser result, we saw our elements and new elements added by the converter. Without a filter our elements may disappear among the others.

Therefore, future work should focus on adjusting existing analysers. There are plans to write an interpreter, that will be able to perform net evaluation in a way similar to the BPEL interpreter.

ACKNOWLEDGEMENTS

Analyzing Meme Propagation in Multimemetic Algorithms: Initial Investigations

Rafael Nogueras, Carlos Cotta

Email: ccottap@lcc.uma.es

***Abstract*—Multimemetic algorithms (MMAs) are a subclass of memetic algorithms in which memes are explicitly attached to genotypes and evolve alongside them. We analyze the propagation of memes in MMAs with spatial structure. For this purpose we propose an idealized selecto-Lamarckian model that only features selection and local improvement, and study under which conditions good, high-potential memes can proliferate. We compare population models with panmictic and toroidal grids topology. We show that the increased takeover time induced by the latter is essential to improve the chances for good memes to express themselves in the population by improving their hosts, hence enhancing their survival rates.**

I. Introduction

FOUR decades ago, Richard Dawkins [3] put forward the definition of meme in analogy to the biological concept of gene. Memes were broadly characterized as units of imitation, that is, ideas or pieces of knowledge that jump from brain to brain, striving and proliferating in some cases and becoming extinct in others. Even more interestingly, memes are not static objects but dynamic entities that mutate during their lifetime; these mutations can make them more strong/interesting/useful/... thus boosting their propagation, or can have the opposite effect, making that particular mutation fade away. This plasticity explains their comparatively faster rate of adaptation with respect to biological genes.

Inspired by this notion of meme, Moscato [13] conceived a new optimization paradigm: memetic algorithms (MAs). MAs are a family of population-based optimization techniques that blend together ideas of different metaheuristics, most notably the orchestrated interplay between global (population-based) search and local (individual-based) search. The most popular incarnation of MAs features an evolutionary search engine endowed with local search add-ons. The notion of memetic evolution is here captured by the Lamarckian lifetime learning to which solutions are subject to, via the use of some local search operators. Incidentally, it has been suggested [17] to use the term *agent* rather than individual or solution in this context, to emphasize the fact that they are active entities that purposefully try to optimize the problem under consideration. We refer to [7], [12], [14], [15], [16] for a broad discussion on MAs.

This work is partially supported by Spanish MICINN under project ANYSELF (TIN2011-28627-C04-01), and by Junta de Andalucía under project DNEMESIS (P10-TIC-6083).

While memes are typically fixed in classical MAs (i.e., they are given by the particular choice of local search operators), several models trying to make them change during the optimization process have been proposed. This can be accomplished at a variety of levels. A simple possibility is the so-called 'meta-lamarckian learning' [18] in which the MA has a collection of local search operators (memes) available a priori, and some mechanism is used to decide which of them is applied on which solution and when (notice the connection with hyperheuristics [2]). A more complex approach features self-adaptation of the memes themselves. An example of this kind of self-adaptation is provided by multi-memetic algorithms (MMAs), in which each solution carries "genes" that indicate which local search has to be applied on it. These can range from simple pointers to existing local search operators to the parametrization of a general local search template [10] or even to the definition of a grammar to specify new complex local search operator [9], [11].

An interesting issue that arises in the context of MMAs is how memes propagate and spread over the population. While population dynamics has been well-studied in the case of evolutionary algorithms – e.g., [1], [6], [19], [20], the scenario is more complex in the case of memes: unlike genotypes (which correspond to solutions and thus can be evaluated according to the problem under consideration), memes can be only indirectly assessed via the effect they have on genotypes. Furthermore, memes evolve in MMAs alongside with solutions by attaching to them. Since this attachment is part of the self-adaptive process, it is up to the algorithm to discover good fits between individual pairs of genotypes and memes, and this is commonly done using only information about the genetic quality of solutions (i.e., fitness information). This work is aimed to study how memes propagate in such an environment driven by genetic selection and spatial structure. To this end, we consider and analyze an idealized model of MMAs. This model is described in next section.

II. Model Description

Let us consider an abstract model of MMAs in which each agent is characterized by a pair $\langle g, m\rangle \in D^2$, for some $D \subset \mathbb{R}$. The first member of the pair $-g-$ represents the genotype, which we equate to fitness for simplicity. As to the second member $-m-$ it represents a meme. More precisely, this value captures the *improvement potential* of that meme, that is,

978-83-60810-53-8/$25.00

a measure of how good solutions can get by applying the meme. We assume there is a monotonically increasing function $f : D^2 \to D$ encapsulating the application of a meme to a genotype, i.e., the effect of a single epoch of Lamarckian learning. Thus, an agent $\langle g, m\rangle$ becomes $\langle f(g,m), m\rangle$ after the application of the meme, where

$$\lim_{n\to\infty} f^n(g,m) = m \quad \text{if } g < m \tag{1}$$

$$f(g,m) = g \quad \text{if } g \geqslant m \tag{2}$$

Here $f^n(g,m)$ is the n-th composition of the function on the first argument, i.e., $f(f(\cdots f(f(g,m),m),\cdots,m),m)$. It must be noted that while this is very idealized characterization of the potential of a meme (since in general this potential is not going to be absolute but may depend on a complex match between the meme, the genotype and the problem landscape) it serves as an initial approximation to study several issues related to meme propagation in the agent pool.

The population P of the MMA is thus a collection of μ such agents, $P = [\langle g_1, m_1\rangle, \cdots, \langle g_\mu, m_\mu\rangle]$, endowed with a spatial structure that constrains agent communication. Let this spatial structure be characterized by a $\mu \times \mu$ Boolean matrix S, where S_{ij} is `true` if, and only if, the agent placed in the i-th location can communicate with the agent placed in the j location. Since we are interested in observing the dynamics of propagation of memes, we consider a extension of the selection-only model of evolutionary algorithms (i.e., using only selection/replacement and no variation operator) in which we add the local improvement stage of memetic algorithms. A scheme of the model is shown below in Algorithm 1.

Algorithm 1: Selecto-Lamarckian Model

```
for i ∈ [1 ··· μ] do
    INITIALIZE⟨g_i, m_i⟩;
end
while ¬ CONVERGED (P) do
    i ← URAND(1, μ) // Pick random location
    ⟨g, m⟩ ←SELECTION(P, S, i);
    g' ← f(g, m) // Local improvement
    P ← REPLACE(P, S, i, ⟨g', m⟩);
end
```

After initializing suitably the contents of the population, the algorithm engages on a cycle of selection plus improvement until the agents converge. Convergence is here approached from a memetic perspective, that is, we terminate the algorithm when the population comprises a homogeneous collection of memes (regardless of whether there is still diversity at the genetic level or not). As to the inner working of the algorithm, it resembles the uniform choice update strategy of cellular automata [21], in which the next location to be activated is selected uniformly at random with replacement.

III. Meme Propagation

Having defined the general model in the previous section, let us consider some qualitative features of meme propagation that can be extracted from it. Let us assume that selection is done by binary tournament, i.e., once a location i selected, a neighboring location j is selected from $\mathcal{N}(i) = \{j \mid S_{ij}\}$, and the agent with the best fitness is retained. As to replacement, let us assume that the improved agent replaces the agent that lost the previous tournament.

We are interested in analyzing the number of copies of each meme in the meme pool, so let us denote by $N(m,g,t)$ the number of instances of meme m attached to genotype g at time t, assuming for simplicity that D is some discrete domain. If we divide this quantity by the pool size μ we obtain $p(m,g,t)$, the fraction of the population comprising meme m attached to genotype g at time t. In each passing iteration of the system the number of copies can be estimated as

$$N(m,g,t+1) = N(m,g,t) + C(m,g,t) - D(m,g,t) \tag{3}$$

where $C(m,g,t)$ and $D(m,g,t)$ represent the expected number of copies of meme m attached to genotype g that are created or destroyed at time t. The creation of a new copy can be accomplished by the combined effect of selection of a suitable agent with meme m and the application of the meme to the corresponding genotype. Let us express this as:

$$C(m,g,t) = \sum_{g'} \sigma(m,g',t) p(g' \xrightarrow{m} g) \tag{4}$$

where $\sigma(m,g',t)$ is the probability of selecting an agent carrying meme m and genotype g' at time t and $p(g' \xrightarrow{m} g)$ is the probability that the application of meme m on genotype g' results in genotype g. The first quantity can be computed as the probability that the binary tournament picks two agents with meme m and genotype g or only one agent with this structure but better fitness than its competitor:

$$\sigma(m,g,t) = p(m,g,t)^2 + \\ + 2\left\{p(m,g,t)\left[1 - p(m,g,t)\right]\right\} \cdot \frac{\sum_{m'}\sum_{g'<g} p(m',g',t)}{1 - p(m,g,t)} \tag{5}$$

where the last factor is the probability that the fitness of the competitor is worse than g provided it is not a $\langle m,g\rangle$ agent. This expression assumes that the global distribution of memes/genotypes across the whole population is the same as for local neighborhoods. Obviously, this holds for the panmictic case in which any two agents are neighbors so we can assume this case initially, and consider it a first approximation to more general situations.

As to the destruction of a copy of a particular pair meme/genotype, it can arise via the selection of such a pair and the subsequent application of local improvement (which will alter the genotype) or via replacement by an agent of higher fitness. The first case also requires that the other agent chosen in the tournament be a copy of the same pair, so that it is later substituted by the improved agent. Thus,

$$D(m,g,t) = \sum_{g' \neq g} p(m,g,t)^2 p(g \xrightarrow{m} g') + \tilde{\sigma}(m,g,t)\ . \tag{6}$$

The replacement probability $\tilde{\sigma}(m,g,t)$ can be expressed as:

$$\tilde{\sigma}(m,g,t) = 2\left\{p(m,g,t)\left[1-p(m,g,t)\right]\right\}\cdot \cdot \frac{\sum_{m'}\sum_{g'>g} p(m',g',t)}{1-p(m,g,t)} \tag{7}$$

Let us know consider the evolution of the system in the early-term and mid-term, before a particular meme starts to saturate the population. In this situation memes are widely spread across genotypes, so $p(m,g,t) \ll 1$, so we can take quadratic terms $p(m,g,t)^2$ as approximately 0 and terms $1-p(m,g,t)$ as approximately 1. We thus have:

$$\sigma(m,g,t) = 2p(m,g,t)\sum_{m'}\sum_{g'<g} p(m',g',t) \tag{8}$$

$$\tilde{\sigma}(m,g,t) = 2p(m,g,t)\sum_{m'}\sum_{g'>g} p(m',g',t) \tag{9}$$

Substituting back into Eqs. (4) and (6) we get:

$$C(m,g,t) = 2\sum_{g',m'} p(m,g',t)\sum_{g''<g'} p(m',g'',t)p(g' \xrightarrow{m} g) \tag{10}$$

$$D(m,g,t) = 2p(m,g,t)\sum_{m'}\sum_{g'>g} p(m',g',t) \tag{11}$$

Since $p(g' \xrightarrow{m} g) = 0$ for $g < g'$ or $m < g$, Eq. (10) reduces to

$$C(m,g,t) = 2\sum_{g''<g'\leqslant g}\sum_{m'} p(m,g',t)p(m',g'',t)p(g' \xrightarrow{m} g) \tag{12}$$

If $m \leqslant g$ then $p(g' \xrightarrow{m} g)$ is 1 if $g' = g$ and 0 otherwise. Subsequently, the difference $\Delta(m,g,t) = C(m,g,t) - D(m,g,t)$ is in this case

$$\begin{aligned}\Delta(m,g,t) = {} & 2p(m,g,t)\sum_{m'}\sum_{g''<g} p(m',g'',t) - \\ & -2p(m,g,t)\sum_{m'}\sum_{g''>g} p(m',g'',t) \\ = {} & 2p(m,g,t)\cdot \\ & \cdot\sum_{m'}\left[\sum_{g''<g} p(m',g'',t) - \sum_{g''>g} p(m',g'',t)\right]\end{aligned} \tag{13}$$

Focusing on the sign of the difference in the above expression, we essentially obtain that *inert* memes (i.e., memes that can no longer improve their hosts) can strive by hitchhiking, that is, if they attach to agents above the median of the population.

Let us on the other hand consider the case $m > g$. In this situation, $p(g' \xrightarrow{m} g)$ is 1 if $g' = f^{-1}(g,m)$ and 0 otherwise, where we denote by $f^{-1}(g,m)$ the genotype value such that $f(f^{-1}(g,m),m) = g$. Using g^{-m} as a shorthand for $f^{-1}(g,m)$,

$$\begin{aligned}\Delta(m,g,t) = {} & 2p(m,g^{-m},t)\sum_{m'}\sum_{g''<g^{-m}} p(m',g'',t) - \\ & -2p(m,g,t)\sum_{m'}\sum_{g'>g} p(m',g',t) \\ = {} & \sum_{m'}\left[2p(m,g^{-m},t)\sum_{g''<g^{-m}} p(m',g'',t) - \right. \\ & \left. -2p(m,g,t)\sum_{g'>g} p(m',g',t)\right].\end{aligned} \tag{14}$$

The sign of this expression depends on the balance between the goodness of genotypes in the basin of attraction of g and the badness of g itself (in both cases goodness/badness relative to the rest of the population). Notice that in general there is a reinforcement between these quantities in the sense that the better a genotype in the basin of attraction of g, the better we can expect g to be. This does not just mean that *active* memes proliferate more and more when they attach to good solutions as one would expect, but also that memes with high potential can find their way to the final stages of the evolution provided they have enough time to improve their hosts (recall that the goodness of solutions evolves with time as an effect of the application of the meme). This suggests that models with slower genetic convergence can have a beneficial effect on the propagation of good memes, allowing the latter enough time to express themselves in the population and overcome the hitchiking effect of bad memes. Next section provides a more quantitative analysis of this effect via numerical simulations.

IV. Numerical Simulations

The numerical experimentation is aimed to explore empirically the dynamics of meme propagation and how it is affected by factors such as the population size, the relative improvement potential of memes and the underlying spatial structure of the population. Regarding population sizes, we have considered values $\mu \in \{100, 256, 400, 625\}$. These values cover a broad range of population sizes and are also perfect squares, which is important in connection with one of the spatial structures considered, namely a square toroidal grid with von Neumann neighborhood: two locations (i,j) and (i',j') are connected if their Manhattan distance $|i-i'|+|j-j'| \leqslant r$, where r is the neighborhood radius. We have considered $r = 1$ which leads to the traditional North-South-East-West (plus the current location) neighborhood. The other spatial structure considered is the panmictic model in which all locations are connected. In either case, we have considered the function

$$f(g,m) = \begin{cases} g & \text{if } g \geqslant m \\ (g+m)/2 & \text{if } g < m \end{cases} \tag{15}$$

to represent the action of memes. Intuitively, this function provides smaller improvements for increasingly good genotypes much like often happens in practice. All experiments

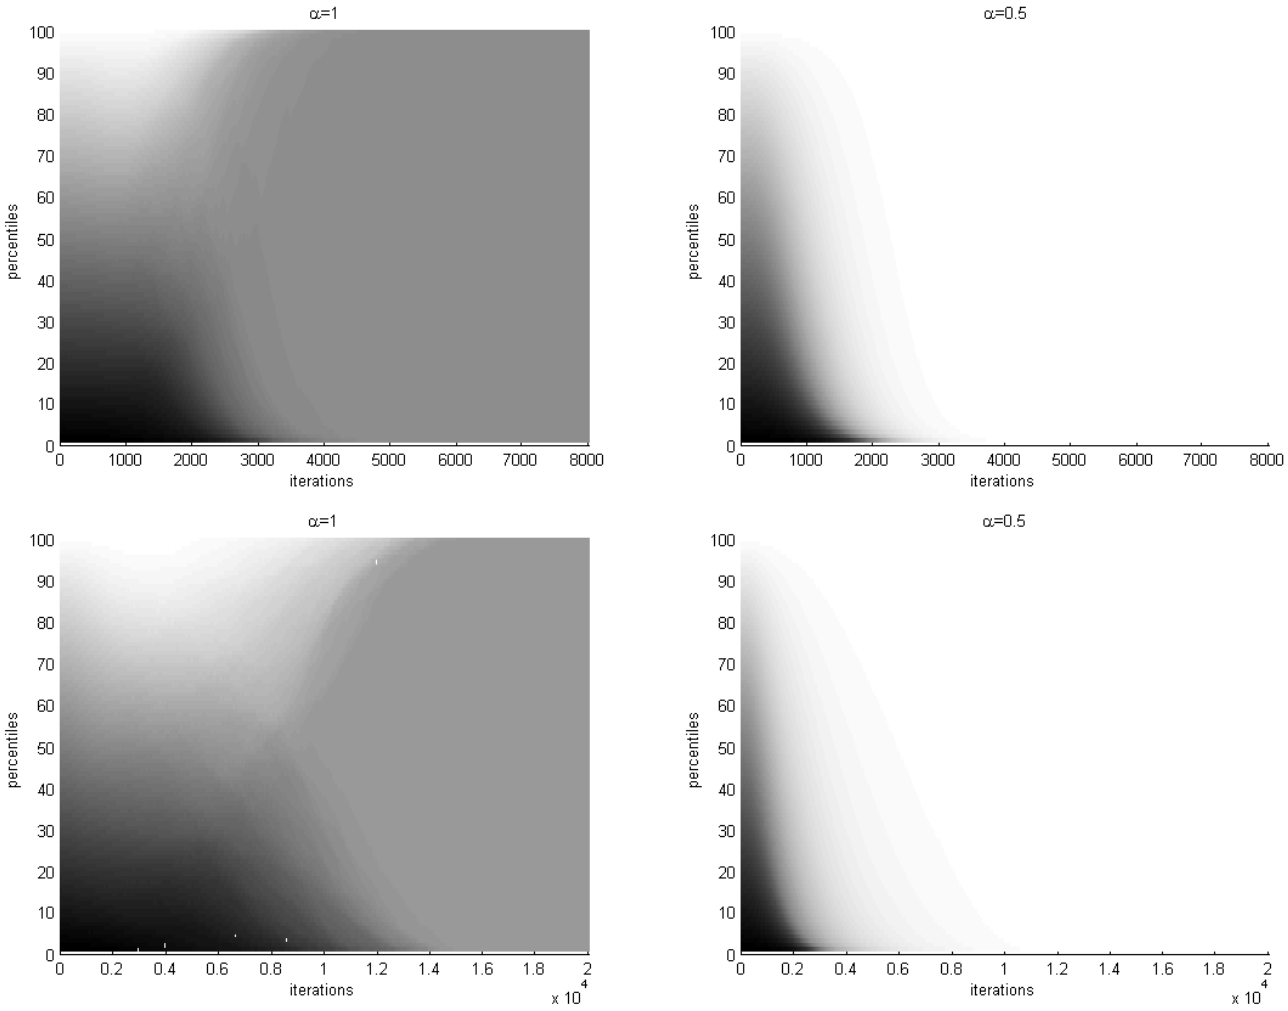

Fig. 1. Meme maps for simulations with $\mu = 625$. The upper row corresponds to panmictic connectivity and the lower row to von Neumann neighborhood. Similarly, the left column corresponds to genotypes initialized in $[0, 1]$ and the right one to initialization in $[0, 0.5]$ (memes are initialized in [0,1] in both cases). Lighter shades of gray indicate higher meme values. The evolution of the algorithm is depicted in each subfigure from left to right, each vertical slice representing the distribution of memes at a certain time t. Notice the different scale in the X-axis.

are averaged over 100 runs in order to obtain representative results. Each run is terminated upon convergence of memes, which for simplicity is determined when all memes are equal to 2 decimal positions.

Let us firstly analyze meme propagation as a function of the relative improvement potential of memes at the beginning of the run. For this purpose, we take $D = [0, 1]$ and consider a scenario in which genotypes and memes are randomly initialized in this range, and another scenario in which genotypes take initial values in $[0, 0.5]$ whereas memes are randomly sampled from $[0, 1]$. Figure 1 shows the distribution of memes at each time step (the lighter the shade of gray, the higher the meme value). Focusing firstly in the upper row (panmictic topology), notice the clearly different behavior depending on genotype initialization. When genes and memes are both initialized in $[0, 1]$ the algorithm does seldom converge to a high-potential meme. Actually, such memes temporarily proliferate in the initial stages of the algorithm but are later driven to extinction by memes hitchhiking on high quality genotypes to which they sticked by chance. The situation is quite different when genotypes are initially drawn from $[0, 0.5]$: in this case the algorithm does gradually converge to the upper part of the meme distribution, with low-potential memes quickly disappearing from the population. A more detailed perspective on this is provided by Figure 2 in which qualified runtime distributions (QRTDs) [8] are provided. These indicate the probability that a certain target (in this case, convergence to a meme in a desired percentile) is reached as a function of the number of iterations. Notice how the probabilities are below 10% for memes above the 95% percentile in the first scenario, whereas this probability is 100% in the second scenario. In the latter a spurious match between a very good genotype and a bad meme cannot happen since these very good solutions do not exist initially. Furthermore, high-potential memes initially

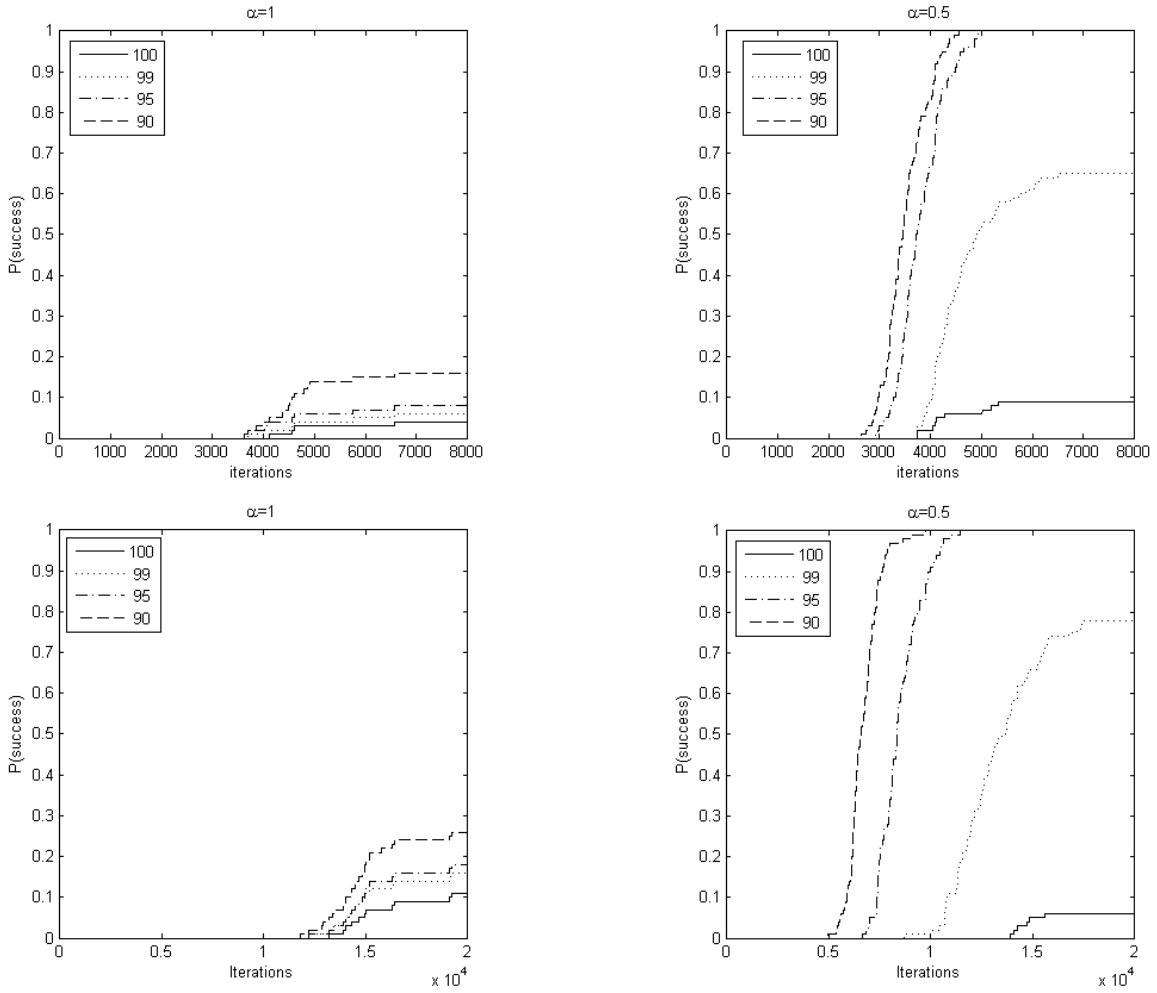

Fig. 2. Qualified runtime distributions for simulations with $\mu = 625$. The upper row corresponds to panmictic connectivity and the lower row to von Neumann neighborhood. Similarly, the left column corresponds to genotypes initialized in $[0, 1]$ and the right one to initialization in $[0, 0.5]$ (memes are initialized in [0,1] in both cases). The curves indicate the probability that the population converges to a meme in the i-th initial percentile of the population as a function of the number of iterations. Notice the different scale in the X-axis.

attaching to bad genotypes can highly improve the quality of the latter in the initial steps, thus increasing their chances of survival.

Let us know turn our attention to the effect of the spatial structure. The bottom row of Figure 1 shows the distribution of memes for the case of von Neumann neighborhood. Notice how a similar pattern as in the panmictic case is observed with respect to genotype initialization. A more detailed inspection indicates several differences though. Firstly, notice how the convergence is slower in this case (e.g., the scale in the X-axis is larger). This is a well-known effect of the use of spatial structure and is commonly exploited in the context of evolutionary algorithms for promoting diversity and thus decreasing the chances of getting stuck in local optima [4], [23]. In the case of MMAs this has an additional advantage, namely the fact that a slower convergence increases the lifespan of individual memes, thus giving them more chances to improve their hosts if they have the potential to do so. Hence, the algorithm is more robust and can better cope with hitchhiking inert memes. This can be seen in the meme map in the bottom row of Figure 1 by a larger prevalence of lighter-gray areas, and more clearly in the QRTDs (bottom row of Figure 2), e.g., the 95% percentile is reached with nearly 20% probability in the case of $[0, 1]$-initialization (cf. below 10% in the panmictic case), and the 99% percentile is reached with nearly 80% probability for $[0, 0.5]$-initialization (cf. about 65% in the panmictic case). A signrank test [24] indicates that the difference in the final percentile reached is statistically significant in both cases ($\alpha = .05$).

Finally, we consider the takeover time, namely the time required for a meme (not necessarily the best one as shown previously) to dominate complete the population. Figure 3 shows the growth curves, depicting the percentage of the meme pool occupied by the most repeated meme (notice that the most repeated meme need not be the same throughout a run; we simply count the number of copies of the most repeated one

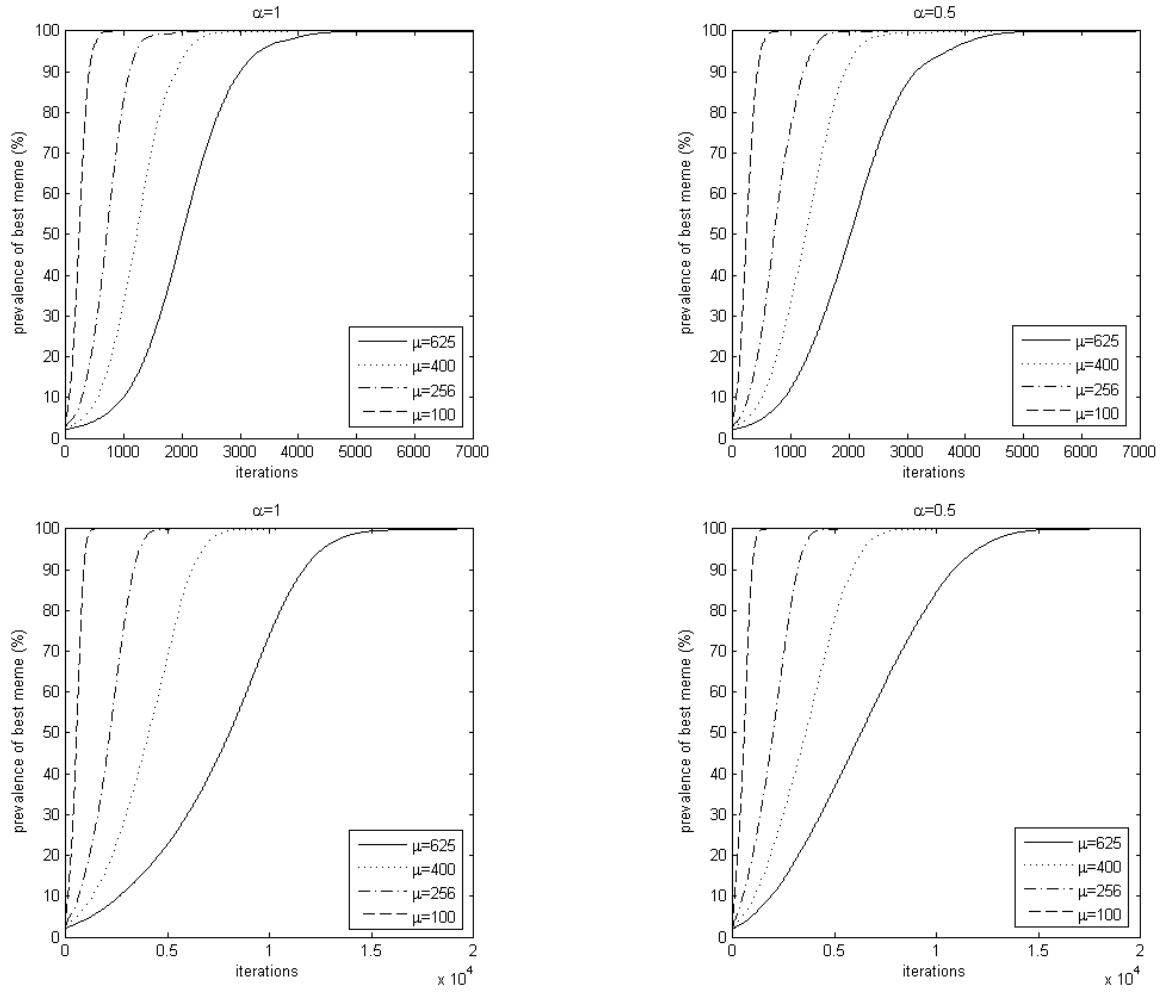

Fig. 3. Growth curves for different population sizes. The upper row corresponds to panmictic connectivity and the lower row to von Neumann neighborhood. Similarly, the left column corresponds to genotypes initialized in $[0, 1]$ and the right one to initialization in $[0, 0.5]$ (memes are initialized in [0,1] in both cases). Notice the different scale in the X-axis.

TABLE I
FITTING GROWTH CURVES TO A LOGISTIC FUNCTION. FOR EACH ALGORITHM CONFIGURATION THE SCALE PARAMETER α AND THE MEAN SQUARED ERROR IS SHOWN.

		population size							
		$\mu = 100$		$\mu = 256$		$\mu = 400$		$\mu = 625$	
topology	G	α	mse	α	mse	α	mse	α	mse
panmictic	0.5	81.628878	0.000042	210.791430	0.000069	324.649846	0.000064	521.933265	0.000017
	1.0	77.708284	0.000008	187.904342	0.000030	297.902782	0.000027	462.866673	0.000010
von Neumann	0.5	186.815036	0.000366	578.914610	0.000554	1046.429102	0.000361	1974.995403	0.000318
	1.0	168.567695	0.000322	585.804249	0.000532	1057.519394	0.000537	1945.625376	0.000705

at each time step). These curves exhibit the typical shape of the well-known logistic model $f(t) = 1/(1 + Ke^{-t/\alpha})$. Indeed, such a model was proposed early in the literature by Sarma and De Jong [20] in the context of spatially structured evolutionary algorithms. While by no means the unique alternative – e.g., see [5]– it serves as a good starting approximation to quantify the growth of the dominant meme. Qualitatively, we observe as expected the well-known pattern of slower convergence for increasing population sizes and for the von Neumann topology [6] as opposed to the panmictic population. From a quantitative point of view, we have fitted the growth data to a logistic curve to identify the scale factor α that renders the number of iterations dimensionless. The resulting data is shown in Table I. As it can be seen, the fit is quite good, yielding very low mean squared errors. The scale parameters are quite similar for variants with the same topology, and are about 2-5 times larger for the von Neumann topology than for the panmictic case, in correspondence with the relative takeover time which

can be seen in Figure 3. With respect to the population size, the increase in the scale parameter admits a linear interpolation $\alpha = a + b\mu$ yielding values of $b = 0.84$ and $b = 0.74$ for the panmictic case and $b = 3.43$ and $b = 3.40$ for grid topology with von Neumann connectivity.

V. Conclusions

We have presented some initial steps in the line of analyzing meme propagation in MMAs. Using an idealized model of genotypes and memes we have shown that the selection intensity plays a very important role in allowing high-potential memes to proliferate. In a panmictic model, good memes will dominate the final population when the starting solutions have a substantial improvement margin on average. When this margin is smaller, average memes can hitchhike their way to the final stages of the evolution and make other comparatively better memes become extinct. In the presence of a spatial structure inducing longer takeover times (in our case a toroidal square grid with von Neumann topology), this hitchhiking effect is somewhat mitigated, allowing good memes to express themselves and increasing their chances for making it to the final population. An interesting line of future research focuses on the consideration of other topologies and study their effect on meme propagation. Work is in progress in this area. Looking beyond, another topic for further research is the extension of this analysis to coevolutionary memetic algorithms [22] in which memes are detached from genotypes and co-evolve alongside the latter in a separate population.

Fair and truthful multiagent resource allocation for conference moderation

Adam Połomski

Email: A.K.Polomski@elka.pw.edu.pl

***Abstract*—Multiuser voice conferencing platforms are more and more popular. Internet bandwidth is becoming very accessible, what makes voice over IP used on an everyday basis. Being able to communicate with multiple people at the same time can be beneficial, but on the other hand increases the need of coordination mechanisms. Determining a moderation scheme which is fair and efficient is not a trivial problem to solve. We define conference moderation as a multiagent resource allocation problem and introduce a process based on Vickrey auctions to solve it. A concept of co-owned communication channel is what stands as a basis of our definition of fairness.**

***Index Terms*—Multiagent systems, Auctions, Social welfare, Moderation, Simulation**

I. Introduction

EXCHANGE of information is a crucial part of our existence. In some situations we have to elaborate with larger groups of people. It might be very valuable, as every member of such group brings some extra knowledge, potentially useful for the whole society. Yet, it comes at a certain price. It requires an additional effort to manage the flow of information as the number of participants grows. In a most general definition, a conference is ”a meeting for consultation, exchange of information, or discussion”. Yet, the conferences may vary a lot in its specifics. A discussion among a group of friends lives by a different rules than a company meeting. An environment in which a large group of random people struggles to exchange some information has the biggest potential of becoming extremely chaotic, thus bringing the flow of information to a minimal level. Open societies with low entry barriers often face problems of disruptive behavior such as flooding or spamming. How do we deal with that? How do we coordinate the flow of information in a way which is efficient and fair? That is a role for moderation mechanism.

Decentralized moderation schemes for large scale social platforms like Usenet or Slashdot is being discussed in a number of papers [1], [2]. Multiagent resource allocation and a concept of bargaining or trading agents is also a common topic of research, with distribution of network bandwidth being one of the possible applications [3].

This is an extended version of the paper in which we first introduced the presented allocation model [4]. We mostly focused on the verification of the model. However, we also provided a new, refreshed view of the problem definition and social welfare, which may be found in the next two sections. We gave some more detailed insight into features a fair and effective social welfare metric should possess. Section V contains a description of Vickrey auction based allocation method. We have also introduced a resale procedure to deal with a problem of choosing a proper allocation time. Next we move on to an overview of verification methodology in Section VI followed by simulation results in Section VII. A JADE based implementation of conferencing agents is presented.

II. Background

The environment with which we are dealing is very specific. It is a huge online audio conference platform connecting people from all parts of the world. It is used by hundreds of thousand users every day. It is very likely that conference participants will not know each other. The discussion topics may vary and cannot be anyhow limited or managed. The only thing that can be assumed or enforced is that all participants in a single discussion share the same language. Also the number of concurrent ongoing conferences may be as high as tens of thousands. The model of a single conference is very simple though. All participants connect to a single device—media server, which is responsible for handling the voice stream. Strictly speaking it broadcasts the voice stream transmitted by a single participant to all others. It also has a steering protocol which allows controlling it to some extent. What is most important, it allows specifying which participants are allowed to transmit voice signal in the given moment of time and which ones are only allowed to receive it.

A. Moderation

For this sort of audio conversation platform to function successfully, a moderation mechanism is required. User experience would suffer otherwise. It is hard to strictly define what would be seen as ”good” or ”bad” conversation by the participants. There is a basic rule that definitely needs to be fulfilled in order to achieve a fair discussion.

No participant will be able dominate the discussion.

Moderation is a mean to fulfill those requirements. If the ability to speak is distributed properly among participants over time, it should be possible to maximize welfare of the whole group. There are a few standard, commonly known moderation mechanisms, which can be observed:

- No moderation—For example a group of friends talking at the cafeteria will not require any moderation to get the most of their discussion. It is important that the group

978-83-60810-53-8/$25.00

is relatively small. The fact that participants know each other well and have no point in dominating the discussion also helps.
- Discussion rules—For example a lecture at the university. Both, the lecturer and the students are aware of discussion rules up front and will respect them.
- Human moderator—A designated person is responsible for leading the discussion by granting/revoking voice to participants. It is also very important that moderator understands and follows the discussion, as it is crucial to pick the right people to speak in a given time slot.
- Queuing—All participants queue up and are the voice is granted in a "round robin" scheme.

All of the above moderation models except queuing cannot be applied in this specific environment. That is mostly because of size of the system. Queuing is the only model that does not require manual management and puts no trust that users will apply to some rules without forcing them into it. A huge drawback of queuing in this case is the maximum pessimistic waiting time. It is possible that a participant who needs the voice most will be forced to wait until everyone else uses the granted time slot. That is an area, where introducing a multi agent solution could bring better results.

B. Multiagent resource allocation

Multiagent resource allocation is a process of distributing a number of items (resources) among a number of agents [5]. This brief definition, however, does not fully describe the problem.

Resources might differ in characteristics. The whole range of resource types is substantial and each might require different allocation technique. For instance, we can distinguish divisible goods (like network bandwidth) and indivisible. Also it may, or may not be allowed to share an indivisible resource among a number of agents.

Agents may have preferences over different allocation outcomes. Not only may they have preferences over resource bundles they receive, but also over bundles received by others. Preferences can be represented in a various ways, like utility function or binary relation on alternatives. Moreover, agents may or may not be truthful while reporting their preferences.

Allocation can be performed with the use of various allocation procedures, which can be either centralized or distributed. Typical examples of centralized procedures are auctions or voting mechanisms, with a central entity empowered to decide on the final allocation. In distributed solutions agents try to come to a common agreement through a sequence of local negotiation steps. In both cases, the objective is to find an allocation which is feasible or optimal. What stands behind the concept of optimal depends on the specific multiagent resource allocation scenario.

III. Problem definition

We formulate conference moderation task as a resource allocation problem. The following definition is general and may find application whenever multiple agents compete over a non divisible resource across multiple time periods.

Let $N = \{a_1, a_2 \dots a_n\}$ be a finite set of participating agents. Each agent takes part in $T \in \mathbb{N}^+$ consecutive resource allocation runs, each for a separate time period. A resource can only be allocated to one agent at a time, therefore the set of feasible allocations $\Delta = N$. Let δ_t denote the allocation outcome for t allocation run $\forall t \leq T$. There is also a special null allocation δ^- which represents a situation when no agent holds a resource. Each of the participating agents has its preference regarding every allocation represented by the utility function $u_{i,t} : \Delta \rightarrow R, \forall t \leq T, a_i \in N$. Let vector $x = (\delta_1, \delta_2 \dots \delta_T)$ hold all allocations across all time periods. We call $S(x)$ a social welfare function. $S : \Delta^T \rightarrow R$. We will discuss it in details in section IV. For now it is only important that it determines an overall happiness of the whole society N for a given allocation vector x. Objective is to find x^*, which will $\max S(x)$.

Utility functions are not known upfront. While deciding upon an allocation δ_t, our knowledge consists of:
- current and past utility functions for all participating agents
- allocations that have been performed up to this point

Note that the shapes of current utility functions u_{it} are very likely to depend on the whole history of allocations up to this point in time $(\delta_1, \delta_2, \delta_3 \dots \delta_{t-1})$ and what those allocations brought. In other words, every allocation decision can affect the way agents shape their utilities in the future. It might also have an impact on the total number of consecutive allocations T.

IV. Social welfare function

Social welfare function S ranks every feasible allocation vector x. This ranking represents a welfare of the whole society N if an allocation x took place. Since S determines whether we choose one allocation vector over the other, it also defines what we consider as fair. It is not a straightforward task to rule what is fair in these specific conditions. Moreover, according to Arrows impossibility theorem [6] there exists no reasonably consistent social welfare metric. It needs to be carefully chosen to fit the specific scenario.

For a given application Nash social welfare metric has advantages over Utilitarian or Egalitarian viewpoints [7]. It leverages between fairness by equalizing utility distribution among agents and higher overall utility. However, we cannot define the social welfare metric as in Equation 1.

$$S_N(x) = \prod_{a_i \in N, t \leq T, t \in \mathbb{N}^+} u_{it}(\delta_t) \tag{1}$$

Consider the scenario presented in Table I and two allocation vectors $x_1 = (a_1, a_1, a_2), x_2 = (a_2, a_2, a_1)$. Both vectors are equally valuable in terms of fairness, as each of the two agents gets his share of resources and the division is as equal as possible. After applying Nash social welfare metric we get $S_N(x_1) = 250 > S_N(x_2) = 200$, thus it clearly favors x_1 over x_2. From the utilitarian perspective we have

TABLE I
SAMPLE WELFARE VALUES

t	δ_t	$u_{1,t}$	$u_{2,t}$
1	a_1	5	1
1	a_2	1	10
2	a_1	5	1
2	a_2	1	2
3	a_1	10	1
3	a_2	1	10

$S_U(x_1) = 23 < S_N(x_2) = 25$, what means that overall utility is lower in case of allocation x_1.

An ideal social welfare metric for this environment should in the first place ensure that all rules of fair discussion proposed in Section II-A are fulfilled. Once this is secured, higher overall profit should be promoted. We propose the conference metric given by equation 2, which mixes the concepts of utilitarian social welfare and Nash product together.

$$S_M(x) = \prod_{a_i \in N} \sum_{t \leq T, t \in \mathbb{N}^+} u_{it}(x_t) + \epsilon \tag{2}$$

A. Unanymity

Unanimity principle is the most important concept of welfare economics [8]. It says that the chosen utility vector should not be Pareto inferior to any other feasible utility vector. Metric defined by Equation 2 fulfills the rule of unanimity, as it prefers allocations which bring strongly Pareto optimal utility vectors. Let x_1 be a feasible allocation vector preferred by the metric. Let x_2 be a different feasible allocation dominating x_1 in terms of Pareto domination. Therefore we have:

- $u_{i,t}(x_{1,t}) \leq u_{i,t}(x_{2,t}), \forall a_i \in N, \forall t < T, t \in \mathbb{N}^+$
- $\exists a_i \in N, \exists t < T, t \in \mathbb{N}^+, u_{i,t}(x_{1,t}) < u_{i,t}(x_{2,t})$

It is easy to see, that $S_M(x_1) < S_M(x_2)$. This means that x_2 would be a preferred allocation vector by the metric.

Note that it does not take place if we remove ϵ from the equation. For instance, if one of the agents had zero utility for every possible allocation, all allocation vectors would be seen as equal.

B. Anonymity

Anonymity (symmetry across the agents) is another important social welfare metric feature. It is especially significant while considering fairness, as it indicates if any member of the society is in a privileged position. S_M is anonymous to some extent. For any choice of agents a_1 and a_2, switching their utility functions, so that $u'_{1t} = u_{2t}, \forall t \leq T$ and $u'_{2t} = u_{1t}, \forall t \leq T$ will not change the rating of any allocation vector. This only holds true if we perform so for all values of t. All allocations $\delta_j, \forall j < t$ and utility functions $u_{n,t}, \forall j < t$ act as an allocation history, which has a significant impact while deciding on δ_j. This historical data makes some agents more privileged then others. That is all in line with our understanding of fairness.

V. FAIR ALLOCATION MODEL

The proposed model is designed based on two assumptions:

- The whole resource is cofounded by each of the participating agents, therefore each member of the society owns an equal share of rights.
- Every agent may only grant some utility to owning the resource himself—$u_{it}(a_j) = 0, \forall i \neq j$. A more general allocation model with no such restriction has been proposed in [4], but it is out of scope of this paper.

The resource is indivisible and can only be utilized if fully owned. No one can use just a part of resource, yet agents can negotiate over the price and purchase or sell it to each other. For this purpose each agent a_i is associated with r_{it}, which might be interpreted as agent's wallet for time period (allocation number) t. Initially $r_{i1} = R, \forall a_i \in N$, where R is a positive constant value to initialize all the wallets. The conference is divided into T shorter periods, at the beginning of each agents may express their desire to obtain full rights to transmission channel. Resource allocation is then performed with the use of Vickrey auction mechanism [9]. The allocation pattern for period t is following:

1) Each participant a_i issues a bid with the valuation v_{it}. The bid cannot be higher than the actual wealth of agent at that time, therefore $v_{it} = \min(u_{it}(a_i), r_{it})$
2) The winning agent a_k and the price to pay p_t is determined with the use of Vickrey auction.
3) Price to pay is deducted from the winner's wallet $r_{k,t+1} = r_{k,t} - p_t$.
4) All agents which sell their resource rights to a_{kt} are rewarded $r_{i,t+1} = r_{i,t} + \frac{p_t}{|N|-1}$.
5) The whole resource is allocated to $\delta_t = a_k$ for time period t

According to the introduced model, resource allocation time is constant and defined upfront. It is a serious limitation given that demands might vary in terms of allocation length. If allocation time was kept constant and set too long, we would waste the resource due to excess allocation period. On the other hand, setting this time too short would cause allocations which only partially meet the demands. Moreover, there is no guarantee that agents assign any utility at all to allocations which only partially meet their demands.

We deal with this problem by setting an allocation time long and introducing a resale procedure. Whenever an agent owns a resource which he no longer requires while there is still some time left before exclusive rights period ends, he can request for an earlier reallocation. If a demand for the resource exists, he might get a fraction of the price he paid back.

Let $\delta_t = a_i$ and $\delta_{t+1} = a_j$. Agent a_i decided to request a resale after utilizing the resource for time l out of full allocation time L. When a_j wins:

- $r_{i,t+2} = r_{i,t+1} + \frac{l}{L} \min(p_t, p_{t+1}) + \frac{p_t - \frac{l}{L} \min(p_t, p_{t+1})}{|N|-1}$
- $r_{k,t+2} = r_{k,t+1} + \frac{p_t - \frac{l}{L} \min(p_t, p_{t+1})}{|N|-1}, \forall k \neq i, j$

It is important that an agent will never gain from the resale procedure. It is only possible to get a fraction of an allocation

price back. Otherwise, it would motivate members of the society to purchase a resource with the hope of future resale at a higher price.

By leveraging Vickrey auction, we gain all characteristics of this auction mechanism. Performing allocation is quick and does not require a lot of overhead network traffic. This is a very important feature, as it is crucial to finish negotiations before the beginning of conference period affected by this allocation. Agents are also highly encouraged to bid their true valuations, as it is in line with the dominant auctioning strategy. It is important to mention here that in the dominant strategy equilibrium is a weak equilibrium for VCG process in case of asymmetrical bid ranges [10]. For the richest agent it is equally reasonable to bid anything from the full value of his wallet to a wallet value of the second richest agent. In this case however, it has no effect on the choice of winner or on the price.

Unfortunately Vickrey auction has a couple of drawbacks. It is vulnerable to bidder collusion agreements. A group of agents with the highest valuations may settle not to vote their true valuations in order to lower the resulting price. The model is also exposed to lying auctioneers. Agents may bid shill votes in order to inflate the price and increase the income.

VI. Methodology

In order to verify the proposed model and how it operates as conference moderation mean, we performed a whole range of simulated discussions. We implemented two types of agents playing a role in the conference—coordinator and participant. Implementation was done with the use of JADE platform [11]. Coordinator is responsible for keeping track and deciding whenever the society should transition to a next allocation phase. It is also up to the coordinator to decide upon the resource allocation based on all data (utilities) collected from participants. Participant's main responsibility is to declare its current utility of holding the resource whenever coordinator announces the bidding phase.

A. Protocol

Naturally, interaction among agents requires a specified communication language. FIPA standard defines a huge set of protocols, which come implemented out of the box with JADE. We have chosen some of as a language for our agents.

"Subscribe" protocol—defined by the FIPA standard. Should be used, whenever "Initiator" agent wishes to monitor the state of an object owned by the "Receiver". For the purpose of this simulation, subscribe protocol is used by the participants to monitor state changes of the communication channel. This information is broadcasted by the coordinator after each performed allocation.

"Allocation" protocol—FIPA standard does not provide a Vickrey auction protocol. We designed the protocol of our own as shown in Figure 1. Every auction is initiated by the coordinator agent, who collects bids from all participants and performs the allocation according to the implemented model.

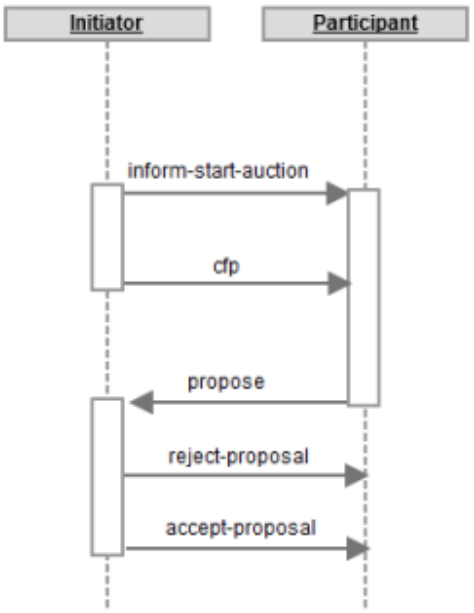

Fig. 1. Allocation protocol

"Request" protocol—defined by the FIPE standard. Used whenever an "Initiator" agent asks the "Receiver" to perform some action. In the discussion simulation, this protocol is used by a participant agent to request for an earlier reallocation procedure.

B. Behaviours

The whole process begins with a subscription phase when coordinator awaits for all participants to submit their conference subscription requests. After a certain time limit the discussion moves on to the main phase, which consists of two alternate behaviors:

- Auction—Collecting bids (valuations) from all conference participants. Making an allocation decision based on collected bids. Informing participants about the auction result.
- Allocation—Granting the resource to the new owner. Collecting and distributing the payment. Informing participants about the resource ownership change.

The whole auction process along with a decision upon the next allocation change is performed in advance (auction speedup time) to the actual change, in the background of the previous allocation time. This procedure is designed to eliminate allocation time fluctuations caused by the auction procedure, as it might involve passing a substantial number of messages over the network or performing timely calculations.

C. Demands

The main task of participant agent is to compete over a resource (communication channel) according to his preferences. Determining current utility is performed based on the agents set of demands. A single demand object is shown in the Figure 2. It is characterized by the following features

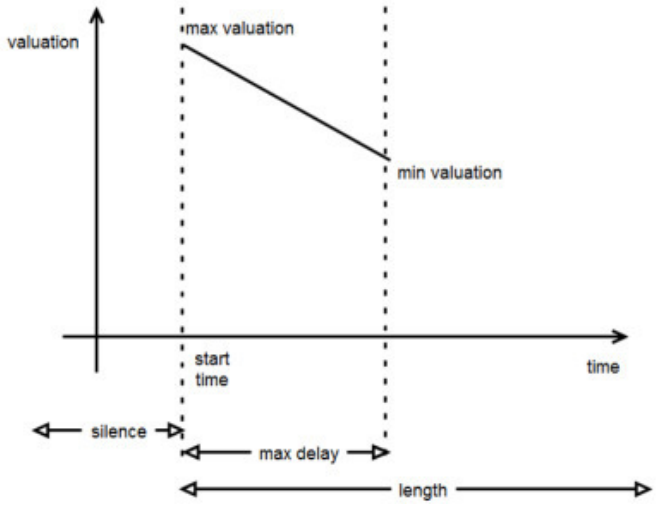

Fig. 2. Demand object

- Start time—the time since when the demand is active and has influence on agent's utility
- Maximal delay—maximal time in which the demand is still active
- Length—allocation time required to satisfy this demand
- Maximal valuation—valuation for an allocation at the demand start time
- Minimal valuation—valuation for an allocation with a maximal delay
- Silence time—time interval from the previous demand

In order to determine the current resource valuation, an agent scans through the whole set of active demands and picks the one with highest active valuation. If a demand is not satisfied right when it arises (start time), valuation deteriorates linearly up till maximal delay.

D. Dynamic demands

Aiming to increase similarity to real live conversational environment, we implemented semi intelligent agents capable of dynamically shaping their utility functions based on discussion history. Human conversation is a process driven by certain rules [12]. Among others, these rules describe how people choose and change the discussion topic:

- RULE 3: In introducing a new topic of conversation, the topic should be chosen so that both speakers have some knowledge and interest in its discussion.
- RULE 6: The topic of conversation may drift to a subject where the conversational participants share a great amount of knowledge.
- RULE 13: Each participant in the conversation has the conversational goal of saying things that are important to the other participant.

Having that in mind, we have developed an agent capable of reacting (adjusting his utility function) to the discussion flow. Such agent is supplied with a set of topic preferences and discussion memory to record the occurrence frequencies of all topics. Given all that as an input data, whenever an agent takes active part in a discussion, it will first choose a theme possibly interesting for all parties and shape it's utility function accordingly. Every topic from the list might be chosen with the probability directly proportional to agent's preferences and the frequency of occurance in the discussion so far.

E. Allocation models

We performed simulations for four different allocation models acting as a moderation procedure. Apart from the "Fair allocation model" proposed in Section V, we use three other allocation schemes for the purpose comparison:

- Queuing—Participants reporting need for the resource (positive valuation) are put into FIFO queue. Resource is always allocated to the first agent in the queue. There is no risk of dominating the discussion, yet it does not give any preference to allocations which increase the overall social welfare.
- Choosing maximal valuation—Resource is allocated to an agent reporting highest valuation at the given time. This model does not encourage agents to bid their true valuations nor does it put any preference to fair allocations. The dominating strategy is to bid just a tiny bit above the highest bidding participant.
- Maximizing social welfare metric—Chooses the allocation which maximizes social welfare metric defined by Equation 2. Prefers allocations which are both fair and increase the overall social welfare. However, participants might try to increase their profits or dominate the discussion by faking their bids. Under the assumption that allocation decision does not have any impact on the future shape of agents' utility functions, this model guarantees to maximize the social welfare.

VII. Evaluations

We came up with three discussion participant profiles which vary in characteristics of their demands set. All demand attributes were generated from uniform distribution on a given range.

- Regular:
  - Silence time: 3 to 15 seconds
  - Maximal delay: 3 to 7 seconds
  - Length: 3 to 10 seconds
  - Maximal valuation: 2 to 10
  - Minimal valuation: 0 to half of maximal valuation
- Aggressive:
  - Silence time: 3 to 3,5 seconds
  - Maximal delay: 3 to 7 seconds
  - Length: 3 to 10 seconds
  - Maximal valuation: 10
  - Minimal valuation: 9 to 10
- Dynamic: (as described in Section VI-D):
  - Silence time: 3 to 15 seconds
  - Maximal delay: 3 to 7 seconds

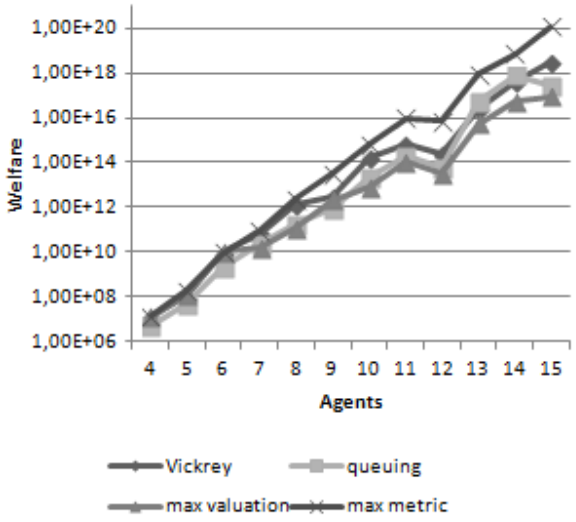

Fig. 3. Regular demands

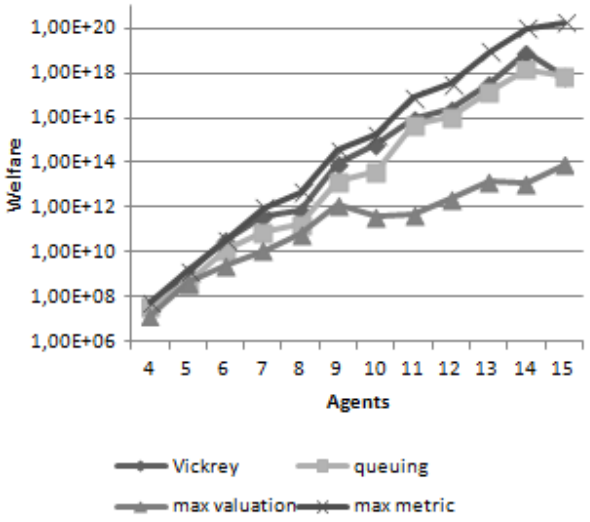

Fig. 4. Regular demands with 10 percent aggressive

- Length: 3 to 10 seconds
- Maximal valuation: 10 * topic preference
- Minimal valuation: 0 to half of maximal valuation
- Topics of interest: 5 randomly chosen topics out of total 10
- Topic preference (for each topic of interest): 0 to 1

We performed model evaluations by simulating a number of discussions with the following parameters:

- Discussion time—5 minutes
- Allocation time—10 seconds
- Auction speedup time—3 seconds
- Number of participants—3 to 15

For a chosen distribution of demand profiles among participants, we performed 10 simulations for every number of participants from the range and every moderation model. Welfare has been calculated according to metric defined by Equation 2 and averaged over those 10 runs. Each agent had his set of demands generated before every single simulation.

Figure 3 contains results for the most ideal scenario, where every agent has a ”regular” demands profile. All allocation methods show decent behaviour, as there is was no special need to bother about fairness or overall welfare. ”Maximize metric” model outperforms all others, as expected.

In the next scenario, we had chosen the ceil of 10% of all agents and set their profiles to ”aggressive”. Results are shown in Figure 4. ”Choosing maximal valuation” clearly prefers allocation vectors which bring lower social welfare. It promotes aggressive agents over others and allows them to dominate the whole process.

Figure 5 shows results for a scenario where all participants represent ”dynamic” demands profile. In such environment ”Queuing” moderation model performed very poorly. It is due to the way it provides fairness. Allocating a resource to the first agent from the queue might very often prevent participants

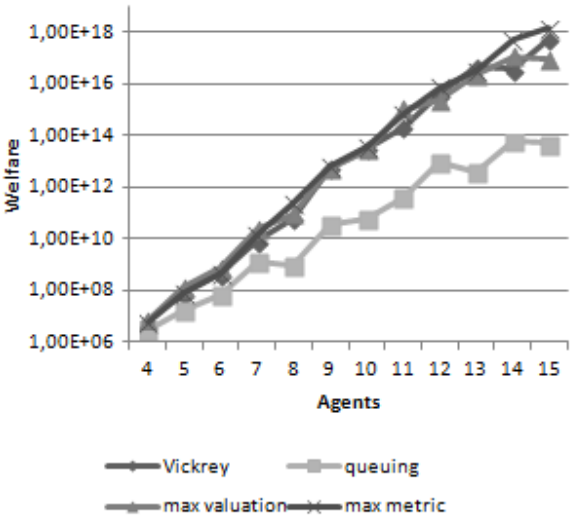

Fig. 5. Dynamic demands

from finding a common set of preferred topics. ”Maximizing welfare metric” is no longer strictly superior to other allocation model, as the choice of allocation might have an impact on participants’ future utility functions.

The last scenario we simulated is a mixture of the previous two. Among the participants with ”dynamic” demands the chosen ceil of 10% of agents have their profiles set to ”aggressive”. This environment highlights the weaknesses of both ”queuing” and ”choosing maximal valuation” which perform visibly worse than the remaining two.

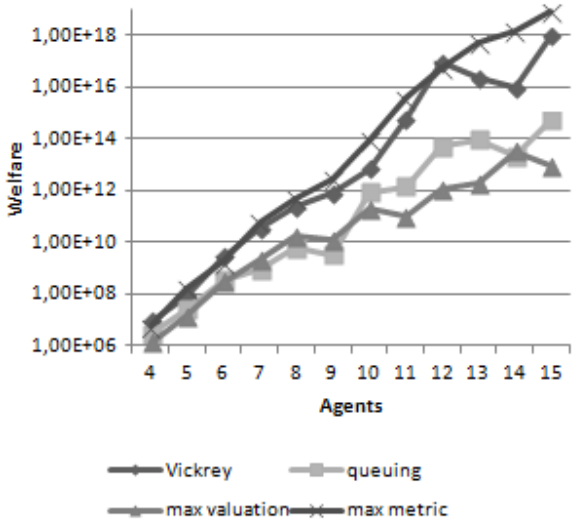

Fig. 6. Dynamic demands with 10 percent aggressive

VIII. Conclusions

In this paper we proposed a social welfare metric to determine the quality of a conference taking fairness aspects into consideration. Further on, we introduced a multiagent resource allocation scheme which embraces the described concept of fairness while getting as much out of overall social welfare as possible. We have performed a whole series of simulated discussions in order to verify the model's quality. Empirical results show that this resource allocation procedure is very much in line with the social welfare metric defined by Equation 2. It generates an allocation which is fair and highly valued by the whole society in a hostile environment with agents trying to dominate. We have also observed good results with semi-intelligent conversation aware agents.

Future work includes testing the model in a real life scenario by deploying to a broad public. We would also like to lay a more solid theoretical foundation to our definition of fair allocation. Analyzing whether our concept is in line with fair dominance [13] should be a good starting point. Another area of theoretical research are budget bound auction mechanisms [14] and investigate the impact on the introduced Vickrey auction based process.

***Abstract*—The paper shows how an agent-based system can be subjected to formal verification using a deductive approach. The particular system for gathering open source intelligence is considered, which is build on a framework for data integration. Techniques allowing for automatic extraction of logical specifications are described with emphasis on pattern-based and rule-based approaches. An example illustrates how the proposed method works in a scenario with iterated agent tasks combining these two approaches.**

I. Introduction

THE key concept in multi-agent systems (MAS) are intelligent interactions (coordination, cooperation, negotiation). Thus multi-agent systems are ideally suited to representing problems that have multiple problem solving methods, multiple perspectives and/or multiple problem solving entities [1]. Yet this variety of perspectives often makes the design and implementation of software MAS a really difficult task.

Formal methods enable the precise formulation of important artifacts and the elimination of ambiguity. There are two well established approaches to formal reasoning and system verification [2]. The first is based on the state exploration ("model checking") and the second is based on deductive reasoning. Model checking is an operational rather than analytic approach [3]. On the other hand, deduction-based formal verification is essential for sustainable verification leverage, characterized by intuitiveness, a top-down way of thinking, logic-based reasoning, coverage of infinite computations, etc. Temporal logic is a well established formalism which allow to describe properties of reactive systems. The semantic tableaux method, which might be descriptively called "satisfiability trees", seems intuitive and may be considered as a goal-based formal reasoning.

The contribution is based on an agent-based framework dedicated to acquiring and processing distributed, heterogeneous data collected from the various Internet sources [4]. Data processing in such a system is structuralized by means of dynamic workflows based on agents' interactions. Our goal is to provide a formal description of these interactions to make sure the system works properly. Since logical specifications are difficult to specify manually, a method for an automatic extraction of logical specifications, considered as a set of temporal logic formulae, was proposed in [5], or for a building requirements models during the software requirements elicitation in [6]. Here, a case of iterated agent tasks is considered and illustrated by a more complex scenario in a slightly different application area. The case includes both an active model and a state model for agent systems.

In the first part of the paper essential logical background is provided and the method of specification generation based on workflow describing agents' interactions is described. Then the general structure of the framework for data integration is presented. This constitutes a base for the discussion of the scenario of the particular system, which shows how the approach works in practice.

II. Logical preliminaries

Logical background which is temporal logic, semantic tableaux, and the deduction-based verification system are discussed below. *Temporal logic* TL is a formal and logical system for the specification and verification of software models and systems [7]. It introduces symbolism (unary and dual operators are $\Diamond$ for "sometime in the future" and $\Box$ for "always in the future") for representing and reasoning about the truth and falsity of formulas throughout the flow of time and taking into consideration changes of their valuation. It allows to describe both temporal relations between reached states and to specify expected properties. The attention is focused on *propositional linear-time temporal logic* PLTL, i.e. the time structure constitutes a linear and unbounded sequence. Each element in the mentioned sequence corresponds to a propositional world, i.e. *atomic propositions* AP are valued in every point of the sequence. Temporal logic and their syntax and semantics are discussed in many works, e.g. [8], [7]. Considerations in the work are limited to the *smallest temporal logic*, e.g. [9], [10], which is extension of a classical propositional calculus' to the axiom $\Box(\Psi \Rightarrow \Phi) \Rightarrow (\Box\Psi \Rightarrow \Box\Phi)$ and the inference rule $\vdash \Psi \Longrightarrow \vdash \Box\Psi$. The minimal logic, also called the K logic, is sufficient to define many system properties (liveness, safety), The following formulas may be considered as examples of this logic: $action \Rightarrow \Diamond reaction$, $\Box(send \Rightarrow \Diamond ack)$, $\Diamond live$, $\Box\neg(event)$, etc.

Semantic tableaux is a decision procedure, based on formula decomposition, for checking formula satisfiability. Even though it is known in classical logic, it can also be applied in temporal logic [11]. At each step of a well-defined procedure, some logical connectives are removed and formulas are decomposed. The method is a proof by contradiction, i.e. after negation of the initial formula, finding a contradiction in all

978-83-60810-53-8/$25.00

branches means that the inference tree is *closed*, and there are no valuations that satisfy a formula. It leads to the statement that the formula before the negation is true. The method provides, through so-called *open* branches of the semantic tree, information about the source of an error, if one is found. The work [12] provides an example of the inference tree.

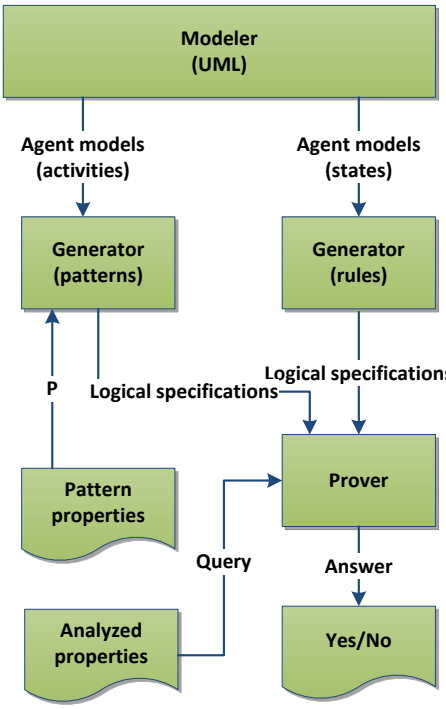

Fig. 1. A deduction-based verification system for agent models

The outline architecture of the proposed deduction-based system for agent models is presented in Fig. 1. There are two generation components. The first one works using the algorithm Γ_1 (described in the next section) and is designed for models expressed in activity diagrams using predefined workflow patterns. The second one works using the algorithm Γ_2 (described in the next section) and is designed for models expressed in state diagrams. The outputs of these generation components are logical specifications understood as sets of temporal logic formulas. The combined specification is treated as a conjunction of all formulas $p_1, \ldots, p_n = L$ and every p_i is a specification formula generated during the extraction Γ_1 or Γ_2. These formulas constitute a logical specification L. The Q formula (query) is a desired system property for the analysed software model.

Both the final specification of a system and the examined properties constitute an input to the prover component, which works using the semantic tableaux method. It enables the automated reasoning. The input for this component is the formula $C(L) \Rightarrow Q$, where $C(L)$ means conjunction of all extracted formulas, or, more precisely:

$$p_1 \wedge \ldots \wedge p_n \Rightarrow Q \tag{1}$$

After negation of formula (1), it is placed at the root of the inference tree and decomposed using the semantic tableaux method's well-defined rules. The work [12] provides an example of the inference tree.

The whole verification procedure can be summarised in the following way:

1) Automatic generation of a logical specification based on design patterns (Γ_1);
2) Automatic generation of a logical specification based on extraction rules (Γ_2)
3) Introduction a property Q as a query for the considered model;
4) The automatic inference using semantic tableaux for the whole formula 1.

Steps 1 to 4, taken as a whole or individually, may be processed many times, whenever models are changed (step 1 or step 2) or there is a need for a new reasoning due to the revised system's property (step 3).

III. Logical specifications

Two generation methods for extraction logical specifications are considered in this section. The first one which is based on predefined workflows is discussed in a more detailed way. However, the rule-based approach is an interesting alternative for generating logical specifications.

A. A pattern-based approach

Presentation of the approach needs to introduce some basic notions and definitions. An *elementary set* of formulas over atomic formulas $a_{i,i=1,\ldots,n}$ is denoted $pat(a_i)$, or simply $pat()$, as a set of temporal logic formulas $\{f_1, ..., f_m\}$ such that all formulas are syntactically correct. The examples of elementary sets are $Pat1(a,b) = \{a \Rightarrow \Diamond b, \neg a \Rightarrow \neg b, \Box\neg(a \wedge b)\}$ and $Pat2(a,b,c) = \{a \Rightarrow \neg\Diamond b \wedge \Diamond c, \Box\neg(b \vee c)\}$. The logical expression enables representing nested and complex structures elementary sets. The *logical expression* W_L is a structure created using the following rules [13]:

- every elementary set $pat(a_i)$, where $i > 0$ and every a_i is an atomic formula, is a logical expression,
- every $pat(A_i)$, where $i > 0$ and every A_i is either
  - an atomic formula a_j, where $j > 0$, or
  - a set $pat(a_j)$, where $j > 0$ and a_j is an atomic formula, or
  - a logical expression $pat(A_j)$, where $j > 0$

  is also a logical expression.

The example of logical expression is $Seq(Flow(a,b,c), Switch(d,e,f))$ which is intuitive, in that it shows the sequence of a parallel split (flow) and then conditional execution (switch) of some activities.

Workflow patterns constitute a kind of primitives and enable the automation of the generation process for logical specifications. It leads to the mapping of workflow patterns to logical specifications. The proposed approach is based on the assumption that the entire activity diagrams are built using only predefined workflow patterns. The assumption is

not a restriction since it enables receiving correct and well-composed systems. *Activity diagrams* of UML enable modelling workflow activities. They support choice, concurrency and iteration. The important goal of diagrams is to show how an activity depends on others [14].

```

Fig. 2. Predefined set of pattern temporal properties

Logical properties of all design patterns are expressed in temporal logic formulas. They are stored in the predefined and fixed *logical properties set* P. An example of such a predefined set P for the UML activity diagrams is shown in Fig. 2. Most elements of the P set, i.e. two temporal logic operators, classical logic operators, etc. are not in doubt. a_1, a_2 and a_3 are atomic formulas and constitute a kind of formal arguments for a pattern. The slash allows to place more than one formula in a single line. $c(a)$ means that the logical condition associated with the activity a has been evaluated and is satisfied. The pattern $SeqSeq$ means the concatenation of sequences as a sequence of three arguments. Variables in and out provide information about activities for a pattern that are the first and the last to be executed, respectively. They enable representing pattern to be considered as a whole. All formulas describe both safety and liveness properties for every pattern [15]. Summing up, the predefined set of pattern temporal properties consists of the following elements $\{Seq, SeqSeq, Flow, Switch, LoopWhile\}$ the meaning of which seems intuitive, i.e. sequence, sequence of a sequence, concurrency, choice and iteration.

Generating a logical specification is not a simple summation of formula collections resulting from a logical expression. The generation algorithm Γ_1 sketch for obtaining a set of temporal formulas is given below.

1) At the beginning, the logical specification is empty, i.e. $L := \emptyset$;
2) Patterns are processed from the most nested pattern to be located more towards the outside and from left to right;
3) If the currently analysed pattern consists only of atomic formulas, the logical specification is extended, by summing sets, by formulas linked to the type of pattern analysed, i.e. $L := L \cup pat()$;
4) If any argument is a pattern itself, then the logical disjunction of all elements that belong to in and out sets, is substituted in a place of the pattern;

The algorithm is a modification of the similar one presented in [13]. All patterns of the logical expression are processed one by one and the algorithm always halts. All parentheses are paired. The example of the algorithm is provided in the section V-B.

A logical specification L_1 consists of all formulas obtained from a logical expression using the algorithm Γ_1, i.e.

$$L_1(W_L) = \{f_i : i > 0 \wedge f_i \in \Gamma_1(W_L, P)\} \tag{2}$$

where f_i is a PLTL formula. The sketch of the generation algorithm is presented below. The generation process has two inputs. The first one is a logical expression and the second one is a predefined set of logical properties. The output is a set of logical formulas.

B. A rule-based approach

However, the rule-based approach for generating logical specifications is an interesting alternative for the previous one, i.e. presented in the section III-A. The approach seems suitable for the UML state diagram when considering set of states (nodes) and transitions (edges). The discussion is limited to some basic situations which are defined in terms of temporal logic formulas. Considering all transitions one by one, a logical specification understood as a set of temporal logic formulas is obtained using the following rules which constitute the generation algorithm Γ_2:

- R.1 (Sequence) – the state b is enabled when the state a is reached and an event e occurred, i.e.:
  $\{(a \wedge e) \Rightarrow \Diamond b, \Box\neg(a \wedge b)\}$;
- R.2 (Split) – when the state a is reached and an event e occurred then single thread of control is splited into two threads of control to enable parallel reaching the state b and the state c, i.e.:
  $\{(a \wedge e) \Rightarrow \Diamond b \wedge \Diamond c, \Box\neg(a \wedge (b \vee c))\}$;
- R.3 (Synchronization) – when two states a and b are reached in parallel and two events $e1$ and $e2$ occurred, respectively, then threads of control are transformed and synchronised into a single thread of control to enable reaching the state c, i.e.:
  $\{(a \wedge e1) \wedge (b \wedge e2) \Rightarrow \Diamond c, \Box\neg((a \vee b) \wedge c)\}$.

A logical specification L_2 consists of all formulas obtained using the algorithm Γ_2, i.e.

$$L_2 = \{f_i : i > 0 \wedge f_i \in \Gamma_2\} \tag{3}$$

where f_i is a PLTL formula. The input for the generation algorithm is a state diagram. The output is a set of logical formulas.

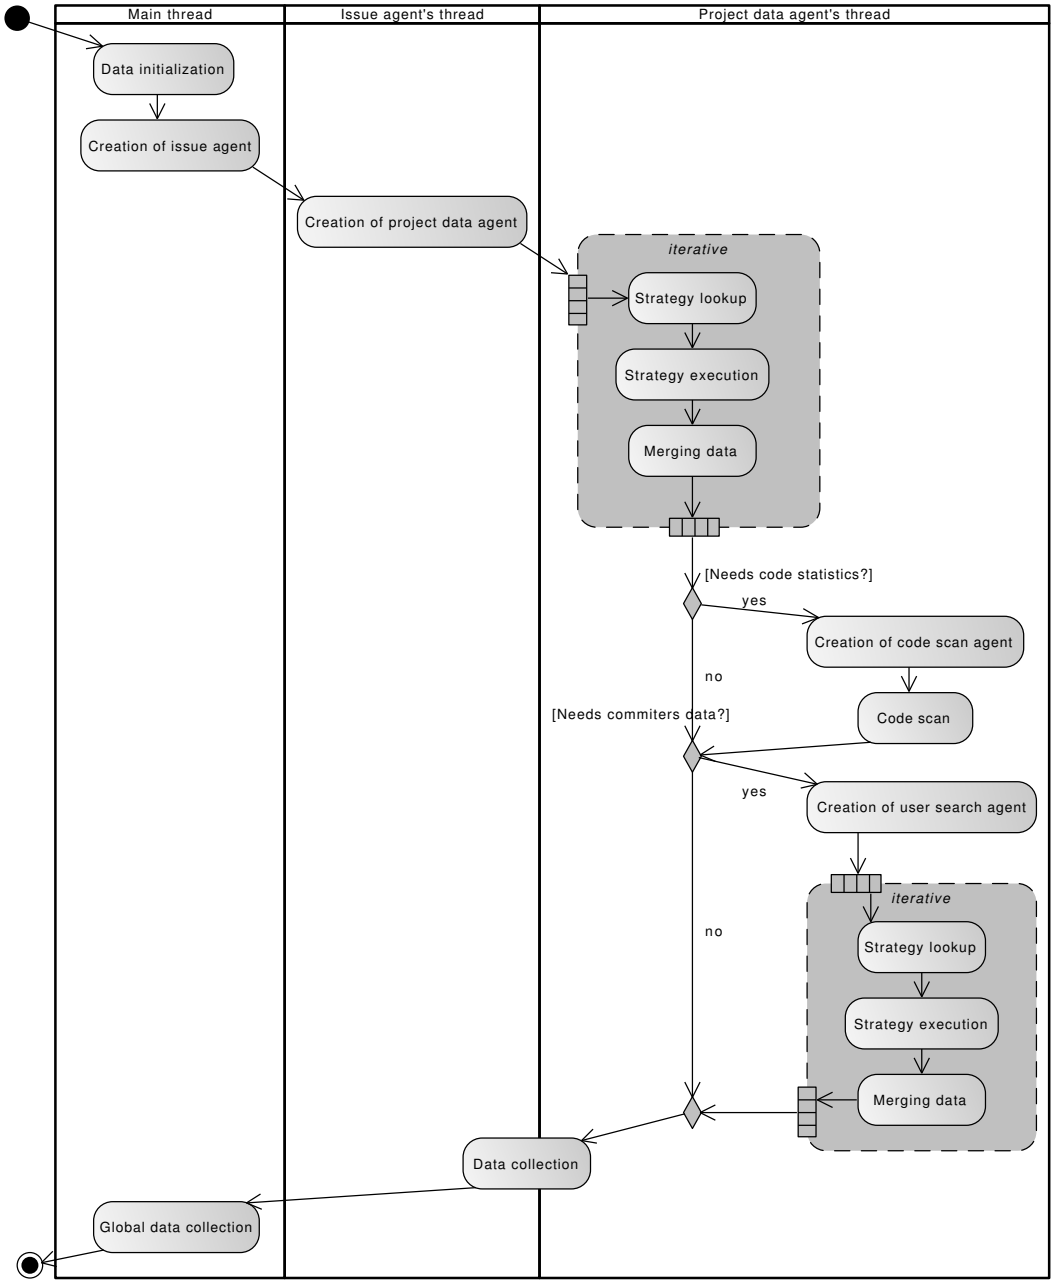

Fig. 3. Activity diagram of the search scenario presented in the section V-A.

IV. Agent-based framework for data integration

The vast amount of information available in the global network calls for complex systems able to perform various analyses with respect to data coming from various, often heterogeneous sources. The described framework provides the data- and task-oriented workflow for collecting and integrating data from a wide range of diverse services [4], [5]. Fig. 4 presents the layered structure of the framework:

- Presentation – the usage of different views is possible. They communicate with the rest of the system and allows the user to interact and control the act of the data integration.
- Middleware – the logical processing of the data is performed here. This part of the system uses the agent paradigm to delegate different parts of the data integration and processing to other parts of the system (or the external software, frameworks, etc.) that are represented also as agents.
- Services and data – wrapping of the various external data sources (and data processing capabilities) takes place here. Interfaces of the systems are adapted and described

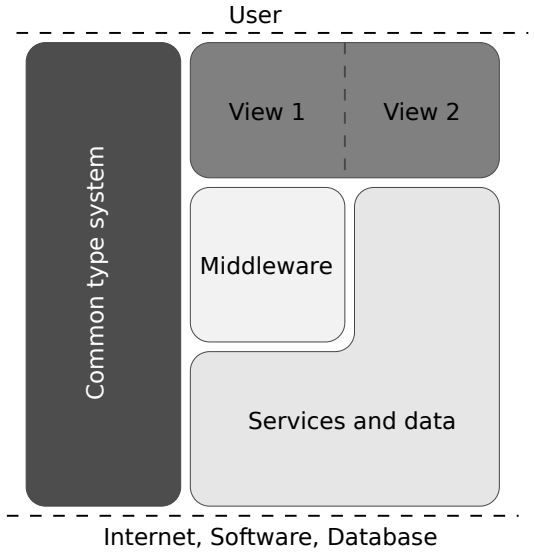

Fig. 4. Layered structure of the implementation

in terms of the common type system.
- Common type system – the whole framework uses the types described here to annotate the processed data, data sources and external systems interfaces or façades.

Queries created by the user are put into the agent system that performs two types of operations: the management of data (by inspecting queries and delegating them to other agents) and execution of demanded actions (including their selection, configuration and fault recovery). The system can divide processing into *issues*. An *issue* is a separate part of data processing, usually centred around an instance of a query object and all related (i.e. found) data.

The current implementation defines three possible functional roles for agents.

- **System agents** provide a bootstrapping and basic functionality. They create new issues, handle errors, monitor the system.
- **Issue Agents** care about a single issue (i.e. user query) and delegate initial tasks to specialised action agents. An Issue Agent retrieves a query from the pool, inspects it and then requests (with messages) a chosen data agent to resolve a query specified in the task.
- **Action (Data) Agents** implement the actual executive part of the search functionality. Upon receiving the task from an issue agent they obtain appropriate strategies and then executes them to answer the query.
  However, they are not constrained only to strategies. They can perform any action on data: merge, simplify, verify, etc.

Issue Agents are identified by a runtime-generated issue identifier that represents an issue hey are taking care of. The Action Agents are described during creation (implementation) with tasks they can perform (called "capabilities") and data types they can operate on.

V. Data collection scenario and its formal analysis

We consider an act of gathering data about open-source projects as one of the possible use-cases. This kind of data can be easily mined from popular infrastructure-providing websites like GitHub, SourceForge, etc. Moreover, it is usually very well interlinked and it makes it possible to gather much broader information about e.g., people working on the project, organisations involved, etc.

A. Base Scenario

The scenario has three sample steps:

1) Gathering data about an open-source project from all available sources.
   The user inputs a query comprising of, for example, a name of the project or the link to its website into the system. The system performs a look-up of possible matches and returns a match of a list of possible matches. In the latter case, there may be a requirement to choose one (the best) match. It can be done manually or delegated to an agent that can rate each result and select the best one.
2) Scanning of the source code of the project.
   If possible, a user may expect the project's code to be scanned to obtain particular statistics. If expected, an agent responsible for project data may create another agent that can scan the code. Such an agent will perform the scan and merge the results back into the data handled by the project data agent.
3) Gathering information about commiters and authors.
   It may be further required to gather data about commiters and authors. The project data agent would create a user search agent that is able to collect users data from project website and other related sources.

On the system level our scenario is implemented as follows:

- The types like Project, Commiter, Code are introduced.
- The action agents that performs operations on types are implemented: Project Data Agent, Code Scan Agent, User Search Agent.
- Strategies for each external service can be created: Project Data Search and Code Scan for e.g., GitHub, SourceForge and User Data Search for, e.g., LinkedIn or Facebook.

Fig. 3 shows the activity diagram of an actual execution of the scenario. The user prepares a query that consists of the initial data to operate on (e.g. a name of the project). The task is placed into the system (*Data Initialization* action). Then, available issue agents are notified about it or a new one is created. The issue agent locates an implementation of a so-called action agent that can handle the specified task (Project Data Agent), instantiates it, and delegates the task execution to this agent.

Project Data Agent inspects the query and calls relevant strategies (to locate and gather project data). Then it may choose to instantiate the Code Scan Agent in order to scan the project's code. The same goes for commiters data – the

Project Data Agent can instantiate a specialised agent that will look up personal data.

Data collection is performed in two phases: first, the data from strategies is merged by a responsible agent (e.g., data about projects by the Project Data Agent); second, all data from an agent is inserted into the object provided by an agent higher in the hierarchy (e.g., Project Data Agent provides a Project object that has a field *commiters* that is filled by the User Search Agent). The query execution is finished by putting results to the pool presented to the user.

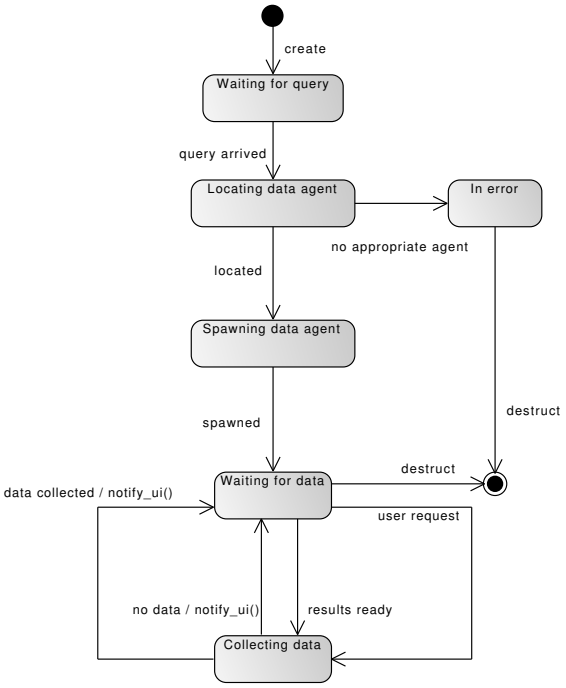

Fig. 5. State diagram of the Issue Agent in the search scenario presented in the section V-A.

Fig. 5 presents sample states of the Issue Agent that is responsible for initiating search for data and forwarding data to the user.

After creation and initialisation, an agent waits for a query from the user. When the query arrives, the agent tries to locate an implementation of a specialised data agent (in the scenario described earlier — Project Data Agent). If such an agent cannot be found it results in a fatal error as it is usually caused by a wrong configuration.

If the data agent is found it is instantiated by the Issue Agent and the query is forwarded to it. Then, the Issue Agent waits for either results from the data agent or request from the UI to get that data. It puts the data, if available, into the user pool and notifies the UI about it. If no data has been found, it generates an error for the UI.

B. Formal analysis and verification

Let us consider the activity diagram shown in Fig. 3. Diagram activities represent propositions which are used for modelling behaviour. Firstly, letters of the Latin alphabet are substituted in a place of propositions. Replacing atomic activities by Latin letters is a technical matter and is suitable only for the work because of its limited size. (In the real world, the original names of activities are used.) The following substitutions are made: a – DataInitialisation, b – CreationIssueAgent, c – CreationProjectDataAgent, d – ProjectDataLookup, e – NeedsCodeStatistics, f – CreationCodeScanAgent, g – CodeScan, h – NeedsCommitersData, i – CreationUserSearchAgent, j – UserSearchLookup, k – DataCollection, and l – GlobalDataCollection. (To simplify considerations, a single proposition instead of a loop is used.) The logical expression W_L for the activity diagram is

$$SeqSeq(SeqSeq(a,b,c), SeqSeq(d, Switch(e, Seq(f,g), N1), Switch(h, Seq(i,j), N2)), Seq(k,l)) \quad (4)$$

Activity diagrams constitute one of two inputs for the deduction system shown in Fig. 1. Two activities $N1$ and $N2$ are introduced since the diagram in Fig. 3 contains two switches without activity (null activity). A logical specification L_1 for the logical expression W_L is built using the algorithm Γ_1 presented in the section III-A. The logical specification is

$$\begin{aligned} L_1 = \{ & f \Rightarrow \Diamond g, \Box\neg(f \wedge g), i \Rightarrow \Diamond j, \Box\neg(i \wedge j), \\ & e \wedge c(e) \Rightarrow \Diamond(f \vee g), e \wedge \neg c(e) \Rightarrow \Diamond N1, \\ & \Box\neg((e \wedge (f \vee g)) \vee (e \wedge N1) \vee ((f \vee g) \wedge N1)), \\ & h \wedge c(h) \Rightarrow \Diamond(i \vee j), h \wedge \neg c(h) \Rightarrow \Diamond N2, \\ & \Box\neg((h \wedge (i \vee j)) \vee (h \wedge N2) \vee ((i \vee j) \wedge N2)), \\ & d \Rightarrow \Diamond e, e \Rightarrow \Diamond(j \vee N2), \\ & \Box\neg((d \wedge e) \vee (e \wedge (j \vee N2)) \vee (d \wedge (j \vee N2))), \\ & a \Rightarrow \Diamond b, b \Rightarrow \Diamond c, \Box\neg((a \wedge b) \vee (b \wedge c) \vee (a \wedge c)), \\ & k \Rightarrow \Diamond l, \Box\neg(k \wedge l), (a \vee c) \Rightarrow \Diamond(d \vee i \vee j), \\ & (d \vee i \vee j) \Rightarrow \Diamond(k \vee l), \\ & \Box\neg(((a \vee c) \wedge (d \vee i \vee j)) \vee ((d \vee i \vee j) \wedge (k \vee l)) \vee \\ & ((a \vee c) \wedge (k \vee l)))\} \end{aligned} \quad (5)$$

Formula 5 represents the output of the generator component in Fig. 1.

Let us consider the state diagram shown in Fig. 5. Firstly, letters of the Latin alphabet are substituted in a place of states. The following substitutions are made: m – WaitingQuery, n – LocatingDataAgent, o – InError, p – SpawningDataAgent, q – WatingData, r – CollectingData, and s – Stop. Next, the following substitutions for events are made: $e'a$ – QueryArrived, $e'b$ – Located, $e'c$ – NoAgent, $e'd$ – Spawned, $e'e$ – Destruct, $e'f$ – UserRequest, $e'g$ – DataCollected, $e'h$ – NoData, and $e'i$ – ResultsReady. State diagrams constitute one of two inputs for the deduction system shown in Fig. 1. A logical specification L_2 is built using the algorithm Γ_2 presented in the section III-B. The logical specification is

$$\begin{aligned} L_2 = \{ & (m \wedge e'a) \Rightarrow \Diamond n, \Box\neg(m \wedge n), (n \wedge e'b) \Rightarrow \Diamond p, \\ & \Box\neg(n \wedge p), (n \wedge e'c) \Rightarrow \Diamond o, \Box\neg(n \wedge o), \\ & (o \wedge e'e) \Rightarrow \Diamond s, \Box\neg(o \wedge s), (p \wedge e'd) \Rightarrow \Diamond q, \end{aligned}$$

$$\Box\neg(p \wedge q), (q \wedge e'e) \Rightarrow \Diamond s, \Box\neg(q \wedge s),$$
$$(q \wedge e'i) \Rightarrow \Diamond r, \Box\neg(q \wedge r), (q \wedge e'f) \Rightarrow \Diamond r,$$
$$(r \wedge e'h) \Rightarrow \Diamond q, (r \wedge e'g) \Rightarrow \Diamond q\} \quad (6)$$

Formula 6 represents the output of the generator component in Fig. 1.

Logical specifications which are built in the above way, i.e. using the proposed algorithms, can be verified formally. Formal *verification* is the act of proving correctness properties of a system. When the semantic tableaux method is used, then the whole reasoning process can be summarised as a process of the verification whether an entailment $F_1, ...F_n \models G$ it suffice to prove that $\{F_1, ..., F_n, \neg G\}$ is unsatisfiable. The *liveness* property of a system means that the computational process achieves its goals, i.e. something good eventually happens. The *safety* property of a system means that the computational process avoids undesirable situations, i.e. something bad never happens. The liveness property for the above model can be

$$b \Rightarrow \Diamond l \quad (7)$$

which means that **if creation of issue agent is satisfied then sometime global data collection is reached**, formally $CreationIssueAgent \Rightarrow \Diamond GlobalDataCollection$. When considering property expressed by formula 7 then the whole formula to be analysed using semantic tableaux, providing a combined input for the prover component in Fig. 1, is

$$C(L_1) \wedge C(L_2) \Rightarrow (b \Rightarrow \Diamond l) \quad (8)$$

where $C(L_x)$ means logical conjunctions of all formulas which belong to L_x, c.f. formula 5 and 6. Presentation of a full inference tree exceeds the size of the work. All branches of the semantic tree are closed, i.e. formula 7, is satisfied in the considered model. The method is easy to scale-up, i.e. extending and summing up logical specifications for other activity diagrams and state diagrams. Then, it is possible to examine logical relationships (liveness, safety) for different activities and states coming from different activity and state diagrams.

VI. Conclusions

The discussed agent-based data integration framework is based on AgE platform [16], which allows to introduce a clear separation of concerns and makes it possible to rapidly build topic-related versions of the system with little configuration. The framework is completely independent of the data it processes and all scenario-related components are provided by the user during the configuration. That is why the proposed verification approach seems to be particularly important to ensure proper configuration of the system.

Future work may include the implementation of the logical specification generation module and the temporal logic prover. Important results might be a CASE software for both the workflow modelling and the deduction-based formal verification. Considering graph transformations [17] is encouraging for models involving distributed representation of knowledge and their efficient implementation. The example of such an implementation is discussed in [18].

***Abstract*—The problem of automatic or computer aided control is still unsolved in many areas of real production processes. In such cases the only one solution is to employ human operator that uses his experience and knowledge in order to manually control parameters of the process. Such approach has many disadvantages relating to characteristics of human work what is the main ground for presented here research. As the solution a methodology is proposed, which follows the decision processes of human operator using his experience. In order to predict capabilities of proposed methodology a test system is designed and implemented with the use of agent technology.**

I. Introduction

THE MAIN genesis of presented here work is an effort to design and to build a computer system supporting control of an industrial process, that is difficult to control with known computational techniques. The main reason for this difficulty is the lack of proper analytical model of such industrial process. This lack prevents obtaining proper values of process parameters by simply computing of optimal values from determined dependence in the form of mathematical equations. Possible solutions can be found in main areas of intelligent control which are fuzzy control, neural networks, expert systems and genetic algorithms [1]. Presented methodologies have some restrictions, which prevent against their use in every case of control problem. One of such restrictions is need for specifying rules or knowledge about proper control (in case of fuzzy control or expert system), what is impossible in many domains of control of industrial processes.

An example of an industrial process, that analytical model is unknown, is the oxidizing roasting process of sulphide zinc concentrates. It is also impossible to formulate knowledge or rules, which specify proper control of this process. Possible solution for control of this process was realized with the use of genetic algorithms and neural network, which predicts the value of fitness function on the basis of previous registered process signals [2]. This approach leads to interpolation of some signals, which are measured with very low frequency. Because some signals are measured once per minute and other only once per day, such interpolation results in obtaining of unreal values of signals, what can be a source of faults and errors and can have disadvantageous influence on process control. The goal of presented here work is presentation of a methodology, that eliminates need for data pre-processing in order to avoid adding of missing data, what is unnatural for decision taking by human workers. The proposed system, as the implementation of presented methodology, should follow decision process of human using his experience, that coincides with case-base reasoning (CBR) methodology (presented in e.g. [3], [4]).

This paper contents 6 sections. In the 2nd section the oxidizing roasting process of sulphide zinc concentrates is presented. The 3rd section presents remarks on experience using and gathering, what is the basis for design of the multi-agent system that is presented in the 4th section. The 5th section presents implementation aspects and tests of developed system, which tests enable to predict usefulness of proposed solutions. The last section presents conclusions.

Financial support of the AGH 11.11.110.085 is acknowledged

II. An Example of Industrial Process

The oxidizing roasting process of sulfide zinc concentrates is the first stage of industrial zinc production. During the roasting process, the aim is to obtain a minimum content of sulphide sulfur in the composition of the product. The generic scenario of control made by a human worker during one production day (that is full production cycle) is presented onto Fig. 1. Shown scenario of control indicates differences in frequency of signal measuring, however all signals have hypothetical influence on quality of products. All signals can be classified into one of three generic groups: independent, controllable and dependent signals.

Independent signals (I) are these parameters, which cannot be modified or changed during production cycle, so it is impossible to change their values in direct or indirect way. In the case of analyzed industrial process independent signals are parameters of chemical composition of raw materials, that are measured only once per a production day. **Dependent signals** (D) are these parameters, which cannot be directly modified. Value of a dependent signal is a hypothetical function of other process parameters and possible time delay. This function is unknown in a case of analyzed process. An example of dependent signal is the pressure or temperature at the upper part of a furnace. **Controllable signals** (C) are these, which can be directly changed or updated during the controlled

978-83-60810-53-8/$25.00

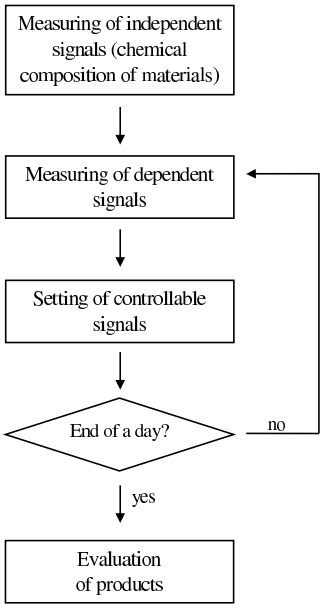

Fig. 1. The generic scenario of process control performed for one day of production

process. The rotary speed of a fan cooling the controlled process can be given as an example of a controllable signal in a case of analyzed process.

In a case of the oxidizing roasting process of sulfide zinc concentrates dependent and controllable signals are measured very often comparing to frequency of independent signal measure. The low frequency of some measures at industrial process control is caused by measured technique - the chemical composition has to be measured manually.

A. Decision Problem

The goal of industrial process control is obtaining products that are characterized by optimal properties. In a case of analyzed industrial process the goal is to obtain minimal concentration of sulphide sulphur in the roasted products, so the **quality evaluation** (Q) is average concentration of sulphide sulphur in the roasted products during production day. Formal definition of decision problem can be presented in the form of statement: how to choose values of controllable signals (C) knowing values of independent (I) and dependent signals (D) in order to obtain best possible quality evaluation (Q). In other words, the quality evaluation is hypothetical function of all signals $Q = f(C, I, D)$, however during process control only controllable signals (C) can be directly changed. Controllable signals (C) should be adjusted to measured values of all other signals in order to maximize quality criterion (Q).

III. Experience and Its Model

Having a goal to follow decision processes that take place in the mind of a human operator of presented industrial process, his work during a day period should be analyzed. A day period is full production cycle. At the beginning of production day the operator knows values of independent signals (I), it means he knows chemical composition of raw materials used for production. The operator assumes, that this chemical composition is constant for the whole production day due to frequency of independent signals measure, which is done only once at the beginning of every production day. Before the start of process control the operator should decide how to control this process, what means how to set present values of controllable signals (C) taking into consideration currently measured values of dependent signals (D). This decision is based on his experience. The experience contains many episodes from past production, which are referred to as cases. Every case in experience contains information concerning solved problem, how this problem was solved and how production was evaluated.

As it was mentioned in the above paragraph, before the start of process control the operator should decide how to control this process with the use of his experience. Accordingly to presented criterion of evaluation, the human operator first searches for cases that concern the same or similar problems and next chooses one case, which brings the best effect described by value of evaluation criterion. Afterwards the human operator is trying to control the process in the way, how it is remembered by him as the solution in chosen case. It means the human operator is following the way, how he has set values of controllable signals (C) knowing measured values of dependent signals (D). This stage of experience using goes on till the end of current production day. When the current production is ended, the human operator obtains information concerning evaluation of made products. So, this time it is possible to update his experience with the case, which concerns just ended production day (in order to use it in the future).

A. Case-Based Reasoning

Presented model of using and gathering experience coincides with case-base reasoning (CBR) methodology. This methodology is relaying on experiences made in the past during solving of concrete problem situations, instead of using any general knowledge related to a problem domain [3], [4]. From a technical point of view a CBR decision system uses a case-base, which is collection of past made and stored experience items, called past cases, or cases. Each time a new problem has to be solved, a CBR cycle is performed, that consists of 4 sequential processes, which are called also phases:

1) Retrieve the most similar case or cases for a current problem that hast to be solved.
2) Reuse the information in the retrieved case in order to solve the current problem.
3) Revise the proposed solution.
4) Retain the experience (the current problem, its solution and results) in order to use it for future problem solving.

The extensive discussion related CBR methodology and its implementation in the domain of industrial process control can be found in [5].

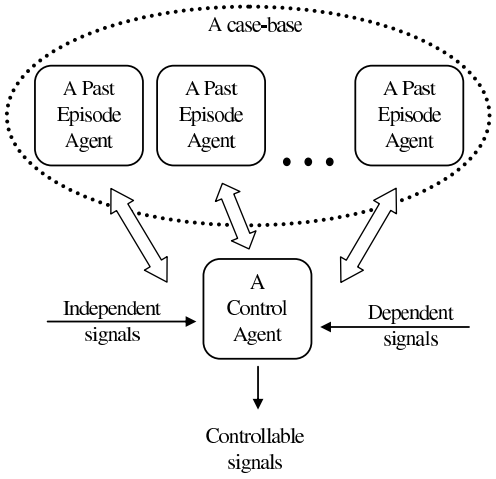

Fig. 2. The structure of proposed multi-agent system

IV. Design of Agent System Modeling Experience

Presented in the previous section assumptions indicate distribution of cases, that are autonomous items of human experience. The autonomy of experience items is the main reason for using of agent technology at design and implementation of this model. Considering autonomy of past cases, it is proposed to design the case-base as a set of autonomous agents, as presented onto Fig. 2. Every agent in this set, called Past Episode Agent should contain all data relating to represented by him episode – a past case of control of the industrial process. Presented onto Fig. 2 Control Agent has a goal to control current production process. The Control Agents communicates with all Past Episode Agents in order to follow processes of experience usage and gathering, which are characteristic for human operator. Referring to CBR methodology, the Control Agent should perform all four phases of the CBR cycle. All interactions in the system are initiated by the Control Agent, so this agent performs also (centralized) management of the whole system. Presented here conception of system does not relate to situational systems.

A. Past Episode Agent

According to the main assumption, that a Past Episode Agent should represent one past case, an agent of this type has to contain data structures related to notion of a past case. A past case should enclose information according solved problem, used solution and evaluation of made products for one past production day. Every Past Episode Agent has to contain:

- single values of independent signals (I) for the whole considered production day (as problem description of represented past case),
- array of values of dependent (D) and controllable (C) signals registered during considered production day (as solution description of represented past case),
- single value of quality evaluation (Q), that is average concentration of sulphide sulphur in made products.

A Past Episode Agent having such data structures filled with proper data models one episode of past production. A Past Episode Agent replays to messages sent by a Control Agents providing information according to stored data.

B. Control Agent

The main goal of a Control Agent is to control current production process. The functioning of the Control Agent starts at the beginning of a current production day. That time values of independent signals (I) characterizing chemical composition of raw materials used for production at the whole current day are known. After the start of its functioning, the Control Agent knows independent signals and starts to sequentially perform phases of CBR cycle: retrieve, reuse, revise, retain.

The main goal of the **retrieve phase** is to find a past case, which concerns similar problem to the current problem of control and contained in this case solution is evaluated as desirable. This goal is realized through below presented interaction between agents:

1) The Control Agent sends request of replay containing values of independent signals (I). This request is sent to all Past Episode Agents existing in the system.
2) Every Past Episode Agent replays to that request by sending back his values of independent signal and the Control Agent receives all replays concerning independent signals.
3) The Control Agent chooses a number of Past Episode Agents representing similar values of independent signals (I). This similarity is based on the Euclidean distance between values of independent signals measured for the current problem and the solved problems represented by Past Episode Agents.
4) The Control Agent sends request of replay containing value of quality evaluation (Q), that is average concentration of sulphide sulphur in the products. This request is sent only to previously chosen Past Episode Agents.
5) Past Episode Agents replay to request by sending back proper value, which indicates evaluation of production. The Control Agent receives all replays concerning evaluation of production. The Control Agent chooses one Past Episode Agent, which represents the best evaluation of made products (what means the smallest value of average concentration of sulphide sulphur in the products).

Execution of above presented interaction scenario results in selecting of one Past Episode Agent that represents a past case used at next phase of CBR cycle.

In the **reuse phase** the solution represented by the previously selected Past Episode Agent should be applied to the current problem of control. The past case contains description of solution in the form of values of dependent signals (D) and values of controllable signals (C). An artificial neuron net can be used to model relation between dependent signals (D) and controllable signals (C). The Control Agent in the reuse phase follows below stated steps:

1) The Control Agent sends to chosen Past Episode Agent request of replay containing array of values of dependent (D) and controllable (C) signals.
2) After receiving of replay, the Control Agent models relation between dependent signals (D) and controllable signals (C). This step the artificial neuron net is created and learned.
3) The Control Agent obtains current values of dependent signals (D) and on this basis predicts values of controllable signals (C) with the help of the learned neuron net. The predicted values of controllable signals should be applied in current process control. This step is repeated till the end of current production day (the reuse phase continues till the end of current production day).

The Control Agent during the **revise phase** obtains evaluation of products made during current production day. This evaluation is in the form of single value of average concentration of sulphide sulphur in the products. Result of the evaluation cannot influence control done by this agent, because production was ended before quality measures.

The **retain phase** enables learning in the CBR cycle, what is analogy to experience gathering by a human operator. This phase starts, when the current problem was solved and evaluation of this solution is known. The current case contains already the description of the problem, description of the applied solution and the evaluation. The goal of Control Agent is now to retain this information by adding a past case that relates to just ended production day. Because every past case is represented by a Past Episode Agent, the Control Agent creates new agent of Past Episode Agent type.

V. System Implementation and Testing

Presented in the previous section description of a system was implemented as a test application, that operates on archival data of an industrial plant. On this stage of research it was impossible to deploy the application in order to influence real production. The lack of mentioned deployment disables to obtain evaluation of real products made under control of developed system, what is the reason for implementation problems. Those problems relate to the revise and retain phase, which require the real evaluation of products. Despite mentioned problems the whole system gives solution for control of the current production day.

Implemented Control Agents uses a neural network, which is a multilayered perceptron, composed of neurons with sigmoid function. All neurons are located in 4 layers composed of 9, 13, 11, 7 neurons. By the modeling step a supervised learning is used. Developed system works in the batch mode and was implemented using Java, JADE and Neuroph.

A. Performed Tests

Performed tests were done with real industrial data, but only 19 days of production were available (every day is full production cycle). The available industrial data was transformed to the case-base of presented system. In the result 19 Past Episode Agent were created (every individual agent represents one past case).

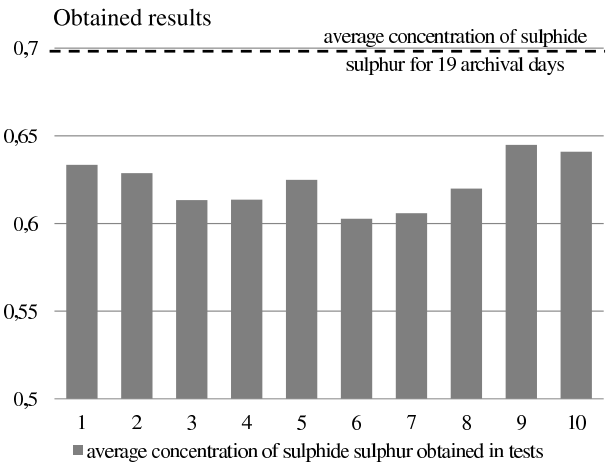

Fig. 3. Results obtained for 10 runs of the implemented system

Presented onto Fig. 3 results concern 10 tests of developed system. Every test relates to one production day, that is full production cycle. The quality measure for performed test was evaluated with the use of an external application, which predicts average concentration of sulphide sulphur in products made during considered production day. As it is shown onto Fig. 3 developed system enabled to obtain more optimal control for every test day, than is was done manually for 19 archival days, because the aim is to minimize concentration of sulphide sulphur in the products.

VI. Conclusions

Presented work shows that it is possible to design and implement an agent system, which follows mechanisms of experience using and gathering. Those mechanisms are consistent with case-base reasoning (CBR) approach and can be used as mechanisms for control of chosen industrial process. Made tests of presented system appoint, that developed system good reflects analyzed mechanisms and obtained results are estimated better than production, which was done in the past by a human worker.

***Abstract*—During interactions, system actors may face up to misunderstandings when their local visions contain inconsistent data about a same fact. Misunderstandings in interaction are likely to reduce interactivity performances (deviation or deadlock) or even affect overall system behavior. In this paper, we present agent-based architecture and scenario-structuring approach to deal with such misunderstandings and consistency. It is based on the notion of "situation" that is an elementary building block dividing the interactions between actors into contextual scenes. This model not only supports the scenario execution, but the consistency management as well. In order to organize and control the interactions, a "situation" contextualizes system's actors' interaction and activity, and includes prevention and tolerances mechanisms to deal with the misunderstandings and their causes. We also simulation experimentation on an Online Distance Learning case study.**

***Keywords*—Interactive system; adaptation; misunderstanding; situation- based scenario; consistency management**

I. Introduction

IN INTERACTIVE SYSTEMS, as games and simulators, the users and the internal agents can modify systems content and progress in real time through input adjustments. The interactive systems may adapt the system execution not only to user's actions, but also to user's profile and behavior, making these systems adaptive... In order to perform the adaptativity, the system must capture users' behaviors from their interactions. Then, according to system's logic and designer's logic, the system adjusts its execution to what it perceives of user's logic. Du to user's actions unpredictability, the execution process of an interactive system is also not predictable.

One of the important problems in interactive system is the potential misunderstanding between the users and the system and more generally between system's actors, virtual or physical. If the system does not capture correctly or confuses user's actions, or if the users do not understand what the system expects, that may lead to an erroneous interpretation of their behavior and an erroneous adaptation of system execution. This misunderstanding may concern user-system interactions, but it can also appear in any kind of interaction between any system's actors. It can be due to the incomplete actors' data or the non-determinism of actors' behavior and cause the interaction deadlock or application failure.

In our recent works, [1], [2], we have defined the misunderstanding in interaction as: when two or more system's actors have incoherent data in their local visions about the same fact f and these data is used during their interaction, that can cause an interaction deviation from the planned scenario. An actor may be human user or virtual system's agent. The local vision is actor's own knowledge about its external world (virtual environment, system's resources...), its relations with the others actors (subset of their states) and its own profile (internal state). So, our work focuses on the management of the consistency between the actor's behaviour logic and the system's logic and the consistency between the actor's local visions in order to handle the potential misunderstandings in interactions.

To handle misunderstandings we propose to contextually structure the application execution into interaction sequences called "situations" and including misunderstanding prevention and tolerance mechanisms. Each situation corresponds to a contextual resource-centered sequence of activities and events and is characterized by preconditions and postconditions. That allows the system to control the execution and to establish the casual links between the situations. This model confines actor's interactions in a given context in order to control them and manage the execution consistency. The consistency handling mechanisms, are inspired by techniques from dependability domain since there is an analogy between the misunderstandings in interactive systems and the errors handled in fault tolerant systems [7].

II. Misunderstanding in Interactions and Related Work

In the recent research, we can find several works dealing with the user-system dialogue where the communication is done through a real human language [3]–[5]. According to Rapaport [5], negotiation is the key to understanding. A cognitive agent understands by negotiating with the interlocutor or by hypothesizing the meaning of an unknown word from the context... A cognitive agent can negotiate with itself about something external by comparing it perception and internal knowledge in order to change or correct its own misunderstandings. Other works propose to use confidence scores to measure the reliability of each word in a recognized sentence [6]. Besides, Lopez-Cozar proposed to implement a frame correction module, which is independent of speech recognizer [4]. This module corrects misunderstandings in a sentence, caused by the errors in speech recognition, by replacing the incorrect frame with an adequate one. Karsenty and Botherel applied the adaptable and adaptive transparency strategies to TRAVELS project with the goal of helping the users to understand and

978-83-60810-53-8/$25.00

react appropriately to system rejections and misunderstandings [3]. The ability of making system's interpretations explicit and informing the users on how to correct misunderstandings are two ways to help users handle them. This strategy is very effective in misunderstanding detection and raises the rate of appropriate user responses after system rejections. All of these works deal with the problem in speech dialogue where the misunderstandings are the more frequent. But the misunderstanding can be found in other forms of interaction like actions, gesture...

Our purpose is to define how we can treat the misunderstandings between the actors themselves, besides the user-system misunderstandings. It is not easy to recognize such class of misunderstandings. In the dependability domain [7], we find the inconsistency problem between systems and operators. The "automation surprise" is inconsistency error occurring when the system behaves differently than its operators expect [8]. It may be due to a mismatch between the actual system behavior and the operator's mental model of that behavior [9], and it can lead to "confusion mode" and sometimes critical failures. In general, misunderstandings come from the gap between user's logic and designer's logic, all along action planning between the actors. Many works, particularly in interactive storytelling, have been done to solve the mismatch between users' behaviors and system logic [10]–[12] by predicting the user's future actions and detecting the invalid ones that deviate the execution from the planned objectives. In general, prediction approach cost is very expensive, such as a short-term player behavior modeling module implanted in [10] to simulate how the world would change to player's actions. Moreover, this approach seems not well suited to a real-time interactive systems, nor to systems in which user's behaviors cannot be modeled easily by a set of rules.

Our approach will focus on software and component design model to integrate simple prevention and treatment mechanisms. Our solution relies on three points. *First*, we build robust agent-based architecture with specific additional components in charge of misunderstandings in interaction management. *Second*, we organize the actors' interactions as a situation-based scenario to facilate the interaction control. *Third*, we integrate into situations' dynamic execution the consistency management, including data synchronization, misunderstanding detection and treatment inspired and adapted from fault-tolerance techniques. These mechanisms do not try to predict users' behavior but will take into account users' state to adapt the system execution in order to avoid misunderstandings between actors. The system observes and analyzes users' states, detect the misunderstandings or their consequences and act to keep the consistency between actors' logics at the beginning and at the end of interaction sequences.

III. Agent-based General Architecture for Interactive Adaptive System

Several architecture models for interactive systems have been proposed according to the specific purpose of each work. We chose the approach of multi-agent system in [16] as a starting point to build our model. The advantage of this approach is that each agent can be organized and work autonomously and strategically. We added a special agent called script agent besides the adaptation unit to manage the consistency. Figure 1 shows our overall architecture.

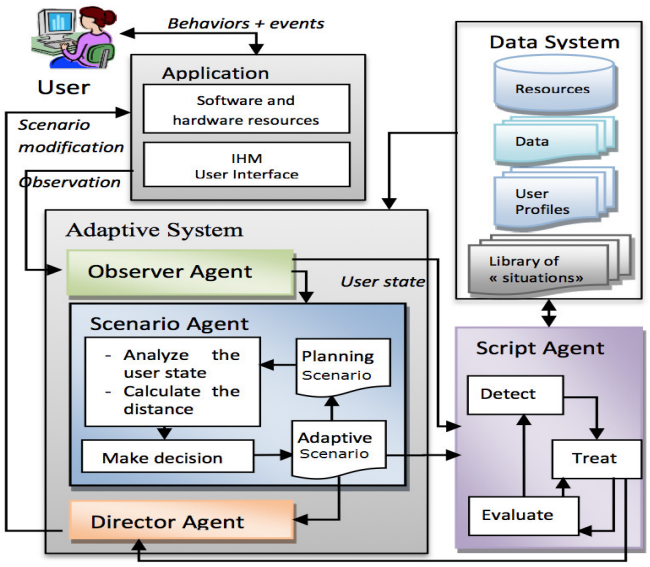

Fig. 1: General agent-based architecture for interactive system

Observer agent: It observes user's behaviors and state, formalizes, normalizes and transfers them to the scenario agent.

Scenario agent: It makes decisions about scenario orientation according to user's state, planned scenario and permanent objective defined by the designer. This agent tries to find the best way to orientate the application execution. Scenario agent takes charge of a library of "situations" planned by the designer. These "situations" (defined in section IV) represent scenario components and are the interaction and the activity sequences that can take place in the application as, for instance, all possible scenes in a theater play.

Director agent: This agent receives the decision taken by the scenario agent. He takes in charge the production of the adaptive scenario and realizes a modification, an answer or an action adapted to the users.

Script agent: Its task is to track inconsistency in 3 steps:

- *Detection*: Detect, confine or partition the inconsistency between situation's actors in order to identify the causes of the misunderstanding.
- *Treatment*: Apply the handling mechanism or strategy to remove the inconsistency and to correct the deflected state that causes the incoherence.
- *Evaluation*: Estimate the efficiency of the treatments in order to improve the applied mechanism for the next time.

IV. Situation-based scenario

A. Approach of interactive storytelling

Our proposition is inspired from the interactive storytelling domain that focuses on scenario execution management.

Interactive storytelling is the unfolding of a story that the player's decisions impact [13], [17]. It also refers to how to generate stories which are both interesting and coherent. We consider that the interactions in an interactive application can be organized, strongly or weakly, as a story scenario. That allows us to adapt ideas from storytelling domain to organizing the interactions.

The scenario in interactive storytelling is represented by a series of actions/events linked together by cause and effect as in [14] or by ordered link as in [10], [15] or by Hierarchical Task Network planning as in [12] where each task is decomposed into subtasks until the primitive actions. But all of these scenario structurings are not suited to built complex interaction sequences where the user's actions are free, non predictable and depending on a great amount of context data. Hence, we propose the notion of "situation" that can be seen as a scene encompassing not only interactions execution but also interactions management and resources use. The situations are the basic narrative elements that facilitate interactions' planning and management by characterizing, contextualizing and confining them.

B. Scenario organizing with situations

1) Situation model: The interactions are split into a set of situations. Each situation is a sequence of interactions between two or more actors in a precise context to achieve a predictive objective, as shows the figure 2. It is characterized by: the preconditions, the postconditions, a set of participating actors and a set of resources. Due to the fact that actors' behaviors, especially human behaviors, are not always precisely modeled, and due to the influence of external events, the progression of a situation can be considered as an execution and adaptation "black box" where the interactions are executed in a non-predictable way. Furthermore, the situation includes consistency management. Itrepresents a set of mechanisms devoted to the prevention, detection and treatment solutions, in order to redress and adjust situation's progression in spite of misunderstanding and inconsistency problems. Consistency management is carried out all along the situation progression

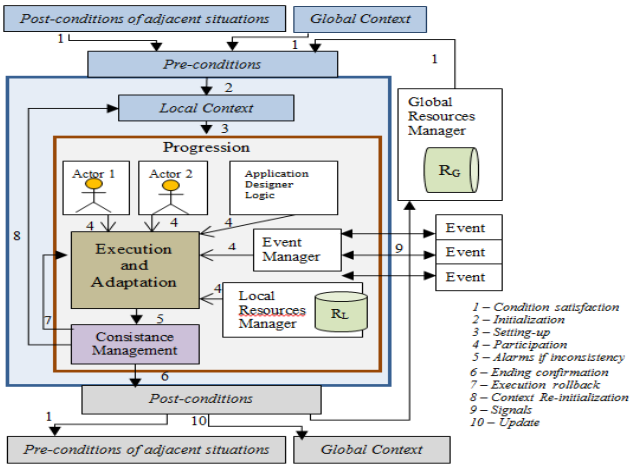

Fig. 2: Elementary Situation Structure

from the local context initialization to the post-condition completion.

2) Situation Graph and Application Execution: The situations are considered as the plot structuring elementary blocks. Each application provide a set of situations defining all the possible interaction sequences that can happen during the application execution. They can be grouped and linked together in order to build the overall application scenario. The scenario is then represented by a directed graph of situations. Each node is a situation and each edge is a transition from one situation to another. The situations graph shows the causal relationships between scenario situations. A scenario may have several beginnings and also some possible endings.

The situation-based scenario approach favorizes the execution control and interaction adaptation. The application progression becomes a scenario unfolding from one starting node to one final node on the predefined situation graph (it is taken in charge by the *scenario agent* in the global architecture). When there is more than one possible situation, the most pertinent one will be chosen by the scenario agent. To increase the adaptability, we can avoid the definition of a predefined graph. In that case, the situation choice is made according to the pre-conditions that best satisfy the global state and decision criteria. This method is flexible, adaptive, and applicable in "real time" during application execution, but it can lead to uncontrollable situation order or infinite loop, if the post-conditions and pre-conditions do not contain sufficient data.

V. Consistency Management Model within Situations

A. Handling Mechanisms

The *consistency management* that we propose consists of a set of specific methods, techniques and mechanisms that aim to handle the misunderstanding problem and to obtain data consistency all along the interactions. They are similar to the dependability techniques [7].

1) Prevention mechanisms: try to suppress misunderstandings occurrence conditions in order to avoid misunderstandings. To avoid data inconsistency, the proposed technique is the explicit declaration of all shared data before situation's interaction sequence start. It aims to identify and share actors' local visions in order to decrease the possibility of interaction deviation. Once the actors have collected the necessary data, they can start the interactions. The data synchronization is another method intending to compare the actors' local visions at a given moment during the interaction sequence in order to avoid the inconsistency of new perceived data. The synchronization can delay the interactions, so it should be done fast and not too frequently to disturb them as less as possible.

2) Tolerance mechanisms: aim to assure interaction continuation despite misunderstanding occurrence via misunderstanding detection and interaction recovery.

Detection: regular check of i) the shared data used during the interactions and ii) the deviation between actors' logics.

Recovery: once a misunderstanding is detected, the system apply one or several of the following techniques : **rollback**

- bringing the system back to a stable state, exempt from misunderstanding, to retry the interactions; **rollforward** - bringing the system to a new misunderstanding free state from which the interactions can go on; **reinforcement** - requiring from one or from all participant actors to do some additional interactions.

3) Removal mechanisms: involve misunderstanding detection and correction, followed by **reinitialisation** of the concerned interaction sequence, or of the whole execution process. The detected misunderstandings will be diagnosed to determine their causes: which data are inconsistent? Which ambiguities exist in the interaction context? Are there protocol faults? After that, an appropriate correction method will be applied to eliminate the related misunderstanding. Finally, the interactions have to be restarted from the last stable point or from the beginning.

B. Inclusion into the Situation Structure

Our situation-based architecture allows the integration of misunderstanding management mechanisms inside the situation in order to control the misunderstandings and their consequences all along situation execution. We define three phases (figure 3).

a) Prologue phase: The explicit declarations of interacting content and data are performed, to synchronize actors' local visions before they start to interact. If the initial data of all actors are identical from the beginning, the possibility of misunderstanding is reduced. If the inconsistency exists, a negotiation step will be performed between the inconsistent actors. Then, one or several of them will modify its/their data, or the divergent data will be isolated/removed and not considered during the interactions.

b) Interaction or Dialogue phase: when the interactions are carried out, the actors will update their local data step by step, as they continuously observe and perceive each other. Despite the initial local vision agreement, misunderstanding may nevertheless occur during the interactions. This is why their local knowledge is synchronized all along the interaction sequence in order to avoid that local data about same facts diverge in actors' local visions. One or several techniques of *reinforcement, rollback, rollforward* can be alternatively used.

c) Epilogue phase: All the interactions are done in the previous phase. If the post-conditions are fulfilled, we can exit the situation with the expected results. But if, for some reason, we do not reach the expected post-condition, the **script agent** has to detect and settle the existing incoherency in order to avoid the propagation of the misunderstandings to other situations. The system may also require actors to do some reinforcing interactions, or if necessary, make a rollback to a last stable state (in this case there must be systematic state saving mechanism), or, even a restart of the whole situation. The main goal of this phase is to quit the situation with the appropriate post-conditions and without latent or active misunderstanding. But, the rollback or reinforcing interactions may not lead the actors towards the planned post-conditions. Therefore, we add in the situation model a special exit point called "exception" that allows the current situation to be stopped at anytime without expected post-conditions and that leads to **exception handling situations**.

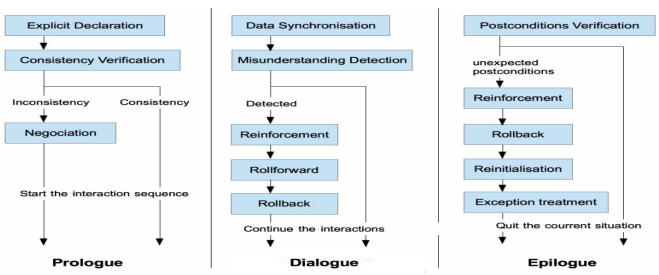

Fig. 3: Consistency management mechanisms

VI. Experiment on Online Distance Learning Case Study

To validate our approach we applied our situation-based methodology in our current online distance learning (ODL) project [2]. The project is devoted to the development of an online distributed platform that simulates a real classroom: teachers and learners carry out learning sessions as in a real life but by interacting through a virtual class environment. The platform integrates an interactive numeric board, camera, microphone and pedagogic tools (as file sharing system or virtual notebook) to support the courses...The figure 4 shows an example of courses scenario based on 6 situations. However, the users may face many difficulties: class supervision, course quality assessment, misunderstandings due to the weak system's interfaces and mechanisms to catch and manage user behaviors. The interactions between the actors in ODL contains numerous factors that may lead to misunderstandings as: multi-meaning or implicit behaviors; supervision tools' observation and interpretation imperfection; system component failures; incomplete, missing, implicit or wrong consigns...

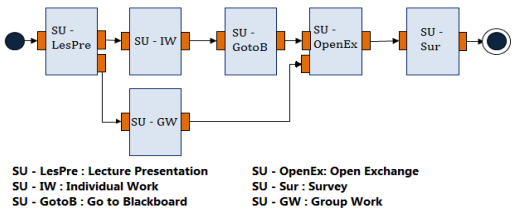

Fig. 4: Situation-based scenario example

A. "Individual Work" Situation Description

To deal with these various misunderstandings, we applied our situation-based solution including consistency management to a particular situation: "Individual Work" (SU - IW in figure 4). Each learner will work individually and has to do the exercises distributed by the system. The system provides additional exercises each time the learners send the previous exercises report. The expected post-condition is that all the learners reach a required knowledge level "*MaxKnowledge*".

Because of the long test duration and development for the real platform prototype, we chose to experiment our misunderstanding management mechanisms and agent-based architecture through a multi-agent simulation with the GAMA

platform[1]. We have 4 types of agents : "Teacher", "Learner", "Observer" and "ODL System". The Observer's role is to observe the state of sent exercises in order to evaluate learners' accumulated knowledge level. The distribution mechanism based on these observations and learners' skill level evaluations is taken in charge by "ODL System" agent that is a combinaison of 3 other agents in our model: scenario, script and director agent (figure 1). Potential misunderstandings in this situation occur when the system distributes the exercises that are incoherent given the learners' skill and expectation. They can result from wrong learners' exercise state observation or from inappropriate distributed exercise level. The misunderstanding handling is done inside the situation during its 3-phase progression (figure 5).

Prologue phase: The system checks each learner's connection status to begin the exercise series distribution.

Dialogue phase: In this situation, the interactions content refers to the exercises distribution and reporting. During learners' work, each observer agent supervises his associated learner's working state and his exercise report to collect data: partial or total termination, work duration, correctness rate. To avoid the wrong estimation of learner's skill and knowledge level, these data have to be synchronized between the observer and his learner after the exercise report is sent and before a new exercise is distributed.

Epilogue phase: To finish the situation the lerners must reach a given skill level after a given number of exercises. If a learner reaches this number without reaching the required skill level, the series will be stopped after a *session deadline* to avoid an abnormal long series. The system sends a *StopSignal* message to all learners to confirm the end of the exercise series after a predefined timeout. It refers to the exception treatment.

B. Experimentation Results

We run the simulation of "Individual Work" situation with the following parameters: 50 learners, 1 teacher, max knowledge level = 25, max difficulty level = 20, session deadline = 250 steps of simulation. We will measure a set of

[1]https://code.google.com/p/gama-platform/

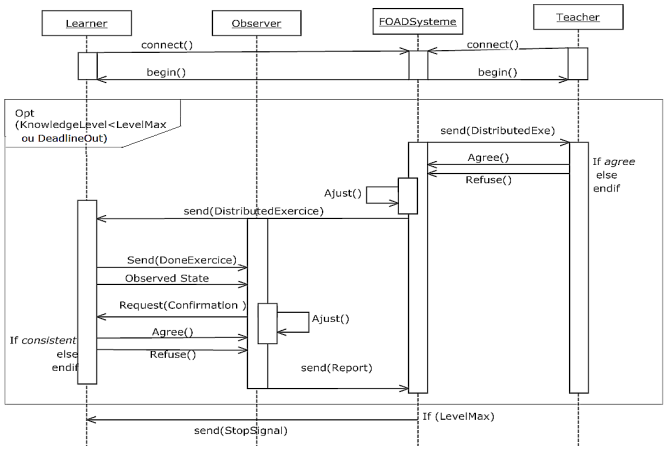

Fig. 5: Agents main interactions in the simulation

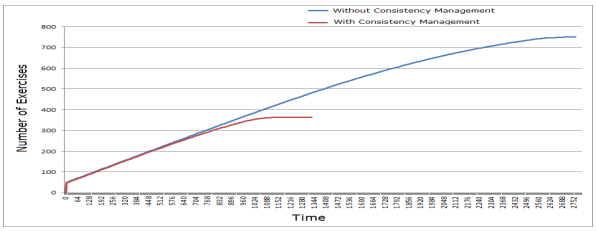
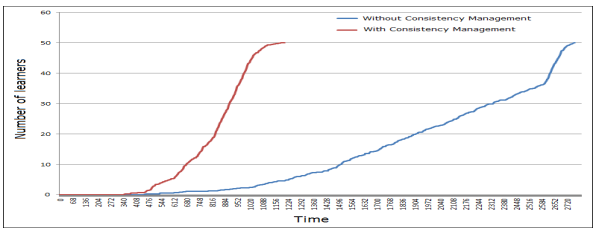
important factors influenced by potential misunderstandings:
N_e: total number of distributed exercises;
N_{notend}: total number of real non-finished exercises;
N_{bad}: number of bad observation by all observers;
N_{cor}: number of system observation corrections while detecting the wrong observed states (it refers to the synchroniaation times where consistency management is performed to remove inconherent data);
LI: learners' interest level that increases when the learners succeed and that decreases when they fail their exercises;
T_{total}: total session times (in *steps*) until the last learner has finished his series.

The data are recorded and calculated for the average values from 10 simulations lauching times in each measure. We compare these data between two cases: "with" and "without" the consistency management. The results are summarized in the table I. The total distributed exercises number N_e is twice more in "without" case compared to the "with" case. The average number of not finished exercises in "without" series is higher than in "with" series: 747.4 vs 363.4 also depicted in the figure 6(a). It is obvious that the session duration in "without" case is almost 2 times longer than in "with" case.



(a) Number of distributed exercices.



(b) Number of learners finishing exercise series.

Fig. 6: Comparason between 2 cases "With" et "Without".

The figure 6(b) shows the number of learners that have finished their whole series during the situation execution in the "with" and "without" consistency management cases. The lines shows that the learners work with more exercises and with longer duration T_{total} in the "without" case. We can make the same observation with the average measure values in table I.

Why do we have this difference result? When the consistency management is integrated in the situation execution to handle the potential misunderstandings, the observers have to adjust their observed data according to learners' "disagree" acknowledgments. Hence, the learner's skill level estimation will converge faster to the real value, and the difficulty level of the distributed exercises is more appropriate to his skill. The result is that learners can finish all the exercises and with higher correctness rate. In contrast, if no mechanism is added to control the inconsistency between learners and observers,

TABLE I: Statistical data comparason between 2 cases: With (Wi) et Without (Wo) the consistency management

	N_e		N_{notend}		N_{bad}		N_{obsnon}		N_{cor}		LI		T_{total}

10	361	774	40	62	93	115	117	134	93	0	74.18	65.92	1084	2728
Ave.	363.4	747.4	42.4	60.1	97.1	99.8	115.9	114.9	17.8	0	76.82	67.71	1092	2641

a non-finished exercise can be perceived as finished, and vice versa. The skill estimation is less correct: higher or lower than the real one. There is a higher probability that the ODL system gives to the learners too difficult or too easy exercises. That delays the skill level progression and explains why the learners take more time to terminate the series.

VII. Conclusion

In this paper, we have presented the situation-based design methodology and consistency management mechanisms to handle the misunderstanding in interactions. Our approach is to contextualize the interactions between actors into "situations" and add to these basic narrative blocks consistency management mechanisms split into 3 steps: the *prologue*, data declaration and consistency verification, the *dialogue*, the interaction unfolding, local visions synchronization and misunderstanding treatment, and the *epilogue*, data update and agreement attainment. We do not seek to find a universal algorithm or a solution to deal with all types of misunderstandings in interaction. Our aim is to provide a management pattern that could be systematically used by the application designers or developers and that allow them to incorporate their own verification, synchronization, prevention and tolerance mechanisms adapted to the specific misunderstandings of their applications.

We have applied our methodology to a case study from an Online Distant Learning project. We have built a simulation of the "Individual Work" situation and integrated into it the proposed solutions to show how the consistency management operates on a simulation example. From the experimentation results, we have found out that our mechanisms reduce the incoherent data between learners and observers and improve the performance of exercise distribution: shorter session duration, lower exercise number, faster required level attainment... Even if the simulation is simple and does not cover exhaustively all the possible interactions that can occur in such situation, it illustrates the benefits of misunderstanding management during interaction progression.

The next step of our work is to perform the same experimentation and measures on the prototype under development with live case study and to check the relevance of our approach in other e-Learning "situations".

***Abstract*—Complexity of tsunami modeling requires designing software system with high level of reusability and interoperability of its components, and flexible resource management. In this paper we investigate how to integrate the tsunami modeling software with an agent-based resource management infrastructure.**

I. Introduction

REFLECTIONS brought about by the Great Japanese Earthquake and Tsunami raise questions how to mitigate the impact of such events at different time scales, from real time tsunami warning, to long-term hazard assessment. This makes the Tsunami Modeling Problem even more important, and requires applying modern software design approaches, including collaboration among distributed clients and computational services. Another challenge is scalability of the approach, which should allow an arbitrary number of users and computational resources to interact in a customizable working environment. Finally, since separate applications and services may be developed for heterogeneous technologies and platforms, reusability and interoperability are important aspects of exposing and combining computational resources and services [1], [2].

Increasing power of personal computers allows their volunteer participation in high-performance computing, by granting computer time for public calculations. For example, the Folding@home project involves distributed computationally intensive simulations of protein folding and other molecular dynamics simulations [3], [4]. Each user can participate in these computations by calculating a part of a problem. Note that volunteer computing does not allow private use of results obtained by a community of users. Furthermore, this project (and many others) is based on applying a single computational kernel, using a BOINC-like client. Unfortunately, tsunami modeling requires more human interactions during the process, to understand the results and on their basis to specify the next round of experiments. Furthermore, as mentioned below, there exists a number of different tsunami models, that often need to be combined to model various phases of the tsunami phenomenon. This makes simple application of the BOIC-like volunteer approach unfeasible. For different reasons, it may not always be possible to use grid-like infrastructures. For instance, in a University with multiple laboratories "belonging to" separate administrators, it may not be easy to combine them into a single grid. This is especially the case when when different resources have different availability schedules.

In response to these challenges, the aim of this note is to outline how to combine tsunami modeling software with an agent-based resource management infrastructure. Here, agents' flexibility and ability for negotiations will allow malevolent use of resources belonging to different administrative domains.

II. State-of-the-art in Tsunami modeling

Let us start from a brief overview of the state-of-the-art in tsunami modeling. In [5], authors suggested that complex mathematical models and high mesh resolution should be used only when and where necessary. They proposed a "parallel hybrid tsunami simulator," based on mixing different models, methods and meshes. Their system was implemented implemented using object-oriented techniques, allowing for easy (re)use of existing codes and adding new ones. Note that the goal was to combine existing approaches to develop high quality hybrid models (rather than high performance).

Authors of [6] experimented with eight parallel tsunami simulators. They applied different programming models; e.g. thread based shared memory, distributed memory, and virtual shared memory. As a result of experiments it was shown that the threading-based approach does not scale well, especially if sufficient "node memory" is not available.

The TsunamiClaw package was developed on the basis of the finite volume method [7]. Here, the solution is represented as piecewise constant and is approximated in discrete computational grid cells. The obtained solution is represented in the form of water depth and momentum. Currently, this project is no longer being actively developed. Instead it has been generalized into the GeoClaw software [24].

The TUNAMI–N2 software [8], uses a hybrid tsunami model with different approaches to deep sea and shallow water / dry land modeling. However, it applies constant grid size in the entire domain. The TUNAMI was developed by Imamura in 1993 by Imamura. The package was written in FORTRAN and had a standard GUI for interaction.

978-83-60810-53-8/$25.00

The Method of Splitting Tsunami (MOST; [9], [10]) was developed at the NOAA (Seattle, USA). It allows real-time tsunami effect forecasting, as it can incorporate data from detection buoys. Furthermore, in the US, the MOST model is used to create inundation maps [11]. Recently, MOST software was combined into a SOA system [1] available through a web enabled interface (ComMIT; [25]).

Summarizing, a number of models exist for tsunami risk mitigation. Typically, they involve: origins of tsunamigenic earthquakes (estimation of magnitude and epicenter location), determination of the initial displacement of the tsunami source, wave propagation, inundation to the dry land, etc. Typical tsunami modeling environment simulates three processes: (1) estimation of residual displacement area, resulting from an earthquake and causing the tsunami, (2) transoceanic propagation of the tsunami through the deep water zones, and (3) contact with the land (run-up and inundation).

III. University of Aizu Tsunami Model

A. Basic Model and Software Tools

Currently, a novel tsunami modeling system is being developed at the University of Aizu. It is based on the principles of the Service-Oriented Architecture (SOA) and follows a Virtual Model-View-Controller pattern (VMVC). The VMVC is an adaptation of the traditional MVC to the SOA ([13]). The starting point for this work was the MOST package ([9], [10]). This method was initially developed in the Tsunami Laboratory of the Computing Center of the USSR Academy of Sciences in Novosibirsk. Subsequently, it was updated in the National Center for Tsunami Research (NCTR, Seattle, USA), and adapted to the models and standards used by the tsunami watch services in the US (and other countries). Here, the propagation of the long wave in the ocean is governed by shallow-water differential equations:

$$\begin{aligned} H_t + (uH)_x + (vH)_y &= 0, \\ u_t + uu_x + vu_y + gH_x &= gD_x, \\ v_t + uv_x + vv_y + gH_y &= gD_y, \end{aligned} \tag{1}$$

where $H(x,y,t) = h(x,y,t) + D(x,y,t)$; h represents water surface displacement, D depth, g gravity, $u(x,y,t)$ and $v(x,y,t)$ are the velocity components along the x and the y axis. Initial conditions should confirm the presence of water in all grid points, except for the tsunami source, where the surface displacement is not equal to zero.

The numerical algorithm is based on splitting in spatial directions the difference scheme, which approximates equations (1). This transforms solution of equations with two space variables to the solution of two one-dimensional equations and allows use of effective finite-difference schemes developed for one-dimensional problems. Moreover, this method permits to set boundary conditions for a finite-difference boundary value problem using a characteristic line method.

B. General Calculation Process

Figure 1 presents the block-diagram summarizing the calculation process. The input data consists of:

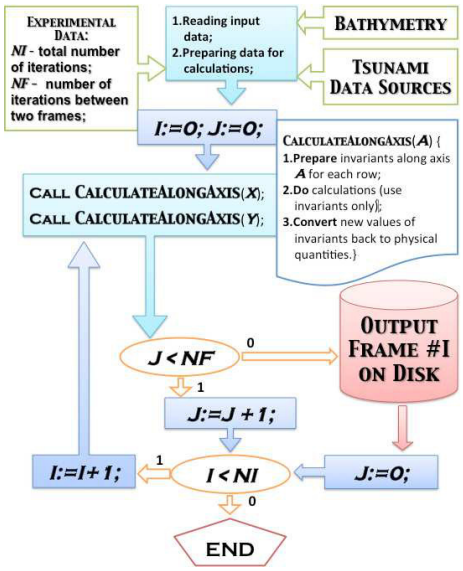

Fig. 1. General Computational Scheme

- bottom topography or bathymetry data,
- initial and boundary conditions,
- other parameters, e.g. time-steps and length of model run.

While running the program implements stores results as a series of frames representing the tsunami propagation process. Parameter NF defines the time interval, during which results are persisted in memory. After this time expires, results of current iteration, containing wave parameters, are stored on the secondary storage devices in the NetCDF format ([11]). The NetCDF format supports the creation, access, and sharing of array-oriented scientific data, while special programs allow its analysis and visualization.

While the original MOST software was implemented in Fortran 90, it was later ported to C/C++. Now, it takes about 3.00 seconds for a single time step on a 4 dual-core (Intel Xeon 2.8GHz) CPUs computer ([13], [14]). Observe that, a typical simulation, consists of about 10000 time steps (8 hours to complete). Therefore, the tsunami modeling needs to be significantly accelerated; especially for real-time tsunami warning guidance. However, speeding up modeling is also crucial for repetitive tsunami simulations.

IV. Service-oriented Architecture and Application Engines

A. Virtual MVC-design Patterns

Variety of methods for tsunami modeling require effective use of heterogeneous components on a variety of platforms and architectures. Furthermore, to achieve reusability, it is more cost effective to integrate applications rather than to rebuild them. Therefore the Virtual MVC design pattern (VMVC) was applied (Figure2). The demarcation of a Functional (View) and an Implementation (Model) task can be achieved by inducing an Integrator (Controller). The Controller can be enriched by encapsulating certain Non-Functional activities

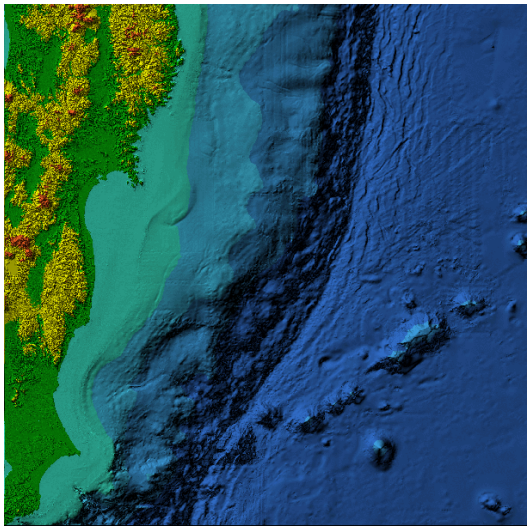

Fig. 3. Visualization of the 2413x2405 gridded relief around NE coast of the Honshu island.

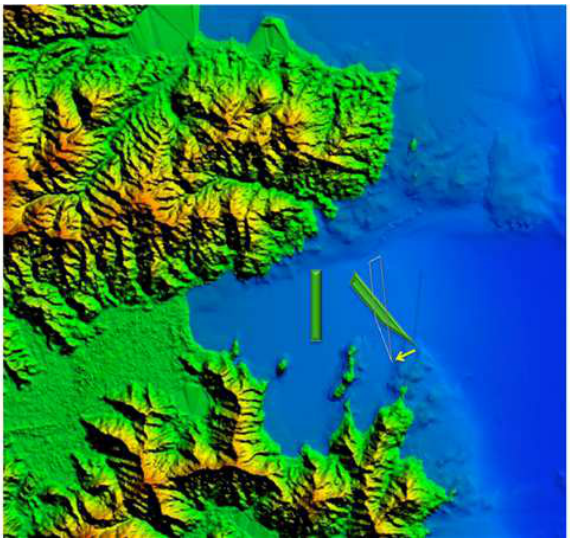

Fig. 4. Bathymetry with artificial objects.

such as security, reliability, scalability, and routing. This enables the separation of Integration Logic from that of Functional Logic (Client Application) and Implementation Logic (Service). The extendable set of application-oriented systems can be realized based on this integration environment including Service-Oriented Multistage Tsunami Modeling [13]. Figure2 shows main elements of this architecture, where the Tsunami Modeling database contains Tsunami Scenarios (input parameters), Results of Modeling, and the Bottom Topography (or Bathymetry) data. The scenarios can be created/edited or downloaded from the Internet. The Tsunami Scenario Loader converts data to the Database format. Similar operations can be provided with the Tsunami Modeling Result Data obtained by external modeling components and published on the Internet.

The quality of the bathymetry data is one of the key parameters defining the accuracy of the model. This data is updated periodically. Here, a special bathymetry was developed, covering the area of the Pacific Ocean adjacent to the northwest parts of the Honshu island (Japan). The gridded digital bathymetry for the numerical modeling was prepared using 500 m resolution bathymetry around Japan [14], and 1 arc sec ASTER Global digital elevation model [15]. A computational rectangular grid of 2413x2405 points includes knots of pre-setup depth values. Length of a spatial step in both directions made 0.0024844 geographical degrees that is about 277 m in a North-South direction and about 221 m in the West-East direction. The bottom relief of the domain is stretching from 34 to 40 degrees of North Latitude and from 140 to 146 degrees of East Longitude, and is shown in Figure 3.

Modeling used tsunami data generated from the Great Japanese Earthquake (38.322°, 142.369°E, Mw = 8.9 at 5:46:23 UTC) on March 11, 2011 [16]. The fault length and width were 400 km $\times$ 150 km. Numerical experiments confirmed the reliability of this technique, and a good fine-grained CUDA acceleration of modeling process [14].

B. Hybrid Tsunami Modeling Combining Natural and Artificial Bathymetry Objects

Lessons from the Great Japanese Tsunami stress importance of reducing impact of tsunamis on different time scales. First, it is necessary to provide real-time tsunami warning. Second, tsunami modeling can be used for long-term hazard assessment (e.g. detailed inundation models across the Japanese sea-line). Third, the well–known "Matsushima effect," the considerable influence of natural geographical objects, like islands and bathymetry, on the wave height and speed of tsunamis, could be considered. Such effect exists in the Matsushima area where presence of islands mitigates effects of tsunamis (while they are absent on the Fukushima coast).

This conjecture is based on [17], where results of a simulation of effects of submarine barriers on tsunami wave propagation were presented. The experiments were conducted in a basin 5 m in length and 10.5 cm in depth. Single and double barriers were used in variable arrangements. Experiments indicated capability of reducing tsunami run-up. It was also shown that parameters of simulations can be translated to natural conditions. Therefore, similar computer simulations could be completed for crucial coastal areas. In this case, aim of the simulation would be to study effects of objects of different shapes, sizes and placement configurations (see, Figure 4). In this way it may be possible to design and build a set of artificial objects (islands) that can be used to protect the coastal areas. In particular, such protection could be of extreme value in highly populated areas, as well as in industrial areas (e.g. nuclear plants, factories, airports, etc.).

Currently, we are enhancing the modeling system by adding the Interactive Bathymetry Editor, supporting object-oriented GUI-editing on bathymetric data, as well as including/removing artificial objects of variable placement, shapes and size, and a plan of changing these parameters during the simulations (see, Figure 5). Here, the modeling process is

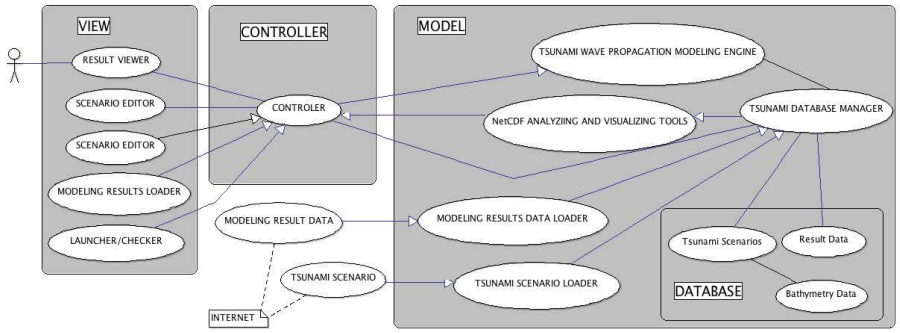

Fig. 2. VMVC-SOA Decomposition of the Tsunami Modeling Environment

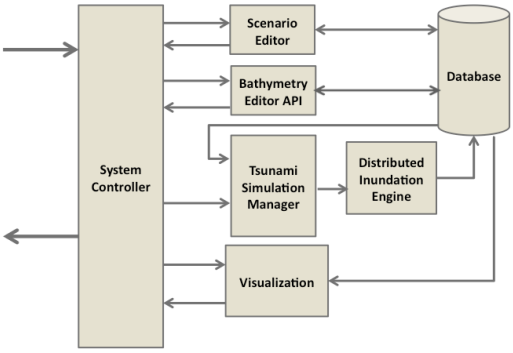

Fig. 5. Components for Hybrid Tsunami Modeling

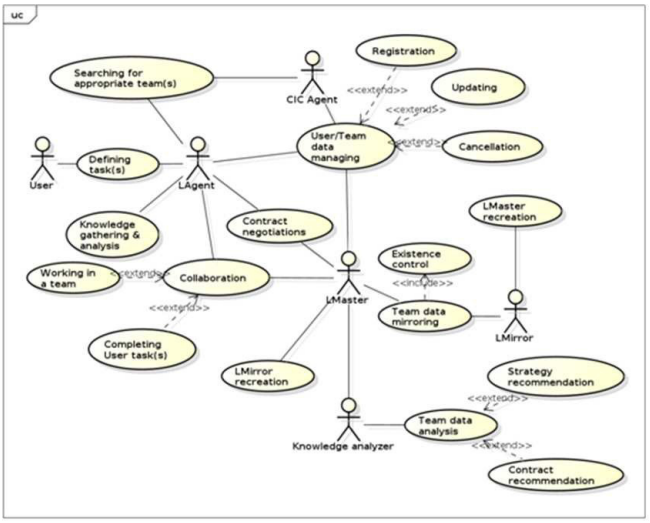

Fig. 6. Use Case diagram of the AiG system

controlled by the Tsunami Simulation Manager, and has as its goal finding suitable number, sizes, and placement of artificial islands and submarine bathymetry objects that minimize the dangerous tsunami wave parameters (height and speed). This problem requires multiple runs of identical tasks with different parameters. While such computing scenario could be realized in a BOINC-like environment, for reasons outlined above, we have decided to attempt at their realization using the agent-based infrastructure.

V. AiG for Tsunami Modeling

The Agents in Grid (AiG) project aims at providing a flexible agent-based infrastructure for managing resources in the Grid ([18], [19]). Application of software agents and semantic technologies makes it well-suited for open, dynamic and heterogeneous environments. The AiG architecture is based on the concept of an open Grid – a network of heterogeneous resources, owned and managed by different organizations. It allows for users to either provide a new resource to the Grid in order to earn money, or to use the Grid to execute a task. Note, that this design nicely fits into the VMVC design pattern, since the Client Application is separated from reusable Services (available resources), while agents representing user and resource manager share characteristics of the Controller. Hence, we can distinguish component responsible for Integration, Functional and Implementation Logic.

The elements of the system have been modeled as software agents: each resource is governed by (and each user is represented by) an *LAgent* and performs its tasks as part of a team, managed by an *LMaster* agent. Teams are registered in a directory service, represented by the *Client Information Center* (CIC) agent, which handles matchmaking of users to teams. The decision, which team to choose to execute the job is a result of autonomous negotiations between the *LAgent* and the *LMaster*s of the appropriate teams. In a similar way, adding a resource to the system involves negotiations with teams looking for new team members. The main features of the system are shown in Figure 6.

In the AiG project all information is represented in ontological format, using the OWL language. The usage of ontologies enables to describe jobs, resources and their relationships in a structured, yet flexible way (for more details, see [20]). Support previously unhandled hardware and software (such as new hardware devices, software libraries or programs) involves only modification of the ontology and does not require any additional customization. As the job descriptions are also defined in OWL, it is possible to specify different parameter

Fig. 7. Example of choosing a property for constraining

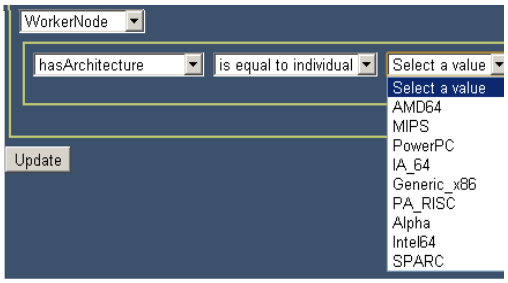

Fig. 8. Example of choosing an individual

sets and required computing resources depending on the type of the task to be performed. This is especially important for the applications described above, where the hardware and software configurations are highly heterogeneous and tools used to perform the experiments may differ from machine to machine.

Attempting at using the AiG architecture at the University of Aizu, one can observe that it is not an open environment (with resources joining and leaving the Grid dynamically). Moreover, there is no economic aspect – if a resource matches the requirements of the job and is available for use, there is no need for negotiations of terms of usage. These differences allow us to simplify its structure and use. As a result, we resign from the notion of resource teams, and place an *LAgent* (playing the role of the *LMaster*) on each computing node. We can also eliminate the scenario of the *LAgent* joining a team. Instead, adding a new resource will mean registering it with the *CIC* as a standalone node (one member team). Finally, we reduce (and re–focus) the negotiations. Their role will be to provide information about current and planned utilization of the resource. This will allow the *LAgent* representing user to decide where to run which job and when.

Let us now describe how the system will allow tsunami modeling using multiple resources in the university laboratory. The user starts by accessing a web based interface, which allows communication with her *LAgent*. Next, she specifies the hardware and software requirements of the job (as constraints on the ontological terms describing needed resources). This task is done using the interface based on the OntoPlay module [21] (its Condition Builder component), giving the user freedom in describing the needed resources, while guiding her through the contents of the ontology without deep knowledge of its structure (of semantic technologies in general). As shown in Figure 7, the Condition Builder is composed of a series of condition boxes used to create constraints on class-property relationships. Depending on the chosen class, the user can select, which class property she wishes to restrict. For example, having selected the *PhysicalMemory* class, the expanded property box will contain properties such as *hasTotalSize* and *hasAvailableSize* (see, Figure 7).

After selecting the class and property the user can choose the required operator and value. Here, she sees only operators applicable to the type of the property. Specifically, this means that for value properties it would be operators such as *equalTo*, *lessThan* or *greaterThan*, while for object, properties the user would be allowed to select, e.g. is equal to individual or is constrained by. Should a user wish to restrict the value of a particular property to a fixed individual from the ontology, Condition Builder lists all individuals that can be used in the context (see, Figure 8).

To illustrate the process, let us assume that the user wishes to find all resources that are running the Linux operating system, have at least 8 GB of memory and a 4-core processor. In this case the user starts with an empty *ComputingElement* specification. First, he would constrain the property isRunningOS of the class *ComputingElement* to any individual belonging to the class Linux. We assume it does not need to be any particular flavor of Linux, so we do not add additional conditions on this class (however, when installing the AiG system at the University of Aizu, we will represent each machine as an individual in an ontology). Second, the user adds condition on the property *hasMemory*, constraining it to the *PhysicalMemory* subclass and adding a nested condition specifying that the *hasTotalSize* property should have a value greater than 8000 MB. Similarly, the user constraints the *hasCPU* to an instance of the CPU class with a value of the *hasCores* property equal to 4.

After user submits the resource requirements, the *LAgent* passes this description to the *CIC*, which performs semantic reasoning on its knowledge base, to find resources satisfying the given criteria and returns a list of matching nodes, including the information how to contact the *LMaster*s at each node.

Note that even in a semi-dynamic environment, such as a university laboratory, there is no guarantee that the resources found by the CIC are, at the moment, available for use. The machine may be offline, used for other purposes, or the agent process may not be running. Therefore, there is a need for additional verification of the availability of resources. This is handled through agent negotiations, albeit in a very simplified form. When the *LAgent* receives the list of *LMaster* addresses, it issues a *Call For Proposal* message to gain confirmation of whether the resources are able to perform the task. The

LMasters confirms (or rejects the proposal), and provides information when it could start executing the job. This helps to handle the case of temporarily occupied / not available nodes. Once the *LAgent* receives offers from the (benevolent) agents, it presents the list to the user, who can choose the nodes on the basis of their availability and parameters.

The final step of submitting jobs is the specification of task parameters. As described in the previous sections, for the tsunami simulations it is necessary to run different algorithms on different data sets and parameters to come up with multiple results. Consequently, user is required to provide multiple job descriptions (one for each model / parameter). The job description is going to be provided using the same Condition Builder mechanism, although using a different part of the ontology and will contain information such as the command or script for running the computation, together with any additional parameters required by the algorithm, such as location of the necessary data and the place for storing the output(s).

Completed job description is sent by the *LAgent* to the respective *LMaster*, which then executes the task. Once the computation is finished, the *LMaster* creates a *JobResult* message, which contains information about the job execution, the outcome and links to the result data and any resources created by the simulation algorithm. The *LAgent*, on the other hand, is responsible for gathering all responses from the nodes taking part in the experiment and presenting them to the user, thus ending the scenario.

VI. Concluding remarks

The aim of this paper was two-fold. First, to introduce important issues that arise in the tsunami modeling and that require a robust resource management to run the needed simulations. Here, the "Matsushima effect" was used as the main grounding scenario. Second, we have argued that the agent-semantic infrastructure, developed within the Agents in Grid, project can provide the needed solution. This is especially in the situation when multiple resources are under administration of separate authorities and may be availale according to their own schedules. Next, we have discussed changes (simplifications) that need to be introduced to the AiG infrastructure to adapt it to the needs of the tsunami modeling, as a task completed using machines available within the University of Aizu. Finally, we have presented a detailed scenario how the user would use the AiG infrastructure to run a simulation. Goal of our future research is to complete the changes outlined in this paper and install the AiG infrastructure on the machines in the laboratory of Prof. Vazhenin and Prof. Watanobe, and run experiments with tsunami modeling.

Acknowledgment

Work of Marcin Paprzycki was completed while visiting the University of Aizu.

11th Conference on Advanced Information Technologies for Management

We are pleased to invite you to participate in the 10th edition of Conference on "Advanced Information Technologies for Management AITM'2012". The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

Topics

The topics of interest include but are not limited to:

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

***Abstract*—Adequate integrated ICT infrastructure and services are a prerequisite for keeping pace with the rapid rise of complexity and service levels in logistics. Recent studies indicate a high attractiveness and impact perspective of cloud computing for logistics service providers within few years in order to cope with the growing IT capacity demands. Within this paper, a comprehensive overview is given on R&D with relation to CC for logistics. Among these, the EU-project LOGICAL is presented in detail since it combines different aspects and benefits of CC for the logistics sector. A generic system of CC use cases in logistics and the corresponding needs for a logistics cloud architecture are discussed and compared with the implementation status of the LOGICAL cloud. Special attention is given to the problem of incompatible data and service interfaces. Instead of following the single-window, single-document concept, a semi-automated on demand interface creation service is presented as an intermediate alternative for the practitioning logistics sector.**

I. Introduction

A. Market Background

THE emergence of new cloud computing services is steadily increasing. More and more companies realize the benefits and opportunities of using IT-resources with unlimited scalability and on-demand services at pay per use conditions over the Internet, as opposed to "classical" on-premise installation and operation. A recent survey of web-hosting and cloud computing specialist *Parallels* [1] indicated that especially small and medium sized enterprises (SME) are drivers of extraordinary growth rates above 20% per year in this market domain worldwide.

The full potential of collaborative business processes, especially for logistics companies, is still not exhausted. The benefits for design and organization of heterogeneously fragmented logistics processes based on new logistics software that is available within minutes and allows an easy integration of customers, suppliers and partners, are about to be appreciated by logistics service providers (LSP). The latest *Logistics Trend Radar* report, published by DHL, ranked cloud computing and supergrid logistics among the trends of highest mid and long term impact perspective [2] due to the expectation that these innovative trends will foster completely new process models and service provider types in logistics of the future.

The work presented in this paper was funded by the CENTRAL EUROPE programme co-financed by the ERDF under the project LOGICAL (www.project-logical.eu)

The trends mentioned above may be seen as a partial facet of a larger trend: *bottom-up economics*, a paradigm change which may lead to a total economic reconfiguration in the 21th century, driven by the Internet. The planning, organization and implementation of complex logistics processes is currently carried out by large logistics companies with complex software systems. Cloud computing fosters the cooperation and collaboration of numerous small and medium-sized logistics enterprises without major capital expenditure in IT hardware and software. An open research question is how to cope with heterogeneous data models and interfaces on one side and how to organize and control these cloud-based collaborative business processes.

B. State of R&D in Cloud Computing for Logistics

The development of cloud computing platforms, services and solutions for various business purposes is driven by different institutions, academic and commercial, both on national and international levels. The project "Future Business Clouds" (FBC) alone lists about sixty different cloud computing R&D-projects which are funded by the EU and its member states [3]. Most of these projects, however, are dealing with general technological aspects of cloud computing for business. Just about. 5% of these business clouds, however, explicitly address the application domain of logistics and supply chain management. In addition to these cloud developments, an impressive number of R&D activities and institutional capacities have been initiated internationally in the EU under the 6th and 7th Framework Programme during the last decade upon the field of information and communication systems in transport and logistics. This R&D-domain is relevant for cloud computing in logistics due to a significant focus on interoperability and standardization of data structures in support of collaborative and smart supply-chain management and resource efficient co-modal transport management, especially for SME. An overview on related EU-projects is given by [4].

The joint efforts to solve the problem of incompatible interfaces and data structures as main obstacles of interoperability in the transport and logistics sector lead to a conceptual *Common Framework for Information and Communication Systems in Transport and Logistics* which follows the single-window, single-document approach to create interoperability by standardization. Finally, a unified single transport document shall be established that can be used for

978-83-60810-53-8/$25.00

all modes of transportation. The framework consists of a definition of different "roles" (stakeholders with unique set of responsibilities), "business processes", related standardized "messages" and common ontology based "data elements". Current plans to connect the common framework community with SMEs and proprietary systems aim at the creation of standard web forms and so-called "connectors" (like "translators between differing formats and data models"). As a part of the EU *Freight Transport Logistics Action Plan* the common framework was developed with a holistic perspective by means of integrating the concepts and results of several EU-projects (e.g. FREIGHTWISE, e-Freight, INTEGRITY, Smart-CM, SMARTFREIGHT, EURIDICE and RISING) in the EU-project DiSCwise [4].

A second integrative initiative upon EU-level is the open innovation network platform ETP (*European Technology Platform on Logistics*) which is the output of the 7th FP EU-project WINN [5], [6] and was launched under the acronym ALICE with participation of global players in logistics and industry in June 2013. Among others, involved R&D institutions are the Dutch Institute of Advanced Logistics DINALOG, the Polish competence centre of logistics ILiM and the German Fraunhofer Institute IML. The major issue of ETP and ALICE is virtual collaboration in supply chains. A case study of a platform (T-Scale) based upon global communication standards, which supports virtual supply chains in real time, is described in [7].

A market-oriented approach to collaboration is matching transport demand and offer by means of virtual market places such as online spot exchange platforms and services. An example of this category is the web-based system for rail freight matching developed in the joint R&D-project CODE 24 of the Rotterdam-Genoa corridor [8], programmed by means of open source tools at Duisburg-Essen University. A second example is the project CloudLogistic [9] of Aachen University and industry partners which develops a cloud platform for matching part loads of trucks (capacities and demands) based upon geo-coordinates. Related issues of the business model, SLAs and billing mechanisms are included in this project.

One of the most prominent examples of establishing a virtual market place by means of cloud computing is the ,*"logistics mall"* of the *Fraunhofer innovation cluster for cloud computing in logistics*, developed by the Fraunhofer institutes IML and ISST and operated by Logata GmbH [10]. Basically, the logistics mall serves as a virtual IaaS and SaaS platform for matching demand and supply of logistics software and related IT services. It comprises both an ASP for running proprietary software and a SaaS engine and SOA-bus for combining atomic services with uniform data model and interfaces. Standardization is achieved by means of a uniform ontology and semantic modeling leading to standard *Business Objects* (BO). The mid-term development perspective is a repository of BOs and granular SaaS components which are selected, linked and orchestrated by means of a *Logistic Process Designer* and an interactive graphics user surface. The developers expect IT-cost reductions up to 50% especially for SME due to the mall and its on-demand services.

The example of the logistics mall illustrates that interoperability of IT services and SaaS components of logistics clouds and platforms are crucial for the capability of generating value added especially for the benefit of SME by means of combining available SaaS components to customized virtual process and supply chains. Numerous developments are characterized by standardization approaches like common ontology, semantic programming (e.g. using the language OWL), federated data management and linked open data concepts. Related projects are for instance CollabCloud [11] and COCKTAIL [12] to mention just a few.

A meanwhile finished R&D-project which among other results produced a uniform ontology (in OWL) for logistics was InterLogGrid [13]. Based upon InterLogGrid the joint R&D-project LOGICAL was initiated in the Central Europe programme in order to integrate several of the issues and benefits of the R&D-activities mentioned before: IT- and business process outsourcing, virtual market place for logistics services, integrative data and collaboration space and platform for the orchestration and optimization of collaborative business especially for the benefit of SME-size LSPs [14].

C. LOGICAL profile

LOGICAL's [14] objective is to enhance the interoperability of logistics businesses of different sizes, to improve the competitiveness of Central European logistics hubs through the development of a modern logistics cloud infrastructure. Beneficiaries of the project are especially small logistics companies that are enabled to use cloud-based logistics software to collaborate with other regional and global players. Cloud computing furthermore enhances the hubs' attractiveness for business activities in logistics.

LOGICAL will be simultaneously implemented at six major Central European logistics hubs: Leipzig (DE), Bologna (IT), Wroclaw (PL), Miskolc (HU), Koper (SI) and Ustí nad Labem (CZ). They represent multi-modal infrastructures such as the Airport of Leipzig/Halle, the freight village Interporto Bologna in Northern Italy, one of the most important sea harbours in the Adriatic Sea (Port of Koper) and the largest logistics centre in Hungary. In this way, cloud computing is used by different companies to organize intermodal transports using innovative cloud services.The project started in May 2011 and ends in October 2014.

The results of a survey in order to determine the initial as is situation among participating LSPs, their information demands, typical business processes and first architecture concepts were described in [15]. In the following the LOGICAL architecture and functionality will be presented in detail both from an application oriented view and in terms of the technical components used. Chapter V covers a special contribution to the issue of connecting data and systems with heterogeneous formats and data models.

II. LOGICAL USE CASES

A. Logistics cloud computing architecture: generic use cases

Based upon the survey findings, the identified user demands and migration requirements, major use cases of cloud computing for logistics were developed from a rather practical point of view. This process, however, cannot be considered to be finished, since understanding the opportunities of cloud computing in the logistics application domain grows with usage experience. Therefore, a two-step methodology was put into practice: at first generic use cases (use case classes) were developed and described in order to cover the utilization potential of a logistics cloud as completely as possible. Afterwards, specific use case instances which originated from communications with the survey participants and project partners were presented. The collection of these specific use cases will never be complete due to the ongoing creative process of finding useful new applications of a logistics cloud by means of ongoing interaction and communication with the growing number of users. For the logistics cloud the following generic use cases were identified and are interrelated in multiple ways (see fig. 1):

1) *Outsourcing* of IT resources and related services, i.e. hardware, software applications, and data pools from local (on-premise) IT-systems into a cloud
2) *Integration, Synchronization and Sharing of data* created and utilized by multiple users
3) *Market Place* for product and service offers and demands, platform for adding e-commerce activities to the corporate business models
4) Platform for the *management and optimization of collaborative business* activities of multiple business partners.

1) Generic Use Case 1: IT-Outsourcing: A meanwhile standard application of web-based systems consists in providing and using web-hosted software applications, either by means of an application service provider or by SaaS.

Typical IT functions which are outsourced in general business environments are accounting software, enterprise resources planning software (ERP), customer relations management software (CRM), document management software (DMS) and project management software (PMS).

Outsourcing of logistics IT services for logistics service providers may include transport management software (TMS), route planning software, fleet management software, tracking & tracing software, warehouse management system (WMS), supply chain management software.

Outsourcing is a method which supports enterprises in concentration upon core competences and cutting down secondary or overhead costs. Consequently, following the step of merely outsourcing the IT services of secondary business processes a higher level of this strategy is reached by completely outsourcing the complete related business process, such as accounting processes e.g. financial accounting, personnel accounting, e-procurement & e-commerce fulfillment.

Usually, for outsourcing just one client (e.g. company) is using the web-hosted application provided by the cloud, even

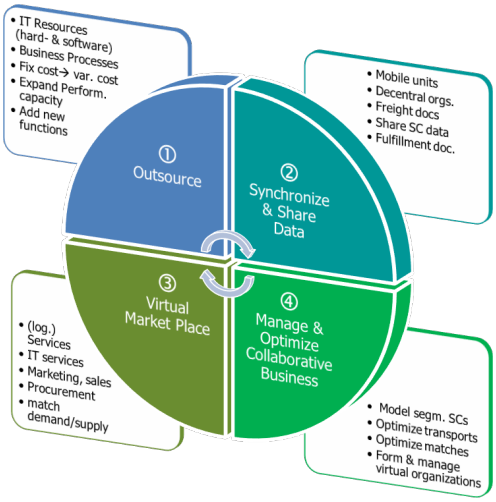

Fig. 1. System of generic use cases of a logistics cloud

if the client is represented by multiple persons (employees, team members). Legally, this relationship can be considered as a 1:1-relation. To find and select web-hosted application or public cloud service a public market place will be used. Another possibility for logistics companies is to develop and use own privte cloud services e.g. with locked data space and encapsulated VM.

The software applications which are offered for IT service outsourcing can be provided as a web-hosted application which instead of running on a local computer is running on a virtual machine. To use *separated instances* of the software, an application service provider (*ASP*) is used as a component of the cloud architecture. To use the *same instances of the software like other users*, the services in the *SaaS runtime engine* are usable.

2) Generic Use Case 2: Synchronize & Share Data: Using cloud computing for the integration, synchronization and sharing of data is one of the original drivers of establishing early cloud systems. A web-hosted managed data space is a basic solution for synchronizing files in simple file-sharing scenarios.

An already well-established representative of this cloud function is the meanwhile widespread DropBox® which offers web-hosted data storage capacity at pay-per-rent conditions (block tariff system based upon booked storage volume independent from actual consumption of the memory space). The Dropbox® is already established with data sharing and access right administration services.

The file synchronize & share function of the cloud can be applied to intra- as well as extra-organization uses of file synchronization and sharing. Typical intra-organizational uses are:

- File synchronization of mobile actors and business units, such as trucks and other vehicles, external service teams, smart devices of employees etc.
- Linkage of subsidiaries, regional or branch offices, ser-

vice posts etc. with the headquarter.
- Business data exchange and synchronization within decentralized organizations.

File Exchange across borderlines of single enterprises and organizations are:

- File exchange with clients
- File exchange among business partners
- File exchange with infrastructure operators such as seaports, airports, intermodal terminals and authorities such as customs authorities

Since data are usually shared among multiple users and the integration space should be a unique one, this relationship can be considered as a n:1-relation. The cloud can be used by clients to give business partners simple access to own files by using a web-hosted storage software suite e.g. DropBox® or OwnCloud.

3) Generic Use Case 3: Market Place: Using the internet as a channel for e-business is state-of-the-art for numerous market participants and traders. Although e-commerce in logistics is still a rather rare phenomenon, a logistics cloud may be the right instrument for adding an online-component to the commercial processes of members of the logistics community. The cloud market place in this context can be a limited access community market or platform open to the public. Since the members of logistics communities cover a wide spectrum of different services, the design of the market place should rather be like a shop of the shops (mall) than a uniform store. Since all functions of the cloud can be considered as a marketable service, the cloud market place can provide access to the whole service repository of the cloud as well as to the complete set of services offered by the logistics communities attached.

A user of the market is addressing to multiple recipients of his sales offer or procurement request. Thus the typical use configuration is a 1:m-relation.

The market place function of a cloud requires the following components of the cloud architecture: e-commerce platform and administration system (affiliate system with purchase monitoring, feed-back system and brokerage provision administration), data base management system, query masks, search & matching engine.

4) Generic Use Case 4: Management platform: The fourth generic use case class represents advanced uses of the cloud which aim at efficiency improvements and value added by means of additional cloud services. Matching demands and supplies in the market place does not automatically mean that a best fit is found. This requires optimization tools, i.e. instruments provided by operations research and systems analysis in order to find an optimum. This optimum may consist in the minimization of cost, carbon footprint, failure risk or a maximum of defined benefit functions. Applications in the logistics domain may be:

- Optimization of transports: best fit of demand and offer of transportation capacities according to predefined goal functions.
- In a generalized form: best fit of any kind of service demand and suitable supplies.

In sophisticated cases, the suitable supply for a service demand may not be offered by a single party but has to composed from the offered capacities of multiple providers as a fragmented sequence of several basic logistic processes, such as transport, storage, cross-docking, transport, intermodal transfer, transport, storage, commissioning, final delivery etc. In such a case, support services are needed for composing the whole process chain and for managing the cooperation of several (heterogeneous) partners. Possible functions of this functionality of collaborative business engineering and management are:

- Composition of suitable logistics process chains (from the online catalogue of single service capacities provided by single partners and covered by the logistics communities)
- Setting up of a "virtual organization" (a special purpose vehicle for logistics projects) of the partnering service providers
- Management and administration of the business processes of the virtual organization with devoted data work space, ERP-service, management tools, job management and billing services and allocation of cost and revenues to the contributing partners.

In these complex cases of multiple actor cooperation, *m* participants are addressed in the composition phase of the fragmented process chain and *n* participants access mutually applied data in the operation phase of the virtual organization. Thus, the use configuration is a m:n-relation.

The collaborative business function of a cloud requires the following components of the cloud architecture: optimization tools, simulation of fragmented logistics process chains, cloud hosted representations and management tools for virtual organizations.

B. Logistics cloud computing architecture: specific use cases

The specific use cases are ordered according to the generic use case classes system presented in the previous chapter.

1) Specific Use Case 1: Logistics software catalog: The logistics software catalog so far contains and provides typical business and logistics software applications. At current state the following applications are available: Standard office software (MS Office 365), ERP software (OpenERP), document management softeare (RICOH DMS), transport management software (PSItms), warehouse management software (*LogBase on Demand*®)

2) Specific Use Case 2: Synchronize & Share: All four use case categories of the LOGICAL cloud require data storage capacity. Thus, use case 2 will be integrated as cloud data space in other use cases.

In addition, the cloud will provide a managed file workspace function for pooling, synchronization and sharing of files in analogy to *Dropbox*®. The related software suite which is going to be used for this function is *OwnCloud*.

Several LOGICAL partners already develop or operate cloud-based systems for the common use and exchange of freight, customs or other official documents and files. These systems and data share functions can be linked to or integrated

into the LOGICAL cloud. Systems to mention in this context are for example:

Logistics Cluster Leipzig-Halle (PP3) and its member SALT Solutions developed a simple software tool for smartphones linked with a web-based data space (e.g. LOGICAL cloud workspace) which helps freight forwarders and other transport service providers to cope with new legal requirements of safety inspection, supervision and documentation. The traffic-manger app of SALT is a direct example of new service products which are developed due to the communication of the R&D projects InterLogGrid and LOGICAL between IT companies and experts and the application community, in our case the logistics service providers organized in the logistics cluster Leipzig-Halle.

Luka Koper (Port of Koper, Slowenia, PP14) developed a planning and scheduling system (TINO) for trucks unloading and loading on the seaport grounds in order to equalize traffic, increase throughput capacity and support freight forwarders as well as the port authorities in planning the logistics processes. In addition, Luka Koper operates a web-hosted information and service platform LUNARIS. Luka Koper now plans to develop a web service and a new module in the cloud platform LUNARIS that would allow registered shipping agents to extract all data from the cloud-solution TINO that are needed to satisfy the customs requirements for the Export Customs manifest.

Another example of using a cloud workspace for the integration of data is the container-information-service provided by port of Koper's platform LUNARIS. The e-zabojnik (e-container) application provides tracking information about containers delivered to, stored within and departing from the seaport grounds.

3) Specific Use Case 3: Market Place: In addition to the logistics IT applications as presented before, the LOGICAL cloud will contain a market place for marketing and matching common logistics services such as transports, warehousing, freight commissioning, and value added services.

As a first step, the offline-partner manual, which was developed in the logistics cluster Leipzig-Halle will be transformed into an online available web solution and extended to all other logistics communities of LOGICAL. This online catalogue of service providers, their available resources (vehicles, technical equipment, warehouses, permits and licenses), logistics competences and frequently served relations as well as features required for international cooperation (language skills, country experiences etc.) can be considered as the online catalogue of the comprehensive logistics service capacities of the LOGICAL community. Parts of the online representation of the web-catalog of partners, competences and capacities shall be publicly accessible for marketing purposes and can be used by shippers for finding appropriate logistics service providers.

The related user and service capacity data are to be stored and managed within the LOGICAL cloud database. In addition to the database itself the LOGICAL cloud surface has to be established with suitable entry- and query masks.

Once the general features of the cloud users are available, the following step will consist in the establishment of the market place open to the public (or only to registered members of the logistics community) where logistics service providers can sell standardized logistics services online via the logistics service market.

The opposite to sales offers, i.e. the placement of logistics service demands by shippers, 4PL-providers and other logistics clients in order to carry out online-tenders for required services has to be introduced as an inverted version (service demand) of the data objects representing offered services (service offers).

The final development level of the logistics service market place will offer a semi-automatic matching service for suitable pairs of matching demand and supply items. This service of the cloud will require a (fuzzy) matching engine.

4) Specific Use Case 4: Management Platform: One of the objectives of logistics communities is to foster cooperation among community members and to develop new forms of collaborative business. The fourth use case of the LOGICAL cloud is meant to combine the functions of the preceding three and to provide supporting cloud services for collaborative business engineering.

Based on atomic logistics services (such as loading, transport, customs handling, storage, packing/unpacking, quality check, labeling, commissioning, cross-docking, final delivery, additional value added activities), the composition of these basic and partial logistics services to complex, fragmented compound logistics services is necessary in order to cover the complete supply chain of preceding, hub-specific and consequent processes. The final objective consists in simulating, monitoring and management of complex logistics processes.

The supply chain process model contains different and multiple process steps (activities) which are executed by different logistics service providers. 4PL-Providers are the main target group of this use case which represents a strategic development direction of logistics clusters (e.g. the logistics cluster Leipzig-Halle). In this way logistics clusters can provide a modern communiction platform for their logistics service providers in order to enable and support cross-company cooperation and collaboration. In particular, the simulation of different combinations and variants for the implementation of complex logistics contracts is interesting to find out the most suitable variant for customers and service providers. Once a suitable chain of basic logistics services is identified and represented as a digital model of the comprehensive logistics process including the description of transport flows, freight quantities, resource volumes, times, cost and other parameters, this model can be used for the management of the process in forward (push-process) or reverse (pull-process) direction.

For the management and optimization of multimodal corridors and transports, Interporto Bologna developed cloud-based platforms and embedded applications CoSPaM and M2 TC.

One of the consequences of composing single logistics services to compound, fragmented service chains by means of collaborative business engineering will be the creation of purpose or project specific consortia of the contributing service

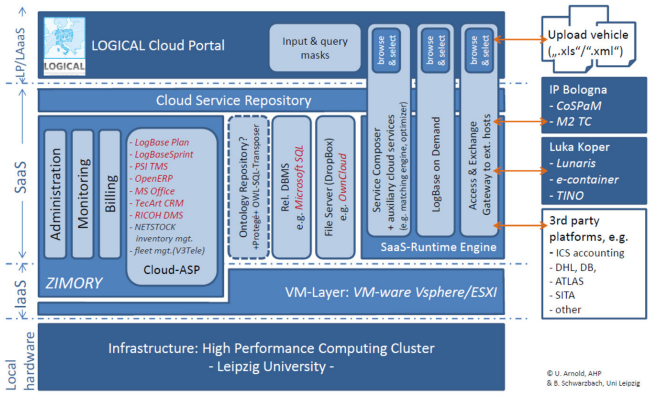

Fig. 2. LOGICAL cloud architecture, technical view

providers. Business administration of these organizations will need additional support like the technical support services of planning, optimizing and controlling the service chains as indicated before.

Thus, the management platform needs to be established with business administration services for the management of "virtual organizations". Like for a single company, the platform will have to provide access and configuration functions in order to apply the IT services of use case 1 to the virtual organization representing the cooperation consortium.

III. LOGICAL Architecture

The following sections describe the technical components and so far selected software products of LOGICAL cloud architecture at current development status in Leipzig.

Fig. 2 displays the technical view of the LOGICAL cloud as presented recently. This architecture consists of the Hardware layer and different software layers:

- IaaS-layer (Infrastructure as a Service),
- SaaS-layer (Software as a Service), with specialisation to logistics software, called "logistics applications as a service" (LAaaS)
- and BPaaS-layer (Busines Process as a Service) with specialisation to logistics processes in sense of "logistics processes as a service" (LPaaS)

So far the applications mentioned in chapter II-B1 are planned to be provided by means of ASP.

The cloud service repository (software catalog) will be used to store, administrate, select and manage the SaaS-offers of the system. The service repository needs to be developed yet. Apart from the software the repository will contain addressing data for the selection and activation of single SaaS applications.

The logistics cloud as outlined in the use case section will need additional SaaS applications to reach full functionality. Eventually required and yet to be specified or developed applications are for instance a search engine, a (fuzzy) matching engine, supply chain simulation tools, transport optimization tools, service composition tools to build complex supply chains, software services for the management of virtual organizations and interfaces to external exchange gateway services.

Logistics applications and logistics processes are specified, addressed, and activated by the cloud user on the top layer of the cloud architecture. The cloud portal serves as entry gate, orientation, service browsing, service selection and control instrument.

The LAaaS-layer and LPaaS-layer consists of the logistics-specific embedded applications and IT-services. In cases of existing web-based user-interfaces of single embedded applications and SaaS applications, these pages very likely need modifications for the integration into the cloud environment, e.g. in order to go back to the preceding cloud portal pages and to link with cloud workspace and composition service components. For the externally hosted platforms which are to be linked with the LOGICAL cloud via data exchange gateway, suitable cross-addressing and linkage tools need to be developed and implemented. The user interface is developed using ASP.NET.

IV. IMPLEMENTATION STATUS

The implementation of the LOGICAL cloud architecture startet in 2012. The implementation is separated into four main implementation project: data management, end user portal, administative portal and service management including user identification.

This section gives an overview of the current state of each of the four subprojects.

A. Model-view-controller

The whole LOGICAL project architecture is following the model-view-controller (MVC)-software architecture pattern that separates data (model), functionality (controller) and end user frontend (view). This approach increases modularity and code reusability. [16]

A model is a POCO (Plain Old CLR Object [17]) that is used to describe the data that is representing a domain specific entity that carries no business logic.

The visual representation of a model is provided by a view that contains information on how the data of the model need to be arranged. Different visual representations, e.g. a print and an onscreen version of the same entity, are generated by multiple views for the same model.

Each view has a corresponding controller that comprises all the functional logic needed by the view, i.e. there is one public method for every single action of the view.

B. Data management

The basis of the cloud is data. There are different kinds of data like data of the cloud users, data of the user's companies and data about alle the services provided by the user's. These data are provided by the data management subproject. It consists of a model of approximately 80 classes, two views for every model and for every view one controller. The first view is the end user's interface to create and edit his data entries into the LOGICAL database.

The more important view in terms of clouding is the API-view of the data. There is one REST-API-view for every model class that provides the methods to access the cloud data by other services inside and outside the cloud. This access is secured by the use of Oauth2.0. This ensures that only authorized services can access this API. The Oauth2.0-server forwards the login information to the OpenId 2 based user identification system.

If there are changes to the model, the adoption of those changes will be done to keep the full coverage of the API

C. Service management and user identification

The user identification is based on OpenId 2 [18] that provides a method to identify a end user without requiring the relying party, i.e. the cloud service, to request the end user's credentials, e.g. username and password. OpenID 2 is using a decentralized system consisting of an OpenID provider and multiple relying parties. The implementation of the OpenID 2 authentication system of the LOGICAL cloud is completed and fully functional.

The same subproject of the logical cloud is responsible for managing all the different available services. Service Providers need to specify some information about their services, i.e. name, description, URL to the logo and a class in a DLL offering state dependent information of the service. This class offers methods for:

- Pricing information returns a string that is shown to the end user to show the current pricing model of the service.
- Service state returns a value out of usable, notbooked, stopped, processing and usable that is representing the current state of the service for a particular user.
- Actions available to the end user that basically are a URL the end user is directed to and a name of the action.

This DLL is dynamically loaded into the service management engine. Since there are a multitude of possible services a webservice for all of this information would not be feasible in terms of timing.

D. Administrative portal

The third subproject is the administrative portal that provides services to the LOGICAL cloud provider to keep the cloud operating. Some of these services are:

- User management: Provides functionality to manage end users of the cloud, especially activation and suspension of an end user.
- Accounting: Provides functionality to charge the end users for their service consumption and to support the cloud service provider by monitoring payments.
- Exception handling: Provides functionality to recover misfuntional services, e.g. reset virtual machines, recovery of wrong data.

E. End user portal

The LOGICAL cloud end user portal is the entry point for end users. It provides information on all the different services that are available via the cloud. The services are assigned to different categories the end users can choose from. After selecting a category the end user receives a list that shows all the information necessary to decide which service is the best fitting for the user and offers the actions defined by the service management layer.

F. Summary

The implementation of the LOGICAL cloud architecture is almost finished. The only major part left is the accounting system which will be implemented in the next months.

Another task for the next months is to identify services that will bring a great benefit to the end users and to incooperate them into the cloud. Since there are always new services this will be an ongoing, task for the whole lifetime of the cloud.

V. SEMI-AUTOMATED INTERFACE CREATION

Compatibility of data structures and interoperability of SaaS components resp. IT-systems of collaborating partners still are prerequisites for achieving the targeted main benefit of the LOGICAL cloud: easy collaboration among different partners along heterogeneous fragmented supply chains. The survey carried out in the initial phase of the LOGICAL project revealed that more than 50% of the existing inhouse-interfaces of software applied by the interviewed LSPs are not at all functioning or insufficient.

Thus, in the beginning of the development a standardized data model concept based upon uniform ontology (InterLog-Grid ontology in OWL, transferred into SQL by means of a specific converter) was selected as a solution to the task of creating IT-interoperability. Workshops and discussions with representatives of the final user group, however, indicated that there is considerable reluctance among practitioners to adopt a standard ontology and to adapt the data models of existent data bases and proprietary software. Therefore, from a practical point of view for intermediate cloud operation an indirect path of linking existing documents and IT-systems with differing data formats and data structures was chosen: like in the Common Framework[4] customized "connectors" (here "upload vehicles", see fig. 2) are introduced for data im- and export.

Now the creation of customized "connectors" turned out to be a new bottleneck of system usability. Assuming an unlimited number of possible source-target-couples of data formats and underlying data models to be mapped, the idea of developing a sufficient repository of preconfigured "connectors" rapidly exceeds feasibility constraints. Thus, in cooperation with Leipzig-Halle cluster-member RICOH, a method of semi-automated creation of data interfaces (connectors) was developed and applied to the problem of mapping differently formatted freight documents (waybills) into each other. With respect to the as-is-situation in the field, the operative cloud concept deliberately refrains from requiring successful establishment of single-window/single-document standards as a mandatory condition. Instead, the system provides a separate tool for the on-demand creation of "connectors" (mapping procedures) which are associated to a specific pair of data

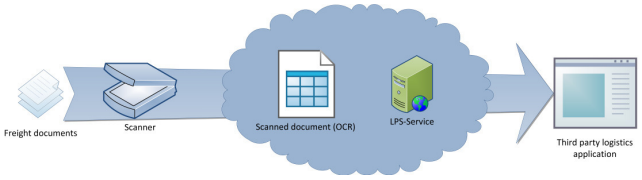

Fig. 3. Workflow of semi-automated interface creation

formats and stored in a mapping repository. Thus, the system is gradually learning during the course of being used and gradually increasing the number of already covered mapping tasks (data/document-format pairings). Once a mapping task occurs which already was tackled before, the mapping procedure does not have to be redeveloped again. Instead a pattern recognition service provides the matching mapping procedure which is applied.

Fig. 3 shows the main parts of the workflow of the semi-automated interface creation use case. Most of documents that need to be processed are paper based, therefore they need to be scanned prior they can be worked on by the software service. The scanning process can be done by existing scanners or a rented scanner that is preconfigured for sending scanned documents directly to the cloud.

Documents that are digitized will be processed directly by the cloud service. To upload such documents, and documents scanned with existing scanners as well, to the cloud a web service with a web interface is provided, that takes files of different formats, e.g. pdf, jpeg and tiff.

After the documents are stored in the cloud they are analyzed by a pattern regocnition service to determine the type of the documents. If the type of the document is known and a mapping is available in the repository the mapping of the data of the document to the LOGICAL database is done by the LPS-service.

Otherwise, a new mapping procedure is created by means of manul linkage of data fields of the original document and the entry mask of the LOGICAL data base. This procedure is supported by the interactive graphics linking features of the LSP and stored as a new mapping procedure in the mapping-repository.

The user of this service can configure a set of third party systems for every document type where these documents should be forwarded to. This process step is done by a Extract, Transform, Load job that extracts the data from the LOGICAL database and loads them to the third party software. If the ETL job requires some data that are not available due to problems with quality (paper based documents and OCR) or input field left blank in the original document, the problem is reported to the user and the user can choose whether to add the missing data or to delete the document.

If the user is operating a third pary software that is not known by the cloud, the user can request a ETL-job for his software. This new job will be available to all cloud users, once it is created.

VI. Conclusion

Cloud computing, with it's service on demand philosophy, enables even small logistics service providers to cooperate with each other. The challenges for the logistics service providers are even more complex if they want to cooperate transnational. The paper has shown the use cases of the LOGICAL cloud in general and detail, that have been developed to enable transnational cooperation. One of these use cases is the semi-automated interface creation that helps logistics service providers with converting documents of one type into another without the need of a comprehensive ontology. The whole set of use cases that are covered by the LOGICAL cloud are resulting in a multitude of new possibilities for logistics service providers to create new added value services with international partners and to be one step ahead compared to the competition.

***Abstract*—This paper presents a model of a navigation system in a public information system, that can be used to improve the structure and content of the information repository via self-organization capabilities based on social interaction. This model has the primary goal of establishing a generic and adaptive social-based self-structuring navigation system. To achieve this goal, the model integrates the concepts of social navigation, interaction and self-adaptivity in a feedback control loop. The model gives focus on self-adaptivity and includes elements of social navigation in all parts of the system which enables the implementations based on this model to get social adaptability based on user actions individually, but also as a social environment, in every possible aspect of the functioning of the system. The introduced feedback control loop gives possibility for further autonomous improvements of the organization of the information.**

I. Introduction

THIS paper proposes a model of a navigation system in a information system, that can be used in public knowledge-bases, information portals, news sites, self-support sites, online directories, etc. The model builds towards the enabling of improvement of the structure and content of the repository. We integrate the concepts of social navigation, interaction and self-adaptivity to enable semi autonomous restructuring of the repository.

The original idea was to have as generic approach as possible in order to model a system usable in a wide domain of applications, so some of the concepts are explored from the roots in the past. The concept of social navigation is used as discussed by Dourish and Chalmers in [1], and the generic model is based on the idea of recording interaction on the path that each visitor (navigator) takes, as discussed by Forsberg [2].

There are two main groups of functionalities that are expected from the new navigation system model:

- social interaction should be recorded at all points in the system, either between the system and the visitor or among visitors that are (concurrent or not) visiting the same place of interest in the system – sharing, pointing, recommending and monitoring the published resources and paths through them.
- social interaction history should be used to improve the organization of the navigation and the structure of content – autonomous self-change of the navigation elements should be possible.

In order to include such functionalities, the model first provides the ability to change all navigation point and paths, the whole structure, and then enables social interaction that is associated to the relevant versions of the elements, current to the moment that the interaction has happened. In addition to that, the model enables controlled self-adaptivity, according to results of performed analysis based on social interaction history.

The first step in building this model is the separation of the navigation structure from the content by using a separate navigation sub-system. This sub-system should use a structure that defines (on a conceptual level) and lists (on a logical level) all basic navigational elements that are interesting from a social point of view, and should also include a structure that performs the mapping of logical elements URLs on a physical level. This separation would allow independence of the physical level, which means that changes of the URLs of resources will not have impact on the logical structure and social navigation visible to users. Then, independence on the logical level is introduced, allowing the addition of new elements of social navigation or modification of existing elements, without any change to the physical level.

These are important points for the realization of the structural adaptivity of the system because the constant change of the navigation elements can be the enemy of social navigation (in terms of sharing changed URL, broken paths etc..) For the same reasons, the navigational structure must allow the storage of the entire history of changes (versions of navigation elements) and to handle the shifting of resources in a controlled way that will not disrupt the navigation.

The basic elements of the generic model developed for the case of a web-based public information system are discussed in the following sections.

II. Navigation Elements

The model is organized in levels. At a conceptual level, we identify the following basic types of social navigation elements (with possible extensions of this list), allowing compositions in more complex structures:

- An atomic resource is the basic building element (e.g. a specific resource of this type is: ”Description of the Databases course in the CS study program”, and it can also be an external resource).

978-83-60810-53-8/$25.00

- Atomic resources can not exist by themselves, they only exist as a part of resource-sets, which in turn can be:
  - unordered set of logical resources (example: ”Guidelines of undergraduate studies at FINKI” or ”Course materials for learning Databases”), where the logical resources can be either other sets or atomic elements;
  - ordered set of resources or a directed path (example: ”Installation Guide of an Oracle DBMS”), and again, the resource are other sets or atomic elements. The order of the elements is specified manually by the administrator.

At the logical level, the navigational structure of the overall system is built, individual resource sets and their connections are enumerated, and so for each type. For example, the resource ”Guidelines of undergraduate studies at FINKI” contains ”Description of the CS study program” and ”Description of the IT study program”. At the physical level, a mapping between atomic resources and physical resources or addresses, is performed. As an example, the logical resource ”Description of the CS study program” is mapped to the URL ”http://www.finki.ukim.mk/mk/studies/KNI”.

Figure 1 shows the model of the navigation structure. The class NavigationElement represents all of the navigational elements that define the logical conceptual level. The type of each element is indicated by the attributes isAtomic and isOrdered. The NavigationElementLink class defines logical links between navigation elements. The Resource class provides the physical mapping of various navigational elements to specific addresses (URL) in the WWW space. Thus, a general graph of all navigation elements and their links is formed. So, this structure can be used to model any web-site or parts of it, or even a ”forest” of web-sites.

III. Supporting Self-structuring in the Model

The presented basic conceptual model is then extended to allow self-structuring. For this purpose, two features of the system are required: changeability of the structure and resources. This means that one can change the ordering of resources, or even types of resources with other types, change links between resources (replacing one form to another, adding and deleting logical resources). Also, one should be allowed to change the content of the atomic resources (replacing the mapped physical address to another). Adding an atomic resource (a set of single element) to another atomic resource can produce either an ordered or unordered set, and this is left as a choice for the administrator.

A. Changeability of the Content and Resources

By changeability of resources we actually mean replacing the physical level. The intention is to only change the mappings of logical resources to physical addresses. Also the history of all changes to the mappings should be kept in order to enable later analysis of the behaviour of the users related to each change and pin-point the appropriate version of a resource that is of interest.

The model further elaborates version keeping. In the second row of classes in Figure 1 the versions of the elements and all changes to the physical level are presented. The mapping of physical resources is such that a navigational element is not directly associated with a single physical resource, but in fact a new version of the navigation element is created for any change in the physical mapping. Each change creates a new version object, which records that the version is associated with a change of some resource to a new address. The date of the change is also kept.

In this way, the version entries of each mapping can introduce new versions of the same physical resource – on another date, which would indicate that the navigation element references the same source, again and again, but on different dates. This can interpreted as if the content of the source is changed from time to time, at the version dates, but the URL is still the same. The idea is to have a way to address changes of the content in the model. Also, a completely new version can be created for a new physical resource with a new address. The current version is considered the one with the latest timestamp. The model allows precise monitoring of the changes of the mapping of navigation elements to physical resources, over time.

B. Changeability of the Navigation Structure

The structure of the navigation system can be changed by modifications of the set of navigation links. But, in order to effectively monitor the changes of the structure and the continuity of social navigation – i.e. enabling continuous monitoring of which were original interests of users and where they have migrated after a change, this model only allow for elementary changes and not fundamental change-set where all traces of the past would be gone. The idea is to maintain traceability of each change of the structure.

Only several basic operations are allowed that are implemented in a way that allows monitoring of changes:

- change the type of a logical resource;
- adding new resources to a logical set;
- removing resource from a logical set;
- moving a resource from one to another set.

Considering the way how the logical resources are implemented in the data model using navigational elements – then the allowed set of change operations can in fact completely rearrange navigation structure in any form, when performed as a composition. So in fact any modification can be made but it must be performed gradually, in order to keep proper records of associations of the navigation elements and their version with the social interactions.

1) Changing the type of a resource: Changing a navigation element with another kind is permitted for ordered and unordered sets. As an example, instead of an unordered set of resources, we can decide to have a directed path through the same set of resources or vice versa.

This change is easy to implement over the existing class versions of navigation elements (see Figure 1), with the added ability to record whether a new version includes change of

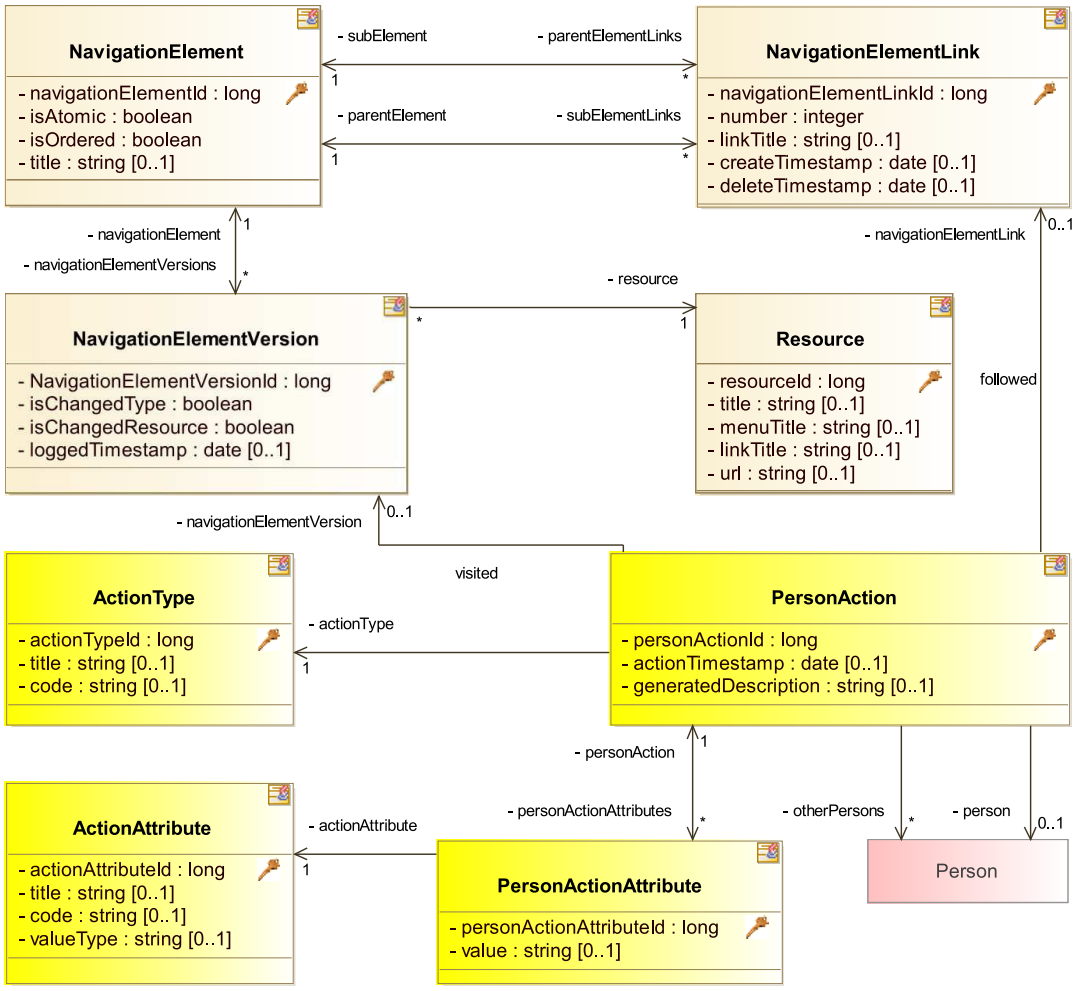

Fig. 1. Data Model of Social Navigation Features.

type. At the same moment, a change of the resource can also be indicated. It is done in this way because it can often be required to reference a new page for the new type and it would be unnatural if even for a small amount of time, first a change of type is visible, and immediately after a change to the mapping to a new content. A change of the element type that does not require a change to the physical resource will be created as a new version and relevant attributes will be denoted, but this new version will still reference the (old) resource. This is done in order to obtain better performance, since search operations are many times more frequent than structural changes.

As discussed at the beginning, an atomic resource itself does not exist, it is always part of a set – in the simplest case it is a set with only one element. For these reasons, a separate consideration of the operation of change of an atomic logical resource into a set, and vice versa, is not necessary. Specific for this case is that what a set has only one element it does not matter if it is ordered or unordered, so the isOrdered attribute is not relevant. So, in this situation the first operation is to replace the type if necessary, and then add new elements or new links where needed and in the required order (especially in the case that the order is important).

2) Adding a logical resource to a set: This operation is realized by creating a new navigation element (if it is a new resource) and then adding a link of the element to the set.

Each link keeps record of the date of creation, which allows one to find out which links were available in a certain period of time.

Note: If the set was made up of only one element, that is atomic, the type of set (isOrdered) has no meaning. So it is ambiguous what will happen once a new element is added. Therefore in this case the administrator must first decide on the new type of the set, perform the change of type operation and only then to execute the operation to add new element.

3) Removal of a logical resource: This operation is realized by setting the value of the attribute deleteTimeStamp in the link that connects the element (child item) to the resource set (parent item). Thus historical data needed for decision making and analytics will not be lost, and navigational elements themselves will continue to exist in the system in case a

new reference to them is needed in another place of the navigation structure. Elements that are not longer connected to other elements, are considered orphan elements and can be monitored in case they are needed again in the future.

Note: The re-inclusion of a navigational element that has already been connected in the past, does not change anything in the historical records, but simply creates a new link by performing the operation of adding an existing resource set.

4) Moving a resource from one to another set: This operation is the same as the composition of two operations: remove a resource from the old location set, and add the existing resource to the new location set.

IV. Social Navigation Support in the Model

Social navigation is always the result of interactions of various entities within the system. In order to enable basic support for social navigation throughout the whole of the navigation system, it is required to keep records of all interactions that have occurred, for each interaction type, with each type of navigational element, and to keep additional parameters for each interaction that occurred. This should be kept as a record in time, associated to the current version of the navigation structure. This means that interaction (viewed, read, accessed) should be recorded for the current version of a navigation element and for the link between elements that was interacted with (followed, clicked, etc.).

These requirements are realized through an extension of the previous model, presented in Figure 1. All types of actions that a person can make (indicated by the Person class) are codified according ActionType and are kept in a log of taken actions (class PersonAction), sorted by the action time stamp.

The actions that have a special meaning and are specially recorded in the journal are:

- interaction with other visitors (list of persons to whom the communication is directed);
- interaction with a navigational element (actual version of the element);
- interaction with a navigational link between two elements.

We have defined that some attributes can be of interest to monitor in association to the actions of the visitors. Such attributes and their values can be recorded. Even more, there is no strict list of attributes to be recorded by activity type, but this is left free depending on the requirements of the implementation.

The Person class is not specified in detail, but should be further elaborated in the implementation of the model according to the requirements and can be used from another system. In the case of public information systems where the majority of visitors are people who are not familiar, there are two options for addressing these visits:

- anonymous option – to use only one anonymous object: Person, toward which all actions are recorded;
- weak authentication – for Each new visitor the system creates a new object of the class Person unless there are kept data from a previous visit, such as data kept in cookies or some other technique to determine that a visitor is actually returning to the system. In such case the new actions are added to towards the found previous instance of the Person class.

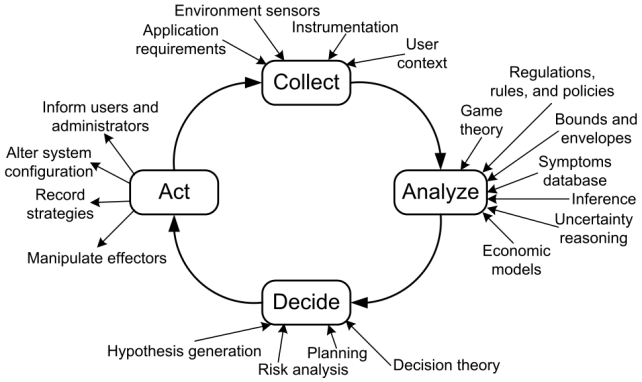

Fig. 2. Feedback control loop[4].

V. Self-adaptivity

The previous discussion identified many elements that allow a constantly changing navigational structure of the system, so it is necessary to monitor all the changes that have occurred and this is necessary for various reasons, the most important being quality control and the ability of the system to constantly adapt to the new needs.

The analysis of the literature in the field of software engineering self-adaptive systems showed different aspects that need to be addressed in such systems, most of which were not relevant for the purposes of social navigation. The most appropriate of all is the model shown in Figure 2, which represents a feedback control loop in a self-adaptive system [3]. This model was originally designed for implementation in terms of communication systems, but can be applied in terms of software engineering self-adaptive software systems [4]. The phases of this cyclic pattern are discussed in the following paragraphs and later the introduction of a control mechanism of that kind is proposed discussed in the generalized model of the navigation system.

In fact this model of a self-adaptive control can be seemed as an appropriate match to the navigation model proposed by Spence [5] (see Figure 3) and the amendments discussed by Riedl [6] for social navigation.

Table I shows the alignment of the concepts of both models. It becomes obvious that one can establish a relation between the two discussed models. The new model uses a feedback control loop to enable self-adaptivity for social navigation in the system.

In fact these are basically two different concepts, one explains the cognitive process of navigation from the perspective of the visitor, and the other describes the process of controlling the operation of a software system that changes its parameters. The idea of linking the two concepts lies in the need of the

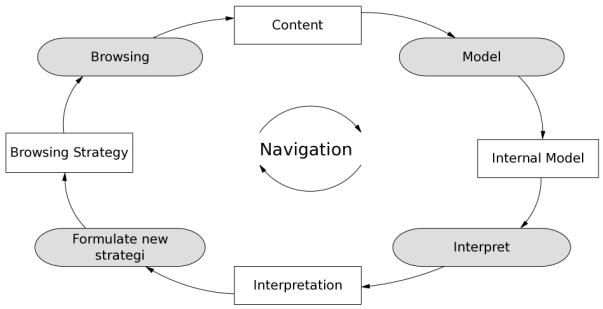

Fig. 3. Navigation Model by Spence[5].

TABLE I
CYCLES OF SOCIAL NAVIGATION AND SELF-ADAPTIVITY.

Social Navigation	Self-adaptivity
review	collecting
modelling	analysis
interpreting	deciding
formulating strategy	action

self-adaptive feedback control loop cycle in order to improve social navigation over the entire set of visitors, but without making direct identification and synchronization of the two processes. The overlap of these two cycles must be understood through an analogy – the mutual coupling of two orthogonally placed gears with varying cogs – the mechanism of social navigation makes many rotations, while the mechanism of self-adaptivity makes one rotation. Through a cycle of the self-adaptive control loop, a number of visitors pass and their (inter)actions are reviewed. The mapping of the cycles in this context would mean:

- viewing information through the system by users generates a multitude of navigational data that some may characterize the overall behaviour of the system, that one needs to collect and analyse;
- symptoms defined by the self-adaptive cycle should apply especially to the navigation system, as they can affect the formation of wrong cognitive model of the visitor or misinterpretation that could lead the visitor leaving the site;
- visitors form their own cognitive model of the system based on how the system is shown and based on personal experience, which can not be directly affected – especially immediately for each user, but one can perform analysis of the behaviour of users, so that in a next cycle assumptions are made about how the visitors perceive the system and what could be changed to improve the navigation
- the interpretation and final formulation of a new strategy for the next search can be influenced by appropriate and timely decisions and actions on behalf of the system, even at low levels - without a major reorganization and just setting some social indicators on well-defended positions, the key in determining whether such interventions help with the navigation process is monitoring the changes made by subsequent self-adaptive cycles in the navigation of the users – what has happened before and after structure changes.

All these features are implementation dependent and are not feasible to be realized in a generic model Therefore it is proposed to plan, define, analyse, design and implement the process of implementation of this generic model with specific issues, depending on the requirements and expectations. What can be generalized is mere conduct the required cycles and their mapping into a generic data model, which will provide the necessary analysis regardless of the implementation at hand. This model is presented in the following text.

A. Structure for Monitoring Control Cycles

Because in social navigation systems it is necessary to monitor all activities of visitors and their usage of resource, in order to establishing rules of behaviour of users and help future visitors, and in addition to that the application system needs to have a certain measure of self-adaptivity – which means that that the system has to adapt itself, and not only at the request and parametrization of visitors, there it is necessary to collect enough data for full system operation and association of these two conceptual models. This requires a detailed data model with the following features:

- tracking all actions that occur in a cycle of the self-adaptive control loop;
- tracking the evolution of all system and process parameters across all cycles of the system.

A basic data model is proposed first, for the control cycle and it is shown in Figure 4. This model enable the monitoring of the system through all the cycles. After that this model is linked to the data model for social navigation.

The part of the model that presents the feedback control loop, records are kept on:

- Sets of defined values of the measured systemic and procedural parameters, normal range of values, increased boundaries and critical limits – in order to analyse the status of processes and objects in the system and
- Journal of measured values of parameters, identified symptoms, made decisions and actions that were taken.

The journal is particularly important element because it tracks the success of the control cycle and can be used to find out if the correct symptom was identified, whether requested action at a time was the one really needed, the results can be seen and the history of decisions checked and to conclusions drawn on the correctness of the decision. Of course, some testing would be done manually by the analytical team and some analysis should be programmed for automated monitoring to work.

The phases of the cycle contain elements which seem directly and solely related and ask why it is necessary separation in four phases. The answer is that this form increases modularity – the system is flexible in terms of combining elements. As an example – setting different symptoms for

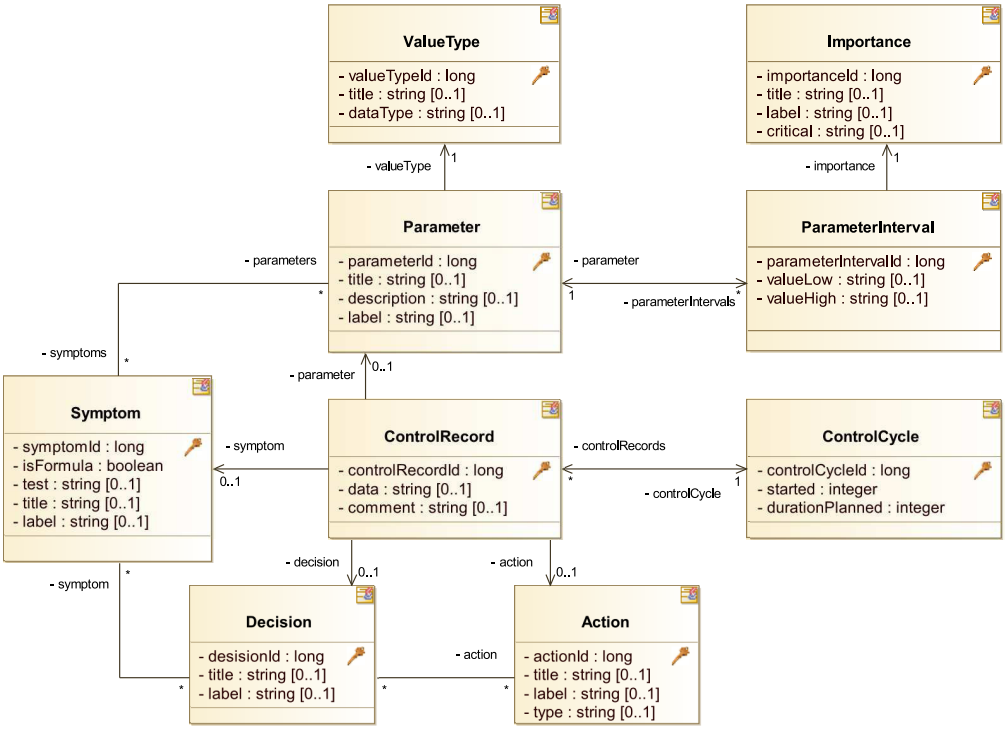

Fig. 4. Data model of the control loop.

the same parameter is allowed, depending on the general context, combination of parameters per symptom, combination of decisions per symptom and combination of actions per decision.

VI. Integration of the Two Models

In order to follow the partial change of the structure of the system and the impact on the behaviour of users, and the impact of changes over the general parameters of the system and boundaries that are allowed, a the system records the changes that have occurred in each self-adaptive cycle.

The model that describes these changes is shown in Figure 5. It should be noted that all associations are optional, which means that the model allows for the incoherent behaviour of the two segments and selecting those components that are required depending on the requirements of the implementation. The RecordedAction class is used to store the information that a certain PersonAction took place within a ControlCycle and is associated with a ControlRecord. Similar to that, the class RecordedModification is used to store the fact that a modification of the structure of content took place and is related to the ControlRecord.

VII. Implementation of the Integrated Model

The steps to implement this generalized model in a production system include final consideration of the requirements of the target system, the amendment of the structures necessary attributes - especially time stamps, recording the users who make administrative changes in the structure and the like.

If the system evolves from the beginning, it is recommended to use this model in all stages as an initial model for defining and navigating through the system.

If the system is implemented as a social and self-adaptive update over the existing system, then you should consider the question of the willingness of the existing system to replace the functionality associated with navigation. If this is not possible, the only solution is the implementation of the navigation model as a separate navigation system, and then mapping and forwarding copies of the shares of users from one system to the other in order to sync the content.

This integrated model can be applied in many different areas, but primarily set in information systems aimed at presenting knowledge and processes related to the management of knowledge and example implementations can be:

- Information portals
- Directories and databases of knowledge systems using
- E-learning
- Social networks oriented learning

VIII. Prototype Implementation and Related Work

The presented model was used to implement a social-navigation based virtual academic adviser[7] that uses recommendations based on social interaction to guide students in the process of course selection, creation of personal study plan until the end of the studies on a longer time scale[8], but also as a self-adaptive control mechanism to create best possible class schedule in term of less conflicts between classes[9]. In

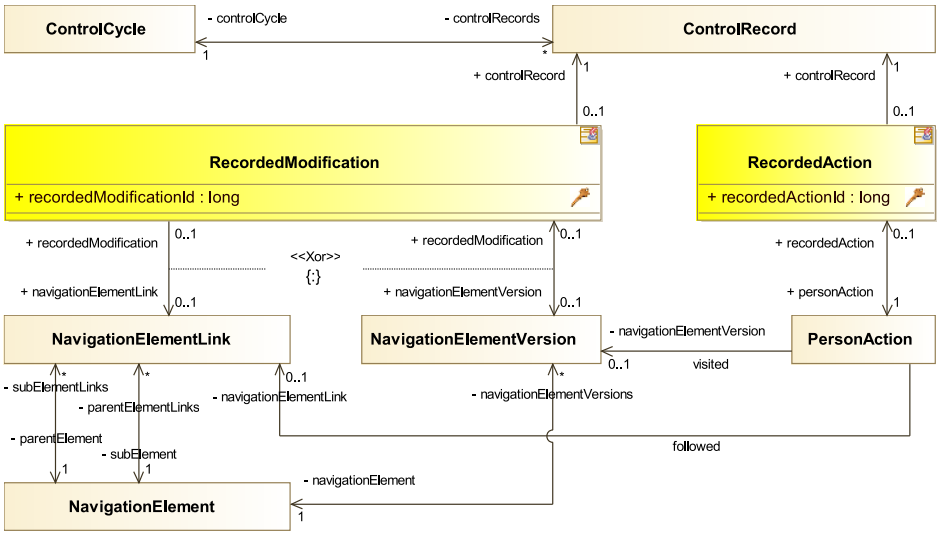

Fig. 5. Integration of the models of social navigation and self-adaptivity.

this implementation, the repository is the database of curricula and study plans for all study programs at a university level.

The virtual academic adviser component gives the student more personal guidance in the process of technical rearrangements of the personal study plan in order to experiment future scenarios with various choices before discussing the final scenario with the real adviser and submitting the application for term enrolment. The first version of the virtual academic adviser enabled the student to try a what if experiment with the various choices on offer such as number of credits per year, choose another study program and specialization profile, rearrange the order of enrolment of courses per future terms etc. After these experiments the student would decide on some preferred scenario and enrol the tern according to the profile and the official rules. In case there were any issues with some scenario, the student could discuss them with the real adviser. It should be noted that the role of the adviser is to give advice and not decide on behalf of the student, and once the choice is legitimate, the adviser can not prevent the student from enrolment, but can only suggest better options.

With the implementation of the new model, the second version of the virtual academic adviser is developed with two additional features: giving the students manual and automated course recommendations and introduction of a new integrated process for term enrolment, class scheduling and construction of timetables. Within this evolution mechanisms for mutual dynamic self-regulation of the processes of term enrolment and class scheduling are investigated. The latest virtual academic adviser is presented in Figure 6.

Each row represents a semester, and each box in the row is a course enrolled in that semester. The semesters are ordered in such a way that the last or active one is on the top, and downwards follow earlier enrollments. Each box shows: the name of the course, whether the lecturer has certified the student was present at majority of lecture hours and is allowed to take exams, the final grade of the student, how many ECTS credits is the course worth if successfully finished. The boxes are colour coded in order to be easily distinguished by the student:

- green boxes represent active courses in current semester
- orange boxes represent courses where the lectures have finished but the student did not have a chance to pass yet
- white boxes represent courses that the student passed
- red boxes represent courses that the student failed.

The system takes into account all interdependencies and course prerequisites and will propose a *realistic plan*. Whether this plan will succeed depends only on the ability of the student to follow and stay through exactly to the new plan and pass all the necessary courses. The system also visually indicates courses that are critical in the future courses where there was a significant amount of failing grades and where students had to re-enroll a course after failing.

The control loop was implemented as a component within the existing information system and used to orchestrate the process of enrollment, phase by phase, student by student or group by group whatever relevant. In the following few paragraphs the four steps of the control loop will are explained with all the included mechanisms.

In the Collect step, the system is monitored and information needed from the students and other system components will be gathered:

- critical time-slots that are almost full
- length of student waiting lists
- numbers of students per status of the enrolment
- numbers of students per year, per group, per status
- number of issues reported by students per category
- number of students without grades for past enrolments

In the Analyse step, the operational status of the system is analysed according to the gathered parameters, historical data and boundary values for several symptoms that are identified

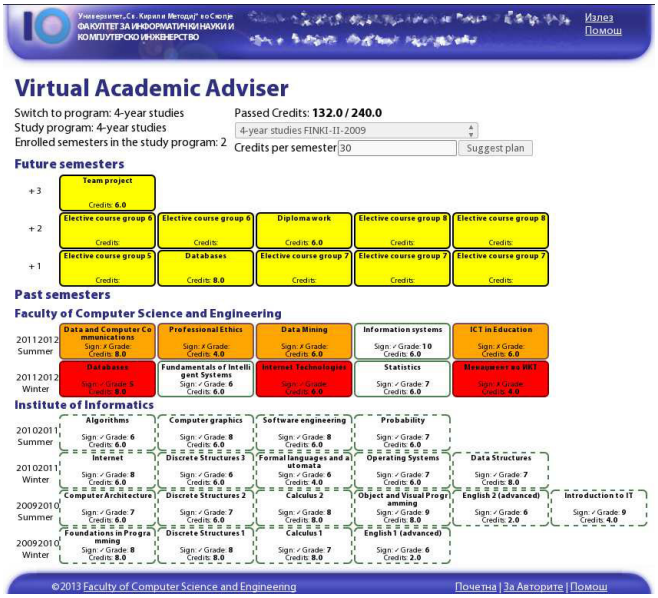

Fig. 6. Integration of the models of social navigation and self-adaptivity.

in the symptom database:

- new groups will be needed soon on a course
- new teachers will be needed soon on a course
- course resources are exhausted
- courses will not be activated due to lack of students
- students ask for courses that are not on offer
- student grades are not input on time
- increasing number of students have complaints

In the Decide step, the system makes decisions on the actions that are to be performed, depending on the severity of the symptomps encountered and how critical are the values of the monitored parameters. In this case mainly the decisions should be made on when and how to act:

- send only information and status via e-mails
- invoke critical alarms to administration staff
- boundary limits can be changed because number of students expected will not exceed significantly
- ask advice on action from administration staff

In the Act step, all actions are orchestrated based on the types of decisions that were made and which simptomps were triggered. The actions that are present are:

- status information is sent to all users
- administration staff is informed that there are issues at hand together with the symptom
- analysis, respective numbers and possible decisions for the decision database
- critical alarms are activated per symptom
- boundary limit are modified and the action is logged
- decisions are logged
- symptoms are logged
- measured parameter values are logged

In such process the course enrolment and time-table creation can be monitored, analysed and acted upon automatically or manually via the proposed control loop framework. In this case it can be argued that the process is successful if finishes on time before the official start of the semester. If that is not the case, the framework gives possibility to monitor the percentage of finished cases of student term and course enrolments and gradually increase the severity of symptoms and frequency of issued critical notifications to the administration staff and to students that have not been active.

IX. Conclusion

The presented model defines a system that is able to change its structure, with traceability of all the modifications of the structure. At the same time records are kept for the interaction of the visitors among themselves and with the system, in association with the exact moment and context regarding how the structure of the system has changed.

This gives possibility to introduce a self-adaptive feedback control loop, that the system will use to monitor itself, identify problems as symptoms and take actions in the form of slight modifications of the structure. The modification are performed in control loop cycles that gives the ability to monitor the causality of the change of behaviour of the visitors and link this change back to a modification in the system, and so investigate if the structural change was an improvement or failure. In such way, the system can undo its steps and take counter measures of bad decisions.

Concept of Platform for Hybrid Composition, Grounding and Execution of Web Services

Lev Belava
AGH University of Science and Technology, Mickiewicza 30, Cracow, Poland
Email: Lev.Belava@gmail.com

***Abstract*—This paper presents a concept of a software platform and a method of hybrid composition of web services and hybrid grounding of abstract composition plans. The paper also describes the architecture of the implemented platform and its modules.**

I. Introduction

RECENT scientific and industrial progress in the field of information technology clearly shows a tendency to switch data processing and computation from traditional models to network architectures. There is also another trend of switching over from large, complex monolithic software systems to groups of smaller, well-defined and interoperable applications. Due to this reason Service Oriented Architecture paradigm and its specific realization – Web Services – naturally fit these general trends. The practice of SOA services composition is a promising approach to developing new software systems with highly refined functionality that is achieved by using a combination of different services chosen from those available in a computer network. Very important parts of such software systems include service composition and grounding. Service composition focuses on creating complex plans from available services, while grounding is a process that transforms abstract composition plans into execution plans so that every abstract service used in an abstract composition plan is effectively associated with a real-world service instance and thus can be called during the execution process.

Hybrid service composition is a method that allows its users to combine different service composition techniques. It offers more flexibility and control of the composition process itself due to the ability to choose different composition techniques for different parts of the composed plan. Hybrid grounding is also a method that allows similar flexibility and control of a grounding process. It allows to mix and match different grounding techniques for different parts of an abstract composition plan.

A. Service Composition and Grounding in SOA

SOA is a software engineering paradigm which generally describes various aspects of software systems that utilize specific entities called services. On the other hand, SOA does not define services strictly – they just have to be relatively independent from each other and offer various functionalities. Such an engineering approach offers different advantages like easier integration of legacy software into new business processes, safer and more reliable upgrades of software components, etc. Web Services are possibly the most common SOA implementation nowadays.

Service composition is a concept of combining different services for data processing purposes. It enables engineers to create complex processes by combining various functionalities offered by available services. So far numerous service composition techniques have been developed.

Manual and semi-automatic service composition methods e.g. [1] and [2] are relatively popular in the scientific community. Such kinds of approaches are fairly easy to understand and implement. When creating service compositions all decisions are made by the user who is provided with some kind of advice or narrowing choice options at most. However, such methods do not offer service composition process automation.

Different automatic service composition approaches have been proposed. Variations of forward and backward chaining methods as in [3], [4], etc. were presented. Hierarchical Task Networks methods were proposed in such works as [5] and [6]. Ontological descriptions of services can be used by reasoners for composition creation [7]. Petri nets were used for service modeling and composition in [8].

Composition methods can, but do not have to, assume that service instances are available and reachable somewhere in a network. So, if a method is not concerned with the availability of service instances, it will produce abstract composition plans. On the other hand, grounding is a process of enriching composition plans with vital information that allows necessary service instances to be used during the execution process. Therefore, abstract composition plans have to be grounded prior to being ready for execution. Several service composition grounding methods have been proposed, some of them are based on brokers [9] while some others are matching-based [10], heuristic [11], agent-based [12] or even ontology-based [13] and [14]. Each one of these approaches uses different perspectives on the grounding process thus allowing their users to fit their needs in a very varied and not always interoperable ways.

B. Problem Statement

There are numerous methods for creating and grounding service compositions. However, every particular approach cannot be an ideal solution from all points of view. Imagine a situation when a user of an SOA software system wants to use some predefined service composition parts and combine

978-83-60810-53-8/$25.00

them with an output of an automatic composition method. The concept of hybrid service composition was specifically proposed in order to solve such kind of problems [15]. This concept allows to use multiple service composition methods during the creation of a service composition plan.

A similar problem is observed in the grounding of abstract composition plans because grounding methods may vary a lot in terms of their work principles as well as optimization targets (QoS, cost, etc.). The concept of hybrid grounding tries to address this problem by utilizing different grounding methods during the grounding of one particular abstract service composition plan.

So far, several service composition platforms have been presented in scientific literature. The most important ones include SWORD [16], METEOR-S [17], MAESTRO [18], SPICE [19]. However, none of them tries to solve the problem of more flexible composition or picking and using a grounding method. SWORD uses first order logic, METEOR-S adopts the Constraint Satisfaction Problem engine for producing a composition, MAESTRO is based on a particular graph method with backward chaining and SPICE uses backward chaining with branching for optimization purposes.

A variety of concepts and methods for service composition and grounding methods, platforms and approaches has been proposed. However, none of them is perfect from every point of view, e.g. such perspectives as composition plan languages or optimization targets for grounding. In order to solve this issue a concept of a hybrid composition, grounding and execution platform was developed. It adopts approaches that enable users to have more flexibility during composition and grounding processes by allowing to use different composition and grounding methods together.

II. Proposed Platform Concept

The architecture of the hybrid composition, grounding and execution platform consists of five key modules that are cooperating together. The concept also incorporates external elements – web services. These services are used by various modules to produce and execute composition plans. Fig. 1 shows the architecture of platform and data flows between different modules.

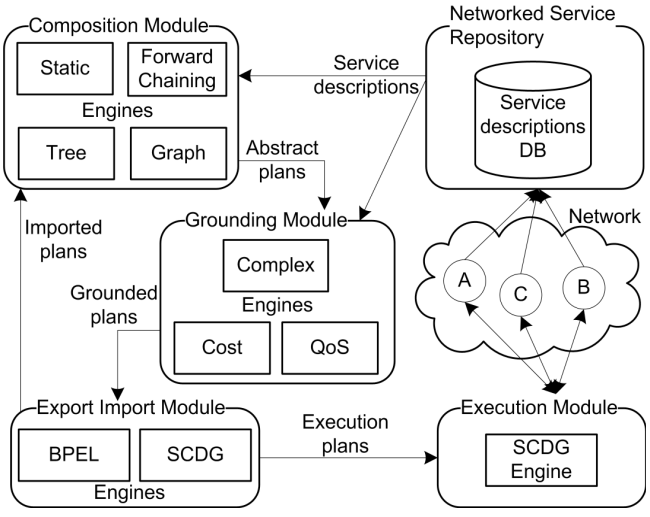

Fig 1. Architecture of Hybrid Composition, Grounding and Execution Platform

The Composition Module is a platform component that actually performs all hybrid service composition tasks and produces abstract composition plans. This module interacts closely with the Networked Service Repository from which it gets web service descriptions. Moreover, it might use the Export Import Module from which it obtains plans for the static composition engine. Abstract composition plans that are produced by this module are forwarded to the Grounding Module for further processing. The module consists of four different service composition engines which can work together to produce composition plans.

The static service composition engine provides necessary functionality to combine different pieces of the composition plan that can be imported or generated by other composition engines. The static engine uses two main operations to work on composition plans: DELETE and INSERT. The "Delete" operation cuts out a specified part of a plan and "Insert" pastes one plan into another. The INSERT (1, 2, plan1, plan2, 4) operation scheme is presented on Fig. 2. Plan1 and plan2 represent two input plans for the operation. Plan3 is the result of inserting plan2 from the first non-root node to "Service 4" node into plan1 between "Service1" and "Ser-

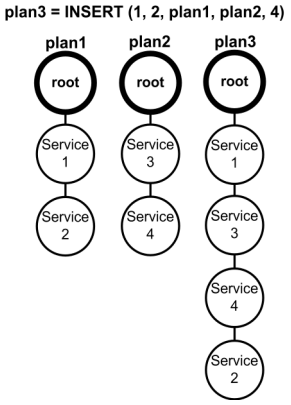

Fig 2. INSERT operation scheme

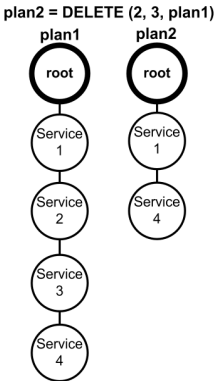

Fig 3. DELETE operation scheme

vice 2" nodes. The DELETE (2, 3, plan1) operation scheme is presented on Fig. 3. Plan2 is the result of cutting a chain of services from plan1 starting at "Service 2" and finishing at "Service 3".

To proceed further we need to provide a definition for a service input and output type. Input or output service types in the proposed approach consist of two parts: the first – a formal description of the data format that the service accepts as input or returns as output, the second – semantic information that describes the meaning of that data.

A forward chaining service composition engine creates service composition plans by using a simple chaining algorithm similar to the one proposed in [4]. Its simplified scheme of action is to successively add new elements to the end of the plan if their input types are consistent with the previous element's output type. The general idea is to create such a chain of elements that its last element will have the desired output type.

A tree-based service composition engine creates service compositions by using a method that creates not just a chain of elements, but a tree. This method is relatively similar to forward chaining but it allows to search the produced trees and because of that the results of its work are more optimal than the results of simple chaining techniques.

A graph-based service composition engine uses a composition method that is similar to the one proposed in [20]. Basically, at the beginning the composition algorithm produces a complete services dependency graph. This directed graph is created by treating abstract services as nodes in a graph and then connecting the nodes with directed arcs if one service's output type is identical to other service's input type. Then such a graph could be processed by Dijkstra or some other pathfinding algorithms. Fig. 4 presents a sample complete services dependency graph. Each node in that graph is described by its input type ("IN") and output type ("OUT").

The Grounding Module allows abstract composition plans, that were produced by the composition module, to be grounded. It cooperates closely with the services repository from which it gets full information profiles about service instances that are available on the network. Such a profile consists not only of the service address and input/output types but also includes additional parameters such as QoS and cost. The three grounding engines in the Grounding Module include QoS, cost and complex. QoS and cost grounding methods were chosen as sample approaches that can be successfully combined in a complex engine. There is a possibility to use and combine other grounding methods as well.

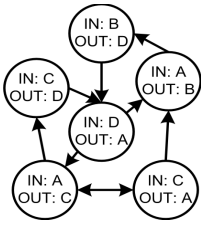

Fig 4. Example of a complete service dependency graph

The goal of the QoS optimization engine is optimizing QoS parameters of composition plans or their parts. For example, one can request that QoS parameters for some part of the abstract composition plan have to reside between some desired maximum and minimum values. In such case the QoS engine will look for service instances that fit the provided values best.

The cost optimization engine works similarly to the QoS engine, but it has a task to optimize the cost of composition plans or their respective parts.

The complex optimization engine allows to create a hierarchical structure of grounding preferences which let the user apply additional optimizations in cases where the engine on a higher level of hierarchy will find several equally fitted service instances. For example, we can imagine a situation in which the cost parameter is the most important target of the composition optimization, but we would like to choose a service with the best QoS in case there are several service candidates with the same cost value.

The Export Import Module provides functionality that allows the abstract and grounded composition plan to be imported or exported from or to files. There are two export-import engines that were implemented for the proposed platform – BPEL and SCDG.

The BPEL engine is able to import [22] and export [21] composition plans that are written in a BPEL language. Not all the BPEL functionality is currently implemented, but core elements like conditionals, loops and the parallel execution of services are fully supported.

The SCDG engine allows to work with composition plans that are presented as Service Composition Directed Graphs. The SCDG is a graph-based model of service composition representation that was proposed in [22].

An Execution Module executes grounded service composition plans. To-date only the SCDG execution engine has been implemented, although there is a possibility to include other engines. To do that one might also need to develop an appropriate import-export engine first.

A Networked Service Repository Module is a web service that on the one hand allows web services to be registered in it and on the other hand provides information about these services for composition and grounding modules. This module also employs a standalone database for service descriptions to be stored in it. A database engine could be either external or internal in relation to the Networked Service Repository. External database engines, however, are much faster and reliable with large data sets and thus more preferable.

III. Use Case Scenario

We can imagine an on-line trading system which allows its users to search for products, place orders and ultimately buy goods by entering financial and personal data into the system. There are all sorts of government regulations and industry standards for personal and financial data because of its sensitive nature. Therefore, we can be sure that some parts of the composition plans in such kind of software platforms will be predefined specifically to obey all sorts of reg-

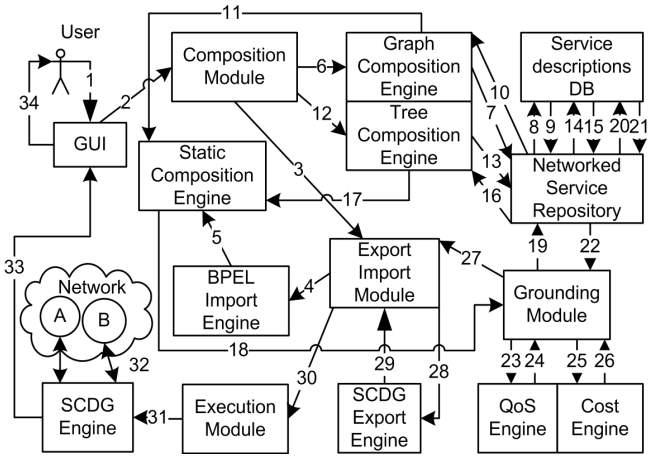

Fig 5. Service composition, grounding and execution diagram

ulations and standards. On the other hand, such systems may benefit from automatic or semi-automatic service composition techniques after all.

Hybrid service composition was proposed to solve exactly such kinds of problems by providing the necessary interoperability between different service composition methods.

A. System's Internal Operation - From Composition to Execution

Fig. 5 presents a diagram with an example of how a service composition plan is made, grounded and executed in a system which implements the platform concept proposed in this article.

1. The user provides necessary personal and financial data and the parameters of the desired products.

2. This data is delivered to a Composition Module.

3. The Composition Module sends a request to an Export Import Module to make an import of a standard-required part of the composition plan which will handle personal and financial data.

4. The Export Import Module transfers the request to a BPEL Import Engine which will actually perform the task of importing.

5. The BPEL Import Engine sends a part of the imported composition plan to a Static Composition Engine, so it can be merged with automatically composed parts later.

6. The Composition Module initiates a Graph Composition Engine and transfers composition parameters to it.

7. The Graph Composition Engine makes a request to a Networked Service Repository and asks for a list of available services types.

8. The Networked Service Repository makes an appropriate query in a Service Descriptions Database.

9. The Service Descriptions Database processes the query and sends back the results.

10. The Networked Service Repository provides the Graph Composition Engine with a list of all available services types (not instances).

11. The Graph Composition Engine sends the prepared part of the future service composition plan to the Static Composition Engine.

Steps 12..17 are similar to steps 6..11.

18. The Static Composition Engine merges all parts of the composition plan into one abstract service composition plan and delivers it to a Grounding Module for grounding.

19. The Grounding Module makes a request to the Networked Service Repository and asks it to provide a list of real-world service instances whose inputs and outputs correspond to the inputs and outputs of the services in the abstract composition plan.

Steps 20 and 21 are similar to steps 8 and 9.

22. The Networked Service Repository provides the Grounding Module with a list of required real-world service instances.

23. The Grounding Module initiates a QoS Engine and delivers the appropriate part of the plan plus the lists of service instances to it.

24. The QoS Engine grounds a part of the greater plan and sends it back to the Grounding Module.

Steps 25 and 26 are similar to steps 23 and 24.

27. The grounded composition plan is delivered to the Export Import Module.

28 The Export Import Module initiates a SCDG Export Engine and provides it with a grounded composition plan.

29. An exported composition plan is delivered back to the Export Import Module.

30. The Export Import Module sends the exported composition plan to the Execution Module for plan execution to be made.

31 The Execution Module initiates a SCDG Execution Engine and provides it with a composition plan.

32. The SCDG Execution Engine executes the composition plan.

33. Plan execution results are delivered to the interface.

34. The interface renders the acquired results and presents them to the user.

B. A Closer Look at Composition and Grounding

Fig. 6 presents a visualization of an abstract composition plan which deals with sensitive personal and financial data provided by the user. There are several service calls in it: “AssignUniqueID” – assigns a unique ID number to a user-provided data set, “Encrypt” – encrypts the data set, “Archive” – archives the previously encrypted data, “ValidateData” – makes appropriate validations of the user-provided data.

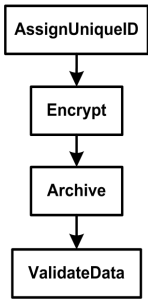

Fig 6. Abstract composition plan in a BPEL language with predefined service calls

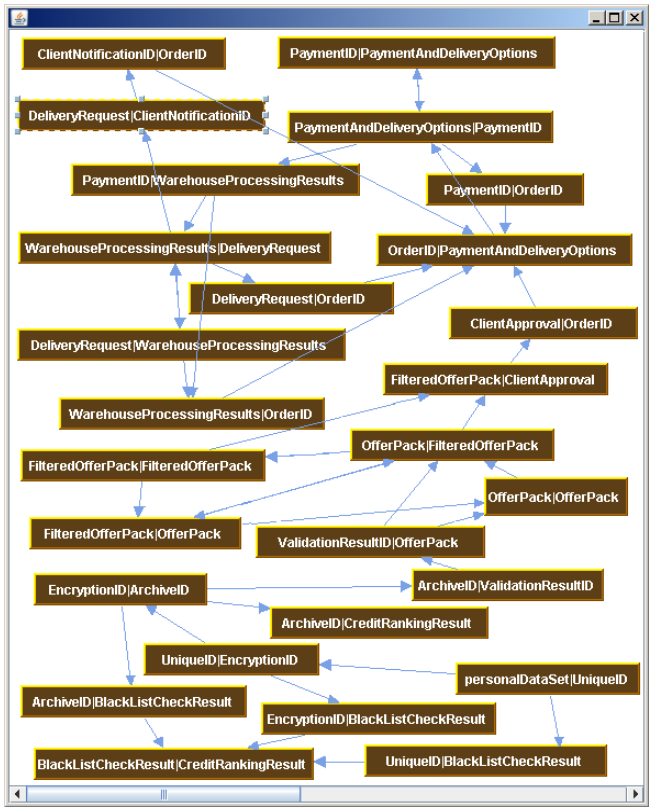

Fig 7. Complete service dependency graph for Service Repository

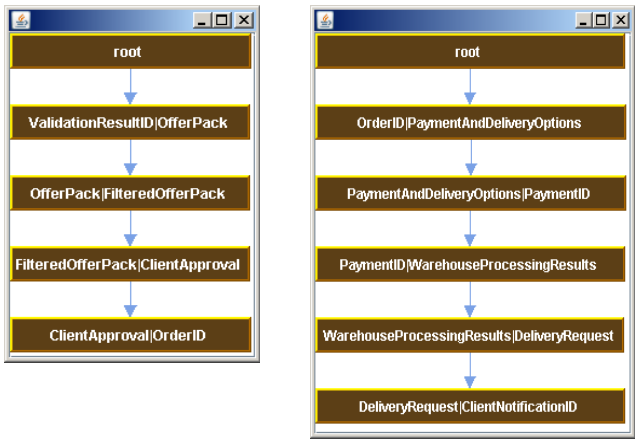

Fig 8. Graph (left) and Tree (right) Composition Engines work results

The automatic generation of the second and third parts of a composition plan was done by graph and tree composition engines. The graph-based engine composed the part of the plan responsible for product finding, selecting and placing an order in a system. The tree-based engine composed the part responsible for the processing of the order that had been placed earlier.

Fig. 7 presents a visualization of a complete services dependency graph of all registered types of web services that were registered in the Networked Service Repository. That exact graph was generated by a Graph Composition Engine during the composition process itself and visualized by the visualization functionality of the software platform. All service type IDs were automatically generated by the Networked Services Repository. Each of these IDs consisted of service input type name, "|" character and service's output type name.

The left part of Fig. 8. presents a visualization of an abstract plan that was generated by a Graph Composition Engine. "ValidationResultID" is an output type of the last service call in a predefined part of the service composition which was imported from a BPEL file, so it was passed to the Graph Composition Engine as a desired input type. "OrderID" type is a type which corresponds to the output type of the order creation service, so it was passed to the composition engine as a desired output type of the composition.

The subsequent steps of a plan generated by the Graph Composition Engine are as follows:

1. "ValidationResultID|OfferPack" represents an automatic wide search of possible products on the client's request.
2. "OfferPack|FilteredOfferPack" represents automatic filtering of the previously found products.
3. "FilteredOfferPack|ClientApproval" represents the client's acceptance of a product offer.
4. "ClientApproval|OrderID" represents generating an order for the offer that had already been accepted.

The right part of Fig. 8. presents a visualization of an abstract plan generated by a Tree Composition Engine. "OrderID" type was passed to the composition engine as a desired input type because it has to be the same as the output type of a Graph Composition Engine's work result. "ClientNotificationID" represents the result of client notification which always happens after an order is processed, so it was passed to the Tree Composition Engine as a desired output type.

The subsequent steps of a plan generated by the Tree Composition Engine are as follows:

1. "OrderID|PaymentAndDeliveryOptions" represents a user's process of choosing payment and delivery options for a created order.
2. "PaymentAndDeliveryOptions|PaymentID" represents the act of payment for the delivery by a client.
3. "PaymentID|WarehouseProcessingResults" represents all background warehousing processing such as searching for the warehouse nearest to the client, scheduling product pickup from the shelf, packing etc.
4. "WarehouseProcessingResults|DeliveryRequest" represents creating a delivery request to a logistic company which will actually deliver the products to the customer.
5. "DeliveryRequest|ClientNotificationID" represents the client notification process during which the client receives information about the delivery and other order related things.

All three parts of a complete abstract service composition plan were merged after they were created or imported by the corresponding engines. After that the complete plan was divided into three grounding areas and grounded in a hybrid mode.

The first grounding area consisted only of the steps from the first part of the plan which had been imported from the

Fig 9. Grounded composition plan

BPEL. Because this part is very important and regulated by government and industry standards, it was grounded only by a QoS Engine which was tuned to select the best available service instance no matter the cost.

The second grounding area was defined as a steps chain from "ValidationResultID|OfferPack" service till "OrderID|PaymentAndDeliveryOptions". The main grounding engine for that area was the Cost Engine and the second one was the QoS engine. The Cost Engine, however, was configured to choose not the absolutely best service from a variety of the available ones, but a range of acceptable services within a provided distance from the best one. The additional grounding engine for the second area was the QoS Engine which was able to choose the service instance with the best cost from the range of the previously selected ones by the Cost Engine.

The third grounding area was defined as a steps chain from "PaymentAndDeliveryOptions|PaymentID" till "DeliveryRequest|ClientNotificationID". It was grounded similarly to the second part but the difference was that the main grounding engine was the QoS Engine and the second one was the Cost Engine.

Fig. 9. presents a visualization of a grounded composition plan. The only difference between the visualizations of the abstract and grounded composition plans are URL addresses of the WSDL files in every step of the composition. These addresses unequivocally correspond to real-world service instances due to that fact that the data in each WSDL file describes a concrete service instance.

The execution of a service composition plan was made with the use of an Execution Module which was making service calls to appropriate instances by their URLs.

C. Implementation Details

The described platform was implemented in Java 6 programming language. Apache Tomcat 7 was used as the servlet container which hosted all the services and the Networked Service Repository as well. Spring Web Services 2 framework was used for the creation of the all web services including the Networked Service Repository. All the communication between the services, repository and Execution Module was carried out using a SOAP protocol over HTTP. Hibernate 4 was used as an object relation mapping framework for storing all service descriptions data in an in-memory H2 version 1.3 database. Such kind of database was used instead of a standalone one because it is easier to use and maintain in projects of the prototype nature. The SCDG was implemented upon JgraphT 0.8 library abstractions which also provided valuable algorithms for the Graph Composition Engine. Jdom 1.3 library for XML was used to handle all XML operations across all platform modules. JGraph 5 library was used to draw the visualizations of service composition plans in the SCDG format such as Fig. 7, 8 and 9.

IV. Conclusion and Future Work

This work presents an approach to creating a software platform that allows its users to combine different composition and grounding methods. Such features enable software users to control composition and grounding processes in a different and more powerful way thus allowing them to create better suited abstract and grounded composition plans.

The proposed approach was also verified during the implementation and execution tests of the described platform. The verification revealed that hybrid composition and hybrid grounding approaches are viable tools that can be used to create a better suited abstract and executable service composition plans.

The main implication of the presented work is the fact that users of software platforms that implement the proposed approach will have more flexibility and control over service composition and grounding processes. Many composition and grounding methods have been proposed, yet each of them is different and may not suit all the needs of the end-point customer. Furthermore, to satisfy all the upcoming and even hitherto unknown customer needs software systems must allow changes to be introduced in them. The ability to choose and combine different service composition and grounding methods addresses these problems by enabling users to select and merge optimal methods for their needs.

There are also three main directions of the upcoming work for the proposed concept. The first one is studying the desired properties of the service universe and service granularity in order to achieve high automation rates. The second one is a hybrid execution of grounded plans. The combined usage of different execution engines might bring some additional features since these engines might employ different approaches and thus be valuable from different points of view. The last direction of the studies has to be made in the field of dynamic composition, grounding and execution methods. Such methods can be very desirable e.g. in soft-

ware platforms where the fault-tolerance level of services is low or the environment itself may constantly be changing.

***Abstract*–the present survey mainly aims at analysing determinants of possibilities of improving processes in an organization. The early fragments of the study are devoted to a theoretical analysis of determinants of the process management and its connection with the project management. Then the assumptions of the survey on the impact of the organizational structure and culture on possibilities of applying business process management were presented. The verification of theoretical deliberations and survey assumptions is included in the last part of the article presenting the initial results of the obtained survey and the resulting conclusions.**

Key words–business process management, organization structure, organization culture.

I. INTRODUCTION

THE basic objective of the present article is an attempt to define the meaning of the organization structure and culture for the purposes of streamlining the business process management within it. Numerous Polish and foreign publications [1], [2], [3], [4], [5], [6], [7] define process management in the wide and narrow scopes. The wide scope shows it as a discipline comprising activities identifying, evaluating and analysing the existing processes performed in an organization and their fit for accomplishment of strategic objectives of the organization, It is the base for improvement, optimization, modification or designing new processes (within projects). In the narrow scope – it is a formalized sequence of systematic, measurable steps concerning management of individual business processes in the organization by means of: intuition, explicit and tacit knowledge, inborn and acquired skills, internal (e.g. employees) and external (e.g. customers) stakeholders; theoretical – methodical solutions in the scope of management (change, quality, time, scope, budget management) and related social sciences (economy, sociology, psychology) etc., tools for analysis and tools for process improvement as well as implementation techniques together with process innovations and projects introducing change on the enterprise level; information technologies – supporting the processes, modelling and designing the organization and allowing design and implementation of IT systems using the process management solutions in the management practice of the organization set in a specific economic environment; oriented and changeably (dynamically) conditioned by: the organizational structure (bidirectional relation structure - processes – more efficiently implemented in a proper organizational structure allowing to monitor, analyze and improve the processes; a specific strategy of the organization (relation structure - processes – more efficiently implemented than through competition on a given market), where proper relations result from combining the results of the processes with Key Performance Indicators (KPI); the organizational structure – with the possibility of questioning the inviolability and optimum of the present state, which serves a basis of a possibility of improving the organization, including also transferring and distributing tacit knowledge through a social component of corporate portals and sharing it with other employees of the organization.

From the practical point of view the relations between processes and projects are also essential. At present determinism, explicitness and statics in defining features and results of projects move towards probability calculus, indeterminacy and dynamism. In theory the span between two basic kinds of activities recognized in the contemporary organization: projects and processes should increase. After all projects were defined – as unique, one-time undertakings requiring proper preparation – while processes are repeatable and may be subject to automation or become routine activities. The main difference is the fact that processes are performed permanently and by nature are repeatable, although they can proceed in an unpredictable and changeable way depending on impulses coming from their environment, and projects are performed when new needs occur, and each of them is totally different. But relations between process management and project management have bilateral dimension. On one side process management is treated just as a technique of streamlining project performance. But on the other hand – in a sense – projects are subsets of processes – they are all processes that we could define as non-routine (change-oriented), innovative, pragmatic, burdened with a big risk and unique. This results from peculiar similarities – both kinds of activity are performed by marked out teams of people, determined by specific and limited in time resources, following the rule of planning, steering, supervising and controlling particular acts. This in turn makes the changes within process management have a direct impact on project management. Projects are performed in order to improve the existing processes, create totally new processes and solve specific problems connected with the necessity to change processes (isn't it a component of process management?). In each organization there are both process and project activities. Contrary to its classic definition, projects basically do not end. Each end of one project is the beginning of another, in essence they sometimes create a never-ending cycle of

978-83-60810-53-8/$25.00

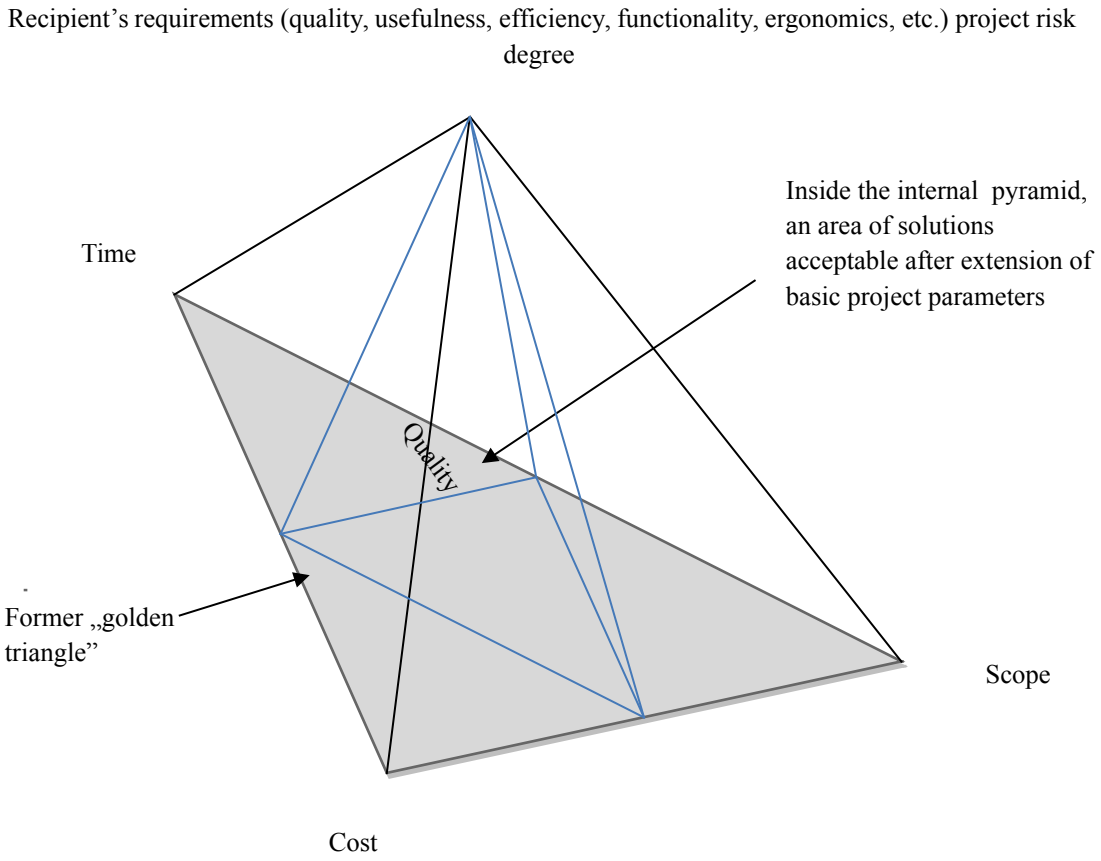

Fig. 1. The area of acceptable combinations of basic project parameters and its extension
Source: own study

projects, which cannot be even named as subprojects because we never know – if only due to uncertainty and high risk – in which direction end users' requirements will develop. But the most symptomatic for project development is the fact that essentially methodologies of project management were in their classic version created, generalized, „toughened", standardized so as to the best possible extent normalize processes occurring in the project. So the paradox – as it shows – consisted in the fact that they got closer and closer to methodologies of process management, as they strived for operating standard rules of solving non-standard problems, which tried to standardize them (that is change into processes) through far reaching formalization.

Due to the above reasons, the notion of a project success at present evolves towards an evaluation exceeding the classic, narrow triangle of balance between costs, time and scope [8]. The point of view of a user – project recipient and his/her way of seeing the project is taken, both in internal projects (in which both persons performing the project and its recipients are employees of the same organization, in which the final product of the project remains), and external projects (products performed for stakeholders from outside of the organization, e.g. customers and may be a source of income of the organization producing them). The extension of the „golden triangle" itself by the fourth parameter – requirements – characteristic for process management – causes also extension of possibilities of making decisions in the scope of its implementation (each decision is described by four sorted out parameters (time, scope, costs, requirements), not by three parameters as before). And the relations between those parameters are becoming – as it seems – non-equivalent – recipients' requirements are superior to other parameters. If we additionally introduce a fifth parameter, which is the quality (one of the component of user requirements) – the number of allowable solutions will again narrow, which will affect multidimensionality of a project and the close connection of a user's requirements with a specific quality level. Not all solutions acceptable within a project and conforming to the user's requirements may meet the assumed quality

standards, and thus the process management (cf. Fig. 1). So changes of relation between project management and process management are affected by their surroundings (environment). The environment, in which projects are implemented, splits into [9]: economic (prices, customs duties, taxes, exchange rates, interest rates, economic policy, markets, economic development degree), legal (legal system, its adjustment to the conditions of implementation, licenses),

technological (technological development, technological state in an organization, quality standards), organizational (organizational structures, management style, managerial staff and employees' skills and knowledge, functionality of the organization, project management method), psychological, (culture, opposition to changes, innovation degree, performance and execution safety) and political (geo-political factors, developmental tendencies, alliances, trends). And here another important issue emerges. The success of a project in the classic perspective and the success of a project in the contemporary perspective (and its management) resulting from practise significantly differ. In the classic perspective (treated this way by many studies) the success is not to exceed costs (and the best thing - execution of the costs), full conformity of the schedule with performance dates and conformity of the performed scope of work with the one specified in the project. Adding the end user's (recipient, customer) point of view means adding to the success evaluation criteria the issue of customer satisfaction with the obtained product or service. Adding a dynamic environment – decrease of a risk of failure, efficiency, effectiveness, flexibility, adaptivity, functionality, etc. And these are evaluations very close to an evaluation of a success of a proper process management in an organization. And very strongly influences them. In streamlining the processes the fact that individual organizations may be at different levels of progress in the scope of process management should also be taken into account. To evaluate this level most often the CMM model (Capability Maturity Model) is applied, which recognizes five basic stages of maturity to process management: first (initial – where processes are not defined at all), second (repeatable – processes were identified in selected departments of an organization and are performed); third (defining) – processes are known in the whole organization and are performed, fourth (managed – conscious use of process management by managers, manifested by collection of data on efficiency of stages of the process and the process as a whole), fifth (optimization – managers and employees monitor on a continuous basis efficiency of processes and introduce necessary modifications). An attempt to introduce process management to an organization, which has not been properly prepared – lacking suitable organizational resources and competence – may result in a failure. Going through each of the organization process maturity levels in this model is an undertaking requiring both extensive knowledge in the scope of process management and using tools dedicated to this purpose and an established and strong internal support centre combining those two elements, for the whole organization, which is e.g. the so-called Process Competence Centre.

The analysis of the results obtained by the Standish Group [10] indicates very practical determinants of the success of project management, and thus of related process management: customer's commitment to the project implementation, project's managerial staff (sponsor) support, clear business objective of the project (specified requirements in the light of existing limits), optimized project scope (adjusted to performance capability), methodology of flexible planning (agile) instead of traditional one, an experienced and competent project manager, proper management of project budget, educated human resources, formal methodology of running the project and standard programming tools and infrastructure.

Among the success factors the „soft" and procedural factors predominate. So it seems that the survey concerning the human and cultural factors as well as the organizational structure as possibly having the most essential impact on organizational improvements, in this situation may be to the fullest extent legitimate.

II. Survey Assumptions

The survey is divided into three parts:

– defining the significance of business process management (BPM) in an organization,

– identifying roles and significance of organizational units dedicated to BPM, for the needs of the survey named Process Competence Centre (PCC),

– defining cultural aspects of process approach implementation.

In the first area attempts were made to define how business process management is perceived by an organization, how this notion is understood and what are strengths and weaknesses of its implementation. Respondents referred to such specific issues as:

– meaning and understanding of business process management (BPM) in an organization (important strategic initiative promoted by managerial staff, essential support for many important projects on a scale of the whole company, support on operating level for medium and small process projects, necessity before implementation of an IT system, studying new possibilities),

– objectives to be achieved by an organization thanks to BPM (create a foundation for development of the whole organization (allow comparison with competition, develop a new organizational structure, improve co-ordination of activities in the company, improve measures and KPI, control risk, increase business process effectiveness, ensure timely delivery of products and services, improve relations with contractors, lower process costs, standardize processes, implement new software, meet employees' requirements for information, try a new approach, introduce new knowledge),

– indication of key processes that require streamlining within a context of income growth (from generic processes list),

– methodologies, techniques and approaches used by an organization: (strategic BPM, Rummel- Brache approach, BPTrends approach, Six Sigma method, Lean - Six Sigma method, Lean method, modelling in BPMN, methods required by ISO, organization's own methods, other),

– subjective perception of organization's process maturity (according to the maturity model based on CMM),

– the extent of implementation of process governance, especially developing (or not) the enterprise process architecture,

– establishing (or not) an organisational unit supporting business process management.

The second area addressed the role and place of organizational structures responsible for construction of the process management system and streamlining business processes, in the scope of the following characteristics: duration of its functioning and its place in the organization's structure; main tasks and services delivered by this organizational unit; resources assigned to an entity dealing with processes; employment of external staff, who deals with the issue of business process management; BPM competence areas required by the organization.

The third area concerned social and psychological factors forming the culture of an organization, such as e.g. defining managerial staff's support for the entity dealing with processes; impact of the entity dealing with processes on the organization's operation; weak points of the entity dealing with processes; strong points of the organizational culture in a given situation.

In each of the defined survey areas a choice was made through marking some proposals from among the ones initially defined by the research team. Moreover, the closed part of the questionnaire ended with open questions, such as: what features should characterize a leader of the team dealing with business processes in an organization?, what features should characterize an employee of the team dealing with business processes in an organization?, what are obstacles in the operation of the Process Competence Centre (PCC)?, what are key support areas for PCC operation?

The survey is at present being implemented by collection of data from the questionnaires filled in via the website www.bpmwpolsce.pl and individual interviews. So far (May 2013) in total more than 50 responses have been collected but the survey is still pending and almost every day new questionnaires are received. The conclusions from selected partial results are presented in chapter three of the present article. The data from the questionnaires were processed by means of IBM SPSS Statistics software. In case of open questions a context interpretation was performed, and then the above-mentioned application was used. A part of the questions in the questionnaire was formulated in a way allowing to compare responses with the results of studies conducted by BPTrends – an American publishing company, whose founders and columnists are experienced practitioners and opinion leaders in the area of business process management, who regularly publish articles and studies presenting the best BPM practices [11]. References concern a part of questions defining understanding and significance of business process management concept and practices in organizations and questions connected with functioning in organizations of special structures dedicated to such activities.

III. Initial Results Of The Conducted Survey

A. *Survey Participants*

Almost a half of the survey participants are representatives of the top and middle management (48%). Another major group of respondents (22%) are experts, who – although usually do not manage teams directly, are employees with high expertise and often create standards of operations for the entire organizations. On the basis of the above results we can state that 70% of respondents are persons with high level of knowledge of the organization and significant impact on its functioning.

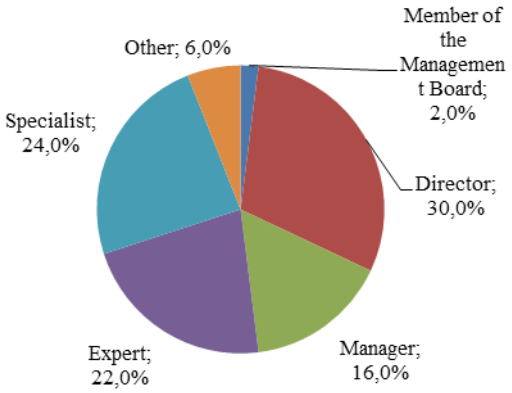

Fig. 2. Survey participants – positions held in an organization
Source: own study

Straight majority of organizations (68%) are big and very big organizations with more than 500 employees, including 26% with more than 5000 employees.

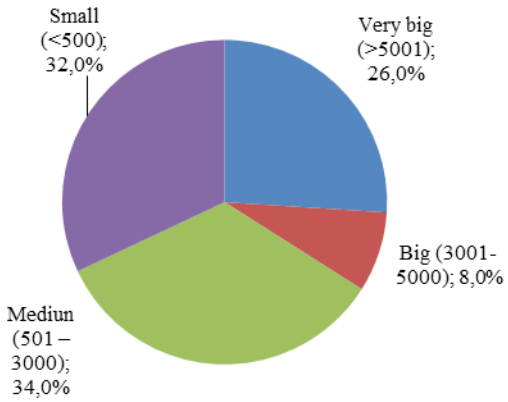

Fig. 3. Survey participants – size of organizations
Source: own study

B. *Significance Of Business Process Management In An Organization*

In one of the questions. t respondents were asked to tick one of the presented below phrases – the one that best describes their understanding of the very concept of business process management. The following results were obtained: 32% of the respondents understand business process management as an approach to manage the entire organization on the strategic level; 30% - as an approach for individual process analysis and improvement; 12% - as a cost reduction and efficiency increasing initiative and for 22% this is just a set of information technologies that help manage and automate processes.

We also wanted to know the significance (importance) of the business process management initiatives for organizations: 30% of the respondents defined it as an

important strategic initiative promoted by management, 24% - stated that the process approach was treated as an essential support for many important cross departmental projects; 18% - sees its significance as a support at the operating level for medium and smaller improvement projects; 16% - as the necessity before IT system implementation; for 12% is only testing of a new approach.

Regardless of the above-mentioned way of understanding BPM and its importance, organizations have some specific expectations connected with investing resources in the area of process management. We asked what goals and objectives were set for the process initiatives in an organization? The respondents could mark all expectations and objectives known to them. We obtained the following answers (see Fig.4).

It is noticeable that the answers selected most often contained generally defined strategic level objectives connected with entire organization systems coordination (foundation for development of the entire organisation, activities coordination). The second most often selected were objectives at the business process level (increase of efficiency, standardization of processes) and only later the detailed, specific, implementation level objectives were selected.

In connection with the above it is logical to ask: do organizations know and use tools (methods, approaches, techniques), which will help to achieve the previously indicated goals and will help to bring expected results. It turned out that the best known process related method is BPMN (52% of the respondents indicated that they know and use it)

This is a popular notation used to describe processes at a very detailed level but it is not useful ether at the process level or at the strategic level as it misses many business elements and symbols. As little as 2% of the respondents indicated specific names of BPM methodologies useful for strategic management, further 32% declared using various unnamed methods of strategic process management. (however they did not specify them later in the item „Other, specify") Awareness and usage of other methods spread out in the following way: Lean (6%), Lean 6 Sigma (16%), 6 Sigma (6%), methods required by ISO (32%), organization's own methods (40%).

So what is the general process maturity level of the surveyed organizations? The participants of the survey were asked for their subjective evaluation of the maturity level in a scale from 1 to 5, corresponding to the levels of the frequently used CMM model applied for process management. This model was selected as there was a solid reference material inter alia coming from regular BPTtrends surveys conducted since 2006. The obtained answers are presented in the first column of the table below and compared with the results of surveys published by BPTrends [11], [12].

In Poland we notice a significantly higher percentage of enterprises, which admit that their organization is at the first stage of maturity, where processes are chaotic and problems are solved ad hoc. We also see a significantly higher percentage of organizations, which place themselves at level 3, where it is expected that organizations have defined their process architecture and key elements of the process management system are implemented. This an interesting result as we take also into account significantly lower (by half) than in the world percentage of organizations, which evaluate their maturity at the preceding level, that is level 2

TABLE 1.
SUBJECTIVE EVALUATION OF THE PROCESS MATURITY LEVEL

Survey result in Poland 2013	BPTrends world survey results 2012	Definition of process maturity level
36%	22%	Processes function thanks to efforts and creativity of employees. Problems are solved ad hoc and not systemically. There are few initiatives referring to processes.
20%	48%	Processes are being improved, but usually within departments or other organizational units. The most important processes have already been described and improved..
32%	22%	Majority of core and enabling processes are identified, published and improved at the organization level. Process architecture is defined. Processes are measured and monitored systematically.
6%	2%	Process owners are appointed, decisions are based on process measures. Processes are managed in the whole organization.
6%	5%	Processes are systematically improved, process governance is executed.

Source: own study and [11], [12]

C. The Role And Significance Of The Process Competence Centre In Organizations

On the basis of collected and presented below data, which concern:

- duration of functioning of a process competence center: less than one year -28,6%; 1 -2 years -14,3%; 3 – 5 years - 25% and above 5 years -32%,
- its position in the organisational structure: at the management board – the manager of the process office reports to the management board - 53,6%; in a division – the manager of the process unit reports to the director of the division 39,3%; in a department – the manager of the process unit reports to the director of the department 7,1%,

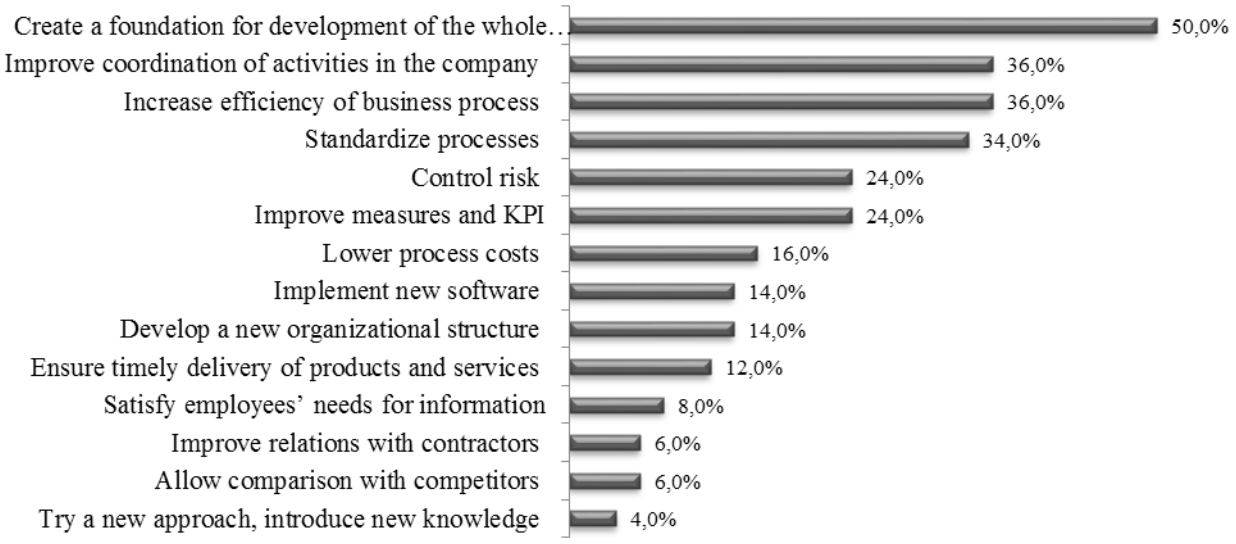

Fig. 4. Objectives to be achieved by an organization thanks to application of methods of process management
Source: own study

– number of employees in this unit: less than 5 employees - 60,7%; 5 – 10 employees - 25%; and 11 – 25 employees -14,3%,

– number of employees in the area of business process management outside this unit: 0 employees -10,7%, 0 – 10 employees 32,1%, 11 – 50 employees 39,3%, 51 – 100 employees -14,3%, more than 10 employees -3,6%,

an image of a typical process competence centre emerges. A statistical process competence centre: functions for less than a year, reports to the management board, employs less than 5 employees but co-operates with a dozen or several dozens (11-50) of persons scattered throughout the whole organization.

Employees of the process competence centre mainly deal with implementation of the following tasks specified in Table 2.

The choices made in the questionnaire by the respondents clearly show their focus on systemic and educational activities. In comparison with tasks implemented by this kind of process competence centre in the world, illustrated by Fig. 5, some fundamental differences can be observed:

1. the Polish competence centres to a significantly greater extent deal with developing rules for the management system, which should not be a surprise as the highest percentage of them is located at the management board and they are expected to build foundations for the whole organization's functioning,
2. the process competence centres in Poland conduct on their own much more training than in other countries,
3. the process competence centres in Poland much less often manage the company's process repository.

The reasons of these visible differences are not subject to an analysis within the present survey. On the basis of our own observations and experience we can suppose that the Polish organizations much less often use IT tools with process repositories but use simpler drawing tools instead and they perform more tasks on their own instead of buying external services (e.g. training).

TABLE 2.
TASKS OF THE PROCESS COMPETENCE CENTRE

Tasks	Participation in realization
Developing rules for the process management system	71%
Conducting training	67%
Maintaining process architecture	57%
Designing new processes	57%
Process modelling	53%
Developing measures and benchmarking	46%
Management of process repository	42%
Popularization of knowledge	42%
Management of project portfolio	14%

Source: own study

Fig. 5. Comparison of tasks performed by the process competence centre in Poland and in the world.
Source: own study

Another question we asked concerned the impact of the process competence centre on an organization. The answers are presented in Table 3. On the basis of the answers we can state that 32% of the respondents have no impact on the organization or performs fake activities – which is even more depressing evaluation of the situation. This is a surprising result in comparison with just 3% of similar answers obtained in the world surveys. At the same time in Poland merely 7% answered that the process competence centre was very important for the success and co-ordination of activities, which – in comparison with exactly such expectation expressed in answers to preceding questions – shows the competence centres mostly still do not meet the expectations and have not yet worked out a position that could help them succeed in an organization.

TABLE 3.
IMPACT OF THE PROCESS COMPETENCE CENTRE ON AN ORGANIZATION

Choice	Our survey – Poland	BPTrends survey – world
Is very important for the success and co-ordination of activities in the whole organization	7%	20%
Has big impact	18%	23%
Just starts to have the impact	32%	53%
Has no serious impact	25%	3%
Performs fake activities	7%	-

Source: own study and [11], [12]

Another question under the study is management support for the process competence centres. Our survey showed that the straight majority (85%) of the respondents said that the management declared support for PCC, but unfortunately only 46% supports them indeed. For the remaining 39% of the management this is just a declaration not supported by actual activities. Other 7% of management is indifferent, and the following 7% even questions the significance of process competence centres.

The survey ended with open questions, from among which we would like to discuss here the following most essential two:

1. What features should characterize a manager of the process competence centre?

Most often the necessity of a very strong and even charismatic leadership was emphasised. The manager holding this position should be able to think strategically, long term and in a holistic way, understand system dependencies, and at the same time should be able to speak in an operating language on details of processes, in order to be credible for line employees. The need of perseverance and consequence was emphasized many times as a necessary characteristics of the PCC manager.

2. What to the greatest extent would help to achieve results by the process competence centre?

The most required is knowledge, resulting also from experience, concerning the way the process organization function. Especially a thorough knowledge is needed, as well as the skill to persuade the advantages of accepting the process approach. The respondents equally often mentioned the need for official support and personal commitment of the organization's management (which in turn confirms the Standish Group's survey).

These and other answers collected during our survey show an image typical for a situation of introducing cultural changes in an organization, where employees' knowledge, belief and attitude play the key role and decide about the success or the failure of a new undertaking.

IV. CONCLUSIONS

Business process improvement initiatives are frequently key projects within an organization – they are managed using project management methods and principles. However the nature of a business process is best recognised and captured by business process management methods. Project management and process management complement each other How does the two approaches interact?

We claim the conjunction point is the newly defined "requirement definition" point at the top of the project management pyramid, which adds the new perspective on traditional project management triangle (scope, cost and time) as described in the previous sections of this paper.

Process management methods are the most suitable for defining the requirements for process improvement projects. The more matured process management the better requirements definition in the project. Therefore it is important to be aware of process maturity of the enterprise, how well it understands its process, how systematic is its view on a business processes how does its culture supports process approach. By combining the process and project methods organisations increase their chances for project success and avoid the situation when improving one process has an adverse affect on other processes

From answers to our survey, it could seem that the strategic understanding of BPM as a holistic system for management of the entire organization predominates. However, if we take a closer look on the results, and refer them to three levels of organization's efficiency described by G. A. Rummler and It A. P. Brache [13], [14] who distinguish the following levels: strategic level, process level and job level – then we find that understanding BPM as an initiative of cost reduction (12%) and as implementation of information technologies (as much as 22%) refer usually to a local management on the job level or even are limited to the area of IT tools. We then state that the interpretation of the concept of business process management spread out more or less evenly among three levels of organization management. There is an equal probability that a person asked by us will classify BPM as an element of strategic management or operating management at the process level or narrowly understood management of the implementation level.

Again it seems that the biggest percentage of an organization (32%) initiates process projects as strategic initiatives at the top management level, thus having

fundamental significance for the whole company's functioning. Not until we set the declared values again at the above referred [13], [14] three level of efficiency, we will be able to for almost a half of surveyed organizations (for 46%) BPM projects have local significance (18%) or are a necessity before implementation of an IT system (16%) or are an experiment and survey of new possibilities (12%).

As research shows organisations expect o lot from the process approach and those expectation refer rather to effective planning of the organization wide systems than to solving specific problems. Taking into account ambitious and system expectations of BPM projects, weak recognition of methods, which could be used for achievement of own objectives, is noteworthy. In connection with it is reasonable to doubt whether organizations will be able to achieve these objectives by means of recognizable and presently applied tools. Probably in most cases – unfortunately not.

The world results show gradual building of process maturity according to the scheme of inverted funnel, that is lower and lower percentage of companies at the following higher and higher levels. In Poland we can observe a leap to the third level. We may propose a thesis that the reason behind this is superficial understanding of system elements characteristic for level three and thus the easy placing home organizations at it. Though also in the world results we can observe a similar, yet smaller, „optimistic leap" but it concerns the fifth level. It is possible that here again we deal with too superficial and unrealistic evaluation of process maturity. As this is a question about a subjective evaluation of the situation, we can suspect that the „leap" phenomenon is more connected to the respondent him-/herself than the very situation of the organization. The issue whether it is connected with the respondents' aspirations or the superficial understanding of the levels too distant from the majority, or whether it results from other reasons – is to be studied in further surveys.

At the same time in Poland merely 7% answered that the process competence centre was very important for the success and co-ordination of activities, which – in comparison with exactly such expectation expressed in answers to preceding questions – shows the competence centres mostly still do not meet the expectations and have not yet worked out a position that could help them succeed in an organization

Summing it up. How well are Polish organisations prepared to derive improvement project requirements from their expertise on business process management?

Probably not too well yet. Business process management has become a popular topic and objectives and expectations towards these initiatives are set high, however the awareness of methods and real managerial support is not there yet. We will need more education and awareness building before business process management methods will be used to define requirements for improvement projects so that project management skills and techniques are used to their full potential to bring process improvements to organisations.

Process-based evaluation and comparison of OTS software alternatives

Maria Jesus Faundes, Hernan Astudillo and Bernhard Hitpass
Universidad Técnica Federico Santa María, Departamento de Informática, Avenida Vicuña Mackena 3939,
San Joaquín, Santiago, Chile

***Abstract*—Many Off-The-Shelf Software (OTSS) assessment techniques have been proposed, most of them using criteria related to standard quality models. However, these techniques are not as useful to evaluate and compare alternative OTSS as solutions to specific process-driven organizational changes. This article proposes PBEC-OTSS (Process-Based Evaluation and Comparison of OTSS), a technique for evaluating and comparing OTSS regarding impact in the organization, based on process models, and using fuzzy decision making systems. The technique was compared with an Ad-Hoc approach (systemized from the literature) in an experimental study with IT professionals, some new to BPM and some experts; the experts obtained similarly good results with either approach, but the novice professionals obtained better results with PBEC-OTSS than with Ad-Hoc. These results suggest that organizations can improve their Business/IT alignment with this technique even if no process experts are available.**

I. Introduction

THE software selection process is a subjective and uncertain decision process [23], where meeting the specific needs of the organization is complex and requires time [8], considering that a company may lose its competitive advantage by investing in wrong alternative technologies or by investing too much time in selecting the right one [18].

In practice, there are numerous organizations that lack a rigorous selection process [11], which is often made under pressure by evaluators who may not have time or the expertise to plan it [8], or that select according to their experience or intuition [20], [21].

A systematic and repeatable selection methodology for *Off-The-Shelf Software* (OTSS), is a crucial need to minimize uncertainty and risk in companies [19]; so, choosing a suitable OTSS, is a non-trivial task for organizations and requires a thorough assessment process. Therefore, the key question seems to remain: how to identify the most appropriate OTSS to meet organizational needs? The recommendation to managers is to choose an appropriate IT infrastructure to facilitate the alignment between strategy and organizational structure, achieving higher performance levels [4]. However, the benefits of an organization's systems are generally known only after some period of use [2].

In the literature, there are studies that emphasize the important relationship between business processes and IT, stating: IT will be used if, and only if, the functions available for the user, support, or fit to their activities [5]. The selection and implementation of proper IT applications, is an important precondition for the efficient execution of business processes [17]. IT will only have a positive effect in the organizational performance, if this fits with the business processes [9].

Therefore, based on the close relationship between business processes and IT, is that this study proposes a new approach to evaluate and compare OTSS, based on processes models and fuzzy decision making systems, which allows:

- Generate alternative reconfigurations of processes models, which serve as input data for processes improvement and processes standardization.
- Identify and measure the potential contribution of the OTSS to the organization, through impact indicators (coverage, automation, and implementation).
- Generate OTSS traceability regarding the processes and activities of the organization.
- Identify collaboration between OTSS, and implemented systems in the organization.

All of which improves decision making, and promotes the Business/IT alignment.

The remainder of this paper is structured as follows: section II presents the Related Work; in Section III the proposed approach, along with an illustrative example; in section IV the Case Study, and finally Section V summarizes and concludes.

II. Related Work

In literature, the software assessment has been a subject of interest of suppliers, and topic of study for academics and professionals, developing and proposing:

- Preliminary proposals, such as: general recommendations for evaluation of commercial software [3], generation of Domain-specific quality model to assess software [7], and approach for determining the software selection strategy [25].
- Proposals for the evaluation of specific types of software, such as: ERP [6], data warehouse system [13], and workflow type software [14], among others.
- Frameworks, methods, and tools of assessment and/or selection of OTSS (see Table I). However, in most of these proposals, criteria are repeated or are similar, and related to standard quality models. Unfortunately, criteria associated to software quality evaluate the product and its interaction with the user, but ignore the importance

978-83-60810-53-8/$25.00

of the contribution that assessed system can make to the organization [1]. Therefore, choosing between a proposal and the other, apparently, depends on the value that is given to: application requirements (time, effort, and tools), evaluation criteria, and the complexity of each.

- Methods of Commercial Off-the-shelf (COTS) Selection, such as [12]: OTSO (1995), PORE (1998), STACE (1999), PECA (2002), and CARE (2004), among others. However, these are specific for components, were created for the software development, and do not seem to be adaptable to the different domains and projects [16].
- Assessment services and online software comparison: TEC[1] and Capterra[2]. Although a comprehensive review is allowed, the evaluation criteria are similar to those of Table I, or are wielded in a generical and superficial manner, as is the case of processes.

Therefore, although there are many evaluation proposals, it can be appreciated that there is no evaluation technique based on process models able to allow assessing and comparing OTSS, which could lead to identify their potential effect in the organization.

III. Process-Based Evaluation and Comparison of OTSS

This section presents the PBEC-OTSS (Process-Based Evaluation and Comparison of OTSS) technique, which consists of five stages, and considers six evaluation criteria (see Figure 1), defined from the process perspective.

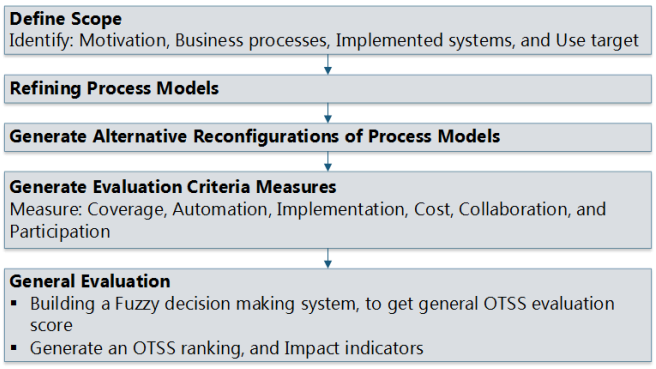

Fig. 1. Process-Based Evaluation and Comparison of OTSS

The details of the stages of the proposal are hereunder described, with an illustrative example, which is based on a real scenario of a Chilean public sector institution, *Solidarity and Social Investment Fund* (FOSIS[3]). The results correspond to evaluation performed by an BPM and IT expert, who was also Case Study expert (see section IV).

A. Define Scope

To establish the assessment dimension, identify: (i)*Motivation*: problems or situations that are intended to be solved or improved, (ii) *Business Processes*, (iii) *Implemented systems*, that participate in the identified processes, and are involved with motivation, and (iv) *Use Target* of each implemented system; i.e., according to the motivation identified, and as a complementary measure, to establish whether to decrease, maintain, or increase current usage level of each implemented system.

Example. (i) *Motivation*: Problems between different areas of the organization with HR, during recruitment. Current Situation: Extensive process cycle, exceeding by 75% the established time limit. Low process standardization, varying its implementation in different regions of the country. High effort, and null automation. High loss information, lack of centralized repository for generated documentation. Low standardization of generated documentation. No versioning of created documents; high dependence of general purpose tools. Therefore, the organization wants to buy a new tool to help them with the problems identified; (ii) *Business process*: Recruitment; (iii) *Implemented systems*: Microsoft Office (Word, Excel, and Access), and e-mail, and (iv) *Use target*: decrease the use of both systems.

B. Refining Process Models

Review process models identified in previous stage. If implemented systems are not specified in process model, or documented as a black box, process model should be refined, specifying for each actor: user's activities, automatic activities, and manual activities (not performed on any system).

Example. Figure. 2 illustrates refined Recruitment process model.

C. Generate Alternative Reconfigurations of Process Models

Review documentation, and identify OTSS functionalities. Subsequently, for each identified process model in previous stage, generate a new process model including OTSS. Each process activities that can cover the OTSS, will exclusively depend on the features identified in the revised documentation. Activities cannot be modified (name and quantity), and automatic activities must be a explicit OTSS feature.

Example. OTSS assessed are PeopleNet Recruitment[4] and Email2DB[5]. Reconfigurations generated are displayed in Figure 3 and 4.

D. Generate Evaluation Criteria Measures

To generate evaluation criteria measures, all models and reconfigurations generated in the previous stages should be considered, and calculate the different types of activities, as specified in Table II.

Example. Table III presents evaluation criteria results, considering Figure 2, 3 and 4.

TA: Total of activities of refined models, **TUA:** Total of user's activities of refined models, **TUAr:**Total of user's activities of alternative reconfigurations, **TAA:** Total of automatical

activities of refined models, **TAAr**: Total of automatical activities of alternative reconfigurations; **TMA:** Total of manual activities of refined models, **TMAr:** Total of manual activities of alternative reconfigurations; **IS:**for each implemented system (of an n total), **G:** Use target (if it is to decrease = -1; if it is to maintain = 0; if it is to increase = 1)

E. Introduction to Fuzzy Logic and Fuzzy Decision Making System

For a better understanding of last stage of the proposal, it is here presented an introduction to the basic concepts of Fuzzy logic [26] and Fuzzy decision making system [15].

Definition 1. *Fuzzy sets*: The fuzzy set theory was proposed in 1965 by Zadeh, where he defines that a fuzzy set is characterized by a membership function that maps the elements of a universe of X discourse to a unit interval [0,1].

Definition 2. *Linguistic variable*: A linguistic variable is a fuzzy variable whose values are categories represented by fuzzy sets. The value of a linguistic variable is a compound term $T(x) = \{L_1, L_2, \ldots, L_n\}$.

Definition 3. *Membership function*: Any function of the form μ_A:X→[0,1] describes a membership function associated with a fuzzy set A. The shape of the membership function depends on the concept to represent and the context in which it is used.

Definition 4. *Fuzzy If-then rules*: They have the structure *If* (x is A_i) and (y is a B_j) *then* (z is C_k)

Definition 5. *Fuzzy decision making system*: Corresponds to a system that is responsible for mapping an input space to a determined output space using fuzzy logic. It comprises four components (see Fig. 5), hereunder detailed.

Fuzzification interface. Inputs are identified, and through membership function, it can be established the degree of membership of each input to the relevant fuzzy set.

Knowledge base. A database that consists of the expert

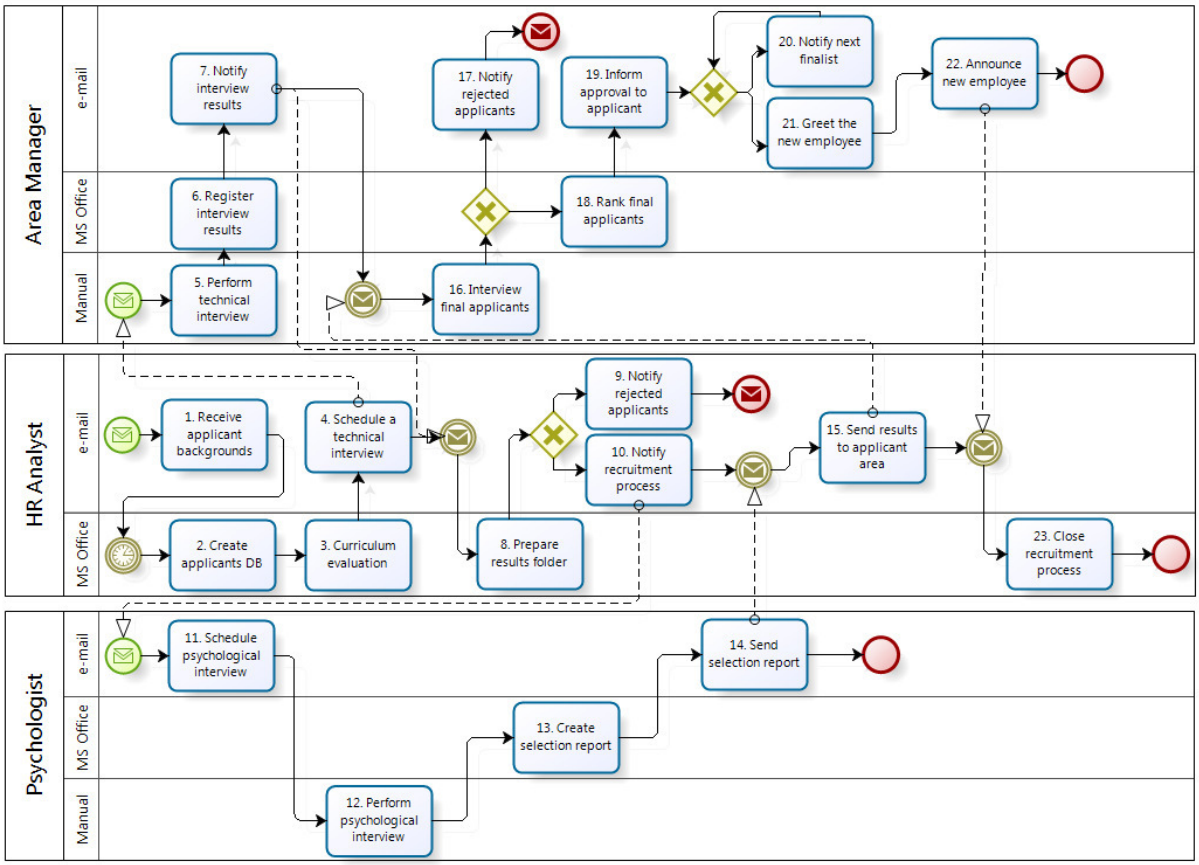

Fig. 2. Refined Recruitment process model

knowledge of the domain in question. In this database are defined the parameters of the membership function, linguistic categories of input and output variables, and set of rules.

Decision making unit. Simulates human decision making, by performing inference using the *fuzzy If-then rules*. For this purpose, first are identified the antecedents of each rule and their relationship; i.e., the various values that every input can take are identified, and related to each other, through logical operators. Subsequently, each antecedent is related to a particular consequent (fuzzy set represented by membership function), by implication operators. Finally, the fuzzy sets representing the output of each rule are grouped in a single fuzzy set.

Defuzzification interface. To the fuzzy set resulting from the previous stage, it is applied a defuzzification method to obtain a single value, which corresponds to the final result.

F. General Evaluation

Building a Fuzzy decision making system, to get general OTSS evaluation score. Following is part of used structure.

Fuzzification interface and Knowledge base. The inputs correspond to evaluation criteria results obtained in the previous stage. Based on the knowledge and experience of two BPM experts, it was defined for each input, linguistic terms, their membership functions, and domain (see Table IV).

Decision making unit. Antecedents of fuzzy rules are: Coverage and Automation and Cost; Coverage and Automation and Implementation; Implementation and Cost; Collaboration and Participation. Consequent for all rules is Evaluation.

Defuzzification interface. Defuzzication method used is centroid, and output corresponds to OTSS evaluation result. Finally, according to OTSS evaluation result, generate an OTSS ranking, indicating percentages obtained by Coverage, Automation, and Implementation criteria, which together correspond to *Impact Indicators*.

Example. Table V presents OTSS evaluation result, delivered by fuzzy decision making system, considering as input the evaluation criteria results of Table III.

G. PBEC-OTSS Benefits

The main benefits of PBEC-OTSS are: (i) favors Business/IT alignment, (ii) improves decision making, i.e., decision making is well informed, and with less uncertainty, (iii) provides new information, which can serve as an antecedent for reducing time and efforts.

IV. Case Study

The purpose of the case study was to evaluate quality of results, duration, and use satisfaction, of PBEC-OTSS. In this regard, it was compared with an Ad-Hoc approach,

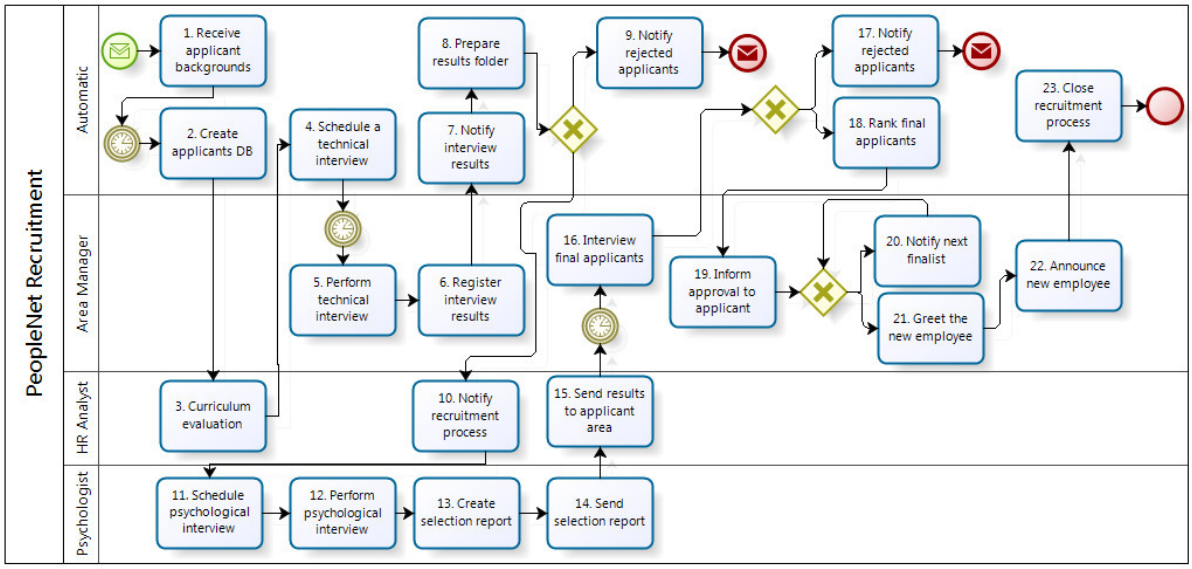

Fig. 3. Reconfiguration of Recruitment process model including PeopleNet Recruitment

TABLE IV
KNOWLEDGE BASE

Input	Linguistic term	Membership function	Domain
Coverage	Very low	Trapezoidal	0% - 21%
	Low	Trapezoidal	19% - 41%
	Medium	Trapezoidal	39% - 61%
	High	Trapezoidal	59% - 81%
	Very high	Trapezoidal	79% - 100%
Automation	Very high decrease	Trapezoidal	-100% - -29%
	High decrease	Trapezoidal	-31% - -19%
	Medium decrease	Trapezoidal	-21% - -9%
	Low decrease	Trapezoidal	-11% - 0%
	Equivalent	Triangular	-2% - 2%
	Low increase	Trapezoidal	0% - 11%
	Medium increase	Trapezoidal	9% - 21%
	High increase	Trapezoidal	19% - 31%
	Very high increase	Trapezoidal	29% - 100%
Implementation	High decrease	Trapezoidal	-100% - -29%
	Medium decrease	Trapezoidal	-31% - -14%
	Low decrease	Trapezoidal	-16% - 0%
	Equivalent	Triangular	-2% - 2%
	Low increase	Trapezoidal	0% - 16%
	Medium increase	Trapezoidal	14% - 31%
	High increase	Trapezoidal	29% - 100%
Cost	Very low	Trapezoidal	0 - 0.21
	Low	Trapezoidal	0.19 - 0.41
	Medium	Trapezoidal	0.39 - 0.61
	High	Trapezoidal	0.59 - 0.81
	Very high	Trapezoidal	0.79 - 1
Collaboration Participation	Null	Triangular	0% - 1%
	Low	Trapezoidal	1% - 10%
	Medium	Trapezoidal	11% - 40%
	High	Trapezoidal	41% - 100%

through an experimental study, where to each approach was simultaneously applied [24].

TABLE V
OTSS EVALUATION RESULTS

No.	OTSS	Impact Indicators
1	PeopleNet **82.5**	**61%** Coverage, **39%** Automation, **13%** Implementation
2	Email2DB **73.5**	**39%** Coverage, **30%** Automation, **0%** Implementation

A. Approaches to Experimental Study

PBEC-OTSS. The aim of this approach is to evaluate and compare OTSS using processes models, and fuzzy decision making systems. The result is OTSS ranking, and impact indicators.

Ad-Hoc Approach. The objective of this [10], [11] is to evaluate OTSS through five criteria (Functionality, Reliability, Cost, Ease of customization, and Ease of use). The result is a score for each OTSS analyzed.

B. Experimental Study Design

Experimental study was designed to be done by professionals who finished a *Diploma in Process Management and IT* (196 hrs. postgraduate program taught by a Chilean university). Of all participants, two groups were formed. Simultaneously, one group applied PBEC-OTSS and other applied Ad-hoc approach. The assignment to each group was random, but mark and professional experience of each participant were considered. Thus, they sought the greatest homogeneity between groups, and prevented the influence on the results of factors such as experience or knowledge.

C. Instrumentation

Materials used by participants of both groups were the same: Instructive, Personal Data Questionnaire, Problem Definition,

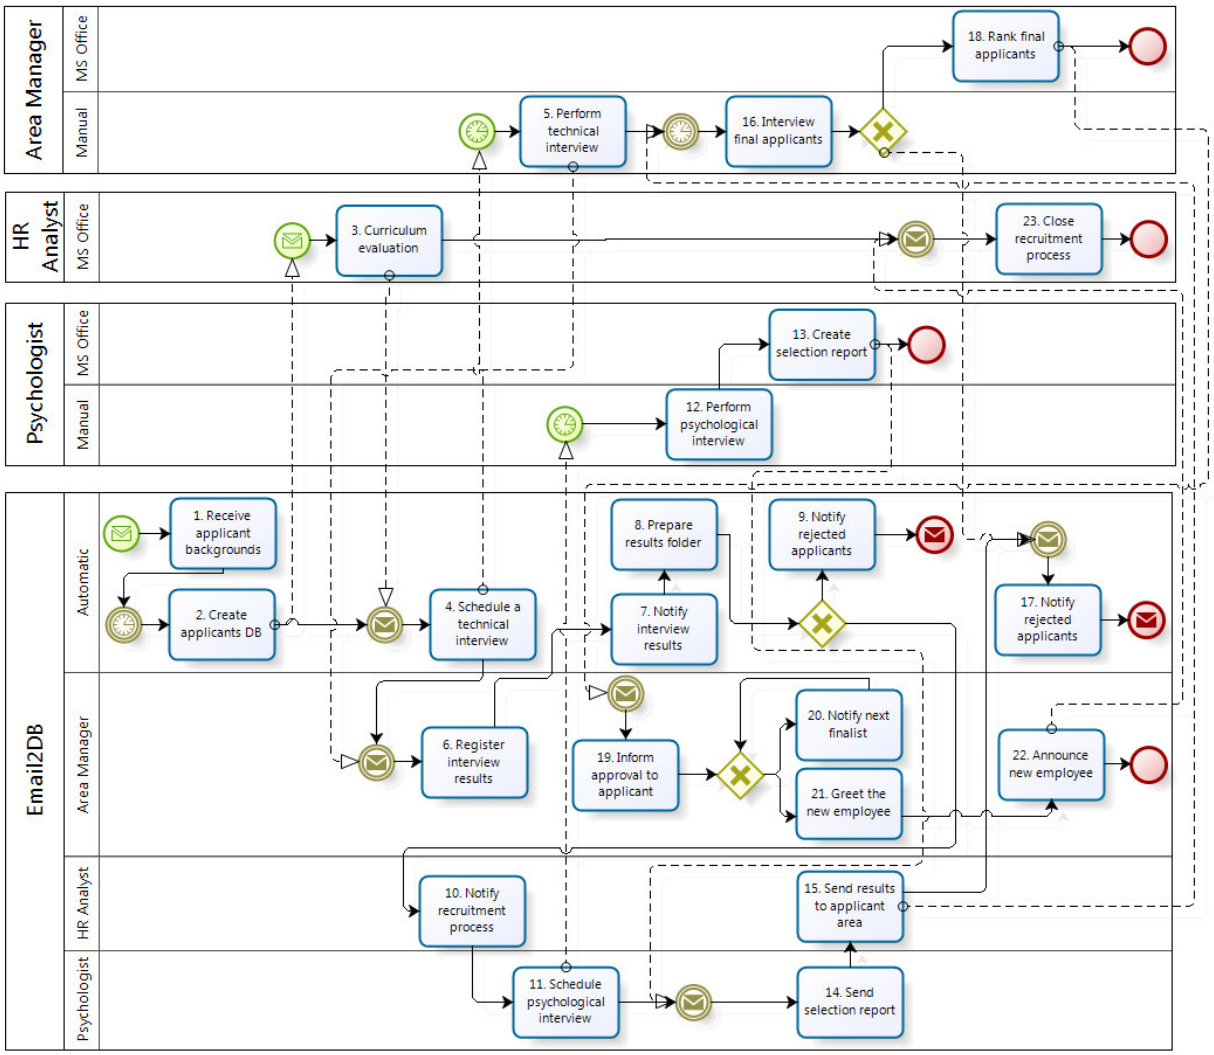

Fig. 4. Reconfiguration of Recruitment process model including Email2DB

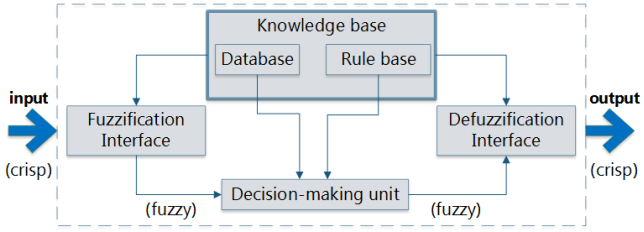

Fig. 5. Fuzzy decision making system [22]

Recruitment Process Description and Model, OTSS Documentation, How-to approach, Questionnaire on applied assessment approach. For both approaches, the problems, process, and OTSS to evaluate were the same as those presented in Section III example, which was adapted to be resolved in a maximum of two hours (time calibrated by previous execution of a pilot experiment). In addition, the OTSS real name was omitted, to avoid influence on the results, due by possible foreknowledge of these.

D. Experimental Study Execution

The participants were 13 Chilean IT professionals, who held positions as Software Engineer, Project Manager, Process Engineer, or Consultant, and Area Assistant Manager. Six of these used PBEC-OTSS, and seven Ad-hoc approach. None of them had previous experience in any of two approaches. Table VI presents group and expert characteristics (in average years).

Each group was trained in its respective approach. The training was conducted in parallel, same day and time, but in different rooms and with different instructors. The results of each approach were compared with results obtained by an BPM and IT expert, who performed the same experiment (see results in Section III example).

TABLE VI
GROUP AND EXPERT CHARACTERISTICS

Characteristic	PBEC-OTSS	Ad-Hoc	Expert
Age	32.3	30.6	56
Professional experience (total)	6.8	6.6	26
Process modeling experience	2.2	2.6	20
Experience about IT decision	1.3	1.4	15

E. Experimental Results and Analysis

Table VII presents participants and expert results. Table VIII shows average duration and average rating of the application of each approach (where 1 is very low and 5 is very high).

TABLE VII
PARTICIPANTS AND EXPERT EXPERIMENTAL RESULTS

	PeopleNet Recruitment		Email2DB	
	PBEC-OTSS	**Ad-Hoc**	**PBEC-OTSS**	**Ad-Hoc**
Subject 1	82.5	72.9	82.5	57.2
Subject 2	82.5	78.4	79.5	69.1
Subject 3	85.5	78.7	73.5	45.2
Subject 4	82.5	75.5	79.5	42.4
Subject 5	73.5	80.3	67.5	58.3
Subject 6	82.5	78.7	82.5	34.7
Subject 7	-	79.2	-	66.8
Average	81.5	77.7	77.5	53.4
Standard Deviation	4.1	2.6	5.9	12.9
Expert	**82.5**	**79.4**	**73.5**	**71.0**

TABLE VIII
DURATION AND QUALIFICATION OF APPROACHES

	PBEC-OTSS	Ad-Hoc
Duration	56.8 minutes	45.7 minutes
Difficulty	3.67 points	3.71 points
Satisfaction	3.67 points	3.57 points
Recommendation	100% yes	86% yes, 14% no

The results in Table VII and VIII show that:

- For PeopleNet Recruitment, both approaches generated similar results with respect to expert, with an acceptable variation of 1% for PBEC-OTSS, and variation of 2% for Ad-Hoc.
- For Email2DB, approaches differ, PBEC-OTSS presents better results than Ad-hoc approach. Respect to expert, PBEC-OTSS has 5% variation, while Ad-hoc approach has 25% variation.
- Regarding duration, PBEC-OTSS takes 11 minutes more than Ad-Hoc, this could be due to greater degree of PBEC-OTSS difficulty. Despite this, average satisfaction qualification, and recommendation rate is higher for PBEC-OTSS.
- Comparing both approaches, expert results are similar, this could be due both techniques have a expert knowledge base. PBEC-OTSS uses fuzzy decision making systems built with parameters identified by two BPM specialists (different to case study expert), and Ad-Hoc approach was based on a survey of MIS managers.

Therefore, for complex cases (Email2DB), PBEC-OTSS reduces the risk of an inadequate evaluation, by presenting reasonable results and close to an expert. While for simple cases (PeopleNet Recruitment), both approaches are similar.

V. CONCLUSION

It was proposed PBEC-OTSS technique, that allows evaluate and compare OTSS, measuring its possible contribution to an organization. This proposal considers six criteria (Coverage, Automation, Implementation, Cost, Collaboration, and Participation), based on process models and fuzzy decision making systems. The main benefits of PBEC-OTSS are: favors the Business/IT alignment, and improves decision making.

PBEC-OTSS was compared with an Ad-Hoc approach, in an experimental study, based on real scenario of a Chilean public sector institution. 13 IT professionals participated, and a BPM and IT expert. The professionals results showed that for simple cases PBEC-OTSS is similar to Ad-hoc approach, while for complex cases, the techniques differ, being PBEC-OTSS the best. Additionally, it was observed that when applying both approaches (PBEC-OTSS and Ad-Hoc) by an expert, the results were very similar, which could infer that PBEC-OTSS results, appear to be comparable with a technique from the literature. Although experimental study was conducted with two specific software, PBEC-OTSS is applicable to other types of software, and in any type of organization, because PBEC-OTSS focuses on Business/IT alignment.

Finally, based on the study and analysis fulfilled, we identified the following topics of interest to perform as future work: adaptation of the technique proposed so that the assessment to include different levels of activities importance, inclusion of new experts to redefine Fuzzy decision making system configuration parameters, and new experimental study with a greater number of professionals, experts, and other real scenario of an public or private sector institution.

***Abstract*—Comparative studies of auction and negotiation exchange mechanisms have typically compared the outcomes obtained from the two mechanisms. Their result are inconclusive. The question which this paper aims to address is the viability of outcome-based comparisons. Such comparisons assume that both mechanisms produce the same types of outcomes but their values differ. An argument can be made that this is not necessarily the case. Based on several experiments of multi-attribute auctions and two formats of multi-bilateral negotiations the paper argues that the two mechanisms produce some outcomes which are comparable and other outcomes which are qualitatively different. A surprising finding of our experiments is that the outcomes of the non-verifiable negotiations were more similar to the outcomes of the reverse auctions than to the verifiable negotiations, despite the fact that the latter employ rules taken from the auction mechanism.**

I. Introduction

AUCTIONS and negotiations are exchange mechanisms used by individuals and institutions including, among others businesses and governments. There are many kinds of auctions and negotiations and their underlying rules and regulations are well established, leaving however, some space for adjustment in individual cases. The opportunities created by the internet technologies and the web engaged researchers in captivating discussions about the viability of conducting business transactions over internet. Early on, arguments were made that on line auctions will replace negotiations, that there will be a paradigm shift where market forces will replace the more subtle domain of negotiation skills [1-3]. In 2000, a group of researchers gathered in Montreal to discuss the issue. They concluded that there are limits to auctions and consequently not all electronic transactions lend themselves to auctions [4]. One of the outcomes of the Montreal workshop was a framework for designing e-negotiations [5].

In order to gain some clarity about the strengths and weaknesses of these two types of transaction mechanisms it is necessary to compare them. Broadly speaking, there are two types of negotiations, i.e. bilateral and multilateral (each type can be either simultaneous or sequential). There are different types of auctions, including price-only and multi-attribute forward and reverse auctions. The discussion here is restricted to multi-bilateral reverse auctions, henceforth called auctions.

Bilateral negotiations appear to be comparable to auctions. Experimental studies [6, 7] and field studies [8-10] comparing auctions with bilateral negotiations indicated that auctions are used in different situations than negotiations, namely, auctions are used when: (1) the exchanged goods (services) have only one attribute – price; (2) there are several (possibly many) suppliers of the good (service); and (3) there is no need to communicate (exchange information). Negotiations, on the other hand, are used when: (1) one or more of the above conditions do not apply; and (2) there is a strong likelihood of future interaction.

It is difficult to compare auctions and negotiations because they are very different mechanisms—on the general level the assumptions underlying each mechanism differ significantly, on the specific level there are differences in participants' knowledge and behavior. Auctions involve multiple bidders who compete for the same good or service; it is assumed that that bidders follow a strict, fixed protocol and that they know the buyer's price (valuation). Other than submitting bids, there is no other form of communication. In contrast, negotiations rely on significantly weaker assumptions; it is assumed that the parties negotiate in good faith and that each party has preferences so that they may compare alternatives. No assumption about the sellers' knowledge of the buyer's valuation is made.

Another reason why it is difficult to compare auctions and negotiations are the differences in settings and protocols. Studies mentioned above compared auctions with *N* bidders with bilateral negotiations (i.e., 1:1). In this situation the competition among sellers, which is a key characteristics of reverse auctions, disappears in negotiations with only one seller. In order to maintain competition among sellers in negotiations, bilateral negotiations need to be replaced with

978-83-60810-53-8/$25.00

multi-bilateral negotiations, in which a single buyer negotiates with many sellers. Furthermore, these negotiations should be simultaneous rather than sequential so that the organization of both auction and negotiation processes are similar.

Thomas and Wilson [11-13] compared auctions and multi-bilateral negotiations. They set up several experiments making sure that for the sake of comparison the mechanisms were structurally similar, namely, there were N participants in auctions and N:1 participants in multi-bilateral negotiations. The experiments lasted 4 minutes and involved a single attribute–price. Despite the particular setting, the auctions' outcomes were not significantly better than the negotiations' outcomes.

Comparative studies of auctions and negotiations are not only difficult, they are also inconclusive. Bulow and Klemperer [14] showed that simple English auction with N+1 bidders (buyers) always yields higher revenue than a scheme they call "negotiation with N participants". Manelli and Vincent [15] demonstrated that the outcomes of auctions and negotiations depend on situations; they noted that in order to judge the effects of the two exchange mechanisms it is necessary to consider the overall context, including the goods, participants, market, and so on. They concluded that auction mechanisms are often inefficient in a procurement environment.

The above examples indicate that typically the process substantive outcomes, that is the values of the attributes, were used to compare auctions and negotiations. This paper also starts from this position. Excluding the discussion on the differences in organizing auctions and negotiations, it is important, from the pragmatic point of view, to identify the potential differences in results achieved if the same contract can be negotiated or established by means of an auction. Therefore, the first question is: *Is it worth spending time and money for often difficult negotiation rather than setting up an auction which reduces the bid-taker involvement in the process of contract designing to the minimum?*

In order to address this question, several experiments were conducted which compared multi-attribute reverse auctions and multi-bilateral negotiations. The auctions and the negotiations experiments comprise the first study discussed here.

In this first study experiments showed that the buyers received higher profits in auctions than in negotiations. Auctions were also more efficient. The possible explanation is that the negotiation protocol followed a typical rule and did not allow the sellers to obtain independent information about the best offer that the buyer received from one of the sellers. The auctions followed the rule that the winning (best) offer is displayed to all bid-makers (sellers). This makes auctions more transparent mechanisms than negotiations and could have placed auctions at an advantage over negotiations.

Thomas and Wilson [13] compared auctions and verifiable negotiations in which the best offer was displayed to all participants. Their experiments were stylized, meaning that there was no context, the sole issue was price, and the time allotted was four minutes. They used the sealed bid auction protocol which removed the dynamics of iterative multiple bids auctions and made it dissimilar to negotiations. Consequently, their results showed that for buyers, auctions produce better outcomes than both negotiation and that verifiable negotiations are better than non-verifiable. This latter result is surprising because it states "that providing sellers with more information about their rivals' price setting behavior unexpectedly leads to higher rather than lower prices" [13, p. 1030].

In our experiments the participants represent firms, their exchange problem is described in detail, there are three issues, and the allotted time is ten days. Following Thomas and Wilson's results we sought to address the following question: *Do multi-attribute verifiable negotiations produce worse results for sellers that the non-verifiable ones in a business context?*

In the second study we conducted exploratory experiment with the two types of negotiations. The result of the second study confirmed results obtained by Thomas and Wilson [13], i.e. the sellers were worse off in the negotiations with verifiable offers than negotiations with no verifiable offers. We were not able, however, to determine whether these results were statistically significant.

The third study builds on the previous two and addresses both questions formulated above. In this study we included auctions in order to compare the three mechanisms. The results of the third study confirmed the results obtained in the earlier two studies. This means that less transparent negotiations produce results which are better for the buyers (and worse for the sellers) and which are closer to the auction results than the results of more transparent negotiations.

The third study led to an observation that the buyers could run verifiable negotiations following the same protocol as the iterative auction protocol, which was not possible in Thomas and Wilson's [13] experiments. Consequently, in verifiable negotiations the buyers could achieve profits similar to the profits achieved by buyers in auctions. A possible reason for this outcome is that negotiation participants seek outcomes which are not possible to achieve in auctions. We conclude this paper with a discussion on the viability of outcome-based comparisons. When comparing outcomes, an assumption is made that both mechanisms produce the same types of outcomes and only their values differ. This is in contradiction with the social exchange theory.

II. Two Studies

Several experiments in which the participants used auction and negotiation web-based systems were conducted. These experiments and their results are briefly.

A. The case and two systems

In the Milika case a producer of perishable goods (the buyer) wants to sign a contract with one of the several logistics providers who offer their services. The minimum quantity of goods to be transported is a fixed part of the contract but three attributes must be negotiated, i.e. standard rate of transportation, rush rate for unexpected delivery, and penalty for the non-delivery or delivery of spoiled goods. Each attribute has a discrete number of options (fifteen per attribute) resulting in the total of 3375 possible agreements. All issues are specified and cannot be changed during the experiment.

The system relies on a single criterion used to compare alternative bids and offers, for example, utility, production, cost and profit functions. In the Milika case the selected function is quasi-linear and it describes profits of the buyer and the sellers. The profit function is different for different participants and its values (normalized between 0 and 100) are not disclosed to anyone.

Also the systems give the sellers breakeven points. Anything below these points means losses for the sellers' companies. This implies that the sellers should be careful not to cross these levels as their objective in both the auction and the negotiation is to obtain a contract that maximizes profit.

Two systems were used in the experiments—both implemented on the Invite e-negotiation system platform [16] -- (1) Imaras (InterNeg multi attribute reverse auction system); and (2) Imbins (InterNeg multi-bilateral negotiation system).

B. Study 1

There were six different lab and online auction and negotiation experiments. The results of these experiments are hardly comparable because of differences in: (1) the controlled variables, e.g., number of sellers (from two to six), number of alternatives (360 vs. 3375), and the participation of software agents (in one experiment); and (2) the process design, (e.g., fixed and flexible rounds, introduction of video, tests, and handouts). The results showed that, with the exception of one experiment, in auctions the sellers achieved very low and the buyers' very high profit. Table 1 illustrates two selected experiments.

TABLE 1.
STUDY 1: AUCTION AND NEGOTIATION EXPERIMENTS.

	Experiment 1		Experiment 2	
	Auction	Negotiation	Auction	Negotiation
No. of instances	17	40	27	23
No. of sellers	74	151	95	89
No. of offers (avg.)	4.4	3.0	**5.6**[*]	3.1
Agreement (%)	—	95	—	96
Seller's profit	3.9	19.9	**-7.4**[*]	23.4
Buyer's profit	66.9	52.6	**75.7**[*]	47.1
Dominating alt. (%)	6.4	1.9	4.0	4.0

[*] Significance compared to negotiations, $p < 0.01$

Sellers in the auctions made more offers than sellers in the negotiations. Their average profit was low, 3.9 in Experiment 1 and -7.4 in Experiment 2. In the latter experiment, the sellers' winning bid was (on average) a little below their breakeven value. In comparison, successful negotiators achieved a profit of 19.9 and 23.4, respectively in Experiment 1 and 2. In Table 1 we show that buyers achieved higher profit in auctions than they did in negotiations.

Table 1 also shows that the efficiency of the two mechanisms' is measured by the percent of alternatives which dominate the agreements. These results are not conclusive. In Experiment 1, auctions were less efficient than negotiations (6.4% of alternatives dominated the winning bids vs. and 1.9% of alternatives dominated agreements), while in Experiment 2 the two mechanisms were equaly efficient.

C. Subjective and objective concessions

An analysis of the results in Experiment 2 led to verification of the concession-making model in the auctions and the negotiations in which subjective and objective concessions were proposed [17]. The difference between these two types of concessions is the basis of comparison. A subjective concession is determined by two consecutive offers, i.e., made at t_1 and t_3 as shown in Fig. 1, both made by the same concession-maker. An objective concession is determined by two offers, the best offer on the table (market), which the concession-taker received at time t_2 from any concession-maker and the offer made at time t_3.

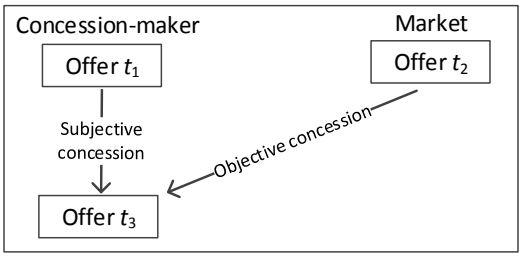

Fig. 1 Objective and subjective concessions

Subjective concessions occur in bilateral negotiations, in which both the concession-maker and the concession-taker can compare offers made by the same concession-maker. In multi-bilateral negotiations, in which one side is represented by many and the other side by a single negotiator (the case presented in Section II, A), objective concessions are possible. Their use requires significant transparency of the process and a fixed protocol, which typically are not employed. We know of only one negotiation study—done by Thomas and Wilson [13], in which objective concessions were made possible. In their study both the process and the systems were highly stylized and devoid of context.

Objective concessions are typical for these auctions in which the winning bid is shown to the bidders. Every bidder either submits a bid that is better (for the bid-taker) than the winning bid or drops out from the auction. The difference between the winning offer (on the market) and the submitted bid is the objective concession.

The sellers' profits given in Table 1 are the results of the concessions they made; the sellers made significantly greater concessions in the auctions than in the negotiations. The reason could be attributed to transparency: in the auctions the sellers knew the best bid, however, not in the negotiations. In the negotiations, even if the buyer sent information about the best offer she had received, this offer could not have been verified, hence the sellers may have considered it as a ploy. Realization of the above led us to a design of a negotiation experiment in which a version of the Imbins system displays the best offer on the table in the same way the Imaras does.

D. Study 2

Table 2 shows the results of the second study (Experiment

3). The column "Non-verifiable" results shows instances, when the Imbins system did not display the best offer; that is, the buyer could have shown the best offer but it could not have been verified by the sellers. The "Verifiable" column shows the results of the multi-bilateral negotiations, in which the system displayed the best offer.

TABLE 2.
STUDY 2: NEGOTIATION EXPERIMENT WITH VERIFIABLE AND NON-VERIFIABLE OFFERS.

	Experiment 3	
Best offers:	Verifiable	Non-verifiable
No. of instances	12	13
Sellers		
No. of sellers	33	35
No. of offers (avg.)	4.0	4.4
No. of offers w/out message (avg.)	1.0	1.2
No. of messages w/out offers (avg.)	1.3	0.6
Agreement (%)	100	92
Seller's profit	19.1	22.3
Dominating alt. (%)	4.0	4.0
Buyers		
No. of offers (avg.)	7.4	7.2
No. of offers w/out message (avg.)	1.0	1.5
No. of messages w/out offers (avg.)	2.9	1.4
Buyer's profit	53.3	48.0

Contrary to our expectations there were no significant differences between the two types of negotiations. We thought that the negotiations with verifiable offers would result in a significantly higher profit for the sellers than the negotiations with non-verifiable offers.

E. Discussion

The restrictions imposed on the negotiation protocol were severe but necessary. A fluid and evolving negotiation process with issues coming and going and preferences changing, cannot be compared with fixed protocol auctions. Verifiable offer negotiations have the same degree of transparency as auctions but they differ in the following three aspects:

1. The negotiating sellers are not forced to make positive objective concessions, i.e., make offers which are better for the buyer than the best offer on the table;
2. The negotiators can exchange messages with and without accompanying offers; and
3. The buyer can make offers.

The impact of the first difference needs to be further studied, but it does not appear to have potential for changing the process because both sides know about the best offer. Hence, sellers who (would) submit a worse offer than the best offer (make negative objective concessions) would do it knowing that the buyer has a better offer on the table. There may be, however, a good reason for these seller to do so, for example, if they offer some additional benefits for the buyer in the message that accompanies the offer.

The free-text communication with the buyer and the buyer's interaction with the seller are the remaining two key differences between auctions and negotiations (with fixed issues and options). Table 2 shows that in both the verifiable and the non-verifiable negotiations the sellers sent messages to the buyers (there were as many buyers as instances). About 75% of offers were accompanied by messages. In addition, every seller sent, on average, 0.6 messages in the non-verifiable negotiations and 1.3 messages to which no offer was attached.

The buyers used their ability to communicate with the sellers, as shown in Table 2. In the negotiation with non-verifiable best offer they made 7.2 offers, of which, on average, only 1.5 were without a message attached. They also sent 1.4 messages without an offer. The results are similar in the verifiable negotiation, with the exception of messages sent with no offer attached—2.9 on average, i.e., over twice as many as in the non-verifiable negotiation. This difference is attributed to two sellers who sent about four times more messages than other sellers. If we remove these two sellers from the dataset, then the averages are similar for both types of negotiations.

The number of offers made by the buyers is much greater than the number of offers made by the sellers because buyers made offers to three sellers, per instance (the number of sellers shown in Table 2 is smaller because inactive sellers were removed from the analysis). The buyers could make an offer and send a message to any subset of sellers (one, two or three), but they often addressed their communique to a single seller.

III. STUDY 3

Experimental comparison of the verifiable and non-verifiable negotiations done in Study 2 did not result in statistically significant results. Although there were some notable differences (e.g., in the buyers' and the sellers' profits), the number of instances was small and the distribution too large to obtain significant results. While there is an indication that, in terms of profits, verifiable negotiations can be positioned in-between auctions and non-verifiable negotiations, we were not able to test this result. Therefore, we conducted a third study that looked at auctions and the two types of negotiations.

A. Auctions and two negotiations experiments' settings

The experiment was conducted in spring 2013 and there were 583 students who participated in it as sellers and 83 students who were buyers. Students came from four universities (located in Canada, the Netherlands, Poland and Taiwan). Because of the differences in the student groups, the requirement that students from one group could participate either in the auction or negotiation but not both, and that students from the same group could not be buyers and sellers, the instances were formed with four and five sellers.

The experiment was conducted online and, as it is often the case, a number of participants were no-shows, dropped out or did not undertake any activity; in this experiment 21% of the students, who played the role of sellers had to be removed from the analysis.

The buyers' average profit values in Experiment 4 were lower than in the earlier experiments because in this experiment the breakeven value for buyers was increased from 16 to 48. The purpose of this change was to place buyers and

sellers on a relatively equal level; both the buyers and the sellers could achieve similar profit values. In negotiations, profit values were greater than the 50-60 units on a [0; 100] scale, which means that the buyers may have been led to make concessions which they would not have otherwise made. This is because of their expectations and the perceived fairness.

B. Results

The results of the third study (Experiment 4) are shown in Table 3. As before, the column "Verifiable" shows the results of the multi-bilateral negotiations, in which the system displayed the best offer made by a seller and the "Non-verifiable" column—where these offers were not displayed. In addition the column "Auctions" refers to the results from the multi-attribute auction experiment.

TABLE 3.
STUDY 3: AUCTIONS AND NEGOTIATIONS WITH VERIFIABLE AND NON-VERIFIABLE OFFERS.

	Experiment 4		
	Auctions	Verifiable	Non-verifiable
No. of instances	38	42	39
No. of sellers	173	147	141
Duration (days, avg.)	**3.35**	**4.63**	**6.20**
Agreement (%)	100	100	100
- Buyer's offer accepted (%)	—	30 (71)	24 (61)
- Seller's offer accepted (%)	38 (100)	12 (29)	15 (39)
Total profit	38.7	39.6	39.7
- Buyers' profit (avg.)	**45.9**	**20.8**	**27.8**
- Sellers' profit (avg.)	**-7.2**	**18.8**	**11.9**
Efficiency			
- Allocative	0.4	0.4	0.4
- Pareto	**3.5**	**81.5**	**38.1**
	Sellers		
No. of offers (avg.)	**9.6**	**5.5**	**4.9**
No. of messages (avg.)	—	**5.9**	**4.7**
Messages' length (words, avg.)	—	**219**	**182**
	Buyers		
No. of offers (avg.)	—	**10.6**	**12.2**
No. of messages (avg.)	—	**12.3**	**15.3**
Messages' length (words, avg.)	—	193	188

The data shows that the auctions took the least time to conclude, followed by the verifiable negotiations, then by non-verifiable negotiation. These differences are significant: for auctions and verifiable negotiation $p < 0.004$; for auctions and non-verifiable negotiation $p < 0.001$; and for verifiable and non-verifiable negotiations $p < 0.001$. This result places verifiable negotiation in-between auction and non-verifiable negotiation in terms of process efficiency.

In addition to the process time we used the number of offers to compare the three mechanisms and the number of messages (with and without offers) to compare the two types of negotiations.

The sellers participating in auctions made significantly more offers (9.6 on average) than the sellers participating in verifiable (5.5, $p < 0.001$) and non-verifiable negotiations (4.9, $p < 0.001$). The difference in the average number of offers made by sellers in the two types of negotiations is not significant.

The average number of messages sent by the sellers was not significantly different in the verifiable and non-verifiable negotiations (5.9 vs. 4.7). However, the average total length of messages (measured in words) was significantly ($p < 0.025$) different in the verifiable and non-verifiable negotiations (219 vs. 182 words).

The buyers participating in the verifiable negotiations made fewer offers (10.6, on average) than the buyers participating in the non-verifiable negotiations (12.2, on average). This difference is not significant ($p = 0.145$).

The average number of messages sent by the buyers is significantly different ($p < 0.05$) in the verifiable and non-verifiable negotiations (12.3 vs. 15.3). However, the average total length of messages (measured in words) is not significantly different ($p = 0.440$) in the verifiable and non-verifiable negotiations (193 vs. 188 words).

The comparison of the three mechanisms based on profits shows a different picture. Both types of negotiations resulted in a very similar total profit; auctions yielded a smaller profit than negotiations. These differences are, however, not significant. This result is interesting because the total profit (social welfare or value allocation) has been frequently used as an indicator of mechanism efficiency [see, e.g., 18, 19, 20]. Our results, however, imply that auctions are no more efficient than the negotiations.

Profit distribution is, however, very different. The auctions were best for the buyers and worst for the sellers, who incurred losses (on average). The non-verifiable negotiations were in-between—they were worse for the buyers and better for the sellers than auctions but better for the buyers and worse for the sellers than the verifiable negotiations (Table 3). These results confirm the negotiation results obtained in Study 2 (Table 2).

The differences between the three mechanisms in terms of the achieved profit are significant. The buyers' profit significance is: for auctions and verifiable negotiations $p < 0.001$; for auctions and non-verifiable negotiations $p < 0.001$; and for verifiable and non-verifiable negotiations $p < 0.01$. The buyers' profit significance is: for auctions and verifiable negotiations $p < 0.001$; for auctions and non-verifiable negotiations $p < 0.001$; and for verifiable and non-verifiable negotiations $p < 0.02$.

Markets are evaluated based on the efficiency of their mechanisms. We used two efficiency measures (see Table 3): allocative efficiency and Pareto efficiency.

Allocative efficiency is the ratio of the average total profit achieved and the maximum total profit that is possible to achieve by the winner. In this work, we used allocative efficiency in a somewhat different way than typically used in economic literature. Rather than using the absolutely maximum total profit, which is the highest possible profit for the theoretical winner (i.e., across all bidders), we used the maximum profit available to the winning bidder. This shows the difference between what the winner achieved and what she could achieve.

The reason for using winner-dependent allocative efficiency is that it can be compared with Pareto efficiency, which is the average number of alternatives dominating the

winning offer. The dominating alternatives need to be selected from the winner's set of feasible alternatives, otherwise the Pareto efficiency is not be comparable across different instances. This is because the value depends on both the winner's and the theoretical winner's feasible sets so that an efficient winning offer can become an inefficient one.

Allocative efficiency is the same for all three mechanisms: they are 40% efficient, which is quite low. Pareto efficiency is significantly different across these mechanisms. On average, there are only 3.5 alternatives, which dominate the winning offer in auctions, but there are 81.5 and 38.1 dominating alternatives in, respectively, verifiable and non-verifiable negotiations. We find these results surprising for two reasons. The first reason is that allocative efficiency is the same but there are significantly more dominating alternatives in negotiations than in auctions. This suggests that the negotiation efficiency can be improved (particularly verifiable negotiation) but there is very limited possibility to improve auctions' efficiency.

The second reason is that auctions produce results, which are close to Pareto frontier (only 3.5 offers dominate the winning offer) but their allocative efficiency is low (0.4). This seems to contradict auction theory which posits that Pareto efficient winning offers are also allocative efficient [18, 21, 22]. This result is related to the exchange problem used in our experiments which did not have a quasi-linear evaluation function, which, in the business case, is profit.

C. Negotiations like auctions

We mentioned above that while the verifiable offer negotiations have the same degree of transparency as auctions, they also differ. The involvement of the buyer (who can present her offers and engage in discussion with individual sellers on any topic they wish) is one of the key differences between auctions and negotiations. This difference, however, need not occur in any given negotiation; because the sellers are shown winning offers the buyers may decide to be inactive. In other words, the buyers may change the negotiation process to auctions without giving any information to sellers a priori.

An analysis of the verifiable negotiations transcripts (Experiment 3) showed that some buyers behaved similarly to the buyers in auctions and did not engage in negotiation activities. This means that this type can be divided into two sub-types: (1) negotiation-like-auctions; and (2) multi-bilateral negotiations.

We investigated the negotiations in which the buyer was inactive for some period of time, analyzing the sellers' actions when they received neither messages nor offers from the buyer. There were 10 instances with 31 sellers who faced the problem of inactive buyer in Experiment 3. These sellers decided to submit new offers, even though they did not receive any answer from the buyer regarding the offers they had sent earlier. In eight instances fourteen sellers sent on average 2.7 offers before their counterpart (buyer) replied. The buyer did not respond until the negotiation deadline in the remaining two instances with nine sellers. In these instances the sellers sent 3.9 offers, on average.

In general, in the inactive-buyer negotiations the sellers submitted on average 2.9 offers, which were not replied to with any counteroffer of the buyer. While reviewing the sellers' negotiation transcripts and their assignment reports we could not find their motivation for doing this.

The sellers could sent offers in order to get the buyer's attention and to induce them to start messaging during which they could convince them to accept the sellers' own offers or they could get involved in the bidding game with other sellers, hoping to eliminate them by sending at this stage of the negotiation process the offers more beneficial for the buyers than the ones submitted by their competitors.

The similarity of the verifiable negotiations and auctions was also noticed by the sellers in their post-negotiation feedback. The participants of auctions described their activities and behaviour in terms of the bidding process (e.g., "I bid", "the other bidders", and "the auction rounds"). In contrast, the participants of non-verifiable negotiations used terms such as: "the counterpart", "I submitted an offer", "tried to achieve a compromise".

The participants of non-verifiable negotiations, however, did not employ negotiation terminology uniformly. In 9 out of 13 feedback messages (69%) they described the negotiation process as a bidding process with bidding rounds and bids submitted by the parties, which is typical for auctions rather than negotiations. This suggests that some participants viewed verifiable negotiations as negotiation-like auctions. Taking into account the fact that some sellers in buyer-inactive instances behaved in a way typical to bidders in auctions (they did not wait for the buyer's response before making a new offer), we may conjecture that verifiable negotiations may be seen as a mechanism in-between auctions and traditional (i.e., non-verifiable) negotiations.

D. Discussion

The purpose of Study 3 was to explore the participants' behavior and the outcomes they achieved in the two types of negotiations and in auctions. The results of this study partially confirm the results of Study 2. Some of the differences may be due to the larger sample in Study 3 and a small??? revision of the assignment which was administered. The revision concerned additional clarification of: (1) the relationship between breakeven values and profits and losses; and the requirement that students achieve profits if they can and avoid losses, for which they are penalized (bonus points are not given); and (3) the allocation of bonus points if student obtained contracts (but not at a loss) as well as if students did not achieve contracts only because making an additional offer would push them into losses. Another difference in this versus the earlier experiments was the change of the breakeven value for the buyers (from 16 to 48), so that the buyers and the sellers could achieve similar profit values.

In Study 3 we were able to determine strong relationship between a number of variables describing auctions and negotiations (Table 3). The purpose of the study was experimental comparison of the three mechanisms and we obtained interesting yet surprising results. We introduced a new negotiation

mechanism which shares one rule with auctions, namely winning offer verifiable disclosure. This rule is critical for auctions (particularly multi-attribute) because it provides guidance for the bidders.

The additional rule provided sellers in both the auctions and the verifiable negotiations with information about the winning offer (i.e., best offer on the table). In these negotiations the buyers could communicate with the sellers, while in the auctions the sellers were given information about admissible bidding sets [23]. These sets comprise alternatives, which are better for the buyer than the winning bid.

The results show that the verifiable offers improved the sellers' position, however at the process costs measured by the number and length of offers. Because the buyers were worse off than in the auctions and the non-verifiable negotiations, they were not likely to introduce the verifiable offer negotiation mechanism.

IV. Conclusions and Future Work

Auctions are *economic processes* in the sense that nothing except for the attribute values can be submitted. Auction outcomes are thus defined solely by the attributes defined by the bid-takers. In negotiation literature this type of outcomes is called "substantive"; their values are discussed over the course of the process and they constitute the agreement [24].

In negotiation literature, substantive outcomes have been contrasted with relational outcomes; the roots of this distinction are attributed to an effort to contrast the economic perspective with the psychological perspective [25, 26]. The argument which we posit here is that negotiations among market participants and businesses are *socio-economic processes* and that neither the "social" nor the "economic" aspects can be ignored.

The social exchange theory is concerned with the formulation and evolution of the relationship between parties engaged in giving and getting "something", and with the rules which govern exchanges between the parties [27, 28]. There are two main types of rules [29]: (1) negotiated rules; and (2) reciprocity rules. The negotiated rules are explicit and simple, they deal with bargaining in which reciprocity is not required. The reciprocity rules are implicit and govern different forms of relationships, which emerge during interactions among people (e.g., trust, empathy, and reputation).

Despite of its recognition of the reciprocity rules, the social exchange theory reduces negotiated exchanges to haggling or double auctions, noting that in negotiations "reciprocity is a trivial byproduct of a bilateral trade, and the same actions that reduce the risk of loss also increase gain." [30]. However, even this narrow perspective on negotiation identifies reciprocity as an important device used by negotiators. An action by one party calls for some kind of a response by the counterpart, it creates an obligation. If it is clear that the party makes an effort, provides explanation, proposes a significant concession, and is genuinely interested in getting the contract, then it is only natural for the counterpart to reciprocate. This is one reason why buyers accept less (lower profit) in the multi-bilateral negotiations, than in auctions.

The participants in our negotiation experiments play roles of buyers and sellers; they perform and interact with others. They may also discuss other issues (e.g., their interests, weather, and universities). The negotiations are anonymous at the outset, but the participants can exchange any information they wish to exchange. The participants' discussions may have a subjective value for them.

A person may not know her counterpart but during the ten-day long interaction may develop some affinity with him, which can lead her to make a bigger concession than she would have made if she felt animosity. This particular motivation for concession-making can be related to the experimental settings, however, in real-life situations we also observe parties trading off some substantive values in an effort to achieve higher relational values. In some job markets, for example, employers engage in multi-bilateral negotiations with several potential candidates in order to determine their trustworthiness, fit to the position and the team, as well as professional skills. If they need to determine skills only, then auction often is the preferred mechanism [31]. This implies that reciprocity need not be a "trivial byproduct" but a set of complex rules which are invoked when the negotiators realize the potential of achieving important relational outcomes.

Relational outcomes are inherently social and they can be achieved in negotiations. However, they cannot be achieved in auctions in which bid-makers do not interact with one another. This shortcoming of auctions has been recognized and led to augmentation of auction protocols, e.g., with post-auction negotiation in buyer-determined auctions [32].

While non-augmented auctions cannot produce relational outcomes, they can produce game-like outcomes, for example, excitement [33]. Auctions produce winners and losers, the outcome is a win or a loss, while negotiations result in agreement or disagreement achieved through negotiation.

Our results confirm the theory that auctions produce better substantive outcomes for the bid-takers who decide on what exchange mechanism to use. The assumption is, however, that the bid-takers are not interested in any other outcomes, relational in particular. If so, the answer to the first question formulated in Section1, is negative: For the buyers, it is not worth spending time and money for negotiation, because they achieve better results from auctions. The results also point to the necessity to study communication between negotiators. Messages affect offers; if they are ignored then the changes in offers (concessions) cannot be explained.

Notwithstanding the results obtained from Study 3 about the verifiable and non-verifiable negotiations, which confirm the results from Study 2, we consider these results as tentative and more work is required to validate them. The reason is due to the participants' different behaviors in each type of the negotiations. We mentioned above that in the verifiable negotiations there were inactive buyers during the first few days of the process; there were also a few inactive buyers during the entire process. While these negotiations concluded with an

agreement, that is, at some point the buyer accepted an offer, they were structurally different from the negotiations in which the buyer made offers and sent messages.

The data obtained from the verifiable and non-verifiable negotiation experiments (Study 2) was inconclusive; the differences in the buyers' and the sellers' profit values were not significant. However, this difference was observable and therefore it suggested that transparency could be better for buyers but not necessarily for sellers (Table 2). The results of Study 3 show that the differences are significant but not in the expected direction.

Contrary to our expectations, the verifiable negotiations did not produce better results for the buyers and worse for the seller that the non-verifiable negotiations (Table 3).

Because transparency has been found to have positive effect on trust and other relational outcomes [34], in some situations verifiable-offer negotiations may be preferred over both auctions and non-verifiable negotiations. It is possible to further augment this type of negotiation by providing information about admissible bidding (offer) sets. In multi-attribute auctions bidders can only submit a bid that is an element of one of these sets. In negotiations they could submit other bids (i.e., worse for the buyers) but this information would give them a better understanding regarding objective positive concessions.

ACKNOWLEDGMENT

We thank Norma Paradis, Dmitri Gimon, and Shikui Wu for their contribution to the system design and experiment organization.

Verification of ArchiMate process specifications based on deductive temporal reasoning

***Abstract*—Formal verification of business models has become recently an intensively researched area. Application of formal methods in this field necessities in overcoming several problems. Firstly, business analyst and designers rarely have enough skills and motivation to manually build abstract and formal specifications, hence, it arises the need to provide tools for an automated translation of business models into a suitable form ready for formal verification. Moreover, notations and languages used to describe enterprises usually have no clear semantics. Finally, the verification itself must be supported by an efficient tool. In this paper we investigate an application of formal and deduction-based techniques to automated verification of behavioral description embedded within ArchiMate models. We describe a set of rules that governs translation of processes specified in ArchiMate language into Linear Temporal Logic (LTL) formulas. The translation step is achieved with the developed software, as a plugin into a popular the Archi modeler. Formal verification of a business process properties is achieved with another tool, the LTL prover based on the semantic tableaux technique. Application of the method is discussed on a small, yet illustrative, example of a taxi service.**

I. Introduction

Formal verification of business models has become recently an intensively researched topic. The growing interest in this area stems to some extend form a historical fact. Issued in 2000 revisions to ISO 9001 and 9004 norms recommended process-oriented approach to quality management. Since then, many organizations have started to identify and describe their processes to fulfill certification requirements, but also they have realized that coherently and unambiguously specified business processes can bring such benefits, as quality of products and services, smaller ratio of operational errors, reduced cost and greater competitiveness.

In this paper we investigate an application of formal deduction-based techniques to automated verification of behavioral description embedded within ArchiMate models. ArchiMate is an lightweight and scalable language supporting analysis and modeling of business and enterprise domains [23]. It has been developed to provide a uniform representation for architecture descriptions. The popularity of ArchiMate language within the enterprise architecture modeling community grows.

Formal methods are understood as a set of principles for precise formulation of important artifacts formed when developing and refining software models. They enable revealing, questioning and removing ambiguities and flaws in specifications. Moreover, the formality of used languages leads to the rigorous analysis and verification. There are two established approaches to formal reasoning and system verification [5], i.e. model checking and deductive reasoning. Model checking is based on the state exploration and is an operational rather than analytic approach [4]. Deductive inference enables analysis of infinite computation sequences.

Temporal logic TL brings in logical symbols for reasoning about varying logical valuations of formulas throughout the flow of time. Two basic unary operators are $\Diamond$ for "sometime (or eventually) in the future" and $\Box$ for "always in the future". Temporal logic is a well-established formalism for specification and verification of reactive and concurrent systems. It allows to describe both temporal relations between reached states or events occurring within a system and to specify expected properties.

Liveness and safety are standard elements of a taxonomy of system properties. *Liveness* means that the computational process achieves its goals, i.e. something good eventually happens. *Safety* means that the computational process avoids undesirable situations, i.e. something bad never happens.

In recent years, a number of temporal logics has been proposed. Temporal logic exists in many varieties, however, these considerations are limited to the *linear-time temporal logic* (LTL). Linear temporal logic refers to infinite sequences of computations considered as linear structures and our attention is focused on the *propositional linear time logic* PLTL. These sequences are formally represented as Kripke structures, which define semantics of TL, i.e. a syntactically correct, or a well-formed, formula can be satisfied by an infinite sequence of truth evaluations over a set of *atomic propositions* AP. The basic issues related to temporal logics and their syntax and semantics are discussed in many works, e.g. [9].

The properties of time structure are fundamental to a logic. Of particular significance is the *minimal temporal logic*, e.g. [25], also known as temporal logic of the class K. The minimal temporal logic is an extension to a classical calculus defining the axiom $\Box(P \Rightarrow Q) \Rightarrow (\Box P \Rightarrow \Box Q)$ and the inference rule $\vdash P \implies \vdash \Box P$. The essence of the logic is the fact that there are no specific assumptions pertaining to the time structure order. The following formulas may be considered as typical examples of this logic: $action \Rightarrow \Diamond reaction$, $\Box(send \Rightarrow \Diamond receive)$, $\Diamond alive$, $\Box\neg(badevent)$, etc. The considerations of this work are limited to this logic since it allows to define many system properties (safety, liveness) and it is also easier

978-83-60810-53-8/$25.00

to build a deduction engine, or use the existing verified provers.

Application of deductive approach to validation of business processes faces the problem of automatic obtaining logical specifications from business models. The need to build them manually can be recognized as a major obstacle to untrained users, due to the fact that the process of specifying of a large collection of formulas is difficult and monotonous, c.f. also the requirements engineering process [13].

For temporal logic, that is a suitable language for expressing behavior and reasoning about it, such specifications are constituted by set of temporal logic formulas $\{F_1, ..., F_n\}$ When the number of formulas is large, what is not an extraordinary situation, then in practice it is not possible to build a logical specification manually. It follows that this process usually requires (very) skilled human intervention. Thus, in order to move the deductive-based formal verification form a pen-and-paper approach to engineers' needs an automation of the generation process seems particularly important.

The motivation for the work is the lack of tools for the deduction-based formal verification of business models. Another motivation is the lack of tools for the automatic generation of logical specifications from Archimate models.

The contribution of the work are the following: rules for automatic generation of logical specifications considered as sets of temporal logic formulas are defined and a complete deduction-based system, which enables an automated and formal verification of Archimate business models is proposed. Reasoning process is performed using the semantic tableaux method for temporal logic. An example of the approach is provided.

The paper is organized as follows: the next Section II discusses approaches to verification of business models, it is followed by Section III briefly describing ArchiMate language. Then, in Section IV an example of a process specification using ArchiMate is provided. Section V defines rules governing translation of ArchiMate models to LTL formulas. In Section VI an architecture of the verification system is described and an example of a checked property is given. Finally Section VII gives concluding remarks.

II. Related work

Recent work by Morimoto [15] surveys formal verification tools for business processes. It discusses in the context of business process management application of such formalisms as: automata, model checking, process algebras and Petri nets. The described approaches can be considered as variations of either model checking or simulation. In particular, model checking seems to be the most often used. There are several reports on application of model checking approach, e.g. to perform verification of of e-business processes, work by Anderson et al. [2], or BPMN models extended with resource constraints, c.f. work by Watahiki et al. [28]. In work by Deutsch at al. [8] verification of data-centric business processes is studied. The correctness problem was expressed in the LTL-FO, an extension to the Linear Temporal Logic, in which propositions were replaced by First Order statements about data objects. A salient consequence of modeling operations on data are infinite domains. Hence, the problem of correctness verification can be undecidable. Application of CTL to verification of BPEL processes was reported in work by Mongiello and Castelluccia [14]. Three types of correctness properties were analyzed: invariants, properties of final states and temporal relations between activities. The first two can be classified as *safeness*, the last as the *liveness* property. Similarly, in work by Fu et al. [11] CTL was applied to the verification of e-services and workflows with both bounded and unbounded number of process instances. Application of deduction based approach is rare in the area of business models verification. The work by Shankar [21] contains a comprehensive study for the area of verification using automated deduction and deduction-based techniques. Up to our best knowledge, no attempts has been made to define formally semantics and perform verification for behavioral elements of ArchiMate. Some suggestions and research direction can be found in an early document [7]. On the other hand, in a few publications [10], [3] ontologies were applied to define semantics for subsets of ArchiMate elements and relations. However, all of the research themes mentioned above are different from the approach presented in the work.

III. Archimate

ArchiMate [23], [26] is a contemporary, open and independent language for description of enterprise architectures. It comprises three main modeling layers: business, application and technology. The *business* layer includes business processes and objects, functions, events, roles and services. The *application* layer contains components, interfaces, application services and data objects. The *technology* layer gathers such elements as artifacts, nodes, software, devices, communication channels and networks. ArchiMate allows to present an architecture in the form of views which, depending on the needs, can include only items in one layer or can show vertical relations between layers, e.g.: a relationship between a business process and a function of the component software. ArchiMate was built in opposition to UML [18], which can be seen as a collection of unrelated diagrams, and Business Process Modeling Notation BPMN [17] which covers mainly behavioral aspect of enterprise architecture. The definition of a language has been accompanied by an assumption, that in order to build an expressive business model, it is necessary to use the relationships between completely different areas, starting from business motivation to business processes, services and infrastructure. ArchiMate goes beyond UML [16]: it defines a metamodel on the basis of which a user can create and illustrate the relationships between elements of different layers.

Archimate provides a small set of constructs that can be used to model behavior. It includes *Business Processes*, *Functions*, *Interactions*, *Events* and various connectors (*Junctions*), which can be attributed with a logical operator specifying, how inputs should be combined or output produced. According to language specification casual or temporal relationships be-

tween behavioral elements are expressed with use of *triggering* relation. On the other hand, Archimate models frequently use *composition* and *aggregation* relations, e.g. to show that a process is built from smaller behavioral elements (subprocesses or functions). In should be also noted that *Business Activity* present in Archimate 1.0 specification was removed in version 2.0. Instead, an atomic process should be used.

Although the set of behavioral elements seems to be very limited when compared with BPMN [17], after adopting a certain modeling convention its expressiveness can be similar [22]. An advantage of the language is that in allows to comprise in a single model a broad context of business processes including roles, services, processed business objects and elements of lower layers responsible for implementation and deployment.

Another process modeling notation that can be almost directly mapped on Archimate constructs is *Event-driven Process Chain* (EPC) [20], [19]. Indeed, all behavioral elements of both languages are exactly the same: events, functions (or processes in Archimate) and various joins and splits (XOR, OR and AND). In spite of almost 20 years presence of EPC tools on a market and thousands of deployments in modeling business organizations, there is no consensus of semantics of EPCs. Analyzes of several semantics variations have revealed certain erroneous patterns, e.g the famous vicious circle [27] resulting in a deadlock caused by improper use of synchronization joins. Due to the correspondence between EPC and Archimate constructs, discussions and discovered problems related to EPCs semantics apply also to Archimate models.

IV. Example of a business model

In this section we give an example of ArchiMate model for a small business process defining Taxi service allowing a client to order a taxi that will carry him or her to the desired destination.

The example shows typical constructs that can be used to model business behavior in ArchiMate. We assume that each high-level process starts and ends with an event. A triggering event originate from the environment, e.g. *Client trip order* in Fig. 1 or *Order cancellation request* in Fig. 4. A complex process can be decomposed into several subprocesses, which are usually presented in separate views. Such processes are linked by intermediate events, e.g. *Trip accepted* appearing on the output of a subprocess in Fig. 1 and on the input of Fig. 3b. Finally, a process stops at *end events*, which may trigger external processes or terminate a thread of execution, as events *Stop 1 – Stop 7*.

For clarity, we omitted in diagrams additional information, which is usually present in ArchiMate models of business layer, e.g. assigned roles and accessed business objects, functions, services, actors and locations. ArchiMate specifications can be much richer, what justifies common practice of decomposing behavior descriptions into smaller patterns presented in multiple views. In this way specifications can cover various important aspects of an enterprise architecture, but control flows become harder to be verified manually, as they require switching between multiple views. In fact, specifications presented in Fig. 1–4 are excerpts restricted to behavioral elements presented in eight views.

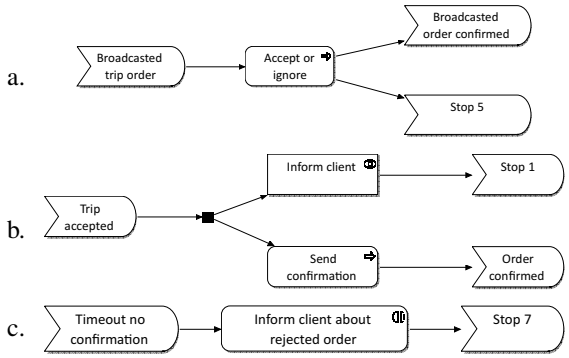

Fig. 3. Extensions to the main operator processes: a. Broadcasting trip order; b. Reaction on accepted order; c. Handling timeout (an order cannot be realized) Broadcast

The main flow of activities within dispatcher's office is shown in Fig. 1.

When a client requests a taxi (*Client trip order*), then the order is handled by a dispatcher. Firstly, all taxicab stands located closest to the present customer's position are searched. If contact with the driver (*Contact taxi driver*), and details of the order, leads to its rejection (*Trip rejected*), then the next taxicab form stands is selected. If a free taxi is found and the trip request is accepted (*Trip Accepted*), then the customer and the driver are provided with information about each other as well as trip's details, and the trip order is stored in the database as approved. If *Look for free taxi cabs* process takes too long time (*Timeout*), then dispatcher broadcasts the trip order to all drivers (in the city area). Such order may also be accepted on the general principles.

Main process of the driver is shown in Fig. 2.

After an order confirmation, the agreed driver goes to the the trip start location (*Reach location*) to pick up the passenger (*Pick up passenger*). Along the way to the pick-up location difficulties may arrise, e.g. heavy traffic or passenger absence. After the completion of the ride (*Trip finished*), its status is changed from approved to finished.

Extensions of the dispatcher processes are shown in Fig. 3 and discussed below.

(a) Waiting for the first declaration which originates from the broadcast.
(b) A kind of a virtual handshake between a taxicab driver (*Send confirmation*) and the passenger (*Inform client*) with an intermediary of dispatcher.
(c) If none of the methods result, the customer is notified and the order is rejected (*Timeout no confirmation*).

Further extensions of the dispatcher processes are shown in Fig. 4 and discussed below.

(a) If there are obstacles when reaching the client, then he/she should be informed about this fact.
(b) When order is canceled, the driver must be notified.

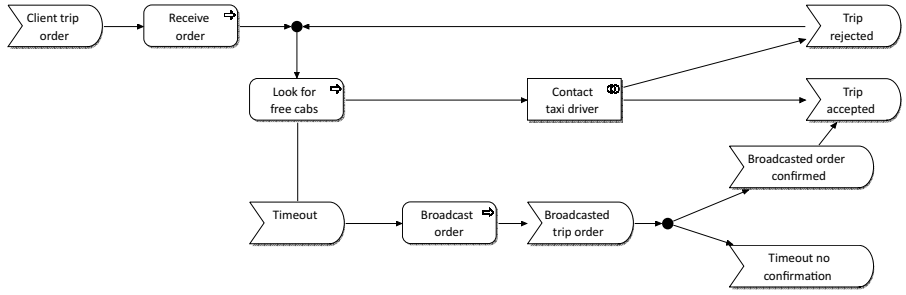

Fig. 1. Main dispatcher process. After receiving a client order, operator looks for registered free cabs. If not found, broadcasts information about the order

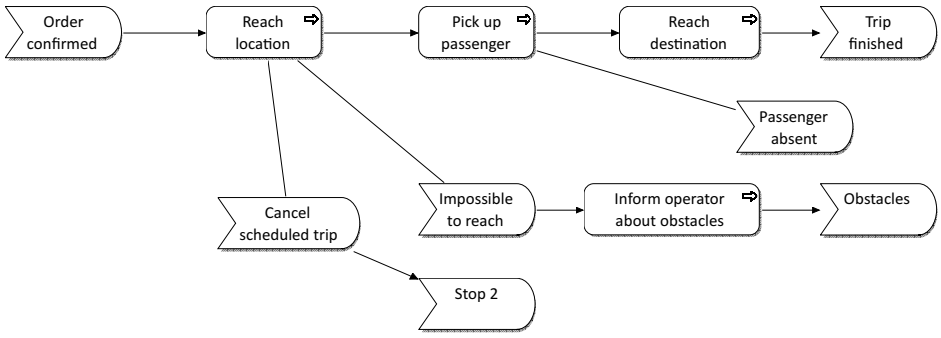

Fig. 2. Main driver process.

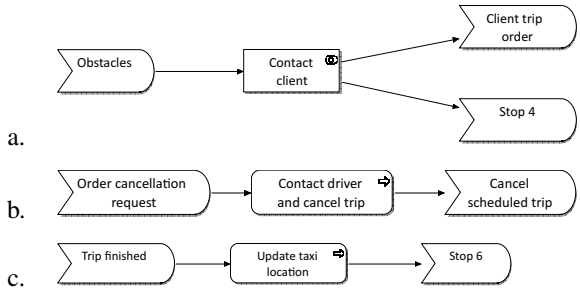

Fig. 4. Further extensions to the main operator processes: a. Contacting client after a taxi driver reports obstacles, e.g. delays ; b. Handling cancellation; c. updating information on taxi location after a finished trip

(c) When the trip is successfully finished, then the new taxicab location is introduced.

V. Modeling Archimate behavioral constructs

This section gives formally defined rules for translation of behavioral elements within an ArchiMate specification into LTL formulas. The internal structure of an Archimate model constitutes a graph of nodes linked by directed edges. Both nodes and edges are attributed with information indicating a type of element or relation. Generating LTL formulas describing behavioral aspects of Archimate model we focus on components of the *Business layer*: processes (or functions), events and various junctions. We apply a linear procedure, which visits nodes, analyzes their successors and generates LTL formulas describing control flow.

It should be noted that Archimate behavioral constructs have no precisely defined semantics. In fact, translation from Archimate specification to LTL assigns a semantics, which, although arbitrarily selected, follows a certain intuition, e.g. how to interpret an activity or an event.

Definition 1 (Archimate model)**.** Archimate model AM is a tuple $\langle V, E, C, R, v, e\rangle$, where

- V is a set of vertices,
- $E \subset V \times V$ is a set of edges,
- C is a set of Archimate element types,
- R is a set of relations,
- $vt\colon V \to C$ is a function that assigns element types to graph vertices
- $et\colon E \to R$ assigns relation types to edges.

As the considerations in the work focus on business layer elements used to specify behavior, it is assumed that $C = \{Process, Function, Interaction, Event, Junction, And\text{-}Junction, OrJunction, Other\}$ and $R = \{triggering, association, composition, other\}$.

A. Modeling atomic activities

By atomic process (function, interaction) we mean a process that is not linked with other elements by a *composition* relation. It represents a basic unit of behavior, which corresponds to the activity concept of other languages, e.g. UML.

A process can be executed if its environment is in a state enabling its activation. After a process terminates, it causes state changes in the surrounding world [12]. While defining

LTL formulas describing processes and other elements, we follow directions of relations and specify only transitions between internal states of elements and caused states. In turn, the reached caused states enable activation of other elements. Hence, after processing all relevant elements, a complete network of states of the whole system specified in LTL is obtained.

To model execution of an atomic process two states (and corresponding propositions in LTL): *start* and *end* are used. A process is considered *imperfect*, even if has a name in imperative mood suggesting achievement, e.g. *register invoice*, *scan document*, *send message*. Once invoked (the *start* state becomes active), the process can successfully complete reaching the *end* state or be interrupted by an event starting an alternative flow of control. Such approach to modeling business processes can be explicitly supported by language constructs. In particular, the BPMN notation allows to attach various types of interrupting events to activities, e.g. timer, error or cancellation. In ArchiMate an association relation between processes and events can be used to distinguish events triggered upon process completion and interrupting a normal flow.

Fig. 5 illustrates this approach. The *end* state and *Interrupting event* are successor of the process *start* state. On the other hand, states of surrounding elements that can be reached by the normal triggering relation are successors of the *end* state.

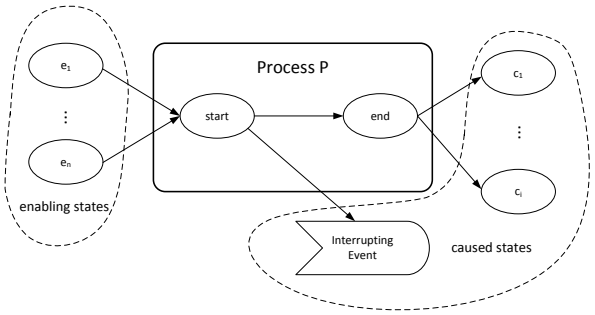

Fig. 5. Two states: *start* and *end* used to model a process

Atomic processes, functions and interactions (ArchiMate equivalents to activities) are imperfect and require two states (and propositions) to model their behavior. In turn events and junctions are perfect and their activation can be modeled by singular states (truth values of propositions). To describe all behavioral elements in an uniform manner we define two functions $start$ and end that map vertices from Archimate model V to a set of propositions $Props$. It is assumed, that if a certain vertex v represents a process, a function or an interaction, i.e. $v(v) \in \{Process, Funtion, Interaction\}$, then $start(v) \neq end(v)$. For other elements: events and junctions $start(v) = end(v)$ holds. We extend these functions to sets of vertices, i.e. $start(X) = \bigcup_{v \in X} start(v)$ and $end(X) = \bigcup_{v \in X} end(v)$.

By $T(v) = \{v' : (v, v') \in E \wedge et(v, v') = triggering\}$ we will denote a set of behaviors that are triggered by v. $A(v) = \{v' : vt(v') = (Event) \wedge (v, v') \in E \wedge et(v, v') = association\}$ is a set of events linked with v by association relation. $C(v) = \{v' : (v, v') \in E \wedge et(v, v') = composition\}$ is a set of children of v as defined by composition relation.

Let $\mathcal{F}(Props)$ be a set of LTL formulas obtained from a set of propositions $Props$ by applying classical or temporal operators and parentheses. For the brevity of notation we will further omit $Props$ and write simply $\mathcal{F}$

We define two auxiliary functions $\delta_{ij}(p)$ mapping formulas $\mathcal{F} \times \mathbb{N} \times \mathbb{N} \rightarrow \mathcal{F}$ (1) and $oneof(P)$ converting a set of propositions P into a formula in disjunctive normal form (2).

$$\delta_{ij}(p) = \begin{cases} p, & \text{if } i \neq j \\ \neg(p), & \text{if } i = j \end{cases} \tag{1}$$

$$oneof(P) = \bigvee_{i=1}^{|P|} \bigwedge_{j=1}^{|P|} \delta_{ij}(p_j) \tag{2}$$

B. Atomic process, function or interaction

LTL formulas defining temporal relations for atomic activities (processes, functions and interactions) are generated according to Rule 1. Rules for other ArchiMate elements have similar form. Each rule contains precondition part separated from its postcondition by a horizontal line. Generated formulas are placed in brackets $[\![\ ]\!]$.

Rule 1. Atomic process, function or interaction

$$\frac{\begin{array}{c} v \in V, \\ vt(v) \in \{Process, Function, Interaction\}, \\ C(v) = \emptyset \end{array}}{\begin{array}{c} [\![\Box(start(v) \Rightarrow \Diamond oneof(start(A(v)) \cup \{end(v)\})]\!] \in \mathcal{F} \\ p \in A(v) \cup \{end(v)\} \rightarrow [\![\Box\neg(start(v) \wedge p)]\!] \in \mathcal{F} \\ T(v) \neq \emptyset \rightarrow [\![\Box(end(v) \Rightarrow \Diamond oneof(start(T(v))))]\!] \in \mathcal{F} \\ p \in T(v) \rightarrow [\![\Box\neg(end(v) \wedge p)]\!] \in \mathcal{F} \end{array}}$$

LTL formulas describing the behavior for the sequence of two active elements *Look for free cabs* and *Contact taxi driver* in Fig. 1 are presented in Fig. 6 (original transcription is preserved). They were generated according to Rule 1.

```
% BusinessProcess (Look for free cabs)
[] (Look_for_free_cabs_start =>
   <> ((Look_for_free_cabs_end & ~Timeout)
   |  (~Look_for_free_cabs_end & Timeout))),
[]~(Look_for_free_cabs_start & Look_for_free_cabs_end),
[]~(Look_for_free_cabs_start & Timeout),
[] (Look_for_free_cabs_end => <>Contact_taxi_driver_start),
[]~(Look_for_free_cabs_end & Contact_taxi_driver_start),
% BusinessInteraction (Contact taxi driver)
[] (Contact_taxi_driver_start => <>Contact_taxi_driver_end),
[]~(Contact_taxi_driver_start & Contact_taxi_driver_end ),
[] (Contact_taxi_driver_end =>
   <> ((Trip_accepted & ~Trip_rejected)
   |  (~Trip_accepted & Trip_rejected ))),
[]~(Contact_taxi_driver_end & Trip_accepted),
[]~(Contact_taxi_driver_end & Trip_rejected),
```

Fig. 6. An excerpt of generated formulas for the main dispatcher process

C. Event

According to Archimate specification [23] business event is something that happens and influences behavioral elements

(processes, functions and interactions). Events has no duration, thus they can be modeled as single boolean variables. Functions $start(v)$ and $end(v)$ map an event v to the same proposition, which change value to true if the event occurs.

An event can be linked by triggering relations with multiple recipients (or *sinks* in the Event Driven Architecture). Events are somehow similar to AndJunctions. An occurrence or the both activates all elements linked by a *triggering* relation. However, we assume that, unlike AndJunctions, activation of elements triggered by an event is not synchronized (c.f. Rule 2).

Rule 2. Event

$$\frac{v \in V \wedge vt(v) = Event}{\begin{array}{c} p \in T(v) \rightarrow [\![\Box(end(v) \Rightarrow \Diamond start(p)]\!] \in \mathcal{F} \\ p \in T(v) \rightarrow [\![\Box(start(p) \Rightarrow \Diamond \neg end(v))]\!] \in \mathcal{F} \end{array}}$$

D. Junctions

Archimate language defines three types of connectors:

- *Junction* that can be considered a typical XOR connector, i.e. it activates exactly one output.
- *OrJunction* being a typical OR connector activating at least one output
- *AndJunction* that can be used in two modes: when used to merge flows on input it requires their synchronization. In the second mode it starts a parallel execution of output flows.

Archimate junctions has counterparts in EPC, BPMN (exclusive, inclusive and parallel gateways) and XPDL transition restrictions [24].

Similarly to events, junctions are modeled by single state variables. If a junction is activated, in a subsequent step elements linked by triggering relations should be activated according to assumed semantics. As there are three types of junctions, we define three rules (Rule 3–5) for translating them to LTL formulas.

Rule 3. Junction

$$\frac{v \in V \wedge vt(v) = Junction}{\begin{array}{c} T(v) \neq \emptyset \rightarrow [\![\Box(end(v) \Rightarrow \Diamond oneof(start(T(v)))]\!] \in \mathcal{F} \\ p \in T(v) \rightarrow [\![\Box\neg(end(v) \wedge p)]\!] \in \mathcal{F} \end{array}}$$

Rule 4. OrJunction

$$\frac{v \in V \wedge vt(v) = OrJunction}{\begin{array}{c} T(v) \neq \emptyset \rightarrow [\![\Box(end(v) \Rightarrow (\bigvee_{z \in T(v)} start(z)))]\!] \in \mathcal{F} \\ T(v) \neq \emptyset \rightarrow [\![\Box\neg(end(v) \wedge (\bigwedge_{z \in T(v)} start(z)))]\!] \in \mathcal{F} \end{array}}$$

Define: $T^{-1}(v) = \{v' : (v', v) \in E \wedge et(v', v) = triggering\}$ - set of input

Rule 5. AndJunction

$$\frac{v \in V \wedge vt(v) = AndJunction}{\begin{array}{c} T^{-1}(v) \neq \emptyset \rightarrow \\ [\![\Box((\bigwedge_{z \in T^{-1}(v)} end(z)) \Rightarrow start(v))]\!] \in \mathcal{F} \\ T^{-1}(v) \neq \emptyset \rightarrow \\ [\![\Box\neg((\bigwedge_{z \in T^{-1}(v)} end(z)) \wedge start(v))]\!] \in \mathcal{F} \\ T(v) \neq \emptyset \rightarrow [\![\Box(end(v) \Rightarrow (\bigwedge_{z \in T(v)} start(z)))]\!] \in \mathcal{F} \\ T(v) \neq \emptyset \rightarrow [\![\Box\neg(end(v) \wedge (\bigwedge_{z \in T(v)} start(z)))]\!] \in \mathcal{F} \end{array}}$$

E. Discussion

In this section formal rules governing translation of basic ArchiMate behavioral elements of business layer into LTL formulas were defined. It should be noted, that ArchiMate syntax defines strictly, how elements of various types can be combined, however, without giving semantics to them (at least in case of behavioral elements). Hence, the rules can be considered to be an assignment of a semantics to language patterns.

After analysis of several examples we decided not to define rules for elements composed of lower level activities. ArchiMate syntax seems to manifest some flaws in this case. An activity modeled as a process, function or interaction can be a part (as defined by the composition relation) of several high-level behavioral elements. Moreover, a complex process can be composed of lower level activities, but junctions and internal events are not included into the composition. Therefore, we decided to treat complex processes as kinds of views helping to organize the models, rather than manageable entities.

VI. Deduction-based verification

System specification in form of LTL formulas $F_1, ...F_n$ obtained by applying rules defined in previous section can be checked for either its validity or entailment: $F_1, ...F_n \models G$. The second case is particularly interesting, as G can express a desired system property pertaining to temporal ordering of states and events. The approach proposed in this work consists in applying a semantic tableaux method to reason about entailment. The method is described briefly in Section VI-A, which is followed by Section VI-B giving an outline of a verification system architecture. Finally we present an example of specification in Section VI-C.

A. Semantic tableaux method

Semantic tableaux is a decision-making procedure for checking satisfiability of a formula. To do so, it shows that the negation of an initial formula cannot be satisfied, hence, the initial formula is a tautology. To verify an entailment $F_1, ...F_n \models G$ it suffice to prove that $\{F_1, ..., F_n, \neg G\}$ is unsatisfiable.

The main principle of propositional tableaux is to "break" complex formulae into smaller ones until complementary pairs of literals are produced or no further expansion is possible The method originates form classical logic but it can be also used for temporal logics [6]. Generally speaking, the method is based on well defined rules of formula decomposition and expansion. They allow to handle each of the logical connectives. When the rules are applied, branches of the inference tree are built. They correspond to alternatives appearing in formulas placed at the tree nodes. An inference tree is *finished*, when no formula can be further broken down, i.e. no complementary pairs of literals can be produced. The branches in the tree can be of two kinds: open or closed. A branch is closed if it can be established that a set of literal formulas, i.e. atomic formulas or its negations, on this branch has no model. In practice, this corresponds to a condition that a pair of

contradictory formulas can be found on the branch. If all branches of the tree have contradictions, the whole inference tree is *closed*. If the negation of the initial formula is placed in the root, this leads to the statement that the initial formula is true. A very simple yet illustrative example of the reasoning tree is shown in Fig. 8. The negation of the initial formula $(a \Rightarrow \Diamond b) \wedge (b \Rightarrow \Diamond c) \Rightarrow (a \Rightarrow \Diamond c)$ is placed in the root of the tree. All branches are closed (red nodes) what means that the initial formula is always satisfied.

B. Deduction based verification system

The architecture of the deduction-based verification system is shown in Fig. 7. The system consists of three components:

1) *Modeler* that allows to prepare and develop business models using ArchiMate language. In this case the Archi software, an excellent free modeling tool [1] was used.
2) *Generator* generates logical specifications from ArchiMate models. We have implemented a component that applies rules described in Section V to elements of a business layer and yields a set (a conjunction) of LTL formulas. It is deployed as a plugin to Archi.
3) *Prover* takes as input logical specifications (a set of temporal logic formulas describing a verified system) and a query, i.e. an examined property represented by a single formula, checks its validity and issues a response (*Yes* or *No*).

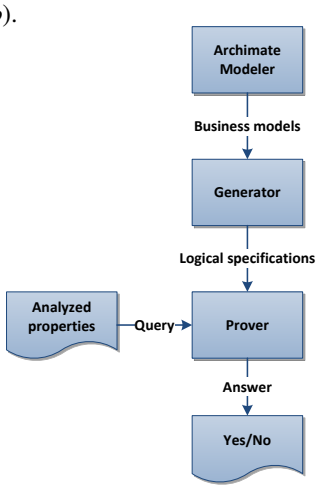

Fig. 7. An architecture of the deduction system

The prover is a crucial component of the verification system. Recently, a prototype reasoning engine for linear and future time minimal temporal logic was implemented[1], c.f. Fig. 8. It allows to examine logical validity for formulas expressing liveness or safeness, as described above. Internally, the prover applies the semantic tableaux method customized to requirements of reasoning on validity of LTL formulas.

An advantage of the described system (Fig. 7) is that it can give instantaneous response whenever the specification of a model is changed or there is a need for a new inference due to a newly introduced property.

[1]The engine was implemented as a students' (Joanna Kulesza and Kamil Łopata) project under the supervision of one of the authors of the work.

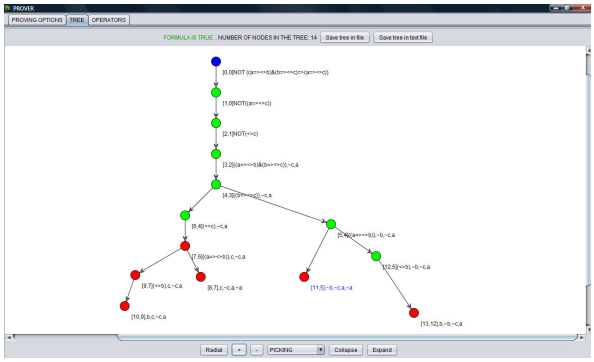

Fig. 8. A prototype system of inference using the semantic tableaux method

C. Example of verification

In this section we return to the ArchiMate model of a taxi service presented in Section IV. For this model 108 temporal formulas were generated. Due to the limited size of the work, it is not possible to show them all. Thus, a subset of the whole logical specification L referring to Fig. 1 and Fig 3.b-c, is shown below.

$$
\begin{aligned}
L = \{&\Box(Contact\_taxi\_driver\_start \Rightarrow \\
&\Diamond Contact\_taxi\_driver\_end), \Box\neg(Contact\_taxi\_driver\_end \wedge \\
&Trip\_accepted), \Box(Broadcasted\_trip\_order \Rightarrow \\
&\Diamond Junction\_0), \Box(Timeout \Rightarrow \\
&\Diamond Broadcast\_order\_start), \Box(Inform\_client\_start \Rightarrow \\
&\Diamond Inform\_client\_end), \Box(Inform\_client\_end \Rightarrow \\
&\Diamond Stop\_1), \Box(Timeout\_no\_confirmation \Rightarrow \\
&\Diamond Inform\_client\_about\_rejected\_order\_start), \\
&\Box(Trip\_accepted \Rightarrow \Diamond And\_Junction), \Box(Junction \Rightarrow \\
&\Diamond Look\_for\_free\_cabs\_start), \\
&\Box(Inform\_client\_about\_rejected\_order\_start \Rightarrow \\
&\Diamond Inform\_client\_about\_rejected\_order\_end), \\
&\Box(Inform\_client\_about\_rejected\_order\_end \Rightarrow \Diamond((Stop\_2 \wedge \\
&\neg Stop\_7) \vee (\neg Stop\_2 \wedge Stop\_7))), \Box(Client\_trip\_order \Rightarrow \\
&\Diamond Receive\_order\_start), \Box(And\_Junction \Rightarrow \\
&\Diamond(Inform\_client\_start \wedge \\
&Send\_confirmation\_start)), \Box(Look\_for\_free\_cabs\_start \Rightarrow \\
&\Diamond((Look\_for\_free\_cabs\_end \wedge \neg Timeout) \vee \\
&(\neg Look\_for\_free\_cabs\_end \wedge \\
&Timeout))), \Box(Look\_for\_free\_cabs\_end \Rightarrow \\
&\Diamond Contact\_taxi\_driver\_start), \Box(Receive\_order\_start \Rightarrow \\
&\Diamond Receive\_order\_end), \Box(Receive\_order\_end \Rightarrow \\
&\Diamond Junction), \Box(Broadcast\_order\_start \Rightarrow \\
&\Diamond Broadcast\_order\_end), \Box(Broadcast\_order\_end \Rightarrow \\
&\Diamond Broadcasted\_trip\_order), \Box(Junction\_0 \Rightarrow \\
&\Diamond((Broadcasted\_order\_confirmed \wedge \\
&\neg Timeout\_no\_confirmation) \vee \\
&(\neg Broadcasted\_order\_confirmed \wedge \\
&Timeout\_no\_confirmation))), \\
&\Box(Broadcasted\_order\_confirmed \Rightarrow \Diamond Trip\_accepted)\}
\end{aligned}
$$

Let us consider a liveness property expressed formally by the following formula

$$\Box(Client\_trip\_order \Rightarrow \Diamond(Stop\_1 \vee Stop\_7)) \qquad (3)$$

which can be understood that, *if a client ordered a trip then sometime in the future the client is informed about assigned cab (Stop_1) or the order is rejected (Stop_7).*

When analyzing if a specification L satisfies the property expressed by the formula (3) a new formula (4) is constructed

and submitted to the prover.

$$C(L) \Rightarrow (\Box(Client\_trip\_order \Rightarrow \Diamond(Stop\_1 \vee Stop\_7))) \quad (4)$$

where $C(L)$ means logical conjunctions of formulas.

Presentation of a full inference tree, which contains more than a thousand nodes, exceeds the size of the work. All branches of the semantic trees are closed, i.e. formula 4 is satisfied in the considered model. If the tree had open branches, this would indicate that the input formula can be not satisfied. In this case the prover would provide information about the source of the error, what can be considered an important advantage of the method.

VII. Conclusion

This paper discusses a problem of automatic verification of behavioral specification embedded within ArchiMate models. We propose to apply an approach consisting in translating ArchiMate specification into a set of LTL formulas and using deductive reasoning technique to check temporal properties of the model. Firstly, on a small example we present language patterns that can be used to model processes, then rules for translation of ArchiMate behavior specification into LTL formulas are formally defined. Finally, we describe the architecture of the implemented reasoning system and show how it can be used to check desired system properties.

Although the considerations in this work are focused on deductive reasoning and semantic tableaux method, automatically generated LTL specifications can be verified with other methods, e.g. the resolution method.

The defined set of rules for transforming ArchiMate models into LTL formulas considers only atomic processes and functions. It is an open question how to give semantics to explicitly specified high-level behavioral elements aggregating low-level behaviors. At present they are treated as views organizing models, however we are analyzing alternative approaches.

Abstract — The article presents the approach to develop the economic and financial knowledge used for the Intelligent Dashboard for Managers. The content of the knowledge is focused on essential concepts related to the management of micro, small and medium enterprises. Knowledge-based functions, not previously available in commercial systems, increase the quality, effectiveness, and efficiency of the decision making process. The Intelligent Dashboard for Managers contains six ontologies describing areas of Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, Financial Market, and General Financial Knowledge. The ontology design process and examples of topic maps and usage in financial data analysis are illustrated and discussed.

I. Introduction

Decision makers of small and medium enterprises (SMEs) using Business Intelligence systems frequently need appropriate knowledge about the economic situation of the enterprise and its environment. Knowledge about key dependences between various financial ratios is essential, because they can indicate important trends and alert one to anomalies and dangers [23, p. 85]. Decision makers in SMEs, in comparison to managers of big companies, may have no access to much essential strategic information. Usually, financial expertise is either not available or too expensive. For financial and personnel reasons most SMEs cannot afford these types of facilities. Furthermore, SMEs operate in a definitely more uncertain and risky environment than big enterprises, because of a complex and dynamic market that has much more important impact on SMEs' financial situation than on big companies'. Tolerance of mistakes is narrower (see among others [12, p. 74-91]). In these conditions, SME's decision makers often act intuitively and as a result, the rationality of their decisions is decidedly smaller. Moreover, the statistics show that SME's decision makers often don't have a solid knowledge of economics and finance.

In general, most existing Business Intelligence (BI) and Executive Information Systems (EIS) provide the functionality of data aggregation and visualization. Many reports and papers in this domain underline that decision makers expect new ICT solutions to interactively provide not only relevant and up-to-date information on the financial situation of their companies, but also explanations taking into account the contextual relationships.

The aim of this article is to present the approach to developing the economic and financial knowledge used in the Intelligent Dashboard for Managers (called further InKoM). The InKoM system has been developed by a consortium consisting of the Wroclaw University of Economics (WUE), which is the leader, and a company UNIT4 TETA BI Center Ltd. (TETA BIC). Credit Agricole Bank Polska S.A. also participates in the project.

Figure 1 presents the main components of the InKoM: a comprehensive description of the TETA BI system with examples of its application is available on the website: [28] (see also [3], [31]). It can be seen that the InKoM uses TETA BI mechanisms for extracting source data from transactional systems (ETL), its data warehouse, and analytical database. However, the available solutions – in particular the standard analyses, reports and analytical statements generated by the system – are complemented by economic and financial knowledge – most importantly ontologies and topic maps – and financial data mining algorithms, including mechanisms for extracting business knowledge from the deep Web. This enables a dynamic, on-line, interactive analysis of key business indicators.

The transactional data obtained from external sources, supplemented with planning data, e.g., budgets, form multidimensional data structures, or cubes, which are stored in a TETA BI Analysis Services database and provide a basis for the on-line, interactive creation of standard analytical queries and/or reports. The InKoM system complements and extends these processes[1]. By providing

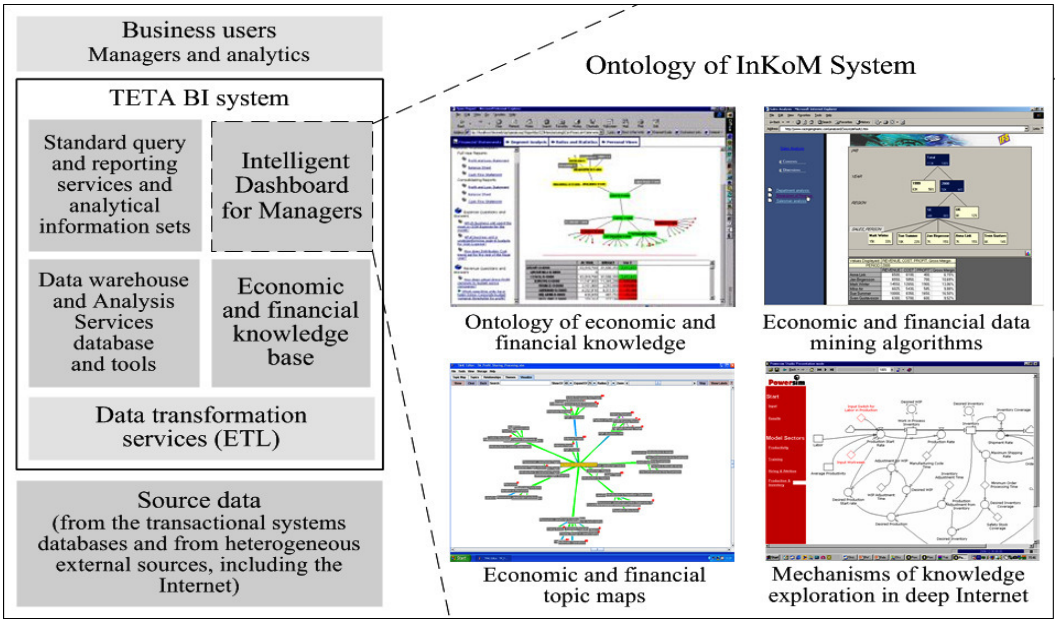

Fig. 1. Components of the Intelligent Dashboard for Managers and their location in the TETA BI system

economic and financial knowledge stored in ontologies and presented in the form of topic maps to facilitate the perception of concepts, InKoM can make the analysis more comprehensive and simpler. This is particularly important for users who are not specialists in the analysis and interpretation of economics and finance.

Over a dozen methods of building ontologies have been developed. Among methods listed in literature, the following are worth noting (more widely characterized inter alia in [13]; [22]): METHAONTOLOGIA (based on the standard IEEE 1074-1995), the method of Noy and McGuinness, On-To-Knowledge, SENSUS, TOVE (TOronto Virtual Enterprise), UPON (Unified Process for ONtology building) and the method of Ushold and King. Noy and McGuinness emphasized that the best model of ontology is the one that best cooperates with existing information system, accomplishes a set of goals, is intuitive and easy to maintain [Noy, McGuinness 2005]. So far there is no single standard of design because creating an ontology is dependent on its application and the needs of specific users (see [22]). However during last years the standardization activities in terms of information have been undertaken at European level; an example is the SMEST project (see http://www.cencenelec.eu/sme/SMEST/).

The structure of the paper is the following: In the next section the ontological approach to knowledge design is described. The third section presents the ontology structure. The fourth section characterizes the ontology design process in the InKoM. To illustrate the use of the InKoM, a case study of ontology for credit scoring is described. The last section summarizes the work already carried out and points out the further research and development tasks.

II. Ontological Approach to Knowledge Design

The main goal of any BI system is to access the right data at the right time to allow proactive decision-making (see among others [9], [26], [30]). The users of BI systems expect access to useful information through an interface easy to understand and use. However, existing BI solutions are designed primarily for users who are able to understand the business data models (see [25]). BI systems provide simple, personal analytical tools which support the exploration of data sources, retrieval of information based on predefined economic and financial relations, and do not require a priori knowledge about data structures and methods of data accessing (see among others [21], [25], [26]).

Today the development of new BI systems is oriented towards BI 2.0 (using semantic search) and 3.0, Service Oriented Architecture (SOA) and Software as a Service (SaaS) (see [21], [25], [26]). The typical features of the systems include: proactive alerts and notifications, event driven (real time) access to information, advanced and predictive analytics, mobile and ubiquitous access, improved visualization, and semantic search information (see also [21]).

One of the main part of modern BI systems is the ontology (see [21]). Ontology in information technology means „an explicit specification of a conceptualization“ [15, p. 907]. In general, the ontology is used to create the necessary knowledge models for defining functionalities in analytical tools. In the development of InKoM, many new features are integrated, such as domain ontology covering key concepts of corporate finance and economics, knowledge discovery algorithms, semantic search

mechanisms, explanation facilities, and tools for visual navigation in domain knowledge.

In the InKoM project, six ontologies were built. Choosing scopes of created ontologies was a difficult task, because of domain complexity and the necessity to develop numerous links between the theory of finance and the contents of BI system databases. The task needed cooperation in pragmatic way with experts on the analysis of finance, economics and business informatics. Experience of our industrial partner, UNIT 4 TETA BI Center, gained from implementing the TETA BI system in enterprises, was also essential in choosing these areas. The result of this work is six ontologies covering economic and financial areas: Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, the Financial Market, and General Financial Knowledge. The ontologies will be detailed in the next section.

Integration of these ontologies into the BI systems assures:

- support for the definition of business rules in order to get proactive information and advice in decision-making;
- a semantic layer describing relationships between the concepts and indicators;
- relevant information according to the different kinds of users that can be found in an organization;
- effective usage of existing data sources and data warehouse structure.

The knowledge representation layer is the most critical aspect of a BI system, since it broadly shapes the core understanding of the information displayed on their screen [30]. In InKoM design, the basic assumption of navigation was that managers should be able to view focus and context areas at the same time to present the relevant knowledge structure [27].

Visual exploration in InKoM is based on a standard Topic Map (TM – ISO/IEC 13250:2003). TM enables the representation of complex structures of knowledge bases [4] and the delivery of a useful model of knowledge representation (see [20, p. 174]), where multiple contextual indexing can be used. TM is a relatively new form of the presentation of knowledge, which puts emphasis on data semantics and the ease of finding desired information (see also [1]; [24, p. 30]). The application of topic maps permitted us to separate the data of the enterprise's information system from operational business activities (see among others [17]). Developed topic maps for analysis of economic indicators (see among others [7], [8], [17]) have demonstrated that the system [6]:

- can be easily used for the representation of economic knowledge about economic and financial measures,
- can express the organizational structure,
- can be adapted to new applications and managers' needs,
- can be supportive of the managerial staff by facilitating access to a wide range of relevant data resources,
- can assure a semantic information search and interpretation for non-technically-minded users,
- can visualize different connections between indicators that make possible the discovery of new relations between economic ratios constituting knowledge still unknown in this area,
- can improve the process of data analysis and reporting by facilitating the obtaining of data from different databases in an enterprise, and finally
- can be easily extended by users who are not IT specialists, e.g. by experts in economic analysis (using tools for creating a topic map application).

The preliminary evaluation of ontologies is very encouraging The knowledge of corporate finance is very useful in the interpretation and explanation of data presented in financial reports of BI systems.

III. Ontology Structure

The essential element of the InKoM systems' knowledge is a part containing topic maps for six created ontologies for selected areas called: Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, Financial Market, and General Financial Knowledge.

CFaR is considered to be one of the best adjusted ratios for the needs of complex risk measurement in enterprises. According to the newest trends in enterprise management and on companies' economic practice, it was determined that the appropriate ratio for complex risk management in enterprises is Cash Flow at Risk (CFaR) using the RiskMetrics Group rules. The choice of Cash Flow at Risk meets managers' needs in the scope of creating single risk ratio illustrating risk level connected with an enterprise's operating activity. Of course, the prerequisite for the manager being able to use this information is the appropriate knowledge level on CFaR ratio.

The ontology of Comprehensive Risk Measurement involves various variants of the model used to estimate the Cash Flow at Risk ratio. The developed ontology concerns the way of understanding and defining inter alia: risk variables, risk models, risk management process.

The ontology of the Early Warning System contains models of cautionary forecasting in supporting a manager's decision. The developed concept uses a group of tools for early warning model creation, in which mainly data from financial reports are used. By using this data, an objective view of company's situation can be quickly and easily obtained, which is essential in managers' efficient and accurate decision making.

The ontology of Credit Scoring describes the model of the credit procedure carried out by a bank. Credit scoring evaluation is an integral part of bank credit procedures (credit processes) and it is an essential stage in conditioning the granting of credit. It is realized by a bank's

organizational units and supporting infrastructural-system solutions, and the company trying to get credit (potential borrower) is the subject of analysis (quantitative and qualitative). The internal logic and details of credit procedures in a specific bank is its unique know-how and is not usually made public.

In literature many approaches to credit scoring can be found, such as stochastic models (e.g. Bayesian models, regression, Markov chain), artificial intelligence techniques (e.g. expert systems, neural network models, genetic algorithms), data mining methods [5]; [10]; [11]; [16]; [32]. The approach implemented in the InKoM system is based on the rules of thumb generally accepted in the practice of financial institutions. Of course there are still open questions which might be considered: which methodology to choose? what models might work? should one look at the profit on each product in isolation or the total profit over all possible products? In general there is no overall best method of credit scoring. The InKoM system is open to include more advanced models and rules, specific to the particular type of company or financial institution.

The Financial Market ontology involves information about the financial market and financial instruments. Knowledge on this topic is an essential element capable of aid manager in making investment decisions and securing from market risk. Financial market may be used by managers to regulate liquidity by using money market instruments.

The ontology of General Financial Knowledge concerns essential economic-financial knowledge which is required to analyze issues of listed ontologies. This ontology includes a set of supplementary topics to other ontologies and will be used in calculating the value of Cash Flow at Risk (the ontology of Cash Flow at Risk), basic economic ratios (the ontology of Early Warning System) and indicators used by banks in the process of credit scoring (the ontology of Credit Scoring).

To sum up, the domain knowledge about relations between economic and financial ratios will make the analysis and interpretation of contextual connections easier. This is very important in the case of SMEs, where a company does not employ experts in economic-financial analysis and using outer consulting is too costly. Reproducing knowledge with the use of a topic map contributes inter alia to better understanding of economic concepts and the interpretation of specific economic and financial indicators.

To navigate in the financial knowledge of InKoM, a semantic search will be applied to avoid difficulties related to decision makers' interpretation of economic and financial information. This gives the opportunity to search data sources taking into account not only structural dependences, but also semantic context.

IV. Ontology Design Process

In the design of the InKoM system five basic stages of creating the ontology were defined. These are:

1. Definition of the goals, scope and constraints of the created ontology. While creating an ontology, assumptions about the created model of knowledge that will apply during its building have to be provided. That requires an answer to the question: what will the created ontology be used for?
2. Conceptualization of the ontology. This is the most important stage in the procedure of ontology development[2]. It includes the identification of all notions, definition of classes and their hierarchic structures (Superclass – Subclass), modeling relations, identification of instances, specification of axioms, and rules of inference.
3. Verification of the ontology's correctness by experts. In this stage the constructed ontology is verified by experts who did not participate in the process of creating it.
4. Coding the ontology in the format compatible with the topic map standard. During this stage the developed ontology is described in the formal language or chosen software. The result of this stage should be the encoded ontology[3].
5. Validation and evaluation of the built ontology. It is the stage during which evaluation of the created ontology meets the needs of the managers.

The important stage in the described procedure of creating an ontology is the conceptualization of the ontology. The process of conceptualization of an ontology is an intellectual activity organizing knowledge from a given field carried out by the person, either an expert or collaborating with an expert, responsible for creating the model of knowledge without the support of automated tools (see inter alia [2, p. 2036]). In this scope, there are few concepts of identification of topics and relations between them within the process of conceptualization. These are the following approaches to carrying out analysis: top-down, bottom-up and middle-out. We used middle-out, because it enables us best to maintain the level of detail control of the created ontology and reduce imprecisions, which translates into reducing iterative work (see [29, p. 21]; see also [2, p. 2036]). Based on literature studies (inter alia [13], [22]), as well as research carried out, the following procedure in conceptualization of the ontology of economic knowledge was used:

1. Identification and definition of all topics.

[2] Independently of the field that is to be modeled by using an ontological approach, it is the most important stage in creating a model based on ontology (see inter alia [2, p. 2036]).

[3] In the InKoM project at first, in order to quickly test developed ontology, it was entered in the program Ontopia. Ultimately it will be realized with the use of software for topic maps developed by the company UNIT 4 TETA BI Center.

A topic, representing any concept, is "a syntactic construct that corresponds to the expression of a real-world in a computer system" [14, p. 60]. In the InKoM project, a topics' list was determined by experts creating ontologies for the given field of economic knowledge. These topics include, beside their names, also their synonyms and descriptions (table 1). The example below illustrates a description of topics related to the case study: Credit Scoring that will be detailed in Section VI.

TABLE 1.
THE EXAMPLE OF TOPICS' LIST

Name	Synonym	Description
Return on Assets	ROA	ROA indicator is a synthetic measure that determines company's assets capability to create profit. It shows the percentage net profit per unit of capital invested in the company.

2. Creating a taxonomy of topics.
Specification of taxonomic relations between distinguished topics and defining classes and subclasses (table 2). This relationship describes the topics generalization. This approach to creating a taxonomy is proposed in METHAONTOLOGIA (see i.e. [13]).

TABLE 2.
THE EXAMPLE OF TOPICS' TAXONOMY

Superclass	Subclass
Indicators	– Debt indicators – Liquidity indicators – Profitability evaluation indicators – Efficiency assessment indicators
Profitability evaluation indicators	– Net Return of Sale – Return on Assets – Return on Equity

3. Definition of all other types of relations between topics.
In the InKoM project, the basic relationship aggregate of (Aggregate – Member) occurring in all six created ontologies was defined. Moreover within each ontology, additional relations were defined, for example: engagement (Engaging – Accession).

4. The list of all the individual relationships existing in the ontology.
The list includes: the name of the relationship, source topic, and target topic (table 3).

TABLE 3.
THE EXAMPLE OF DESCRIPTION OF THE RELATIONSHIPS

Name of relationship	Source topic	Target topic
Engagement	Profitability evaluation	Net Return on Sale
Engagement	Profitability evaluation	Return on Assets
Engagement	Profitability evaluation	Return on Equity

5. Description of functions and rules.
The following function description, specifies the example of the indicator Return on Assets (ROA), implemented in the InKoM system:

Name:
Indicator Return onAssets (ROA)
Input:
- Result of Net profit (NP)
  type: number, value with balance sheet
- Total Assets (TA)
  type: number, value with balance sheet

Output:
- Return on Assets

Initial conditions:
- available data from balance sheet

Final conditions:
- Message 1: *"Value of indicator ROA"*
- If ROA<5%,
  Then to Message *2: "*Low value of ROA*";*
- If 5% < ROA< 10%,
  Then to Message 3: *"*Average value of ROA*";*
- If ROA > 10%,
  Then to Message 4*: "*High value of ROA*";*

Description/formula:
ROA = NP/ TA

6. Description of usage scenarios.
Usage scenarios, also called use case view, describe demonstration analyses of economic topics occurring in this ontology. For example, if a manager is interested in the opportunity of applying for a bank loan:

1. The manager analyzes the semantic network, from which it follows that the credit score assessment is based on the analysis of indicators belonging to four groups: debt indicators, liquidity indicators, profitability evaluation, and efficiency assessment.
2. From the TETA BI system the manager receives the values of financial indicators that make up the credit score assessment. According to them, the company has bad parameters concerning the profitability evaluation, especially the value of ROA indicator.
3. The manager analyzes the semantic network connected to the data from the TETA BI system on account of semantic connections of the ROA indicator with other indicators. The aim of the action undertaken by the manager is to identify causes of unfavorable values from the ROA indicator.
4. Basing on conclusions from the analysis conducted of economic indicators, the manager can undertake corrective actions which may potentially result in improving the company's condition. Improvement of company's parameter essentials in the score assessment can allow actions to be undertaken concerned with receiving bank loan.

That work has required multi-domain expert knowledge, both theoretical and practical, in economics, finance, and informatics.

In InKoM, a semantic search is provided to avoid difficulties related to decision makers' interpretation of

economic and financial information. This gives the opportunity to search data sources taking into account not only structural dependences, but also the semantic context.

V. CASE STUDY – ONTOLOGY FOR CREDIT SCORING

The case study presented illustrates only a fragment of analysis of the company's financial situation with the use of the ontology of the credit scoring and the databases of TETA Business Intelligence system. Let us assume that the manager is interested in the ROA indicator. The ontology shows that the quantitative financial analysis consists of indicators: debt indicators, liquidity indicators, profitability evaluation indicators, and efficiency assessment indicators (Figure 2). On the Figure 2, solid lines denote taxonomic relations (relation Superclass – Subclasses), whereas broken lines denote all other types of relations between topics.

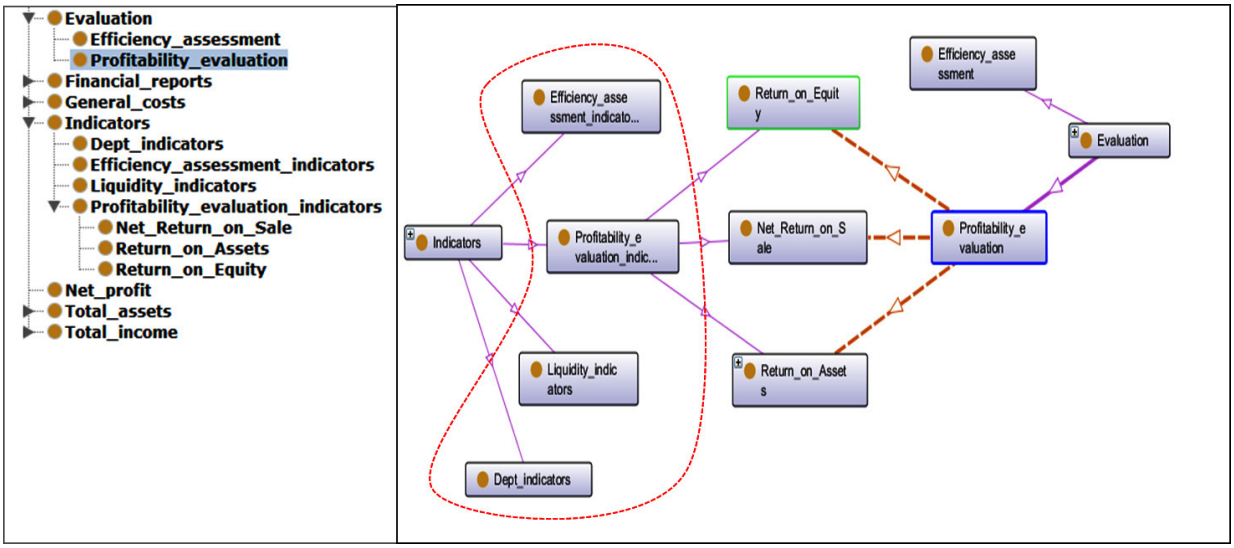

Figure 2. Example of topic map including the quantitative financial indicators

Returning to the ROA, it is known that the more effectively a company manages its assets, the higher the value of this indicator. It is assumed that its value should be greater than 5%. The ROA indicator is calculated on data from the balance report, that is Net profit (NP) and Total Assets (TA) (Figure 3):

$$ROA = NP / TA$$

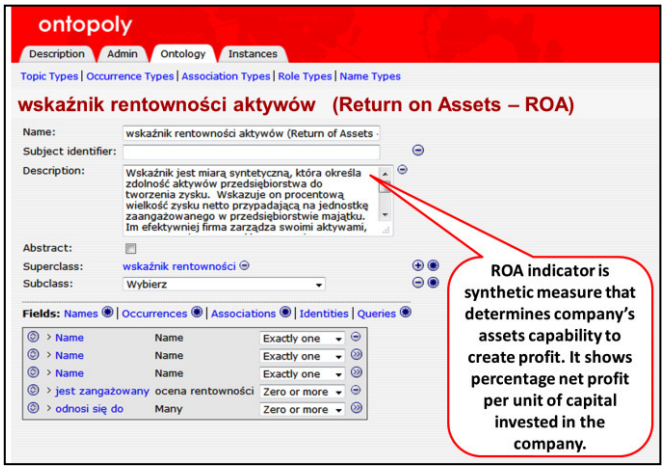

Figure 3. Topic definition – ROA

in year 2011 is equal to 12 908,00, and in the year 2012 equals 14 169,00, whereas the value of Total Assets in the year 2011 equals 184 400,00 and in the year 2012 354 000,00. Based on this data, the ROA indicator in 2011

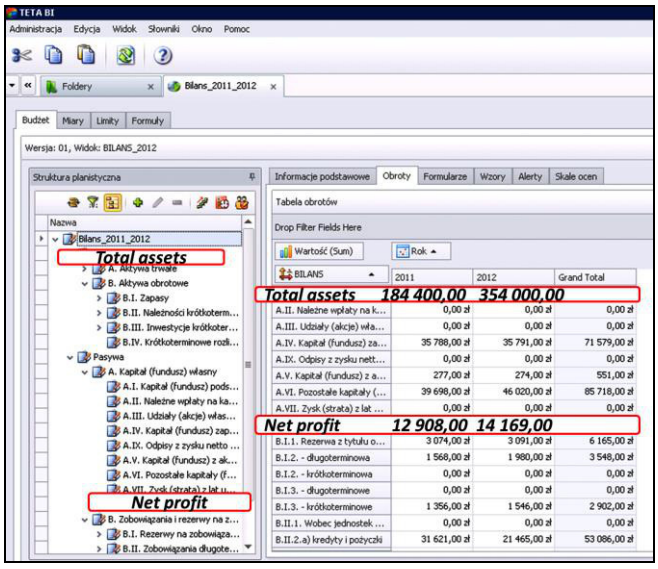

Figure 4. Example of balance sheet extracted from the TETA BI system

On figure 4 is presented an example of a balance report for the years 2011 and 2012 extracted from the TETA BI system. For the analyzed company, the value of Net Profit is equal to 7%, and in 2012 is equal to 4%. This means that the company's condition in 2012 is bad. In order to improve this situation, the manager needs to identify the cause of

these values. Therefore, following the topic map, the manager notes that the value of Net Profit in 2012 was higher than in 2011, so the disadvantageous ROA indicator results from value of Total Assets. To identify the sources of the ensuing situation, the manager has to examine the semantic relations between Total Assets and other financial topics. Exemplary decomposition of the chosen topic is presented on the Figure 5. The screenshot shows the expansion of the selected topic: Total Assets. On the diagram it is the area encircled by a dashed line, with new topics being a subclass of topic Total Assets.

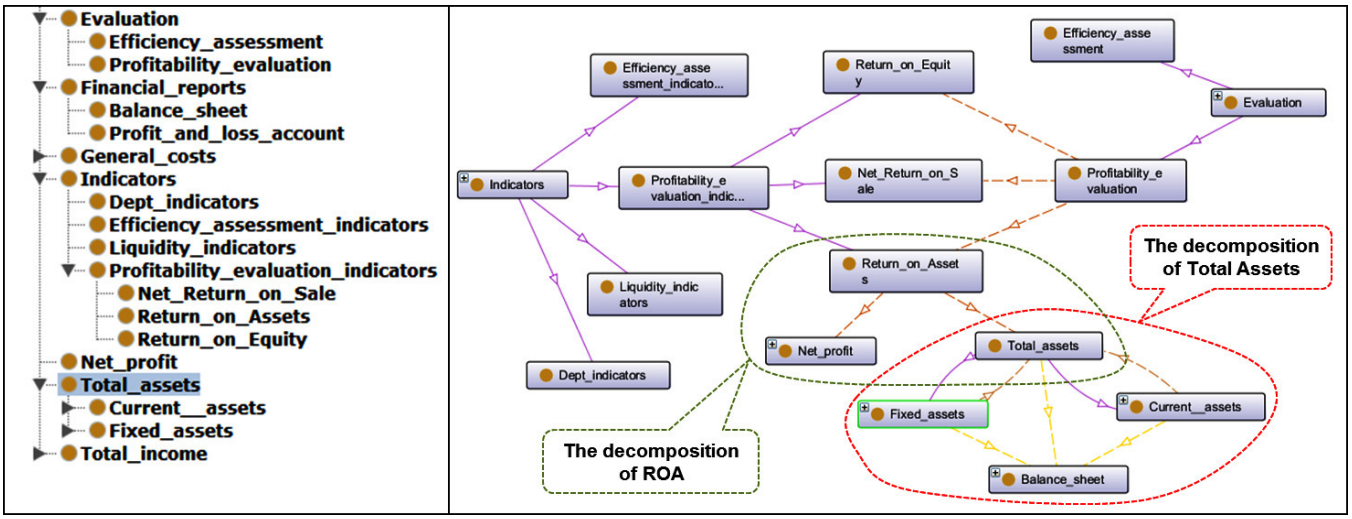

Figure 5. Example of topic map including Total Assets

In the InKoM system the manager can use the topic map application which allows relations between analyzed topics to be shown. This approach can be very useful for managers, because it is difficult a priori to identify causes that show by using only the balance sheet or other financial reports.

To interpret financial reports correctly, many measures and ratios need to be examined that either directly or indirectly influence the final result. Visualizing the relationships explicitly not only it makes the interpretation of indicators easier, but also contributes to finding out explanations of the current values of indicators. The topic map provides a user-friendly interface which allows managers to navigate easily from topic to topic in an interactive manner. Therefore various types of associations are visualized in different ways. For example, the lines which have the same relation have the same color. This enables an easy overview of concepts, visualisations and navigation of hierarchical structures, whilst also providing short definitions on each topic. The visualization is highly interactive: interesting nodes can be put in the foreground with zooms, translations, and rotations. Managers can delete non relevant branches of the graph or expand interesting ones.

VI. Summary And Future Work

In this paper, the approach to developing the ontology of InKoM was presented. The created ontologies are currently integrated in the TETA BI system and will be soon available in beta version. In the next step of the project, the effectiveness of the final system will be examined and assessed by SME managers. Further studies will be conducted on, among others, representation and interpretation of financial indicators, such as NPV and IRR, and methods specific to IT investment, such as TCO.

***Abstract*—The authors of this paper present an approach to trading strategy design for a multi-agent system which supports investment decisions on the stock market. The individual components of the system, the functionalities, and the mechanism of assessing the individual agents are briefly described. The main component, the supervisor agent, uses as a strategy a consensus method to reduce the level of investment risk. This method allows the coordination of the work of agents, and on the basis of decisions provided by the agents, and presents trading advice to the investor. The strategy testing has been done on FOREX quotes, namely on the pair EUR/USD. The results of the research are described and the directions of the further development of the platform are provided in the conclusion.**

I. Introduction

GENERALLY, the algorithms used in stock trading decision support systems can be based on mathematics, statistics, economics, or artificial intelligence [1;2;3;4;5;8]. Investing in financial instruments is always related to the occurrence of risk as the uncertainty of the future performance of investments. This uncertainty occurs due to links between the functioning of the capital market and factors such as the economic policy of the Government, the level of interest rates, exchange rates, or phases of the business cycle

A very important element of risk management is to measure these risks, to estimate the level of risk that is being taken in relation to the size of the capital which is at the disposal of the investor, as well as the investment limits. In general, the risk measures can be divided into three basic categories [8] :

- volatility measures (i.e. average deviation, average coefficient of variation),
- sensitivity measures (i.e. beta coefficient, delta coefficient),
- downside measures (i.e. Value at Risk).

In order to reduce the risk, diversification is applied. That is, investing in different types of instruments as well as various instruments of the same type. The diversity of investment reduces the risk of the instrument with the greatest level of risk, however, but on other site also lowers the expected investment rate of return . Another technique to reduce the level of risk is to take investment decisions with the use of multiple methods at the same time.

The aim of this paper is to present the trading strategy in a multi-agent system which avoids risky investment decisions due to the integration and cooperation of the agents. In the design of our system, called A-Trader, the accuracy of predictions, the orientation on online trading, the improvement of the financial knowledge base, and the ability to adapt to the changing market environment were all important requirements.

The paper is divided into three main sections. The first one presents the functional architecture of the system. The individual components of the system and the manner of communication between them are discussed. In the second, the consensus strategy used by the Supervisor agent to reduce the level of investment risk is described. The last part is a description of the results of the Supervisor strategy testing and performance analysis on the FOREX quotes. In conclusion, the further development direction of the A-Trader system are also described.

II. Multi-agent system – architecture and functions

The key ideas of A-Trader have been already detailed in our previous papers [9;10]. As a brief reminder: the A-Trader architecture in fig.1 sketches the main agents and components, namely: Notification Agent (NA), Historical Data Agent (HDA), Cloud of Computing Agents (CCA), Market Communication Agent (MCA), User Communication Agent (UCA), Database System (DS), Supervisor (S).

Let us describe briefly each agent of the system. The Notification Agent (NA) ensures efficient communication within the system. The Notification Agent forwards the information on the status change of a given agent to all agents that are recorded in the Notification register as the clients/observers of its signals. The notification is performed by triggering an appropriate Web method (SOAP) in all the agents from the list of listeners to the indicated signal. Next, it records the information on the status change of the

978-83-60810-53-8/$25.00

Notification Agent in the database. This capability of the Notification Agent makes the system flexible and scalable, provides the possibility to add and remove agents easily, and ensures the independence of the system from the physical position of the agent. Notification Agent sends the Base Agents and Intelligent Agents signals (decisions) to the Supervisor Agent. On the basis of these decisions, the Supervisor strategies are realized.

Another system agent downloads financial data from the Database System (SD) and delivers them to the agents according to their needs. This is the role of the Historical Data Agent (HDA).

The next system component is the Cloud of Computing Agents (CCA), consisting of Basic Agents Cloud (BAC), Intelligent Agents Cloud (IAC), and User Agents Cloud (UAC).

The Basic Agents Cloud (BAC) is a group of agents which pre-process data and compute the basic technical analysis indicators. The agents which possess their own knowledge base, which can learn and change their parameters and their internal state, create another component of the agents cloud, called the Intelligent Agents Cloud (IAC). This group of agents includes all the solutions based on artificial intelligence (genetic algorithms, neural networks, expert systems, etc.), agents analyzing text messages, agents observing user behaviour. The result of the operation of Basic Agents and the Intelligent Agents are the decisions which are transferred to the Supervisor Agent.

The User Agents Cloud (UAC), in turn, is the cloud containing the agents created by external users. Separating this part of the system provides the possibility of integrating the User Agents with the system without the necessity of installing the agent on the servers.

The communication of the system with the external environment is ensured by the Market Communication Agents (MCA). On the one hand, these agents supply the news from financial markets and quotations of the available securities. On the other hand, they are responsible for performing open and close position orders.

Fast and easy visualisation of the results of the agents is an important aspect in verifying the correctness of its operation. Such visualisation is possible in the system due to the User Communication Agents (UCA). The Communication Agent allows the user to communicate its own recommendations to the Intelligent Agents. It enables the change of the parameters of a selected agent or the suggestion for the Supervisor on which mechanisms are supposed to influence investment decisions, and to what extent.

The key component of the system is the Supervisor (S). The main goal of this agent is to generate profitable trading advice that reduces the investment risk. The supervisor, by using different strategies, coordinates the computing on the basis of decisions generated by Basic and Intelligent agents, and provides the final decision to the trader. Fig. 2 presents the general functional schema of A-Trader. A few strategies were developed in the system such as the consensus strategy, the rule-based strategy, and the evolution-based strategy.

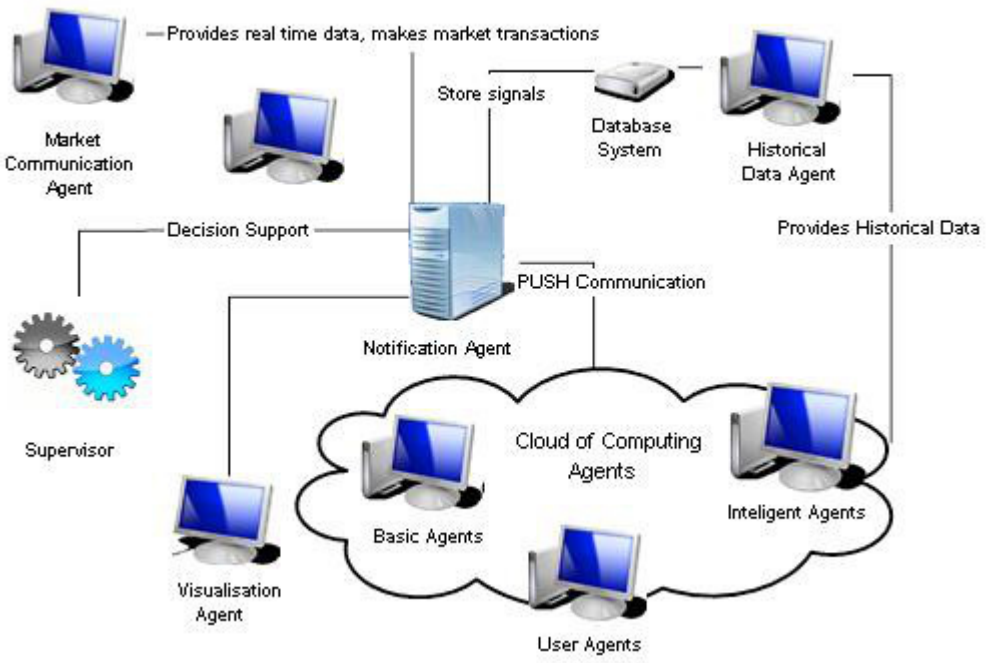

Fig.1 A-Trader system architecture
Source: Own work.

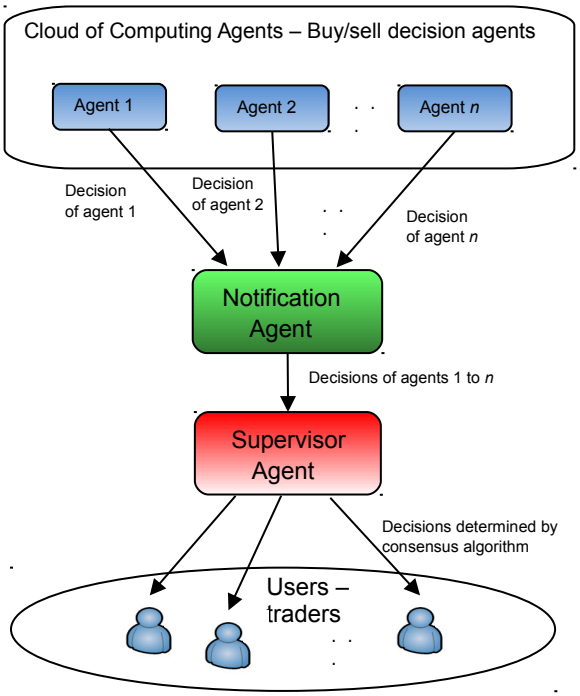

Fig.2 Functional schema of A-Trader
Source: Own work.

The strategies operate on the following assumptions:

1. Cloud of computing agents – Buy/sell decision agents, the intelligent programs, which, on the basis of the signals received from the Notification Agent, take the specified decision on buy/sale. Each agent has been implemented with a different method of computation and decision making. Buy/sell decision agents send the decisions to Notification Agent.
2. The Supervisor Agent – functions on the basis of the strategies that allow the determination of the final decisions on the basis of separate decisions generated by individual agents (read from Notification Agent), which are to be presented to the users (Traders). As a consequence, it is possible to reduce the level of risk associated with investing in a financial instrument.
3. Users – mostly traders who invest on financial markets, or bots (automatic traders).

The multi-agent system is composed of the agents being capable of generating independent decisions. These may be mutually consistent or completely contradictory decisions. Such mutually exclusive decisions are e.g. the open and close positions generated by two independent agents at the same time. The conflicts are resolved by the Supervisor, which observes the decisions of all the Cloud of Computing Agents and the Intelligent Agents, and assesses their effectiveness in investing and risk. The Supervisor determines which agents are taken into consideration when making an investment decision and whose advice is ignored based on the collected information.

The Supervisor may apply various strategies to generate the final trading decision. In the paper, the consensus method is detailed and tested. The relevant literature [13] defines consensus as an agreement and originates from choice theory. Consensus is based on the existing solutions to a given problem, is very close to them, but does not have to be one of these solutions. Hence, the financial decision presented to the user is a decision formed on the basis of the generated trading decisions [11].

The consensus is elaborated in three major stages. In the first stage it is necessary to carefully examine the structure of the set of financial decisions. In the second stage it is necessary to define the distance functions among particular decisions. The third stage is an elaboration of consensus algorithms that generate a decision, that the distance between this decision (consensus), and the individual decisions is minimal (according different criteria) [12].

The specificity of the problem being solved (a large set of open and close position signals) due to the dynamically changing market environment, the implementation requires an extremely high performance of the system. Therefore, from a software point of view, to make the implementation easier, each agent is activated within its container, which isolates it from the environment and which encapsulates the communication with the Notification Agent. Note that multiple containers may be activated on one machine.

The objective of the isolated agents and their transfer to the cloud is to ensure asynchronous cooperation and to enable the performance of specialised operations on the dedicated environment. For example, computing algorithms may be performed synchronously on the computers equipped with multi-processor NVIDIA graphic cards.

III. `Supervisor - Consensus Strategy

The consensus method was implemented as one of the main strategies of the Supervisor. The consensus algorithm runs automatically after providing the decision advices by individual agents.

Each financial decision must be represented by using a concrete structure (the first stage of consensus determining). Such structure was defined in work [6]. In our system, the financial decision consists in a trading position relating to a given quote, such as EUR/USD, USD/GBP, etc. The formal definition of this structure is the following:

Definition 1.

Decision P about finite set of financial instruments $E=\{e_1, e_2, \ldots, e_N\}$ is defined as a set:

$$P=\langle \{EW^+\}, \{EW^\pm\}, \{EW^-\}, Z, SP, DT \rangle \quad (1)$$

where:

1) $EW^\pm=\langle e_o, pe_o\rangle, \langle e_q, pe_q\rangle, \ldots, \langle e_p, pe_p\rangle$

Couple $\langle e_x, pe_x \rangle$, where: $e_x \in E$ and $pe_x \in [0,1]$ denote a financial instrument and this instrument's participation in set EW^+.

Financial instrument $e_x \in EW^+$ is denoted by e_x^+.

The set EW^+ is called a positive set; in other words, it is a set of financial instruments about which the agent knows the decisions to buy, and the volume of this buying.

2) $EW^{\pm} = \langle e_r, pe_r \rangle, \langle e_s, pe_s \rangle, \ldots, \langle e_t, pe_t \rangle$.

Couple $\langle e_x, pe_x \rangle$, where: $e_x \in E$ and $pe_x \in [0,1]$ denote a financial instrument and this instrument's participation in set $EW^{\pm}$.

Financial instrument $e_x \in EW^{\pm}$ will be denoted by $e_x^{\pm}$.

The set $EW^{\pm}$ is called a neutral set, in other words, it is a set of financial instruments, about which the agent does not know that buy or sell. If these instruments are held by an investor, that they should not be sold, or if they are not in possession of the investor, should not be bought by them.

3) $EW^- = \langle e_u, pe_u \rangle, \langle e_v, pe_v \rangle, \ldots, \langle e_w, pe_w \rangle$.

Couple $\langle e_x, pe_x \rangle$, where: $e_x \in E$ and $pe_x \in [0,1]$, denote financial instrument and this instrument's participation in set EW^-.

Financial instrument $e_x \in EW^-$ will be denoted by e_x^-.

The set EW^- is called a negative set; in other words it is a set of financial instruments of which the agent knows that these elements should sell.

4) $Z \in [0,1]$ - predicted rate of return.

5) $SP \in [0,1]$ - degree of certainty of rate Z. It can be calculated on the basis of the level of risk related with the decision.

6) DT - date of decision.

A situation in which the structures of a decision in the system differ, or the values of their attributes are different, is called a knowledge conflict of these agents. This conflict results in the taking by agents of various, often contradictory decisions concerning buying and selling a financial instrument.

Consensus is determined on the basis of a decision generated by different agents working in a system. We call a set of such decisions a profile and define it as follows [7]:

Definition 2.

E set of financial instruments $E = \{e_1, e_2, \ldots, e_N\}$ is given. In the case of A-Trader it is a set of pairs of currencies, e.g. EUR/USD, USD/GBP.

A profile $A = \{A^{(1)}, A^{(2)}, \ldots, A^{(M)}\}$ is called a set of M decisions of finite set of financial instrument E, such that:

$$A^{(1)} = \langle \{EW^+\}^{(1)}, \{EW^{\pm}\}^{(1)}, \{EW^-\}^{(1)}, Z^{(1)}, SP^{(1)}, DT^{(1)} \rangle$$
$$A^{(2)} = \langle \{EW^+\}^{(2)}, \{EW^{\pm}\}^{(2)}, \{EW^-\}^{(2)}, Z^{(2)}, SP^{(2)}, DT^{(2)} \rangle$$
$$\ldots\ldots\ldots\ldots$$
$$A^{(M)} = \langle \{EW^+\}^{(M)}, \{EW^{\pm}\}^{(M)}, \{EW^-\}^{(M)}, Z^{(M)}, SP^{(M)}, DT^{(M)} \rangle \quad (2)$$

In the case of A-Trader the profile is a set of decisions generated by Base Agents and Intelligent Agents. On the basis of these decisions, the Supervisor strategy is executed.

At the A-Trader system, the values Z, SP are provided by Base Agents and Intelligent Agents (e.g. by using statistical forecasting methods, or artificial intelligence methods) or by Supervisor (e.g. on the basis of agent performance evaluation). The values DT are generated, by all agents, together with the signals (decisions).

The Supervisor strategy is carried out according to the following consensus algorithm:

Algorithm 1.

Data: The profile A= $\{A^{(1)}, A^{(2)}, \ldots A^{(M)}\}$ consists of M agents' decisions.

Result: Consensus

$CON = \langle CON_+, CON_{\pm}, CON_-, CON_Z, CON_{SP}, CON_{DT} \rangle$ according to A. The consensus is a decision generated by the Supervisor Agent. This decision consists of the same attributes as the decision of the agents (e.g. CON_+ mean consensus of the EW^+ set), but the values of these attributes differ.

Begin

1: $CON_+ = CON_{\pm} = CON_- = \emptyset, CON_Z = CON_{SP} = CON_{DT} = 0$
2: $j := 1$.
3: $i := +$.
4: If $t_i(j) > M/2$ then $CON_i := CON_i \cup \{e_j\}$
Go to:6.
5: If i=+ then $i := \pm$
If $i = \pm$ then i:=-
If i=-, then Go to:6
Go to:4.
6: If $j < N$ then $j := j+1$ Go to:3
If $j \geq N$ then Go to:7.
7: $i := Z$.
8: Determine $pr(i)$.
9: $k_i^1 = (M + 1) / 2$, $k_i^2 = (M + 2) / 2$.
10: $k_i^1 \leq CON_i \leq k_i^2$.
11: If $i = Z$ then $i := SP$
If $i := SP$ then $i := DT$
If $i := DT$ then End
Go to: 8.

End

The computational complexity of this algorithm is O(3NM).

The presented algorithm of consensus proposes a decision to the trader, who does not need to think about the choice of decision generated by Basic Agents and Intelligent Agents, which significantly reduces the time it takes to make a decision. Since a decision is taken on the basis of multiple

agents' decisions, it also reduces the risk of taking this decision, because it eliminates the possibility to make an incorrect decision by one of the agents a-Trader system agents.

The verification of the Supervisor strategy is presented in the next section of the article.

IV. EXPERIMENTS

FOREX (Foreign Exchange Market) is the market where one currency is traded for another. It is one of the largest markets in the world. Currencies are traded against one another in pairs. For instance, the quotation EUR/USD (EUR/USD) 1.3465 is the price of the euro expressed in US dollars, meaning 1 euro = 1.3465 dollars. To evaluate the Supervisor performance the pair EUR/USD is chosen from the FOREX market. In the evaluation the following assumptions have been imposed:

1. The minute-by-minute quotations EUR/USD are randomly selected, covering the following periods:
   I. 17-04-2013 hours: 12:47 to 15:00,
   II. 30-04-2013 hours: 18:36 to 23:16,
   III. 08-05-2013 hours: 21:45 to 23:34,
   IV. 09-05-2013 hours: 00:00 to 2:50.
   For instance, Fig. 3 presents a quotation of the pair EUR/USD in period IV.
2. During verification, the Supervisor uses the decisions (signals buy-value: 1, sell-value: -1, remain unchanged-value: 0) generated by program agents, which operate on the basis of a combination of technical analysis indicators (i.e.. agent no. 1 taking decisions on the basis of RSI, Stochastic Oscillator, MACD indicators combination, agent no. 2 – CCI, WILLIAMS, OBV, etc.). Due to the computational complexity and time constraints, the experiment was illustrated in the article by the Supervisor's signals generated by 6 agents.
3. Final Buy-Sell decisions are taken on the basis of the Supervisor's signals (fig. 4).
4. It is assumed that the initial trader capital equals 1000 USD, and that the investment rate of return shall be calculated as the difference between the initial capital and the amount that the investor will have after the last sales in a given period. The rate of return is expressed in (USD).
5. No transaction costs are taken into consideration.
6. Money management – assume that in each transaction, the investor commits 100% of capital. Money management strategy can be set by the user. The investor invests every time 1000 USD - leverage 10:1.
7. Performance evaluation is based on following ratios:
   a) the number of transactions,
   b) gross profit,
   c) gross loss,
   d) total profit,
   e) the number of profitable transactions,
   f) the number of profitable transactions in a row,
   g) the number of unprofitable transactions in a row,
   h) the average coefficient of variation is the ratio of the average deviation of the arithmetic average multiplied by 100% and is expressed:

$$V = \frac{s}{|E(r)|} \cdot 100\,\% \ . \tag{3}$$

   where:
   V – average coefficient of variation,
   s – average deviation of the rate of return,
   E(r) – arithmetic average of the rate of return.

Fig.3 EUR/USD quotations
Source: Own work.

Fig.4 Decisions of Supervisor, Buy-and-Hold and EMA in the period IV
Source: Own work.

i) Value at Risk – the measure known as value exposed to the risk - that is the maximum loss of the market value of the financial instrument possible to bear in a specific timeframe and at a given confidence level [2].

$$VaR = P*O*k \quad (4)$$

where:
P – the initial capital,
O – volatility - standard deviation of rates of return during the period ,
k –the inverse of the standard normal cumulative distribution (assumed confidence level 95%, the value of k is 1,65).

8. The results obtained by the Supervisor have been compared with the passive strategy Buy-and-Hold and the benchmark using EMA.

The test was carried out in the following way:

1. On the basis of the quotation from the first period, each agent referred to when to buy and when to sell a currency EUR/USD.
2. Next, taking into consideration the decisions of all the agents, the consensus was determined.
3. The performance of the Supervisor and benchmarks Buy-and-Hold and EMA are reported.
4. Next, the steps 1 to 4 were repeated using the next periods of the financial time series.
5. In the final stage, the performance ratio values were calculated corresponding to rates of return resulting from all decisions generated by the Supervisor, Buy-and-Hold and EMA strategies (not only of the final rates of return, but with all the rates of return calculated after each sale decision).

Comparison of final capital and rates of return obtained are shown in table 1.

TABLE 1. COMPARISON OF FINAL CAPITAL AND RATES OF RETURN

	Consensus		**B & H**		**EMA**	
period	Rate of return [USD]	Rate of return [%]	Rate of return [USD]	Rate of return [%]	Rate of return [USD]	Rate of return [%]
I.	10,59	0,011	-19,01	-0,019	-29,64	-0,030
II.	19,09	0,019	11,10	0,011	7,68	0,008
III.	4,56	0,005	3,50	0,004	4,71	0,005
IV.	6,84	0,007	-0,23	-0,0002	4,26	0,004
average	10,27	0,010	-1,16	-0,0001	-3,25	-0,0003

Source: Own work.

Summing up the results obtained through the use of the consensus method, in each period, a higher rate of return is shown compared with the decisions generated by the Buy-and-Hold and EMA. It should also be noted that the average rate of return of the Supervisor's decision is positive (profit), while the average rate of return of the Buy-and-Hold and EMA is a negative value (loss).

The performance analysis (table 2) shows that the Supervisor generated a smaller number of transactions than using the EMA, but with the EMA, however, the gross profit from these transactions is higher than the gross profit generated by EMA and Buy-and-Hold.

At the same time, the gross loss generated by the Supervisor is relatively lower in comparison with the benchmarks. It should also be noted that the Supervisor conducted a 93,33% profitable transactions (Buy-and-Hold 50%, EMA 47,06%). Important is also the fact that the Supervisor does not generate a series of unprofitable transactions in a row, but for instance the EMA generated such transactions. Analyzing the risk of decisions, it can be

TABLE 2.
RESULTS OF PERFORMANCE ANALYSIS

Performance ratio	Supervisor - Consensus	B & H	EMA
Number of transactions,	15	4	34
Gross profit	41,54 USD	14,60 USD	27,60 USD
Gross loss	-0,46 USD	-19,24 USD	-40,59 USD
Total profit	41,08 USD	-4,64 USD	12,99 USD
Number of profitable transactions (%)	14 (93,33%)	2 (50%)	16 (47,06%)
Number of profitable transactions in row	8	1	6
Number of unprofitable transactions in row	1	1	6
Average coefficient of variation	6,29%	7,95%	10,51%
Value at Risk	8,26 USD	18,30USD	18,53 USD

Source: Own work

noticed that the use of consensus methods by the Supervisor allows the lowest level of risk investment. The value of Average coefficient of variation equals 6.29%, while for Buy-and-Hold equals 7,95%, and for EMA 10,51%, instead. The Value at Risk of decisions generated by the Supervisor was 8,26 USD, which means that using the consensus method the trader can lose up to 8,26 USD in about a 2 hours period. Regarding Buy-and-Hold and EMA, this value was appropriately 18,30 and 18,53.

The verification of using the consensus method by the Supervisor agent therefore suggested that the decisions supported by the A-Trader system are the decisions which allow the investor to get satisfactory investor's results. It should be noted, of course, that the consensus method will not necessarily always get the highest rate of return. However, it can be assumed that, as a general rule, it allows the investor to obtain a lower level of risk associated with the investment. Note that if an investor had to make the choice which agent has to "listen to", then, assuming that the probability of selection of the agents by the investor is the same, he could more often choose a decision (hint) of an agent that allows one to get a lower rate of return. Besides, the evaluated agents using simple indicators are characterised by the large disparity in rates of return, confirming, for example, the value of the average coefficient of variation of EMA or Buy-and-Hold.

In conclusion, we can say that financial decisions generated by the consensus method allow to get a higher rate of return in comparison to benchmarks such as Buy-and-Hold and EMA, and get a faster determination of the decision, than if the investor takes the decision himself, among the decisions generated by the agents. Currently, due to the turbulent economic environment, investing in financial instruments must be carried out in close to real time. First and foremost, however, the use of consensus algorithms by the Supervisor allows the investor to decrease the level of risk related to financial instrument investing. Therefore, it also increases the level of usefulness of the decisions, and this can bring the user satisfying benefits.

It should be noted that the agents that were used in this experiment applied only to technical analysis indicators. It should be stressed that the A-Trader system gives a possibility of implementing the agents using fundamental analysis, or behavioral analysis. Work on the extension and variety of the agents' knowledge is in progress.

V. CONCLUSION

The first attempts to implement a multi-agent environment proved encouraging. The Supervisor decreased the investment risk by restricting the independent operations of more risk-taking agents for joint decisions of the entire environment. The cooperating agents made profitable decisions more frequently and close the loss-generating positions considerably earlier.

It should be stressed that the goal of multi-agent financial decision support systems, also the A-Trader system, is not only to maximize the rate of return on investment, but also to limit the level of risk associated with this investment. Taking into account the EUR/USD quotation dealt with in the article, it can be concluded that the level of risk is associated with, among other things, the fact that the financial situation of the euro depends on the economic and political situation in many countries. Whereas the dollar depends on a variety of government regulations and the United States engagement in the world economy.

Of the experiment in the article, it can be concluded that the use by the Supervisor of the consensus method makes it possible to lower the level of investment risk in consequence.

This can lead the investor to achieve a satisfactory investment rate of return.

The platform allows the implementation of different, intelligent or behavioral Supervisor strategies. The described multi-agent system makes testing and validating these new algorithms easier by supplying the basic functionalities and data. It enables the concentration of work on constructing new Supervisor strategies without being concerned about the basic data and message supply mechanisms

The A-Trader platform is now in the testing and expansion phase. The number and scope of the applied methods is being continuously expanded. New agents based on the recent methods are created. Of course, to obtain more objective conclusions about the consensus strategy, the tests should be done on a longer periods, with other quotes.

Abstract—**Horizon scanning is being increasingly regarded as an instrument to support strategic decision making. It requires the systematic examination of information to identify potential threats, emerging issues and opportunities to improve resilience and decrease risk exposure. Horizon scanning can use the Web to augment the acquisition of information, though this involves a search for novel and emerging issues without knowing them beforehand. To optimise such a search, we propose the use of relevance feedback, which involves human interaction in the retrieval process so as to improve results. As a proof-of-concept demonstration, we have carried out a horizon scanning exercise which showed that our implementation of relevance feedback was able to maintain the retrieval of relevant documents constant over the length of the experiment, without any reduction. This represents an improvement over previous studies where relevance feedback was not considered.**

I Introduction

The use of the World Wide Web for futures research has been gaining increasing attention [1-3]. Largely, the aim of futures research is to anticipate and prepare for new and changing risks, and to consider the implications that emerging issues will have on the distribution of resources and existing priorities. Given the current environment of change and uncertainty, both public and private sectors have identified the need to strengthen futures research and integrate it into strategic thinking and planning.

In the UK, the importance of futures research has been highlighted by a series of perceived failures in science and policy, such as the failure to recognise the concerns of the public about genetically modified crops until they emerged in the media, and the inadequate reaction to the outbreak of the foot/hoof and mouth disease in 2001 [4]. As a consequence of these setbacks, the UK Government has emphasised its use of horizon scanning, *"the systematic examination of information to identify potential threats, risks, emerging issues and opportunities, beyond the Parliamentary term, allowing for better preparedness and the incorporation of mitigation and exploitation into the policy making process"* [5]. Explicit objectives of horizon scanning are to anticipate issues, accumulate reliable data and knowledge about those issues and thus inform policy making and implementation [6].

Data collection associated with horizon scanning has blossomed with the availability of electronic databases and Web search engines. Regrettably, the process of searching for potential threats and emerging issues is not transparent. While searching is a retrieval process where the searcher knows in advance what she is looking for, horizon scanning is a process where we are trying to discover what is novel and surfacing without knowing it ahead of time. As explained by Palomino et al [7], we have access to ''search engines'' on the Web, but not to ''scanning engines''.

The impossibility of establishing precisely what is being sought before beginning the search makes it difficult to formulate information queries that are well designed for horizon scanning purposes. This suggests that the first retrieval operation involved in the process of scanning the horizon should be conducted with a tentative, initial query, and should be treated as a trial only, designed to locate a few useful items, which could then be examined for relevance so that later on new and improved query formulations can be constructed with the expectation of retrieving additional useful items in subsequent search operations. This is the reason why we have decided to explore the use of a controlled, automatic process for query reformulation, namely, relevance feedback, a technique utilised by some information retrieval systems [8].

The aim of this paper is to assess the use of relevance feedback as part of a horizon scanning system. To this extent, the remainder of this paper is organised as follows: Section II reviews related work on relevance feedback and briefly outlines previous research on Web-based horizon scanning. Section III details our implementation of relevance feedback in the context of a horizon scanning prototype which we are employing as a proof-of-concept demonstration. Section IV discusses a horizon scanning exercise that was conducted for a European Union Framework 7 project in association with RAL Space [9]—a world-class space research centre—to review current and future technologies for detecting and monitoring diseases in vegetation. We used this exercise as a case study to test our implementation of relevance feedback. Section V reports on the evaluation of the results of RAL Space's exercise, and, finally, Section VI states our conclusions.

II RELATED WORK

Relevance feedback has been extensively studied since its development in the mid-1960s [8, 10-12]. It refers to an interactive process that helps to improve retrieval performance: when a user submits a query, an information retrieval system would first return an original set of documents that satisfy the query and then ask the user to judge whether these documents are relevant or not; after that, the system would reformulate the query based on the user's judgments, and return a new set of documents. To some extent, relevance feedback is an alternative to save users from articulating queries in a trial-and-error manner.

Most of the research on relevance feedback undertaken thus far has approached its implementation as a supervised learning problem [8, 10, 11], where the key is to optimally balance the original query and the feedback information [13]—a special track to look into the effects of different factors on the success of relevance feedback has been organised by the Text Retrieval Conference (TREC) [14]. However, the use of relevance feedback in the context of horizon scanning has not been investigated yet. References to the applications of horizon scanning and the results of specific scans keep growing [4, 6, 15-21], as the interest in the subject increases, but only a few academic papers describe the methodology to carry out an automated scan [7, 22, 23], and the combined use of horizon scanning and relevance feedback has not been documented until now.

Shaping Tomorrow [24] and Recorded Future [25] are two private firms using Web-based scanning tools. Shaping Tomorrow helps organisations make better decisions through anticipating and preparing for the future. It uses a variety of manual, semi-manual and automated scanning processes to track and share information from around the world. It is first supported by a virtual network of volunteer and client researchers who "scan the scanners"—experts in the field—for material. Shaping Tomorrow also employs its own purpose-built Web-robot to scrape high value future websites and its service has accumulated 100,000 scan hits on emerging change, gathered over ten years from 5,000 plus sources, and 3,600 issues—trends, uncertainties and surprises—evidenced and linked to the scan hits. Shaping Tomorrow will soon release software to read the scan hit and do almost all of the researchers work automatically [26].

Recorded Future is established on the premise that all the information available on the Web is useful to support forecasting methods, financial or otherwise. Recorded Future continuously harvests news from more than 40,000 online sources, ranging from media and government websites to individual blogs and selected twitter streams [25]. Recorded Future aims to create and maintain a database of facts—pairs of timed entities and event instances—to track trends and historical developments and predict future events. As opposed to Recorded Future, we are not interested in predicting the future, but rather in improving resilience and the capability to react to new risks and opportunities.

In the public sector, horizon scanning has proved useful to identify new and emerging health technologies [20, 27, 28]. However, due to the large amount of information published online, it is difficult to recognise valuable data [29]. In an attempt to establish how exactly the Web should be used in health technology assessments, Douw et al [27] circulated a questionnaire among organisations known to use the Web for horizon scanning purposes. The questionnaire focussed on the type of websites scanned, the frequency of the scanning, and the importance of the Web for the identification of new health technologies. Responses to the questionnaire indicated that the organisations surveyed found new information through word of mouth, and links found on websites that they monitor continuously. Even though this highlights the importance of personal networking in horizon scanning, and the expertise of the scanners to choose the best links to follow, our work is directed towards the automation of the human-intensive practice of detecting and summarising emerging information. Hence, rather than surveying organisations, we have concentrated on the methodology to carry out a Web-based scan of the horizon.

Our methodology for Web-based horizon scanning comprises several interlinked components, as described by Palomino et al [7]: emerging information is retrieved—manually or otherwise—and / or received—e.g., via selected RSS feeds—from a variety of Web-based sources—such as, online scientific, peer-reviewed literature and news websites, which were sources of high importance for the work with RAL Space that we will describe in Section IV. Key parts of the retrieved information may be extracted and later on categorised. Afterwards, the information is often archived in a database. Periodically, outputs are presented to decision makers or used to write up reports or newsletters.

III RELEVANCE FEEDBACK

The main idea behind our implementation of relevance feedback consists of choosing important keywords attached to certain previously retrieved documents that have been characterised as relevant by the users, and of enhancing the importance of those keywords in future queries. Correspondingly, keywords included in previously retrieved non-relevant documents could be deemphasised in any future query formulation. Ideally, the effect of this query alteration process is to "steer" the query in the direction of the relevant documents and away from the non-relevant ones, with the expectation of retrieving more useful and fewer non-useful documents in later steps of the search.

Figure 1 shows a general Web-based horizon scanning approach for strategic decision support that uses relevance feedback. It accentuates the importance of the continuous scanning, noting that the processes of retrieving documents, and analysing, categorising and archiving information are iterated as part of a continuous process—static or sporadic scans become outdated quickly. The outputs of horizon scanning can be interfaced with further tools for opportunity and risk analysis [14] and scenario development.

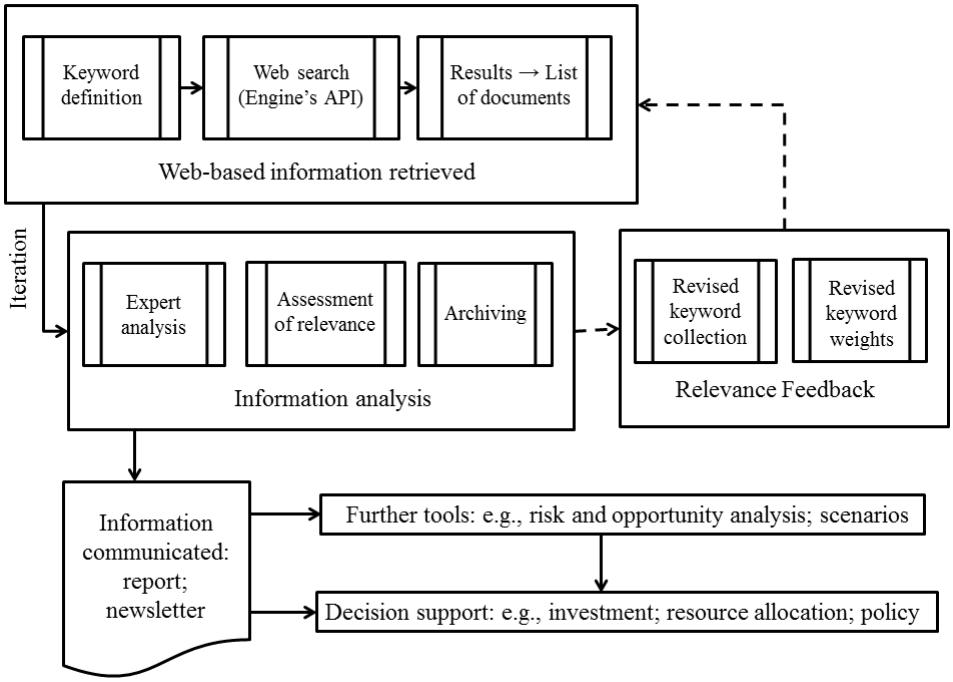

Figure 1. A generalised approach to Web-based horizon scanning for decision support using relevance feedback—based on Palomino et al [7]

Relevance feedback offers the following advantages to the analysts in charge of scanning the horizon:

(i) It frees the analysts from the details of the query formulation process—especially in late stages of the search.
(ii) It splits the search into an organised sequence of steps to reach the desired information gradually.
(iii) It devises useful queries without former analysis of the availability of data on the Web.
(iv) It features a controlled query alteration process designed to emphasise some keywords and deemphasise others, as required to accomplish a particular search.

Relevance feedback was originally developed as a technique to be used in conjunction with vector queries—i.e., queries represented by vectors with as many entries as keywords comprised in the query. Each entry refers to a "weight" symbolising the importance of the corresponding keyword within the query. For example, a particular query Q composed of n keywords may be written as

$$Q = (w_1, w_2, \ldots, w_n),$$

where w_i is the weight of the i-th keyword. Keyword weights are restricted to the range 0 to 1, where 0 means the corresponding keyword is absent from the query and 1 means it is so critical to the query that it has a full weight.

Given a vector such as Q, the relevance feedback process starts by generating a new vector

$$Q' = (w_1', w_2', \ldots, w_n'),$$

where w_i' represents a modified weight for the i-th keyword in the query—new keywords can be introduced to the query, and old keywords can be removed by reducing to 0 its weight. The process continues by creating yet another vector Q'' by modifying the weights of Q' according to new feedback, and so on and so forth until the required documents are found or the process reaches a pre-established number of iterations. Graphically, the relevance feedback process can be depicted as a relocation of the query vector from one place to another in the n-dimensional space defined by the n keywords under consideration.

A poorly conceived query reformulation can result in deterioration in retrieval performance [30]. Hence, a suitable set of keywords to search for information should be selected at each step in the process. We always choose our keywords with the support of software for the automatic extraction of keywords. Specifically, we use Yahoo!'s Content Analysis Web Service [31].

Normally, a scan of the horizon begins by defining the goals of the scan with a few sentences. We then submit those sentences to Yahoo!'s Content Analysis Web Service to automatically extract keywords—when available, entire documents relevant to the scan, called seed documents, are submitted to extract keywords.

These keywords are used to create the initial queries to search the Web for information. Normally, these keywords are combined with terms and phrases such as `new development`, `revolutionary`, `first time`, and others which have been suggested by the UK Defence Science and Technology Laboratory (Dstl) as descriptors of emerging issues [32]. These combinations of automatically extracted keywords and descriptors of emerging issues constitute the queries employed to bootstrap the relevance feedback process—i.e., these are the queries whose formulation we will attempt to refine along the process.

Once we have retrieved a first list of documents as a result of releasing our queries, we proceed to collect feedback. Usually, an expert, or a group of experts, in the field of the scan, or the same people who developed the requirements for the scan, are asked to indicate, for each document in our results, whether it is relevant, very relevant or non-relevant. The documents that are marked as very relevant are submitted to Yahoo!'s Content Analysis Web Service to extract new keywords. Keywords that were not considered in the initial queries, but are at the top of the new list of keywords yielded by Yahoo!'s Content Analysis Web Service are added to the original keywords and used to formulate new queries—keywords at the top of the list are expected to be more characteristic of the documents submitted than those near the bottom [31].

For each document that we retrieve, we keep a record of the keywords that were included in the queries used to retrieve it—note that a particular document can be retrieved as a result of more than one query and therefore be associated with several keywords. The weights of keywords used in queries that retrieved documents that were marked as very relevant are increased by a factor proportional to the number of very relevant documents associated with them. Likewise, the weights of keywords associated with documents marked as non-relevant is decreased by a factor proportional to the number of non-relevant documents associated with them—see Figure 2. The weights of keywords associated with documents marked as relevant—but not very relevant—is not modified and remains the same for the following iteration.

Once the set of keywords has been amended to integrate the initial feedback received, and the weight of each keyword has been adjusted to reflect the number of relevant, very-relevant and non-relevant documents retrieved with them, we proceed to release new queries, whose formulation can be thought of as a refinement of the initial ones, and the entire process can be repeated again until we complete a pre-established number of iterations. To automate our search for documents on the Web, we programmatically released our queries via Google's Custom Search API [33]. We chose Google's Custom Search API, because Google is the most popular search engine [34]; yet, other engines with an API interface could be used too—in other words, we will focus on Google for testing purposes, but the approach described here is not restricted to a specific search engine.

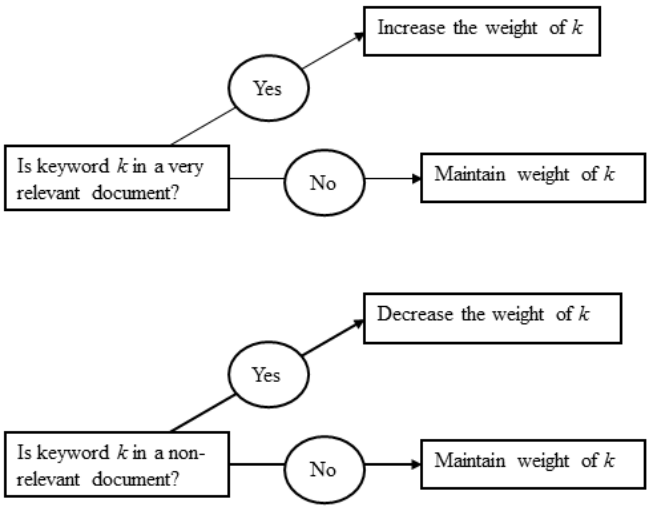

Figure 2. Keyword weight adjustment

Google has one of the largest databases of Web pages, including many types of documents—blog posts, wiki pages, group discussion threads—and document formats—PDF, Microsoft Word or PowerPoint documents, among many others. Despite the presence of all these types of documents and formats, Google's method of ranking on the basis of the PageRank citation algorithm [35] often places relevant documents near the top of the search results, and Google's Custom Search API allows us to query Google's repository directly and frequently in an automated way. Indeed, the frequency with which we query Google's repository can be adapted to the particular needs of the scan.

A. Queries with weighted keywords

A critical aspect of our relevance feedback implementation is the use of weights to express the importance keywords. Appropriately using those weights is what guarantees that our process reaches the desired information gradually; otherwise, the continuous extraction of keywords from newly retrieved documents would simply increase the number of keywords and queries, which would in turn increase the number of collected documents, without guaranteeing that we are actually gathering more useful information. Devising a way to adequately use the weights so that subsequent queries assign higher importance to keywords with greater weights is one of the most challenging features to accomplish.

Our implementation is based on using the weights of the keywords to decide how we should employ those keywords to look for documents:

(i) Keywords with low weights are used to search for documents that include the keywords anywhere in the text—not necessarily in prominent places.
(ii) Keywords with high weights are used to search for documents that include the keywords in their titles—according to Page et al [35], titles are more descriptive of the contents of a document than the rest of the text.

(iii) Keywords with very high weights are used to search for documents which are referenced to by hyperlinks whose text includes the keywords—Page et al [35] have stated that the text contained in the hyperlinks that point to a document, also known as the anchor text, link text, or link title, is greatly descriptive of the contents of the document referred to.

(iv) Keywords whose weights have been reduced to 0, which means that they have no relevance at all to the search, are preceded by the "minus" operator in our queries to explicitly indicate that they must not appear in the retrieved documents.

(v) All keywords have the same weight at the start, when the first search takes place and no feedback has been gathered yet. For the first iteration, all keywords are used to search for documents that contain them anywhere in the text.

(vi) Keywords that are meant to be descriptors of emerging issues—for instance, `ground breaking` and `closer to reality`—have constant weights that are never modified through the entire process. We always search for documents that contain these keywords anywhere in the text.

Our implementation of relevance feedback ensures that keywords with higher weights are looked for in places which are expected to have higher importance and therefore be more descriptive of the documents that contain them. Table I displays the association between weight ranges for keywords and the locations—hyperlinks, titles, or general text—where we search for those keywords to retrieve new documents that contain them.

TABLE I. KEYWORD RANGES AND KEYWORD LOCATIONS

Weight range	Keyword location
0	Nowhere in the document
(0,0.33]	Anywhere in the text
(0.33,0.66]	In the title
(0.66,1]	In the anchor text

In order to illustrate the relevance feedback process in detail, we will use an example. The example derives from a horizon scanning exercise proposed by RAL Space in October 2012 and it is explained in the following section.

IV RAL SPACE SCANNING EXERCISE

In October 2012, RAL Space, based at the Rutherford Appleton Laboratory (RAL), undertook a review for the European Union Framework 7 project Q Detect: Developing Quarantine Pest Detection Methods for use by National Plant Protection Organizations (NPPO) and Inspection Services [36]. In this review, RAL Space looked into current and future aerial platform technologies and instrumentation options for detecting and monitoring diseases in vegetation, and the mapping of pests through the use of aerial platforms.

The review aimed to assess the efficacy of remote sensing techniques—such as direct imaging and spectrally resolving reflected light—from different aerial platforms—ranging from small unmanned aircraft to low altitude satellites—to evaluate and monitor the health of plant life over long periods of time with little human inspection. The report was not meant to target specific plant diseases, but to provide an overview of various, if not all, potential diseases, whilst providing a thorough examination of the state-of-the-art in remote sensing instrumentation and platform technology.

As part of the review, RAL Space assessed how low, medium and high-altitude platforms integrated with high spectral and spatial resolution instrumentation could be used to come up with different performance metrics within a specific user requirement framework, which included cost, endurance, spatial resolution and frequency of measurement. RAL Space's review contributed to compare the economic benefit and practical realisation of present and forthcoming technology to assist in the detection of quarantined disease remotely. Since decision making on the uptake and use of emerging technology for disease monitoring has to be supported by timely and high quality information, RAL Space made use of horizon scanning to produce the review.

The horizon scanning exercise began by establishing the seed documents. These documents—listed in Table II—were mostly academic papers chosen by RAL Space.

Sharples, J.A. 'The Corn Blight Watch Experiment: Economic implications for use of remote sensing for collecting data on major crops'. LARS information note 110173.

The text of all the abstracts of the academic papers in Table II was submitted to Yahoo!'s Content Analysis Web Service, and a large list of keywords was produced in return. Together with an analyst from RAL Space, we chose the keywords that we considered most useful and grouped them into three different categories:

(i) Subject keywords, which refer to the main subject of RAL Space's review—for example, `crop monitoring` and `plant health`.
(ii) Technology keywords, which refer to different technological alternatives for detecting and monitoring diseases in vegetation—for example, `satellite` and `remote sensing`.
(iii) Descriptors of emerging issues, which are keywords defined by Dstl to capture "fresh" information on relevant subjects.

Table III shows the precise set of keywords that we use to start the process. Combinations of these keywords produced a total of 140 queries: each query included one, and only one, keyword from each category. Those 140 queries were used to start the search.

TABLE III. INITIAL SETS OF KEYWORDS

Subject	Technology	Emerging issues
crop disease	aerial platforms	breakthrough
crop monitoring	remote sensing	closer to reality
environmental monitor	satellite	first time
forest monitoring	unmanned aerial vehicle	ground breaking
plant health		new development
		novel
		revolutionary

Although we set up our prototype to limit to 64 the number of results per query, this still allowed up to 8,960 documents to be retrieved for each automatic release of the 140 queries employed in the initial search—indeed, nearly 4,000 unique documents, approximately, were retrieved per iteration. It would be unmanageable for a RAL Space analyst to review all those documents, given the short time allocated to this activity. Hence, we committed to deliver 50 documents, exclusively, per iteration to RAL Space, because this was the number of estimated documents that could be reviewed by a RAL Space analyst per iteration.

We assumed that the documents of most importance—i.e., those of greatest relevance—would be the ones that consistently appear at the top of the search results. We thus presented a ranked list of documents to RAL Space, with the ranking being based on the number of times that the document was retrieved by Google's Custom Search API over the course of each iteration—i.e., cumulative retrieval occurrences from programmatic releases of queries—see Palomino et al [22] for more details regarding the use of Google's Custom Search API.

Once the top-ranked 50 documents per iteration were chosen, we divided them into three different categories: academic papers, news articles and standard documents. The academic papers comprised, mostly, peer-reviewed papers relevant to the scan. The news articles were, mostly, press releases and news articles available on the Web; and the list of standard documents consisted of documents retrieved as a result of our queries that were not published by news websites or online academic journals. All the documents that we delivered, regardless of the category, were published between 2010 and 2012, exclusively.

V RESULTS

We previously conducted a benchmarking study between September and October 2010 in collaboration with Lloyd's of London [37], one of the global leaders in the insurance market. The goal of that study was to use our prototype for framing decision making on novel risks—specifically risks associated with space weather and how these might affect terrestrial and near-Earth insurable assets [22]. As part of the study, we were able to identify several documents that Lloyd's Emerging Risks Group analysts considered very relevant to assess insurance exposure; yet, the number of very relevant documents retrieved per week decreased as the experiment progressed, while the number of non-relevant documents retrieved increased over the same period [22].

Table IV displays the precise numbers of very relevant, relevant and non-relevant documents retrieved weekly in our study with Lloyd's of London—relevance feedback was not employed in that study and the relevance of the documents was evaluated according to the criteria developed by Lloyd's analysts —see Palomino et al [22] for full details.

TABLE IV. LLOYD'S EVALUATION RESULTS

	Week 1	Week 2	Week 3	Week 4
Very relevant	29	19	11	5
Relevant	66	64	74	74
Non-relevant	5	17	15	21

Although there were reasons to justify why most of the very relevant documents retrieved in our Lloyd's study were discovered in the first week, one of the major goals of the current study, and a motivation for our interest in relevance feedback, was to improve the performance of our prototype to make sure that the retrieval of relevant documents remains constant over the length of the experiment.

The scanning exercise undertaken with RAL Space comprised three iterations between 12 and 19 October 2012. Table V shows the exact number of very relevant, relevant and non-relevant documents retrieved per iteration. Table V shows that the number of very relevant documents decreased by one in the second iteration but then remained constant, which is an improvement over the results of the Lloyd's experiment, where the number of very relevant documents decreased by 10 after the first set of results and kept decreasing afterwards—see the first row in Table IV.

TABLE V. RAL SPACE EVALUATION RESULTS

	Iteration 1	Iteration 2	Iteration 3
Very relevant	16	15	15
Relevant	15	23	24
Non-relevant	19	12	11

As explained above, the 50 documents that we delivered per iteration to RAL Space were divided into academic papers, news articles and standard documents—all of them published between 2010 and 2012, exclusively. The specific breakdown per category and iteration is shown in Table VI.

TABLE VI. RAL SPACE EVALUATION RESULTS PER CATEGORY

First iteration

	Very relevant	Relevant	Non-Relevant
Academic	8	8	6
Standard	6	5	4
News	2	2	9

Second iteration

	Very relevant	Relevant	Non-Relevant
Academic	7	15	5
Standard	7	6	5
News	1	2	2

Third iteration

	Very relevant	Relevant	Non-Relevant
Academic	8	14	4
Standard	5	7	3
News	2	3	4

Due to the involvement of RAL Space in the Q-Detect project, academic papers were considered of particular importance for RAL Space's review. Table VI shows that the number of very relevant academic papers discovered by our prototype decreased only in the second week—decreased by one—but remained almost constant for the entire length of the experiment, which shows the potential of relevance feedback for searches within online journals.

To further evaluate the performance of our prototype, we used precision, one of the most common measures for evaluating the performance of information retrieval systems [38]. Precision is defined as the fraction of retrieved documents that are relevant to the search. For this experiment, we computed precision by considering all the documents evaluated by the analyst as being relevant or very relevant to be at least relevant, and compared these to the total number of documents presented to RAL Space each week—i.e., 50. Table VII displays the precision of our prototype per iteration. The final column shows the overall precision value for the entire experiment—namely, 72%. Note that the precision of the prototype actually increased on a weekly basis. Also note that the number of non-relevant documents—as indicated in Table V—decreased over the experiment, though not by much.

TABLE VII. PRECISION MEASURED PER ITERATION

	Iteration 1	Iteration 2	Iteration 3	Overall
Precision	62%	76%	78%	72%

A possible explanation as to why the number of relevant documents decreased as the Lloyd's experiment progressed is related to the timescale of the evolution of space weather documents on the Web. A period of four weeks might be insufficient to capture a significant number of additional newly published documents on space weather after our first search—i.e., after the first release of queries has been made. Consequently, the very relevant documents retrieved in the first week of the experiment were likely to be the most relevant ones for the entire experimental period of one month. To support this, we were able to verify that most of the documents marked as very relevant by Lloyd's Emerging Risks Group analysts were discovered in the first week of the experiment, but we could not include them in the results for the first week because we were restricted to a maximum of 100 documents per week.

As opposed to the case of the Lloyd's experiment, in the horizon scanning exercise undertaken with RAL Space, where we experimented with the use of relevance feedback, we can confirm that none of the documents delivered to RAL Space in the final iteration was discovered previously, and only two of the relevant documents delivered in the second iteration were discovered in the first week. The reason why we were able to find new documents and maintain the number of very relevant documents per week was that our relevance feedback implementation allowed us to modify the queries to reach different areas of the Web that we would not have been able to approach by releasing the same queries for all the iterations of the experiment.

Ideally, we would have liked to use recall as well to evaluate the performance of the prototype [38]. However, it is infeasible to measure recall for a Web-based system, since it is very difficult to determine all the existing documents on a given topic that are available online at a particular time. In addition, it should be noted that the horizon scanning prototype proposed here is not designed to return all relevant documents, but instead 50 documents per iteration.

VI CONCLUSIONS

Relevance feedback provides a method for reformulating queries based on previously retrieved relevant and non-relevant documents. A simple vector modification process that adds new keywords to queries and scales up or down the importance of existing keywords seems very useful. In view of its simplicity, we recommend that this process should be incorporated into operational text retrieval for horizon scanning systems and applications. Poorly processed feedback may lead to deterioration in retrieval effectiveness, which is a major limitation for relevance feedback implementations, but, when properly employed, the overall precision is improved, as shown in Section V.

As an opportunity for future work, we are considering mining social networks—particularly Twitter [39]—as a potential source of data for horizon scanning work. We are aware of the use of Twitter in financial applications, such as those employed by Derwent Capital Markets [40] and Palantir Technologies [41], whose foundations rely on the work by Bollen et al [42], and we realise that relevant information for horizon scanning that has been published originally by science and technology websites has appeared in Twitter streams. Thus, it is worth contemplating the monitoring of such streams for horizon scanning purposes.

ACKNOWLEDGMENTS

We are very grateful to Michael Jackson—founder member, ambassador and consultant of Shaping Tomorrow—for reading our manuscript and clarifying text on Shaping Tomorrow.

Software Implementation of Common Criteria Related Design Patterns

Dariusz Rogowski
Institute of Innovative Technologies EMAG ul. Leopolda 31, 40-189 Katowice, Poland
Email: drogowski@emag.pl

***Abstract*—Writing evidence documents for evaluation and certification processes according to the Common Criteria security standard is a very difficult, time-consuming and complex task. Nowadays there are only a few, limited solutions based on templates and software tools which can efficiently support developers in preparing evaluation deliverables. This paper describes the results of an R&D project whose aim was to work out a computer-aided tool with built-in design patterns. Firstly, according to all security assurance requirements the design patterns in a paper version were prepared. Secondly, they were verified and validated by the developers in order to make some amendments and improvements. The conclusions were used as the source of functional requirements for a computer-aided tool. As a result a complete computer system was designed which implements the design patterns, knowledge base, evaluation methodology, and additional external supporting software. That solution facilitates and speeds up the development of the evidence documentation.**

I. Introduction

SECURITY features of IT products have received much attention in recent years due to quickly rising numbers of cyber-attacks on important data and information. That is why there is a big demand coming from governments and private users for trusted IT products countering such threats. These products can be more reliable thanks to the evaluation and certification of their built-in security functions. Assessment processes should be conducted by an independent licensed laboratory which can use a security standard with requirements for a product development and documentation.

Here, the Common Criteria for Information Technology Security Evaluation standard (referred to as "Common Criteria" or "CC" throughout this paper), also known as ISO/IEC 15408 [1]–[3], provides a set of development rules and evaluation requirements [4] for the security measures applied in IT products. The results of CC-based evaluation are accepted in countries which joined the Common Criteria Recognition Arrangement (CCRA). This arrangement allows end users to recognize certificates regardless of the country in which they were issued. Therefore the certified products of different vendors can be easily compared by the users which can choose the best option. On the other hand we should remember that CC does not define the product security features or functionality but it provides assurance that the process of specification, implementation and evaluation of the product has been made in a rigorous manner. This assurance is assigned to one of seven assurance levels reflecting the requirements met in the development process of the product.

The product is the subject of the evaluation against the given EAL requirements and then it is called the Target of Evaluation (TOE). Evaluation Assurance Level (EAL) reflects the degree of confidence a user can have in the results of the evaluation and performance of the TOE. The lower assurance levels, EAL 1 through 4, concern most products, and do not require evaluation of the software, only of the development process and documentation. These lower levels are recognized under CCRA whereas the higher EALs are generally country-specific [5] and require a source code of the product to be analyzed.

However, it has been found by many developers of IT secure products that preparation for the Common Criteria evaluation process is very difficult, time-consuming and needs a lot of knowledge of CC requirements, all due to the fact that a lot of evidence documents have to be prepared. That problem is very important and has to be solved in order to make the whole evaluation process cost-effective and developers-friendly.

One solution was based on a series of guidelines and supporting documents issued by German Federal Office of Information Security (BSI) – the leader of researches in the field of the Common Criteria standard. This guidance documentation gives some advice on the structure and contents of evidence documents. Some templates were issued and could be used by developers but still too much work has to be done on their own [6], [7].

The second solution was based on very few software applications which could support users in the preparation of evidence documents and security development process. Unfortunately, these applications provided only basic functionality. They are limited to making only two main security specification documents (Security Target – ST, Protection Profile – PP), discussed later in this paper [8], [9]. Moreover, some of the software tools are not supported and developed by their producers any more.

Although the solutions mentioned above were offered a few years ago, relatively little attention has been paid to other evidence documents needed for the evaluation process. The guides and computer-aided tools are focused mainly on the preparation of STs and PPs documents. Apart from that, there is weak integration of the guidance knowledge within the software tools. In addition, if the developers want to create the evidence document only by using the guidelines and

978-83-60810-53-8/$25.00

templates, they still have a lot of work to do by themselves. They have to plan the structure of the document and find out what kind of information they should write down in the given section. That is why preparing the documentation is still difficult and not effective enough to encourage the developers to do this task.

This paper presents a complete and integrated solution which was worked out in the CCMODE R&D project (Common Criteria compliant, Modular, Open IT security Development Environment) carried out by the Institute of Innovative Technologies EMAG. The aim of the project was to work out a methodology and tools to develop and manage development environments of IT security-enhanced products for the purposes of their future Common Criteria certification. As a result a set of design patterns (the core of the methodology) was developed and next implemented in the computer-aided system CCMODE Tools. Thanks to the software implementation of the design patterns the developers receive one complete solution which facilitates production processes of the TOE and related documentation.

The paper is organized as follows. Section II presents the state of the art. Section III describes shortly the basic evidence documents required for the CC evaluation process. Section IV explains the methodology used for working out the design patterns and their implementation into the computer tool. Section V gives an overview of the CCMODE Tools main modules and their functionality used for evidence documents preparation. Section VI contains conclusions and experiences gained during the usage of the tool with built-in design patterns.

II. State of the art

The best starting point for building the design patterns is the Common Criteria standard which comprises three parts [1]–[3]. The current version of CC was issued in 2012. The first part is a general introduction to the CC methodology with explanation of basic terms and definitions. The second part describes security functional requirements which determine the desired security behavior of a TOE. The third part, the most important for building the patterns, defines the assurance requirements for a TOE and evaluation criteria for PPs, STs and other evidence documents. There are many companion documents to the CC standard. One of them is the Common Evaluation Methodology (CEM) [4] which helps evaluators to conduct the TOE assessment process. It defines evaluation activities to be done by the evaluators and presents work units – the most granular level of evaluation work – that help to issue verdicts about the quality of security implemented in the TOE. Other documents like technical reports and users guides explain step by step how to build evidence documentation. For instance, the ISO/IEC Technical Committee for Information Technology issued a technical report that is a guide for the production of PPs and STs [10]. This report provides methodologies, techniques and practical tips that developers can use to prepare security specification documents in an efficient and consistent manner. BSI issued a guide for developers of the STs and PPs [11]. Apart from that there is a guide that offers assistance to less experienced developers by extracting the information about the evidence from CC [12]. It explains requirements concerning the structure and contents of documents to be provided for the CC evaluation process. Another guide concerns evaluation reports according to CC and gives some advice and recommendations on the structure of information provided in these reports [13]. The CC standard and all guides mentioned above are used by the developers in common practice for writing evidence documents. But this way of work is very inconvenient because the developers must carefully read recommendations, check requirements and think about the necessary information to be provided in every new document each time they begin a project.

Although this guidelines-based approach helps the developers to work out documentation, it still does not allow to get rid of inefficient and time-consuming work. That is why some software aiding tools were applied to enhance the work with design patterns. Most of the software tools are dedicated only to preparing security specification documents (ST, PP) [14]. For example, an MS Windows application "CC Toolbox" sponsored by the National Information Assurance Partnership (NIAP, the US government initiative) used to assist users in writing ST and PP but is not longer supported and available. In [15] a generator of security target templates, named "GEST" was presented that can automatically generate security target templates from already evaluated and certified security targets. One of the Spanish CC licensed laboratories "Applus" presented a tool that reduces and automates some developer's activities of evidence documents preparation [8]. Another software tool, "TL SET", was introduced by Trusted Labs [16]. It is a smart editor for Security Targets and Protection Profiles. It integrates predefined libraries of the Common Criteria functional and assurance requirements and a user-friendly graphical interface to fill out the documents. There are also tools with built-in OWL language (OWL – Web Ontology Language) [17]–[20]. These tools are dedicated to build functional specification of the TOE and security problem definition.

So far all the solutions based on guidelines and computer tools have concerned mainly two basic documents: ST and PP. This paper presents a solution which allows to produce all the necessary documents and uses the context-sensitive help based on the CC standard and supplementary documents. The next section describes how complex a task of preparing all the evidence documents can be due to the fact that several documents have to be created.

III. Evidence documents

In the Common Criteria evaluation process security functions of the TOE are evaluated according to security assurance requirements (SARs) in the given EAL. Many documents should be prepared for the needs of the evaluation.

The most important is the Security Target (ST). The ST describes a specific TOE and is written by the developer. The ST can be based on a document called the Protection Profile (PP). The PP describes the general requirements for a TOE type and is used as a template for many different ST

documents. The ST consists of a security problem definition; security objectives; security requirements; a summary specification – showing how the security functions are implemented in the TOE. The ST document claims conformance with the declared EAL and this determines all requirements which have to be fulfilled by the product and described in evidence documentation.

The EAL package consists of assurance components which are organized into classes and families. The following descriptions of classes also include their short names (in brackets) which are commonly used in the CC standard. The Protection Profile Evaluation (APE) and Security Target Evaluation (ASE) classes describe the content and presentation of the PP and ST documents. The Development (ADV) class encompasses six families and nineteen components; it provides information about structuring of the TOE security functionality. The Guidance Documents (AGD) class is divided into two families (with one component for each family); it provides the requirements for preparative and operational user guides. The Life-cycle Support (ALC) class consists of seven families and twenty one components; it concerns the aspects of establishing discipline and control in the TOE development and maintenance during its whole life-cycle. The Tests (ATE) class encompasses four families and twelve components; it provides assurance that the TOE security functions were tested and they operate according to their design descriptions. The Vulnerability Assessment (AVA) class has only one family with five components; it addresses the possibility of exploitable vulnerabilities introduced in the TOE or in its development or operational environment. The Composition (ACO) class encompasses five families and eleven components; it assures that the TOE composed of other evaluated TOEs will operate securely. For instance, the EAL 3 package has fifteen components and for each one a proper evidence document has to be prepared.

On the basis of all assurance components taken from EAL packages the design patterns were worked out and then implemented into the computer tool.

IV. Methodology

In the first part of the CCMODE project a set of design patterns in the form of MS Word documents with predefined chapters and sections was prepared. The patterns were validated and assessed by independent experts in the field. Although they assessed the patterns as very helpful, they proposed some difficult and repeatable operations which can be automated by a computer tool. These insights allowed to make some functional assumptions for the CCMODE Tools system.

In the project there were design patterns created for all components of security assurance requirements (SARs). Next the patterns were verified and validated by developers chosen from the software and hardware industry. The validation was made upon the use cases method. The developers used selected design patterns to make evidence documentation of their software and hardware IT products. As a result of the validation, necessary changes and amendments were incorporated into the patterns. Furthermore, the developers concluded that some automation features should be implemented into the patterns.

In the next project stages a prototype of the software was developed. The prototype was next validated in two selected development environments of software and hardware IT products by using the case study method. A few evidence materials were prepared by developers. Documents for the TOE (ADV class) and for the environment (ALC class) were prepared. The case studies showed what else should be implemented in the computer tool to make the work with documents more effective and easier.

As a result, the CCMODE Tools system was worked out. The system integrates: modules of the development environment management, design patterns, knowledge base, evaluation methodology, and external supporting software. The system can be integrated with other security standards, like an information security management standard (ISMS, based on ISO/IEC 27001) or business continuity management standard (BCMS, based on BS 25999) [21].

Next chapters describe functionality of the software system which implements the design patterns.

V. Applying design patterns in a computer system

Developers use the software tool to start the project of an IT product in accordance with the chosen EAL level. They configure necessary external systems and deliver basic information about the type of the product, roles and duties of the system users, life-cycle model of the TOE, software and hardware tools used, security standards and regulations. Consequently, the following developers' actions can be automated by the software tool:

- verification of the development environment conformance with the CC standard;
- developing a security specification of the TOE in the ST document;
- providing the security problem definition that has to be solved by the TOE;
- specifying security objectives and security functional requirements to resolve the security problem;
- preparing evidence documentation with the use of the design patterns;
- defining life-cycle models for different types of IT products;
- testing the TOE and flaws remediation; establishing communication channels for flaws reports.

The actions mentioned above were next implemented in dedicated modules of the CCMODE Tools system. The following subsections describe the main modules.

A. CCMODE Tools system

A general model of the system is depicted in Fig. 1. The model consists of the Environment Management Tool (EMT), documents generator (GenDoc), knowledge base, evaluation module, external supporting systems, optional security systems (BCMS or ISMS) which can be used as an additional source of assurance to the whole development environment [22].

EMT is the main module which supports the configuration and management of the IT products that are to be built in the development environment. EMT makes it possible to define the system users and their roles in the project, the desired EAL level and life-cycle model.

The knowledge base is a source of context-sensitive help about the CC requirements and guidelines. It includes design patterns, terms and definitions which can be obtained by other modules. It also comprises the guidelines that help to resolve typical security problems with the use of predefined security objectives, threats, assumptions, and security policies.

There are also external systems in CCMODE Tools which support:

- assigning a version number to files and documents – Subversion (SVN) application;
- modeling, development and analyses which are made with the use of UML (Unified Modeling Language) – Enterprise Architect (EA);
- flaws reporting and flaws remediation – Redmine;
- management and planning of TOE tests – TestLink.

The evaluation module is used to verify the development environment against the CC requirements and to evaluate evidence documents according to the CEM methodology.

If the project of the IT product is completely configured then creating evidence documents can start by using the documents generator called GenDoc for short.

B. Documents generator (GenDoc)

GenDoc is used for editing evidence documents based on the design patterns. In order to evaluate the TOE, an ST document and accompanying documents must be prepared. These additional documents are determined by the chosen EAL and its SAR components.

This section shows on the example of an ST document how the software tool is used for filling in the patterns. Fig. 2 depicts the example of the GenDoc window with the ST design pattern. The general structure of the patterns, context-sensitive help and data fields were described. The precise details of the security development procedure and working out the evidence documents in the context of biometric devices can be found in [23].

Every pattern in GenDoc was prepared as a tree of data fields which represent chapters, sections and subsections of the output document. The tree is based on the requirements of the given CC component. The colors of branches show which fields have to be filled in by the user (red ones), which are already filled (black ones), and which are without any data (brown ones). The gray colored fields are automatically filled in with the information taken from the knowledge base and external modules: EA, EMT, SVN, TestLink.

In order to complete the document, the user must follow all the tree branches and find out which fields have to be completed. Every field has its own context-sensitive help which gives necessary guidelines and hints about the information to be delivered.

C. Context-sensitive help

Preparation of data fields content can be facilitated by context-sensitive help. This help is accessible from the main window of GenDoc by the link “Help – access to knowledge base”. There were five types of help applied: “ready to use” – it comprises a text which is ready to use by the user without the necessity to change any information in it; “Common Criteria help” – it comprises all the information and requirements taken from CC; “hints” – these are interpretations, tips and guidelines; “example” – it is an optional text which illustrates what kind of data can be written in the given field; “data source” – it indicates an external system which is the

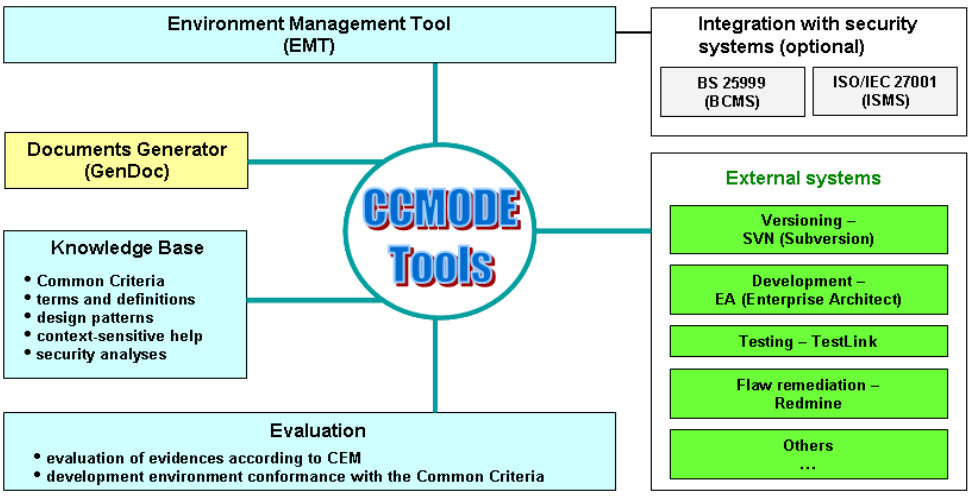

Fig. 1. The general model of the CCMODE Tools system

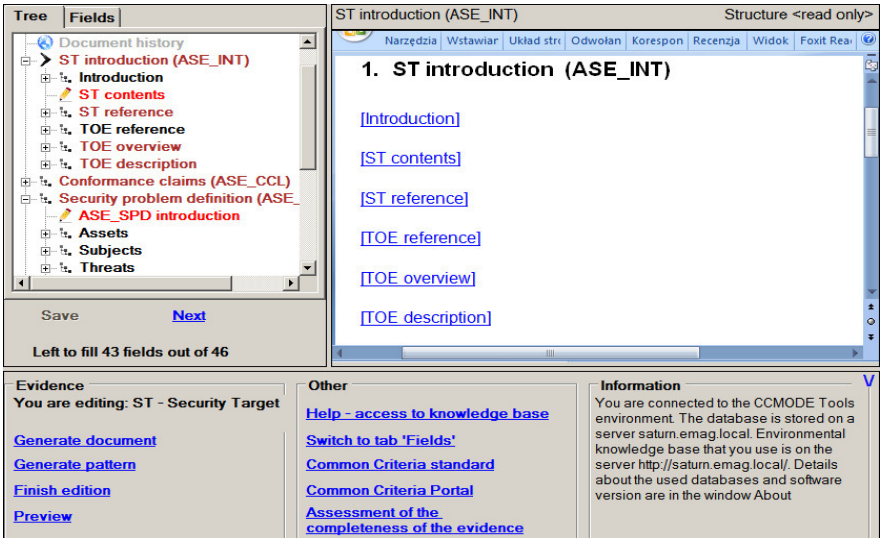

Fig. 2. The GenDoc window with the ST design pattern

source of data for the given data field. All the design patterns implemented into the CCMODE Tools system have similar representations. They contain data fields with precise instructions how to generate a complete evidence document.

At every stage of the edition process the data fields can be reviewed and checked. Verification of the document can be done with the use of the evaluation module as it is described in the next section.

D. Generation and revision of evidence documents

After completing all the information in the pattern, the user can verify the output document by using an evaluation module which is a part of the EMT system (Fig. 3). This module enables to check the document according to the CEM evaluation methodology.

In general, the methodology specifies elements which describe evaluation tasks to be done by the evaluator. These tasks give precise information how each security assurance component should be checked. Every task consists of a set of questions referring to the content and form of the evidence document. These questions are grouped in the so called work units. The answers lead to work units verdicts which can have one of three possible states: pass, fail or inconclusive. Each verdict needs short justification. All verdicts are initially inconclusive and remain so until either a pass or fail verdict is assigned. Verification of the evidence document is positive when all the verdicts are passed.

The evaluation module consists of work units with their detailed descriptions and has an answer form with a built-in justification field as it is depicted in Fig. 3. The developer has to answer all these questions which pertain to the verified document.

The enhanced version of the evaluation module was applied in GenDoc where the work units are directly connected to the relevant chapters and subsections of the evidence document in order to make the verification process easier and faster. This way the developer can see the content to be checked and the relevant work unit in one GenDoc window.

After verification, the complete document can be generated as an MS Word document and saved in the SVN repository. This document can be edited in a standard MS Word editor. The document has a fixed structure with chapters, sections and subsections. It contains also footnotes with hints and guidelines.

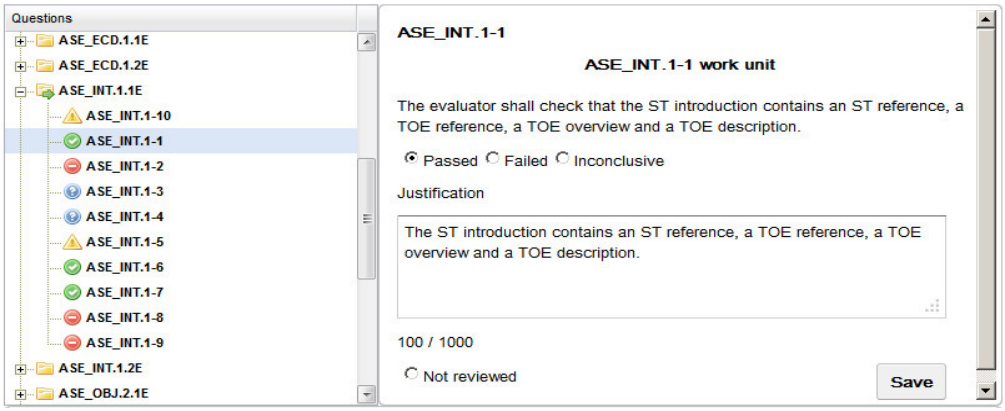

Fig. 3. The evaluation module of the EMT system

VI. Conclusions

This work presented software implementation of the design patterns which were worked out in the CCMODE project. The patterns were positively checked and validated by developers of IT secure products but at the same time they demanded for some automation features. This is why the CCMODE Tools system and the documents generator GenDoc were developed in order to support preparing of evidence documentation.

The proposed solution based on the patterns-based approach improves the IT security development process. It overcomes a lack of knowledge and experience of the user. The context-sensitive help connected to every field of the pattern allows the developers to concentrate only on writing the proper content.

The software tool facilitates and speeds up the IT security development process and improves the quality of evidences, which become more consistent and include all details required by the CC assurance requirements. The CCMODE Tools system gives a great chance to prepare all documentation for successful Common Criteria evaluation process. Additional self-evaluation and verification enhanced functions are also implemented in the GenDoc tool. These offer a practical way of documents evaluation according to the CEM methodology but it will be the topic of the next paper.

Future work will be focused on building a standalone, independent GenDoc application which could work without the EMT framework. It is demanded by some developers who elaborate only evidence documentation. In the future work it will also be considered to adapt the documents generator to produce documents according to different typesetting systems.

***Abstract*— New information technologies have been developing nowadays at an amazing speed, affecting the functioning of organizations significantly. Due to the development of new technologies, especially mobile ones, borders in the functioning of modern organizations diminish and models of running business change. Almost all organizations are involved in some way in sourcing activities, and each of them develops a sourcing relationship that suits its particular needs. In this article different kinds of outsourcing models were discussed, which are applied in the contemporary management, with particular emphasis put on cloud computing.**

The main aim of this article is to present the most important risks related to the introduction of management models based on the most recent IT technologies, e.g. cloud computing, and emphasizing the role of appropriate IT security management in the times of globalization of organization virtualization.

I. Introduction

Information resources have nowadays strategic significance and have key influence on gaining the competitive advantage by all types of enterprises. Organizations are forced to look for still better and more effective IT solutions that enable for example: IT cost reduction, access to the best technology and best IT hardware and software experts, IT systems security etc. One of such new models referring to IT services is cloud computing.

Ongoing research projects investigate client and vendor capabilities required to successfully implement these sourcing models and initiatives, and how to manage knowledge and expertise in various sourcing contexts to improve efficiency and outcomes of sourcing engagements. Organizations are facing a large variety of possibilities to choose from when making sourcing decision. They should take into consideration a lot of factors (both positive and negative) to be able to make the right decision.

The London School of Economics's research regularly finds that firms that outsource give away too much of their technical capability. It is a challenge to retain skilled people in house paying them the market rate and offering them interesting, value-adding work. The alternative to such an "invest to save" HR approach is to put at risk the long-term health of the deal [4, p.10]. This can be especially true dealing with immature markets, such as cloud services.

In the next part of the paper we will discuss what makes cloud computing popular and what are the main risks of cloud computing sourcing model.

II. Evolution of Sourcing Models

Oshri, Kotlarsky and Willcocks, who have observed outsourcing market since years, notice that various types of global sourcing models have begun to emerge. The major difference between these models lies in whether the function is performed by a subsidiary business unit of the firm or an external vendor (or by both, as a joint effort), and also whether the function is performed on the firm's premises (i.e., on-site) or off-site, which can be onshore (in the country where the organization is located), nearshore (in a neighbor country), or in an offshore location [3, p. 25].

Insourcing means managing the provision of services internally, if needed- through buying in skills that are not available in-house, on temporary basis (for example by staff augmentation). Offshore or nearshore outsourcing means outsourcing contract with vendors situated in a different country from the client organization. Out-tasking- it is outsourcing on a small scale. It usually implies ongoing management of and support for selected packaged applications. Joint venture in the outsourcing or offshoring context – means a partnership between a client firm and offshore vendor whereby the parties contribute resources to the new deal/project Shared services- it is an operational approach of centralizing administrative and business processes that were once performing in separate divisions or locations- for example: finance, IT, human resources. In literature there are listed also the following sourcing models based on Internet delivery of products or services: cloud computing, software as a service, crowdsourcing, and microsourcing. Sourcing decisions should be made jointly by business and IT executives [4, p.11].

III. Attributes of Cloud Computing Model

Although the idea of cloud computing has been around for quite some time, it is an emerging field of computer science. Cloud computing can be defined as a computing environment where computing needs by one party can be

978-83-60810-53-8/$25.00

outsourced to another party and when need be arise to use the computing power or resources like database or emails, they can access them via Internet. Cloud computing is a recent trend in IT that moves computing and data away from desktop and portable PCs into large data centers.

During the past few years, cloud computing has grown from being a promising business idea to one of the fastest growing parts of the IT industry. IT organizations have expresses concern about critical issues (such as security) that exist with the widespread implementation of cloud computing. These types of concerns originate from the fact that data is stored remotely from the customer's location; in fact, it can be stored at any location. Security, in particular, is one of the most argued-about issues in the cloud computing field. Comparison of the benefits and risks of cloud computing with those of the status quo are necessary for a full evaluation of the viability of cloud computing.

In Hauke's and Owoc's opinion facilities available via cloud computing are strictly determined by properties of this technology based on Internet resources [2, p. 125]. One can identify two essential concepts in "cloud" environment-abstraction and virtualization and several properties that can be expressed as secondary (such as scalability, flexibility, availability, measurability, efficiency, low costs of services, low barrier to entry, security).

Security – the most "sensitive" and disputable feature of CC. Theoretically all potential problems should disappear (all necessary tasks are performed by specialized partner). No doubts, problems with database recovery should be served professionally, however, a risk of data loosing or data leaking can occur [2, p.126].

Cloud computing solutions are offered by such large organizations as IBM, Microsoft, Amazon, Google and others. They can give a lot of benefits but they have also some limitations. There are numerous challenges facing organizations when considering cloud computing. Willcocks and Lacity, in their analysis, focus on the four challenges which seem particularly critical in the development of cloud use within organizations: weighing up the security and legal risks, defining the relationship through contracting, the lock-in dilemma, managing the cloud [5, p.290-296].

Cloud represents a great opportunity, but there are also strong challenges to take if an organization wants to use its potential for business advantage.

IV. New Challenges for IT security management

The existence of a company in cyberspace and an opportunity to communicate with it via electronic media is often a minimum condition for the company to be perceived as a reliable and solid partner. Unfortunately, the development of IT, e-commerce and new business models (including various kind of IT sourcing) carries new risks apart from huge benefits. There are new threats, often incomprehensible and underestimated by company management. The basic premises indicating the emergence of new kinds of risk accompanying the functioning of management IT systems, include e.g. the following facts and circumstances [6, p. 11-13] [7, p. 80-82]:

- information has become one of the most important goods on the market, which hence increases its price, meanwhile generating a risk of its unauthorized interception,
- ruthless chase after information, which is especially typical of business and media environments, blurs the border between legal and illegal actions aimed at acquiring it,
- increasing the availability of IT systems, which are considered to be the condition of society civilization development expansion, which facilitates the development of cybercrime,
- most of documents and information, which were dispersed so far, now are stored in one place – in a computer, which makes them easily accessible, but in case of unauthorized access the scope of damage is extensive,
- technological complexity of company IT systems and their security, which makes it impossible for an average user to use them rationally in order to minimize all threats,
- common lack of knowledge or unawareness of information systems threats, which results in lack of compliance to certain requirements, procedures etc.,
- data gathered in IT systems remain under the supervision of system administrators, which results in the fact that a few people have an insight into very important data and can modify them practically without anybody noticing,
- security systems are expensive and happen to be neglected for the sake of efficient performance of an individual,
- companies offering security tools for IT systems are often uncertified, which makes their products fallible and often of low quality,
- companies developing various IT solutions often offer fallible systems, which are full of mistakes,
- the Internet brings in new threats, since it is where you can easily find software for hacking IT systems.

Nowadays specialized institutions (e.g. CERT, Computer Security Institute, etc.) publish statistical data concerning the probability of occurrence of given kinds of threats [see: 8, 9]. According to various statistics, intentional or unintentional actions of organization staff (negligence, lack of concentration, incompetence) and purposeful actions of dissatisfied or sacked employees.

It is worth discussing here conclusions derived from the report 2011 TMT Global Security Study, prepared by the counseling company Deloitte. According to this report, one fifth of companies from the technology, media and telecommunication sector (TMT) find personnel mistakes to be the major threat for the company IT security. Another huge risk for the company IT systems security is the use of

mobile devices by employees (personal smartphones, tablets, laptops) at work. The risk is in this case related to data confidentiality, application popularization and IT support.

Similar conclusions can be derived from studies conducted by the counseling company PricewaterhouseCoopers (PwC). The 2012 Global State of Information Security Study was conducted in 2011 all over the world. The results were obtained on the basis of answers provided by more than 9600 managers, vice-presidents and IT and information security directors from 138 countries, including Poland. According to them, current or former employees are perceived by companies as the major source of risks for IT systems. However, respondents pay more and more attention to a different category of external risks: 17% of respondents indicate clients, and 15% - business partners and suppliers as the key risk sources. In Europe during the past two decades the percentage of companies which require that the suppliers adjust security policies to their requirements, dropped from 31% to alarming 22%; only 18% of companies keeps records of all suppliers processing personal data of customers of employees.

Threats which are less likely to occur include ICT networks and IT systems failures and natural disasters (fire, flood, hurricane and earthquake). Threats related to unauthorized access (of e.g. hackers) and activities of malicious software are relatively unlikely to happen. When assessing the frequency of occurrence of such risks, it is recommended to take into account the specificity of the given company and its environment. The basic classification of IT systems security threats is presented in table 1.

V. THREATS RELATED TO VIRTUALIZATION AND CLOUD COMPUTING

Ernst & Young company conducted the 'Global Information Security Survey' in 2011 [12]. The study group consisted of 1700 organizations, including the largest and the most dynamic companies from 52 countries, from different trades (banking, finance, insurance, motorization industry, public administration, transport, health service, trade). The company has been conducting such studies for 14 years, and their aim is e.g. identification of the most critical kinds of risk in the field of new IT technologies. As it can be concluded from this study, respondents recognize trends related to new kinds of risk, since more than 72% of them estimates that the level of risk related to the development of such technologies, as the aforementioned mobile devices, cloud computing and social networking sites, is larger and larger. 46% of organizations recognize also increasing risk levels related to internal company threats. Polish results are consistent with global results as far as the assessment of the key threats is concerned. The study conducted by the company in 2010 [12] revealed that more than 64% of respondents found data safety to be one of the five key risk areas. It results directly from the fact that for 73% of Polish

TABLE I.
CLASSIFICATION OF IT SYSTEMS SECURITY THREATS

Criterion	Classification of threats	Examples of threats
Role of a man	Threats independent on a man	Atmospheric discharge, flood, fire, humidity etc.
	Threats dependent on a man	Illegal modification of software or data, disclosure or deletion of data, illegal copying and installation of software, damage or deletion of software or data, stealing computer equipment or accessories, storage of resources prohibited by law, mistakes made due to the lack of knowledge, unintentional loss, damage, deletion or disclosure of data to unauthorized persons, etc.
Subject of influence	Threats related to computer systems	Interruptions in electric energy supply, intentional and unintentional human actions (e.g. mechanical damage, configuration errors, incompetent use or maintenance, etc.), unexpected failures of mechanical and electronic elements of computer equipment, etc.
	Threats related to software	Mistakes made by the software manufacturer, mistakes made intentionally or unintentionally by employees or third parties (e.g. incorrect installation, configuration, implementation, deletion or modification of software, introducing malicious programs, blocking correctly functioning applications, illegal access, illegal usage or copying of software, etc.
	Threats related to data	Unauthorized access to data, unauthorized modification of data (e.g. damage, change of content, deletion, etc.), unauthorized copying of data, monitoring (phishing) of data, introducing incorrect data, denying the reception/sending of data, etc.
	Threats related to ICT networks	Intentional or unintentional human actions (e.g. stealing network components, physical damage of a network, wrong configuration, partial or complete blockage of network activity, phishing or unauthorized use of a network, etc.), ICT network failures caused by external factors (e.g. atmospheric discharge, fire, etc.), unexpected damage of electronic elements of a network, etc.
	Threats related to people	Failing to keep business and trade secrets by economic entity personnel (e.g. unintentional release or transfer of data due to the so called 'social engineering), informing workmates or third parties about security systems used in a company, sudden loss or resignation from work by the personnel as well as a situation, when employees having access to confidential information start working for a competitor.
	Threats causing financial losses	Loss of clients, business partners, decrease in turnover and company share in the market, interruptions in the functioning of a business entity, the necessity to exchange the offered products (especially in case of bank services), loss or damage of technology and software, financial sanctions, increase of insurance premiums, decrease in process efficiency and activities carried out in a company, necessity to hire additional employees, costs of outsourcing, judicial costs, penalty interest for breaching agreements)
Action results	Threats causing intangible damage	Loss of prestige and good name, loss of economic subject credibility in the eyes of clients and business partners (due to e.g. media interest in data safety breach), organizational chaos, loss of IT infrastructure efficiency, incorrect decisions made on the basis of falsified or incomplete data.
	Threats independent on a man	Atmospheric discharge, flood, fire, humidity etc.

Source: [16, p. 160-161]

respondents (and 53% of global respondents) the protection of brand and reputation is the most important aim of organizational safety policy, even more important than ensuring compliance with regulations in this field (60% of respondents in Poland and 56% around the world).

An example of a technology, which is developing very dynamically nowadays, is cloud computing, described in more details in point 3 of this article. The biggest problem for entrepreneurs interested in cloud services is issues related to the loss of data safety. According to the study conducted by Harris Interactive center, as many as 91% of respondents worry about the safety of public clouds, and approximately 50% of them indicate that safety issues are the largest obstacle in popularizing cloud solutions. Eelastic-security.com portal also decided to analyze this topic and surveyed suppliers of such services. The aim of the study was to check, how suppliers and cloud users perceive safety issues. The results how divergent the expectations of these groups are. 69% out of 127 surveyed suppliers claimed ensuring safety of cloud services was the sole responsibility of users, who thought the contrary. Most of them said that service providers are responsible for cloud safety or it is the resultant of suppliers' and users' action [13].

Although cloud computing has been known for a few years, it still remains a mysterious technology for most users, and hence it is perceived as highly risky [14]. As Gartner Group analysts confirm in their report entitled 'Safety risk assessment in cloud computing', processing data outside a company is related to a risk, therefore in order to minimize it, only checked solutions have to be applied [15]. Also the study conducted by E&Y explores the topic of cloud computing technology safety. 52% of respondents are concerned about data leakage, and 39% of them worry about the loss of control over information processed in a cloud.

Materialization of the above kinds of risk is one of the greatest threats for organizations using modern technologies. The consequence could be the loss of clients and business partners, decreased turnover and company's market share, the necessity to exchange the offered products.

Tangible damage of an organization may include damage of IT infrastructure, loss of valuable data and hence the necessity to restore it. Another consequence is the inaccessibility of IT systems, which may trigger financial losses, e.g. additional operational costs, loss of profits, claims of business partners, suppliers and clients for not performing services or performing them improperly, increased insurance premiums, claims under civil law resulting from torts, e.g. disclosing personal data, punishments imposed by public institutions, etc.

CONCLUSION

Nowadays, the dominant source of risk for an organization is the fallibility of IT systems, and one of the major sources – the level of data security. The presented studies confirm that new technologies, and with them – new business models/tools – generate new, so far nonexistent, threats, and are a source of new types of risks. Significant changes in the functioning of an organization – which result from ongoing globalization, increasing competition, automation, and in particular – development of IT and virtualization, become the fundament of a new perspective of the risk management process concerning IT security in organizations.

The cloud computing discussed in the paper may dominate IT services market; however, it has several drawbacks. Cloud computing does not remove the need for a sound process [1, p. 17]. As discussed in this paper, it may bring some opportunities, but even if organizations themselves feel "cloud ready" they must anticipate the capacity requirements in the cloud, be aware of new risks and manage IT security in accordance with new operation conditions.

Abstract— **Bullwhip effect (BWE) refers to the accumulation of stock flowing up and down along the supply chain management (SCM). It reduces the operating efficiency of the chain and blocks the operating resources. Some of the common causes of BWE are demand order variations, long lead times, competence defects between supply chain links, lack of communication among links in the chain, etc. There have been efforts to overcome these issues. However, very little work has been reported based on formal representation and analysis of resource flow in the supply chain system. In this work, a novel framework is proposed using Generalized Stochastic Petri-net (GSPN) model towards handling this issue in a distributed scenario. The analysis on the stochastic nets allows identifying the bottlenecks in the supply chain echelons along with customer relationship management (CRM). This has been used to rebuild infrastructure with the end-objective of reducing the BWE.**

Keywords: **SCM, BWE, BWE-Index, GSPN, Retail Network, CRM**

I. INTRODUCTION

Bullwhip effect (BWE) [37] is one of the trickiest evils for supply management systems. Sustainability for small and medium size enterprises becomes an issue when BWE is moderately high. Prompt delivery of product is more and more a key issue that provides competitive advantage of collaborative process [22]. Business challenges have increased along with the globalization with a view to adopt the changes and advance. A single stage, single tier chain with single customer is the simplest form of SCM, where there is no BWE, e.g., when a government. is a buyer of an item from a single supplier and no other roll players are involved in the process, or in case of a bend market where only manufacturer and buyer exists. However, we are getting to global collaborative retail chains like food retail, health and beauty products, clothing, durable goods, etc, where the success of the chain primarily depends on customer satisfaction, and the different actors play their role in different, distributed, geographical contexts, e.g., a South African garment manufacturing company may have retailers in America or Europe; orders issued from Europe, raw material is purchased in Korea, the material is dyed in Taiwan, and finished garments is assembled in Thailand.

The main aim of this work is to investigate the reasons of BWE at every stage of Supply Chain (SC) and measure it. Some of the common observations of BWE are communication gap, information twisting, and gaming for destabilizing the chain among the SC partners [20]. This leads to disproportionate inventory, fund blockage, loss of revenue and inept customer service [2]. Prompt decision making, demand order processing and monitoring of delivery logistics, a large distributed multi dimensional real time data repository is necessary [10]. The existing works on BWE points out qualitative aspects, and suggested measures to reduce BWE based on such qualitative analysis. The first quantitative measure of BWE was attempted using BWE index [11]. The present work provides experimental evidence by a significant simulation of the impact of stochastic Petri Nets enhanced with data mart controlling the entire Supply Chain operations in order to reduce the BWE.

Section 2 presents a brief literature survey on related scientific contributions. Section 3 introduces multi stage multi tier retail chain for demand analysis; Subsection 3.1 provides the GSPN model of the retail chain. Section 4 presents a revised GSPN model of the Retail Network. Section 5 describes some warehouse applications. The paper ends with concluding remarks in section 6.

II. LITERATURE SURVEY

A good number of works published in leading journals in last 15 years dealing with BWE are briefly reviewed and analyzed in this section. BWE can be seen as a random measure of performance of a SCM over some specific period of time. SCM performance is measured as a ratio of demand against delivery. If the ratio is greater than unity, the performance is considered to be negative [11], i.e., BWE prevails. The four broad classes of BWE studies Behavioral, Analytical, Industrial, and Dynamic approaches are presented herein.

Behavioral: Uneven customer demand is identified and capacity adjustment to do keeping inventory level unchanged is studied in [5]. Demand forecasting and order lead times are identified as root causes of BWE [6]. US census bureau data is used to observe dependency on the order variance ratio, and demand distortion of BWE [7]. Seasonal BWE is discussed and three forecasting levels are

This work has been carried out in the Department of Computer Science & Engineering, University of Calcutta, India.

978-83-60810-53-8/$25.00

used to monitor lead time to control BWE [8]. When seasonal variation is larger than demand uncertainty then demand to order variance ratio becomes insignificant for measuring BWE [12]. Rationing, Gaming, and Order Batching are the causes and VMI is used to control the BWE [16]. Amplified demand, data incompleteness and data aggregation are the primary causes of BWE discussed in [19]. Four operational aspects of BWE are demand forecast updating, order batching, price fluctuation, rationing and shortage due to gaming are identified [20]. Five basic functions of SC; plan, source, make, deliver and return are mapped to SCOR model and measure SC performance to monitor BWE [23]. A class room model with four echelon is used to explain the BWE, no formalism suggested [38].

Analytical: Logistic cost minimization techniques are discussed to control the BWE [1]. Transfer function plot is used to monitor the BWE on replenishment rules [15]. A nonlinear optimization model is proposed to reduce BWE by using a four stage echelon system on demand distortion, misperception of feedback, price variation, batch ordering, and strategic decisions. [21]. BWE is measured using the statistical technique ANOVA over information enrichment percentage, time to adjust inventory; time to adjust work in progress; production delay; and sales exponential smoothing {25]. Time delays are major causes of BWE at every stage of SCM. A mixed integer model is used to measure and monitor the BWE [34]. BWE propagation is measured using Fourier Transform [42].

Industrial: Surveyed thirty fast moving consumer goods (FMCG) to emphasize quantitative presence of BWE in SCM. In [18], as many as eleven key design guidelines are suggested to optimize SC. BWE studied over perishable products, customer demand, retailers and wholesalers order cycle varies, and delay in delivery at various touch points occurs. By adjusting the order cycle and delivery delay time the model can be optimized to stabilize the convergence function [45].

Dynamic: BWE at packaging business is studied. A stochastic demand reduction SC model suggested and confirms shorter the lead time, lesser will be the BWE [30]. IT enabled Service Oriented Architecture (SOA) proposes performance measurement (PM) matrices to evaluate SC performance and corresponding BWE effects over multiple channels [32]. An ERP framework is recommended for understanding all types of enterprise applications that maintain the SC and its corresponding BWE at each echelon [39]. A four stage tree structured SC model and a software simulation is designed and suggested the causes of reverse BWE [47].

In a single or a multi echelon SC one culminating point is that either from the behavioral side or from analytical viewpoint or industry specific models or it is IT enabled software driven systems there are some issues in common for occurring the BWE. However, not much holistic approach to control the BWE in a dynamic, multi-aspect decentralized, stochastic and non-linear environment is yet to be explored. It requires efficient modeling using appropriate tool suitable for distributed environment to embed stochastic behavior of demands in the model itself.

In this work, a high-level net model is proposed analyzed and used for demand driven SC to substantially control the BWE, if not eliminated. We choose Petri Net for modeling due to its strong mathematical formalism. A short review on Petri net and its high level extensions are presented in subsection 2.1.

2.1 HIGH LEVEL REVIEW ON NET MODELS

Petri Nets are directed bipartite graphical notations for modeling of discrete dynamic systems developed by Carl Adam Petri. It is often used as a meta-modeling tool to study and analyze the complexity among the large number of collaborative devices, business processes, distributed communications, and various process simulations. It provides two models: Structural and Behavioral [29].

A Structural Model is a directed graph representing the static part of the system. There are two kinds of nodes, places and transitions, represented by circles and rectangles. Places represent state variables and transitions represent transformers. The net is said to be ordinary when all arc weights are equal to one, i.e. each occurrence of adjacent transitions consumes one token from input to output place. Behavioral Models captures the dynamics of the system behavior using evolution rules for the marking. Markings are represented by tokens. The token at a place is its state value. The values change in adjacent states with the occurrence of transitions. Modeling of some service with simultaneous arrival of tokens to a queue ordinary net can't model such situations: concurrency is not handled.

Extension of ordinary Petri net is therefore needed, where a transition is enabled when its pre-conditions hold but not post-conditions. However, the boundedness is ensured with a maximum token capacity at each place. Similarly, the ordinary net or the elementary net can't model the time dependent system flows or workflows or delayed time transition flows or uncertainties in transitions. In order to model real time systems, various time extensions are proposed through Petri Nets. Time Petri Net model (TPN) is a powerful formalism and conciliation between modeling power and verification complexity. The timed nets are classified as timed place Petri Nets (TPPN) and timed transition Petri Nets (TTPN) depending on whether the timing bounds annotate places or transitions. TPN are useful for performance evaluation and can be implemented using stochastic or constant timing [3]. The stochastic timing is useful to model events where time is important and all the enabled transitions in the model are equally likely to occur. Constant timed Petri Nets are useful to model time dependent events where transitions occur after some predetermined time [43].

Another dimension in high-level net modeling is Color. The Colored Petri Nets (CPN) associate attributes with the individual token. It is commonly used in network protocol simulation and of course, mathematically well-founded. CPN provides a fitting formalism for the description, construction and analysis of distributed and concurrent

systems [27]. Good models depend on data quality, tools and clear thinking. The non-definitive nature of the large retail networks is perfectly suitable for modeling such systems using the Generalized Stochastic Petri Nets (GSPN). The GSPN supports a unique combination of graphical as well as mathematical formalism to model a dynamic system. Rich mathematical foundations permit in-depth analysis of work-flow nets [13].

A generalized SPN (GSPN) supports both immediate and timed transitions. A GSPN with initial markings can be described uniquely by a 6-tuple: GSPN (P, T, I, O, M, λ), where, (P, T, I, O, M) is a marked PN. A marked Petri Net is a 5-tuple composed of Places; P and Transitions; T. The sets P and T are mutually exclusive. I is the Input function, where the value I (p, t) is the number of directed arcs from the place p to the transition t. O is the output function, where the value O(t, p) is the number of arcs from the transition t to the place p. M is the Initial marking of places, where the value M(p) is the number of tokens that are located in the place p. λ = (λ1, λ2, λ3, … , λn) are marking dependent firing rates associated with transitions. Firing delay is an elapse time associated with every transition.

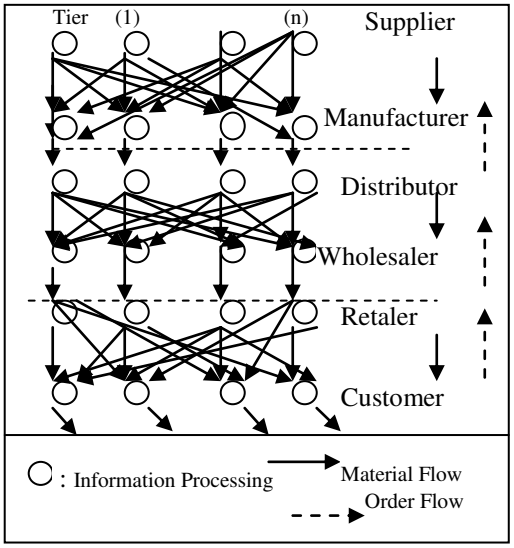

Fig. 1 Multi Stage Multi Tier SC

This delay is a random variable with negative exponential probability density function. For any marking dependent transition ti with associated firing rate λi, can be expressed as λi(mi) and the average firing delay of transition ti in marking mi is [λi (mi)]-1[9].

III. MULTI STAGE MULTI TIER RETAIL CHAIN

There are some frequently used SCM models like SCOR [23]. Epicor a SOA based SCM software, AMT is a SCM ERP application (http://www.softwareadvice.com) may be referred for FlexRFP, which is a web based ERP application.

Figure 1 is the proposed schematic of a multi echelon and multi tier system to deal with multiple products, multiple suppliers in a location independent manner. Managing the inventory in a stochastic natured multi echelon model is a complex process consisting of a set of virtually linked upstream and downstream flows of products, services, finances and information meeting customer's demand.

The supply-chain echelon of our proposed model is composed of customer, retailer, wholesaler, distributor, manufacturer, and supplier. The multiple tiers and its sequence are horizontally presented from left to right at each echelon. Multi stage is presented vertically. Top down flow indicates material flow and bottom up direction represents information flow, e.g., the Beer game is a four Stage model [38], [28]. However, not much discussion is found in the existing literature on multi-tier issues within one supply chain.

This paper aims to model the schematic of figure 1using a GSPN model and reduce or eliminate Bullwhip effect by analyzing the proposed model. The proposed model is simulated using PIPE 2.5 simulation tool.

3.1. GSPN MODEL OF THE RETAIL CHAIN

Let us now model the multi stage multi tier SC using high level net. The GSPN model as shown in figure 2 symbolizes P0, P1, P2 as suppliers, P3, P4, P5 as manufacturers, P6, P7, P8, P9 as distributors, P10, P11, P12, P13, P14 as wholesalers, P15, P16, P17, P18 as Retailers and P19, P20, P21 as customers in tires. {T0 to T18} are the corresponding timed transitions with rate=1.

The net is designed with a constrain that material flow will be to any of the role players in the succeeding layer and information flow will be to its preceding layer only. There is no restriction of tokens at any of the places. The process is initiated with inhibitor arcs from the initial suppliers P0, P1, P2. The PIPE 2.5 tool, used for the GSPN simulation classifies that the proposed is an extended simple type ordinary net as all arc weights are unity.

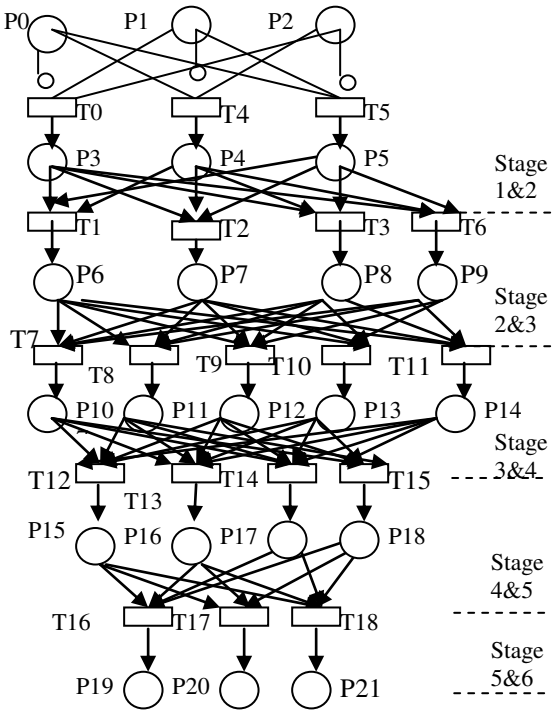

Fig 2: GSPN Model of the Retail Network

The state space analysis pronounces that the GSPN model is not safe. Besides as all the places in the net are not directly connected to each other, so it is not strongly connected. Also there is no live markings and no nonzero safe marking for the proposed model.

Table 1: Token Accumulation after Random Trials

LOC	OB1	OB2	OB3	OB4	Total
P0	6.93	16.83	84.16	94.06	201.98
P1	7.92	17.82	89.11	99.01	213.86
P2	8.91	10.89	54.46	56.44	130.69
Supplier	**23.76**	**45.54**	**227.72**	**249.51**	**546.54**
P3	9.90	12.87	77.23	80.20	80.20

Manufacturer	**9.90**	**26.73**	**146.54**	**163.37**	**346.54**
P6	5.94	9.90	49.50	53.47	53.47
P7	5.94	3.96	19.80	17.82	17.82
P8	1.98	2.97	14.85	15.84	15.84
P9	4.95	6.93	34.65	36.63	36.63
Distributer	**18.81**	**23.76**	**118.81**	**123.76**	**285.15**
P10	4.95	4.95	24.75	24.75	59.41
P11	4.95	4.95	24.75	24.75	59.41
P12	0	1.98	9.90	11.88	23.76
P13	0	1.98	9.90	11.88	23.76
P14	4.95	4.95	9.90	9.90	29.70
Wholesaler	**14.85**	**18.81**	**79.21**	**83.17**	**196.04**
P15	9.90	6.91	19.80	16.81	53.43
P16	3.95	4.94	13.86	14.85	37.60
P17	0	1.98	5.94	7.92	15.84
P18	0	1.98	7.92	9.90	19.80
Retailer	**13.85**	**15.81**	**47.52**	**49.49**	**126.67**
P19	4.95	4.95	4.95	4.95	19.80
P20	4.95	4.95	4.95	4.95	19.80
P21	4.95	3.96	3.96	2.97	15.84
Customer	**14.85**	**13.86**	**13.86**	**12.87**	**55.45**

The GSPN model in figure 2 is not bounded and there can be deadlocks. This is because the number of tokens at any place is a positive integer and each transition gets an output place in the immediate succeeding layer [6], [40].

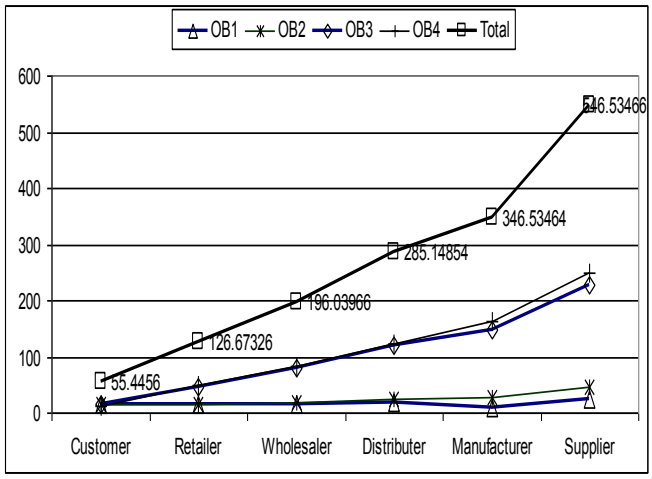

Fig. 3: Simulated Stock Status at different SC Partners

A random number of continuous observations were performed on the GSPN model of figure 2 over four stages OB1 to OB4. These are recorded in Table 1. Figure 3 clearly shows that as the operation progresses, the performance of the system becomes non-linear.

Further, the Bullwhip effect indexes are measured between the pair of communicating role players in the supply chain like distributor and wholesaler, wholesaler and retailer, and retailer and customer. The corresponding bar graphs are presented in figure 4(a) thru 4(c).

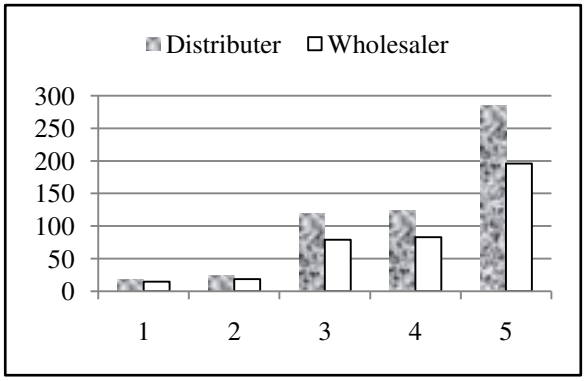

Fig. 4a BWE between distributor and wholesaler

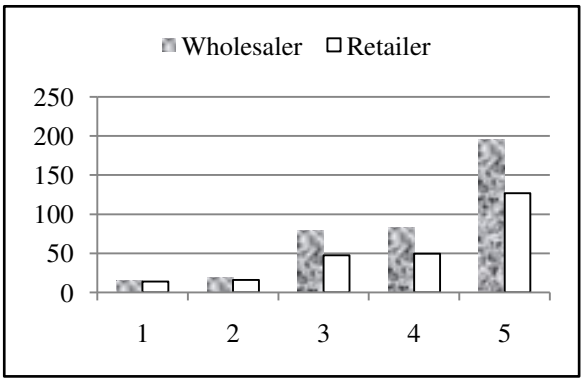

Fig. 4b: BWE between Wholesaler and Retailer

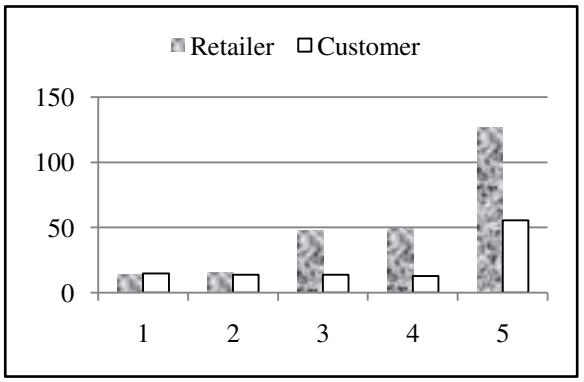

Fig. 4c: BWE between Retailer and Customer

The fact that the BWE index is greater than 1 shows the presence of BWE in the system. Our objective is to model the system in such a way that the BWE should be minimum without affecting the customer's interest. Hence the model demands some major revisions. The revised model is presented in section IV.

IV. THE REVISED GSPN MODEL

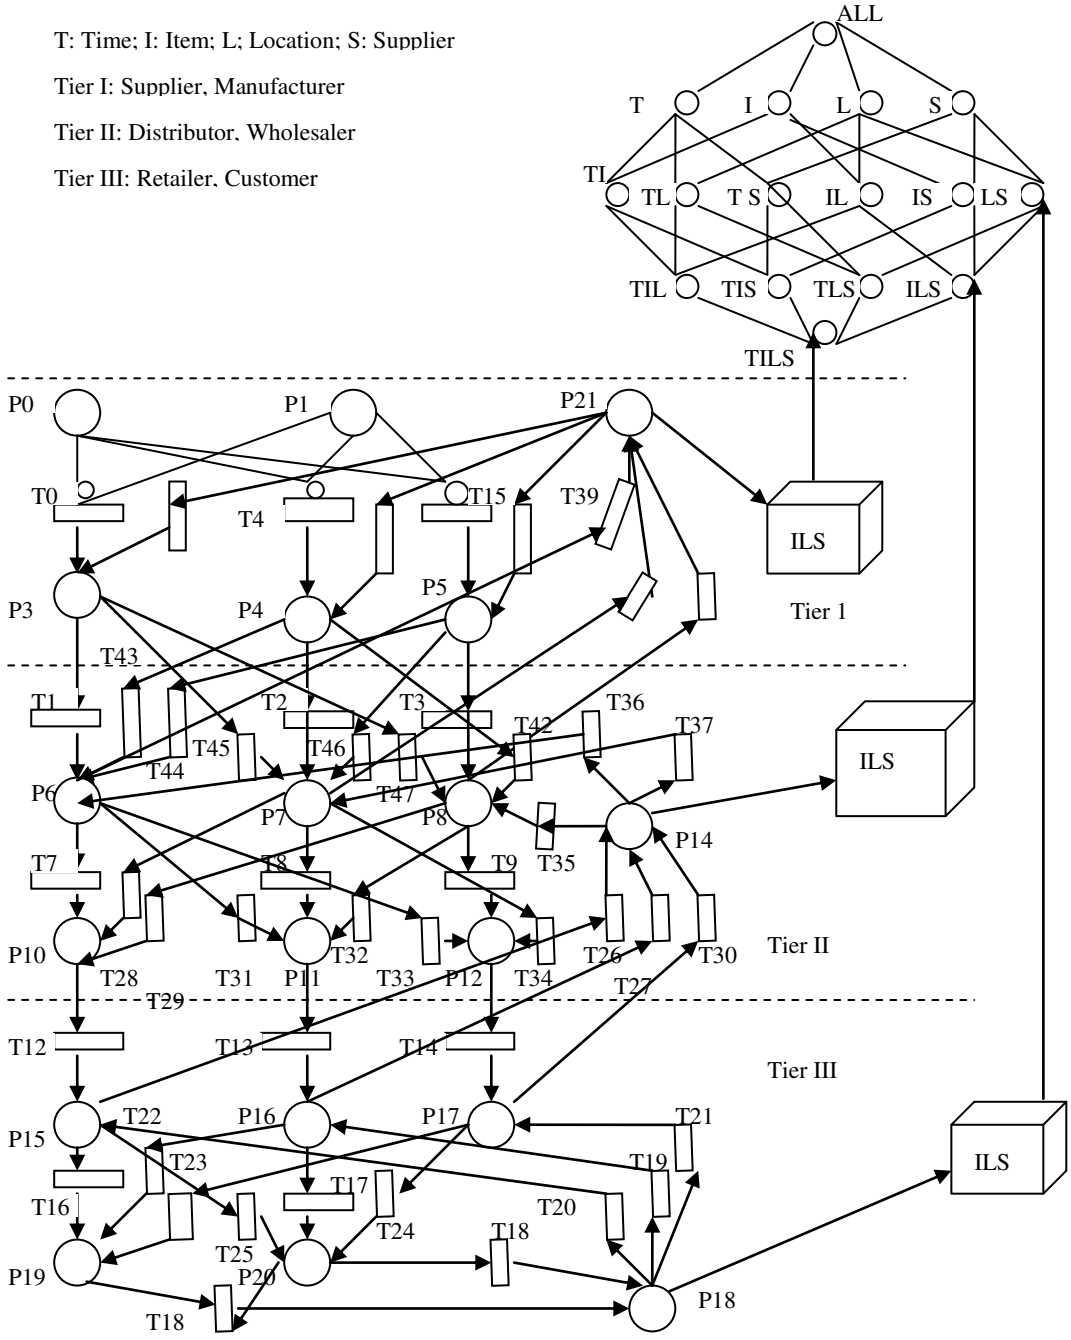

Fig. 5: Revised GSPN model of Retail Network

In this section we introduce an enhanced GSPN model for Retail Network. Its main objective is to remove the non linearity from the SCM process and control the BWE. In order to revise the process, tier wise separate data marts are planned to cater the retailing need of the particular tier. These data marts finally encompass an enterprise warehouse to check for the global retailing needs.

Data marts are subjective and time variant to the respective tiers provides up-to-date requirement need of the immediate succeeding tier and also update the enterprise warehouse for global monitoring and controlling the BWE. With this view we introduce three data marts each at layer 1, layer 2 and at layer3.The success of the retail chains depends on customer relationship and managing the issue the presence of data marts and the corresponding warehouse is inevitable.

With this view the revised model of figure 5 holds two suppliers, three manufacturers, distributors, retailers, and two customers separated over three tires. Each tier holds one data mart with the demand information over the concept hierarchy of item, location, and supplier. The data mart at tier 3 is linked with the server at location P18 dealing with customer and retailer, tier 2 data mart is linked with the server at P19 dealing with distributor and wholesaler, tier 1

data mart is linked with the server at P21 dealing with manufacturer and supplier, and finally the operational data marts of tier I to tier III builds the enterprise warehouse with the concept hierarchy time, item, location, and supplier.

Table 2: Token Accumulation in revised model

LOC	OB1	OB2	Total
P0	21.78218	49.50495	71.28713

Customer	**89.1089**	**128.713**	**217.822**

The tire wise servers and corresponding data marts are used for communication, material flow and the business intelligence applications. In order to control the entire SC operations and customer relationship management (CRM), some retail chain demands a centralized source of information for effective operation of the chain and the warehouse so built will serve that purpose.

The warehouse server can be placed and maintained in the cloud for efficient distributed application. The properties of the net in figure 5 remains same as that of figure 2 analyzed by the tool [6], [40]. A random number of continuous observations were performed on the high level net of figure 5 over two stages OB1 and OB2 and the data is recorded in table 2.

It clearly shows that with the progresses in operation the non linearity of figure 3 is substantially reduced in figure 6. Further we have measured the BWE index between the pair of communicating role players and presented the results in figure 7(a) – 7(c). The bullwhip effect between distributor and wholesaler as well as between Wholesaler and Retailer are eliminated.

These are demonstrated in figure (7a) and in figure (7b) respectively. However, the BWE between the retailer and customer is reduced but could not be completely eliminated as shown in figure (7c). Table 2 reflects that BWE index between other pairs of operators like supplier-manufacturer-distributor or wholesaler-distributor, in most of the cases are less than unity.

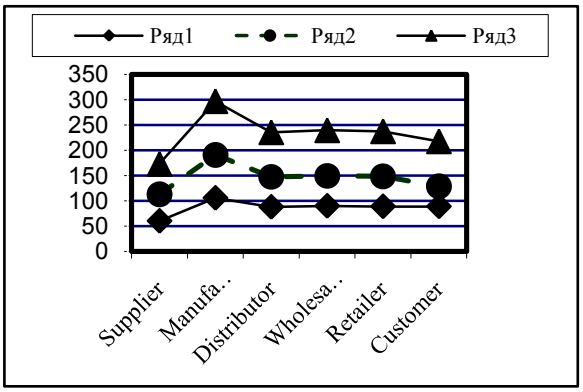

Fig. 6: Token Accumulation for the Revised Model

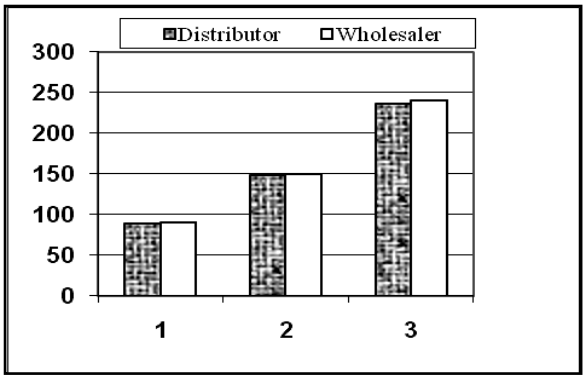

Fig. 7a: Revised BWE for Distributor and Wholesaler

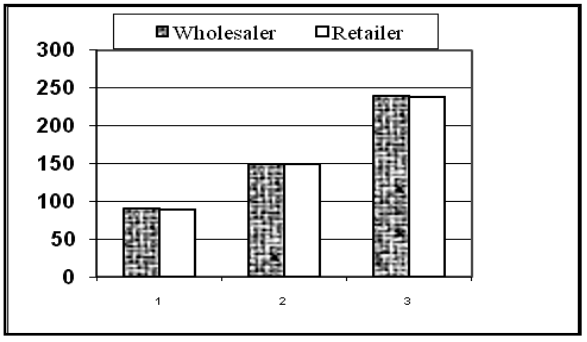

Fig. 7b: Revised BWE for Wholesaler and Retailer

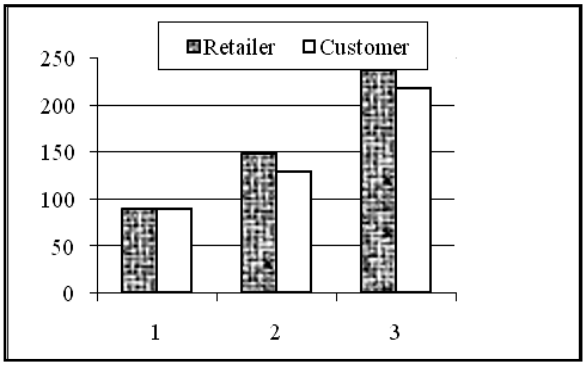

Fig. 7c: Revised BWE for Retailer and Customer

The empirical observations were random and the outcomes are tabulated to reflect the facts that BWE has been reduced due to the inclusion of the data mart in the form of a server to share the information and material flow. However, some existence of BWE may be needed on a player to player basis as a part of CRM strategies. In section V, we discuss some of the derived advantages of the warehouse.

V. WAREHOUSE APPLICATIONS

CRM is the key to success of the retailing business. Some of the CRM queries that can be generated from the multi dimensional data cube are:

- Which distribution channels contribute the greatest revenue and gross margin?
- Which customers are most profitable based upon gross margin and revenue?
- How many unique customers are purchasing this year compared to last year?

The first query generates the total amount sold and the second query checks for the location in which maximum sales has taken place. There could be many such queries can be generated by adding customer as one of the dimension of the warehouse, which will be an added overhead to the warehouse. Instead, local data marts can be used to generate more interesting queries for efficient CRM operations. The objective of the lattice of figure 5 is to carry out online analytical processing (OLAP) of the multi echelon SC. The local OLAP operations can be performed from the data marts of the respective tiers. The data warehouse model can be used to find the most valuable customer through Recent access, Frequency, and Monetary value (RFM) for CRM activities defined as a strategy to enable the organization proactive and profitable. It helps the organizations to have right focus and allocate sufficient resources to where is needed [14]. The star schema of the model for query processing is presented in figure 8.

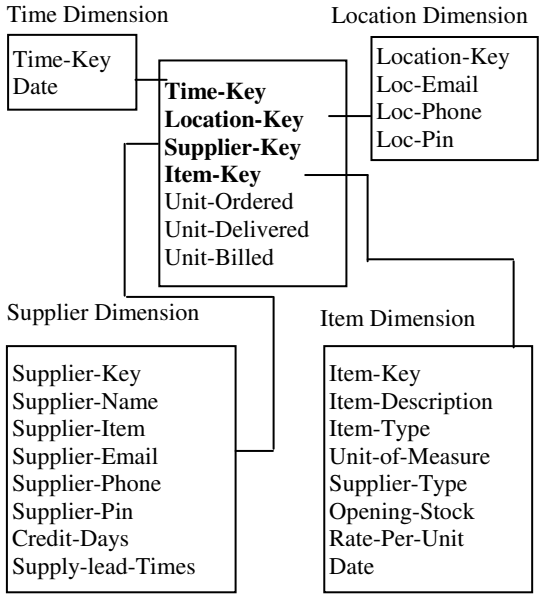

Fig 8: Star schema of the Lattice of figure 5

VI. CONCLUSION

Autonomous forecasting by the Supply Chain players invites BWE. Information visibility and stage wise centralized repositories reduce the BWE. The proposed model is capable of handling demand driven real time activities among the SCM partners. Operational soundness can be pioneered with the augmentation of multi dimensional data cubes and a central warehouse, such components helps in real time CRM applications. Initially a multi echelon, multi-tier retail network has been proposed in section 3 and after a set of simulation run, it is observed that inventory is getting piled along the SC partners, which provokes risks of uncertainty of demand and supply and obsolescence of product. In figure 5, the revised GSPN model is proposed with a demand driven procurement strategy along with stage wise data marts and a central warehouse to avoid the effect of demand variability and real time CRM application.

The proposed virtual multi-tier retail network is collaborative, data intensive and distributed. The large repository will support real time demand analysis, market forecast and strategic decision making. From the operational view point there are only a few global large size retailers who may be interested in maintaining the integrated chain but for the sake of scalability of the proposed model stage wise data marts are also employed for medium and small size retailers. It will not be out of place to mention that ERP based SCM chains can handle transactions and control BWE but beyond transaction management is CRM as SCM starts with the customer and ends with the customer and our proposed model is capable of handling real time CRM operations.

***Abstract*—This article presents the problem of consensus determining postulates defining in financial decision support systems. The consensus determining methods and function is characterized in the first part. Next the general postulates for consensus estimation and their characteristics are presented. The final part of article suggest new postulates pertaining to financial decisions, and the possibility of their use in practical solutions. The application of these postulates, as a consequence, can lead to the process of making financial decisions will be more flexible, and the risk involved in financial decisions will be significantly reduced.**

I. Introduction

MAKING decisions in financial matters has become a key component of any business activity. Problems in this area are typically associated with highly volatile character of financial market [9]. Decisions must be made virtually in real time, since only prompt and accurate reaction to changing market conditions provides tangible benefits, for example high return rate. Another important determinant is the high level of risk involved in financial decisions. Since analysis of information and drawing valid conclusions is a time-consuming process, and since real-time computing is beyond human processing capabilities, the process of making financial decisions is typically supported by computer software, employing a range of computing methods, such as artificial intelligence systems, capable of identifying relevant information and drawing conclusions based on input data. Important area of development in recent years is the use of agent and multi-agent systems [10,18] – these, unlike other AI systems, offer the capability of unaided operation and unaided decision-making, i.e. without user input and irrespective of any external factors.

At present, financial decision support systems (DSS) are typically distributed [2]. These systems offer the potential of fast processing of large amount of data. However, in most cases, distributed systems used for support of financial decision-making processes tend to generate multiple variants of solutions, which may result in knowledge conflict within the system. For example, in multi-agent systems, each individual agent may utilize a different method of decision support and, consequently, arrive at a different solution. Users expect a unified variant – or, to put it in simple terms, they want a single decision. Decision-making process is followed by implementation, and only one decision can be implemented at any given time – ideally, one that will bring tangible benefit to the user, while simultaneously limiting the level of risk involved. If a decision support system generates multiple variants, users face the problem of selecting the best possible variant – the ultimate decision. Since the task of selecting the best possible variant, as already mentioned, should ideally be realized in (or close to) real time, it is expected that the DSS will automatically present a single variant that offers best possible results for the user, thus solving the knowledge conflict. Professional literature presents a wealth of methods that can be used to this effect, such as negotiation methods [4] and deductive computing methods [1]. Negotiation methods allow for determining a solution that best suits all parties involved, based on compromise, but it is burdened with the problem of mass exchange of information between system components, which makes the postulate of real-time computing particularly difficult to achieve – or even impossible. On the other hand, deductive methods of computing (such as those based on game theory, classical mechanics and selection methods) offer high computing power, but do not easily satisfy the requirement of identifying best possible variant with simultaneously limiting the risk of inadequate selection.

It seems that the above inconveniences (and the resulting knowledge conflict) can be resolved with the use of consensus methods [8,15]. Consensus methods offer the benefit of determining a single best variant (or a single decision, in this context) out of multiple possible variants. It must be noted that the single decision determined using consensus methods will not necessarily belong to the domain of variants generated by the system in the first place. This is because consensus methods take into consideration all conflicting parties and interests. The ultimate decision is endorsed by all modules (parties) and the decision represents interests of all parties to a degree that satisfies all conflicting parties.

Sobieska-Karpińska and Hernes [10, 5] argue that using consensus methods for the purpose of identifying and presenting a target solution to the user will offer a reduction of decision-making time, since users are not burdened with the task of analysing and selecting the best possible variant. It also reduces the risk involved in the process, since variants identified and selected by the user may fail to bring the expected benefit, or even result in a loss.

978-83-60810-53-8/$25.00

It must be noted, however, that consensus algorithms used in DSS systems, including systems for financial decision support, must satisfy certain consensus postulates. These postulates represent conditions to be met by consensus-calculating functions. Only proper definition of these conditions will ensure that decisions made with the help of consensus algorithms will bring tangible benefit to the user.

Professional literature (see, e.g. [1,13,14]) does provide some general (universal) postulates for consensus estimation, but those assumptions fail to take into account some important aspects of financial decision-making, such as the risk and uncertainty involved. Therefore, it seems necessary to broaden the list of postulated parameters.

The purpose of this paper is to present the general postulates for consensus estimation (that need to be included, regardless of the problem they are meant to address via consensus calculation) and their characteristics, as well as suggest new postulates pertaining to financial decisions. This will allow for more accurate construction of consensus algorithms and, consequently, development of IT solutions able to calculate consensus results automatically, based on a set of solutions generated by the system. In this approach, the system will present the user with one ultimate decision that may be implemented to best effect. Consequently, the process of making financial decisions will be more flexible, since the system will suggest the most appropriate solution in (or close to) real-time. In addition, the risk involved in financial decisions will be significantly reduced, since users will not be able to manually select a decision that may be burdened with such risk at implementation phase.

II. General Postulates Of Consensus Determining

Purpose of introduction the postulates is determination on their bases classes of functions of consensus or otherwise saying, different methods of a consensus determining.

In addition, because the postulates are conditions which are expected to meet on consensus function, you can get it to justify the use of these functions in practice.

In farthest part of article we will use following symbols:

$\Gamma(U)$ - set of all don't empty subsets of universe U (e.g. set of objects-financial instruments),

$\Gamma'(U)$ - set of all don't empty subsets with repetitions of universe U,

$\cup'$ – sum of set with repetitions.

Let $X, X_1, X_2 \in \Gamma'(U)$, $x \in U$. In farthest part of article we will use next parameters:

$o(x,X)=\sum_{y\in X} o(x,y)$,

$o^n(x,X)=\sum_{y\in X}[o(x,y)]^n$ for $n\in \mathrm{N}$.

Let's notice, that parameter $o(x,X)$ represents sum of distance from element x belongs to universe U for elements of profiles X , but largeness $o^n(x,X)$ represents sum of n-powers it distance. This value can be interpreted as measure of evenness of distance from element x for elements of profiles (eg. det of financial decisions) X. if value n is greatest memorial then n, distances are more even.

In work [15] consensus function is defined next:

Definition 1.

Consensus function at space (U,o) we call optional functions of forms:

$$c: \Gamma'(U) \rightarrow \Gamma(U). \quad (1)$$

For profile $X\in\Gamma'(U)$ each of elements set $c(X)$ we call his *consensus,* however all set $c(X)$ we call *representation of profile X.* . Let C is set of all consensus functions in a space *(U, o).*

Using the overall function of the consensus you can then define the more detailed class consensus functions, relating to the various methods of its determination, including [15]:

a) Constructive methods, rely on solving problem of consensus on two levels: microstructures and macrostructures universe U. Microstructure is a structure of elements U, macrostructure is structure of universe U.
b) Optimizing methods, rely on defining function of consensus behind assistance of optimizing rules. Often in this methods functions quasi-mediane are applying, consensus is most approximated for all solutions from which be appointed, distances of consensuses are even for individual solutions simultaneously.
c) Methods taking advantage bool conclude, rely in the form encoding problem of consensus in bool formula to such manner that each first implicant this formula appoints solution of problem.

Therefore, in order to define the classes of functions relating to the above methods, it can use the postulates for consensus defined as follows (on the basis of [1, 13, 14]):

Definition 2.

Let X is optional profile we say, that consensus function $c\in C$ grants postulate:

1. *Reliability (Re), if*
$$C(X)\neq\emptyset \quad (2)$$
2. *Consistency (Co), if*
$$(x\in C(x))\Rightarrow(x\in c(X\cup' \{x\})) \quad (3)$$
3. *Quasi-unanimous (Qu), if*
$$(x\notin C(x))\Rightarrow((\exists n\in \mathrm{N})x\in c(X\cup' \{n*x\})) \quad (4)$$
4. *Proportional(Pr), if*
$$(X_1\subseteq X_2\wedge x\in c(X_1)\wedge y\in c(X_2))\Rightarrow(o(x,X_1)\leq o(y,X_2) \quad (5)$$
5. *1-Optymality (O_1), if*
$$(x\in C(x))\Rightarrow(o(x,X)=\min_{y\in U} o(y,X)) \quad (6)$$
6. *2-Optymality (O_2), if*
$$(x\in C(x))\Rightarrow(o^2(x,X)=\min_{y\in U} o^2(y,X)). \quad (7)$$

These postulates for function of consensus express primary condition define different method consensus. First postulate (*reliability*) sets up, that it is possible to appoint consensus for each profile always. It answers optimistic attitude each conflict give solve. Reliability is known criterion in theory of choice [3].

Postulate *consistency* requires implementation of condition, that if some element x is consensus for profile X , then after expansion this profile about x ($X\cup' \{x\}$), this element should be consensus for new profile. Consistency is important ownership of consensus, because it allows users to forecast behavior of rule of appointment of consensus, when premises of independent choices are jointed.

According to postulate *quasi-unanimous,* if certain element x is not consensus for profile X, that it will be consensus for profile X^1 inclusive X and n protrude element x for certain n. In other words, each of elements of universe U should be chosen as consensus for such profile, if number of its pronouncement is sufficiently big.

Proportionality postulate is natural ownership enough, because if profile is greatest memorial then difference between its elements and consensus is greatest.

Last two postulates are very particular. First of it, postulate *1-Optymality* require that consensus is nearest (most similar) to elements of profile. This postulate, in literature very well known, it defines concrete function class, called medians. Instead postulate *2-Optymality*, on the other hand, requires, in order to sum of square of distance from consensus for elements of profiles was smallest. Cause of introduction of this postulate results from (also very natural) following condition concerning determination function consensus: consensus have to be „fair"; it means, that its distance for elements of profiles should be the most even. Let's notice, that number $o^n(x,X)$ defined earlier, can be treated as measure of evenness of distance between certain object x and elements of profiles X. Therefore, above-mentioned condition requires, in order to value o^n (consensus, X) be minimal. In work [6, 7] show, that functions granting postulate *2-optymality* are better than function granting postulate *1-optymality*, by the reason of greatest evenness, but they differ from other function of consensus greatest similarity for elements of profiles. From it result, that postulate *2-optymality* is good criterion of appointment of consensus.

Let us note that the first three postulates, namely *Re*, *Co* and *Qu*, are independent of the structure of universe U, represented by a distance function o (used to establish consensus function class in methods based on Boolean reasoning), while the last three postulates (*Pr*, O_1 and O_2) are formulated on the basis of o function (these postulates are employed in optimization methods). Postulates *Re*, *Co* and *Qu* are also used in cases when distance function (or, in more general terms – the macro-structure) for universe U cannot be specified. For financial decisions, function of distance can always be reliably defined, therefore all postulates can be employed, allowing for the use of both constructive and optimization methods of consensus estimation.

The above general postulates of consensus estimation, as already mentioned, are not sufficient for financial purposes. For this reason, this author puts forward two additional postulates to supplement the above list.

III. The Proposal To Extend The List Of Postulates In Terms Of Making Financial Decisions

A good approach in estimating best possible decisions in financial matters, i.e. when dealing with problems typically burdened with risk and uncertainty, is to employ evenly distributed consensus – that is, one that takes into account all possible solutions, with each solution estimated at equal measure. This helps minimize the risk of ultimate decision, since the potential of putting more weight to an incorrect decision is eliminated. Therefore, if *2-Optimality* postulate offers more even distribution that *1-Optimality* postulate, then a postulate of *n-Optimality* should be defined, to offer even smoother distribution than *2-Optimality* for n>2. Consequently, definition for such new postulate will take the following form:

Definition 3.

The consensus function $c \in C$ grants an n-Optimality postulate (O_n), if

$$(x \in C(x)) \Rightarrow (o^n(x,X) = \min_{y \in U} o^n(y,X)). \quad (8)$$

This postulate is a generalization postulates *1-Optimality* and *2-Optimality*.

Another extended postulate on consensus determining in financial decision support systems is a inconsistency of knowledge postulate:

Definition 4.

Consensus function $c \in C$ grants an inconsistency of knowledge postulate (Uk), if

$$(x \in C(x)) \Rightarrow (o^n(x,X) > \min_{y \in U} o^n(\{X \setminus y\},X)). \quad (9)$$

The above postulate allows for determination of an element, for which the distance to consensus is larger than the sum of consensus distances of all the remaining elements (in other words, one of the profile elements is markedly more distant from the consensus than the others). Such situation may result from inadequate knowledge on the part of one of the conflicting parties (for example, a software agent). If this is the case, then decisions generated by the defaulting party should not be taken into account. This problem may be solved by adopting a multi-stage process of consensus estimation, as suggested in [16]. Such method is under implementing in a-Trader multiagent system for FOREX platform [11]. These systems consist of the large number (hundreds) of processing agents, which on the basis of the FOREX signals, take the specified decision on buy/sale. The paper [12] presents using the consensus methods to reduce the level of the investment risk, as a strategy of Supervisor Agent in a-Trader System.

Building consensus algorithms on the above postulates is not necessarily a guarantee of success in arriving at best possible solution. For example, the algorithms may find a consensus solution for which a given element of the decision-making process is at the same time adopted and rejected, leading to a contradiction. Some authors also take into account the profile's consensus susceptibility [8]. If a profile (a set of decisions) is not prone to consensus, methods of satisfying its susceptibility may be adopted, such as inclusion of decisions generated by new parties (e.g. new software agents).

However, it must be noted that consensus estimation functions used for the purpose of supporting financial decisions must meet both general consensus postulates and the expanded postulates (these postulates may also be used in order to the other, than only financial problems). Otherwise, the estimated consensus may not warrant tangible benefit to the user, for example – by placing more weight on an inappropriate decision contained in the profile.

IV. Conclusion

Making decisions in financial matters is a complicated process, particularly in the face of high risk and uncertainty associated with this form of activity, since it may lead to unpredictable results. Improper decisions may detriment the functioning of a whole organisation. Distributed systems offering support for financial decisions are a viable solution, provided that they are able to generate a single, reliable recommendation. However, if individual nodes of the system (such as software agents) generate multiple instances of solutions, the overall reliability of the system is considerably lower. Therefore, proper care should be taken to ensure that the user receives the best possible solution generated automatically by the system, so that he or she can make a correct decision that will result in benefit for the organization. Use of consensus methods provides the potential of arriving at a single best decision – one that not necessarily belongs to the original domain of decisions generated by individual nodes, but adequately similar. Consequently, the level of risk involved is considerably lower. If users were to perform own analyses and manually select from decisions generated by the system under time pressure, their choices would be potentially burdened with error – the more so if we take into account the time pressure involved. In addition, consensus methods allow for considerable reduction of decision time, since the system presents the user with a single best solution determined automatically on the basis of variants generated by individual nodes.

For obvious reasons, consensus methods do not warrant absolute accuracy of resultant decision, but they do warrant some degree of satisfaction. Some of the individual variants generated by system nodes may prove more appropriate than the automatic suggestion determined using consensus methods, but one can never be certain that the user would have selected such best variant (if he were to analyse and select it manually). In such a case, selecting the worst possible variant is also possible, which can only increase the risk involved.

However, correct algorithms for consensus estimation should incorporate and take into account all the postulates presented above. Negligence in this respect may result in ill-advised suggestions with negative consequences.

Proper implementation of consensus postulates is, therefore, a prerequisite for correct design of consensus algorithms to be used in financial DSS (decision support systems).

***Abstract*—What makes the development of decision support systems (DSS) particularly challenging is the change dynamics of the design space, the instability of initial specifications, and the lack of an adequate model of the decision making process. Facing these, one can appreciate a methodology that can drive the designer's creative effort within a particular decision context. The paper aims to outline the origin and the evolution of research on the DSS architecture commenced by Sprague and Carlson and carried on under the auspices of the International Federation for Information Processing (IFIP) and the International Society for Decision Support Systems (ISDSS)[1]. In particular, the paper presents insights, findings, recommendations and conclusions derived from case studies conducted in domestic medium-sized and large enterprises.**

I. Introduction

GROUND-breaking studies that gave rise to the computerized decision support strand appeared around mid-20th century[2]. By mid-1980s, a new science discipline emerged, concentrating a vast research potential. The term "decision support system" (DSS) has a number of connotations. Most scholars have accepted the term to mean "an interactive computer based system that helps decision-makers use data and models to solve ill-structured, unstructured or semi-structured problems" [1], although some argue that this definition is too narrow, pointing out that a DSS should be able to support ill-structured decisions as well as structured tasks. This leads to a more general definition ([4], [2]) as an interactive computer-based system or sub-system intended to help decision makers use communication technologies, data, documents, knowledge and/or models to identify and solve problems, complete decision process tasks and make decisions. In his seminal doctoral thesis, Steve Alter [3] put down the following three axioms of the unfolding paradigm which were approved by most of his fellow researchers: (1) that DSS are designed specifically to facilitate decision processes; (2) that DSS should support rather than automate decision making; and (3) that DSS should be able to respond quickly to the changing needs of decision makers.

However, neither theory-oriented research approaching decision support from the management science perspective nor the few experimental studies have been able to lay solid foundations for DSS designers to build upon. The following research outcomes have proved useful to developers:

- Recommendations concerning the architecture of computer decision support based on the Data – Dialog – Modeling paradigm. The principal idea behind the paradigm represents that the designer's responsibility in designing a decision support system is to build the data, dialog and modeling components and to ensure interaction among these. The idea underpins the theoretical work referenced above, e.g. in adopting a DSS definition. The paradigm has made it possible for Sprague and Carlson [1] to articulate an influential architectural model and helped their followers ([5], [4], [22], [12]) further advance it and extend it.
- The guidelines of "meta-design" methodology pioneered by Moore and Chang [6]: "(…) the classic MIS development life-cycle approach is insufficient as a prescriptive guide for building DSS [since it] (…) does not lay out a step-by-step procedure or even an exhaustive list of topics (…). We synthesize ideas from existing DSS design frameworks to produce a meta-design methodology from which individual DSS designers can develop their own design frameworks, appropriate to their particular needs." The meta-design approach had its advocates who undertook to further develop it (cf. [7], [8], [10]). Due to the volatility and change dynamics of the design space, frequently coupled with a need for organizational change entailed by IT

[1] Now known as Association for Information Systems Special Interest Group on DSS.

[2] One of those was definitely Michael S. Scott-Morton's Ph.D. dissertation written in 1964-1967 at Harvard Business School and published in book form by HBS Press in 1971 under the title "Management Decision Systems." Recalling his work on the dissertation in *DSSResources*, Scott-Morton mentions collaboration with such prominent scholars as H. Simon, J. McKeney, or F. Carr. Other famous contributors to the decision support concept include H. Leavit, T. Gorry, D. Ness, J. Little, T. Gerrity, P. Keen and C. Stabell. As regards institutional involvement, one could agree with P. Keen when he states that the concept originates in the theoretical studies of organizational decision making done at Carnegie Institute of Technology during the late 1950s and early 1960s and the technical work on interactive computer systems, mainly carried out at Massachusetts Institute of Technology in the 1960s.

978-83-60810-53-8/$25.00

deployment, we see ongoing integration of current trends in system design and organizational change [11].

The paper seeks to address both these research areas. The following discussion draws on views that have been voiced in prior publications:

- "The traditional view of DSS components remains useful because it identifies commonalities between different types of DSS, but it provides only an initial perspective for understanding DSS architectures." [5]
- "The architectural design should set a common level of understanding among technical, non-technical and management participants." [9]
- "DSS (…) ideas and concepts were developing in the early 1970s, the technology became widely available at reasonable cost in the 1980s, and in 2008 are rarely used effectively. When they are, they are huge beneficial impacts; indeed some firms could not exist without them. (…) The general unresolved issue I see is one of understanding the management of change." [17]

A thorough analysis of refutations and cracks flawing the theoretical foundations of DSS has led us to propose the extended DDMKCC paradigm: Data – Dialog – Modeling – Knowledge – Communication – Creativity [7]. Further in the paper, a theoretical underpinning is provided alongside a description of architectural recommendations, resulting from our recent research as well as from a wealth of practical experience with the proposed paradigm. The research involved a group of 10 business companies selected from among some 200 in which DSS implementation projects were completed by Consorg S.A. between 2000 and 2012. Each implementation has been examined for the degree to which each of the DDMKCC architectural components is used in making decisions at (1) operational, (2) tactical and (3) strategic level.

I. Traditional DSS Architectures Based on the DDM Paradigm

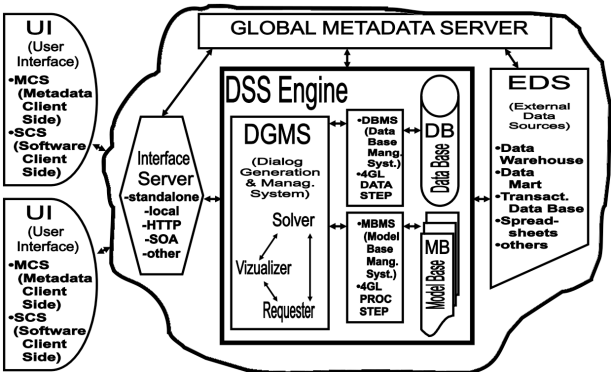

Fig. 1 A traditional DSS architecture in an IT development context

A traditional architecture, such as the one shown in Fig. 1, afforded a possibility to exploit available information technologies in implementing early computer decision support concepts founded on the DDM paradigm and embracing the reflection on interactions between architectural elements such as Data Base, Model Base, Visualizer, Generator, and Solver within a network environment. Looking back at the expansion of specific technologies and the evolution of theory, one easily recognizes the advances in technical solutions identified e.g. with multi-layer architectures, grid computing, data analysis and presentation using data warehouses, or Business Intelligence environments. One of the remaining challenges is to link the DSS model base with models existing in organizations. A lot of such models are in the form of hardly scalable spreadsheets developed by painstaking or enthusiastic users. Their flat meta-data structure is just another important weakness. By introducing further levels, we may be able to implement many of the proposals stemming from IFIP research on the problems of context within DSS ([16], [13]).

II. Origin of the DDMKCC Paradigm

We have already remembered the DSS design paradigm framed by Sprague and Carlson, demanding that DSS consist of three sets of capabilities belonging in the areas of dialog, data and modeling. Many researchers insist that a good DSS should retain balance among the three capabilities. It should be easy to use, too, allowing non-technical decision makers to interact freely with the system. It should be able to access a wide variety of data and provide ample analytical and modeling capabilities [18]. However, observation clearly demonstrates that practice does not fully raise to the promises of theory. Sprague and Watson [19], for instance, contend that many early systems would adopt the name DSS when they were strong in one area and weak in the other. Having analyzed 56 DSS cases, within the two main groups Alter distinguished seven sub-groups based on "the degree to which the system's output can directly determine the decision" [3]:

- Data-oriented DSS: (1) File Drawer Systems, whose purpose is to automate certain manual processes and provide access to data items; (2) Data Analysis Systems, which facilitate the analysis of current and historical data, in order to produce reports for managers; (3) Analysis Information Systems, which provide access to a multitude of support data bases for the decisional process, as well as a series of simple models in order to supply information necessary for solving particular decisional situations.
- Model-oriented DSS: (4) systems oriented on accounting and financial models. The models employed are of "what-if" and "goal-seeking" types and they are frequently utilized in producing profitability estimates for new products, estimative balances, etc; (5) systems oriented on representational models, which use simulation models to estimate consequences; they are used extensively in risk analysis, in production simulation etc.; (6) systems oriented on optimization models which help produce optimal solutions for different activities; (7) systems oriented on suggestion models which carry out the logical process leading to a suggested decision for activities with

a certain degree of structuring (such as determining the frequency of insurance renewal, models for the optimization of bond supply, etc.).

Further studies on existing decision support systems confirm the growing dynamics, diversity, complexity and diffusion of the DSS area. The outcomes become contradictory, the foundations of DSS are crumbling, and special cases are increasingly often reported that supersede or undermine prior research findings. Investigating the "cracks" enables (or compels) researchers to lay broad and solid foundations on which to build up the knowledge [20]. "Many software vendors, information systems consultants, and even some academic researchers are periodically tempted to create a revised vocabulary for existing concepts. Synonyms are variants on accepted concepts which can sometimes aid in understanding, but they can also lead to conceptual confusion. The globalization of discourse on topics like decision support has added to the challenge of communicating meaningfully about our research; more terms increase the difficulty. The academic community needs to control the word labels that are used in our research and discourse for important concepts and constructs. This task is important if researches want to manage and evolve a stream of systematic research on decision support." [21].

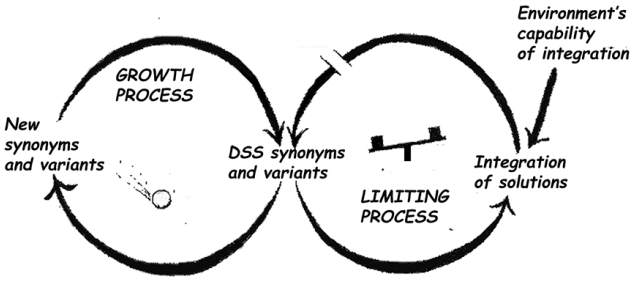

Fig. 2 A Casual loop diagram for a solution to the explosive growth of DSS synonyms and varieties in line with the Limits to Growth Systems Archetype

Theory-oriented research indicates the emergence of the birth effect: a growing number of DSS synonyms and variants generates a larger number of new concepts. For outcomes to be comparable with one another, integration of research sub-areas is required [22], which – according to the Limits to Growth Systems Archetype – involves a negative balancing loop (Fig. 2).

The extended DDMKCC (Data – Dialog – Modeling – Knowledge – Communication – Creativity) arises from the need for integration (cf. Fig. 3), in the context of existing "cracks" in the traditional DSS architecture, drawing on research on the deployment of information technology in organizations [26] and acknowledging the incorporation of soft systems methodology into DSS research. In subsequent publications, further architectural details are added or elaborated.

At the same time, Power [5] develops an integrated DSS classification aligned with the idea of pivotal component proposed by Sprague and Watson (cf. Table I).

Document base **Document-Driven DSS**	Specialists and user group is expanding	Search Web pages Find documents	Web
Knowledge base **Knowledge-Driven DSS**	Internal users, now customers	Management Advice Choose products	Client/Server, Web
Models **Model-Driven DSS**	Managers and staff, now customers	Crew Scheduling Decision Analysis	Stand-alone PC

Source: [5]

In this paper, the central research question concerns the software architecture for a decision support system. Theoretical insights and prior validation efforts have led to an extension of the classical Sprague-Carlson DDM proposal toward the DDMKCC paradigm. The paradigm not only implies the building blocks of a decision support system but also provides a basis for addressing and analyzing a broad array of cases. In the following chapters, the findings of research on decision support system design are presented that substantiate the above propositions and underpin practical recommendations.

III. A STUDY OF THE PERFORMANCE OF DDMKCC MODEL COMPONENTS

We selected 10 out of 200 implementation projects run in 2000-2012 by Consorg S.A. In this way, we arrived at a group of 10 business organizations from both the production and the services sectors which we deemed the most representative for our analysis and appraisal of the

proposed approach – viz. its performance and practical effects. The sample included large enterprises as well as capital groups. Some of them are listed on the Warsaw Stock Exchange, while 3 of them (being international capital groups) have parent companies based outside Poland. Most of the companies operate in production industries. The average number of DSS users ranges from 5 to 10 advanced users and 20 to 30 novices or occasional users (see Table II).

In all of the organizations support is centered on decision making processes in the area of financial control. The solution was implemented in an effort to support decisions at all (operational, tactical, and strategic) management levels. At each level, a different set of analytical tools was offered, following the classification of models proposed by Turban and Aronson [26] (see Table III).

TABLE II.
THE 10 SELECTED BUSINESS ORGANIZATIONS FROM THE MANUFACTURING AND SERVICES SECTORS

	Customer	Industry	Organization structure	DSS users	Project duration	Headquarters
1	**Tauron Wytwarzanie** (formerly Południowy Koncern Energetyczny S.A. [Southern Power Corporation]) Parent quoted on Warsaw Stock Exchange	power generation	one-layer capital group	50 primary users 150 other users	2000–2004	Katowice, Poland *www.pke.pl*
2	**Vattenfall Heat Poland S.A.** (Elekrociepłownie Warszawskie S.A.)	power generation	multi-layer capital group	25 primary users 20 other users	2002–2004 upgrade: 2009–2010	Warszawa, Poland (subsidiary) *www.ewsa.com.pl*
3	**Odra Trans S.A.**	inland navigation	multi-layer capital group, 20 subsidiaries (including a Germany based sub-group)	5 primary users 35 other users	implementation period: 2006–2007	Szczecin, Poland
4	**Black Red White S.A.**	furniture manufacturing	one-layer capital group, 30 subsidiaries	5 primary users 30 other users	2007–2008	Biłgoraj, Poland
5	**Pradyż / Ceramika Paradyż sp. z o.o.**	white ware	no capital group	10 primary users 30 other users	2006–2008	Opoczno, Poland
6	**Cersanit S.A.** Parent company quoted on Warsaw Stock Exchange	white ware	multi-layer capital group, 40 subsidiaries (including a Russia based sub-group)	10 primary users 25 other users	2009–2010	Kielce, Poland
7	**EC Będzin S.A.** Listed on Warsaw Stock Exchange	heat generation	member (subsidiary) of RWE capital group	12 primary users	2009–2010	Będzin, Poland (subsidiary)
8	**Kamis S.A.** Listed on Warsaw Stock Exchange	food industry	no capital group	12 primary users 92 other users	2010 –2011	Lubliniec, Poland
9	**Lentex S.A.** Parent company quoted on Warsaw Stock Exchange	chemical industry	one-layer capital group, 1 subsidiary		2010–2011	Poland
10	**Paccor S.A. / Veriplast S.A.**	food packaging	multi-layer capital group, 25 subsidiaries	5 primary users 45 other users	2010–2011	Luxembourg

TABLE III.
DECISIONS, TOOLS AND DECISION MAKING MODELS USED WITHIN THE DDMKCC MODEL

	DECISIONS — TOOLS and MODELS	
	Capital groups	**Other**
1	• Consolidation of financial statements for external reporting (IFRS) • Financial monitoring and budgeting • Corporate supervisory activities • Cash flow planning and monitoring under cash-pooling models	• Operating budget planning and financial analysis • Cash flow analysis models • Pricing models
2	• Simulations and financial monitoring using expert system reports • Benchmarking of functions and processes (diagnosing the causes of deviations in key performance indicators within capital group's strategy performance monitoring) • Models of asset allocation throughout the capital group	• Simulations and financial monitoring using expert systems reports • Benchmarking of the functions and processes of operating budget planning within the corporation's production units (diagnosing causes of deviations in key performance indicators) • Key investment project analysis models

3	• Multi-dimensional simulations of capital sub-group structures; strategic and financial monitoring for management purposes • Value management models for capital groups	• EVA corporate value management models • BSC strategic management models • Strategic resource planning models

where:
1. Operational decisions
2. Tactical decisions
3. Strategic decisions

Besides, the distinct nature of capital group management was reflected in specially tailored business models enabling decision support to be addressed at the parent company level [27]–[30].

Data Sources and Data Models

In the following discussion of the DDMKCC model's "data" component and its usage statistics, data sources and data models will receive separate treatment.

- Data sources

The taxonomy of data sources (cf. Table IV) was based on the classification proposed by R. Sprague and H. Watson [28]. The findings of our observations and analyses are consistent the widely known fact that, although data come from diverse sources, strategic decisions will involve greater use of external sources and less reliance on internal ones (e.g. ERP/MRP systems). The way corporate knowledge bases are exploited in making tactical decisions is notable, too. It is easy to see that relevant data are most commonly sourced from investment project analysis cases stored in archives, since such cases often provide valuable insights into how similar projects were evaluated in the past and offer analogies which can be instrumental in assessing the risk of new investments.

TABLE IV.
DATA SOURCES FOR THE DDMKCC MODEL

DECISIONS	1	2	3	4
Operational	xxx	x	-	-
Tactical	xx	xxx	xx	x
Strategic	x	xx	xxx	xxx

where:
1. Traditional ERP/MRP
2. Text processing and document processing systems; corporate knowledge bases
3. Open access data bases
4. Business information libraries; economic intelligence agencies

- Data models

Likewise, usage analysis of data models led us to believe that data warehouses were used the most when making strategic decisions (cf. Table V), and they were central to capital group management, particularly in groups that have not implemented a single transactional system. For them, a data warehouse can become a integrating DSS component, unifying data and processes across the group. This corresponds to employing a data warehouse to support both operational and strategic decisions.

Interesting observations can be made in examining the use of multi-dimensional OLAP data structures in business decision making processes. When a well designed OLAP cube is combined with an ergonomic viewer, all of the reporting process can be handled via multi-dimensional structures, regardless of the type of decision to be made. It does not matter at all whether OLAP is embedded in a data warehouse or the multi-dimensional repository accesses transactional data directly. Obviously, at the operational level the application of OLAP technologies is reduced to relatively simple (and repetitious) reporting. Advanced functionalities, on the other hand, such as those of data mining and hypothesis validation, are employed at the other decision levels. By surveying the businesses from our sample we were able to ascertain that wherever OLAP technology has been successfully implemented, reporting almost exclusively hinges on data supplied in this way, while other methods have been nearly abandoned.

TABLE V.
DATA MODELS EMPLOYED WITHIN THE DDMKCC PARADIGM

DECISIONS	1	2	3	4
Operational	xx	xx	xxx	x
Tactical	x	xx	xxx	x
Strategic	-	xxx	xxx	xxx

1. Relational data bases
2. Relational data bases – data warehouses
3. Multi-dimensional OLAP data base models
4. File system / document repository

Dialog and Communication Components

The discussion of the dialog component's functionality will be broken down in a pattern proposed by Bennett for the assessment of DSS user interface [4]: (1) knowledge base, conceived as a set of users' essential skills (knowledge) enabling them to work with the system, (2) command language – the way in which users operate the system, and (3) presentation language, i.e. the way in which output is represented [4].

- Knowledge base

Nearly every user highly appreciates the availability of complete system documentation including operating instructions (cf. Table VI). Few, however, actually use it and, as a result, most of them require individual training. As

long as it is fairly sufficient for users at the operational management level, those having to cope with less structured decision problems will normally need to have a good understanding of the problem solving process and to know the applicable techniques. Without this know-how, users situated beyond the operational level might not be able to use the system resources efficiently: even if an expert system is activated to provide them with support in choosing the most suitable tools (models) for their problem, the choice has to be ultimately made by the user. Observation reveals that the most common reason why some systems are not used in tactical or strategic problem solving is not the technology itself but the relatively high demand they put on users' competence (knowledge base).

- Command language

No matter what kind of problems are solved, the ability to communicate with the system via standard and context menus is usually taken for granted or seen as a minimum requirement concerning functionality. Individuals solving tactical problems in companies where an enterprise data warehouse module has been implemented also demanded the option of similar case finding in knowledge bases.

TABLE VI.
THE KNOWLEDGE BASE OF THE DSS USER INTERFACE WITHIN THE DDMKCC MODEL

DECISIONS	1	2	3	4	5
Operational	xxx	x	xxx	x	x
Tactical	xxx	xxx	xx	xxx	x
Strategic	xxx	xx	x	x	xxx

1. Interactive operation manual
2. Examples suited to user skill level
3. Support functions for system navigation
4. Problem solving skills training facility
5. Support options for user learning

Users engaged in solving tactical and strategic problems will rather expect the system to become a "partner in problem solving." Interestingly enough, we found that the lowest skill levels are associated with the highest expectations from the system, including a proactive attitude in assisting the user. Conversely, the expectations of most advanced and creative problem solvers are limited to being offered an efficient technology and a rich collection of presentation tools.

TABLE VII.
USE OF COMMAND LANGUAGE FUNCTIONS IN THE DDMKCC MODEL

DECISIONS	1	2	3	4	5	6
Operational	xxx	xxx	xxx	-	-	-
Tactical	xxx	xxx	x	-	xxx	xx
Strategic	xxx	xxx	-	-	-	xxx

1. Standard system menu
2. Context menu
3. Data base query languages
4. Communication based on natural language processing
5. Knowledge base search for similar cases
6. Ability to guide user dialog toward problem resolution

- Presentation language

Our survey demonstrated that users' expectations concerning the presentation language are closely tied with the mental model of the decision maker being the end user of information output by the system. For example, financial analysts working for top executives expect the presentation language to be as rich as possible and hence capable of satisfying the needs of any user further enhancements to the system. The extent to which specific functions of the presentation language are used will vary largely depending on who uses the output information (e.g. corporate board members will have other preferences than line managers).

TABLE VIII.
FUNCTIONS OF THE PRESENTATION LANGUAGE IN THE DDMKCC MODEL

DECISIONS	1	2	3
Operational	xxx	x	x
Tactical	xxx	xxx	xx
Strategic	xxx	xxx	xxx

1. Data and report presentation in a variety of forms – tables, text, presentation graphics
2. Report definition in terms of detail level and format of delivery (PDF, HTML, Word DOC, etc.)
3. Parallel work with multiple data sections, presentation in multiple forms using multi-window technology

Knowledge and Modeling Components

Within the DDMKCC model, the knowledge component is defined as a resource comprising mathematical models and algorithms designed to transform data into information (deep knowledge) alongside heuristics used to support the decision making process (shallow knowledge) – rules, constraints, boundary conditions or any other information which may be generated within the DSS or acquired during the system's productive operation [5, p. 16]. This approach allowed us to perform usage analysis of specific knowledge components vis-á-vis the type of decision problem. The findings provide important insights that can inform further evolution of the DDMKCC paradigm.

First of all, addressing support to decision making processes at the operational management level does not involve any major modifications to the pre-defined decision making models. These are typically simple cause-effect models focused on explaining deviations of actual performance from plan. It is vital, nevertheless, that simulation and prediction functions be implemented in this class of models to enable "what if" and "what else" analysis (cf. Table IX).

TABLE IX.
FUNCTIONS OF THE PRESENTATION LANGUAGE WITHIN THE DDMKCC MODEL

DECISIONS	1	2	3

Operational	xxx	x	-
Tactical	x	xxx	xx
Strategic	x	xx	xxx

1. Pre-defined models embedded in the DSS
2. Expandable pre-defined models
3. Custom model development and integration tools

The conclusions will be very different as soon as we look at how the system supports strategic decision making processes. What is required of the system in such circumstances is, in the first place, adaptability and expandability by appending new decision models. The DSS not only has to offer the requisite tools to freely build decision models but also needs be able to instantly integrate (owing to two-way data interchange) with dedicated external systems addressing specific business problems. (This would be necessary, for example, in a situation where an investment bank will not agree to open a long-term credit facility unless project performance is assessed and monitored using a model preferred by the bank.).

Secondly, the DDMKCC model includes a special resource containing knowledge on business processes utilized in decision making (decision workflows). Identifying the key business processes and analyzing the decision making processes intrinsic to them makes it possible to accumulate knowledge needed to discover and assess relationships between decisions and their outcomes. This appears critical, in the light of our research, for decision analysis at all levels – operational, tactical, and strategic (cf. Table X).

TABLE X.
FUNCTIONS OF THE PRESENTATION LANGUAGE WITHIN THE DDMKCC MODEL

DECISIONS	**1**	**2**	**3**	**4**
Operational	xxx	xxx	x	x
Tactical	xxx	xxx	xx	xxx
Strategic	x	xxx	xxx	x

1. Mathematical models and algorithms
2. Workflow procedures
3. Heuristics based on expert knowledge
4. Algorithms founded on fuzzy expert rules

Thirdly, our observations suggest that other than deterministic models are used relatively rarely. The most common approach is that founded on deterministic scenario building techniques where the best- and the worst-case scenario are identified. Where probabilistic models are used, preference is given to approaches based on subjective probability.

TABLE XI.
FUNCTIONS OF THE PRESENTATION LANGUAGE WITHIN THE DDMKCC MODEL

DECISIONS	**1**	**2**	**3**

2. Fuzzy
3. Probabilistic

Creativity Component

Our survey indicates that the most frequently used creative problem solving tools include: (1) context-sensitive help along with access to historical data and similar cases, (2) a multi-dimensional OLAP data base viewer for convenient hypothesis testing during the creative problem solving process, (3) group work support tools, such as dedicated discussion forums or widely popular instant messengers, (4) SWOT analysis support tools, (5) tools and models for multi-criteria "what if" analyses, and (6) context-oriented reports recapitulating the user's work outcomes; to deliver these outcomes, such reports make use of e.g. expert systems, presentation graphics, tabular views and layouts [6].

The use of each type of tool was examined by observing the subsequent stages of budget planning and budget control processes (monitoring deviations from targets) in capital groups – cf. Table XII.

TABLE XII.
CREATIVITY SUPPORT TOOLS MOST HEAVILY USED BY CAPITAL GROUPS WITHIN BUDGET PLANNING AND CONTROL PROCESSES TO MONITOR DEVIATIONS FROM PLAN

	PROCESS	**1**	**2**	**3**	**4**	**5**	**6**
1	setting budget targets for subsidiary companies	xxx	-	x	-	x	x
2	budget modeling in daughter companies	x	xxx	x	-	xxx	xx
3	management-led consolidation of financial budgets	x	xx	-	-	-	x
4	analysis of threats and opportunities to performance of consolidated group budget	x	xx	x	xxx	xxx	xxx
5	analysis of strengths and weaknesses of subsidiary companies' financial budgets	x	xxx	x	xxx	xxx	xxx
6	budget negotiations	-	xx	xxx	-	xxx	x
7	identifying KPIs/CSFs for subsidiary companies' and group's budgets	xx	x	x	-	xxx	xxx
8	monitoring deviations from plan, early warning of potential threats	xx	xx	xx	-	xxx	xxx
9	validation and control of financial budgets	xx	xxx	xx	xx	xxx	xxx

1. Intelligent context-based assistance for problem solving
2. Multi-dimensional OLAP data base viewer
3. Group work support tools
4. SWOT analysis support tools
5. "What if" analytical models

Importantly, we perceived the necessity to make DSS capable of fast and easy integration with specialized external solutions designed to support certain creative problem solving techniques (e.g. brainstorming or morphology analysis).

IV. Conclusions

Researchers dealing with computerized decision support exhibit growing interest in integrating individual and domain-specific insights and building common theoretical, methodological and applicational frameworks that can sustain systemic thinking.

In the long run, thinking in terms of software architectures facilitates DSS development and maintenance. A holistic view fosters diverse applications, iterative development and, in particular, this distinctive approach, perhaps unique to DSS, whereby systems are developed in response to changes in the decision space. Many DSS have evolved from a data-oriented system through modeling a specific domain, e.g. financial control, which became a starting point, then arousing broader interest in the system itself and inspiring innovative efforts at large. Next, there arises a need for group work and creativity support.

By investigating, across multiple aspects, the ways in which specific DDMKCC model components are used in the practice of making business decisions, we have identified the key determinants of an effective development context for computerized decision support systems. The paper presents research findings which encourage a belief that further development of context-dependent DSS design meta-methodology should be approached from the system designer's perspective.

***Abstract*—Agility as a term is widely known today. However, a common understanding of what agility means and what it consists of is missing. Until today, a lot of frameworks have been developed, but they are very heterogeneous regarding content and structure. This paper approaches that issue by conducting a systematic comparison of 28 available agility frameworks out of the domains of agile manufacturing, agile software development, agile organization, and agile workforce. Altogether, 33 concepts related to agility were identified. The results of the comparison show that even within the examined specific domains a lack of consensus is obvious. In addition, the utilized concepts are very ambigious and overlapping. So, the interdependencies between the identified concepts were analyzed in detail. This revealed five recurring "clusters" that each combine several concepts with similar content, but despite the amount of available frameworks, none of it reflects these clusters directly. Hence, the study shows that the factors beyond the construct of agility are not fully uncovered yet.**

I. Introduction

FOR several years, businesses and organizations have faced a more and more volatile environment, marked with challenges such as increased competition, globalized markets, and individualized customer requirements accompanied with many changes in every organizational field. Such scenarios were already described in the 90s, for instance by Goldman et al. [1] or the Iacocca Institute [2]. As a response, different concepts emerged that should enable organizations to master these challenges. The most recent is the concept of agility, but others like flexibility and leanness are mentioned often, too.

A lot of research activities about agility and its related concepts have been conducted in the meantime. However, until today there exists no common understanding of what constitutes agility. Although many frameworks and models describe agility and its characteristics, they often heavily differ in content and structure. This makes it difficult for both, researcher and practitioner audiences, to build upon the insights obtained until today. On the one hand, researchers are missing a well-founded basis to develop the topic further, on the other hand, practitioners cannot easily uncover what parts of their organizations have to be changed and to what respect they have to be changed to respond to new market challenges.

This is particularly of interest for organizations in the software and information technology (IT) industry. With the appearance of agile software developing methodologies, or in a broader sense agile values and principles (see for instance [3]–[5]), in the early 2000s, the advantages of these new approaches became visible. However, it turned out to be difficult to transfer the experienced benefits beyond the team level [6]–[8]. But this step is necessary so that the whole organization can benefit from agility.

The idea for this paper arose from the attempt to select a suitable agility framework that represents the structure and components of agility in an organization for a further empirical study. Unfortunately, it turned out that due to the aforementioned problem of a lack of consensus, a selection of one framework seemed unsatisfactory. Some were unsuitable to describe the organization as a whole, others specialized on a specific aspect only. Generally, the literature was confusing and inconsistent. Therefore, it seemed necessary to get through the literature and systematically compare available frameworks. The aim of this work is to analyze the frameworks regarding common ground and differences and to search for recurring concepts. Finally, this will create a basis for further work on a common understanding of agility.

A review about agility is already given by Sherehiy et al. [9] which serves as an important starting point for this study, too. However, they mainly included work of the agile manufacturing domain, because publications about the agile organization as a whole were scarce at this time. The aim of the authors was to deduce a summarized framework describing the agile organization. Interestingly later published frameworks again differ heavily from the one developed by Sherehiy et al. That shows that their work was still not sufficient and a further investigation is necessary.

The remainder of the paper is structured as follows: In section II the concept of agility and its history are shortly described and its connections to the principles of lean and flexible are mentioned. Section III introduces the agility frameworks that are analyzed in this paper. The systematic comparison of these frameworks and the discussion of the results are given in section IV. The paper ends with a conclusion and an outlook to further research currently conducted in section V.

II. The Concept of Agility

Looking up the term agile in a dictionary delivers "having the faculty of quick motion; nimble, active, ready" [10, p. 255], whereby agility is the "quality of being agile" [10, p. 256]. Given this explanation as a basis, a huge variety of definitions emerged today, heavily influenced by context and application domain. A discussion of all available definitions is

978-83-60810-53-8/$25.00

beyond the scope of this paper. Different authors already list various definitions of agility, for instance [11], [12]. Another comprehensive collection is given in the appendix of [13].

An extensive definition, which fits well to the context of this work, was developed by Ganguly et al. [14] based on the work of Dove [15], [16]. They define agility as "an effective integration of response ability and knowledge management in order to rapidly, efficiently and accurately adapt to any unexpected (or unpredictable) change in both proactive and reactive business / customer needs and opportunities without compromising with the cost or the quality of the product / process" [14, p. 411]. The handling of change as a fundamental prerequisite for agility is confirmed by Conboy, who named creation of change, proaction in advance of change, reaction to change, and learning from change as components of agility [17].

The concept of agility is nothing new. Early works are already found within social sciences and date back to the 1950s [18]. However, agility gained significantly more attention in the 1990s, especially after the so called "Lehigh report" [2] was published explaining a new idea of manufacturing strategies. This development was accompanied by the increasing emphasis on customer orientation and proactivity instead of reactivity. Later on, mainly after the year 2000, process orientation was focused on additionally and led to an examination of agility from an organizational perspective [13]. Simultaneously, agility became well known within the software industry, whereby the "Agile Manifesto" [3] triggered a lot of research in this field.

While research about agility progresses continously, there are two other closely connected and underlying concepts: flexibility and leanness. Although both share some common ground with agility, they are not the same and should be distinguished. A detailed discussion is given in [17], which is shortly summarized here. First, flexibility is very similar to agility. The main differences of flexibility lie in issues like the lack of speed and rapid action, continual change instead of a one-off change, a missing inclusion of knowledge and learning, and the application as single practices in specific parts of the company instead of an organization-wide view. The difference of leanness, however, is much more straight forward. In contrast to agility, leanness is unsuitable to variability and uncertainty and emphasizes simple cost reduction over value-related issues, mainly value for the customer [17].

III. Agility Frameworks

A review of the literature revealed a variety of frameworks and models describing the concepts that determine agility or at least proposed different items to measure agility. Finally, 28 frameworks or similar concepts could be identified that can be categorized into four domains and will shortly be introduced in the following:

- Agile Manufacturing,
- Agile Software Development,
- Agile Organization/Agile Enterprise, and
- Agile Workforce.

A. Agility Frameworks Focusing on Agile Manufacturing

As explained in section II, the concept of agility mainly originates from the manufacturing domain. Hence, ten of the identified frameworks focus on agile manufacturing [11], [19]–[27].

One of the earlier frameworks was developed in 1999 by Sharifi & Zhang [19]. The core idea is the distinction between Agility Drivers, Agility Capabilities, and Agility Providers. Drivers are mainly changes in the environment. Capabilities like responsiveness, competency, flexibility, and speed are the the required abilities of the company to respond to these changes. Providers are the means to achieve these capabilities in the areas of organization, technology, people, and innovation [19]. This framework was refined and extended later by Sharifi et al. [20], however, the main structure remained stable. Finally, it led to a theoretical approach to develop an agile manufacturing strategy [21].

A similar structure was chosen by Vázquez-Bustelo et al. [22], by grouping the elements of their conceptual model into Agility Drivers, Agility Enablers (or Practices), and Outcomes. The core concept is the Agile Enablers, which are similar to the Capabilities mentioned above, but are further detailed into Human Resources, Value Chain Integration, Concurrent Engineering, Technologies, and Knowledge Management [22].

Two other early frameworks were developed by Gunasekaran [23] and Yusuf et al. [24], whereby both identify four major dimensions affecting the agile manufacturing system. Gunasekaran mentions Strategies, Technologies, People, and Systems [23]. Yusuf et al., however, state Core Competence Management, a Capability for Reconfiguration, a Knowledge-driven Enterprise, and the formation of Virtual Enterprises as core concepts. They furthermore detail them into 32 attributes [24]. In 2002, Gunasekaran & Yusuf published another framework of agile manufacturing strategies and techniques that implemented concepts of both predecessors [11].

The remaining three frameworks show different approaches. Meredith & Francis propose a so called "Agile Wheel" structuring agility into Strategy, Processes, Linkages, and People each with four sub-practices [25]. Agarwal et al. focus on the agile supply chain by stating four main characteristics dealing with Market, Information Integration, Process Integration, and Planning [26]. Addditionally, Kisperska-Moron & Swierczek conducted an exploratory factor analysis with Polish companies and obtained a framework built of the four factors Relation with Customers, Relation with Suppliers, Relation with Competitors, and Intensity of IT Use [27].

B. Agility Frameworks Focusing on Software Development

Research about agile software development is much younger. As described in section II, the Agile Manifesto [3] can be seen as a trigger for further studies. The 17 initiators postulate four key values of agile software development with an emphasis on individuals and interactions, working software, customer collaboration, and response to change. These values are further detailed into 12 principles [3]. Afterwards, in the years 2008 and 2009, five frameworks dealing with the topic of

agile software development were identified [28]–[32], whereby they often focus only on specific issues within the domain.

Two of the more general frameworks dealing with success factors of agile development practices are given by Chow & Cao [28] and Misra et al. [29]. Both publications show comprehensive lists of success factors grouped in different dimensions. Chow & Cao use organization, people, process, technical, and project factors [28], whereby Misra et al. only distinguish between organizational and people factors [29]. However, both narrow down these lists to six (delivery strategy, proper agile software engineering techniques, high team capabilities, good agile project management process, agile-friendly team environment, and strong customer involvement) [28] and nine (customer satisfaction, customer collaboration, customer commitment, decision time, corporate culture, control, personal characteristics, societal culture, and training and learning) [29] critical success factors via emprical investigations, respectively.

In contrast, Chan & Thong [30] ask what affects the acceptance of agile methodolgies. In this context, they build a conceptual framework where acceptance is dependent from the characteristics of the agile methodologies and knowledge management-related activities like creation, retention, and transfer of knowledge and experience. They furthermore identify three concepts affecting knowledge management: factors related to abilities, motivation, and opportunities [30].

Agility in the specific domain of distributed development teams was analyzed by Sarker & Sarker [31]. They distinguish three different dimensions of agility. First, Resource Agility that mainly consists of people and technology. Second, Process Agility that includes aspects like methodology, environmental awareness, or bridging time zones. And finally, Linkage Agility that is based on cultural and communicative issues [31].

Furthermore, Kettunen [32] did not develop a framework in a stricter sense, but compared practices of agile manufacturing to those of agile software development. For this purpose, he used a comparison matrix covering five concepts: Organization, Process, Product, Operation, and People. He concludes that issues of all manufacturing concepts are covered in different amounts by agile software development models, too [32].

C. Agility Frameworks Focusing on Agile Organization/Agile Enterprise

Research about the agile organization as a whole unit started contemporarily to research about agile manufacturing in the 90s. However, a concentration can be seen at the time the interest in agile software development grew. Additionally, the newest publications (from 2010 and 2011) of all analyzed frameworks belong to this group. This might be an indicator that it becomes more important to understand the effects of agility to the overall organization beyond single development teams or the manufacturing domain. All together, 11 frameworks were identified covering the topic of the agile organization [1], [9], [33]–[41].

One of the first and a well-known publications is the book of Goldman et al. [1]. They label agility as "A Framework for Mastering Change" and define four dimensions to stay competitive: enriching the customer, cooperating to enhance competetiveness, organizing to master change and uncertainty, and leveraging the impact of people and information [1].

Besides this, different approaches dealing with organizational agilty have been developed. A part of the literature focuses on measurement tools. Ren et al. [33], for instance, propose a measurement system utilizing the Analytical Hierarchy Process (AHP) based on the four dimensions of Goldman et al. [1], [33].

Other authors utilize fuzzy logic as a measurement tool. Tsourveloudis & Valavanis [34] name a set of parameters to measure agility by assessing the infrastructure of production, market, people, and information [34] whereas Lin et al. [35] closely connect their fuzzy logic model to the concepts of agile manufacturing with agility enablers, capabilities, and drivers (see section III-A) [35]. Later on, Tseng & Lin use this model to introduce an agility development method [36].

The use of agile manufacturing concepts can also be observed in other publications. Eshlagy et al. [37] again use the distinction in agility enablers, capabilities, and drivers in their research. They finally identified 12 factors that have an effect on organizational agility by applying path analysis. Interestingly, the most significant are leadership, organization commitment, and job satisfaction while typical manufacturing issues like supply chains and the like play a less important role [37]. In a similar way, Bottani [38] uses the framework of Yusuf et al. [24] to conduct an empirical study with the aim of analyzing what profile agile companies have and which tools they use [38].

A comprehensive work to develop a measurement scale with qualitative and quantitative studies can be found in Charbonnier-Voirin [39]. The given scale consists of four factors that can be seen as a framework for agility, too. The factors are somewhat similar to the dimensions of Goldman et al. [1]. They are named practices directed towards mastering change, practices valuing human resources, cooperative practices, and practices of value creation for customers [39].

Similar to section III-B, there also exist some publications dealing with very specific topics. Tallon & Pinsonneault investigate the impact of strategic IT alignment on agility [40]. Zelbst et al. show that the utilization of RFID technology enhances agility [41]. Both additionally identify a positive effect of agility on the performance of the firm [40], [41].

Finally, a review of concepts related to enterprise agility is given by Sherehiy et al. [9]. They reviewed a number of frameworks, models, and measurement tools of agility and extracted a list of characteristics of the agile enterprise. They distinguished into characteristics related to global strategies including customer, cooperation, organizational learning, and culture of change as well as characteristics related to organization and workforce including authority, rules and procedures, coordination, structure, human resource management, proactivity, adaptivity, and resiliency [9].

D. Agility Frameworks Focusing on Agile Workforce

Within the domain of agile workforce, only one publication could be identified [42]. However, in its content specializing on people without referring to manufacturing or software development, it forms a unique sub-domain of agility. Breu et al. identify ten key attributes of an agile workforce that are grouped into the five capabilities intelligence, competencies, collaboration, culture, and information systems [42].

IV. Systematic Comparison of Agility Frameworks

A. Procedure

To achieve a systematic comparison of the frameworks introduced in section III, the following procedure has been applied: First, the core concepts (for instance "customer," "processes," "change," etc.) of the first framework were listed. Then, the core concepts of the next frameworks were assigned to appropriate existing ones or they were added to the list, if they were new. If there were only different labels, but the the same content (for instance "people" vs. "workforce" vs. "teams" vs. "employees") these concepts were treated as one. This step was repeated for every framework. At the end, this resulted in a list of 33 concepts of agility.

As mentioned in section III, the concepts sometimes were detailed into further indicators, attributes, etc. This information was used afterwards to assess whether or not two or more concepts were linked to each other content wise. As a result, a network could be drawn showing the interdependencies between the concepts.

B. Mapping of the frameworks

Figure 1 shows the complete mapping of the analyzed frameworks to the extracted concepts of agility. The numbers on the right side show how often a concept was used over all frameworks. It becomes clear that the concepts and frameworks are very ambigious. In none of the domains is there a more or less stable structure. This indicates that despite the ongoing research, there is still no common understanding of what constitutes agility.

A few of the concepts are prevalent in every domain. Most used was the concept "Workforce/Teams." That seems obvious, because workforce plays an important role when talking about agility. Closely connected are the "Organizational Competences/Abilities," which are also often used and nearly equally distributed over all domains. In addition, two other concepts are interesting: "Cooperation" and "Technology" are among the most used concepts. However, they are both only once named within the domain of agile software development.

Figure 2 summarizes the mapping per domain. The numbers in the cells represent the number of frameworks that use the corresponding concept. Figure 2 reveals that the domain of the agile organization is the most comprehensive one by covering 30 of the 33 identified concepts. But, as mentioned in section III-C, many of the frameworks in this domain utilize structures of agile manufacturing. This is also visible by the fact that every concept of the manufacturing domain is used at least once within the domain of the agile organization. However, Eshlaghy et al. showed that pure manufacturing related concepts had the least significant effects on agility from an organizational perspective [37] (see section III-C). So, one should ask, if it is useful to simply transfer the concepts of agile manufacturing to the agile organization.

Another interesting fact lies in the domain of the agile workforce. Of course, the number of concepts is the lowest, because only one framework was identified. However, two concepts, namely "Intelligence" and "Collaboration," are only present in this domain. This is surprising, because it could be assumed that these workforce-related concepts are important in every domain.

At this point it becomes clear that the inherent ambiguity makes it difficult to compare the frameworks in more detail. Of course, concepts that occur only once may also be covered by differently named concepts. For instance, "Adaptivity," "Resiliency," "Collaboration," or "Intelligence" may also be covered by "Organizational Culture" or others. Also the fact that for instance "Workforce/Teams" is not used in every framework may be an indicator that it is also covered by other concepts. Hence, as described in section IV-A, the links between the concepts are analyzed further.

C. Interdependencies of agility concepts

After looking into the details of every concept, it was possible to determine connections between them. Some are on higher abstraction levels, so that they include others. In other situations, two concepts overlap in some parts (for instance "Customer" and "Market," or "Education" and "Intelligence"). Yet, they could not be merged, because both also covered unique content. Generally spoken, a connection between two concepts means that they are linked to each other content wise, but without a further semantic specification. After identification of every connection, a network was drawn visualizing the interdependencies. This network was created with the open-source tool Gephi [43] using the layout algorithm ForceAtlas 2 with the concepts as nodes and the connections between them as unweighted edges. The resulting graph is given in figure 3.

The first noticeable issue is the high number of linkages between the single concepts. This again underlines the fact that a common understanding of agility is missing. However, by arranging the network with the layout algorithm mentioned above, some "clusters" that have connections to a lot of other concepts become visible. These are illustrated as colored ellipses in figure 3 and are namely:

- Organizational Culture,
- Workforce,
- Customer,
- Organizational Abilities, and
- Technology.

Comparing the analyzed frameworks with this new structure, it turns out that only seven cover concepts of all five clusters [20], [21], [24], [33], [35], [37], [38]. These seven frameworks are out of the domains of agile manufacturing or the agile organization. In contrast, nine frameworks only cover concepts from three out of the five clusters: four frameworks in the

Focus Agile Manufacturing | Focus Agile Organization / Enterprise | Focus Agile Software Development | Focus Agile Workforce

Fig. 1. Mapping of agility frameworks and agility concepts

domain of agile manufacturing [19], [23], [26], [27], two in the domain of agile software development [28], [32], and three in the domain of the agile organization [36], [39], [40].

There are also differences between which clusters are missing within the frameworks. The cluster that is covered by most frameworks is "Customer." Only three frameworks are missing any concept of this cluster. Five respectively six frameworks do not cover concepts of the clusters "Organizational Abilities" and "Workforce." The remaining two clusters are missing most within the frameworks. Eight do not share concepts of "Organizational Culture" and even ten neglect "Technology."

Interestingly, all but one framework of agile software development are missing the latter one. The only one covering the technology aspect is [31]. The reason may be that in agile software development technologies and systems are basic prerequisites and therefore not seen as factors affecting agility. Also the gaps in "Organizational Abilities" are prevalent in frameworks of the software development domain [28], [31], [32]. There are studies reporting a lot of problems when adopting agile methods beyond the development team (see, for instance, [6]–[8]). The gaps in the analyzed frameworks regarding organizational abilities may be a cause of these problems.

A similar accumulation of gaps can be observed for the cluster "Organizational Culture." Four frameworks within agile manufacturing do not cover concepts of this cluster [11], [20],

	Agile Manufacturing	Agile Workforce	Agile Software Development	Agile Enterprise / Organization

Fig. 2. Number of frameworks regarding agility concepts

[26], [27]. Surprisingly, the other four frameworks missing any concept of organizational culture are to be found in the domain of the agile organization [34], [36], [39], [40]. However, these frameworks cover many more concepts of the clusters "Workforce" and "Organizational Abilities."

Besides, another issue draws attention. The two concepts "Processes" and "Change" have a very central position with many connections to other concepts, but it is difficult to identify new clusters around them. Change itself is often named as one of the key drivers of agility. Processes are an important internal element of every organization. Without changing processes, it will not be possible to change the way of work. Hence, their central position may be an indicator that many authors consider it relevant within other concepts. However, this issue has to be examined in more detail in future studies.

V. Conclusion and Outlook

This study identified and systematically compared 28 frameworks of agility. These covered the domains of agile manufacturing, agile software development, agile organization, and agile workforce. As the observations in section IV clearly reveal, it is difficult to draw a sharp line between the five identified clusters. Furthermore, there is absolutely no consensus of what really constitutes the construct of agility. The analyzed frameworks are very different regarding their structure and content. Even within the specific domains of agility, the frameworks vary a lot.

This has significant implications for research. Due to the lack of consensus, it is difficult to conduct empirical studies or to build upon existing frameworks. When researchers have to decide between one or another of the available frameworks as the basis for their research, they will most likely miss some concepts of agility, as shown in section IV-C.

Hence, this study may serve as a good starting point to choose one of the frameworks, because it will give the reader an overview of the covered concepts of every framework. It sharpens awareness that the frameworks have gaps and gives the reader the opportunity to close these gaps with parts of other suitable agility frameworks. However, to date there is no empirical study that delivered a comprehensive picture of agility in an exploratory way. So it remains unclear, which concepts of the frameworks are prevalent in practice and how the factors behind agility are composed.

Of course, some of the analyzed publications included exploratory studies, but they all show some limitations. Examples are the works of Kisperska-Moron & Swierczek [27] and Charbonnier-Voirin [39] that both also conducted exploratory factor anaysis. However, both are missing some important concepts (see section IV-C). Apart from that, other authors conducted empirical studies, too, but only used a specific framework that, again, does not cover all identified agility concepts. For example, Bottani [38], who used the framework of Yusuf et al. [24], or Zhang & Sharifi [21], who used their own developed framework [19]–[21].

Due to this limitation, the author of this paper currently is conducting an empirical study about the question of what constitutes an agile enterprise at an organizational level. Hence, the identified agility concepts were merged into a questionnaire with 68 items. The final aim is to conduct a factor analysis to uncover the structure that lies behind the construct of agility. The currently focused target group are both general and IT-related decision makers in companies of the software and IT-service industry. In contrast to the aforementioned studies, it contains all of the concepts given in figure 1. Therefore, it will deliver a comprehensive and, to date, not available view on agility. According to Conboy, who states that "the search for a definitive, all-encompassing concept of agility might not be found simply through an examination of

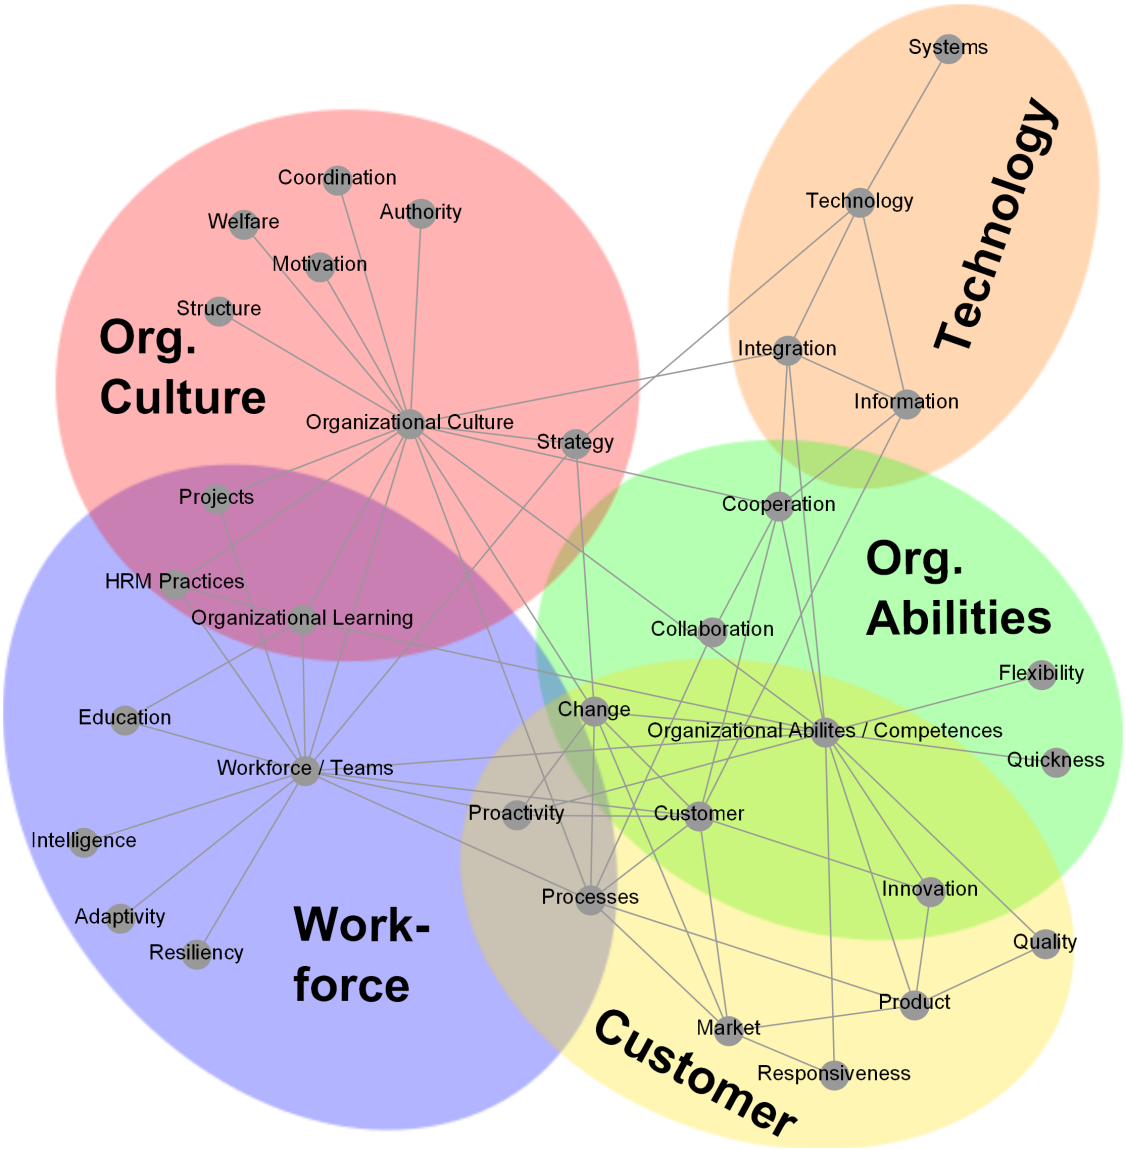

Fig. 3. Interdependencies of agility concepts

agility in other fields" [17, p. 334], this ongoing research will ideally solve the contradictions identified within this paper and contribute to an increasing consensus of what constitutes agility.

***Abstract*—This paper focuses on measurement of information society in Poland. The aim of this paper is twofold. The first objective is to present a coherent picture of measurement methods for information society. The second aim of the paper is to show measurement findings of information society in Poland. Firstly, the paper presents available methods of information society measurement and a core set of internationally agreed information society indicators. Secondly, the measurement of information society in Poland has been performed with the application of two methods – measuring the influence of ICT on GDP and measuring ICT Development Index. Finally, a discussion has been undertaken in order to establish a framework for development of information society quantitative measurement methods in Poland.**

I. Introduction

INCREASING role of information, knowledge, information and communication technology (ICT) determines the complexity and variability of a social system and its sub-systems, and especially the economic one. Transitions of these systems have been reflected in many research concepts. According to the assumptions being put forward, the basic factors of socio-economic development are information and its derivative – knowledge.

The pioneering work in this field was undertaken by Bell who first used the term postindustrial society in Salzburg in 1959. By its means he denominated a society which transitioned from the stage of foods production to the stage of service society [1]. These studies were further developed by Bell in the direction of identifying the position of knowledge in social development [2]. The concepts of knowledge economy, knowledge industry, types of entities managing knowledge and types of knowledge were introduced to economic research by Machlup [3]. In parallel, e.g. at the beginning of 1960s the term information society came out in the Japanese social science [4]. At the end of the 1970s Drucker stressed the significance of transition to the so-called post-capitalist society, based on knowledge and knowledge economy [5]. He developed this idea in his further work by introducing the notion of knowledge economics [6]. On the basis of Bell's, Machlup's and Drucker's approaches Porat stemmed his research devoted to the information economy and information industry [7]. In the 1980s Toffler presented the idea of "the third wave" – post-industrial civilization where the basic resources are: information and ICT [8]. The informational manner of development of contemporary capitalist societies (network societies) based on ICT expansion, which creates the ground for a complete change of conditions and style of social life was studied by Castells [9], [10], [11]. Issues concerning information society and knowledge based society have become widely discussed in publications in Poland [12], [13], [14], [15], [16], [17], [18], [19], [20]. Economies and societies using information and knowledge, to extend unprecedented ever before, are denominated in various ways e.g. as based on knowledge, digital, post-industrial, new or information.

The researchers face many cognitive and empirical challenges referring to information society (IS). The cognitive challenges refer to terminology describing information society, identification of phenomena, processes and success factors of this society and also the methodology of information society measurement. The empirical challenges are mainly connected with building information society and its measurement. Research of this scope is conducted in the academic environment [20], [21], as well as among practitioners [22].

The measurement is an important issue in the debate about the information society and the role it plays in economic and social development [21], [20], [23], especially in transition and emerging economies. This paper focuses on measurement of information society in Poland. The aim of this paper is twofold. The first objective is to present a coherent picture of measurement methods for information society. The second aim of the paper is to show measurement findings of information society in Poland.

To achieve those aims, the paper takes the following structure. Firstly, the paper presents available methods of information society measurement and a core set of internationally agreed information society indicators. Secondly, the measurement of information society in Poland has been performed with the application of two methods – measuring the influence of ICT on GDP and measuring ICT Development Index. Finally, a discussion has been undertaken in order to establish a framework for development of information society quantitative measurement methods in Poland.

Hopefully, the achieved research findings can become useful in diagnosing information society, planning for information society undertakings as well as monitoring and evaluating the conducted undertakings.

II. Research Methodology

The primary objectives of the research required commencing work of theoretical and empirical characteristics. Various research methods were applied here. In order to present the methods of information society measurement, a critical analysis of foreign and Polish subject literature has been carried out as well as reports prepared by international organizations. The Internet statistical databases were explored at the 72 industry level for all non growth accounting variables, i.e. EU KLEMS [24]. Additionally, data from the International Telecommunication Union and European Statistical Office (Eurostat) were used for the measurement of the information society in Poland. The calculations, figures and tables were prepared in the Microsoft Excel program.

III. Theoretical Background – Information Society As Measurement Subject

To date there has not been in operation a commonly accepted definition of information society [2], [8], [4], [25], [14], [26], [18]. Lack of consensus with regard to the definition of information society is undoubtedly a derivative of complexity of processes taking place in a social system, characteristics of information as a resource, and the dynamics of ICT changes. This brings specific consequences for the undertaken attempts for measuring phenomena within the frame of a category, which might be and is understood in various ways.

Nonetheless, despite the conceptual limitations there are attempts taken to describe the information society quantitatively. These ideas were presented in the following sources:

- scientific monographies and papers, i.a. Machlup [3], Porat [7], Timmer, Inklaar, O'Mahony, van Ark [27], Dziuba [28], Goliński [20], Oleński [29], Batorski [30], Żelazny [21];
- reports and studies prepared by international organizations, i.a. International Telecommunication Union – ITU [31], [32], Organisation for Economic Cooperation and Development – OECD [33], United Nations – UN [34], European Union – EU [35], [36], World Bank [37], World Information Technology and Services Alliance – WITSA [38];
- reports of commercial organizations, i.a. World Economic Forum – WEF [39], International Data Corporation – IDC [40], Economist Intelligence Unit – EIU [41]; and
- monographies of national and trans-national services of public statistics and authorities, i.a. Central Statistical Office – GUS [42], Statistical Office of the European Union – Eurostat [43], Office of Electronic Communication – UKE [44], Ministry of Administration and Digitization of Poland – MAC [45], [46].

Generally speaking there are two approaches to the quantitative description of information society. The first one comprises the preparation of the list of indicators characterizing information society. The other is connected with compiling the so-called composite indexes which are aggregate measures. It should be stressed that the composite index is based on the previously chosen set of indicators. Some significant constraints can be pinpointed in both approaches. The arbitrariness of the choice of indicators, disorderliness of gathering source data, lack of standardization and time-space comparability, substantive errors in assigning indicators to specified information society dimensions and errors in constructing a given index – those are some of the significant drawbacks and constraints.

The above mentioned constraints gave rise to taking efforts on the international scale to institutionalize the methodology of information society quantification. Work in this field was commenced by OECD. In 1997 the OECD established the Working Party on Indicators for the Information Society, which main objective was development of index-based description of information society. One of its major achievements was identifying ICT sector. In 1998 an ICT sector definition was provided basing on the so-called International Standard Industry Classification (ISIC Rev. 3), according to which [33]:

- for manufacturing industries, (1) the products must be intended to fulfill the function of information processing and communication including transmission and display, and (2) the products must be use electronic processing to detect, measure and/or record physical phenomena or control a physical process; and
- for services industries, the products must be intended to enable the function of information processing and communication by electronic means.

Taking into account the above approach, the following were regarded as ICT industries: manufacture of office, accounting and computing machinery (3000), manufacture of insulated wire and cable (3130), manufacture of electronic valves and tubes and other electronic components (3210), manufacture of television and radio transmitters and apparatus for line telephony and line telegraphy (3220), manufacture of television and radio receivers, sound or video recording or reproducing apparatus, and associated goods (3230), manufacture of instruments and appliances for measuring, checking, testing, navigating and other purposes, industrial process control equipment (3312 – 3313), wholesale of machinery, equipment and supplies (5150), renting of office machinery and equipment (including computers) (7123), telecommunications (6420) as well as computer and related activities (7200). The OECD's activity-based definition of ICT was slightly reviewed in 2002 (ISIC Rev. 3.1). The entry 5150 was replaced then by its components i.e.: wholesale of computers, computer peripheral equipment and software (5151), wholesale of electronic and telecommunications parts and equipment (5152).

One important feature of the ICT sector definition by OECD is that it breaks the traditional ISIC dichotomy between manufacturing and services activities. Activities producing or distributing ICT products can be found everywhere in the economy. Moreover, by identifying the key sectors whose main activity is producing or distributing ICT products, this definition constitutes a first order approxima-

tion of the "ICT producing sector". Hence, ICT producing sector means both ICT manufacturing industries (items: 3000, 3130, 3210, 3220, 3230, 3312, 3313) and ICT services industries (items: 5151, 5152, 7123, 6420, 7200) [33].

The following modifications of definitions of ICT sector resulted from the review of ISIC rev. 4 and ended in 2007. The presented above definition of ICT sector was narrowed in the part referring to manufacturing industries accounting only for activity and products which fulfill the function of information processing and communication including transmission and display [23], [47]. The present complete set of ICT sector is shown in [23].

An identical view of ICT sector can be found in the statistical classification of business activities in the European Union – Nomenclature statistique des Activités économiques dans la Communauté Européenne (NACE rev. 2), being in force from January 2008. To the ICT sector were included the following types of business activities: 261, 262, 263, 264, 268 (ICT manufacturing) and 465, 582, 61, 62, 631, 951 (ICT services) [48].

Another milestone in the development of information society statistics, after defining ICT sector, was the establishment of the Partnership on Measuring ICT for Development [49]. The participants of this forum became the following organizations and their agencies: ITU, OECD, Eurostat, United Nations Conference on Trade and Development (UNCTAD), UNESCO Institute for Statistics (UIS), World Bank, United Nations Department of Economic and Social Affairs (UNDESA), United Nations Economic Commission for Africa (ECA), United Nations Economic Commission for Latin America and the Caribbean (ECLAC), United Nations Economic and Social Commission for Asia and the Pacific (ESCAP), United Nations Economic and Social Commission for Western Asia (ESCWA), and United Nations Environment Programme/Secretariat of the Basel Convention (UNEP/SBC). As a result of the activities taken up by the Partnership on Measuring ICT for Development, a core list of ICT indicators was developed. The core list of ICT indicators is composed of over 50 indicators in the following areas:

- ICT infrastructure and access (A – 10 indicators);
- ICT access and use by households and individuals (HH – 12 indicators);
- ICT access and use by enterprises (B – 12 indicators);
- ICT sector and trade in ICT goods (ICT – 4 indicators);
- ICT in education (ED – 8 indicators); and
- ICT in government (EG – 7 indicators).

The list, which is revised regularly (the last time in 2012), was identified to help guide countries in measuring the information society. The full list of basic ICT indicators is available in [50].

The above indicators endorsed by the UN Statistical Commission are recommended as a measurement standard of information society on the international scale. As it has already been indicated, this set is a subject to supplementation and modification in response to the dynamic processes occurring in the economic and social environment. Such a consensual composition of a common set of indicators by major international institutions should be evaluated positively. A divergent issue stays the scope of implementation of this proposal in the statistical practice of the states, especially developing ones.

Indicatory description of the information society can be found in works of many organizations, both the members of the Partnership on Measuring ICT for Development, e.g. Eurostat, ITU, OECD or World Bank, and those remaining outside (WEF, IDC, EIU). These organizations collect and publish statistical data monitoring information society in various dimensions. Hence their proposals of composite indexes are an important element of their activities. As Goliński [20] argues the increasing popularity of composite indexes is connected with, among the others:

- ease of their interpretation and creation of prices on their basis;
- media attractiveness of composite indexes in relation to the necessity of conducting complex analyses based on single indicators;
- ICT development expediting the acquisition of statistical data, their processing and presentation; and
- demand for attractive tools expediting the evaluation of new socio-economic challenges.

Currently the most popular composite indexes measuring the information society are – ICT Development Index (IDI) of the authorship of the International Telecommunication Union and Networked Readiness Index (NRI) of the authorship of the World Economic Forum.

Considering the significance of works undertaken by the world oldest international organization – ITU on research and measurement of IS, and its active membership in the Partnership on Measuring ICT for Development, the further analysis was conducted on IDI. ITU experience in works on information society measurement was taken into account in the methodology for compiling this indicator. The theoretical framework for this indicator was based on the three-stage model for information society development, i.e. readiness, intensity and impact [31], [23]. The first stage – readiness – reflects the level of networked infrastructure and access to ICT. The second stage – intensity – reflects the level of use of ICTs in the society. The third stage – impact – reflects the result of efficient and effective ICT use. Therefore, the construction of IDI is based on three sub-indexes – access sub-index, use sub-index and skills sub-index. Relevant statistical dependence is presented in Table I.

The IDI was computed applying the following steps – preparation of the complete data set, normalization of data, rescaling of data and weighting of indicators and sub-indices. The IDI is currently calculated for 155 countries.

IV. Research findings – measurement of information society in Poland

A. Share of ICT producing sector in GDP in Poland

Evaluating the share of ICT sector in GDP the most current available data were used from Eurostat referring to 2009 [52], and the database of EU KLEMS [24] referring to the period of 1995-2006.

The value added at factor cost in the ICT sector as percentage of total value added at factor cost of the selected EU countries in 2009 is presented in Figure 1. The value added at factor cost is defined as gross value added (at basic prices) minus other taxes less other subsidies on production.

The lowest share of ICT in GDP (3.15%) was found in Poland among the researched countries (Figure 2). In the group of the Central and East European countries the best result was achieved by Hungary (5.93%). An interesting fact is that in the majority of the countries there was a drop in the share of ICT in GDP in the period of 2000-2009. The increase was only noted in case of Hungary (from 5.91% in 2000 to 5.93% in 2009) and in Bulgaria – from 4.63% in 2000 to 5.36% in 2008. A significant decrease took place in Finland – from 10.16% to 5.31%. [52]

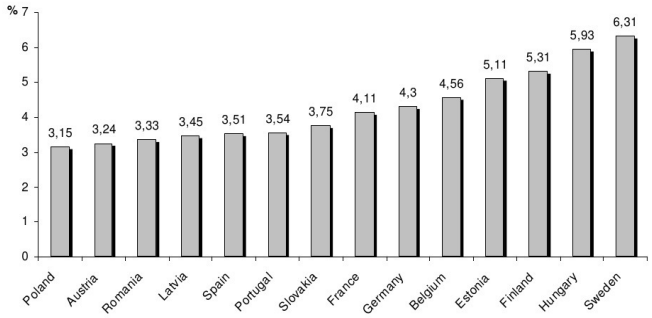

Fig. 1. Percentage of the ICT sector on GDP in selected EU countries with available data in 2009
Source: own study based on Eurostat data [48]

Accounting for the components of the ICT sector i.e. manufacturing industries and service industries, the major

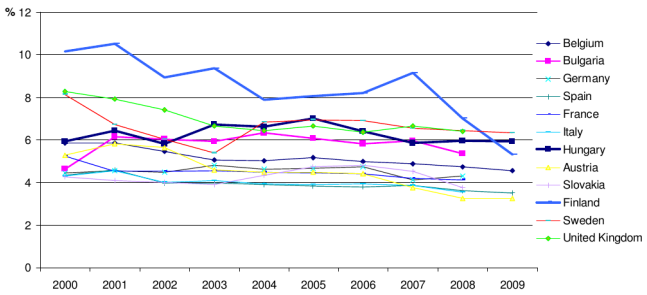

Fig. 2. Percentage of the ICT sector on GDP in selected EU countries with available data in 2000-2009
Source: own study based on Eurostat data [48]

role of business activities based on services needs to be emphasized in all countries. The only exception was Finland in the period of 2000-2007, when the share of ICT manufacturing industries in GDP was higher than the share of ICT service industries. In the Eurostat database there is a lack of data referring to the share of ICT manufacturing industries, as well as ICT service industries in Poland's GDP. In Poland the presented share of ICT sector in GDP at the level of 3.15% in Figure 1 took place in 2009 and was composed respectively of 0.35% manufacturing industries and 2.8% service industries. The share of net ICT sector revenues from sales in the total net sector revenues from sales was about 4.8% in 2009, 5.3% in 2010 and 5.1% in 2011 in Poland [42].

Manufacturing goods and providing ICT services directly influence the increase of the value added generated in the economy. The ICT influence on economic growth is calculated as a product of a nominal ICT producing sector share in GDP and a real output growth and provision of services by this sector. In order to estimate the ICT producing sector share in GDP one should: (1) select the period for an analysis, (2) on the basis of a chosen classification (in this paper ISIC Rev. 3) estimate the share of ICT producing sector in GDP, and (3) calculate the product of ICT producing sector share in GDP and the real growth rate of ICT producing sector. The result of using this algorithm is the value of ICT producing sector share in the GDP growth rate in percentage

TABLE I.
ICT DEVELOPMENT INDEX (IDI) – SUB-INDEXES, INDICATORS AND WEIGHTS

Sub-index	Weights (sub-indexes)	Indicators	Weights (indicators)	Reference value
ICT access	40%	Fixed-telephone lines per 100 inhabitants	20%	60
		Mobile-cellular telephone subscriptions per 100 inhabitants	20%	180
		International Internet bandwidth (bit/s) per Internet user	20%	408'813
		Percentage of households with a computer	20%	100
		Percentage of households with Internet access	20%	100
ICT use	40%	Percentage of individuals using the Internet	30%	100
		Fixed (wired)-broadband Internet subscriptions per 100 inhabitants	30%	60
		Active mobile-broadband subscriptions per 100 inhabitants	30%	100
ICT skills	20%	Adult literacy rate	30%	100
		Secondary gross enrolment ratio	30%	100
		Tertiary gross enrolment ratio	30%	100

Source: [31].

points. A suitable data and original calculations in this respect are presented in Table II.

B. ICT Development Index in Poland

As it has been mentioned earlier, the ICT Development Index (IDI) is very often used in order to measure the information society. The values of ICT Development Index, sub-indexes and individual indicators for the years 2011 and 2010 are presented in Table III.

C. Discussion of research findings

The measurement of information society in Poland has been conducted by applying two diagnostics approaches. The influence of ICT sector on GDP has been measured and the composite index – IDI has been presented.

The performed calculations and statistical data analysis proved a small share of ICT sector in Poland's GDP. The average share of ICT producing sector in GDP in the period of 1995–2006 in Poland constituted only about 17% of the total GDP growth rate, i.e. 0.62% out of 3.7%. The percentage of ICT producing sector value added (ICT manufacturing industries and ICT services industries) in GDP in the period of 1995-2006 equaled in real value 4.17% average. The ICT services industries decidedly dominated over the ICT manufacturing industries – the annual average in the period of 1995-2006 was at 2.9% and 1.3%. In 2009 it was respectively 2.8% and 0.35% with the total share of 3.15%. It proves a relatively weaker position of Poland in producing ICT (like hardware) in comparison to other countries. At the same time, significant difficulties were identified in getting to current data allowing for making appropriate calculations and international comparisons. Generally speaking, the attempts to study the ICT sector in Poland (even though they embrace the business entities with workforce over 10 persons) by the Central Statistical Office should be evaluated positively [42]. The access to data with regard to the number of enterprises and employees of the ICT sector, the size and structure of net revenues from sales, labor efficiency, operating costs of ICT sector, profitability of sales or import and export of ICT goods are essential, all the same it should be complemented by the measurement of this sector influence channels over economic growth, also at the regional level.

Taking into account the IDI in 2011, Poland occupied the 31st position out of 155 studied countries. With the value of the IDI equals 6.19 it took the 21st position among the studied European countries, and 17th among the EU countries. The theoretical maximum value of the indicator can amount to 10. In comparison to 2010 the result improved by 0.1, however in the global ranking Poland fell by one position. It is the result of faster development of the countries close to Poland with regard to information society development. South Korea opens the ranking with the IDI value equals 8.56, on the second position is ranked Sweden (8.34), and the third Denmark (8.29). Assuming for the particular sub-indexes (the maximum possible result–10), Poland achieved the best result in the field of skills, next access and in order – use. According to this method, the level of IS development in Poland, taking into account the group of developed countries, is moderate.

V. CONCLUSIONS AND FUTURE WORKS

This research can be useful for researchers and practitioners who are interested in measuring information society. It suggests important issues for measuring information society. The replication of this study in emerging and developing countries will be useful to improve their knowledge related to information society, its measurement and its monitoring.

Both diagnostic approaches to the information society measurement have benefits and drawbacks. Manufacturing goods and providing ICT services directly increase the value added generated by an economy. However, the calculation of ICT service industries and ICT manufacturing industries share in GDP is mainly based on hardly accessible historical data on the international scale. Apart from that there is the necessity of accounting for the qualitative dynamic changes and using deflators allowing for these changes. Their use allows for calculating prices proportionate to the changes in ICT products and services quality. The ICT producing sectors identification by itself and on the regular basis accounting for changes in the methodology of calculations are the steps in the right direction, heading to diligent measurement of information society. They allow for conducting comprehensive estimates of the values of the sector in particular countries and conducting trans-national comparisons.

Despite the advantage of IDI over other proposed composite indexes (e.g. NRI) with respect to methodological correctness it cannot be used for the complex evaluation of information society in a given country. It is worth to notice that in the construction of IDI just few indicators from the core list of ICT indicators were used. The compatibility of some indicators to the description of IDI sub-index seems to be disputable, e.g. the percentage of households with a computer indicator to the ICT access characteristics, or the adult literacy rate indicator to the ICT skills. The weighting of selected sub-indexes for the IDI calculation also pose some doubts. Lower weighting for ICT skills is explained by the adoption of proxy indicators with regard to the absence of more targeted indicators, such as ICT literacy. Taking into account the methodology applied to the Principal Components Analysis (PCA) such an approach seems to be controversial [32].

The methodology of information society measurement showed in this research should be explored in greater depth. In the opinion of this paper authors', in works on the measurement of information society, the critical success factors for implementing information society in a given country or region should be accounted for. For every identified factor, an indicator or indicators should be pointed which will allow for its quantitative description. Surely, such an approach will provide for reflecting on current issues of information society implementation. Simultaneously, it may turn out to be helpful in modification of the existing methods of the information society measurement. Such research is conducted by the authors.

***Abstract*–The development of information management systems stimulates the search for new forms of supporting business processes which take place in the organization. One of the solutions that can be applied here is software agents that enable support activities to the employee and the customer promoting information and knowledge about the organization. Such solutions are commercially available for several years in the form of interface agents, but there is insufficient research on the modeling, the applications and the impact on the organization and its environment. The purpose of this paper is to present theoretical research in this area regarding companies providing such solutions on Polish territory.**

I. Introduction

THE development of information management systems stimulates the search for new forms of supporting business processes. In addition to the systems aimed at processing and distribution of data and information, organizations are increasingly looking for solutions that support the processing of the knowledge held by their staff and its environment.

Recent research in this area indicates that such solutions should be built in the current concept of WEB 3.0, based on methods of semantic knowledge representation [10] and support the various stages of the business process. One of such solutions may be software agents. Knowledge driven multiagent systems are one of the current trends in the development of software agent technologies [1].

The primary goal of this scientific research is the creation of new trends in the development of the concept of society of software agents in terms of ubiquitous communication for the purpose of supporting and improving business processes in knowledge-based organizations involving semantic solutions.

Such solutions can support the process of disseminating information and knowledge about the organization, contributing to the improvement of processes occurring in them by improving customer satisfaction and affecting him, not only during the implementation of the business process such as sales, but can strengthen ties with customers by presenting information and transferring intra-organizational knowledge also not related to the process. These solutions, built on elements of artificial intelligence, need to equip them with adequately prepared and codified knowledge, which allows the user to communicate with the system.

The structure of the knowledge of the system and its features goes beyond the existing expert systems and other information systems which means that, in the case of its construction, it is necessary to search for new methods of their modeling and implementation.

One aspect of the research conducted by the authors was to demonstrate the approach of Polish companies regarding the construction of such solutions. For this purpose, a series of interviews with organizations based on the knowledge, that are dealing with programming agents during performing their everyday operations, had been conducted. This study consists of a diagnosis of key areas of application software agents in knowledge-based organizations. As an introduction to this research, organizations were divided into two groups: manufacturers or distributors and users of the software. At the same time the assumption was made that the manufacturers may also be the users, using this type of solution in the course of their business. The first stage of the qualitative research was the analysis of areas in which organizations creating or distributing this type of solutions support business processes and the problems faced by such organizations in the process of doing so. At the moment, we have conducted structured interviews with five larger manufacturers of this type of solutions in Poland. Some companies did not agree for an interview.

Interviews with representatives of those organizations were supposed to help in answering the following questions:

- To what extent software agents society can find its application in knowledge-based organizations?
- In what areas software agents society can support the business processes?
- What factors influence the limited applicability of the concept of software agents society?
- How is it possible to use intra-organizational knowledge in the process of achieving the objectives of software agents society?
- How to augment the organization's knowledge resources with the participation of agent technologies?

978-83-60810-53-8/$25.00

In the first part of the article the basic typologies of agent systems will be shown in the context of their intra-organizational use. The second part will present partial results of research on the issue of modeling agent solutions in the context of companies implementing such software in organizations that observe the need for computer support for the process of identification, codification, distribution and dissemination of knowledge in the area of business process execution.

II. Agent Technologies in organizations

Due to the characteristics of agents, i.e. autonomy, ability to recognize the context, pro activity and reactivity, and the ability to communicate and interact, the agents are mainly used in tasks that require distributed processing and exchange of information. The most frequently mentioned examples of agent-based approaches may include supporting the circulation of electronic documents, distributed problem solving, e-business and the use of agents on the Internet. However, they are not sufficient, as shown by the current study conducted by the authors, regarding application of software agents in knowledge-based organizations [6].

It is difficult to discern a consensus about definitions and a similar position among researchers and authors of various works. In terms of the life cycle of knowledge management systems, the approach presented here refers to the stage of dissemination and promotion of intra-organizational knowledge. One of the most interesting classification of agent systems applications are shown by Paprzycki in his work [5]. Referring to the use of software agents, he proposes the division of a sphere of existing applications of agents into three classes.

The first group includes the use of agents playing a role of components of distributed systems, in particular, those which are associated with Internet use. In this group, one can specify searching agents which mission is to find a well-defined information based on a specific sequence of keywords, or on the basis of questions posed in natural language.

The second group of agents mentioned in this scheme is used as a tool for modeling complex systems. Agents are seen as mechanisms that allow for mapping and modeling of real world phenomena. In particular, in this group business process modeling should be distinguished.

The third group are agents used to manage and personalize information supporting the user by means of, for example, animated characters. Now, thanks to continuous development of IT tools using this kind of technology becoming increasingly common, especially in systems using sites or web portals, which have become the natural environment of operation for interface agents or chatter bots. Agents are often inspired by their living counterparts. The animation uses movie clips and images of people who become a prototype of the agent. This type of user agents support services such as banking, corporate web pages, and wide range of online shops. Typically, they are built on the basis of aiml language i.e. [7].

This type of agent-based solutions can be divided into the following groups [2]:

Purchase agents (shopping agents) represent particular interests of customers by searching for the best offer for the customer and facilitating the process of making a purchase in the online store. Agents in this role shall make, on the client's behalf, a selection of a commercial information available via the Internet. Often it is possible to use them to formulate orders and finalization of commercial transaction without direct user intervention.

Selling agents represent the interests of the sellers and are used to streamline the sales process. Frequently such agents are supported by animated characters which role is to ensure the communication with customers in a natural language or close to natural. Agents participate in the whole business transaction, or in some stages. It is possible to conduct negotiations between purchase agents and selling agents. Selling agents have the ability to tailor their offerings to the needs posed by potential customers – the diagnosis takes place through dialogue with the customer, or personalized user profiles.

Marketing agents gather, through dialogue or searching the web, all available customer information and analyze it using statistical and econometric methods to optimize and allow preparing marketing campaigns targeting specific customers. Also they are used to adjust a supply to the strategy and the expectations of the market.

Virtual assistants support the user in the search for a specific item, or while visiting a particular site. Agents of this type can: represent the company by answering questions asked by clients, give visitors advise about how to navigate through the website, or help with the choice of a particular product. Agents have mechanisms which help them in searching for information/messages useful for the customer. Assistants support the promotion of new products as well. Software agents should support natural language processing and generate explanations for customers [8].

Specified typologies, related to the perception of agents in the context of the solutions that are part of information systems, can be extended on the basis of the research on agent-based support for knowledge-based organizations and are the easiest type of solutions in the context of building software agents society [10].

The classifications discussed here are related to modeling software agents and indicate that we should consider them in terms of solutions supporting and perfecting processes within the organization. These solutions allow the distribution of codified intra-organizational knowledge in the course of and besides the implemented business processes. They are able to become not only a part of the information system, but also a knowledge management system.

As indicated by L. Dignum and V. Abecker [4], from the point of view of the organization, there is an inherent dichotomy between the goals of the business processes and the objectives of knowledge management processes – employees always try in the first place to achieve business goals,

because they are to be held accountable for its execution. Taking care of organizational knowledge, or adding to the common pool of knowledge, its organization or even browsing is perceived as the goal of much less importance then effective performance of business-related tasks. Therefore, for effective implementation of knowledge management it is necessary to emphasize its importance for achieving the business objectives of the organization.

Knowledge management addresses issues that change over time – all of the elements of an organization, affecting the knowledge management system, is a subject to change [4]. Therefore, it is difficult to design and implement a system that is at the same time generic, equally useful for all departments and members of the organization and will be evolving without losing its usefulness. Another disadvantage is the fact that very rare knowledge management system is being implemented at one time across the whole organization – in majority of cases an incremental approach is used, when system is at first implemented within a single department, and then made available to the others.

Taking into account these assumptions about requirements and challenges for the design of modern knowledge management systems it must be noted that such systems should have a built-in ability to adapt to a changing environment. At the same time, these changes can affect both IT infrastructure – especially considering the trends associated with the growing use of mobile devices for accessing the shared resources of knowledge, as well as the changing needs of users whose demand for knowledge continues to grow along with the participation of knowledge in the creation of value added. This trend, involving the use of mobile devices also affects a second important aspect related to the design of modern knowledge management systems. It is the growing importance of the social nature of knowledge which in recent years has been becoming increasingly important, mainly due to the prevalence of social media [3].

Considering the increasing demand for the interaction between humans results in an increased interest on the role of information systems, including knowledge management systems, in building relationships. On the other hand, global competition and the increasing rate of information processing necessitates the development efforts related to the enrichment of knowledge management systems by adding user context, what is supposed to result in their personalization – see the above-mentioned demand for knowledge management systems adaptation to the specific needs of users, related to their organizational roles. Always present is also a need for systems that will not only provide adequate information, to the right people at the right time, but also will work proactively towards enhancing audience's creativity. The development trends of ubiquitous processing and geolocation indicate the need for the study on the integration of knowledge management systems into the human's environment, so that they become an integral and, from the point of view of the user, invisible part.

As pointed out, an interesting and increasingly wide spreading use of software agents is supporting activities related to the overall communication with the customer. Software agents, in the form of virtual advisors, appear on the websites of companies, taking on the role of a seller who is able to enter into dialogue with the customer, assess and identify customer needs and propose the solution in form of a particular product. Of course, the virtual advisor is also able to properly advertise the product. Similarly, though in a slightly different fragment of marketing communications, agents providing after-sales service work. Their job is to answer customer questions related either to the product or service and receiving complaints and / or propose a solution to the problem. As a result these solutions are used not only to provide knowledge regarding business processes during their execution, but they can help users who are looking for answers to questions that go beyond the core business of the organization. Thus, in terms of the construction of modern knowledge management systems, software agents can be a coherent part of such systems, supporting the different stages of its life cycle and actively supporting the knowledge-based organizations.

The issues related to the software agents usage indicate that modeling software agents society is not a trivial task and requires reference not only to the knowledge about the architecture of information systems, but also to the model of knowledge for such system. This knowledge model will not only serve as a knowledge structure for an agent, but will provide links to the knowledge embedded into other information systems of an organization, which is of great importance especially in the context of building heterogeneous software agents society [10].

III. The Outcomes of the Research So Far

The advancement in the concept of software agents society and a variety of approaches to its architecture and methods of construction, caused that the research has been focused on providing the theoretical framework for building the multiagent solutions that offer support for the organizations, in particular, knowledge-based organizations. Such agent societies support the processing and distribution of information and knowledge using the mechanisms of semantic knowledge representation and operate in context of ubiquitous communication. Four of the indicated assumptions limited our research to the application of agent-based solutions in supporting the human – computer interaction and in the context of their possible use as part of knowledge management systems.

As indicated earlier, these solutions can be considered in the context of interface agents, each with its own codified knowledge base, associated with the information systems of an organization and actively participating in the ongoing business processes. Analysis of commercially available solutions pointed out that the vast majority of applications of agents in organizations are "Virtual advisors". All surveyed organizations offer such solutions. Various solutions, how-

ever, differ from each other significantly. Most of the solutions with primary goal in the form of finding and providing information to users, use a limited set of questions, that they are able to recognize, so their functionality is very limited. As a mean to overcome this limitation some solutions use tips in the form of 'choose-from-list' mechanism. One of the analyzed solutions uses natural language analysis speech that is used in interpreting user's statements, coupled with the speech recognition and biometric methods, which makes the solution more user-friendly, efficient, and significantly expands the range of other possible applications and makes them more versatile. One of the producers also highlights the special feature of their solution, which is the ability to focus on the essence of a "conversation" and the ability to return and resume the interrupted thread. Another solution integrates seamlessly with the entire service platform designed for supporting the public sector. Among other features automatic handling of callers to the call center can be distinguished. This solution, as the only one, uses a greater number of agents at the same time. Despite the focus on the same topic, they don't cooperate, nor create a society. However, it is possible to examine the software agents acting individually.

A. The benefits of using the software agents in an organization.

Organizations using software agents take advantage of a wide variety of benefits, among which the most frequently mentioned is an improvement for internal and external communication channels. The main functionality of virtual advisors is to provide the end customer with instant access to information without having to call the hotline or search for a specific Web page. This is undoubtedly the improvement of the process of communication and provides new channels of communication for external users. Virtual advisor also facilitates the usage of internal applications for employees. It provides a kind of help desk, which is the first line of support, and eliminates the need for traditional help files. An employee who is not proficient in terms of the usage of the software may simply ask a question related to the functionality of the software, and agent gives him or her the expected answer. Given this it surely improves the internal communication and speeds up access to information and knowledge for internal stakeholders. The use of software agents in a call center to answer the most common customers' questions brings measurable benefits for the organization, by reducing the cost of its service and by increasing customer satisfaction.

B. Software agents as a tool for perfecting business processes in the organization.

With regard to perfecting business processes in the organization of various types of software agents are utilized in many different ways. The use of agents typically require clarification and formalization of the knowledge processing or even the introduction of knowledge management given the fact that the virtual advisor requires actual knowledge. The most obvious seems to be looking for improvement in the distribution of knowledge, e.g. the provision of information, and the customer service process, especially in those organizations where existing procedures are the most formal and well documented.

Agent interface representing intelligent search mechanism, streamlines the process of handling an applicant in the office, which, due to its use, becomes more efficient and faster. Similarly, software agent can support internal users which execute formal, well-defined and well-described processes, by reducing the time and improving access to information necessary for the resolution of the problems. Thus consulting the agent will optimize the business processes.

Organizations recognize another opportunity to improve business processes in running the trainings via the Internet supported by software agent, what makes it possible to carry out an individual training program, which depends on the needs and expectations of participants. Despite the fact that the lecture is run by a machine the participant may, in the course of his or hers study, receive help in the form of answers to his or hers questions. According to a representative of one of the companies participating in the survey it is a significant improvement in the business process. Software agents are also reported to bring benefits in the case of supporting the process of taking orders in an online shop. The survey results include a description of sales service process improvement in which information software agents are used to replace the traditional communication channels like inquiries, E-mail, or instant messaging like Skype or MSN Messenger, in situations where it is necessary to identify and/or specify the technical parameters of equipment sold or to clarify some definitions. The customer can get the answer on-line from the agent. In addition to the obvious benefits of cost savings and speeding up the process, companies indicated a higher attractiveness of this form of assistance.

C. Factors affecting the limited applicability of the concept of software agents society in the organization

Organizations share the same view when it comes to the identification of key factors influencing the limited applicability of the concept of software agents society in the organization. Typically, respondents indicated three main factors.

As a main reason social factor was indicated, i.e. lack of awareness of the existence of such solutions and potential benefits of its application, or perceiving them as a toy, amusing marketing gadget on the site, and not the real support. Both organizations and consumers are not yet ready for the introduction of software agents. Usually it is related to a misunderstanding of its purpose, as stated above, and a fear that stems from believing that they are a tool for spying on the users. Users are also not convinced about the reasonableness of the use of such mechanisms. Agent systems producers count on the fact that the situation will change over time, what will result in enhancing the intelligence of these solutions, which will enable them to assertively respond to user's behavior and intelligently adapt to his way of thinking.

Manufacturers also point to the problems that affect the older part of the population which is related to using the keyboard to communicate with the agents. Vendors try to develop new interfaces that eliminate the issue of typing. Probably the most interesting thing happening nowadays, regarding that matter, is the introduction of speech recognition and touch screens that release older people from necessity of using a keyboard. With speech recognition fluent conversation with the agent will be possible, rather than using written text.

Important factors limiting the implementation of software agents are organizational problems. We identified several of such problems that are the most common organizational factors hindering the use of agent-based solutions:

- lack of preparation of the organization for the introduction of agent systems, arising from organizational culture,
- lack of appropriate procedures,
- lack of separated and unambiguous definitions of business processes.

Manufacturers assume that a wider promotional campaign carried out by both the companies offering these solutions, as well as institutions that procure them, would result in their wider adoption in the organizations.

Problems related to knowledge management in organizations which plan to implement software agents are also indicated. There are potential users, organizations that would gladly implement such solutions, which have the necessary budget, are aware of the interest of the customers, but they realize that they are unable to adequately manage the knowledge, deliver it on time or in the correct amount that could be used by an virtual adviser.

An important factor limiting the applicability of agent solutions are technical and technological conditions. We distinguish two groups of such conditions. The first one is the constraints in the network infrastructure, making it difficult to make service call. For example, "virtual advisors" are the solutions which depend heavily on the access to the Internet connections. In Poland, the network infrastructure is still not sufficiently developed, what makes it difficult for everyone to gain access to and communicate with the virtual consultant. Residents of highly urbanized areas, usually the big cities, do not have this problem, while those living in poor urban areas, country side and terrain such as mountains may experience difficulties in accessing the Internet, which may be one of the main technical barriers.

Although informational technology is a subject for constant development, despite the significant progress and enormous achievements in the field of artificial intelligence, from the point of view of the technology that is used, we still are not able to create solutions which "thinks" like a human being and is able to "come up with" something to talk about on its own. Agent may conclude faster and much "better" than a man, it can make use of an analytical knowledge it has accumulated, but it is not in a position to come up with the subject of conversation. It can only base on pre-defined themes.

Most manufacturers indicate inadequacy or lack of mechanisms that would allow for a complete "mapping" features of the human brain that would allow for their repetition by the machine. Surely a computer, the machine, the computer program will neither act and "think" in a way the human being does, nor operate on the basis of associations. Most manufacturers also point to inadequacy or lack of tools for effective speech recognition, which, in their view, is blocking the applicability of the available solutions. Those that are currently available on the Polish market are still not mature enough and do not allow free communication and unambiguous speech recognition. Most of these tools allow to communicate in English, and users of agent systems, especially the virtual advisors, rely mostly on Polish, which is country's official language. It is possible, as shown by some manufacturers, to unblock the communication channel with use of software agents, which in turn should greatly improve their adaptation.

Another blocking factor, indicated by the respondents, is economic in its nature – namely agent solutions are not cheap. On the other hand the survey revealed that it is possible to overcome this one by applying for different types of subsidies that offer financing the implementation of such innovative solutions.

D. Use of intra-organizational knowledge in the process of achieving the objectives of software agents.

Key activities in the utilization of intra-organizational knowledge recognized by respondents comprise any action performed in order to collect and organize the knowledge base, for example creating a repository of knowledge, which can be used in the future. Filling the agent system with a domain knowledge requires the collection of this knowledge in different places and in different ways. Accumulated knowledge should be structured, but in different organizations, such structure will be achieved differently.

Agent systems vendors often report a lack of proper knowledge and preparation on the customer's side and difficulties in persuading the client to systematize the knowledge necessary for the functioning of the system.

Another vital activity appearing in customer service area, both internal and external, is the acquisition and distribution of knowledge, which should be strongly tailored to the individual needs of the user. As the survey shows it is always easier to implement such behavior in the case of a client who is aware of knowledge management and accumulation.

The organization aware of the needs of the knowledge management is more eager to collect the knowledge needed by the implemented solution. However, there are many organizations that lack the awareness of having such knowledge structured and stored. It is then necessary to establish close cooperation with persons designated and responsible for ordering and systematizing knowledge and implementation of specific procedures. This results in increased awareness of

the need for the process of collecting, organizing the knowledge and preparing appropriate procedures for structuring and organizing the knowledge within the organization.

E. Agent technologies in enrichment of organizational knowledge

Basically, the enrichment of organizational knowledge with the use of software agents is possible mainly by their usage in the acquisition of knowledge which is necessary to effectively carry out business processes of the organization. The agent system has to be taught. In the context of agent systems it means that agent have to be able to learn, i.e. gain knowledge from different organizational sources. There is also a body of knowledge outside of an organization which can be used by agents indirectly, for example through a solution of "browser of quotations" or through the integration with different types of external knowledge bases.

Agent-based solutions may be able to query different databases. Usually it is not a problem to teach agent the knowledge in a particular field. It can be done through connecting him to the existing knowledge base but to do so we need a help of a knowledge engineer.

The required knowledge can be sought out through a semantic search engine that collects information from various websites. Another way to supply resources of organizational knowledge may be communication with the user in natural language. Respondents also indicated the possibility of using surveys, interviews, questionnaires to gather knowledge in the specific area of interest.

Also, the knowledge needed for the operation of software agents enhances organizational knowledge resources. From the point of view of knowledge engineer the resources of knowledge used by the agent should be structured in the machine-readable form, so by definition such vocabulary can be entered into the agent's knowledge base. Such knowledge is frequently extending scenarios of usage that contain threads related to the specific knowledge pools. Threads are grouped into scenarios. We can say that knowledge that is used by the agents is two-folded: a part of it takes a form of vocabulary, and the other part is a knowledge about the scenarios of usage.

IV. CONCLUSION

Conducted partial studies indicate that such solutions are now heavily used by organizations and require further consideration in terms of the methodology of agent construction solutions. The studies have shown that companies implementing such solutions do not sufficiently take a methodical approach to the problem of the design and deployment of agents. This is due to the fact that the construction of such solutions requires, on the one hand, to address the issues of software development methods, and on the other theories of knowledge engineering that are required in the context of modeling the knowledge base of agents. This necessitates the search for the new methodologies for the design and construction of such solutions. In particular, in the context of semantic methods of agents' knowledge representation, which should be linked to the information systems of the organization. These issues were highlighted by the participants of this study.

Despite the differences in the details of the methodologies used in the design and the tools used, companies generally agree on the steps of the implementation of agent-based solutions. In simple terms it can be assumed that implementation is based on four main processes. The first one is to analyze and collect information from the user, based on which the knowledge of an agent will be formulated. The information comes from many sources, such as individual interviews, the results of searching through the paper-based and electronic documents. Because such knowledge usually is not codified in clear and understandable manner, it is necessary to systematize the acquired information. Thus the next step is to design a model of the knowledge which will be used to its structuring. Once the information is structured it can be used by an agent to identify the thread and give you the right answers to users' queries. The next step is the implementation of the agent system. The last stage is usually testing the system by the user and getting feedback on its operation. Feedback information allows designers to assess whether the knowledge that has been introduced to the agent is correct, if something has been missed and can be supplemented, if the scope or substance of knowledge has been changed in some way. Then it is necessary to update the knowledge. Despite the use of their own methodologies agent systems' vendors base on proven, UML-based tools. Such tools facilitate modeling of knowledge structures for knowledge bases, allow the ordering of knowledge structures and to describe some of relations in the knowledge base. They are also used when it comes to designing the architecture of agent systems. We can name several of them, both universal, such as Enterprise Architect, Power Designer and Eclipse, the Semantic Works or more specific like Protege for building ontologies. Companies recognize the benefits of using tools like CASE even when they can confirm that their usage has to be preceded by the learning process which poses some difficulties for its users. Consistency in the use of such solutions provides good documentation of its architecture and guarantees the appropriate level of maintainability of the agent system.

The process of building agents using the semantic mechanisms of knowledge representation requires that, at the design stage of the system, it is necessary to determine how the knowledge of agents will be sourced from within the organization and how it will be updated and managed. This requires that the organization, in which this solution is built, has been focused on knowledge management processes, which can support the use of such solutions. Respondents also pointed out that finished implementations allowed to disclose previously unknown places in the organization, in which the domain knowledge is stored. As a result, the process of implementing such a solution should not end with its completion, but requires further improvement of knowl-

edge bases of agents. Although it requires posting staff members to supervise the knowledge base of agents, but it is feasible from the point of view of the organization efficiency because agents can handle multiple clients simultaneously using the resource of codified knowledge. This aspect becomes a vital part of a research in the context of agent solutions, since contemporary methods of their construction are mainly focused on designing their architecture and, in a small percentage, indicate the possibility of modeling the knowledge of the system. The issue of methodological approaches to the modeling of knowledge structures for software agent societies, using the semantic mechanisms of knowledge representation, will be a main focus of authors' further research.

ACKNOWLEDGMENT

The issues presented constitute a preliminary stage of the authors' research into the aspect of modeling software agent societies in knowledge-based organizations. The project was financed from the funds of National Science Centre 2011/03/D/HS4/00782. At the same time the authors want to thank the following companies (alphabetical order): 2CONN Tech Sp. z o.o, Instytut Technik Innowacyjnych EMAG, PIRIOS S.A., Stanusch Technologies S.A., Sztuczna Inteligencja Sp. z o.o. for their cooperation and willing participation in the study.

2nd Workshop on Information Technologies for Logistics

The main purpose of the workshop is to provide a forum for researchers and practitioners to present and discuss current issues concerning use of ICT in logistic applications (hardware and software). There will be also an opportunity for hardware integrators, software developers and logistics companies to demonstrate their solutions, as well as achievements, in different logistic systems.

Topics

The topics of interest include but are not limited to:

- Innovations in information systems supporting logistics and its management (WMS, SCM, TMS, LIS, VMI, CRP, PLM, and others)
- Innovative technologies in warehouse management: RFID, Voice Picking, Image Recognition, Pick Radar, etc.
- Logistics process modeling, including influence of warehouse automatic
- Optimization of logistics processes:
  - optimal vehicle routing and management, boundary conditions
  - optimal picking routing (global optimization, fast search, collision prediction and prevention)
  - shared mobility systems
  - day-to-day dynamic traffic assignment models
  - effective methods of picking (multi picking, batch picking ect.)
  - relationships between picking efficiency and products decomposition in warehouse area
- Environmental protection (for example carbon-aware transportation)
- Artificial intelligence systems and decision support systems in logistics
- BI, data mining and process mining in logistics
- Quality management algorithms and methods
- Material Flow Theory and applications

Product Swapping and Transfer Sales between Suppliers in a Balanced Network

Ikbal E. Dizbay, Omer Ozturkoglu
Yasar University, Universite cd. Selcuk Yasar Kampusu, Agacliyol
Izmir, Turkey
Email: {ece.dizbay, omer.ozturkoglu}@yasar.edu.tr

***Abstract*—In this paper we present a preliminary, deterministic mathematical model of cooperative supply chain network of suppliers and customers. We consider horizontal cooperation among suppliers such that they can swap their orders to reduce their transportation cost, and they can purchase products from each other to reduce their shortage cost. Hence, the objective is to examine the potential swap and horizontal purchasing operations between suppliers under perfect information sharing. Assuming a balanced network in a single-period, in which total capacity of suppliers is greater than or equal to the total demand of customers, we conduct an empirical analysis for six suppliers and eight customers. The analysis suggests for many suppliers the benefits of order swapping and lateral purchasing.**

I. Introduction

IN today's competitive environment, customer satisfaction is one of the most prominent performance measures for companies, especially for the ones that serve consumers. In order to increase customer satisfaction, companies might focus on increasing customer service level, responding orders quickly, shipping the right items in the right amount. To be able to achieve these, there are several classical strategies implemented by companies such as opening new depots or warehouses close to customers, increasing inventory levels at the stores including safety stocks, using fast transportation modes or less-than-truck load shipments, etc. However, these methods cause increase in logistics and supply chain cost, hence reduces competitiveness of the companies. Therefore, reference [1] discussed that implementing co-opetition strategies, which identifies the existence of competition and cooperation strategies among different companies, provide companies to maximize their individual profits. Hence, companies look for win-win scenarios by sharing information that has an important effect on competition and the success of cooperation strategies [2]. So, what might be an example of cooperation strategies for different companies or different branches of a company? Examples to these strategies in literature might be inventory sharing, inventory pooling, lateral transshipment, and order swapping and exchanging by sharing partial or full information. In this paper, we focus on order swapping and lateral transshipment.

Swapping can be defined as an agreement between businesses, which are competing or non-competing, exchanging shipping, production, assets or market position to reduce overall costs. Our main purpose and motivation of using order swapping is to provide reduction in transportation costs by shipping products to closer customers on behalf of each other. Details and assumptions of this operation is discussed in the next section.

There are very limited research about swap operations in the context of supply chain and logistics. Reference [3] is the most relevant study to our study. Reference [3] developed a multi period mathematical model that seeks for an efficient coordination of swap and exchange transactions between supply chain partners in the field of oil and petroleum industry. They assume perfect information sharing, known demand and sufficient production to meet customers' demand. Reference [4] discussed the possible benefits and risks of swapping commodities and capacity with competitors by giving real-life examples. For example, two different manufacturers in chemical industry, one located in USA the other is in Europe, agreed to swap their monomers to use in their polymer operations after verifying that the product is the same. Hence, both company saved tens of million dollars in logistics cost per year. They also mentioned that industries that produce textile, paper, iron and steel products might include potential savings by implementing swap strategies. Lateral transshipment strategy allows suppliers or retailers in the same echelon to pool their inventories in order to enhance lower inventory levels and costs while providing at least the required customer service level. [5] define two types of lateral transshipment according to the timing of transshipments: proactive and reactive. While proactive transshipment can be planned in advance, reactive transshipment is performed when needed, for example when a company stocks out or faces a risk of stock out. Almost all of the studies about lateral transshipment reviewed by reference [5] focuses on inventory problems in stock points or branches of the same company. However, we consider different, competing companies in our study. Because of this reason, we suggest readers to read detailed review on lateral transshipment in [5].

In the light of these references, we want to notice that the contribution this study is to integrate two effective cooperation strategies in a mathematical model of single echelon supply chain network. Hence, in Section II we present assumptions of our model and the model formulation. Then, we conclude our study with an empirical analysis of the developed model and discussion of the results and future research questions.

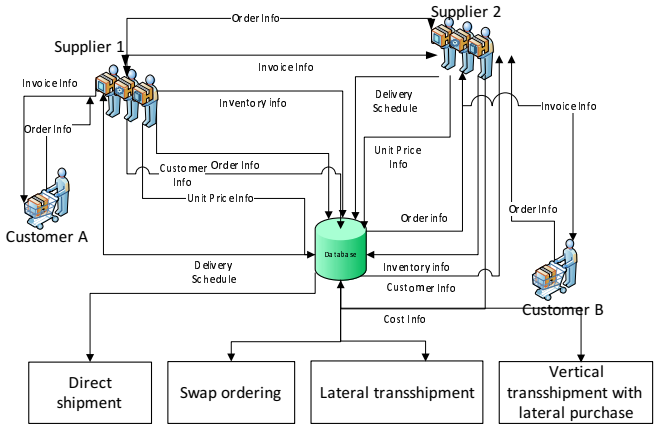

Fig. 1. Information system to generate shipping orders for suppliers in cooperation.

II. Model Assumptions and Formulation

In this study a single, commodity product network is examined which consists of a group of competing, but co-operating suppliers, where each supplier produces at their respective capacity which is known and constant. Customer demands are also known and constant. After customer sends their order requests to a supplier, the supplier share all the relevant data with other cooperating suppliers such as unit cost of purchase, unit market price, unit cost of transportation, inventory levels, location of customers and their orders. Hence, we assume pure information sharing among competing but cooperating suppliers. After all the data are processed and the mathematical model is utilized to generate the shipping orders to meet customer demands, there might appear four cases: direct shipment, swap ordering, lateral transshipment, vertical transshipment with lateral purchase (see Figure 1).

The demand at each supplier may be satisfied by shipping available on-hand inventory directly to a specific customer if there is no savings in swap ordering with another cooperating supplier. If swap decision is generated by the information systems, then the system sends swap orders to the suppliers that are going to ship the determined amount of products on behalf of each other to other's customer. Hence, the model aims to provide savings in transportation cost for both suppliers in cooperation by shipping products from closer suppliers to the customers. Here, we assume a balanced swap between two suppliers to construct equity between them such that each supplier should ship the same amount of product on behalf of each other. The appropriate documents and information flows among suppliers and customers flow as seen in Figure 1.

The suppliers share inventory and pricing information and might participate in an lateral transshipment arrangement in which every supplier must receive some benefit from the lateral transshipments. Because these cooperating suppliers are also competing each other, a lateral transshipment is realized only when a supplier that stocks out (called "dependant" hereafter) decides to purchase products from another supplier that has excess stock on hand (called "seller" hereafter). Due to lateral transshipment agreement, sellers should sell and ship the required amount to the dependants unless they face a stock out. In this preliminary model, we assume that the purchasing (or selling) price of the product between a seller and a dependant is deterministic and determined by averaging the unit market price of the dependant and the unit cost of the seller. In order to provide benefit to these suppliers, we assume that the unit market price of any supplier is greater than the unit cost of any supplier. This enhances that a dependant always buys products from other suppliers with a lesser price than its market price. While this pricing mechanism is relatively simplistic, it provides a standard policy to calculate the transfer price between suppliers. Even though this strategy aims to provide benefit to cooperating suppliers, it is still possible for shortage to occur if there is no benefit of purchasing excess inventory when cost of lost sales is less than total cost of purchasing and transportation between dependant and seller. The cost of lost sales is assumed to be the sales price of a product for that supplier. Additionally, there are no holding costs associated with excess inventory because this analysis only covers one period.

In vertical transshipment with lateral purchase agreement, if a dependant decides to purchase its need from a seller, he may require the seller to ship the product to its own customer if the customer is closer the seller than the dependant. Then, the dependant pays the cost of purchasing and the transportation cost to the seller. Hence, it can provide savings in transportation cost. In summary, the mathematical model we develop considers the sequence of cases we discussed above. First, suppliers decide if there is any benefit to executing a swap for their orders. If there is a benefit for two suppliers, a balanced swap occurs in which supplier i ships products to the supplier k's customer, and vice versa. If there is no benefit from executing a swap, the supplier ships directly to their customer. If a supplier's demand exceeds their inventory level, then that supplier seeks to purchase product from suppliers that have excess inventory. Then, he may either receive transshipments from other suppliers or the product may be shipped directly from seller to the customer on behalf of the dependant. Hence, the model parameters and variables are discussed as the followings.

The relevant parameters for the model are as follows:
c_{ij} :contracted unit transportation cost between supplier i and customer j.
D_{ij} : quantity demanded from supplier i by customer j.
I_i : inventory level on-hand at supplier i.
p_i : unit market price of supplier i.
u_i : unit cost of supplier i.
The model variables are as follows: q_{ij} : quantity shipped directly from supplier i to customer j.
b_{ij} : amount of lost sales between supplier i and customer j due to shortage.
y_{ijk} : quantity shipped from supplier i to customer j on behalf of supplier k due to order swap.
x_{ki} : quantity shipped from supplier k to supplier i due to

purchase by supplier i under lateral transshipment agreement. w_{ijk} : quantity shipped from supplier i to customer j on behalf of supplier k due to purchase by supplier k under vertical transshipment with lateral purchase.
The upper bound of the cost of the i^{th} supplier (Z_i^u), which provides the worst case, is the total transshipment cost of the i^{th} supplier that ships to only its respective customers and its total cost of lost sales, if exist. The sum of Z_i^u for all suppliers is the upper bound of the cost of supply chain network (Z^u).

$$Z_i^u = \sum_{j=1}^{n} q_{ij}c_{ij} + b_{ij}p_i \tag{1}$$

$$\text{subject to} \tag{2}$$

$$\sum_{j=1}^{n} q_{ij} \leq I_i \tag{3}$$

$$q_{ij} + b_{ij} = D_{ij}, \forall i, j \tag{4}$$

$$q_{ij}, b_{ij} \geq 0. \tag{5}$$

Hence, the objective function of the model (Z) considers order swap and the lateral purchase among cooperating but competing suppliers if an excess demand exists.

$$\begin{aligned} minZ = &\sum_{i=1}^{m}\sum_{j=1}^{n}(c_{ij}q_{ij} + p_i b_{ij}) \\ &+ \sum_{k=1,i\neq k}^{m}\sum_{i=1}^{m}\sum_{j=1}^{n}(c_{ij}y_{ijk} + c_{kj}w_{kji}) \\ &+ \sum_{k=1,i\neq k}^{m}\sum_{i=1}^{m}\sum_{j=1}^{n}\left(\frac{u_k + p_i}{2}\right)w_{kji} \\ &+ \sum_{k=1,i\neq k}^{m}\sum_{i=1}^{m}\left(t_{ki}x_{ki} + \left(\frac{u_k + p_i}{2}\right)x_{ki}\right) \end{aligned} \tag{6}$$

The first constraint is related to the inventory level for every supplier that is greater than or equal to the quantity shipped directly to their customers, the quantity shipped to other supplier's customers due to swaps, and the changes in capacity from the buying or selling of product from other suppliers.

$$\begin{aligned} &\sum_{j=1}^{n} q_{ij} + \sum_{j=1}^{n}\sum_{k=1,k\neq i}^{m}(y_{ijk} + w_{ijk}) \\ &\qquad + \sum_{k=1}^{m}(x_{ik} - x_{ki}) \leq I_i, \forall i. \end{aligned} \tag{7}$$

Demand for every supplier and customer relationship must be satisfied by shipment from supplier i, shipment from a different supplier due to swaps, the shipment of material sold to other suppliers to their customers, or lost sales.

$$q_{ij} + b_{ij} + \sum_{k=1,k\neq i}^{m}(y_{kji} + w_{kji}) = D_{ij}, \forall i, j. \tag{8}$$

Every swap must be balanced between two suppliers.

$$\begin{aligned} \sum_{j=1}^{n} y_{ijk} - \sum_{j=1}^{n} y_{kji} = 0, \quad &\forall i = 1, 2, ..., (m-1); \\ &\forall k = (i+1), ..., m; i \neq k \end{aligned} \tag{9}$$

Every supplier must benefit under the network swapping arrangement considering the costs for shipment from supplier i, shipment from a different supplier due to swaps, the cost of purchasing product from other suppliers, and cost of lost sales are less than or equal to its upper bound.

$$\begin{aligned} &\sum_{j=1}^{n}(c_{ij}q_{ij} + p_i b_{ij}) + \sum_{k=1}^{m}\sum_{j=1}^{n}(c_{ij}y_{ijk} + c_{ij}w_{ijk}) \\ &+ \sum_{k=1,i\neq k}^{m}\sum_{j=1}^{n}\left(\frac{u_k + p_i}{2}\right)w_{kji} \\ &+ \sum_{k=1,i\neq k}^{m}\left(t_{ki}x_{ki} + \left(\frac{u_k + p_i}{2}\right)x_{ki}\right) \leq Z_i^u, \forall i. \end{aligned} \tag{10}$$

Finally, quantity shipped directly, lost sales, quantities shipped to other suppliers' customers, quantities purchased by other suppliers, and quantities transshipped between suppliers must be non-negative.

$$q_{ij}, b_{ij}, y_{ijk}, w_{ijk}, x_{ki} \geq 0. \tag{11}$$

III. Numerical Investigation and Conclusion

A demand of a customer is randomly generated number between 100 and 1000 using uniform distribution. A supplier's capacity is also assumed to distribute uniformly between 1000 and 4000 such that total stock in the network is greater than the total demand of the network. Hence, a supplier observes either a shortage or an excess inventory. Excess inventory may be sold to a supplier facing shortage at a price between the seller's unit cost and the dependant's market price. Unit cost of products was generated between 300 and 330, and then market price of a supplier is generated by multiplying its unit cost by a uniformly generated profit margin between 10% and 30%.

The upper bound and the proposed model developed in the previous section run for a network of six suppliers and eight customers. As seen in Figure 2, every supplier receives some benefit either from the swapping or lateral transshipment agreement, or from both. Hence, the model provides benefit in transportation cost by a swap agreement and reduction in cost of lost sales by allowing cooperation among suppliers for their excess demand and supply in a single period. In order to investigate the effect of the proposed model on the supply chain network cost of each individual supplier, we aim to work on multi period with holding cost and partial information sharing.

	supplier 1	supplier 2	supplier 3	supplier 4	supplier 5	supplier 6
Upper Bound	14.994	11.576	358.626	220.489	39.645	26.370
Swap and Lateral	12760,0	7749,9	335035,7	198013,3	35691,6	14421,8

Fig. 2. Total transportation and backorder costs of each supplier with and without swap and lateral transshipment.

***Abstract*—This paper presents a concept of use of the rule-based reasoning systems for evaluation and classification of the suppliers. The problem of suppliers selection is widely discussed in literature. Majority of the authors apply the method of multi-criteria evaluation for selection of suppliers, mainly the Analytic Hierarchy Process (AHP) algorithm and related ones, to find its solution. In this paper it has been proved that a suitably expressive system of rules management can be used as an effective tool for suppliers evaluation. In the presented work we have applied the Rebit system which was elaborated by the AGH University of Science and Technology. An example of evaluation of a supplier of primary charging materials for metal processing enterprise has been presented. It has been shown how individual evaluation criteria are grouped into sets of independent rules and how one may use tools to enhance the knowledge acquisition.**

I. Introduction

THE PROBLEM of supplier selection plays a prominent role in the modern economy. Supplier selection and evaluation is one of the most vital actions of enterprises in a supply chain. Undertaking faulty decisions in this area may be a cause of critical disturbances in execution of the fundamental tasks of the manufacturing enterprises.

Over the past several years, with the recent trend on just-in-time (JIT) manufacturing systems, there is an emphasis on strategic sourcing that establishes long-term mutually beneficial relationship with fewer but better suppliers [1].

Strategic decisions concerning supplies with raw materials are tied up with evaluation and selection of potential strategic suppliers. Selection of suppliers presents itself a complex decision-making problem which is featured with multi-criteria, of different nature of the criteria (quantitative, qualitative) and with multi-stages of the decision. In today's global and open innovation economy strategic supplier selection and evaluation decisions must not be solely based on traditional selection criteria, such as cost, quality and delivery. In strategic sourcing, many other criteria should be considered with the aim of developing a long-term supplier relationship such as quality management practices, long-term management practices, financial strength, technology and innovativeness level, suppliers' cooperative attitude, supplier's co-design capabilities, and cost reduction capabilities [1].

Both the procedure and algorithms for supplier selection cannot rely exclusively on the "historic" experience of a manager. It must reflect some strategy of the enterprise as defined by the management of the enterprise in scope of execution of its fundamental activity. This strategy determines then the purchase strategy including such factors as acceptable standard of prices, required quality, desirable conditions of the long-term cooperation etc. Thereby the selection of suppliers can be treated as an integral element of definition of the processes and business rules. Therefore, the rule-based approach which is characteristic for Business Rules Management Systems can be useful while solving the problem of selection and ranking of the suppliers. Nevertheless, there is a pre-condition that one must have at one's disposal a suitably expressive and reliable tool. And there is such a tool: The Business and Technological Rules Management - The Rebit System elaborated by the AGH University of Science and Technology.

The aim of the paper is to present the possibility of use of tools purposed for business management rules to solve the problem of supplier selection. We have presented the results of our research directed on proposing a solution which would enable one to get flexible formation of purchase strategy and current adaptation of the selection criteria for the choice of suppliers to changing market conditions.

This paper concerns problems of selection and grouping of suppliers of charging materials in respect to the quality of the services provided by them, as well as the quality and parameters of the delivered materials. Furthermore, we have analyzed the influence of factors resulting from the purchase strategy and such external factors as the destination of the acquired materials on the issue of supplier selection.

In the first part of the paper there will be formulated a problem of evaluation and classification of the suppliers and we will present a review of the relevant literature. Then we will present the Business and Technological Rules Management - the Rebit System and its specific features used to solve the problem of suppliers evaluation. An example of evaluation of a supplier of charging materials accomplished with use of the Rebit system will be also presented. The paper will be finished with a critical comparison of the proposed solution with some concepts known from the literature; some suggestions concerning further works will be also presented.

II. Supplier evaluation and selection

The problem of supplier selection can be considered from different points of view. Firstly, this is a task relying on a

This work is supported by the Innovative Economy Operational Programme EU-founded project (UDA-POIG.01.03.02-12-008/11-00)

978-83-60810-53-8/$25.00

single selection, from the list of the suppliers, such supplier who in the best way fulfills the requirements resulting from execution of the specific production order. In such case we have to do with a simple issue of multi-criteria evaluation. The set of the criteria, their inter-relation, as well as the method of their evaluation may be different in each individual case.

In business management practice much more important meaning has a task of creation and periodic updating of the list of suppliers for different groups of charging materials permanently tied up with the recipient. Depending on the nature of the realized manufacturing processes we can have to do with complex deliveries covering different kind of materials (and in some cases also services) or with special-purpose deliveries including deliveries of strictly defined sort of products. The way of solving the problem of supplier selection depends also on kind of the material needs. One shall consider the selection issue in case of materials directly consumed in the production process and otherwise in case of accessory materials. The very procedure of evaluation of the potential suppliers will be in case of any of the above mentioned situations similar and will resolve itself into establishing a ranking list of the evaluated subjects or classifying them into the previously established categories (e.g. permanent main supplier, permanent auxiliary supplier, occasional supplier). However, the evaluation criteria will differ. Due to the number of criteria and their interrelation, the procedure can be executed in one stage or in multi-stages. A special group of decision issues are decisions of strategic nature that bind the recipient with the supplier for a long time.

Supplier evaluation and problem selection have been presented in the literature as the goal of the development research or as the task related with creation of the software applications. In most cases we have to do with proposals of creation of the Decision Support Systems (DSS) which could be applied in business practice. Thus, an issue of essential significance is not only the way of solving the problem of multi-criteria evaluation but also assumptions and methods of execution of an application meeting user's requirements. These both decisions must be considered together, because the characteristics of the evaluation algorithms exerts an essential influence on the way of realization of the application and particularly on creation of conditions for current updating of the assumptions without the necessity of modification of the very structure of the programming modules. Therefore, the way of proper knowledge modeling and management is very important.

The object of our research is the problem of classification of potential suppliers of the primary charging materials. Taking the above into consideration and assuming that the adopted methodological solutions should permit one to achieve easy creation of flexible application serving, inter alia, in practical realization of the current purchase strategy, we have made the following assumptions specifying the research problem:

- any potential supplier will be evaluated individually and not with use of the method of pairwise comparisons, as it happens in the Analytic Hierarchy Process (AHP) and similar methods;
- criteria related with complexity of the deliveries are not taken into consideration;
- while evaluating the deliveries one takes into account the destination of the materials earmarked to produce different groups of product;
- the way of presentation of the criteria in the model and criteria evaluation must be readable for the managers and allow them to present the purchase strategy;
- the application based on the proposed solution must allow one to perform simple updating of the evaluation criteria with no interference in the code.

The fulfillment of every of the above presumptions places specific requirements to the method used in knowledge representation and consequently - also to the inference mechanisms. We have acknowledged that the most profitable solution would be use of the rule based knowledge representation. A symbolic (linguistic) mapping of the assessment criteria and declarative nature of the knowledge optimally corresponds with the requirements and needs of the managers responsible for execution of the business operations.

III. Literature review

In the face of acute global competition, supplier management is rapidly emerging as a crucial issue to any enterprises striving for business success and sustainable development. As it was mentioned above, supplier evaluation and order allocation are complex, multi-criteria decisions.

Incorporating multi-dimensional information into vendor evaluation is important and well established in both academic and practitioner's literature [3], [4]. Over the years, several multi-criteria techniques have been proposed for the effective evaluation and selection of vendors. According to the literature, some supplier selection criteria are found to vary in different situations, and experts agree that there is no one best way to evaluate, select suppliers and that organizations use a variety of different approaches in their evaluating processes.

As it has been previously mentioned, the evaluation of a supplier is realized in different phases of the process of supply management and may concern different special cases. Depending on the purpose of the evaluation and the adopted assumptions, different criteria are taken into consideration.

Ha and Krishnan [3] summarizes some of these criteria which have appeared in literature since 1966. Among them one can mention (ordered according to the frequency of quoting in the literature): price, quality, delivery warranties and claims, after sales service, technical support, training aids, attitude performance history, financial position, geographical location, management and organization, labor relations, communication system, response to customer request, e-commerce capability, JiT capability, technical capability, production facilities and capacity, packaging ability, operational controls, ease-of-use maintainability, amount of past business, reputation and position in industry, reciprocal arrangements, impression, environmentally friendly products, product appearance, catalog technology.

In an overall analysis of 181 articles referenced within the studies made by Erdem and Göçen [2], AHP related

methodologies seem to be the most popular techniques which are applied in over 36% of the studies. This is mostly due to the fact that AHP incorporates both qualitative and quantitative evaluation of the decision maker by use of tangible and intangible factors designed in a hierarchical manner. It is suitable, flexible and easy-to-use for multi-criteria decision making and can be applied in group decision making environments as well.

Along with usage of the AHP method one can find in the literature other solutions [1], [5], [6], [7]: multicriteria classification and sorting methods (among other sorting method based on the PROMETHEE methodology), Game Theory, Decision Trees, Factor Analysis, Structural Equations, Loss Functions, Process Capability Index, Expert Systems, Case Based Reasoning (CBR), data envelopment analysis (DEA), and neural network (NN).

Although several techniques and models have been utilized for the selecting and evaluating of vendors, efficient partner selection, combining multiple techniques (AHP, DEA, and NN), has not been suggested previously with regard to the purchasing evaluation process [3]. The hybrid method uses an AHP to assign weight to the qualitative selection criteria, and it uses a DEA, NN or other methods in order to choose efficient vendors in the final selection process. Exemplary, the study [1] aims to develop models and generate a decision support system (DSS) for the improvement of supplier evaluation and order allocation decisions in a supply chain. Initially, an analytic hierarchy process (AHP) model is developed for qualitative and quantitative evaluation of suppliers. Based on these evaluations, a goal programming (GP) model is developed for order allocation among suppliers.

As it has already been stated decisions concerning organization of the supply of strategic nature are of specific character. An example of such situation one can find in work [8] where the problem of warehouse selection for a company was presented. This is a valuable and realistic decision problem in logistic and supply chain management (LSCM). The authors provided a solution for solving the raised problem via knowledge discovery and utilization. The decision knowledge in the form of ”if. . . then . . .” rules are generated based on known information of owned warehouses and then utilized for predicting the preference order of alternatives according to their profitability. The process of solving of the problem is realized in four stages. In the two first stages the expert knowledge and the knowledge derived from previous experiences is gathered. The third stage relies on elaboration of rules purposed for evaluation of the decision variants, whereas the fourth stage relies on their implementation in the specific case. Because both certain and uncertain information are taken into account, the authors introduce interval-valued intuitionistic fuzzy set (IVIFS), which consists of a membership function and a non-membership function, whose values are intervals rather than exact numbers. The presented procedures are sophisticated, time- and cost-consuming (due to engagement of external experts) and serve to solving individual problems.

One can also find some works which discuss the use of the rule-based approach in less complex problems related with undertaking multi-criteria decisions. Vokurka, Choobineh, and Vadi [9] develop a prototype expert system to evaluate the potential suppliers. Interesting approach to the preference modeling in the form of a set of "if..., then..." decision rules discovered from the data by inductive learning is presented in [10]. To structure the data prior to induction of rules, the authors use the Dominance-based Rough Set Approach (DRSA).

Summarizing the review of the literature one may find that the dominant method applied in the multi-criteria evaluation of the suppliers is the AHP method. Its imperfection one tries to level with use of supplementing method that permit objectification of the inherently subjective evaluations of experts. Nevertheless, there is lack of reports on the problem of the suppliers selection which would permit to treat them as activities aiming at business processes standardization. There are also no reports regarding usage of the concept of management with business rules in the matter under discussion.

IV. Business and Technological Rules Management System

Rebit System belongs to the category of Business Rule Management System (BRMS). It consists of rule and workflow engines, knowledge base editor, generic client, testing, validation and simulation tools, knowledge base repositories and resource management module. All these components may be configured and integrated into a standalone application. However, the main advantage is that they are also a set of loosely coupled components working in Service Oriented Architecture (SOA).

Rebit System supports all stages of knowledge base development process. Knowledge base editor is generally the first tool used in this process. It allows knowledge base creating and editing in a graphical or textual way with the help of intelligent prompts. All classic elements used in knowledge representation are available in Rebit editor. The main building blocks are rules, variables and functions. Rebit rules belong to the category of productions rules. Rule premises are logical conditions based on variables and functions. Rule conclusions are simple assignments. Rules are organized in so called rule sets, i.e. a group of logically connected rules. Rebit language provides more sophisticated elements, such as grids and decision tables. They allow for more concise and user friendly knowledge representation. The knowledge contained in decision tables and grids may be converted into ordinary rules. Rebit System is equipped with algorithms of learning by examples which allow for rational translation of decision tables into an effective rule set. The translation process usually takes place just before deployment.

The next steps in the process of knowledge base development are validation and testing. Rebit System provides an efficient validation and testing tools. Testing and validation algorithms allows for finding most inconsistencies and incompleteness. In order to perform validation and testing the knowledge base must be translated to Prolog language. The translation process is automatic and transparent to the

user. The user sees only the results and some additional statistics. The standard verification procedure include testing for knowledge base integrity, consistency and completeness. This procedure may be optionally extended by looking for hidden cycles and other unsafe phenomena.

Rebit inference engine handles three modes of inference: forward, backward and mixed, i.e., inference with predefined target variable. In the first inference mode the engine tries to infer all possible facts (variable values) from input data. The inference session may be continued after entering new input data. Backward reasoning is the verification of the hypothesis (concerning the value of some variable) on the base of information entered by the user at the request of the engine. The third inference mode, co-called mixed, combines forward and backward reasoning. The user specifies the final variable, i.e. the variable which must have the value. The inference engine finds the most efficient path and the set of variables that must have values. After that the mixed process of forward and backward chaining is accomplished. The process is stopped when the goal is reached or there is an evidence that the goal cannot be reached. The unique feature of Rebit engine is the possibility of controlling the reasoning process. It allow to reduce the total number of questions asked to the user.

Generic client is integrated with simulation module which enables automatic or semi-automatic simulation. The simulation allows finding groups of "not optimal rules", unused variables or rules, repeating or overlapping rules and other harmful elements. The first step in simulation procedure is the setup of statistical properties of all input variables. In the next step constraints and typical simulation properties like exit conditions are defined. The result of simulation procedure is a detailed report containing many useful statistics relating to variables and rules.

The knowledge base development process has not been as extensively explored as the software development process. However, general guidelines on how to proceed are the same in both processes. The iterative and incremental approach known from software development seems to be the most appropriate also in knowledge base development. The general idea is as follow: each iteration consists of identification, conceptualization and formalization of a selected portion of the domain. Next iteration starts after successful testing. It usually extends the previous portion of the domain. The iteration process ends when the entire domain is covered in knowledge base.

A special role in Rebit model of knowledge representation play elements called resources. They are introduced to enable access to data stored in SQL databases and other data sources. The current version of Rebit System includes connection strings, queries, variables and bindings. Query combined with variable - which represents the result of this query - form a new element called binding.

V. RULE-BASED APPROACH IMPLEMENTATION

A. Exemplary problem description

Our proposal has been verified on an example of selection and grouping of suppliers in enterprises producing metal products. All the enterprises for which the supplier selection problems play key role and are operating currently on the market have their own, substantially formalized procedures of suppliers selection. Standards in this domain are formally specified by ISO 9001:2000 norms (Clouse 7.4 Purchasing). Below there are shortly discussed: a process of evaluation and qualification of a supplier applied by a chosen producer of structural closed cold formed steel profiles.

A new supplier is evaluated from the point of view of the foreseen quality of cooperation with the enterprise and from the point of view of possibility of purchasing from him the commodity from given assortment group.

The supplier, in view of the quality of cooperation, is classified to the one of three groups: permanent main supplier, permanent auxiliary supplier, and occasional supplier. The classification based on the possibility of delivery of different assortments of the charging materials distinguishes three group of product providers: low cost, standard and HQ (high quality).

The assessment of the supplier takes into consideration the following aspects of cooperation:

- the experience in the cooperation,
- the contractual cooperation,
- the effectiveness of the complaints,
- servicing procedures,
- the reputation of the supplier,
- the balance of liabilities and receivables.

The supplier evaluation model in exemplary case is as shown in Fig. 1.

B. Knowledge base formulation

The considerable number of the criteria brings about need of grouping them in accordance with partition presented in Fig. 1. Simultaneously it is necessary to provide independent updating, testing and verification of groups of rules evaluating individual criteria. The Rebit system allows one to group rules into relatively independent rule sets.

Individual partial criteria can be both of quantitative or qualitative. Taking into consideration the necessity of adaptation of the knowledge model to symbolic reasoning which is specific for human being, it was assumed that the "rough" model would operate exclusively on qualitative variables. An additional justification of such solution is the fact that quantities which could be recorded as a constant or numerical variables can undergo dynamic changes. The updating of the knowledge model would require then frequent verification of many rules, what in turn is time-consuming and can be a source of errors. On the other hand, one shall assume that to some extend the values necessary to rules evaluation will be collected from external sources of data and perforce will be of quantitative type. This apparent contradiction can be solved with use of the mechanisms and tools of the Rebit system.

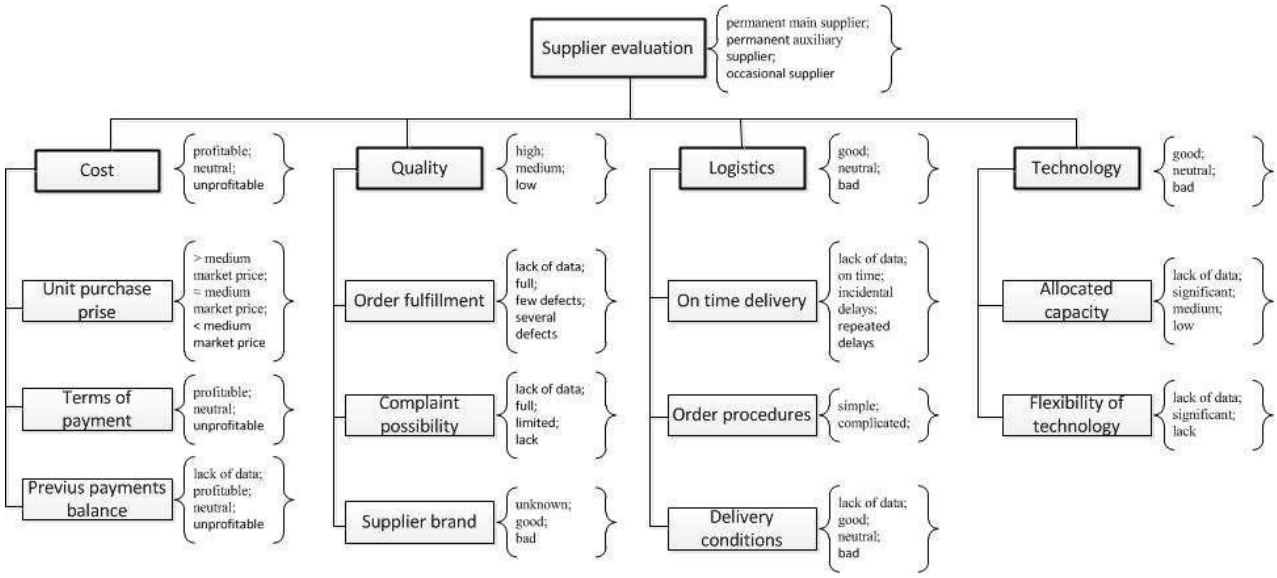

Fig. 1. The supplier evaluation

The adopted concepts can be illustrated on an example of knowledge acquisition for needs of evaluation of the criterion "Cost".

In case of the linguistic variables the most convenient form of knowledge representation is the decision table. In the Rebit system there is a possibility of generating such table after having previously declared appropriate enumerated types. Figure 2 presents a fragment of such table. The algorithm of learning by examples based on ID3, which is incorporated into the Rebit system, allows one to generate the "minimal" set of rules for the examples recorded in the decision table.

Fig. 2. Decision table for criterion Cost

Below one can find some exemplary rules:

```
RULE Cost_21
IF UnitePurchasePrice =
"greater then medium market price" AND
PreviousPaymentsBalance = "lack of data"
THEN Cost = "unprofitable"

RULE Cost_22
IF UnitePurchasePrice =
"greater then medium market price" AND
PreviousPaymentsBalance = "neutral"
THEN Cost = "unprofitable"

RULE Cost_23
IF UnitePurchasePrice =
"greater then medium market price" AND
PreviousPaymentsBalance = "unprofitable"
THEN Cost = "unprofitable"

RULE Cost_24
IF UnitePurchasePrice =
"greater then "medium market price" AND
PreviousPaymentsBalance = "profitable" AND
TermsOfPayment = "profitable"
THEN Cost = "neutral"
```

For the needs of symbolic representation of knowledge it was convenient to present the variable `UnitePurchasePrice` as a linguistic variable. In practice it is however compared with numerical quantities. This problem can be solved by introducing additional numerical variables `AskPrice`, `LowerPriceBound` and `UpperPriceBound`, as well as rules allowing for mapping a numerical to linguistic variable.

The pertinent rules have been presented below:

```
RULE CostPar_0
IF AskPrice <= LowerPriceBound
THEN UnitePurchasePrice =
"less then medium market price"

RULE CostPar_1
IF AskPrice >= LowerPriceBound AND
Ask_price <= UpperPriceBound
THEN UnitePurchasePrice =
"equal to medium market price"

RULE CostPar_2
IF AskPrice > UpperPriceBound
THEN UnitePurchasePrice =
```

```
"greater then medium market price"
```

As a result one obtains a model of knowledge which on the one hand is readable and easy to updating from the point of view of the manager but on the other hand, it permits one to data acquisition without the participation of the user (quantitative values can be downloaded directly from databases by means of the module of resources management). It is also worth pointing out that updating of the knowledge (e.g. in case of change of the purchase strategy) takes place on level of decision tables and does not require any interference into rules which are updated "automatically".

As it has been previously mentioned, one of the main criteria of evaluation of the supplier is the destination of the materials acquired from him. Depending on the requirements placed against the final goods which will be produced from the purchased materials, the way of the evaluation of the supplier's offer will also be different. The simplest solution would be to construct three separate models of the knowledge for: low cost, standard and high quality products. However, it is not justified whereas in case of a suitably expressive model of knowledge - which can be recorded in the Rebit system - not necessary. Some of the criteria are independent from the destination of the purchased materials (e.g. economic parameters). However, in case of some materials one can, thanks to parametrization, construct a model of knowledge that is common for different cases.

One can illustrate this on an example of quality evaluation of the delivered materials. Like in the former case the "rough" - linguistic knowledge base is created with the aid of a decision table transformed into the form of rules:

```
RULE Quality_12
IF OrderFulfillment = "full" AND
ComplaintPossibility = "full"
THEN Quality = "high"

RULE Quality_13
IF OrderFulfillment = "full" AND
ComplaintPossibility = "lack"
THEN Quality = "medium"

RULE Quality_14
IF OrderFulfillment = "full" AND
ComplaintPossibility = "limited" AND
SuplierBrand = "unknow"
THEN Quality = "medium"

RULE Quality_15
IF OrderFulfillment = "full" AND
ComplaintPossibility = "limited" AND
SuplierBrand = "good"
THEN Quality = "high"
```

In this case, parameterization of rules will consist of introduction of numerical variables and appropriate rules:

```
QualityPar_0
IF DefectsRatio <= FirstDefectsBound
THEN OrderFulfillment = "full"

RULE QualityPar_1
IF DefectsRatio >= FirstDefectsBound AND
Defects_ratio <= SecondDefectsBound
THEN OrderFulfillment = "few defects"

RULE QualityPar_2
IF DefectsRatio > SecondDefectsBound
THEN OrderFulfillment = "several defects"

RULE QualityPar_3
IF ProductRange = "low cost"
THEN FirstDefectsBound = 10

RULE QualityPar_4
IF ProductRange = "low cost"
THEN SecondDefectsBound = 15

RULE QualityPar_5
IF ProductRange = "standard"
THEN FirstDefectsBound = 8

RULE QualityPar_6
IF ProductRange = "standard"
THEN SecondDefectsBound = 10

RULE QualityPar_7
IF ProductRange = "high quality"
THEN FirstDefectsBound = 4

RULE QualityPar_8
IF ProductRange = "high quality"
THEN SecondDefectsBound = 7
```

Let us notice that quality of the materials from the supplier with a nine percent level of discard will be evaluated as meeting the requirements in case their destination is a low-cost product, as "few defects" in case of "standard" products and as "several defects" for "high quality" products.

In this case, the restrictions concerning the level of the expected discards have been entered as constants in the rules. This is justified by relative permanence of these values, as well as by the fact that each of them appeared in one rule only.

The problem of modification of the way of inference, depending on certain parameters, can be more complex. Let us assume that the criteria grouped to the class "Technology" are not evaluated in case of destination of the materials on "low cost" products. In order to not complicate the universal set of rules designed for final classification of the supplier one may assume that in case of "low cost" products the parameter `Technology` is set to "good" whereas parameters `AllocatedCapacity` and `FlexibilityOfTtechnology` are not verified. Some properties of the inference engine of the Rebit system allow

one to carry out this task in a very simple way. It is enough that to the set of rules defining the value of the variable Technology and generated on the basis of appropriate decision table:

```
RULE Technology_9
IF AllocatedCapacity = "lack of data" AND
FlexibilityOfTechnology = "lack of data"
THEN Technology = "bad"

RULE Technology_10
IF AllocatedCapacity = "lack of data" AND
FlexibilityOfTechnology = "significant"
THEN Technology = "neutral"

RULE Technology_11
IF AllocatedCapacity = "lack of data" AND
FlexibilityOfTechnology = "low"
THEN Technology = "bad"
```

one adds the following rule:

```
RULE TechnologyPar_01
IF Product_range = "low cost"
THEN Technology = "good"
```

The inference engine of the Rebit system, at each stage of evaluation of the rules, searches for the least expensive (i.e. requiring the least number of "questions" for variables) path of premises confirmation. In case of rules defining the value of the variable `Technology` "the cheapest" rule will be the rule `TechnologyPar_01`. This allows the engine will always have to do with "low cost" products, it will set up the value of the variable "Technology" on "good" and will not verify the consecutive rules defining this variable.

According to the principles identical with the above presented there are constructed all rule sets which describe four partial criteria. Then one constructs superior rule set which connects partial evaluations so as the final classification of the recipient is possible. In this case, one can also take advantage of the decision table (Fig. 3).

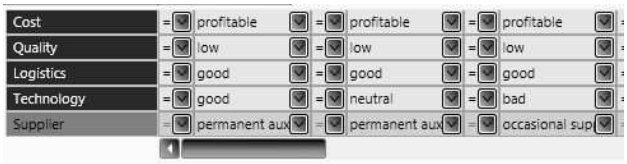

Fig. 3. Decision table for final evaluation criterion

As a result of all these actions one gets the model of knowledge composed of 146 rules.

Rebit inference engine, working in mixed mode and using this knowledgebase, allows for evaluation of each case of suppliers description in much effective way.

C. Business Application Recommendation

The interactive Rebit environment allows for creating, validation, testing and simulation of knowledge bases in a user friendly way. Although there is a possibility to use Rebit System as a standalone solution, it seems that the tighter integration of Rebit components with target environment would be more useful in cases when reasoning and knowledge base are a part of more complex business activity.

It is worth to consider two scenarios of such integration. They differ in scope and depth. The first one is based on SOA architecture of Rebit components. In this scenario rule engine acts as an external, independent component providing services for inference for a selected knowledge base. Knowledge bases may be stored in Rebit or in local repository. This scenario requires an implementation of SOA client and its integration with the target application. The main advantage of this form of integration is that the resulting system consists of loosely-coupled components which are easy to manage and update. Rebit package supports this form of integration by providing library for building a dedicated SOA client.

In the second integration scenario rule engine work as an integral part of the target application. There are two ways to communicate with the rule engine: directly or by means of inter-process communication based on pipes. Since this scenario is moving towards tight integration with the target application, it is recommended to store knowledge bases in local repository. The main limitation of this scenario is that it can only be realized on the .NET platform. As in the previous case, it is necessary to implement the client code. Rebit package provides library supporting integration based on direct access as well as the one based on pipe communication.

VI. Conclusion and Further Works

The problem of evaluation, selection and classification of suppliers is generally considered as one of the more essential issues in practice of enterprises management. Such statement is confirmed by numerous publications. On the other hand, in the organizational documentation (procedures) of all significant enterprises much attention is paid to procedures of supplier selection. Most often one can find in the literature examples of application of the AHP method and related ones, as the most effective ways of solving the problem of multi-criteria evaluation. Therefore, effective methodologies that have the capability of evaluating and continually monitoring suppliers' performance are still needed.

The above mentioned AHP method is the subject of many scientific research studies which confirm its usability and correctness. Nevertheless, there are also critical opinions. Among them the following issues are worth mentioning:

- the existence of large number of pairwise comparisons characteristic for this method brings some limitations on the number of criteria used [2],
- high degree of subjectivity of the evaluations and scale conventionality,
- lack of possibility of verification and reasoning of the evaluations resulting from numerical nature of the aggregation procedures,
- problems related to the phenomenon called rank reversal.

In majority of publications with critical approach to the AHP method a special attention is paid on the problem of objectivation of the evaluation criteria or their more flexible expression, particularly in case when the information on criteria may be deficient, uncertain and incomplete. There are proposed, inter alia, solutions basing on Fuzzy Sets Theory or Rough Sets Theory.

In our opinion an issue of much greater importance, from the point of view of the needs of the users responsible for the management processes, are these restrictions of the AHP method and similar ones which hinder expressing conscious and desirable preferences in the decision making model. While designing the management system of an enterprise as a set of rules, the manager realizes his own preferences and sees no need for their examination. Such situation is diametrically different when compared with research basing on the evaluation of external experts. Experts foresee that e.g. prices can exert influence on the efficiency of the supply greater than quality of the materials. The purchasing officer determines the weight of these criteria.

Therefore, in our opinion, the methods used in Business Rules Management Systems may be successfully applied in case of solving the problem of supplier evaluation and selection. They can be used provided that the tools are expressive enough and there is a possibility of an easy generation of useful business application. The Rebit system presented in the this paper has got these properties.

Rule based approach to the multi-criteria evaluation creates however some problems. They are related with exponentially growing number of examples which should be analyzed in case of formulating the knowledge. Solving this problem through segmentation of the evaluation on increasingly detailed partial criteria creates similar problems as in the AHP method. It is true that explicit presentation of principles of aggregation allows one to avoid most of the problems specific to the methods which, in this case, use computational procedures. Nevertheless, it is a source of flattering of the results of successive aggregation. Therefore, the target of the successive works will be examining, based on the data describing real examples of selection and their results, how big is the scale of this phenomenon and its influence on the correctness and repeatability of decision- making.

***Abstract*—One of the contemporary problems, and at the same time a big opportunity, in business networks of supply chains are the issues associated with the vast amounts of data arising there. The data may be utilized by the decision support systems in logistics; nevertheless, often there is an information integration problem. The problems with information interchange are related to issues with exchange between independently designed data systems. The networked supply chains will need appropriate IT architectures to support the cooperating business units utilizing structured and unstructured big data and the mechanisms to integrate data in heterogeneous supply chains. In this paper we analyze the capabilities of the big data technology architectures with cloud computing under usage of Linked Data in business process management in supply chains to cope with unstructured near-time data and data silos problems. We present our approach on a 4PL (Fourth-party Logistics) integrator business process example.**

I. Introduction

In the contemporary world the business companies have to face unprecedented challenges. As a result of globalization the amount of data arising in supply chains is raising, the competition is becoming fiercer and the customers often expect integrated services, what requires a close cooperation between several involved organizations. The companies have to adapt to new, such as networked, business models and rethink their role and position in their value chain regarding the potential possibilities given by the utilization of big data to add value for their customer and suppliers. This requires some changes from companies in their organizational view, but at the same time in their information technology view. The appropriate technology environment is needed to support their interoperable business cooperation.

The problem of the appropriate information technology environments for collaborative processes between business participants is twofold. Firstly, the appropriate IT infrastructure for utilization of big data is needed, and secondly, there are data 'siloes' from diverse applications. The last problem has been approached with several solutions like common IT platforms consisting of (possibly common) components based on established standards, standard enterprise information systems, and standard business protocols. Nevertheless, the IT environment platforms still contain proprietary applications like enterprise resource planning systems (ERP), customer relationship management systems (CRM), etc. The foreseen scale of collaboration between business partners may require undertaking further steps for IT environment integration, such as one of the known enterprise application integration solutions or usage of the Web services [1].

The inter-company networks are defined as complex arrays of relationships between companies, which establish these relationships by interacting with each other [2]. Whilst the markets are expanding toward inter-company networks (webs) of collaborating organizations, mentioned above IT integration solution approaches, do not seem to be sufficing and satisfactory. This level of an organizational form of the market participants requires mutual adjustment in information sharing and data management, and further a coordination of collaborative business processes of the supply chain's participants.

In the paper we will approach the problem of possibly advantageous utilization of vast amounts of data (in variety of formats) in supply chains and also the information integration issues in order to overcome the data silo problem. We will investigate the appropriate IT architectures for big data used in association of cloud computing facilities [3] and the utilization of common (open stated) data format as it is offered by Linked Data [4] for data silos integration purposes. We consider the network from a supply chain perspective with emphasis on the value-adding partnerships. The proposal of possible utilization of the Linked Data as an integration solution for business process management BPM in supply chains networks we have already presented in [5]. In this paper we investigate the usage of big data IT architectures, appropriate for supply chains in conjunction with data silos integration possibilities for supply chains on the basis of (open) Linked Data.

A supply chain is defined as a network that comprehends all the organizations and activities associated with the flow and transformation of goods, starting from raw material stage through the whole process, to the end user, as well as the associated information flow [6]. In the paper we will concentrate on the networked supply chain activities and information flow.

In the inter-organizational information systems, which link companies to their suppliers, distributors and customers, a movement of information through electronic links (e.g. XML/EDI - Extensible Markup Language/ Electronic Data Interchange) takes place across organizational boundaries

978-83-60810-53-8/$25.00

between separately owned organizations. It requires not only electronic linkage in form of basic electronic data interchange systems (as for purchase orders, delivery notes, cash flows, etc.), but also interactions between complex cash management systems or by accessing shared technical databases. So the problems with sharing and exchange of information are still viable in supply chains contexts.

The existing EDI standard [7], as message-centric solution, has limited possibilities in enabling interactions in the value chain. The representation of business processes and vocabularies in a domain to potentially automate the trading partners interactions is missing. Another important aspect regarding supply chains networks is integration of additional data from semantic Web applications into logistic systems.

A business process consists of one or more than one related activities that combined together respond to the need for a business action [6]. The processing steps in a workflow might go through numerous data transformations (geographic, technological, linguistic, syntactical and semantic transformations). Communication is an important part of the process and (e-) business processes exist within certain environments. In the dynamic business environment, such as networks of venture participants involved in logistic value chains, where coordination problems in the business process management plays the key role, the appropriate IT architecture, data amount and format, are essential.

Therefore, as stated previously in our paper, we will analyze big data architectures and Linked Data for business processes in supply chains in business networks. For this aim the rest of the paper is organized as follows.

In Section 2 we characterize main features of big data and architectural elements needed by IT infrastructures to support big data during business process management in supply chains. In Section 3 we summarize the Linked Data principles and concepts. In Section 4 we provide an example scenario for 4PL (Fourth-party Logistics) integrator managing the package delivery from Webshops in Asia to customers in Europe. We examine the possible added value resulting from usage of big data and open Linked Data elements that may possibly be useful for the purpose of decision support in supply chain networks. We will also try to show (in Section 5) how the information integration on the base of the Linked Data in conjunction with the big data IT architectures may be applied to achieve the improvement of supply chain environments. In the last Section we conclude our work.

II. Big Data

A. Big Data Features

The big scale usage of available and generated data is made possible for organizations owing to cloud computing paradigms, such as Infrastructure as a Service (IaaS), Storage as a Service (SaaS), which revolutionized the way the computing infrastructures are used [3]. Big data is referred to data that goes beyond the processing capacity of the conventional database systems. In addition to the aspect that it is big (e.g. a huge number of small transactions, or continuous data streams from sensors, mobile devices etc.) it may move too fast, or does not fit the structure of traditional (i.e. relational) database architectures. Big data also may have a low value for further usage before processing it [8].

According to [8] when we denote a big amount of data as "big data" it has to cover the three "Vs" (features) such as: volume, velocity and variety. Other authors (e.g. [9], [10]) add the fourth V-feature: value.

The first feature - volume of big data - denotes its massive character. The big volume of data is beneficial for the data analysts. It may improve the analytics models by having more cases available for forecasts and increase the number of factors to be considered in the models making them more accurate. Nevertheless, the volume bears potential challenge for IT infrastructures to deal with big amounts of data, especially when taking into account its second feature – velocity.

The second feature of big data is the velocity in which data flows into organization or the expected response time to the data. Big data may arrive quickly - in real-time, or near real-time (denoted in this paper as near-time). If data arrives too quickly the IT infrastructures of the organization may be not able to respond timely to it, or even to store all of it. Such situations may lead to data inconsistencies. We will regard further the issue of possible velocity consequences in the next section considering the suitable architectures for big data applications.

The third feature of big data is the variety of data. Big data may have diverse structures and forms, not falling into the rigid relational structures of SQL databases without loss of information. Some of data may be saved as blobs in inside traditional data bases. Therefore the IT infrastructures for big data are denoted as NoSQL, which means that data is "not only SQL" [10]. Several examples for diverse kinds of data are standard business documents, transactional records, and unstructured data in form of images, recordings, HTML documents (web pages), text and email messages, streams from meters and environment sensors, GPS tracks, click streams from Web queries, social media updates, data streams from machines' communication or wearable computing sensors, and many others.

The big data value feature denotes the need for processing it before using it in order to make it valuable for analysis purposes.

B. Big Data Architectures

In the previous section the four characteristic features of big data have been discussed. It is apparent that conventional IT structures may encounter problems with storing variety of data and immediately reacting to it. Firstly, it is because of big data amounts on unstructured data arriving in near-time. The fact that data is unstructured, or rather, it lacks a structure appropriate for storage in conventional SQL databases, implies that other solutions will be needed.

The first issue to consider is the common usage of SQL data bases. IT infrastructures in supply chains include structured data in form of OLTP (Online Transaction Processing) and OLAP (Online Analytical Processing) systems. While the traditional OLTP systems support the transactional systems with highly structured SQL databases, the OLAP sys-

tems contain aggregated historical data in form of cubes. The OLTP systems deliver simple reports, while OLAP systems (known as Data Warehouses) are suited for (traditional) business intelligence applications with reporting facilities on business statistics, performance, etc. on the basis of structured (analytical) historical data. These both databases forms are unsuitable for big data purposes. The data stored there has to have fixed structure, which is conflicting with variety of big data. The OLAP and OLTP contain only high quality data, what is not the situation in case of low value big data (on the opposite to low value big data).

Another problem arises due to the velocity of big data. For the reason that analytical OLAP systems contain only historical data, they are unsuitable for big data applications.

The rigid SQL data structures are insufficient for big data applications, but there are other OLT solutions like "NoSQL OLTP" – MongoDB, AmazonDynamo or Windows Azure Table Storage [10]. This type of database is known as the 'key-value stores' where the data is stored by key and its value is a blob and this solution is widely adopted by enterprises [3].

There is also a known solution for "NoSQL warehousing" for storing and analyzing massive data sets – Apache Hadoop [11]. The Hadoop is a framework for development of open-source software with its own highly distributed HDFS file system, MapReduce framework for writing and executing distributed algorithms and its own query languages – Hive and Pig. The Hadoop components are not only highly distributed but also high tolerant.

Another aspect of big data which is different from SQL databases, is that the results from big data analysis are immediately used and often discarded after that. If not, some bridging solutions are needed, e.g. SQQOP for connecting SQL and Hadoop [10], but they may turn inefficient. Moreover, for handling variety of big data, another solutions like dedicated XML store or graph databases are available [12].

The volume feature of big data can be handled with the usage of capacities and platforms offered by cloud computing [3]. With the pay-as-you-go and low time-to-market solutions, it became affordable even for small organizations.

The big data applications are possible as combinations of diverse technologies (products mash-ups) [12].

The volume, variety and value problems of big data can be tackled by solutions mentioned above. There still remains the dilemma with big data velocity. If data streams arrive quickly in real-time (or near-time) there may be a problem with storing them. One solution possibility would be temporary batch of data in the data pools. This problem is resolved by the Lambda architecture proposed in [13]. Its authors assume that a query is a function on the whole data pool:

```
query = function (all data)
```

Therefore Lambda is a three layers architecture with the batch layer, serving layer and speed layer (see Fig. 1).

The bottom layer (the batch layer) is dedicated to the precomputing on the whole data pool. Its two functions are storing master data set and computation of arbitrary (i.e. any) views. The batch processing principle is well known; for big data the Hadoop is a canonical example [13]. In the Lambda architecture the batch layer continuously recomputes the batch view from scratch.

The middle layer, the serving layer delivers the random accesss to batch views and also is updated by the batch layer.

The top layer, the speed layer deals only with the latest data received during running precomputations in batch layers. According to [13], it compensates for high latency of updates to the serving layer and uses fast incremental algorithms; the batch layer ultimately overrides the speed layer.

In [13], there are big data applications examples as combinations of diverse technologies (products mash-ups) and providers of big data solutions, such as SAP, Oracle, IBM, HP, etc.

With the usage of Hadoop a very fast historical data analysis will be possible based on the Hadoop file system and the MapReduce technology. Nevertheless, it would not be sufficient for some kinds of applications, because the data analysis of current incoming data would be missing. Therefore, in addition to Hadoop we may use the Complex event processing technology (CEP) [14] for dealing with the huge amounts of other real-time data incoming during the running processes. With data supplied to the system and with the appropriate rule sets a dedicated decision support system would be able to react in a suitable way in critical situations, each time when a near-real-time decision will be needed.

The main idea of the introduced concept includes two aspects: the historical context of the Hadoop data, while reacting to the current situation with the CEP technology

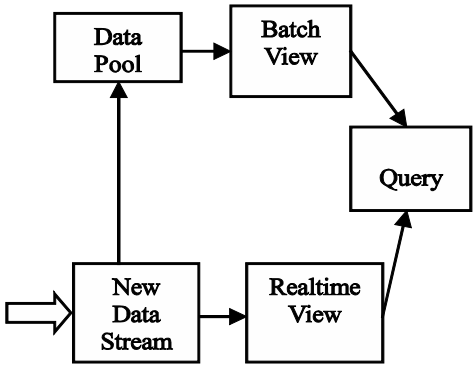

Fig. 1 Lambda architecture diagram [12]

usage. Merging of actual and historical data would add a new value in the decision making processes.

III. LINKED (PPEN) DATA

The Linked Data principles were introduced by Tim Berners-Lee at the TED 2009 presentation [15]. He outlined four rules for making human or machine-readable links for the exploration of web of data. The first rule refers to the usage of Uniform Resource Identifier URI [16] for identification of items (called "things"). The second given rule specifies that only HTTP URIs are meant, so that people can look at them and these can be found by the standard established Domain Name Space (DNS) system. The third rule was formu-

lated for the purpose of providing additional useful information for the items defined by URI. The information should be denoted in a standard format, such as Resource Description Framework RDF* [17], in form of RDF/XML or an alternative serialization (N3, Turtle). The last, fourth rule concerns providing the linkage of such described items with other related items (data), so that the related information on the Web can be discovered more easily.

The further development was the Linked *Open* Data LOD, the concept recommended by the World Wide Web Consortium W3C [4]. It is a star rating system of linked data that allows for proving to which extent the linked data can be regarded as open. The rating is formulated as a five principles scheme, where each next scheme principle extends (for the next star added) the former one by integrating an additional feature. The first principle states that the data should be available on the Web, no matter in which format, but it should be one with an open license. The second principle adds that it should be machine-readable structured data. The third principle adds that the format of the data should be a non-proprietary format. The fourth principle assumes achievement of the former three principles and additionally presumes the usage of an open W3C standard for identification of items, like RDF (RDF/XML, N3 or Turtle) or SPARQL [4] formats (SPARQL Protocol and RDF Query Language) for larger data amounts of data sets. The last principle, required for getting the five star grading assumes contextual linkage of rated data to other resources described in the same way.

IV. 4PL Integrator Example

The development in contemporary logistic networks leans toward possible outsourcing of various logistic functions or services. Further trends include possible integration of outsourced functions/services or even the outsourcing of the whole business processes. At present the dominant are so-called 3PL (Third-party Logistics) solutions [18]. At the next developmental stage the concept of the 4PL (Fourth-party Logistics) emerged. It encompasses the functions offered by a 4PL logistic provider, which is acting as an integrator, assembling the resources, capabilities and technology needed for design, building and running of the comprehensive supply chain solutions [19]. The international 4PL do not need to have their own transport [20]. They may work directly with companies offering transport, or with the 3PL providers, what includes different kinds of carriers, consolidators and forwarders such as ocean carriers, airfreight forwarders and local carriers. The 4PL govern the settlements of the agreements with all involved partners.

As an example of the ideas presented in previous Sections, we consider an example of a 4PL logistic provider which is managing the shipping of commodities bought from the Webshops located in Asia by the customers residing in Europe. The Webshops in our example are located in different Asian cities and offer toys and consumer electronics goods. Our 4PL logistic integrator outsources a warehouse (a hub) in Asia, so that he can consolidate the shipments, which are sent from different Webshops for their further transport to Europe. He also outsources space and commissioning capacity at few hubs in Europe (i.e., near London and Lyon), where the goods first arrive from Asia. The 4PL integrator operates a software platform that integrates the orders from diverse shops and processes the communication with the integrated shipping software dedicated for labeling the shipments for the European carriers. It includes up-to-datedness of the solutions (i.e., carrier-dedicated label layouts) for the European market. Thus, the carrier integration purpose of the 4PL-software fulfills one of most important roles of the 4PL.

Below we will show a standard solution, which is traditionally offered by the 4PL and in a next Section we describe an improvement bringing added value, which could be potentially achieved by the supplementary usage of big data and open Linked Data.

In the basic scenario the 4PL relies on the Webshop`s order data and on the agreements with the freight forwarders and the carriers. At first the goods are ordered by the customers in Europe, who choose a particular European carrier company while ordering products. We consider the situation of delivering of valuable, bulky goods equipped with RFID. The ordered goods are then labeled with the European carrier shipping labels by the Webshops, which download these outputs from the 4PL's IT platform. This results in every single parcel having a shipping label, which fully complies with particular European carrier labeling specification and is augmented with the corresponding Webshop logo.

In the next step the labeled shipments from a particular Webshop are consolidated on palette(s) and brought per freight forwarders to the Asian hub, where the goods are re-consolidated (individual shipments from different Webshops are packed on palettes for a particular hub in Europe) and sent overseas to appropriate European hubs. In Europe the palettes are unpacked and the individual shipments are scanned as ready for a European carrier pickup. The carrier, which was selected by the Webshop customer, will transport the goods within Europe, after they have reached European hub. The carrier's driver receives the printed list with information about the parcels he takes from the hub. At the same time electronic information with the data of the shipment is sent via EDI to the carrier system. From this moment on tracking in Europe is possible, but on the carrier website only.

A. Enhanced 4PL Scenario

The enhanced 4PL's platform scenario performs the same tasks as in the above basic scenario, but the 4PL also gathers a lot of additional data, which will be used for the improvement of the transport decisions through the route.

Every individual shipment prepared by the Webshop is tracked in the 4PL's platform, starting from the point it leaves the Webshop and is picked by the Asian freight forwarder. The freight forwarder provides GPS tracking for the road carried pallet. Further scans are made in the Asian and in the European hubs. The tracking after this point is processed through the carrier tracking system; the corresponding data is imported into the 4PL's IT platform through web service requests, sftp status file transfers or by automated

read outs of the carrier tracking website - depending on the solutions provided by the particular carrier company.

Import and analysis of tracking data from different carriers is a demanding task, which may be supported by Linked Data. Over 17 thousand status event descriptions, which are used by European carriers, can be synthesized to less than one hundred events. Thanks to the full tracking transparency the 4PL is able to collect and analyze the data, and deduct how long it takes to transport goods from point A to point B. In case of delayed shipments, which are reported in his platform in real-time, the 4PL has the possibility of picking out an additional feature such as an express route for further parcel transportation. The gathered tracking data also enables finding out the reasons for the delays, which could help avoiding these in the future.

Another important big data source gathered and analyzed by the 4PL's platform comprise the Asian weather reports and also road and airport traffic reports (available as open Linked Data). Such information is inevitable to support real-time decisions of choosing appropriate transport way (air, road) within Asia. For example, the road transport may turn faster, if the nearest airport is expected to be covered in fog for the next two days.

The 4PL may also use social media and blog data, so that the trends in popularity of e.g. the toys and electronics offered by the Webshops can be regularly observed and evaluated for different regions of Europe. Based on this information, order and transport volumes can be better forecasted, enabling preparation of appropriate transport routes (changing the agreements with the freight forwarders, carriers and warehouses/hubs) in case of forecasted booming or collapsing demand.

Among others tasks, the 4PL has to manage big amounts of data coming from the carriers and other participants in the SCM with different formats and further with diverse semantic interpretation for each identifier. For instance, each carrier has its unique scope of the services (in addition, not always available for all cases) with its own sets of identifiers and furthermore, of the possible package statuses.

Thus, there is a lot data mainly associated with the delivery status of the parcel, denoted in proprietary format. For instance the package, which has been delivered to the client, can get the status "delivered", "closed", "ready", etc. dependent on the carrier firm, etc. So the Integrator has to perform the task of mapping all the unique package status names to one standard format in order to be able to further process the associated data. This way also all the data with the same semantics gets reduced to one uniform internal name and format of the status. Broadly speaking, a company dealing with about hundred carriers in different countries has to understand about 20 thousand possible package statuses, which can be reduced by the 4PL integrator to about one hundred mapped status descriptions. These will be further needed in the supply chain EDI data exchange. The usage of the Linked Data could facilitate the mapping of the equivalent data, not only on the 4PL side, but also among other supply chain participants.

In the next Section we show the possibility of integration of logistic data by using open Linked Data facilities.

V. Data Integration With Linked Data In Value Chains

As stated at the previous Sections, the process steps in a workflow could undertake numerous transformations of data. A common format could improve the communication between the participants collaborating in the process environments and serve as a broker between SQL and NoSQL data, especially in the big data environments.

In our example, the source data acquired from a Webshop is, until delivery of the commodities to the customer, administered in the subsequent stages, changing format and being adjusted and enriched through numerous additional transformations, which are needed for accomplishment of the activities of the participants in a joint business venture.

The Semantic Web concept supports the basic idea of the Web considered as an open community sharing information around the world. As pointed out in our hypothetic Webshop parcels example, one part of the data integrated into the data exchange flow of business networks could be the data supplied into the 4PL integrator software platform from Web applications like the Geo, metrological or traffic data, partially enriched with semantic information described with RDF triples.

Since there still are no known established business solutions successfully working on the base of ontologies we consider application of Linked Data concepts as a more of a lightweight solution than the semantic description of data which is exchanged in networks connected through Internet and enriched with data from web applications like OpenStreetMap [22] or DBpedia [23].

The information assumed is to be presented as Linked Open Data, presumes that the data not in a proprietary format. Therefore it is important that the communication software (e.g. of 4PL) will support open data formats, such as CSV (Comma-separated values) [24] or transformation to such an open format.

The data exchanged between supply chain participants may be enriched with semantic information by means of the RDF graphs. At present time information is stored mostly in relational databases. There are some solutions for data transformations, i.e. Triplify for transforming of the data stored in transactional SQL databases into RDF representations [25]. Other possibilities, like object serialization or hierarchical representation, should be mapped into the graph data models. Meanwhile there are multiple semantic database implementations known, such as Triplestores, a purpose-built database type dedicated for the storage and retrieval of triples, e.g. Virtuoso [26]. In addition to queries the triples can be imported and exported using RDF or other formats.

The mapping between customized IT solutions and different data formats into the triple representation could be undertaken by means of dedicated software.

The usage of open formats with RDF-defined semantic could support easier data entries into the digital value chains. The enrichment of data with the semantic informa-

tion can help with communication and mediation between multiple points. The semantic enriched (big) data stored in an open format can be made widely available for the participants of the value chains if it could be further managed by using of cloud computing – the web-based, dynamical IT services. Cloud computing solutions moreover warrant the security on the infrastructure and data level, and also eliminate the need of initial investments in IT infrastructures and shorten the time-to-market.

The usage of open formats may considerably contribute to rising of flexibility and content transfer within supply chains, organized as webs, and simplifying the data transformation into diverse e-business standards.

The drawback of the given approach is the need of its integration into various IT solutions. To be useful it should be supported by the numerous diverse E-business standards as shown in [5].

VI. Conclusion

In the past times the vendors had to exploit earlier period's structured data (stored in SQL OLTP or OLAP systems) in order to analyze customer's attitudes and increase sales. Nowadays, a raising all-embracing connectivity with potentially all stakeholders in supply chains networks results in the possibility of accessing to all needed current data in real-time and also in getting a near-time feedback. This bears the genuine chances for almost immediate improvement of the relationships with the supply chain's stakeholders and therefore increases the agility and ability for just-in-time in reactions to the changing requirements [27]. Accordingly, the high quality decision support becomes possible, which enables achieving optimal performance.

It became feasible to take advantage of this situation facilitated owing to usage of cloud computing and big data by the organizations taking part in the supply chain networks. Nevertheless, the amassed data encountered in the supply chains demand solutions for suited processing of coexistent structured and unstructured data (NoSQL) on the base of appropriate software architectures, and also require a common base as the exchange format of the data shared and exchanged in the supply chains networks.

In the paper we have analyzed the nowadays common solutions for structured and unstructured data storage options for the decision making support. With the opportunity of big data and cloud computing technologies application, the amount of partially unstructured data increases and it needs to be taken into account while making logistic decisions the previous solutions are not enough to cope with the problem dealing with them in the real time or in the near-time.

We see big chances in using such architectures as the layered Lambda architecture (for big data processing), which was designed to cope with the near-time exploitation of big amounts of data arriving. The data exchanged in supply chains has diverse formats, therefore we further propose using an open common data format in supply chains. For an additional advantage a standard solution with Linked Data may be further enriched with semantic information for further support of supply chain collaboration.

It is expected that the application of open Linked Data may substantially support the automated extraction of the information published on the Web by using open standards and additionally describing with semantic meaning and contextual relationships of the data.

We have shown on the 4PL integrator example the need for the integration of social media data for forecasting aims. Also diverse Linked Data from Virtuoso databases can be applied in the decision making support. As a common standard for data exchange between the various IT applications interacting in the logistic value chains we have considered incorporating the semantic concepts associated with the Linked Data into the supply chain management, especially for the aims of the common format integration between the SQL data silos in the value chains using big data.

The usage of the Linked Data by a broker may contribute to the data integration and transfer speed up. The saving of the costs previously needed for the transformations between diverse formats will create the added value for the network participants.

The suggested improvements raise new possibilities for adding value in supply chains. The network effect causes that with increased number of participations the added value for the participants of the network grows.

The Lambda architecture allows merging huge amounts of historical data with near real-time data creating context-oriented data needed for reacting and appropriate responding to different situations like transport events in the logistics.

In the paper we presented the ongoing research work. In the future work the further aspects like economic evaluation of Applying Big Data and Linked Data Concepts in Supply Chain Management should be considered. Also the integration of the further open Linked Data instances from the Virtuoso databases into the supply chains may be investigated.

***Abstract*—The paper presents the concept and an outline of the implementation of a hybrid approach to supply chain modeling and optimization. Two environments mathematical programming (MP) and logic programming (LP) were integrated. The strengths of integer programming (IP) and constraint logic programming (CLP), in which constraints are treated in a different way and different methods are implemented, were combined to use the strengths of both. The proposed approach is particularly important for the decision models with an objective function and many discrete decision variables added up in multiple constraints. In order to verify the proposed approach, the optimization models were presented and implemented in both traditional mathematical programming and the hybrid environment.**

I. Introduction

A SUPPLY chain is referred to as an integrated systems which synchronizes a series of related business processes in order to acquire raw materials and parts, transform them into finished products and distribute to customers and retailers. The supply chain plays an important role in the automotive, electronics and food industries.

Huang et al. [1] studied information sharing in supply chain management. They considered and proposed four classification criteria: supply chain structure, decision level, modeling approach and shared information.

Supply chain structure: It defines the way various organizations within the supply chain are arranged and related to each other.

Decision level: Three decision levels may be distinguished in terms of the decision to be made: strategic, tactical and operational, with their corresponding period, i.e., long-term, mid-term and short-term.

Supply chain analytical modeling approach: This approach focuses on type of representation, in this case, mathematical relationships, and the aspects to be considered in the supply chain. The literature mostly describes and discusses mathematical programming-based modeling: linear programming, integer programming or mixed integer linear programming models [2]–[6]. Minimization of integrated costs is the main purpose of the models presented in the literature [6]–[10]. Maximization of revenues or sales is considered to a lesser extent [4], [11].

Shared information: Information is shared between network nodes determined by the model. This enables production, distribution, inventory and transport planning, depending on the purpose. The information sharing process is a vital aspect in an effective supply chain. The following groups of parameters are taken into account: resources, inventory, production, transport, demand, time, etc.

This paper focuses on the modeling approach to optimization problems in supply chain. A type of representation together with aspects to consider in the supply chain makes up a modeling approach. The vast majority of the works reviewed have formulated their models as linear programming (LP), integer programming (IP) and mixed integer linear programming (MILP) problems and solved them using the Operations Research methods. Nonlinear programming, multi-objective programming, fuzzy programming with stochastic programming are used much less frequently [12].

Problems related to the design, integration and management of the supply chain affect many aspects of production, distribution, warehouse management, supply chain structure, transport modes etc. Those problems are usually closely related to each other, some may influence one another to a greater or lesser extent. Because of the interconnectedness and a very large number of different constraints: resource, time, technological, and financial, the constraint–based environments are suitable for producing "natural" solutions for highly combinatorial problems. In the literature, references to modeling and optimizing supply chain problems using constraint–based environments are relatively few in number [11], [12].

A. Constraint-based environments

Constraint satisfaction problems (CSPs), constraint programming (CP) and constraint logic programming (CLP) [13]–[15] offer a very good framework for representing the knowledge and information needed to deal with supply chain problems.

Constraint satisfaction problems (CSPs) are mathematical problems defined as a set of elements whose state must satisfy a number of constraints. CSPs represent the entities in a problem as a homogeneous collection of finite constraints over variables, which are solved by constraint satisfaction methods. CSPs are the subject of intense study in both artificial intelligence and operations research, since the regularity in their formulation provides a common basis

978-83-60810-53-8/$25.00

to analyze and solve problems of many unrelated families [13]. Formally, a constraint satisfaction problem is defined as a triple (X,D,C), where X is a set of variables, D is a domain of values, and C is a set of constraints. Every constraint is in turn a pair (t,R) (usually represented as a matrix), where t is an n-tuple of variables and R is an n-ary relation on D. An evaluation of the variables is a function from the set of variables to the domain of values, $v:X \rightarrow D$. An evaluation v satisfies constraint $((x_1,\ldots,x_n),R)$ if $(v(x_1),..v(x_n)) \in R$. A solution is an evaluation that satisfies all constraints.

Constraint satisfaction problems on finite domains are typically solved using a form of search. The most used techniques are variants of backtracking, constraint propagation, and local search. Our experience as well as that of other researchers, confirms that constraint propagation is central to the process of solving a constraint problem [13], [14], [16]. Constraint propagation embeds any reasoning that consists in explicitly forbidding values or combinations of values for some decision variables of a problem because a given subset of its constraints cannot be satisfied otherwise.

CSPs are often used in constraint programming. Constraint programming is the use of constraints as a programming language to encode and solve problems. Constraint logic programming is a form of constraint programming, in which logic programming is extended to include concepts from constraint satisfaction. A constraint logic program is a logic program that contains constraints in the body of clauses. Constraints can also be present in the goal. These environments are declarative.

B. Organization and structure of the paper

In this paper, we focus on the problem of hybrid modeling and optimization of the supply chain problems in the hybrid environment. We propose a novel approach to supply chain modeling and optimization by developing integrated models and methods using the complementary strengths of MILP and CP/CLP (II, III). In this approach, both the hybrid model (V) and the hybrid framework (IV) to its efficient solution were developed.

In order to verify the proposed approach, the optimization model in mixed linear integer programming (MILP) was created and implemented in traditional (IP) and hybrid approaches. Finally, the hybrid model was optimized in the hybrid framework (V).

II. MOTIVATION

Based on [1], [2], [13], [15], [16] and our previous work [14], [17], [18] we observed some advantages and disadvantages of these environments.

An integrated approach of constraint programming (CP) and mixed integer programming (MIP) can help to solve optimization problems that are intractable with either of the two methods alone [20]–[22]. Although Operations Research (OR) and Constraint Programming (CP) have different roots, the links between the two environments have grown stronger in recent years.

Both MIP/MILP/IP and finite domain CP/CLP involve variables and constraints. However, the types of the variables and constraints that are used, and the way the constraints are solved, are different in the two approaches [23], [24].

III. STATE OF THE ART

As mentioned earlier, the vast majority of decision-making models for the problems of production, logistics, supply chain are formulated in the form of mathematical programming (MIP, MILP, IP).

Due to the structure of these models (adding together discrete decision variables in the constraints and the objective function) and a large number of discrete decision variables (integer and binary), they can only be applied to small problems. Another weakness is that only linear constraints can be used. In practice, the issues related to the production, distribution and supply chain constraints are often logical, nonlinear, etc. For these reasons the problem was formulated in a new way

In our hybrid approach to modeling and optimization supply chain problems, we proposed the environment, where:

- knowledge related to supply chain can be presented in a linear and logical constraints (implement all types of constraints of previous MILP/MIP models [18], [19] and introduce new types of constraints (logical, nonlinear, symbolic etc.));
- the optimization model solved by using the framework can be formulated as a pure MILP/MIP model, a CP/CLP model or as a hybrid model;
- the novel method of constraint propagation is introduced (obtained by transformation of the optimization model to explore its structure (feasible routes, capacities, etc.));
- constrained domains of decision variables, new constraints and values for some variables are transferred from CP/CLP to MILP/MIP;
- the efficiency of finding solutions to the problems of larger sizes is increased.

As a result, we obtained the hybrid optimization environment that ensures a better and easier way of modeling and optimization, and more effective search solution for a certain class of optimization problems. This class includes quantitative models related to costs, customer service and inventories. Models of this class are characterized by adding up many discrete decision variables in both constraints and the objective function.

IV. HYBRID OPTIMIZATION ENVIRONMENT

In order to implement all the assumptions and requirements outlined in the previous chapter, both constraint logic programming (CLP) and integer programming (MILP/MIP) had to be combined and linked.

The hybrid environment consists of MILP/CLP/Hybrid models and hybrid optimization framework to solve them (Fig. 1). The concept of this framework and its phases (P1 .. P5, G1..G3) are presented in Fig. 2.

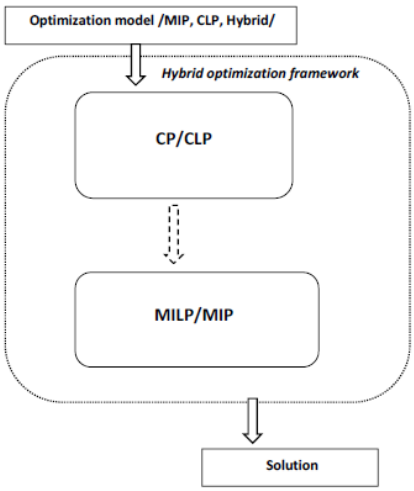

Fig. 1 Scheme of the hybrid optimization environment

The details of the hybrid environment have been discussed in [24]. The motivation was to offer the most effective tools for model–specific constraints and solution efficiency.

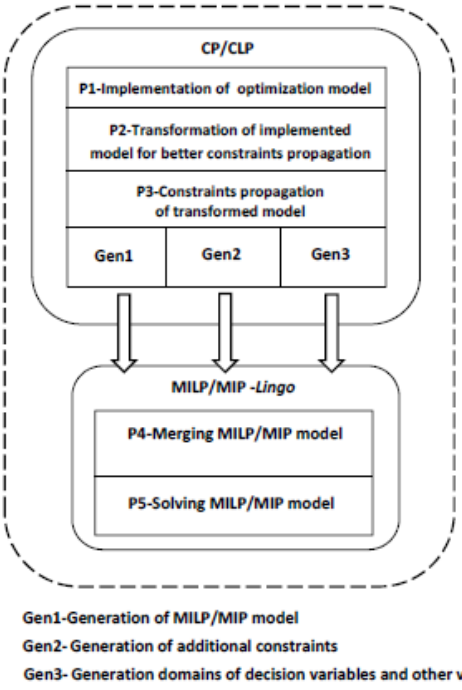

Fig. 2 Scheme of the hybrid optimization framework

The constraints propagation of the transformed model (phase–P3) largely affected the efficiency of the solution. Therefore phase P2 was introduced. During this phase, the transformation was performed using the structure and properties of the model. The details of this transformation are described in the following chapter. From a variety of tools for the implementation of the CP/CLP environment, ECLiPSe software [25] was selected. ECLiPSe is an open-source software system for the cost–effective development and deployment of constraint programming applications. Environment for the implementation of MILP/MIP was LINGO by LINDO Systems. LINGO Optimization Modeling Software is a powerful tool for building and solving mathematical optimization models [26].

V. EXAMPLES OF SUPPLY CHAIN OPTIMIZATION

The proposed HSE environment was verified and tested on two models.

First model was formulated as a mixed linear integer programming (MILP) problem [18], [19] under constraints (2) .. (23) in order to test the proposed environment (Fig. 1) against the classical integer programming environment [26]. Then the hybrid model (1) .. (25) was implemented and solved. Indices, parameters and decision variables used in the models together with their descriptions are summarized in Tab. 1. The simplified structure of the supply chain network for this model, composed of producers, distributors and customers is presented in Fig. 3.

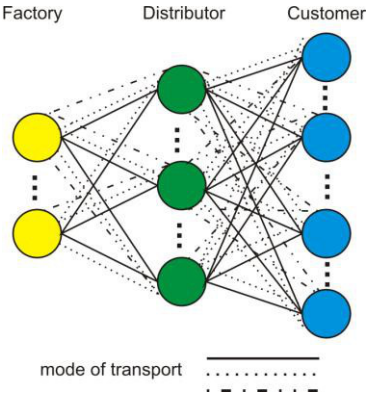

Fig. 3 The simplified structure of the supply chain network

Both models are the cost models that take into account three other types of parameters, i.e., the spatial parameters (area/volume occupied by the product, distributor capacity and capacity of transport unit), time (duration of delivery and service by distributor, etc.) and the transport mode.

The main assumptions made in the construction of these models were as follows:

- the shared information process in the supply chain consists of resources (capacity, versatility, costs), inventory (capacity, versatility, costs, time), production (capacity, versatility, costs), product (volume), transport (cost, mode, time), demand, etc;
- part of the supply chain has a structure as in Fig. 3.;
- transport is multimodal (several modes of transport, a limited number of means of transport for each mode);
- the environmental aspects of use of transport modes are taken into account;
- different products are combined in one batch of transport;
- the cost of supplies is presented in the form of a function (in this approach, linear function of fixed and variable costs);

- the models have linear or linear and logical constraints.

TABLE I
INDICES, PARAMETERS AND DECISION VARIABLES

Symbol	Description
Indices	
k	product type (k=1..O)
j	delivery point/customer/city (j=1..M)
i	manufacturer/factory (i=1..N)
s	distributor /distribution center (s=1..E)
d	mode of transport (d=1..L)
N	number of manufacturers/factories
M	number of delivery points/customers
E	number of distributors
O	number of product types
L	number of mode of transport
Input parameters	
F_s	the fixed cost of distributor/distribution center s
P_k	the area/volume occupied by product k
V_s	distributor s maximum capacity/volume
$W_{i,k}$	production capacity at factory i for product k
$C_{i,k}$	the cost of product k at factory i
$R_{s,k}$	if distributor s can deliver product k then $R_{s,k}$=1, otherwise $R_{s,k}$=0
$Tp_{s,k}$	the time needed for distributor s to prepare the shipment of product k
$Tc_{j,k}$	the cut-off time of delivery to the delivery point/customer j of product k
$Z_{j,k}$	customer demand/order j for product k
Zt_d	the number of transport units using mode of transport d
Pt_d	the capacity of transport unit using mode of transport d
$Tf_{i,s,d}$	the time of delivery from manufacturer i to distributor s using mode of transport d
$K1_{i,s,k,d}$	the variable cost of delivery of product k from manufacturer i to distributor s using mode of transport d
$R1_{i,s,d}$	if manufacturer i can deliver to distributor s using mode of transport d then $R1_{i,s,d}$=1, otherwise $R1_{i,s,d}$=0
$A_{i,s,d}$	the fixed cost of delivery from manufacturer i to distributor s using mode of transport d
$Koa_{s,j,d}$	the total cost of delivery from distributor s to customer j using mode of transport d
$Tm_{s,j,d}$	the time of delivery from distributor s to customer j using mode of transport d
$K2_{s,j,k,d}$	the variable cost of delivery of product k from distributor s to customer j using mode of transport d
$R2_{s,j,d}$	if distributor s can deliver to customer j using mode of transport d then $R2_{s,j,d}$=1, otherwise $R2_{s,j,d}$=0
$G_{s,j,d}$	the fixed cost of delivery from distributor s to customer j using mode of transport d
$Kog_{s,j,d}$	the total cost of delivery from distributor s to customer j using mode of transport d
Od_d	the environmental cost of using mode of transport d
Decision variables	
$X_{i,s,k,d}$	delivery quantity of product k from manufacturer i to distributor s using mode of transport d
$Xa_{i,s,d}$	if delivery is from manufacturer i to distributor s using mode of transport d then $Xa_{i,s,d}$=1, otherwise $Xa_{i,s,d}$=0
$Xb_{i,s,d}$	the number of courses from manufacturer i to distributor s using mode of transport d
$Y_{s,j,k,d}$	delivery quantity of product k from distributor s to customer j using mode of transport d
$Ya_{s,j,d}$	if delivery is from distributor s to customer j using mode of transport d then $Ya_{s,j,d}$ =1, otherwise $Ya_{s,j,d}$ =0
$Yb_{s,j,d}$	the number of courses from distributor s to customer j using mode of transport d
Tc_s	if distributor s participates in deliveries, then Tc_s=1, otherwise Tc_s=0
CW	Arbitrarily large constant

A. Objective function

The objective function (1) defines the aggregate costs of the entire chain and consists of five elements. The first element comprises the fixed costs associated with the operation of the distributor involved in the delivery (e.g. distribution centre, warehouse, etc.). The second element corresponds to environmental costs of using various means of transport. Those costs are dependent on the number of courses of the given means of transport, and on the other hand, on the environmental levy, which in turn may depend on the use of fossil fuels and carbon-dioxide emissions.

The third component determines the cost of the delivery from the manufacturer to the distributor. Another component is responsible for the costs of the delivery from the distributor to the end user (the store, the individual client, etc.). The last component of the objective function determines the cost of manufacturing the product by the given manufacturer.

Formulating the objective function in this manner allows comprehensive cost optimization of various aspects of supply chain management. Each subset of the objective function with the same constrains provides a subset of the optimization area and makes it much easier to search for a solution.

$$\sum_{s=1}^{E} F_s \cdot Tc_s + \sum_{d=1}^{L} Od_d \left(\sum_{i=1}^{N}\sum_{s=1}^{E} Xb_{i,s,d} + \sum_{s=1}^{E}\sum_{j=1}^{M} Yb_{j,s,d}\right) + \sum_{i=1}^{N}\sum_{s=1}^{E}\sum_{d=1}^{L} Koa_{i,s,d} + \sum_{s=1}^{E}\sum_{j=1}^{M}\sum_{d=1}^{L} Kog_{s,j,d} + \sum_{i=1}^{N}\sum_{k=1}^{O}\left(C_{ik} \cdot \sum_{s=1}^{E}\sum_{d=1}^{L} X_{i,s,k,d}\right) \quad (1)$$

B. Constraints

The model was based on constraints (2) .. (24) Constraint (2) specifies that all deliveries of product k produced by the manufacturer i and delivered to all distributors s using mode of transport d do not exceed the manufacturer's production capacity.

Constraint (3) covers all customer j demands for product k ($Z_{j,k}$) through the implementation of delivery by distributors s (the values of decision variables $Y_{i,s,k,d}$). The flow balance of each distributor s corresponds to constraint (4). The possibility of delivery is dependent on the distributor's technical capabilities - constraint (5). Time constraint (6) ensures the terms of delivery are met. Constraints (7a), (7b), (8) guarantee deliveries with available transport taken into account. Constraints (9), (10), (11) set values of decision variables based on binary variables Tc_s, $Xa_{i,s,d}$, $Ya_{s,j,d}$. Dependencies (12) and (13) represent the relationship based on which total costs are calculated. In general, these may be any linear functions. The remaining constraints (14)..(23) arise from the nature of the model (MILP).

Constraint (24) allows the distribution of exclusively one of the two selected products in the distribution center s. Similarly, constraint (25) allows the production of exclusively one of the two selected products in the factory i.

Those constraints result from technological, marketing, sales or safety reasons. Therefore, some products cannot be distributed and/or produced together. The constraint can be re-used for different pairs of product k and for some of or all

distribution centers s and factories i. A logical constraint like this cannot be easily implemented in a linear model. Only declarative application environments based on constraint satisfaction problem (CSP) make it possible to implement constraints such as (24), (25).

The addition of constraints of that type changes the model class. It is a hybrid model.

$$\sum_{s=1}^{E}\sum_{d=1}^{L} X_{i,s,k,d} \cdot R_{s,k} \le W_{i,k} \text{ for } i=1..N, k=1..O \tag{2}$$

$$\sum_{s=1}^{E}\sum_{d=1}^{L} (Y_{s,j,k,d} \cdot R_{s,k}) \ge Z_{j,k} \text{ for } j=1..M, k=1..O \tag{3}$$

$$\sum_{i=1}^{N}\sum_{d=1}^{L} X_{i,s,k,d} = \sum_{j=1}^{M}\sum_{d=1}^{L} Y_{s,j,k,d} \text{ for } s=1..E, k=1..O \tag{4}$$

$$\sum_{k=1}^{O} (P_k \cdot \sum_{i=1}^{N}\sum_{d=1}^{L} X_{i,s,k,d}) \le Tc_s \cdot V_s \text{ for } s=1..E \tag{5}$$

$$Xa_{i,s,d} \cdot Tf_{i,s,d} + Xa_{i,s,d} \cdot Tp_{s,k} + Ya_{s,j,d} \cdot Tm_{s,j,d} \le Tc_{j,k} \text{ for } i=1..N,\ s=1..E, j=1..M,\ k=1..O, d=1..L \tag{6}$$

$$R1_{i,s,d} \cdot Xb_{i,s,d} \cdot Pt_d \ge X_{i,s,k,d} \cdot P_k \text{ for } i=1..N, s=1..E, k=1..O, d=1..L \tag{7a}$$

$$Tc_s \in \{0,1\} \text{ for } s=1..E \tag{23}$$

$$\text{ExclusionD}(X_{i,s,k,d}, X_{i,s,l,d}, s) \text{ for } k \neq l,\ s=1..S \tag{24}$$

$$\text{ExclusionP}(X_{i,s,k,d}, X_{i,s,l,d}, i) \text{ for } k \neq l,\ i=1..N \tag{25}$$

C. Model transformation

Due to the nature of the decision problem (adding up decision variables and constraints involving a lot of variables), the constraint propagation efficiency decreases dramatically. Constraint propagation is one of the most important methods in CLP affecting the efficiency and effectiveness of the CLP and hybrid optimization environment (Fig. 1). For that reason, research into more efficient and more effective methods of constraint propagation was conducted. The results included different representation of the problem and the manner of its implementation. The classical problem modeling in the CLP environment consists in building a set of predicates with parameters. Each CLP predicate has a corresponding multi-dimensional vector representation. While modeling both problems, (1) .. (23) and (1) .. (25), quantities i, s, k, d and decision variable $X_{i,s,k,d}$ were vector parameters. The process of finding the solution may consist in using the constraints propagation methods, labeling of variables and the backtracking mechanism. The quality of constraints propagation and the number of backtrackings are affected to a high extent by the number of parameters that must be specified/labeled in the given predicate/vector. In both models presented above, the classical problem representation included five parameters: i, s, k, d and $X_{i,s,k,d}$. Considering the domain size of each parameter, the process is complex and time-consuming. Our idea was to transform the problem by changing its representation without changing the very problem. All permissible routes were first generated based on the fixed data and a set of orders, then the specific values of parameters i, s, k, d were assigned to each of the routes. In this way, only decision variables $X_{i,s,k,d}$ (deliveries) had to be specified. This transformation fundamentally improved the efficiency of the constraint propagation and reduced the number of backtracks. A route model is a name adopted for the models that underwent the transformation.

D. Decision-making support

The proposed models can support decision-making in the following areas:

- the optimization of total cost of the supply chain (objective function, decision variables-Appendix A2);
- the selection of the transport fleet number, capacity and modes for specific total costs;
- the sizing of distributor warehouses and the study of their impact on the overall costs (Appendix A3, Fig. 4, Fig. 5, Tab. V);
- the selection of transport routes for optimal total cost.

Detailed studies of these topics are being conducted and will be described in our future articles. We use the hybrid approach to both modeling and solving.

VI. NUMERICAL EXPERIMENTS

In order to verify and evaluate the proposed approach, many numerical experiments were performed. All the examples relate to the supply chain with two manufacturers (i=1..2), three distributors (s=1..3), five customers (j=1..5), three modes of transport (d=1..3), and ten types of products (k=1..10). Experiments began with three examples of P1, P2, P3 for the optimization MILP model (1) .. (23). The examples differ in terms of capacity available to the distributors s (V_s), the number of transport units using the mode of transport d (Zt_d) and the number of orders (No). The first series of experiments was designed to show the benefits and advantages of the hybrid approach. For this purpose the

model (1) .. (23) was implemented in both the hybrid and integer programming environments. In addition, hybrid implementation of the transformed model was performed with and without constraint propagation, (MILPT2) and (MILPT1), respectively. The experiments that follow were conducted to optimize examples P4, P5, which are implementations of the model (1) .. (25) for the hybrid approach. Examples P4, P5 were obtained from P1, P3 by the addition of logical constraints (24), (25).

Numeric data of input parameters for examples P1, P2, P3, P4, P5 are shown in Appendix A1. The results in the form of the objective function and the computation time are shown in Table II. Other results including the decision variables for the optimal value of the objective function are given in Appendix A2.

TABLE II
THE RESULTS OF NUMERICAL EXAMPLES FOR BOTH APPROACHES

P(No)	Hybrid				Integer Programming	
	MILPT1		MILPT2		MILP	
	Fc	T	Fc	T	Fc	T
P1(10)	22401*	600**	22394^{O}	18	22404*	600**
P2(10)	21167*	600**	21142^{O}	150	21343*	600**
P3(20)	45654^{O}	95	45654^{O}	8	45710*	600**

P(No)	MH	
	Fc	T
P4(10)	22397^{O}	255
P5(20)	46419^{O}	43

Fc	the value of the objective function
T	time of finding solution (in seconds)
^{O}	the optimal value of the objective function after the time T
*****	the feasible value of the objective function after the time T
****	calculation was stopped after 600 s
MILP	MILP model implementation in the IP environment.
MILPT1	MILP model after transformation - implementation in the hybrid optimization framework without phase P3
MILPT2	MILP model after transformation-implementation in the hybrid optimization framework.
MH	Hybrid model after transformation-implementation in the hybrid optimization framework.

For each example the solution for the MILPT2 implementation was found faster than that for the MILP implementation. Moreover, for examples P1 .. P3, the traditional approach based on integer programming gives only feasible solution (calculation was stopped after 600 s) despite using highly efficient LINGO solvers. It is obvious that the solution of the hybrid model (MH) was, due to its nature, only possible using the hybrid environment. Also, the proposed environment brought the expected results. The results were obtained in only a slightly longer period of time than that necessary for examples P1 and P3.

VII. CONCLUSION

The efficiency of the proposed approach is based on the reduction of the combinatorial problem. This means that using the hybrid approach practically for all models of this class, the same or better solutions are found faster (the optimal instead of the feasible solutions). Another element contributing to the high efficiency of the method is a possibility to determine the values or ranges of values for some of the decision variables (phase P3). All effective LINGO solvers can be used in the hybrid method.

Therefore, the proposed solution is highly recommended for all types of decision problems in supply chain or for other problems with similar structure. This structure is characterized by the constraints of many discrete decision variables and their summation. Furthermore, this method can model and solve problems with logical constraints.

Further work will focus on running the optimization models with non-linear and other logical constraints, multi-objective, uncertainty etc. in the hybrid optimization framework.

19th Conference on Knowledge Acquisition and Management

We have the pleasure to invite you to contribute to and participate in the conference "Knowledge Acquisition and Management" (KAM'2012). The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. The aim of the conference is to create possibility of presenting and discussing approaches, methods, techniques and tools in the knowledge acquisition and the knowledge management areas. We expect that the conference will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge acquisition and management processes.

Topics

The following group topics, concerning both theory and applications, will be included (unavoidably incomplete):

- Data mining and knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching
- Knowledge diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution
- Knowledge grid and social networks
- Knowledge modeling and visualization
- Knowledge management and e-government
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual agents

Event Chairs

***Abstract*—One of the challenges of knowledge management is handling inconsistency. Traditionally, it was often perceived as indication of invalid data or behavior and as such should be avoided or eliminated. However, there are also numerous situations where inconsistency is a natural phenomena or carry useful information. In order to decide how to manage inconsistent knowledge, it is thus important to recognize its origin, aspect and influence on the behavior of the system. In this paper, we analyze a case of collaborative knowledge management with hybrid knowledge representation. This serves as a starting point for a discussion about various types of inconsistencies and approaches to handle it. We analyze sources, interpretation and possible approaches to identified types of inconsistencies. We discuss practical use cases to illustrate selected approaches.**

I. Introduction

INCONSISTENCY, defined in various sources as inability for all conceived statements or beliefs to be simultaneously true, is a major issue in knowledge management (KM). Contradiction, often used as a synonym, is an especially strong kind of inconsistency between sentences such that one sentence must be true and the other must be false [1].

Inconsistency management has found application in various areas including: knowlege-based systems analysis [2], [3] and verification [4], multiagent systems, information retrieval, recommender systems, and intelligent tutoring systems [5].

While inconsistency of data is usually undesirable, inconsistency of knowledge constitutes a more complex challenge [6]. Firstly, it is not always easy to discover, because it may appear on different levels of knowledge representation and reasoning. Secondly, in distributed and dynamic environments, it may be a natural phenomena that carry useful information.

There exist various approaches to handle inconsistency [7], [8], from elimination, through consensus methods [5], [9] and argumentation frameworks [10], [11], up to paraconsistent reasoning tolerating inconsistent information [12]. Sometimes it is useful to first measure the inconsistency [13], [14] and based on the results decide what to do with it [15], [16].

In our research, we analyze inconsistency in a collaborative knowledge management environment (see Fig. 1). With the rapid development of new technologies, collaborative environments for knowledge management become increasingly complex. Knowledge in such environments is represented with use of diversified formal, semi-formal and informal methods [18].

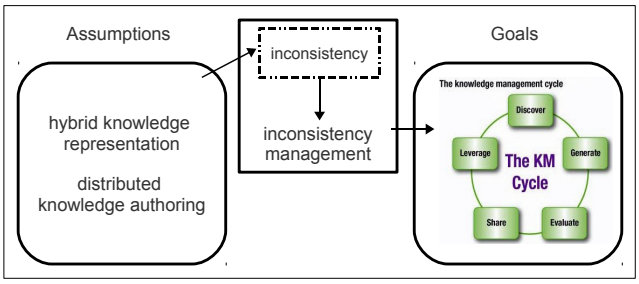

Figure 1. Inconsistency in Collaborative Knowledge Management (the knowledge management cycle as in [17]).

In this work, we concentrate on knowledge representation with Semantic Web technologies. Within this area, we investigate:

- Challenges and problems related to inconsistency,
- Sources of inconsistency, and
- Approaches to handle inconsistency.

This paper is organized as follows: Motivation for our research is given in Section II. Theoretical background of handling inconsistency is outlined in Section III. Selected problems and approaches to handle inconsistency on the Semantic Web are then discussed in Section IV. In Section V, an analysis of the approaches with respect to knowledge management is given. Use case scenarios are presented in Section VI. The paper is concluded in Section VII.

II. Motivation

Motivation for research presented in this work stems from the experiences of BIMLOQ[1] and INDECT [19], [20] research projects. The former was focused on quality of knowledge represented with business processes, rules and semantics. Within the latter a collaborative knowledge management environment was developed that used semantic technologies and social features to foster collaboration. The projects revealed the importance of practical challenges of inconsistency in knowledge management, related specifically to:

1) Dynamics of the system (integration, revision, merge),
2) Distributed knowledge authoring, and
3) Different methods of knowledge representation.

[1]See http://bimloq.ia.agh.edu.pl.

978-83-60810-53-8/$25.00

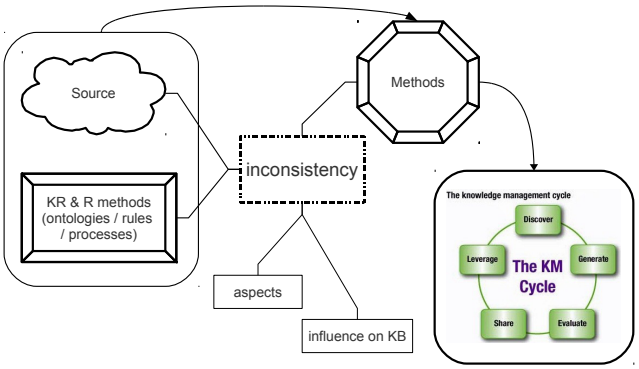

Figure 2. Map of areas for inconsistency analysis.

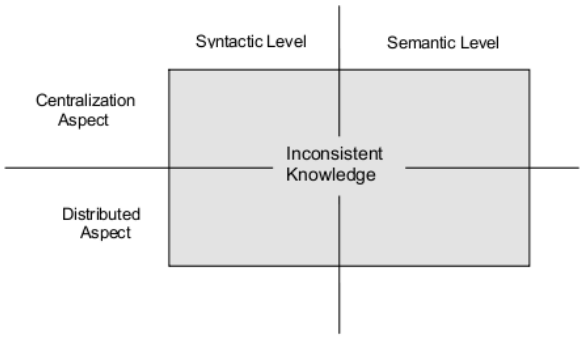

Figure 3. Aspects and levels of inconsistency [29].

Therefore, when considering a collaborative knowledge management environment with hybrid knowledge representation we aim to analyze (see Fig. 2):

1) How knowledge representation influence inconsistency?
2) What are the sources of inconsistency in selected areas?
3) What are possible approaches to handle it?

Our basic testing platform is a semantic knowledge-based wiki that supports semantic technologies and rule-based reasoning [21]. Semantic wikis proved to be useful in collaborative knowledge management and engineering [22]. They constitute a flexible tool for knowledge representation and reasoning [23], as well as distributed knowledge acquisition [24]. Our implementation supports semantic technologies and rule-based reasoning. Combining different method of knowledge representation within a semantic wiki have been proposed by authors in several works: business processes with rules [25], and rules with semantics [26], [27]. There are ongoing works on integrating semantics with business processes [28].

Currently, the system (available at http://loki.ia.agh.edu.pl) is not equipped with any mechanisms for handling inconsistencies. Ultimately, we aim to develop a system that will allow for knowledge representation with semantic technologies, rules and business processes, able to deal with inconsistency.

We claim that in such an environment handling inconsistency is a complex challenge and one should consider methods that *accept* it rather than eliminate. In the following section, we briefly review selected concepts, approaches and theoretical bases for the problem of inconsistency. This is the starting point for more detailed and focused review given in Section IV. In this paper, we analyze the case of the Semantic Web technologies and present selected approaches to deal with inconsistent knowledge.

III. Theoretical Foundations

A. Vocabulary related to Inconsistency

When talking about *inconsistency*, one can find several definitions and interpretations of the core terms used in the area. Here we assume the following definitions:

- Inconsistency – when set of sentences or beliefs cannot be true at the same time or under the same interpretation
- Contradiction – when having two sentences or beliefs if one is true, then the other cannot be true,
- Paraconsistency – way of amending classical logic to be able to reason (conclude meaningful statements) in presence of inconsistency (ECQ does not hold).

B. Aspects and Levels of Inconsistency

One can consider different aspects and levels of inconsistency (see Fig. 3). In *distribution aspect*, basic cause of inconsistency is the independence of knowledge agents or knowledge processing mechanisms, while in *centralization aspect* inconsistency is related to dynamic changes of a world.

Inconsistency can be identified and processed on a *syntactic* and *semantic* level [29]. Analogously, inconsistency can be checked for in a purely *logical* way (e.g. p and $\neg p$ are present in the knowledge under discourse), or as *material* inconsistency, when two pieces of knowledge are invalid together due to the assumed interpretation [30].

Taking into consideration possible actions in the presence of inconsistency, one may take a *actual-contradictions* view or *potential-contradictions* view [7]. The former assumes that contradictions can appear in a knowledge base and no ”degenerate” reasoning should occur when contradictory statements are jointly asserted. Every statement should be treated equally. However there are two main approaches: First is that contradictions are ”bad”: if they appear, then reasoning collapses and results are trivial. The other is that the contradictions arise naturally and can be more informative than any consistent revision of the theory. Potential-contradictions view claims that contradictions do not actually exist, so there are either some statements ”responsible” for the inconsistency or the contradictions can be resolved by using argumentation. Concrete realization of potential condradictions view is in defeasible reasoning.

C. Formal Representation of Inconsistency

In order to formalize inconsistency handling in logic, there must be a formal representation of inconsistency itself. In [7], where logics are defined as ”formal systems consisting of a language L (in the form of a set of formulas) on which

an inference operation C is defined." three approaches to represent inconsistency are distinguished:

- *C-scheme*: to relate contradictions to inference, stating that inconsistency arises when all formulas are inferred,
- *A-scheme*: to pick a subset of the language, and use each element of the subset as a representation of absurdity, and
- *N-scheme*: contradictions are captured through an auxiliary notion of negation ($A, \neg A$ or $A \wedge \neg A$ if conjunction is available, is a syntactical account for inconsistency).

Inconsistency may be also represented in a form of *conflict profiles* as explained in [5]. Finally, contradictions can be *incorporated* into the formal logic by augmenting the classical logic. One of the most successful is Belnap's 4-valued logic [31] in which we can represent a statement that can be inferred to be true and false at the same time. This logic has been successfully used in the context of DL ontologies as will be shown in Section IV-B.

IV. Inconsistency on the Semantic Web

Semantic technologies are used to represent and process data, information and knowledge on several abstraction levels. Relations between objects are described with RDF [32] and simple classification can be done in RDFS [33]. Ontologies constitute the main method of knowledge representation. Integration with rules as well as incorporation of them within ontologies is an active research area. Inconsistency can be therefore considered on various levels as presented in the following subsections.

A. Inconsistency in RDF/S

RDF allows to describe objects by means of statements about their attributes and relations to other objects. The statements build a graph representing positive knowledge about the conceived world. In order to ascribe a category and build simple taxonomies, RDF Schema was introduced. It supports basic relation that define the *type* of an object, *domain* and *range* of certain relations etc. Reasoning in RDF/S is based on their defined semantics and set of entailment rules.

In order to avoid inconsistency, it was not allowed to use explicit negation in RDF/S. Open World Assumption that traditionally holds on the Semantic Web means that if something is not stated, it does not mean that it is not true. However, despite this restriction, there still exist inconsistent RDFS statements, e.g., ones that violate domain/range restrictions.

To deal with inconsistency, Extended RDF (ERDF) [34] has been proposed. Its semantics is based on *partial logic* that allows to express both *strong* and *weak* negation and can support reasoning with Closed-World Assumption as well as Open-World Assumption (this can be set by author of a semantic knowledge base). Stable model semantics of Extended RDF (ERDF) ontologies has also been proposed.

The approach is realized in MWeb framework[2]. The tool uses *restricted propagation of local inconsistencies*, making it possible to reasoning even in the presence of an inconsistency, local to a Web rule base and reasoning mode.

[2]See http://centria.di.fct.unl.pt/~cd/mweb/.

B. Inconsistent Ontologies

Formal ontologies, understood as logical theories, should typically be consistent. However, there are different situations where inconsistency may appear.

1) Problems and Sources of Inconsistency: Several problems related to inconsistent ontologies are distinguished [35]: ontology mismatch and conflict, ontology merging, and integration. Two former are related to specific relations between two or more ontologies. Two latter refer to some activities performed on ontologies. Main scenarios for a formation of inconsistency are given in [36]:

- *Multiple sources*, for example if the ontology is built by several authors, or during such processes as merging, integrating and aligning ontologies.
- *Mis-representation of defaults*, for instance if a more general concept is inconsistent with more specific facts.
- *Moving from other formalism*, for example if in the target formalism there are restrictions that make the translated information contradictory.
- *Polysemy*, if the same name refers to different concepts with inconsistent definitions.

2) Inconsistency Levels: Differences between ontologies may appear on various levels. While instances can be identified on the physical level (referring to their being in the real world), concepts are identified only on the logical one, that is referring to their names and structures. Nguyen [35] distinguishes the following levels of inconsistency between ontologies (called *ontology conflicts*):

- *Inconsistency on the instance level*: the same instance belonging to different ontologies does not satisfy the instance integration condition which states that if the instance is described differently in different concepts then in referring to the same attributes they should have the same value.
- *Inconsistency on the concept level*: There are several concepts with the same name having different structures in different ontologies.
- *Inconsistency on the relation level*: Between the same two concepts there are inconsistent relations in different ontologies.

3) Selected Approaches to Handle Inconsistency: Several approaches to inconsistency have been adapted for ontologies. On the one hand, inconsistency in ontologies can be diagnosed and repaired before reasoning [37] (including forgetting-based approach [38]). On the other, one can use conflicts to generate new knowledge or perform meaningful reasoning over inconsistent ontologies. Sometimes, it is not practical or even possible to resolve inconsistency (due to the access restrictions or possible information loss). The following examples illustrate selected approaches that seems especially suitable for collaborative knowledge management:

a) Consensus-based methods: Consensus-based methods have been discussed in [35] as a way to resolve inconsistency during ontology integration. Algorithms to determine a consensus on the instance, concept and relation level have

been proposed. For a set of different versions of data (so called *conflict profile*) they determine such a version that best represents the given versions.

b) Argumentative frameworks: Argumentative framework for reasoning with inconsistent DL ontologies has been proposed in [10], [11]. The proposal involves expressing DL ontologies as Defeasible Logic Programs (DeLP). Once a query is posed to an inconsistent ontology, a dialectical analysis on a DeLP program (obtained from such ontology) is performed and all arguments in favor and against the final answer of the query are taken into account [10].

c) Selecting consistent subsets: This approach, introduced in [36] and extended in [39] is based on selecting consistent sub-theories from inconsistent ontologies using selection functions based on syntactic [36] or semantic [39] relevance. Reasoning is then executed on the consistent subset and if a satisfying answer cannot be found, the sub-theory is appropriately extended. In [40], minimal inconsistent sets (MIS) and a resolution method are proposed to improve the run-time performance of the inconsistency reasoner. The approaches have been implemented in PION (Processing Inconsistency ONtologies) tool within the LarKC project.[3]

d) Paraconsistent reasoning: One can also extend the classical logic for OWL (Description Logics are subsets of First Order Logic) to many-valued paraconsistent logic. A proposal of representing inconsistent ontologies with 4-valued logic has been proposed in [41], [42]. In this approach, two additional truth values, namely *underdefined* and *overdefined* (i.e. contradictory) are used. Thanks to the mapping between the logics, it is possible to use classical OWL reasoners to operate on inconsistent knowledge. This idea has been implemented in RaDON NeoN Toolkit Plugin.

V. Analysis and Discussion

Traditionally, in analysis and verification of knowledge-based systems, inconsistency was undesirable and negatively influenced the quality of a knowledge. With the advent of modern Web-based environments, collaborative knowledge management becomes vital. Inconsistency in such environments seems unavoidable. It can be considered in distribution and centralization aspect, i.e., related to the multiple sources or dynamic changes over time. Inconsistency may be discovered during a process of knowledge integration, e.g. ontology aligning or merging, or observed in a static knowledge base, e.g., a fact base may contain inconsistent statements.

Even within the narrowed field of knowledge representation with Semantic Web technologies, there exist various approaches to handle inconsistency that partially depend on the representation level. In case of RDF/S, the knowledge base consists of positive statements, assertions with limited semantics. Inconsistency here is closely linked to the issue of negation. ERDF aims to solve this problem by introducing strong and weak negation into the language and allowing the knowledge engineer to state whether Closed- or Open-World Assumption should be adopted. OWL Ontologies are logical theories based on formal logic. If classical semantics is adopted, then inconsistency make them unusable and thus should be suppressed, e.g., by consensus finding or repairing methods. However, if the semantics is re-defined, one can tolerate and represent inconsistent information e.g., by using one of paraconsistent logics.

Particular phases of knowledge management cycle [17], poses various challenges related to inconsistency, including:

- *Discover*: information fusion from multiple sources, independent experts, independent knowledge processing,
- *Generate*: various views or opinions expressed in mutually inconsistent concept descriptions, self-contradictions,
- *Evaluate*: measuring inconsistency, meaningful query answering and reasoning in inconsistent knowledge bases,
- *Share*: merging, aligning, integrating knowledge,
- *Leverage*: searching for a consensus or argumentation.

Circumstances in which inconsistency appears and the level of knowledge representation it affects may have a deciding influence on the method one will choose to manage the inconsistency. Selected approaches, presented in this paper and summarized in Table I, illustrate various aspects and scenarios that may be adapted in collaborative knowledge management.

VI. Use Case Examples

In this section, we present selected use cases of handling inconsistency in collaborative knowledge management. Let us consider a semantic wiki with underlying logical knowledge representation that supports semantic technologies, rule-based reasoning and business process modeling [21], [23], [28].

A. Collaborative Ontology Development

In this case, autonomous experts jointly model a single knowledge base (e.g. an ontology). During the process, the ontology becomes inconsistent.

1) Case: Inconsistency on relation/concept/instance level.

2) Source of the Inconsistency: Distributed authoring.

3) Interpretation of the Inconsistency: Authors may have different opinions or diversified knowledge about the subject.

4) Suggested Approach: If classical semantics is adopted, consistency should be regained. Consensus methods (taking into account different opinions) or argumentation framework (identifying the best option) could be used to resolve conflicts.

B. Collaborative Recommendation System

In this case, autonomous knowledge agents independently assert their opinions and ratings about movies in the system.

1) Case: Pieces of knowledge (facts) are inconsistent.

2) Source of the Inconsistency: Distributed authoring / Dynamic updates.

3) Interpretation of the Inconsistency: Authors may have different opinions and there is no way to arbitrarily say which one is good and which one should be eliminated. / Authors add, remove or change their opinions over time.

4) Suggested Approach: Inconsistency should be accepted (all opinions should be represented, regardless of contradictions). Paraconsistent reasoning, e.g. using four-valued logic could be used.

VII. SUMMARY AND FUTURE WORK

Collaborative Knowledge Management poses numerous challenges related to inconsistency. It may result from the distributed authoring as well as dynamic changes of the world and the system. Inconsistency may be considered on a purely syntactic level or on a level where the semantics play a significant role. While in some situations inconsistency signals erratic data or behavior and should be resolved, sometimes it is natural or even useful. In order to apply appropriate technique to handle inconsistency, it is necessary to recognize and understand its origin and influence on the system. In this paper, we analyzed inconsistency in collaborative knowledge management. We presented selected problems of inconsistency and approaches to handle it.

In order to build a comprehensive collaborative environment with hybrid knowledge representation that is capable of handling various sorts of inconsistency, we consistently investigate each area of considered knowledge representation (see Fig. 4). In this paper, we have analyzed the area of Semantic Web taking into account various levels of knowledge representation and different situations in which inconsistency may arise.

In future, we plan to analyze inconsistency handling in rule-based systems [43], [44], business processes, and Multi-Context Systems [45]. Quality of knowledge will also be addressed, taking into consideration Information Quality criteria.

Internet as the Source for Acquiring the Medical Information

Magdalena Czerwińska
Lublin University of Technology
ul. Nadbystrzycka 38, 20-618
Lublin, Poland
Email: m.czerwinska@pollub.pl

***Abstract*—The purpose of the present paper is to discuss the results of research conducted in 2012 in order to determine the role of Internet as the source for acquiring the medical information in a group of students. Obtained results confirm the assumed working hypothesis about big role of Internet as the source of medical information that the searching for medical information in Internet is the principal sign of the use of ICT solutions in health protection (as one of e-health elements). It has been examined what kind of information is searched by the patients, what Internet sources are used, what is the reason of the searching for medical information in Internet, what are the barriers encountered by the patients. Details are included in this paper.**

I. Introduction

IN contemporary world, information and communication technologies (ICT) become more and more popular and are used in almost all areas of human activity. E – trade, bank transactions (e-banking), communication (e-mail and mobile telephony), e-learning etc. are the examples of specific applications. The information and communication technologies can be also successfully used in the health care systems and in the whole sector associated with medical services. Thanks to the development of computer technologies and Internet it was possible to create new possibilities for doctor, health service managers and the patients. In case of patients, it is possible to apply e-health tools in services addressed directly to this group (electronic health accounts, medical information and education accounts, Internet pharmacies). E-health is one of the most significant and complex types of e-business [1-4].

As a result of the creation of Internet network we have been introduced into the period of "information society". Continuously increasing amount of media messages (information) is perceived by an average recipient like "information noise" generally occurring in mass-media, particularly in Internet [5]. Therefore the evaluation, selection and conscious choice of valuable, credible and reliable information is an extremely important ability today [6].

Internet became one of essential sources of medical and health information [7]. Said information is quickly and easily accessible in network resources. However their quality, reliability and credibility may give rise to many concerns [8]. Therefore the use of media for pro-health education should be associated with the formation of a positive but simultaneously critical attitude toward media messages.

Because the Internet more and more frequently is used as a serious and often the first source of information about diseases and health, the reliability of information available on the Internet is problematic [9]. The growing role of the Internet as a source of medical information and the quality of the information is highlighted in the literature [10–17]. Another alarming phenomenon is the use of information obtained on-line instead of real doctor's visit.

Increasing group of Internet users search on line for the medical information concerning healthy style of life, nutrition, diseases and their treatment. Internet health services constitute a dynamically developing sector – five years ago they have been visited by every fifth Internet user and currently by the every other [18].

The spectrum of proposals offered in that scope by the Internet is very wide: encompasses comprehensive information about the symptoms of diseases and their treatment, possibility of consultation with the specialist or exchange of experience with other patients, searching of location of medical entities, checking of patients opinions about specified doctor or entity, possibility of drugs purchase etc. without the necessity to leave home.

The fact that the Internet is often used by the Internet users as the source of information about health has been showed by studies carried out in a narrow local scope as well as studies on international level for example Global Health Survey 2011 – the studies carried out in 28 countries worldwide by research institutes associated in Iris network (International Research Institutions). The survey was carried out on population consisting of 22493 adults between August and October 2011 by means of diversified research methods: online questionnaires, CATI and direct interviews. The following countries participated in the survey: Ireland, Hungary, Slovenia, United Kingdom, Finland, Poland, Holland, Lithuania, Greece, France, Romania, Germany, Turkey, Russia, Italy, Ukraine, USA, Chile, Canada, Columbia, Thailand, Indonesia, Pakistan, Malaysia, China, India, Egypt, Australia. In Poland, the survey was completed by ARC Rynek and Opinia on the group consisting of 812 respondents.

The information on health is increasingly popular among Internet users – and searched more often than information concerning the culture and entertainment. The searching spectrum is very wide (information about diseases, their symptoms and treatment, opinions about doctors and medical entities, services offered by the entities, consultations

978-83-60810-53-8/$25.00

with specialists and other Internet users, healthy style of life, diet etc.). Acquired knowledge is very often used by the Internet users in practice. Particular attention deserves huge impact of opinions expressed by other persons not associated with medical sector on behaviours associated with the health and treatment – as many as 63% Internet users declare that they search for the opinions of other Internet users who had similar problem [19]. Obtained result have been also confirmed by the studies carried out for the needs of the present article where analogical indicator was equal to 59.6%.

The searching for information about health by the patient out of the doctor's office is nothing new. Only the alternative information sources are changed. Before the family, friends, neighbours were the information sources. Currently, in the period of ICT technology and society development, such role is performed by Internet. Its character is more anonymous. The knowledge obtained from Interned is verified by a part of patients in course of their visit in doctor's office. Unfortunately, some patients use the information found in the network without contacting the doctor and try to cure themselves. It is not problematic in case of minor diseases but is very alarming and negative phenomenon in case of major health problems. The quality of obtained information is also important. The functioning of specialized portals and forums dedicated for specific diseases should be evaluated positively, because they are visited not only by the patients but also by high class medical specialists and can be used as the source of reliable, useful and practical information.

II. Results of Empirical Research

The present article is an attempt to examine the role of Internet as the source of medical information.

The purpose of conducted research was to determine the types of information searched for by the patients, the kinds of Internet sources used, the reasons of medical information searching in the Internet and the barriers encountered by them. The intention of the author was to determine the attitudes and opinions concerning the acceptance of Internet as the source of medical information, the inclination to use this type of solution and awareness of importance of and potential benefits from the information obtained this way.

A. Own research methodology

The results presented herein constitute a fragment of wider studies concerning the social awareness, level of knowledge and perception of e-health.

The respondents group consisted of students subdivided into two groups. The members of the first group were the full-time students of public health field of study in the Medical University in Lublin (MU) and the members of the second group were the students of extramural management studies in Lublin University of Technology (PL).

The first group of respondents has been selected due to the fact that they will employed in the environment associated with the rendering of medical services in future and that they will among others responsible for efficient implementation of e-health applications and for use of Internet for the needs associated with medical services. Because e-health is the future of medical services, future doctors, health service managers as well as the patients will be to some extent "sen-

Source: own study on the basis of conducted research

tenced" to functioning in virtual environment. Therefore it seems to be interesting to examine among others how is e-health perceived by the students of medical disciplines, what is their knowledge and awareness in that field and what are their attitudes to Internet as the source of medical information.

Obtained results have been compared with those obtained from the group of students in Lublin University of Technology in order to check whether the professional profile of the respondent diversifies the respondents attitudes to Internet as the source of medical information.

The survey was conducted in the both groups in June 2012. The size of each group of respondents was identical and equal to 47 persons. A structured questionnaire form containing the open and closed questions has been used as the research tool (41 questions in the main questionnaire form and 6 questions in demographics).

B. Profile of respondents

The social and demographic features of the respondents are presented in Table I. The women were prevailing group in the survey (64.9%) i.e. in the group of students in the Medical University in Lublin (59.6%) as well as in the group of students in Lublin University of Technology (70.2%). More than one third of respondents were the members of four persons household (35.1%). 55.3% respondents have a regular job. It is obvious that the percentage of working respondents was higher in the group of students of extramural management studies (PL) and was equal to 70.2%. The inhabitants of Lublin prevailed in the group of full-time students (MU) (61.7%) and the students of extramural management studies came from the rural areas (49%).

C. Use of the Internet for health purposes

The place and intensity of the use of Internet network as well as aims of its use in the context of medical information searching were analyzed in examined group of students. The intensity has been determined through the frequency and the period of experience in the use of Internet network. There is no significant difference in the scope of a/m indicators between the students of Medical University and Lublin University of Technology.

Table II contains the information about the use of computers and Internet by the respondents. All respondents have their own computers and are active users of Internet. Majority of respondents use the Internet everyday (77.7%). Almost one fourth of respondents gained more than 10 years' experience in the use of Internet. Mainly the following places of Internet use are specified: home (90.4%), work place (40.4%), university (24.5%) and the use in any place by means of wireless access (24.5%). 93.6% of respondents evaluated their skills associated with the use of computers and Internet as good or very good. The students of Medical University were more critical in their assessments. Part of them evaluated their skills as sufficient (10.6%) or poor (2.1%).

Internet is used by the respondents mainly for searching of information about health, diseases and treatment methods. Therefore it is used by 89.4% of respondents from MU and 80.9% of respondents from Lublin University of Technol-

ogy. The aims of the use of Internet are presented in Table III. Obtained results confirmed the studies [20], carried out previously and demonstrating that e-health mainly consists in searching the information concerning the health and healthy style of life and, in further alternative, shopping in virtual pharmacies or performing other activities. Therefore the practical use of Internet in the area of medical services mainly consists in searching for information. High percentage of responses informing about the making use of advices given by other patients (almost 60% of respondents) is an alarming phenomenon without any impact of professional profile of the respondent. The scope of use of Internet is narrower in case of students from Lublin University of Technology – the following activities did not occur in this group at all: checking of dosages and undesired effects of drugs prescribed by doctor, asking questions concerning determined medical problem at discussion forum, advices given to other patients, ordering a prescription, ordering a doctor home visit.

The main Internet sources used by the respondents searching for information associated with the health and medicine are: search engines (70.2%), health portals for everyone (63.8%), general (48.9%) and specialized (31.9%) discussion forums, thematic websites prepared by large portals (39.4%), Internet pharmacies and medical shops (36.2%), websites of doctors and medical entities (34%), Internet portals for patients (17%), community services (8.5%), websites of scientific associations (5.3%), websites of drugs manufacturers (5.3%), websites of National Health Fund (8.5%) and Ministry of Health (4.3%). The search engines, health portals for everyone, the general (48.9%) and specialized discussion forums as well as Internet portals for patients are more frequently used by the students of Medical University. However the community services, websites of scientific associations, websites of drugs manufacturers and website of Ministry of Health did not occur at all in the group of sources indicated by the students from Lublin University of Technology.

The respondents asked to arrange various elements associated with health protection from the most important to completely insignificant ones gave the answers contained in the Table IV. In the group of students of Medical University, the largest group of respondents (51.1%) finds that the access to information / advices concerning health, diseases prevention or correct nutrition is very important.

The other issues found important by the respondents were: access via Internet to the list of medical entities and catalogue of their services, to personal health records and the possibility to purchase drugs and medical equipment via Internet. The possibility of on-line consultation with the doctor has been found less important and the possession of health card in electronic version completely unimportant.

But none of expressed opinions prevailed as very important in the group of the students from Lublin University of Technology. The access via Internet to the list of medical entities and their services, to information/advices concerning health, diseases prevention and correct nutrition etc. as well as the access to personal health/diseases records was found important by the respondents. The possibility of on-line consultation with the doctor, possibility to purchase drugs and medical equipment via Internet, possibility of discussion on forums about medical issues and appointment of visits at the doctor has been found less important and the possession of health card in electronic version completely unimportant.

The respondents identify the positive effects of applications of information technologies in the health service. The students from Medical University emphasize that said effects improve the health care system (70.2%), make it possi-

TABLE III.
AIM OF INTERNET USE

Source: own study on the basis of conducted research

ble to save the doctor's and patient's time (66%), improve the quality of medical services (57.4%). They also make the contacts with health service and medical services providers more efficient (55.3%), reducing the functioning costs of medical entities (51.1%) and increasing the access to medical services (46.8%). Almost every third respondent (29.8%) reported a positive impact of Internet on the society education in the scope of health protection. In the opinion of respondents the competition on medical services market is also positively affected by ICT technologies (23.4%). According to the natural order of things, the students from Medical University emphasized the positive aspects of computerization from the point of view of the suppliers or organizers of medical services not from the patients' point of view.

In the opinion of the students from Lublin University of Technology, the most important effect of health service computerization is better efficiency of the contacts with health service and medical services providers (70.2%) and saving the doctor's and patient's time (61.7%). Then they report the improvement of the health care system (48.9%) and increased access to medical services (48.9%). The next effects are: reduced costs of medical entity operation (40.4%), assistance in maintenance of health (21.3%) and improved quality of medical services (19.1%). The positive effects of applications of information technologies in the health service are identified with the society education in the scope of health protection in the scope of health protection and with the improvement in competition on medical services market by every tenth respondent only.

Due to the awareness of existence of the effects of applications of information technologies in the health service, 44.7% of respondents in the group of students from Medical University strongly believes that Internet is the future of medicine. Similar group (48.9%) is more sceptic but also can see the chances for health care development in Poland by means of Internet.

However the attitude presented by the students from Lublin University of Technology is a little bit different. The answer: Definitely YES to the question whether Internet is the future of medicine was given in this group by every tenth respondent only. The answer: YES was declared by 38.3% of respondents but as many as 40.4% did not expressed any opinion about this subject.

As appears from the conducted research, Internet is a medium most frequently and preferably used by the respondents gain the knowledge in the scope of health, diseases and treatment. The network as the preferred source of information about health, diseases and treatment is indicated by 77.7% respondents. The next answers were as follows: doctors/ representatives of health service – 74.5%, family – 56.4%, friends – 44.7%, books/handbooks – 29.8%.

The hierarchy of knowledge sources was different in the both groups of respondents. The following hierarchy occurred in case of MU students: doctors/ representatives of health service (80.9%), Internet (72.3%), family (40.4%), books/handbooks (40.4%). The following opinions prevailed in case of the students from Lublin University of Technology: Internet (83%), family (72.3%), doctors/ representatives of health service (68.1%), friends (63.8%).

As many as 85.1% of respondents (89.4% of MU students and 80.9% of the students from Lublin University of Technology) searched for health information in Internet. Such information is searched by 40.4% of respondents (MU students) frequently and as many as 61.7% of the students from Lublin University of Technology do it always if it is necessary.

Most frequently information about health encompass the information about diseases and their symptoms (78.7% MU and 91.5% PL), location and the offer of medical entities (59.6% MU and 59.6% PL) as well as effect and composi-

TABLE IV.
OPINIONS ABOUT VARIOUS ELEMENTS ASSOCIATED WITH HEALTH PROTECTION

Topics	Very important		Important		Less important		Completely unimportant	
	MU	PL	MU	PL	MU	PL	MU	PL
Access via Internet to the list of medical entities and their services in your voivodship	18	15	24	22	5	10	0	0
Access via Internet to the information / advices concerning health, diseases prevention and correct nutrition etc..	24	15	18	24	4	4	1	4
Appointment of visits at the doctor via Internet/email	12	0	23	18	10	25	2	4
Access via Internet to the to personal health / diseases records	13	4	24	24	8	10	2	9
possession of health card in electronic version	10	0	14	13	16	20	7	14
Possibility to purchase drugs and medical equipment via Internet	8	0	24	9	13	29	2	9
On-line consultation with the doctor	8	0	19	13	18	30	2	4
Possibility of discussion on forums about medical issues	7	0	18	15	17	28	5	4

Source: own study on the basis of conducted research

tion of drugs (55.3% MU and 61.7% PL). Other areas of medical information searched in Internet are presented in Table V.

The great majority of respondents (87.2%) reported Internet as the most popular information source due to the fact that the information are accessible quickly and easily. For almost the half of respondents (47.9%) it is also important that this medium makes it possible to enhance the knowledge about health. Such information is searched by 35.1% of respondents driven just by curiosity.

The respondents placed also the value on: lack of necessity of waiting in queue for doctor's visit (27.7%), time saving (25.5%), possibility to maintain anonymous status (9.6%) and quick diagnosis (8.5%). The quick and easy access to information prevails in the answers given by MU students (83%) and PL (91.5%). The next answers are characterized by differences. The next item specified by MU students is the lack of necessity of waiting in queue for doctor's visit (55.3%), time saving (40.4%), possibility to enhance the knowledge about health (36.2%) and curiosity (31.9%). The next important reasons for the students from Lublin University of Technology is the possibility to enhance the knowledge about health (59.6%) and curiosity (38.3%) only.

The respondents search for medical information in Internet but almost ¾ never arranged a doctor's visit by means of Internet or E-mail. The reason of this state of things in case of MU students is the fact that medical entity being their service provider does not accept the registration in such form (76.5%). However almost every third respondent informs that he/she never checked if it is possible to use this form of registration. However the students from Lublin University of Technology who do not arrange the doctor's visit in this manner prefer conventional methods (55.9%), do not use the entities offering such possibilities (44.1%), or did not check if it is possible to use this form of registration (44.1%). Every fifth respondent in this group informs that it is more quickly and convenient to arrange the doctor's visit by phone. It should be noted that the lack of computer skills or impeded access to Internet is not reported as the reason of failure to arrange the doctor's by means of Internet or E-mail in any group.

The barriers in use of the state of art technologies (Internet, telephony, computers) are also identified by the respondents. What's interesting is that no barriers were reported in that scope by as many as 42.6% respondents in MU students group but such answer was not given at all by the students from Lublin University of Technology. How to explain such optimistic opinions of MU students? Probably it is caused by poor knowledge and awareness of potential hazards. In the present research phase it is possible to suspect the reasons of this state of things i.e. wider knowledge and consequently awareness of potential hazards in the group of students of technical university. Certainly, the issues presented herein can constitute an interesting subject of further research. In the opinion of MU students reporting the barriers in use of the ICT technologies, the principal barriers are the personal data safety concerns (46.8%), hazards associated with viruses, hackers, undesired mail (34%) and doubts regarding Internet transactions safety (19.1%).

The same three barriers are also specified by the students from Lublin University of Technology but in different order i.e.: personal data safety concerns (78.7%), doubts regarding Internet transactions safety (59.6%) and hazards associated with viruses, hackers, undesired mail (21.3%).

III. Conclusion

Conducted research demonstrated that Internet is a valid source of medical information for potential patients. It also appears that searching for medical information in Internet is the principal sign of the use of ICT solutions in health protection and practical use of Internet in the area of medical services is limited to the searching for information mainly. It

Table V.
Thematic areas of medical information searched in Internet

Topics	MU		PL		Total	
	Freq.	%	Freq.	%	Freq.	%
Diseases and their symptoms	37	78,7	43	91,5	80	85,1
Interpretation of examinations results	17	36,2	24	51,1	41	43,6

Allergic reactions	8	17	5	10,6	13	13,8

Source: own study on the basis of conducted research

can be questioned whether it is caused by poor spectrum of e-health services or lack of awareness of the respondents in the scope of such opportunity or the respondents are unable to change their previous habits. These issues can constitute an interesting subject of further research.

There are no significant differences between the students from Medical University and the students from Lublin University of Technology in the scope of indices characterizing the place and intensity of Internet use.

It seems that the attitude of respondents toward Internet as the source of medical information is diversified by the Professional profile of respondent, as demonstrated in course of the research.

Significant differences in examined groups have been observed in the following:

1) subjective evaluation of their own computer and Internet skills:
   - the students from Lublin University of Technology better assess their ability to use computers and the Internet,
2) searching spectrum width:
   - the scope of use of Internet is narrower in case of students from Lublin University of Technology – the following activities did not occur in this group at all: checking of dosages and undesired effects of drugs prescribed by doctor, asking questions concerning determined medical problem at discussion forum, advices given to other patients, ordering a prescription, ordering a doctor home visit,
3) size of catalogue of Internet sources used by those who search for medical information:
   - students from Lublin University of Technology also exibit limited range of online sources used in search of medical information,
4) identification of positive effects of information technologies application in health service:
   - the students from Medical University emphasized the positive aspects of computerization from the point of view of the suppliers or organizers of medical services not from the patients' point of view,
5) forecasting of the future of medical services rendered by means of Internet:
   - the students from Medical University are more confident that the Internet is the future of medicine,
6) structure of medical knowledge sources:
   - for the students from Medical University the main sources of medical knowledge are doctors/ representatives of health service, for the students from Lublin University of Technology the main source of medical knowledge is Internet,
7) structure of reasons causing that the Internet is the most popular source of information:
   - for all respondents the main reason why the Internet is the most popular source of information is the fact that it provides quick and easy access to information; however, for other reasons, both groups of students give their different structure,
8) identification of barriers in use of the state of art technologies:
   - no barriers were reported in that scope by as many as 42.6% respondents in Medical University students group but such answer was not given at all by the students from Lublin University of Technology.

Corporate Amnesia in the Micro Business Environment

Stephen J. Hall and Clifford De Raffaele *IEEE Member*
Middlesex University Malta,
Pembroke, Malta,
Email: stephenhall@bcs.org.uk, cderaffaele@ieee.org

***Abstract*—Corporate amnesia is a phenomenon that has persistently threatened the livelihood of business organizations and their success in commercial activity. Several substantial studies on this observable fact have been undertaken with focus primarily aimed at the large corporations and the small to medium sized organizations. This vulnerability is however evermore present and significant within the smaller of businesses. In the micro enterprise, the impact of corporate amnesia is realized when even a single member of staff is absent for any lengthy period of time or vacates their post altogether. With more than 80% of the workforce in the US and separately in the UK directly engaged within a micro enterprise, the competitive benefits that can potentially be realized by addressing corporate amnesia is significant. This paper will identify the main causes of corporate amnesia within the micro business environment and propose a suitable framework for the enterprise to effectively facilitate the adoption of Knowledge Management and realize the associated competitive benefits.**

I. Introduction

THE information economy has brought about a new wave of opportunities and challenges that have the potential to give organizations a competitive edge over their market rivals. Knowledge Management (KM) is one such potential opportunity, and although the grouping of such terminology is relatively recent, its concepts and methods have been in existence since time immemorial [8]. At a conceptual level, the management of knowledge is represented differently by academics and industrialists. However, it is generally well-agreed that fundamentally KM can deliver operational efficiency resulting in financial benefits to commercial activities. *Blair & Wallman* [3] found that properly implemented KM projects do result in substantial returns on investment (ROI), and *Stankosky* [20] determined that KM has the ability to enhance the performance of an organization by positively influencing intellectual resources.

Today, KM is generally accepted to be represented by a cycle, with iterations commencing with the identification of existing knowledge, and subsequently followed with planning the knowledge to collect, processing of the actual selected knowledge collected, distribution of new knowledge to where it is required, fostering the usage within the organization, controlling and maintaining its use and finally disposing of it when it is no longer required.

A. Corporate Memory

The storage of all knowledge pertaining to an organization is commonly referred to as Corporate Memory (CM). It is the result of collecting, storing and organizing knowledge in a way that it becomes of use (and consequently of value) to the organization. *Dalkir* calls this the repository of organizational knowledge [6]. Inversely, Corporate Amnesia (CA) is viewed as the loss of this organizational knowledge as a result of factors such as staff mobility, absenteeism, shift work and various others. *Kransdorff* describes CA as the failure of an organizations ability to efficiently and effectively use its experience and historical activity to its advantage [12]. This inevitably results in repeated mistakes and at times embarrassing and easily avoidable blunders. The CA phenomenon is further highlighted by *Tiwana* who states that organizations are not aware that they know what they already know [21].

Field describes a case where a large company was forced to withhold the launch of a product due to technical problems, only to find after their competitors beat them to the market, that they had developed a solution to this technical problem fifteen years earlier [10]. In a 2006 report, *Noria Corporation* forecast that by the year 2010, 60 percent of experienced managers will retire from the oil and gas industry resulting in the loss of an incalculable wealth of knowledge [17]. Similarly, NASA has publicly admitted that the knowledge of how to put a man on the moon has been lost and had it to attempt putting a man on the moon at any point in the future, all the research toward that objective would have to be redone [6]. *Andrade, et al.,* hence concludes that the benefits of KM can only be realized if a form of corporate memory is in place [2].

B. The Micro Enterprise

In contrast to the resources of these larger organizations, smaller firms – particularly the micro enterprise, face a rather different reality. Although the staff compliment is much smaller and therefore also the collective knowledge present within the organization, the share of knowledge per capita is often overlooked. In addition, the major economies of the world consist of a very high percentage of micro enterprises [23,24].

An organization that has a research department composed of a team of staff can share knowledge between them; hence if one member is absent other members of the team can utilize their combined knowledge to continue the work.

978-83-60810-53-8/$25.00

Conversely, a smaller organization employing only a single person for research would consequently be crippled if that person left the firm or is absent for any significant amount of time. Moreover, the limited resources found in the micro enterprise results in the excessive reliance on tacit knowledge. Thus implies that a micro-sized organization is consistently on the threshold of corporate amnesia with even the slightest of influence. Since staff members gather and harvest critical knowledge on the way processes are executed and how practices are applied without redundancy, the impact generated by the departure of a staff member inevitably yields severe knowledge gaps within the organization [4]. Moreover, current KM systems administratively overwhelm the micro enterprise and are as such a major contributor towards the reluctance factor this size of organizations face in employing KM systems. Hence, the micro enterprise typically reverts to over reliance on tacit knowledge and unconditional exploitation of generic knowledge found through internet resources.

Following an analysis and review of related articles in literature in Section II, this paper will address the issue of CA by initially identifying the main causes within a micro enterprise in Section III. Section IV will subsequently focus on the Knowledge Capture aspect of the KM cycle - Identification, Planning and Acquirement, since this is the most significant obstacle encountered by micro enterprises when attempting to employ KM to protect their organizations' memory. Finally, Section V will conclude this article by deriving the conclusions of the proposed framework.

II. Literature Review

The essential value of Corporate Memory to an organization was highlighted by *Dalkir* [6], with further research by *Kransdorff* adding detail to the concept by expanding its boundary of benefit [12]. This results in a definition and understanding of its common occurring converse Corporate Amnesia [12]. *Tiwana* [21] accents the reality that most organizations are unaware of the knowledge they possess [21], and confirms this by actual cases of corporate amnesia [6, 10, 17]. *Brossler* [4] undergoes a study to explain knowledge gaps derived as a result of staff mobility, a concern which *Moteleb* identifies and deems relevant for both large as well as small to medium sized organizations [15].

The shortage of material in the context of knowledge management specifically addressing the micro enterprise required a definition of this size of business to first be established. This was done by European legislation which considers organizations that have an annual turnover of below two million Euro and employ's less than ten people to be classified as a 'micro-enterprise' [9]. Seen within the KM context, this small size definition of a micro business brings inherent challenges to light such as; the selection of staff incentives for contribution toward knowledge collection [19], the hidden time factor and cost involved in maintaining a knowledge management system [11] and the learning disability found in this size of enterprise [6]. Although these challenges are shared in common with Small and Medium Enterprises, the issues of poor communication of knowledge, fear of knowledge loss and staff reluctant to sharing their knowledge are ever more pronounced in the micro environment [15].

The level of dependency that such organizations have on tacit knowledge and the recognition to its mobility is also worth noting [21]. An interesting study in [1] investigates the reason why Small and Medium Businesses (SMBs) are reluctant to transferring tacit knowledge into explicit knowledge and relevant tacit capture methods are evaluated against suitability qualities that impact the micro enterprise [6, 18].

III. The source of CA

The limited financial and human resources present within a micro enterprise leads it to perceive the benefits of KM and ultimately corporate memory as 'nice to have' but often hard to justify. This is primarily due to the excessive administrative overhead required to implement it. Following an analysis of the components leading to the implementation of KM practices within larger businesses [7], a number of factors hindering implementation in micro organizations are hereunder presented;

A. Incentive

The largest apparent hurdle in implementing a KM system is that of providing and maintaining sufficient incentive for staff to continually contribute knowledge to the system. In law firm environments, it was found that several attorneys see the product of their work as 'their own' rather than that of the firm [19]. This often results in an organizational culture in which employees refuse to share their knowledge in fear of losing the hold on their position. Furthermore, unless properly incentivized employees will seldom find the necessary time to transfer (document) their tacit knowledge into a KM system, a problem ever more pronounced within a micro enterprise due to the various roles each employee is assigned.

B. Cost

Another indirect hurdle which leads an organization to ponder on the applicability of KM is the cost of implementing and maintaining the KM system itself. Management may perceive the investment on the infrastructure and changes to procedures required to support a KM system as prohibitive and unjustifiable. Despite the tangible measures of predicted profitability and competitive advantage, it is nevertheless very difficult to justify the volume of time and money that is invested into managing disparate knowledge resources in a small budget firm [11].

C. Causes

Throughout its lifecycle, an enterprise experiences varied learning capacity difficulties. If an organization forgets its past endeavors and the reason why such tasks were even attempted, it would be equally unable to record and retrieve significant aspects of what it actually knew [6]. Despite the clear advantages of KM, the micro enterprise will typically

not employ a formal system but instead rely exclusively on the tacit knowledge of its staff for the purpose of CM. As a result of this over-reliance on tacit knowledge, CA in a micro enterprise can be summarized as being caused by the downsizing of staff levels, shift-work rotations, high staff turnover, outsourcing of processes and the fact that tacit knowledge is forgotten or not used because it was not associated to the location of its use. Since these identified causes represent the inherent nature of the human workforce in a corporate environment they are not directly preventable. However, by optimizing the conversion and storage of knowledge purposefully, a KM system can help minimize the impact that each of these causes can have on the micro enterprises' corporate memory.

IV. Optimizing K-Capture

Like any other form of business organisation, a micro enterprise harvests two fundamental types of knowledge - tacit and explicit. Tacit KM is the process of capturing, managing and sharing one's experience and expertise when and where it is required [6]. Tacit knowledge is itself split into two areas – Individual and organizational. Individual tacit knowledge, usually present within the minds of 'knowers' and often contributed voluntarily by individual members of staff. Organizational tacit knowledge is carried by the collective grouping of individual tacit knowledge. The other fundamental form of knowledge for the organization is of explicit nature, and this is commonly present in the procedures, processes and documentation stored within the enterprise.

Tacit knowledge is the more volatile of the two types since it is carried by staff members who have a dynamic relationship with the firm and can be considered as an unstable asset in the company's future. This issue, which is highlighted as a risk factor in SMB's who rely on this mobile knowledge [21] is ever more challenging to manage inside a micro enterprise.

A. Knowledge Transfer

The four modes of knowledge transfer represented by *Nonaka & Takeuchi* within their SECI model clearly define the states in which these two types of knowledge can exist [16]. They also indentify the continuous spiral process of organizational learning. KM systems work toward keeping this process of organizational learning in motion by means of implementing a KM cycle. Several established KM cycles have been developed such as those by *Wiig, Meyer & Zack, McElroy, and Bukovitz & Williams* and a general consensus is present throughout these models whereby knowledge capture is recognized as the first phase of each of these cycles. This initial phase is also specified to be the most intrusive and administratively time consuming phase of the entire cycle. Due to such an initial hurdle, SME's regularly opt to retaining most of their knowledge in tacit form primarily due to the shortage of time and resources available to converting it into explicit form [1].

B. Qualities that matter to the Micro Enterprise

The limited human and financial resources available to the micro enterprise mandates that any additional resources allocated towards the processing of knowledge is kept to an absolute minimum. Consequently, as highlighted within the limiting factors of Section III, a successful KM model for micro enterprises requires the process of capturing knowledge to be accurate in nature, performed in a transparent and time-efficient manner and require the least amount of incentive. These factors are further elucidated in this section to concretely analyze the manner in which a micro-enterprise can assure compliance to this required framework.

Transparency - The process of capturing explicit knowledge demands different methods to be explored than that of actually transferring tacit into captured explicit knowledge. The one aspect common to capturing both types of knowledge however is the level of transparency involved in the actual capture process. Due to limitations of human resources and the value attributed to time, the micro enterprise is highly sensitive to having processes and procedures loaded with additional tasks to maintain a system which does not provide much incentive to the contributor or any form of immediate return. *Dalkir* emphasizes that the most important challenge of KM success is user incentive [6]. In the absence of the ideal - a way to transfer tacit knowledge directly into explicit knowledge and the importance of approaching as transparent (time-efficient) a method as possible is a mandatory prerequisite to implementing a KM system in the micro enterprise.

Capture Points - Equally important to the transparency requirement, is the point at which the knowledge is actually captured. In contrast to asking the 'knower' to offload his tacit knowledge on a particular topic by interview or other established means, a transparent point to capture and convert this knowledge is when it is in a state of 'transit'.

Bringing *Nonaka's* SECI model [16] into perspective clearly reveals instances of these so-called 'transit' points.

During the internalization and combination phases tacit knowledge is in 'transit' and can be transparently captured. Equally so occurs during the socialization and externalization phases which are much easier to encounter within the familiar context operated by micro enterprises of few employees.

C. Tacit capture methods

Tacit knowledge is the more challenging of the two knowledge types to capture. *Dalkir* explores several methods of individual Knowledge Capture. The first group explored is that proposed by *Parsaye* [18]. These are; Interviewing experts, learning by being told and learning by observation. Each of these three methods involves disruption of the 'knowers' productivity during the knowledge transfer session and requires an additional person to conduct the session and document the 'externalized' knowledge. A process that is clearly unfeasible with the limited resources available to the micro enterprise. The second group of methods explores the Ad hoc sessions, Road maps, Learning

		Qualities that impact the micro enterprise						
		Conducive to productivity?	Self-motivating?	Tacit to Explicit transfer using existing staff?	Relatively accurate?	Perceved as Transparent?	Readily available Capture Points?	SIUTABILITY (YES COUNT)
K - Capture Methods	Interviewing Experts	NO	NO	NO	YES	NO	YES	2
	Learning by being Told	NO	NO	NO	YES	NO	YES	2
	Learning by Observing	NO	NO	NO	YES	NO	YES	2
	Ad hoc sessions	YES	YES	YES	NO	YES	YES	5
	Road maps	NO	YES	NO	YES	YES	YES	4
	Learning histories	NO	NO	NO	YES	NO	YES	2
	Action learning	NO	NO	NO	YES	NO	NO	1
	E-learning	YES	NO	YES	YES	NO	YES	4
	Learning from others (guests)	N0	NO	YES	NO	NO	YES	2

Fig. 1 The Knowledge Capture comparative matrix

histories, Action learning, E-Learning and Learning from others.

These methodologies are compared within a suitability matrix in Fig. 1 which analysis the potential presented by each Knowledge Capture method to adhere to the desirable qualities required by micro enterprises. Each of the qualities has been given equal weighting to maintain clarity and simplicity but should be evaluated on a per case basis upon application. Fig. 1 imminently portrays the fact that despite the accuracy and quality commonly associated with the Action Learning method, this technique is the least suitable for the micro enterprise. This resulted since the method is disruptive to the 'knowers' productivity, incurs additional costs due to the extra staff required to conduct the exercise, relies on some form of incentive being in place and is also not transparent to the usual day-to-day business procedures and processes. The methods of expert interview, learning by being told and learning by observation are nearly equally unsuitable to the micro enterprise since they require staff incentive, are disruptive to productivity and also require additional human resources to conduct the respective sessions [18]. Conversely, the Ad hoc Sessions represents the most favorable method for the micro enterprise. It impacts positively on all aspects and only falls short on the accuracy of the captured knowledge as a result of its 'real-time' recording of the sessions' events. Of particular interest is that this method can be easily adapted to make use of current communication technologies such as email, chat, video conferencing and instant messaging sessions [6]. These technologies also assist the implementation of suitable and non-invasive capture points within the organizations. Moreover, Ad hoc sessions lack a formal structure and thus can be adapted to whatever format is most suited to the knowledge being captured.

D. Adapting the methodology

The adaptability to various technologies and the informal structure inherent in the Ad hoc method provides for tremendous scope in capturing knowledge from several sources automatically, transparently and at minimal additional cost in time. This is useful since each technology demands its own evaluation and analysis of suitability in relation to the nature of the enterprise.

Capturing knowledge from any form of communication session can be considered as an ideal 'transit' capture point in relation to *Nonaka's* SECI model. Using the right technology to tap-in to these transit feeds can serve to efficiently capture vast amounts of knowledge on any topic that is being processed and exchanged by the 'knowers'. Several technologies to convert speech (tacit) to text (explicit) from telephone or other forms of voice conversations are available on the market. These technologies can also serve to index the capture and make it searchable to the organization. Furthermore, the capturing process can also be easily adopted within the organization for utilization in problems of various domains.

Two important considerations to ensure suitability and reliability of the knowledgebase involve the need to be selective about the sources and the reliable categorization of the captured knowledge to avoid corrupt or redundant entries being generated. The latter can be addressed by adding appropriate meta-data to the event [7], which in turn assists the utilization of auto-categorization algorithms. This meta-data can either be keyed-in by the 'knower' or can alternatively be extracted automatically from the content of the event. Categorizing the capture will provide scope for the knowledge and establish a fundamental level of accuracy for further KM cycle processes to utilize.

V. CONCLUSION

This paper has identified the lack of research that exists on the application of Knowledge Management in the micro enterprise. It has defined Corporate Amnesia and recognized its principle causes in the micro enterprise. Following the identification of knowledge capture as the initial and most

significant hurdle in adopting KM, the research conducted has established the need for an optimized method for capturing knowledge. During the discussion stage, particular focus was placed on the evaluation of established methods used for knowledge capture and thus leads to a framework that is optimized for use in a micro enterprise environment to be proposed.

***Abstract*—This document presents a problem of knowledge conflict appearing in Business Intelligence systems. The structure of such class system in context of knowledge creating is presented in the first part of article. Next, the formal definition of knowledge structure of Business Intelligence, which is necessary to comparing these knowledge, was elaborated. The characteristic, sources and examples of knowledge conflicts is presented in the final part of article. The detecting and resolving of this type of conflicts is necessary, because this allows receiving by user, from the system, the proper reports as a results of analyses. On the basis of these reports the user can takes the decision that lead to satisfying benefits.**

I. Introduction

CONTEMPORARY social and economic environment makes quick and accurate decision-making crucial for the competitiveness of a company. Economy forces company managers to make complex operational, tactical, yet most of all, strategic decisions that influence the future of the organization. Those who actually make decisions in a company, are usually exposed to risk and uncertainty, because they cannot foresee the consequences of their decisions or their predictions have very low probability. Therefore, the entire decision-making process is very complicated. Nowadays, decision making processes employ decision-making support computer systems, as well as Business Intelligence (BI) class systems which are being used more and more often. They are used to support business decision making through smart use of data resources already available in companies [8]. The purpose of Business Intelligence systems is to enable easy and safe access to information in a company, operation of its analysis and distribution of reports within the company and among its business partners, which in turn enables quick and flexible decision making. This allows the company to reach a higher level of flexibility and competitiveness. Because of the necessity to fully integrate business processes in a company, BI systems should currently operate within a sub-system of an integrated management computer system. [2].

However, it often occurs that a BI system generates conflicts of different kinds, especially conflicts of knowledge generated from various types of analyses. Conflicts of knowledge result from the fact that the system may offer different analysis results or solutions of a single problem to the user. In other words, conflict of knowledge occurs when the same objects in the world and the features are given different values [7]. This mainly results from using different methods for business processes analysis. If a conflict of knowledge occurs in the system, the system will not be able to generate a satisfactory decision for the user and, consequently, the decision maker will find it hard to conduct the decision-making process properly. The decision maker will then be forced to make a decision with no help from the system, which is time-consuming, requires much work and can lead to a decision that is out-of-date (belated) and made with incomplete information. This situation has obviously negative influence on the work of the entire organization.

Therefore, the key element of BI systems' operation is to detect and, consequently, properly resolve conflicts of knowledge. This article presented a formal definition of knowledge structure in BI system, as well as sources and characteristics of conflicts of knowledge regarding BI class systems

II. The structure of Business intelligence systems

At present, companies incur significant losses due to improper use of knowledge. Losses resulting from incorrect operation of knowledge management processes are very high and often constitute the main reason for companies going bankrupt. Symptoms for improper use of knowledge in a company are as follows [6]:

- overdue reaction to changes in market environment - the company does not keep up with competition and market needs,
- lack of knowledge at each level of organization - when the quality of work decreases,
- slow performance of tasks - occurs when it takes employees too long to locate the necessary knowledge,
- the problem of production quality - when the adaptation of production process do quality requirements drastically extends the process,
- long sales cycles - when the response time of the seller to the customer's needs extends.

The decisive factor that affects the use of knowledge as intangible resource of a company is efficient management. The essential purpose of knowledge resources management

978-83-60810-53-8/$25.00

is to provide information for managers, which is then used for planning, control and decision making. Access to information needed for efficient management should be enabled by Business Intelligence system, because it has the ability to transform 'raw' (not processed) data into useful information that helps make more accurate decisions in a short time, with operational conditions constantly changing for the company in its environment, which evokes high risk and uncertainty.

Bi systems are often offered by various computer system producers as a complete system that supports a certain business area. Currently, the tools used in BI systems usually include the following technologies:

- ETL - Extraction, Transformation and Loading,
- DW - Data Warehouse,
- OLAP - OnLine Analytical Processing (multi-dimensional real-time data analysis tool),
- DM - Data Mining, software for safe presentation of information (analyses, reports) on the net.

All elements mentioned above are aimed at meeting the needs of different groups of users, such as managers that use pre-defined reports on a daily basis or analysts that design reports individually and prepare various business analyses. Most elements presented use Data Warehouse as one of the potential sources of information (see pic. 1).

The main source of data for Business Intelligence systems are transaction systems such as ERP, CRM, SCM or call center. Sometimes data is also extracted from text files, Excel, Access, e-mail software or websites. All data should be gathered in one place (e.g. data warehouse) so that reports and analyses based on the data are complete. Data gathered in warehouses usually come from many different sources that store particular values in different ways and for that reason they must first undergo the process of ETL 'standardization' (Extraction, Transformation and Loading) [12]. ETL programs transform data. The process begins with extraction which consists in selective mining and loading data from transaction systems and other data sets. Next phase is transformation, i.e. necessary modification of data. For instance, transformation of numerical values signs, conversion of dates or currencies (e.g. dates being converted from English format into polish format, PLN currency into EUR). Last phase is upload of 'refined' data into the warehouse.

Fig 1 clearly shows that BI system uses advanced analytical tools for real-time data analysis, including OLAP or data mining.

OLAP is a tool that allows to perform multi-dimensional analyses and display the results in approximately real time. There are two common groups of OLAP whose main difference is the type of server used to build them. The first group includes all solutions based on ROLAP (Relation OLAP) data base, whilst the second group is built based on specialized MOLAP (MultiDimensional OLAP) servers, also known as MD-OLAP.

Both techniques have their own pros and cons. ROLAP solutions are characterized by the ability to store large volumes of data, relatively easy data modification (resulting from the software used and data structure), but they also have their own disadvantages, such as: data structure complexity (resulting from the necessity to represent multi-dimensional relations in a relation-like manner) as well as performance problems the result from lack of adaptation of relation structures to multi-dimensional analysis [2].

Whereas, MOLAP do have much smaller capabilities of data storage and find it difficult to modify data (it often occurs that data modification leads to rebuilding multi-dimensional structure), but they are also characterized by high performance of multi-dimensional analysis and natural representation of multi-dimensional structures.

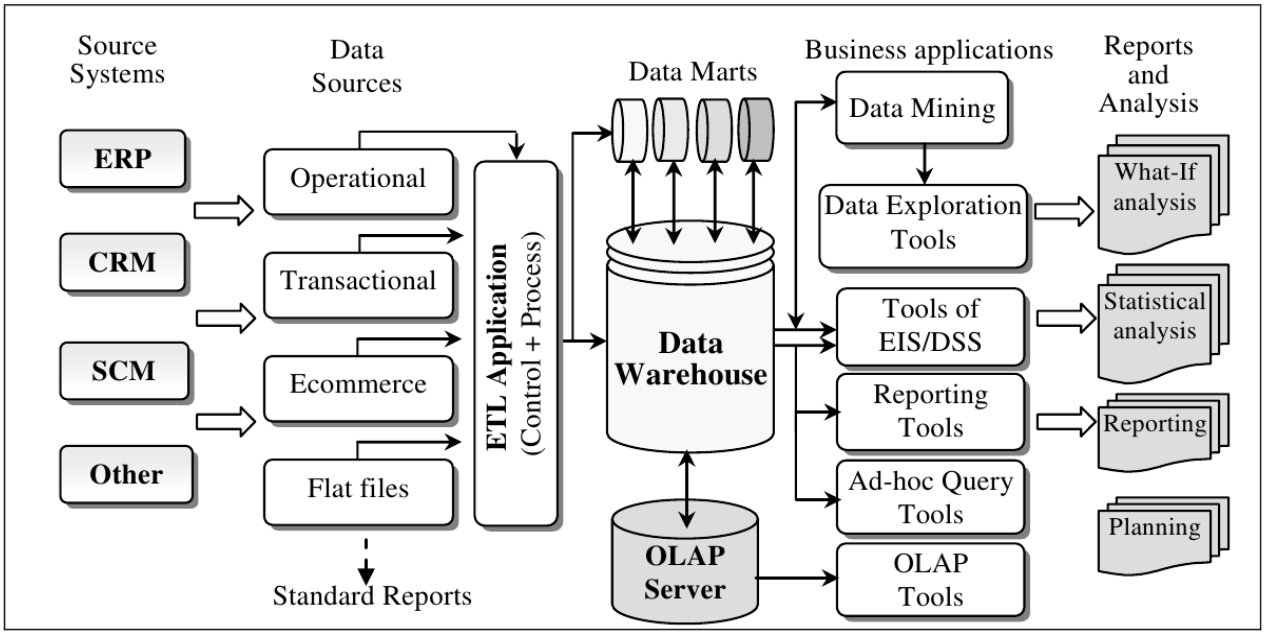

Fig. 1 The overall structure of BI system and its cooperation with other information systems in the enterprise

Source: own work.

A combination of both technologies may ensure a solution that will unite the ability to store large amounts of data and effective multi-dimensional analysis. It will consist in employing a relation data base as data warehouse containing the entire set of elementary data, and MOLAP systems as Data Mart.

A user of OLAP analytical solutions has the ability to perform analysis on available multi-dimensional base (the so-called ROLAP or MOLAP block) or use ready-made reports, defined with the block. Each block has dimensions, also known as perspectives, hierarchies and measures. Data analysis in many dimensions is very intuitive. For instance, while searching for sales figures for a product or a group of products, we are not only interested in general sales figures, but also sales figures categorized by customers and divided into particular periods of time. The area, the customer and time are the dimensions of the analysis and the sales figures are the measures [13].

Reports defined with the OLAP block are being updated while they are generated, therefore they contain current data as accurate as possible until the multi-dimensional block is refreshed again.

ROLAP or MOLAP block analysis consists in performing the following operations: [2]:

- change in detail of data(drill-down, drill-up),
- change in section of analyzed data (slice and dice),
- search for extreme values (exceptions),
- presenting results in the form of graphs,
- contextual switching to detailed data (drill-through).

The 'drill-through' enables the user to proceed within a certain business area and then to switch to other areas with filters engaged beforehand (e.g. time, customer or product dimension). Consequently, it is possible to begin with another multi-dimensional analysis or a pre-defined report or to proceed to 'ad hoc' query environment.

Whereas, Data Mining is an analysis of business data (usually available from data warehouse) in order to detect any rules, relations, patterns and trends contained in them or to set forecasts that may prove useful when making decisions. Therefore, the methods allow to transform data into knowledge.

Data Mining is often considered a contemporary candidate for Artificial Intelligence (Data Mining widely uses neural networks or decision trees). Most often, however, Data Mining employs statistical methods, such as regression, association or classification analysis. The methods are grounds for creating models used to analyze large amounts of data or samples for the existence of certain regularities, hidden relations and similar connections [10]. There are two distinct types of Data Mining [13]:

- hypothesis verification – used when there is a supposition about a significant relation among certain pieces of data and we want to verify it,
- knowledge discovery – used when we want to check if there are connections between pieces of data that man is unable to detect.

The most common use of Data Mining is, for instance, precise segmentation of customers and setting an optimal 'customer basket'. Data Mining allows to know customers better, with their habits, preferences and the risk resulting from customer service. Thus, the company is able to offer proper products or services and gain customers' loyalty.

Using different methods of data analysis enables the system to generate new knowledge, mostly about business processes performed in the company. However, the variety of analyses and the fact that they can be performed with information from heterogeneous sources [8] often leads to a situation where a conflict of generated knowledge occurs. Automated diagnostics and resolving conflicts of such nature by the system is essential, mainly for the sake of proper operation of BI systems, which in turn influences the quickness and accuracy of decisions made by decision makers. However, conducting diagnostic and resolving a conflict of knowledge is only possible when the knowledge is represented as unitary structure, whose definition is will be given in this article.

III. KNOWLEDGE STRUCTURE OF BUSINESS INTELLIGENCE

In order to determine the sources and characteristics of knowledge conflicts in BI it is necessary to formally define the structure of the knowledge gathered in the system. The literature of the subject contains, admittedly, the issues related to this issue, however, they concern only one slice of BI, for example the OLAP cubes [4]. This article presents, the general definition of knowledge structure taking into account the BI as whole.

Assume that the database structure is represented in the form as shown in Figure 2:

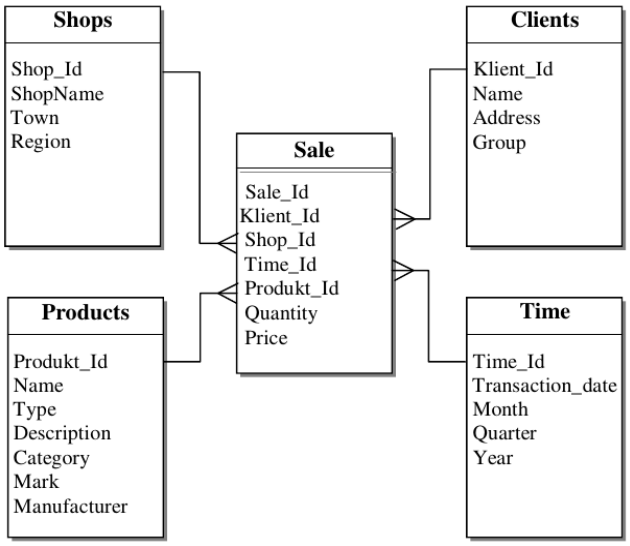

Fig 2. Structure of Data Warehouse

Source: own work.

Accumulation of large amounts of data describing the activities of the company. According to presented the structure of the database, in the long run makes it possible to carry out a detailed analysis of this activity, detection of certain applications, depending on the draw and what further proceedings. For example, company executives may be interested in the implementation of the following analyses:

1. A value for the sales of products by increasing the levels of aggregation: from the city, state and country brand for different time periods.
2. Examine the profit from the sale of goods for individual producers in the designated months. Arrange the months according to the increasing value of the profit.
3. If the deviations contained in the average transaction of individual months are important?

Answering this type of question is made, using the tools to multidimensional data analysis in real time - OLAP. With these types of activities takes over that [9]:

1. Analyzed data resides in databases (operating databases, in data warehouses or data stores), where the volume can be very diverse and reach from mega to multiple terabytes. In maintaining and processing such databases the conventional capabilities of database servers are used.
2. The analytical multidimensional processing, requires the presentation of data using a multidimensional model, where there are terms such as: a table of facts, aggregate functions, dimensions, dimension members, cells, and cell block.
3. The formulation of multidimensional query language-oriented requires multidimensional data query languages. Multidimensional data, as well as the results of the analysis of these data are very clear, when they are visualized graphically.

On the basis of characteristic of BI system, the structure of knowledge is defined as follows:

Definition 1.

The structure of knowledge in BI systems is called following sequence:

$$WBI = \langle \{F\}, \{WYM\}, \{AN\}, \{R\}, \vartheta, SP, DT \rangle$$

where:

1) $F = \langle \left\{ f_1, t_1, m_1^1, m_1^2, \ldots, m_1^n \right\}, \left\{ f_2, t_2, m_2^1, m_2^2, \ldots, m_2^n \right\}, \ldots \ldots \left\{ f_k, t_k, m_k^1, m_k^2, \ldots, m_k^n \right\} \rangle$,

where:

$\left\{ f_1, f_2, \ldots, f_k \right\}$ - denote the set of facts,

$\left\{ t_1, t_2, \ldots, t_k \right\}$ - denote the set of the date of the facts,

$\left\{ m_1^1, m_y^x, \ldots, m_k^k \right\}$ - denote the set of measures assigned another facts $\left\{ f_1, f_2, \ldots, f_k \right\}$ $\left(y \in [1 \ldots k], x \in [1 \ldots n] \right)$,

2) $WYM = \left\{ w_1, w_2, \ldots, w_i \right\}$ - denote set of dimensions,

3) $AN = \left\{ a_1, a_2, \ldots, a_j \right\}$ - denote the set of types of analysis,

4) $R = \left\{ r_1, r_2, \ldots, r_h \right\}$ - denote the set of types of reports,

5) $\vartheta : F \times WYM \times AN \rightarrow R$ - is at least partially a function of knowledge, that mirrors elements of the Cartesian product $F \times WYM \times AN$ in elements of R set. Function ϑ will be partially, when only selected elements of the Cartesian product $F \times WYM \times AN$ will be as its arguments,

6) SP - denote the degree of certainty of reports,

7) DT - denote the date of reports made on the basis of the analysis.

The example of BI structure of knowledge is as follows:

Set of facts (*F*):

Fact1 - On 06-04-2013 sold 10 pieces of the product X – the value of sales 100 EUR.

Fact2: On 07-04-2013 sold 6 pieces of the product Y – value of sales 300 EUR.

Fact3: On 10-04-2013 sold 20 pieces of the product Z – value of sales 200 EUR.

Dimensions (WYM):

Time={06-04-2013 … 10-04-2013},

Product={X, Y, Z}

Territory={Wielkopolskie: Client1, Client2, Dolnośląskie: Client3, Client4},

Client={Client 1: value of sales:100 EUR, Client 2: value of sales: lack of data, Client3: value of sales: lack of data, Client4: value of sales: 200 EUR}.

Set of types of analyses (AN):

Analysis1 - The total value of sales of individual products in the period: 01-04-2013 to 30-04-2013.

Analysis2 - The total value of sales by territory and individual clients in the period: 01-04-2013 to 30-04-2013.

Reports (R):

The report presents the results of the analysis, grouped according to the criteria specified by the with the ability to use pivot tables.

Report1

ϑ(Fact1…Fact*N*,{Time,Product},Analisys1,Report)= Time period=01-04-2013…30-04-2013, Value of sales: ProductX=100;ProductY=300,Product=200, The total value of sales: 600EUR;

Report2

ϑ(Fact1…Fact*N*,{Territory,Client},Analysis2,Report)= Time period=01-04-2013…30-04-2013, Value of sales: Dolnośląskie Voivodeship – Client1=100, Client2=???, Wielkopolskie Voivodeship – Client3=???; Client4=200, The total value of sales: 300 EUR;

There are two reports showing the value of sales grouped according to the given criteria (specified in the function arguments). It can be seen, that although the sales summary should be the same on both reports, however it differ. This may result, for example, of incorrectly entered data or re-

strictions related to the methods of analysis. Therefore, the conflict of knowledge was appeared. It should be clearly pointed out that at the time of the generation of results of analyses as a reports, the user of the system (decision-maker) do not think, why these values differ, because in the turbulently environment decisions must be taken very quickly. It is not a time, for example, to correction by an employee, wrongly entered data (of course, this correction at a later stage should be made, however, this fact may not pause the decision-making process).

So if, as in this example, the structures of knowledge in BI system differ the quantity or the value of the attributes, then the knowledge conflicts appear in this system. These conflicts have been characterized in the later part of the article.

IV. The Knowledge conflicts

Conflicts of knowledge in BI systems result from inconsistency or contradictions in knowledge contained in the system. Inconsistency occurs when one side of the conflict (for instance, one method of analysis) claims that a given attribute (feature) of the world occurs or does not occur in a given period of time, while the other side of the conflict does not have any information or is unable to assess the attribute. Contradiction occurs when one side of the conflict claims that a given attribute of the world occurs in a given period of time, while the other side of the conflict claims that the same attribute does not occur, or the values of the same attribute differ [3,5]. Therefore, conflicts of knowledge when the same objects of the world are given different attributes by different sides of the conflict or the same attributes (features) are given different values by different sides [11]. Obviously, an assumption is made at this point, that the knowledge is represented in a structure, elaborated in this article.

The [8] defined sources of knowledge conflicts, as follows:

1. The fight for managing specific resources. A conflict appears, when first side of the conflict is considered, that the second side of conflict should not has knowledge about a given resource, instead the second side of conflict is considered, that it such knowledge should has.
2. Ideological conflict. It occurs when the parties to the conflict have different beliefs on the subject. These beliefs may arise, for example, with the kind of environment of system works or with adopted algorithms.
3. Requiring the integration of various elements of the system. If there is a need to integrate some elements of the system in one unit, it's naturally a conflict occurs (i.e. different structures of knowledge, different types of knowledge representation).
4. Conflicts resulting from direct knowledge management system. A conflict occurs when each party considers, that it should manage the knowledge accumulated in the system, because it has the current and consistent status of this knowledge.

The last two sources of conflicts of knowledge are most common in BI systems. They are connected with integrating facts, dimensions and analyses into one unit, in order to obtain coherent reports; they are also connected with differences in the system's knowledge represented in structures that differ from one another.

It is worth noting that conflicts of knowledge mainly apply to the difference in amount or value of attributes in structures of knowledge in BI. The situation can be easily illustrated with the following example:

One of the users of the system needs a report on the analysis o sales figures of product X in a given period of time, while another user needs a report on the analysis o sales figures of the same product in the same period of time, categorized by particular characteristics of the product (e.g. the color). It may occur, that the employed method of analysis does not enable performing analysis with categorization by a given attribute (color). Thus, the first user will obtain a specified amount of sales (for instance, 10,000) while the other user will obtain sales at 0. This generates a conflict of knowledge, because the structures of knowledge differ in number of attributes (for example, the 'color' attribute will not occur in the first analysis, but it will occur in the second analysis) and in values of attributes (sales figures will be different in each report).

Another example may be the analysis of settlement of accounts with contractors. We assume that the user needs a report on the analysis of settlement of accounts with customers, categorized by particular products, based on balance of accounts. Next, the user will require a report on the same analysis, but in this case, categorized by particular customers. It may occur that total amounts in both analyses will differ, because, for example, some customers have not been assigned a particular product. This also generates a conflict of knowledge.

A separate problem is generating reports on forecasts by BI system. In this case, structures of knowledge may differ in attributes for many reasons. For instance, different methods of analysis (or different parameters) may generate different figures of predicted sales in the future, even when based on the same range of data. Additionally, even using the same method of analysis, but with detailed categorization by different dimensions, may generate varied values of attributes in each report (for example, if an analysis is performed on the forecasted sales referring to the future, categorized by particular customers and then another analysis is performed in the forecasted sales in the same period of time, but categorized by particular products, then each report may contain a different total amount of forecasted sales).

One must remember that one cannot ignore conflicts of knowledge that occur in BI systems nor uproot them. The conflicts must be located and resolved. Only then the system can perform analyses properly and present reports to the user, and only then can the system do its job.

Knowledge conflict resolving can be carried out using various methods, such as:

a) negotiation methods;

b) deductive-computing methods, based on:

- game theory,
- classical mechanics,
- operational studies,
- behavioral and social sciences,
- choice,
- consensus.

The negotiation methods guarantee the desired compromise, however, this is realized at the expense of increased communication between the nodes of the system, which of course adversely affect its performance. While the methods of deductive-computing group do not affect to a great extent on the speed of operation of the system, they, except the consensus methods, does not guarantee the achievement of a good compromise. Decision-maker, instead, requires a good system performance (often working near the real time) and efficient knowledge conflicts resolving, so the system will effectively support the decision making process.

In order to resolve the knowledge conflicts in BI system, most appropriate methods will be used for the choice or consensus methods, as opposed to other methods, they do not require interference in the internal system statuses (for example you do not need to interfere with the existing programming code). Choice methods rely on the election (on the basis of certain criteria) one of the conflicting knowledge states (represented in the form of the structure presented in this article), which is presented to user. The rest of the states of knowledge are not taken into account in this case, therefore, a high level of risk associated with the choice of the incorrect state of the knowledge. Consensus methods, instead, rely on determining such state of knowledge, that will represent all of conflicting states of knowledge, generated earlier by system. In other words all parties to the conflict will be taken into consideration. This will consequently reduce the level of risk related to choice incorrect state of knowledge. Choice or consensus methods can be implemented as a separate modules of system.

The work on the development of conflict resolving module, with the use of consensus methods, are in progress. The consensus is elaborated in three major stages. In the first stage it is necessary to carefully examine the structure of knowledge. In the second stage it is necessary to define the distance functions among particular structures. The third stage is an elaboration of consensus algorithms that generate a structure, that the distance between this structure (consensus), and the individual structures is minimal (according different criterions).

Algorithms for detecting and resolving the conflicts should be implemented in the system and running, when the structures of knowledge differ. Of course, these algorithms running automatically, without human interaction. Detecting and resolving knowledge conflicts in BI systems allow to certainty of system functioning, in other words, reports generated by system as result of analysis is consistent from the point of view of the criteria defined by the user. Only in this case decision-makers can take full advantage of the system.

V. Conclusion

Conflicts of knowledge occur in virtually every BI system. The system designers should remember that methods for detecting and resolving conflicts should be considered at the first stage of system development. Implementing them after the system has been commissioned may be very difficult due to the need to input additional software code. Proper detection and resolving conflicts is extremely important especially in BI systems, because their operation greatly influences the decisions made by decision makers and, consequently, the operation of the entire organization. Resolving the conflicts is also very important, because only then the system can suggest proper decisions. If the system ignores these aspects, then the user (decision maker) is likely to have problems making a quick and correct decision, because the system may suggest an improper decision, or may suggest several different decisions, forcing the decision maker to spend time selecting one of them, which makes the whole process very time-consuming and impossible to perform in approximately real time.

***Abstract*—Diagrams are an effective and popular tool for visual knowledge structuring. Managers also often use them to acquire and transfer business knowledge. There are many currently available diagrams or visual modeling languages for managerial needs, unfortunately the choice between them is frequently error-prone and inconsistent. This situation raises the next questions. What diagrams/ visual modeling languages are the most suitable for the specific type of business content? What domain-specific diagrams are the most suitable for the visualization of the particular elements of organizational ontology? In order to provide the answers, the paper suggests light-weight specification of diagrams and knowledge content types, which is based on the competency questions and ontology design patterns. The proposed approach provides the classification of qualitative business diagrams.**

I. Introduction

KNOWLEDGE visualization proved to be an effective tool for knowledge creation, acquisition and transfer [5, 6, 13]. Diagrams [2] constitute the basis for visual knowledge representation and elaborated diagrammatic techniques typically form visual modeling languages [17]. In computer science these techniques are reflected in such languages as UML and IDEF. They are also integrated in software engineering methods, e.g. the Structured Analysis and Design Technique (SADT) and are organized by the architecture frameworks, such as the Zachman framework [28].

The focus of this paper is put on the realm of management. Manager also frequently use diagrams in their work [11, 18, 25] but the choice of diagrams is often error-prone and inconsistent [7].

For the effective choice of the visualization method, at least five perspectives should be considered [6]. These perspectives answer five key questions with regard to visualizing knowledge, namely:

1. What type of knowledge is visualized (content)?
2. Why should that knowledge be visualized (purpose, knowledge management process)?
3. For whom is the knowledge visualized (target group)?
4. In which context should it be visualized (communicative situation: participants, place/media)?
5. How can the knowledge be represented (method, format)?

The knowledge type perspective as the focus of the paper, can be used for identifying the type of knowledge with respect to its content. Any complex entity can be represented from several aspects (facets) and at different strata (layers) [13, 28]. The following question-based aspects can be proposed and differentiated [1, 6, 13, 28]:

WHAT-Knowledge: Conceptual representation.
WHAT_FOR-Knowledge: Strategic representation.
HOW_TO-Knowledge: Functional representation.
WHO-Knowledge: Organisational representation.
WHERE-Knowledge: Spatial representation.
WHEN-Knowledge: Temporal representation.
WHY-Knowledge: Causal representation.

Today, there is no validated prescriptive framework that links business diagrams with knowledge types and that offers specific diagram for particular knowledge types. This issue defines the first research question*: What diagrams/ visual modeling languages are the most suitable for the specific type of knowledge (content)?*

The second research question of the paper stems from the task of ontology visualization within different applications. Ontology is a formal, explicit specification of a shared conceptualization. Ontologies and corresponding semantic technologies are actively used for knowledge management, e-commerce, education and semantic web. Currently, each concept of ontology is represented with the same graphical representation independently of its meaning. Graphical representations of ontologies are concerned with the representation of concepts, relations or instances but do not consider a domain specific meaning [21]. Special ontology-based frameworks are developed in order to visualize ontology using domain-specific notations [20, 22, 26]. Some of these frameworks are oriented towards managers and must include knowledge of the currently available popular business diagrams/visual modeling languages with the associated semantics. It defines the second research question: *What diagrams/ visual modeling languages are the most suitable for the visualization of the particular ontology view (elements of ontology)?*

The research was held with the financial support of the Russian Foundation for Basic Research (RFBR), project # 11-07-00140-a, and the Saint Petersburg State University (SPbSU)

II. Related work

Periodic table of visualization methods [23] provides a good top-level diagrams overview for managers. These authors decided that the classification dimensions should be easy to use and have some proven benefits. The organization principles were related to the situation in which the visualization is used (when?), the type of content that is represented (what?) the expected visualization benefits (why?), and the actual visualization format used (how?). As a result, the following five dimensions were suggested:

• *Complexity of Visualization:* Low to High, referring to the number of rules applied for use and/or the number of interdependences of the elements to be visualized.

• *Main Application or Content Area [how?,what?]:* Data, Information, Concept, Metaphor, Strategy, Compound Knowledge.

• *Point of View [when?]:* Detail (highlighting individual Items), Overview (big picture), Detail and Overview (both at the same time).

• *Type of Thinking Aid [why?]:* Convergent (reducing complexity) vs. Divergent (adding complexity).

• *Type of Representation [what?]:* Process (stepwise cyclical in time and/or continuous sequential), Structure (i.e., hierarchy or causal networks)

The authors organized these dimensions in the specific table of visualization methods. But we may conclude that while it is a very impressive result the values for these dimensions are rather general, overlapping and are specified insufficiently.

Lohse et al. [24] reported a structural classification of visual representations. These authors identified 11 major clusters of visual representations: graphs, tables, graphical tables; time charts; networks; structure diagrams; process diagrams; maps; cartograms; icons; pictures. Criteria for classification were represented using 10 anchor-point phrases: spacial-nonspacial; temporal-nontemporal; hard to understand-easy to understand; concrete-abstract; continuous-discrete; attractive-unattractive; emphasize whole-emphasizes parts; numeric-nonnumeric; static structure-dynamic process; convey a lot of information-convey little information. We may conclude that this classification mostly works with structural dimension. Semantic dimension of diagrams is not covered.

Some of the diagramming tools provide its own classifications of the templates. Visio 2010 (http://office.microsoft.com/en-us/visio/) provides the following 8 embedded categories: Business; Engineering; Flowchart; General; Maps and floor plans; Network; Schedule; Software and Database. Visio 2010 Online library (http://visiotoolbox.com/2010/templates.aspx): Application Architecture; Asset Management; Business Analysis; Business; Capacity Planning; Database Planning; Educational; Facilities; Financial; Human Resource templates et al. 25 categories totally. Smart Draw (http://www.smartdraw.com/): Charts: Flowcharts, Project, Org; Education; Engineering; Forms; Mind Maps; Presentations; Timelines; Decision Trees; Cause & Effect Diagrams; Marketing Charts; Strategy & Planning et al. 29 categories totally. Our general conclusion is that Visio embedded categories do not cover all the knowledge types and have rather inconsistent classification criteria. Smart Draw categories are extremely overlapping, have different level of abstraction and also use inconsistent classification criteria.

Also there exist several enterprise architecture based classifications, e.g. Archimate [19], MEMO [10], IBM Enterprise framework or populated Zachman Framework (http://publib.boulder.ibm.com/infocenter/rsysarch/v11/topic/com.ibm.sa.bpr.doc/topics/r_IBM_Enterprise_fmwk.html). But these classifications and frameworks do not include all the types of diagrams used by managers and in general such taxonomies cover mostly IT-oriented diagrams and proprietary diagrams.

We also would like to mention some independent conceptual specifications for the popular business diagrams / visual languages [3, 14]. Unfortunately these descriptions do not involve all the popular business diagrams / visual languages. Also the existing specifications mostly incorporate the area of business processes, while the other areas are insufficiently specified.

III. Methodology And Results

We suggest to use ontology-based specifications for knowledge types and diagrams/visual modeling languages. Alignment between these two specifications will enable managers to choose diagrams for the particular knowledge type. Additionally it will provide opportunity to select the diagram for the specific competency question and for the visualization of the particular ontology view (elements of ontology).

In order to describe informally the knowledge types and to take a step towards the ontology-based specification we suggest to use competency questions technique [16].

Ontology-based knowledge types specification consists of a set of Ontology Design Patterns (ODP) [12]. ODP — a modeling solution to solve a recurrent ontology design problem. It is a template that represents a schema for specific design solutions. An ODP consists of a set of "prototypical" ontology entities that constitute the "abstract form" of a pattern, and of a set of metadata about its use cases, motivations, provenance, the pros and cons of its application, the links to other patterns, etc. Design solutions based on ODPs encode ontology entities that apply, specialize, or instantiate the prototypical entities defined by the schema. Some of the popular ready-made ODPs are represented at http://ontologydesignpatterns.org/. The other ODPs can be extracted from enterprise-related ontologies [4, 9, 27].

The suggested ideas are integrated in the method of business knowledge diagrams classification (Table 1).

Ontology-based diagram specification is based on the ideas of [15], but we suggest to use "light-weight" ontology-based specifications. They do not require the complete ontological model for every diagram, but conceptualize just the core elements of each diagram. The incompleteness of the specifications is justified by the purpose of the specification — the classification and the choice of modeling language.

Alignment between the two ontology-based specifications can be provided by means of ontology mapping/matching techniques and tools [8].

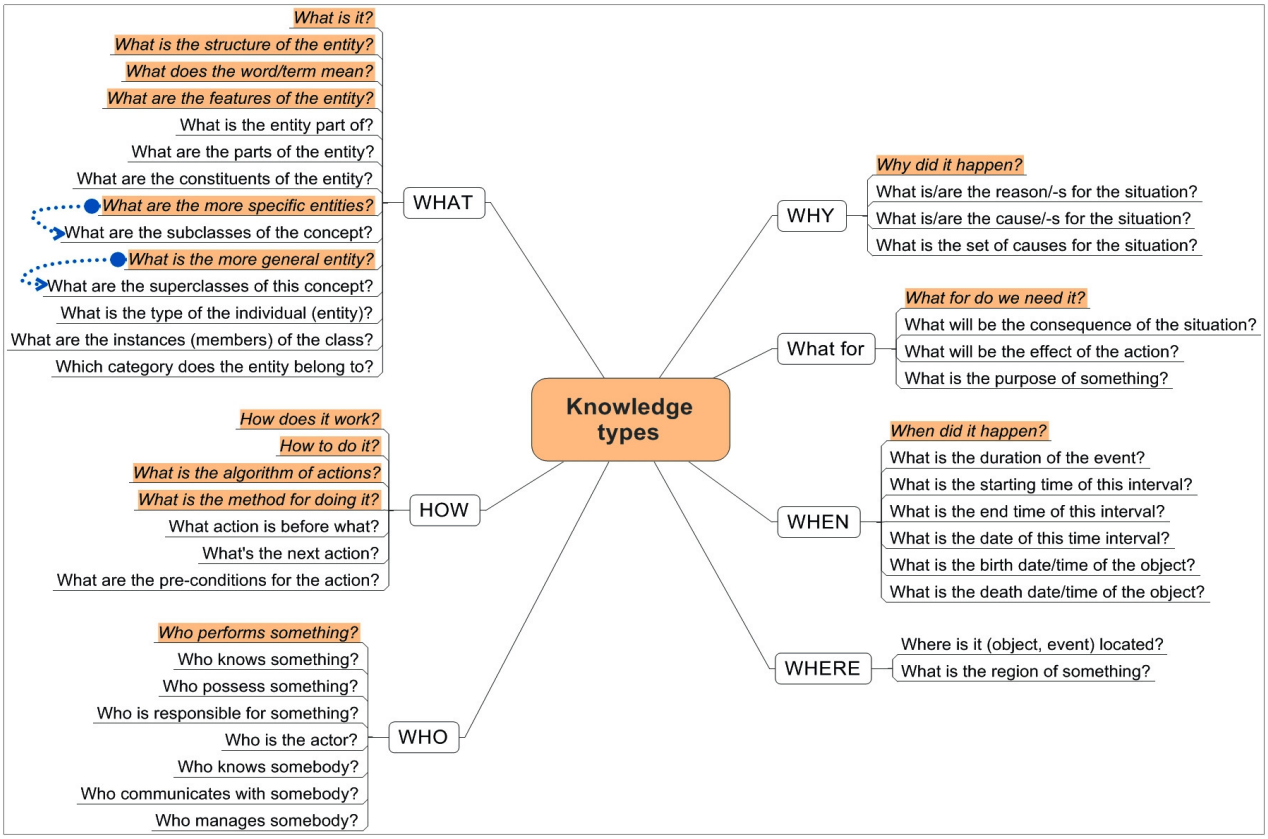
IV. Usage Scenarios

We can introduce three possible scenarios of results usage.

Scenario A (answering the first research question). The user choose the diagrams based on the competency ques-

Table I.
Method of business knowledge diagrams classification

№	Steps	Results
1	Define and describe the knowledge types using competency questions.	Informal description of the knowledge types is represented in Fig. 1.
2	Specify the chosen knowledge types using ODPs — each type of knowledge answering the concrete managerial question may be specified by ontology patterns	ODP specification of knowledge types is based on the Content ODP annotation schema and include the following elements: Pattern name, Intent, Competency questions, Diagram, Elements and examples, Source, Reusable OWL file, Submitted by. The incomplete list of the ODPs for several knowledge types can be found in Table II. Table III shows an example of the ODP specification. Knowledge types descriptions in terms of concepts and relationships can be developed based on the ODP specifications — see Fig. 2.
3	Identify diagrams, which will potentially correspond to the suggested knowledge types, e.g. from Visio, SmartDraw, [23] and provide ontology-based specifications of these diagrams.	Ontology-based specification of diagrams include: diagram name, thumbnail, brief description/purpose, Conceptual model (classes and properties), Conceptual model diagram. Table IV shows an example of the diagram specification.
4	Align ontology-based specifications of knowledge types and diagrams. The alignment is provided using the ontology-based specifications (see steps 2 and 3).	Example alignment between ontology-based specifications of knowledge type and diagram is shown in Table V.
5	Classify diagrams according to knowledge types based on the ODP alignment (from step 4).	The above-proposed approach helps us to work out the classification which may be useful for the practitioners in selecting the appropriate type of business diagram (Fig. 3).



*non-specific competency questions are highlighted (won't be directly relate to ODPs)

Fig. 1. Knowledge types description using competency questions

tions only. If the competency question is non-specific ("voice of the customer") and doesn't directly relates to ODPs, then he/she selects all the diagrams associated with the knowledge type (which is associated with the chosen competency question. The choice among the suggested diagrams is based on the supported ODPs.

Scenario B (answer for the first research question). The advanced user may choose the diagrams using ODPs and the competency questions can be used for preliminary filtering.

Scenario C (answer for the second research question). The user or service wants to represent his/her ontology or ontology view using domain-specific visual language. Then

user aligns ontology which must be represented, with ontology-based descriptions of diagrams and then selects the appropriate diagrams for the ontology or ontology view based on the alignment.

V. DISCUSSION AND CONCLUSION

The main novelty of our approach is the mapping between knowledge types and popular business diagram types, which grounded on ontological specifications. Such the mapping together with the suggested informal descriptions of knowledge types can support managers, while working with visual models. Our novel classification is only the attempt as the list of diagrams for knowledge types is incomplete. Creation of the extended catalogue/repository for diagrams should be a collaborative effort. The suggested method of business knowledge diagrams classification can be used within this effort. ODP–based diagram classification method is also a

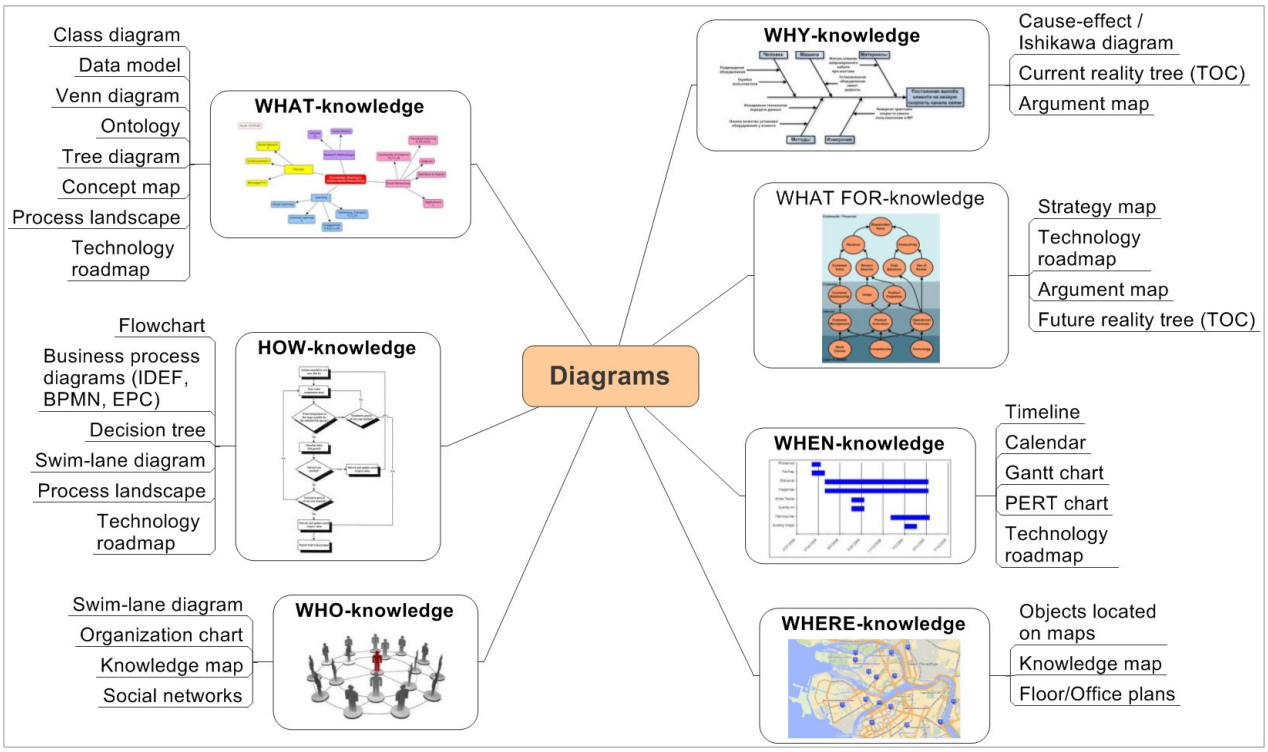

Fig. 3. Diagrams vs. knowledge types

contribution of the paper. Thesaurus based descriptions (synonyms) for ODPs and ontology-based diagram specifications can be a useful appendix (see WordNet). The suggested diagrams can be typically considered as diagram types, which may have a lot of variations and particular notations. We've tried to extract the most generic or prototypical inherent elements of diagram / visual modeling language. Additionally, informal description of knowledge types provides new classification the existing ODPs.

Such pattern-based approach can be considered as the first step towards ontologically founded usage of diagrams among managers. Business diagrams are typically describes some components of enterprise architecture. So according to the "Maturity Model" for Enterprise Architecture Representations [29] adhoc visual models of enterprise architecture correspond to the 1st level of maturity. This approach to enterprise architecture, though a natural, common and easy place to start, does not scale well. Any sizeable organization generally has more than one person or a single group doing enterprise. The ultimate goal is the design of a consistent organizational ontology or ontology network behind a collection of diagrams. This will allow organizations to have ontology-based knowledge repository with consistent domain-specific visual views.

***Abstract*—Functioning in an era of knowledge is forcing organizations to manage this valuable resource in exact way. Very frequently activities of organizations are dependent on the application of knowledge, sometimes even means "to be or not to be" for enterprise. Nowadays, to fulfill business goals of institutions it becomes fundamental for them to use intelligent systems supporting comprehensive management of the organization. Such support allows to increase efficiency and better effectiveness of the running businesses. As we are living in age of international integration, where world economy is tending to reach type of knowledge-based economy (KBE), universities are forced also to change way of their functioning. It is important for modern universities to be not only education centers but mainly the successfully prospering organizations-based-on-knowledge. Such approach is going to provide higher competitiveness of particular institution and will make its functioning more useful for economy of the region. Implementing a comprehensive and intelligent IT solution within a university and providing educational services, which are personalized to the needs of the market, will allow universities to reach a type of institution called "smart". The aim of the paper is explanation why university centers should evolve in a type of institution based on knowledge. The paper is managed as follows. After short introduction concerning research context the discussed concepts of Knowledge Management and Smart Universities are presented. In the main section real examples of Knowledge Management Systems implementation and examples of Smart Universities are investigated in order to identify and describe roles of Knowledge Management Systems in this area. It allows for formulation conclusions on intersection of two investigated approaches.**

I. Introduction

IT IS noticeable, that particular word countries are realizing implementation process of knowledge-based economy concept within its own economies. Such step is treated from scientific point of view as a fundamental step for the implementation and maintenance of balanced development of the country. Today, where the management is based on knowledge, it is crucial to use new technologies as a support of decision making process in organization. Currently main factors of entrepreneurship are: highly qualified human capital, universities, along with research centres, IT infrastructure and legal environment conducive to the construction and development of selected sectors of the economy. Accordingly, key elements of the knowledge-based economy in the modern management model becomes important to generate rapid pace of intangible capital, the implementation of innovation in every possible aspect of the business environment and the generation of high-quality knowledge.[24]

Terms of the knowledge economy is crucial for the functioning of businesses. Even Peter Drucker - recognized in the world as the father of modern concepts of management - management expert said that traditional enterprise resources such as land, labour, capital, constitute a bigger barrier than the driving force behind the development of the company. According to Drucker, a mission-critical determinant of creativity in all aspects of the knowledge.[8] Following Drucker, knowledge is a key factor determining the existence of the company and gives the public a new, unique character.[22] In addition, it is important to pay attention to the fact that it is impossible to say about the delivery of the knowledge-based economy, while acting within state organizations - including the institutions do not operate on the basis of the knowledge management process. Hence adopted to say that organizations which take into account aspects related to the management of knowledge management are called knowledge-based businesses. For the purposes of this article, for such an undertaking means an organization that "actively create knowledge and can use it in their daily activities"[14]. In addition, it is needed to note that the creation of knowledge is not only a task of companies involved in the provision of purely market knowledge but should manifest itself in the functioning of each operator - which in turn implies KBE.

How organizations generate and manage knowledge, which information systems are used to support such process, why universities can be classified as a corporation and for what reason authors tried to nominate them as a "smart" is going to be describe in this paper. Article will therefore include the characteristics of the company knowledge, a description of the key concepts of knowledge management, including meaning of information in order to present the essence of having intelligent solutions within the organization. In next sections it will be also explained why universities should be seen as the company providing the market "creative people" (called "smart people"), through the provision of educational services, functioning on the basis of intelligent information solutions.

II. Company knowledge

Knowledge is not only one of the key resources of the enterprise, but also is the foundation, the starting point for determining the company's strategy, particularly for the implementation of management information systems. Knowledge of the computer science is defined, in part, dependent on the data and information. The data does set of facts, measurements, statistics. Information, in turn, is nothing more than structured data. Thus, in this sense, knowledge is a collection of information that can be used in practice. However, the organization cannot exist without human capital, so to be able to say that the company has the knowledge, it is needed to take into account in addition to possession of selected information skills, experience and qualifications of specialists in selected fields. The combination of these two elements is a complete understanding of each company. Pay attention to the continuity of the process of converting data into information and information into knowledge. [2]

Because of the persistence of the two currents are still classifying knowledge: as an information resource and as an element of human capital. Each company needs both of these resources to function properly, so it is reasonable to say that knowledge is nothing else than "a combination of everything: facts, phenomena and relationships between them, which is consciously perceived and recorded (in any way saved as real entities or conceptual) and can give to others, according to the intention of having knowledge in specific conditions and circumstances to arouse certain behaviours". [6]

This is how the company manages knowledge depends on how knowledge in the enterprise is defined and what type it is preferred to carry out their activities. In theory, knowledge management is distinguished by personalized knowledge, which consists of the explicit knowledge and discreet. The formal knowledge are recognized as a formal document prosperity of the organization. However, informal knowledge - discreet, is nothing else but the skills, qualifications and experience of the employees. This knowledge is nowhere recorded, is set in their minds, so there is a barrier to capture the sensitive knowledge of that. [19] However, there is no longer a barrier to overcome. The knowledge of a discreet, distinguished by the so-called core, which allows the conversion of that knowledge in a standardized, codified form and vice versa. Due to the prevailing organizational culture within the organization and information system properly prepared can be personalized to gather knowledge and to process it and share as needed to other members of the organization. Although, it is depended on employee what part of knowledge is he/she going to "give" the company, it is also possible by using suitably generated mechanisms of organizational learning. Supporting such process, company is able to obtain a well-established knowledge that remains within its borders regardless of the availability of human capital.[16]

III. Knowledge Management

Being aware of all possible kinds of company's knowledge resources and knowing value of this crucial factor, it automatically refers to the essence of knowledge management, treated as a priority in the strategic management techniques. Knowledge management, as a young field of management encompasses the latest methods and techniques that are designed to provide most spectacular use of knowledge.[15] To make it more detailed, "knowledge management system is a modern concept, involving the effective use of knowledge and transforming the company into a lasting value for customers and employees of the organization"[20]. Moving forward, "knowledge management is clearly defined and systematic management of vital knowledge for the organization and its associated processes of creating, gathering, organizing, diffusion, use and exploitation of knowledge, carried out in pursuit of the objectives of the organization"[19]. Knowledge management can also be treated as a specially designed "system that helps organizations to acquire, analyse the use (re-use) of knowledge in order to make faster, smarter and better decisions, so that they can achieve a competitive advantage"[10]. In order to obtain a complete picture of knowledge management need to mention two aspects. The first talking about the fact that knowledge management is "management of information, knowledge and expertise available within the organization, i.e. the creation, collection, storage, sharing and use, to ensure the organization's future development of existing resources"[12]. Second, where knowledge management is regarded as a "deliberate business strategy, which selects, distils, stores, organizes, packs and provides information relevant to the company's business in a way that improves staff efficiency and competitiveness"[5].

As we can see, authors of the above definition also emphasizes the two items related to knowledge management. Both accessible to, the information, experience, staff and their expertise and the technological, where the focus is on codifying knowledge, its acquisition, collection, analysis, storing and sharing at any time, by a specific user. The logical also is the fact that the development of knowledge takes place through the exchange of experiences, analysis, opinion, finding new sources of information, where the information systems are the basis to allow all of the actions.

IV. Knowledge management tools

As mentioned earlier, knowledge management is to create added value for the company and its environment proximal and distal. Due to the ongoing intensive technological development has now become a common use of communication tools allowing the use of accumulated knowledge and its proper share respectively of all company employees. According to prevailing quality standards for functional knowledge management systems, it is desirable that the software is compatible with other environments that

utilizes the company or its partners in the supply chain. It is true that currently supplied management information systems do not focus on the separation of the component dedicated to the management of knowledge, but rather allow it to manage in the "background", without limiting in any way the access to knowledge or to give support key company processes.

Due to integrated information system, it should be understood as a modularly organized system, supporting all areas of its business, from marketing and planning and procurement, through the technical preparation of production and the control, distribution, sale, management of repair work financially - accounting and management human resources. [1]

The integrated system is a system in which data or information is entered only once, and they are available to all users of the various processes in the enterprise. The most common, the most distinguished units in integrated systems are:

- an organizational chart - taking into account the structure: vertical and horizontal - user login to the system,
- input - screen formats for data entry,
- order - the products / services - short / long-term, temporary of contractors - implementation schedules - time and value of the contracts short / long term of complaints - the frequency,
- planning - sales of short / long-term production capacity, about forecasting in demand, prices, the scheduling of purchases - material procurement automation, the distribution needs - transport, forwarding
- production / services - technological resources, location, staff, materials, semi-finished products
- staff - directory management employees, managers, employees, executive, administrative, a database of periodical co-workers,
- materials management - information on materials (eg, prices)a database of suppliers, about purchase history, the timing of purchases
- fixed assets: production by division, assets, condition of assets,
- control - of finishing orders of jobs, areas of control, the amount of control about the control points, reports,
- book sales - a record audience, issued documents: the amounts received and receivable of sales analysis, implementation plans, short / long term
- module obligations - register suppliers of necessary goods and their normal consumption of goods purchased,
- master register - maintaining the organization's financial data, simulations of possible states
- module financial - accounting - analysis of energy and raw materials, wages, load workstations of finance - budget, bank, payment procedure. [11]

Carefully selected an integrated management information system now enables efficient management of the entire organization, carrying out the functions of the enterprise environment taking into account both internal and external, and therefore, appropriate management of enterprise knowledge. "The selection of specific solutions and technologies in the field of knowledge management should be based on the specific nature of the company, its profile, personal economic situation, its strategy and approach to knowledge management. Any company or institution should be considered as characteristic for the organization of the organizational culture, creative workers, rules and norms prevailing within it and look at it from the perspective of ongoing business processes. In addition, each organization must be aware that a comprehensive knowledge management system cannot be based only on an appropriately selected technology"[19].

V. UNIVERSITY=ORGANIZATION

To be able to say that higher education institutions can be considered for the organization, in terms of management, one must start from the definition of the firm. Companies in Polish law is defined as "an organized set of tangible and intangible assets intended for business" [7]. Institution (according to management sciences), as defined by T. Pszczołowski is the "organization, which is a team of people interacting with each other and properly resourced" [17]. Continuing, J. Zieleniewski states that the term "institution" is a social creation, called. "Thing organized," which factors are creative human capital and tooling needed. [21] In the literature it is also possible to find the phenomenon, where the concept of the organization is used interchangeably with the term institution.[4] It can be concluded, that the concept of institutions is synonymous with the concept of the organization in terms of factual. Knowing that Polish universities are institutions, we can consider the above classification that should be treated as an organization that can be managed in a comprehensive manner.

Taking into account the objectives of Economy Based of Knowledge and National Development Strategy, as well as other documents and regulations speak of the need to develop and adapt to the new market situation, taking into account the assumptions of the concept of sustainable development, it can be concluded about the need to implement appropriate IT tools within the "forward-thinking organization". As colleges and universities that provide comprehensive solution of the organization, have their own resources, a strict hierarchy and organizational structure, culture, and provide specific services, they are forced to face this present demographic projections take steps to ensure the survival of a heavier period and in a short time to adapt to new trends in the

labour market, in order to refocus the education directly under the existing demand.

Knowing that every company is made up of individual stocks, processes and the environment in which it operates, it is necessary that each learning organization, have implemented an integrated information system. Information systems are nowadays an integral part of most organizations. As previously shown, information systems affect the basic structure and design of the organization. The main purpose of information systems is to satisfy all existing information needs generated by the organization in order to be able to make the right decisions for appropriate decision-making bodies.[3] It is also known that the larger the organization, the knowledge management system using the information becomes more difficult. However, due to technical capabilities, integrated management systems support mainly horizontal communication, without compromising on the priority of vertical communication. Properly designed information system should also allow for quick and easy communication with the environment of the organization, such as customers, and in the case of higher education such as students.

Why universities should have within its structure an integrated information system? The answer is very simple. Universities are being developed organization providing educational services primarily with the use of highly skilled human capital, the use of modern technologies, and other essential resources needed to carry out business activities, providing the market of people defined by psychologists as "creative". Because the university is the responsible of the obligation to seek to achieve the objectives of the KBE and the National Development Strategy, it is necessary to establish their business as a company - put an integrated information system that will not only improve operational efficiency by almost immediately verify the responsibility of individual positions, structured different levels of management, but also through better organization of business processes occurring inside and outside the university, along with the improvement of communication between internal customers and external institutions.

What is an integrated information system? It is nothing other than a comprehensive system designed to optimize business processes both inside and outside the company, using tools to automate the exchange of information between clients throughout the logistics chain. Considered as the most effective integrated information systems are Enterprise Resource Planning systems (ERP). ERP represent a group of integrated computer systems, such as modular structured enterprise information systems. They gather in one coherent system of all the traditional functions of management (related to financial and management accounting, finance, human resources and payroll, technical preparation of production and its control, procurement, warehouse management, planning and execution of sales and logistics, quality management)"[23]. Their main objective is to integrate internal and external environment of organization. This process is supported by the latest information technology solutions, such as multidimensional data analysis in data warehouses. The modular ERP also provides comprehensive knowledge management in organization. Confirmation of this view can be found even in the same characteristic features of ERP systems:[11]

- functional complexity - covers all spheres of business activity,
- integration of data and processes - including the exchange of data and information between modules, internal organization and its environment (EDI),
- functional and structural flexibility - is designed to provide maximum adaptability, customization and hardware solutions - software to the needs of the individual modules,
- open-enables you to extend the system with another, new modules
- substantive progress - provides full support for the processes of information - decision-making using the full data extraction and aggregation, as well as practical support system for logistics strategies such as JIT, MRP II and TQM
- technological advancement - ensures compliance with current standards of hardware - the programming with the ability to migrate to new platforms,
- compliance with law such as the law on accounting.

VI. Smart University

Based on the assumptions, known in the world concepts of smart city, smart business, or even smart building, it is possible to say that colleges and universities can also get a smart domain name. Based on the assumptions of the Research Group of IBM Specialists, which attempts to outline the concept of smart institution as a smart city, where it is defined as "the integration of infrastructure: physical, social, business and IT"[9], by analogy we can try to concretize basis of smart university. Figure 1 shows five segments, which authors assume as relevant to the concept of smart.

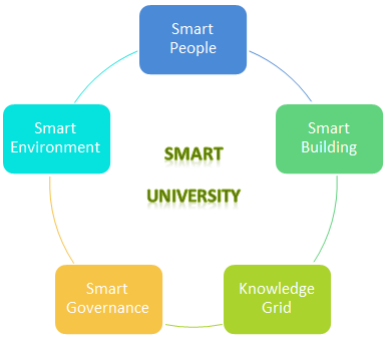

Figure 1. Components of smart university.

To be able to say that the university achieves type of smart, it must be managed in an intelligent way. It means, the authorities during making decision have to include all

five university contractual determinants: human and social capital (called smart people), available physical infrastructure (called smart building), an integrated information infrastructure (called knowledge grid), strategic decision-making processes (called smart governance) and aspects related to the protection of the environment (called smart environment). In order to manage institution according to such approach, decision-makers must consider institution as a whole, as a single organism. Therefore authorities of universities should be aware that making changes in one specified area has influence in second one. Considering such obvious mechanism it becoming needed to manage all segments of the university in a coordinated manner through the use of available information solutions enabling consolidation of knowledge and efficient management. Hence the necessity of implementation properly prepared, dedicated, fully-integrated management information system enhanced by intelligent modules, allowing to carry out a number of advanced business analytics. Computerization of communication between university-customers will help to facilitate the collection of information and improve communication between system users. In addition, the accumulation of large amounts of information, both in the form of reports, studies, statistics, or in the form of answers to questions, contribute to the development of the wisdom of the institution. Operation of university decision-making bodies in terms of sufficient information can therefore be involved in creating the best conditions for the development of the institution, as well as serve the needs of the labour market and the customers themselves universities. Improving the quality of services provided by universities can be guaranteed only taking into consideration the resource information from its environment. Therefore, it is important that the participants had the opportunity to free, independent, re-use of public resources, tools and information.

In addition, smart university should have:

- complex interaction (called comprehensive contact), including intelligent management of resources, equipment and utilities, allowing to specify the location of objects in real time using ICT infrastructure
- full integration (called fully-integrated), assuming that the basic scheme of the system infrastructure supporting university heterogeneous data are fully integrated together,
- incentive for innovation (called encouragement for innovation), covering all activities of the university intended mainly for its interior and exterior public institutions in order to spread the use of its new technology as a way to ensure the development of their own, as well as regional
- group work (called collaborative operation), based on intelligent infrastructure, critical systems and cooperating users - employees of the university, both administrative and scientific, which will help to improve the efficiency of the university.

A perfect example of higher education in Poland, which aims to provide smart can be a School of Social Sciences (pl. SWPS), based in Warsaw, together with affiliated divisions in Poznan, Wroclaw, Katowice, Sopot have deployed dedicated to the needs of the institution integrated management information system ERP SIMPLE.EDU [25]. The use of a comprehensive IT solution by School of Social Sciences allowed for more efficient management of the institution and the proper management of its resources, mainly knowledge organization.

VII. Conclusion

The discussion conducted in the pages of this article can be concluded that the company's success is conditioned by the precise knowledge management company. It also means that organizational success depends on access to high-quality information, appropriately implemented IT solutions and business culture of institutions. “Managing organization requires efficient management of knowledge and human capital, treated as assets that are purchased, maintains, develops, evaluates and monitors. To enable the organization to be fully competitive in the global and local market should meet two conditions: have adequate knowledge and be able to take advantage of their knowledge"[13]. As can be seen in the pages of this article, knowledge is a sensitive factor in determining business value.

Additionally, caring about knowledge management at every level of organization enables creating opportunities of organization growth. It allows also to implement innovation, conduct studies on the effectiveness of organization considering processes inside and outside the organization. Such strategy may improve functioning of the supply chain, in which the institution operates. Also, implementation of customized information system supporting managing allows improving communication within the organization. Ensuring integration within organization supported by a comprehensive intelligent information system management is the starting point for achieving the objectives contained in the concepts such as Sustainable Development Strategy and Knowledge-Based Economy. Meeting the objectives of computerization of enterprises, which is crucial for the use of highly skilled human capital, business management in a holistic way, where decisions to solve one problem take into account potential changes in other aspects of company is none other than the foundation of modern management concepts, where the business seeks to type named “smart”.

***Abstract*—Publicly available Web search engines suffer from several limitations, which significantly reduce usability in particular cases. The most important limitations are out-of-date information, very simple query language and limited number of results. In many cases, users of the Internet are interested in finding new information which appear in the particular Web portal. In this paper, a system for monitoring of Web sites is presented. The system can continuously analyze the content of specified Web pages using advanced text processing algorithms. It actively notifies the user when required information is found in newly-added content. It can be deployed on a single PC as well as on a cluster of computers, providing good scalability. The paper presents an abstract architecture of the system, details of the implementation and real-life experiments results.**

I. Introduction and related works

THE GROWTH of the World Wide Web, which has been observed over last years, has resulted in the greatest base of electronic data. It is hard to even estimate real size of the Web. The WorldWideWebSize.com portal claims that the most popular search services index more than 50 billion Web pages [1]. Four years ago Google published an information, that the indexer found 1 trillion unique addresses [3]. These estimates definitely do not show the real size of the Web because the indexers deliberately ignore particular fragments, like content generators, link farms or pages with illegal content.

The features of the Web pose huge challenges for searching systems. The size itself creates significant scalability and performance issues. What is more, it is very hard to acquire information about what a user is really looking for and detect pages containing information needed by the user.

Publicly available Web search services offer access to very simple and fast ways of finding pages. The services use Web crawlers to visit as many pages as possible and build an inverted index of all processed content. The indexes make it possible to find Web pages which contain specified words in few milliseconds. This method of finding information in the Web is used every day by each Web user. However, several significant drawbacks and limitations of the approach do exist:

- If several pages contain all specified words, ordering of results is imposed by the search engine. Sorting is typically based on popularity. This feature connected with the limit in the number of found pages results in inability of finding some pages.
- The query language is typically very simple. It is impossible to express advanced patterns concerning sentences or use synonyms. It is even impossible to specify rules specifying letters casing, distance between words or words ordering.
- Low frequency of crawling causes outdated results. The searchers often find pages which contain different content or no longer exist.
- High popularity of search engines results in an interesting feature of the Web: if a page cannot be found using search services it is considered nonexistent.

These limitations encourage researchers to continue work on different ways of finding valuable information in the Web. The subject of focused crawling has received significant attention over last few years. The idea of a crawler which can select pages relevant to a specified topic [7] has been implemented using various techniques [8], [10]. Most obvious application of a focused crawler is a topic-specific search service, which can provide more accurate results.

Use of index-based search engines can successfully direct a user to potentially interesting Web sites. However when the content of the Web sites changes fast and the information must be detected as soon as possible after it is published, indexing-based methods becomes insufficient. When a user knows where to look for results, but it is impossible to watch the Web sites continuously, a different approach to the problem of searching the Web is needed.

Some complex solutions in this area were also presented. Liu et al. [4][5] proposed a system that monitors web resources and reports changes of web content by sending messages for system's users. Although, those solution does not focus on various methods of information pattern detection, as it's presented in this article. The another system - WebMon [9] - is also a tool for web information monitoring, and could be applied to monitor date, keywords or links. It's intended for multiuser access and provides a useful functionalities, but it also doesn't support various pattern detection mechanism. There are also publicly available solutions as Corona tool [6], which is easily scalable decentralized system available for multiple subscribers, but it's detection pattern flexibility is limited.

In this paper a system for monitoring selected fragments of the Web is presented. It provides a service, which can monitor precisely specified fragments of the Web and actively report when a particular pattern is found in a newly-published content. The various pattern detection methods were tested and compared. Also crawl performance and pattern detection is

978-83-60810-53-8/$25.00

tested and presented, in comparison to standard Google search results. Proposed system could be deployed on a PC, server or cluster - based architecture, to fulfill required performance. Possible applications of the system include monitoring auctions services or job advertisements. It can also be used by law enforcement services for detecting illegal content quickly.

II. Architecture of the Web Monitoring System

The architecture of the system is inspired by a Java-based general purpose Web crawler with indexer presented in [11], [12]. The crawler uses a cluster of computers for parallel processing of different Web sites. It provides a distributed inverted index of all words found on visited pages. The general architecture of the Web monitoring system is presented in a Figure 1.

The Crawler component is a single processing thread. It contains a queue of URLs to download and analyze. It is responsible for performing all operations needed to process a Web Page – details on processing algorithms will be presented in the next section. The most important result of the processing is URLs detection – the URLs are returned to the Smith Component.

The Smith component controls multiple Crawler threads. It starts specified number of Crawlers, manages URLs queues, receives found URLs and communicates with the Node Manager.

Each node used by a system has a single Node Manager is responsible for communication with global System Manager. Each Node Manager provides administration interface for monitoring and management. It also provides a service interface, which is used for executing search queries.

The System Manager is responsible for controlling nodes. It collects and distributes found URLs, performs distributed search and provides access to management interface of every node. It also provides a Web Service interface for clients of the system.

The Client application uses provided Web Service interface. It is implemented in a different technology and provides convenient graphical user interface.

The system can be deployed in three different ways:

1) PC-based,
2) server-based,
3) cluster-based.

The smallest configuration can be executed on a single modern PC. In this configuration all components are running on the same computer. This configuration uses particular settings, which significantly limit required system resources. It does not need expensive hardware however, it can be used only for monitoring several small Web sites.

In the configuration using a single server, the MySQL database server and the JBoss application server are executed on a powerful machine, which is working constantly. User application can be started from time to time in order to verify searching progress. In this configuration several users can use the same server. Tests showed that a single server can process around 100 000 Web pages every hour.

The most advanced configuration uses a cluster of servers. The performance of processing in this configuration can be easily increased by adding new servers to the cluster.

III. Resources Processing Algorithm

The most important part of the system is implemented by the Crawler component. It performs processing of Web pages content downloaded from the Internet. A diagram of steps performed by the Crawler is shown in a Figure 2.

The process of crawling is controlled by the Manager, which stores a queue of URLs to process. All URLs found by the node are stored in the Urls database. The Manager continuously executes the processing sequence, which consists of the following steps:

- Resource downloading, which results in HTML source stored in a memory buffer. This step includes filtering unsupported file formats, HTTP servers error handling and maximum source length verification.
- HTML parsing by the Lexer. This is the most complex and time-consuming step of the processing which builds document model.
- Changes detection, which results in selecting fragments of a Web page content that have never been processed.
- Content processing by various plugins operating on the document model created by the Lexer. One of the plugins returns a list of URLs found in the processed content, that are added to the queue of the Manager.

This sequence is being executed by every single URL which appears on the list of the Manager. The following sections provide more details on the processing algorithms.

A. Content Parsing and Resource Model Building

The Lexer converts the HTML source into a resource model. The model represents a tree structure built of segments. Each segment represents a selected structural element of the Web page (tables, paragraphs and lists). Segments can contain other segments or they can constitute leafs of the tree containing lists of words, special characters and HTML tags.

Each element of the HTML source is converted to an element of the tree structure or to a token. There are three basic types of tokens:

1) words,
2) tags,
3) special characters.

Each token has its unique identifier – an eight byte integer. Selected ranges of the identifiers are reserved for tags and special characters. The rest is being dynamically assigned to new words found in the content. This approach converts the content of each leaf segment into a list of identifiers, making following processing very efficient.

The dictionary of words is a very large data structure. Average Web page contains several thousand words, however typically very few are new words. Nevertheless the size of

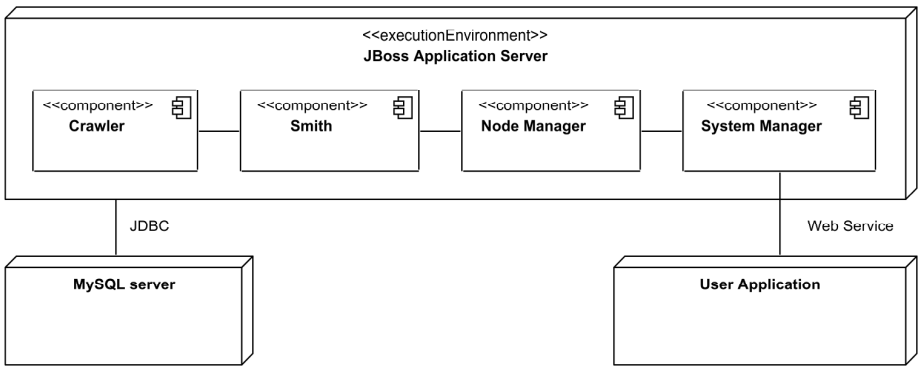

Fig. 1. Abstract architecture of the Web Monitoring System

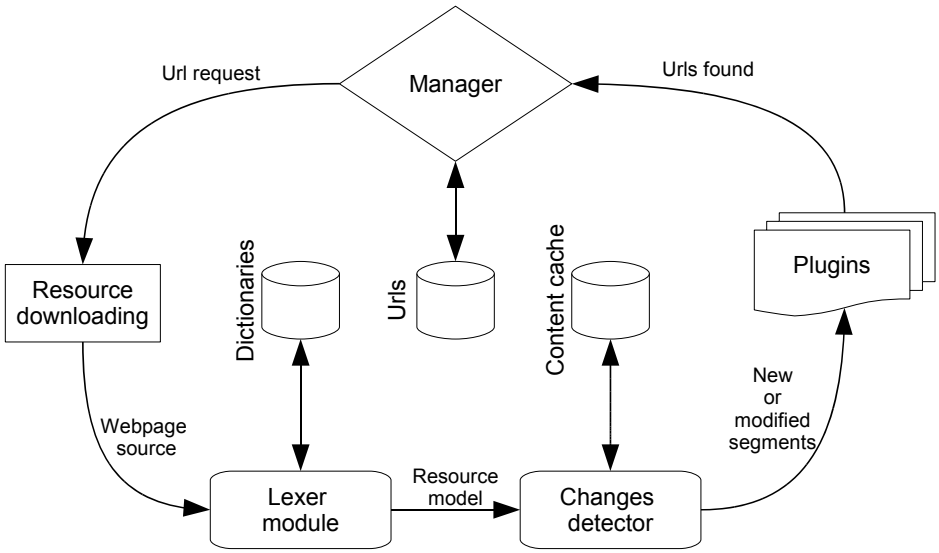

Fig. 2. Processing performed by a single Crawler component.

the words dictionary can reach millions of entries after a few days of crawling. Therefore, the implementation uses large in-memory caches based on hash maps to make the word-to-identifier conversion as fast as possible.

B. Changes Detection Algorithm

The changes detection algorithm is based on hash codes calculated for analyzed content. The hash code for a segment seg containing n tokens is calculated using tokens' ids in the following way:

$$hash(seg) = \sum_{i=0}^{n-1} seg[i] \cdot 31^{n-1-i} \quad (1)$$

where $seg[i]$ is the identifier of the i^{th} token in the segment. The algorithm is very similar to the one used by Java String class implementation.

The hash codes are calculated for every leaf segment. If the hash code has been found in any previous processing of the same Web page, the segment is considered unchanged and is not processed any further. Theoretically, two different segments could have the same hash code, however, using 64 bit identifiers and 64 bit hash codes makes it almost impossible.

To determine what values of hash codes have been already processed, the Content cache database is used. It stores all hash codes of leaf segments found in a page content. Typical Web page contains between 10 and 100 leaf segments.

C. Content Processing

Leaf segments that are considered new or modified, are processed by all enabled plugins. A plugin is a component which provides a common interface – it accepts resource model or its parts.

There is one plugin which is mandatory for proper functioning of the system. The URL detector plugin must be enabled to continue crawling process. It finds URLs in the content of provided segments, searching for anchor HTML tags.

The Web Monitoring System provides several other plug-ins that are used for finding Web pages containing patterns specified by a user. The plugins provide several methods for defining the patterns.

a) List of words: – a user provides a list of words in particular form. A segment will match the pattern if all words are present in the segment.

b) List of stems: – a user provides a list of words in any form. A segment will match the pattern if any form of each word is present in the segment. To implement the functionality a plugin uses a stemmer component which can convert any word to its basic form and provide all possible forms for a given word. The stemmer typically requires a language-specific dictionary of all words and possible forms.

c) List of close words: – a user provides a list of words and maximum distance (in words) between all the words. A segment will match the pattern if all words are present in the segment and the distance between the most distant words is less than the value provided. The order of words in the list is ignored. This plugin can also use stems instead of words.

d) List of words in a sentence: – a user provides a list of words. A segment will match the pattern if all words are present in a single sentence in analyzed the segment. This plugin can also use stems instead of words.

e) List of optional words: – a user provides a list of words and required threshold. A segment will match the pattern if the number of specified words found in the segment exceeds the threshold. This plugin can also use stems instead of words.

The plugins provide several convenient ways of defining precise patterns which a user is looking for. They provide much more flexibility than the query languages provided by the most popular publicly available search services. Particular examples of the patterns and found content will be provided in the next section.

IV. Tests

Special set of tests of the system has been performed after implementing proposed solutions. For testing purposes, four most popular news portals, according to Alexa [2] ranking, were selected :

- interia.pl [1],
- gazeta.pl [2],
- onet.pl [3],
- wp.pl [4].

For the crawl process, five detectors based on the methods described in previous chapter were configured. All of detectors searched for patterns in Polish language, due the fact that in the implementation of the stemmer algorithm and its database was available only for Polish language. It could be easily adapted to other languages by implementing the stemmer algorithm and its database in other languages.

[1]www.fakty.interia.pl
[2]www.wiadomosci.gazeta.pl
[3]www.wiadomosci.onet.pl
[4]www.wiadomosci.wp.pl

Detectors that were used to search for results, are:

- *Simple* – based on *List of words* method, parametrized by words ”virus” and ”flu”,
- *Stem* – based on *List of stems* method, parametrized by words ”virus” and ”flu” and it’s stems,
- *Distance* – based on *List of close words* method, parametrized by words ”virus” and ”flu” and it’s stems and distance between first and last word equal 5,
- *InPhrase* – based on *List of words in sentence* method, parametrized by words ”virus” and ”flu” and it’s stems,
- *Percentage* – based on *List of optional words* method, parametrized by four words: ”virus”, ”flu”, ”AH1N1” (which is special kind of flu widespread in Poland in December 2012), ”disease” and it’s stems, with minimum 50% percent of threshold.

Detectors search for defined patterns within the processed web page body and return the results if all searched criteria are fulfilled. The big advantage of the proposed system is the results memory mechanism. It allows to return the result only if it appears on processed web page for the first time, or if the surrounding content has changed since the previous processing.

TABLE I
Crawl performance

Domain	NoC/FC	GS	AFU/APU	ACT	EFF	UM/PM
interia.pl	17/11	3,8mln	3320/3150	1h 45m	0,5	0/0
gazeta.pl	17/12	3,6mln	4375/3951	1h 52m	0,58	24/283
onet.pl	15/10	2,4mln	6112/5950	3h 10m	0,52	119/286
wp.pl	17/8	6,9mln	2602/2520	1h 45m	0,4	258/581

- NoC - number of crawls
- FC - number of full crawl processes
- GS - number of pages returned by Google ”site:” query
- AFU - average number of urls found on domain during single crawl
- APU - average number of urls processed on domain during single crawl
- ACT - average total domain crawl time
- EFF - average crawl efficiency [urls/second]
- UM - number of urls with with any patterns matched
- PM - number of patterns matched within the domain

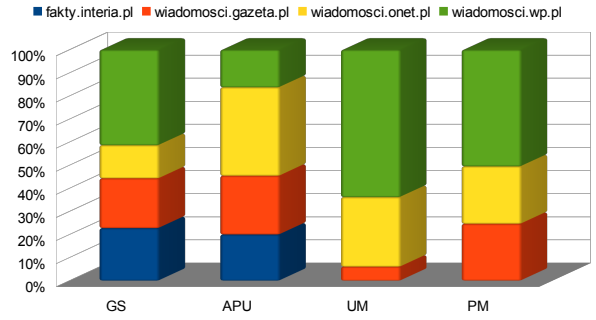

Fig. 3. Crawl performance diagram

The test period last 48 hours – it started on Saturday at 10am and it finished on Monday at 10am. Crawl performance

recorded during the test are shown in Table I and Figure 3. There could be observed some interesting facts:

- Number of urls within the domains returned by the Google "site:" search query varied from 2,4 to almost 7 millions. The number is huge, because it includes archive urls from the Google storage. Performed crawl returned at most about 6000 urls on single crawled domain. This is less than 0.3% of urls declared by the Google search engine, but those urls are all currently available urls, accessible by links spread from top domain url.
- Time of the single domain crawl process varied from 1h30min to 4 hours per domain. Average domain crawl efficiency was comparable for all the domains, about 0,5 processed url per second.
- Not every crawl process succeeded with full url list being processed. Some crawls has been terminated after crawling just a few percent of urls from domain. This is probably a result of temporary ban for IP of the crawling system.
- The number of returned results is neither related to the estimate (returned by Google "site:" query), nor real urls number of the domain. Most results were found on the smallest of crawled domains. The biggest domain was on the second position regarding number of unique web pages with matched pattern.
- One of the domains (fakty.interia.pl) did not contain any results for whole test crawl period.
- About 95% (average) of urls found during crawl process are the documents in textual (text or html) format and they are processed by the detectors.

Crawl and detection effects are presented in Table II. Results are grouped into two hour time units. First two rows of table indicate hour of test ("HoT") and related hour of day ("HoD") of crawl process. "NoU" row represents a number of unique urls found by all detectors within every domain crawled during the test. "NoP" represents a number of patterns found on web pages by all detectors. Below, there are statistics for all detectors separately, displayed as "NoU" and "NoP" values.

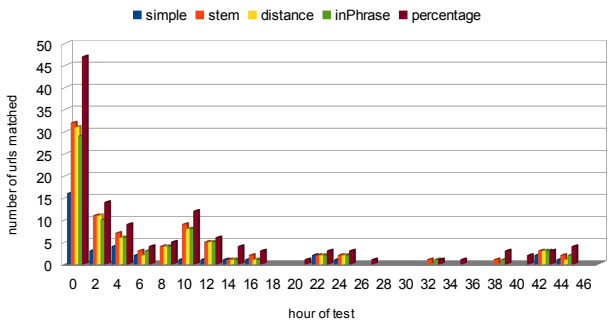

Fig. 4. Number of web pages found during crawl

Interesting remarks that could be observed on a base of test results are:

- The detector with biggest number of urls returned is the *Percentage* one – based on *List of optional words*. It is also result of its search criteria - 2 of of 4 words were required to report as pattern matched.
- Detectors based on word's stems (Stem/Distance/InPhrase) return very similar number of results (about 90% of average common results).
- Detector Simple (without word's stems) returns about 40% of stem-based detector results and matches about 30% of patterns found by stem-based detectors.
- In the figure 4, there is clearly shown, that most of the results (above 51%) are found during first crawl process (in first 4 hours of test).
- There could be observed some tendencies and periodicity of new information appearance. New patterns are found every morning, between 22 and 26 hour of test (8-12am), and also between 42 and 46 hour of test (4-8am). It differs slightly but it is probably caused by crawl density process. Also Saturday afternoon is the time, when the information peak could be observed. Both of this remarks could be result of:
  - new articles published (morning news),
  - increased activities of users commenting articles (evenings).
- an average number of detected pattens observed in the Figure 5 correspond to the trend of the number of unique urls containing pattern. Although there can be observed some deviations. On the 6 and the 16th hour of crawl, there are conspicuous peek of number of detected patterns, which is not related to an adequate incrementation of number of unique pages containing results (8 pages with 79 results and 14 pages with 210 results). Such result was caused by crawling the portal's search engine webpages, containing set of queries and query results related to search topic.

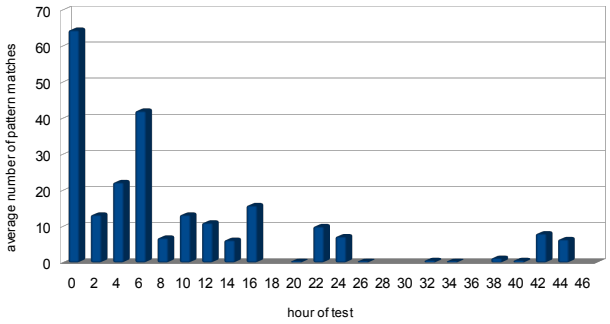

Fig. 5. Number of patterns matched on web pages during crawl

Table III presents statistics about number of patterns found on single web page. The remarks based on those results are:

TABLE II
DETECTOR RESULTS

HoT	0	2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38	40	42	44	46

- HoT - hour of a test (0 - 47)
- HoD - hour of a day (0 - 23)
- NoU - number of unique urls with results (for all detectors)
- NoP - number of pattern occurrences (for all detectors)
- NoU-X, NoP-X - NoU or NoP for particular detector

TABLE III
NUMBER OF PATTERNS FOUND ON WEB PAGE

Number of patterns on page	1	2	3	4	5	6	7	8	9	10	11	12	13	14	28	34	35	57	65
Number of occurrences	203	93	28	30	8	6	10	10	2	1	1	1	1	1	1	2	1	1	1

- above 50% contained only one pattern within its body,
- almost 25% contained 2 pattern matches within its body,
- about 15% of web pages contained 3 or 4 pattern matches,
- 9% of results contained 5 to 8 results within its body,
- less than 3% of results contained more than 8 pattern occurrences.

The tests showed clearly, that the solutions used in the presented system works correctly. The performance was satisfactory during whole two-day long experiment. The changes detection algorithm was able to find fragments of Web pages, which have actually changed between visits. The detectors using the stemmer algorithm have demonstrated advantages over a simple, word-based query language.

V. CONCLUSIONS AND FURTHER WORK

The system presented in this paper is a promising base for further works and development, in the area of information retrieval from WEB resources. After certains improvements it could provide useful functionalities, that can definitely find applications in real-life scenarios. Created method for detecting modifications in the webpages' content provides an efficient way of finding only newly-added information.

The proposed solution may also have a variety of applications in open source intelligence analysis. The crawler can be used to build a knowledge base that contains information about objects, events and relations between them (e.g. companies and involved people). This can be further integrated with other analytical tools, such as LINK platform, which supports mainly criminal analysis [13]. This way the crawler can be used as valuable data source for performing various analyses (for example searching relations between people and companies involved in fraud).

Further research on the approach will include performance improvements and development of more advanced methods for defining content patterns. Moreover, tags-avoiding methods are planned, in order to optimize results quality. A possibility of defining semantic meaning of a content or of a similarity to a given text would be more useful than specifying a list of words. This could be achieved by methods of machine learning [14] for building classifiers for particular types of content

ACKNOWLEDGMENT

The research leading to these results has received funding from the research project No. O ROB 0008 01 "Advanced IT techniques supporting data processing in criminal analysis", funded by the Polish National Centre for Research and Development.

Business Intelligence as a service in a cloud environment

Maciej Pondel

ul. Komandorska 118/120,
53-345 Wrocław, Poland
Email: maciej.pondel@ue.wroc.pl

Abstract— Business Intellligence should be described as a way of managing our company more than a set of functionalities in a computer software. Acquiring a real profit requires enterprise management to understand the value of the data and the way data describe business processes. Being aware of the business and measuring its performance we are able to improve the processes and make whole the business more effective. To achieve business improvement we require efficient Business Intelligence system as a combination of a software, hardware, the communication infrastructure and services regarding data preparation, integration and delivery to the system.

In this paper author considers if the service oriented approach and cloud computing can make BI implementation more efficient.

I. Introduction

BUSINESS INTELLIGENCE for sure is the way for the enterprise to make the business more efficient. BI systems are fed by a big volumes of data coming from the transactional systems working inside company. That is why the BI systems are most often on-premise software which mean they are hosted on the servers inside the building the company is located.

Another way of using software is called software as a service or cloud computing which can bring the significant benefits for a company. Are these benefits strong enough to make BI implementation in cloud environment more efficient than on-premise?

II. BI Implementation

Different definitions show that the components of business intelligence software are inter ailia[1]:

- Data warehousing
- Multidimensional analysis, for example OLAP
- Data mining
- Business analysis
- Visualization
- Querying, reporting and charting (including just-in-time and agent-based alerts)
- Geospatial analysis

The software is supplied by the following categories of data:

- Operational data (regarding financial, logistics, sales, orders, personnel, billing)
- Private data (mainly spreadsheets prepared by business analysts, knowledge workers, statisticians and managers regarding analysis and reports)
- External data (purchased from vendors specializing in collecting industry-specific information such as: Health care statistics, customer profile information, customer credit reports, trends, currency fluctuations, stock prices demographic data and many more)

Operational data in most cases come from the transactional systems hosted inside the company. They are the biggest data volumes from all mentioned categories. Operational data is probably the most important data category because the data describe directly our business.

In a current situation most of BI systems are implemented basing on the following assumptions:

- BI system is located in the same LAN as the main transactional systems, because it collects the huge amount of data from transactional systems,
- Data loading is performed once a day at the time when users do not access the systems,
- The internal structure of the data warehouse is unique for every implementation (because every enterprise has unique combination of transactional systems that they use).
- The user interfaces are usually typical for business analytics, reporting, visualizations, charting and manager dashboards
- BI system needs a lot of resources, mainly: disk storage because of the volumes of data, network capacity during data loading, processor and memory during data processing.

We have to admit, that BI is evolving. The new possibilities of use appear what implies new challenges for Business Intelligence. We can find among them [3],[8]:

- Big Data analytics

978-83-60810-53-8/$25.00

- Mobile BI
- In memory BI
- Self service BI
- Consumerization of Enterprise Software

III. SERVICE ORIENTED ARCHITECTURE

Service oriented architecture of software is not a new technology [4]. It is rather the idea of creating software as a set of modules called services that collectively provide the complete functionality of a large software application. The services should cooperate by exchanging data and information with other services without any human interaction. The services should be treated as black boxes with precisely defined input parameters and output results. For the architect of enterprise application consisted of services the algorithms implemented inside the service are not so important. The services can have various types. We can have:

- business service – simple IT component responsible for a part of business,
- Web Service – as a method of communication between 2 programs based on World Wide Web protocol
- IT Service – as a business process of supplying benefits to the recipient by a supplier

In order to build efficient SOA solutions the services must meet following requirements:

- Interoperability between different programming languages, systems that allow integration of services
- Federation of resources that allows transparently mapping multiple autonomous resources to be treated by users as one federated resource

Cloud is becoming more and more popular environment for hosting business applications. All greatest IT vendors in the world provide their software as a service available in the cloud. It means the systems are hosted in the vendor's environment on vendor's severs and the systems are available by Internet connection. To the most popular IT systems provided in cloud belong:

- Enterprise email systems together with tools regarding workgroup like shared calendars, resources reservation and applications improving employees' productivity,
- Document management systems,
- Content management systems,
- Databases (like Google Cloud SQL or Windows Azure SQL),
- Business applications like CRM, ERP,
- Application hosting services with programmers API allowing customer to build his own software and host it in the cloud.

The main assumption of cloud services according to Forrester's definition is supplying standardized IT capacity over Internet in a pay-per-use and self-service way [7]. We can understand, that it is suitable way of using IT for all systems that works in a standard way. It we have to use dedicated software the cloud can be too limited for us. According to the Internet technologies – cloud is supporting the standards prevalent in mobile devices. Most of the standardized cloud services can be run at any devices with any operating systems.

What are the main benefits or using cloud services in business[6]?

- It lowers the costs of entry for smaller companies who are trying to use the same software and technologies as the big corporations.
- If the IT solution needs a large amount of computing power for relatively short time the cloud can provide us the resources dynamically what is financially available even for small companies.
- It provides immediate access to hardware resources without any upfront investments. It shortens the time to market for many IT solutions.
- Even for large enterprises cloud can allow to scale their applications in a simpler way. The company has an easy access to the new computer resources whenever then are necessary.
- Cloud computing requires payments only for the resources the company really utilizes. In many cases it is more effective financially than investing the money on the start.

When we compare the characteristics of the cloud environment and the benefits with the assumptions of BI implementations and challenges of BI we can observe that they match each other. Many of those benefits concerning cloud are suitable for Business Intelligence solutions. The features of BI Systems and cloud are summarized in table 1. As we can observe there are some features that do not fit each other. The basic problem concern the huge data transfer from transactional systems hosted mainly on-premise to the solution kept in cloud. The second issue is about dedicated integration procedures and unique data warehouse structure what do not match the standardization of the cloud solutions. We have to admit that those issues will not occur when we have transactional systems hosted also in the cloud – the cloud BI system is a very natural solution because:

- data during the loading stay in the same environment and do not overload the network connection
- the procedures of integration will be typical because the cloud transactional systems must be implemented in a common way

TABLE I.
BI SYSTEMS AND CLOUD CHARACTERISTICS

BI Characteristics and challenges\ cloud features	Standardized solutions	Internet technologies	Pay-for-use	Dynamic allocation of resources	Hosting in the vendor environment
Huge data transfer from transactional systems					-
Data loading once a day				+	
Unique data warehouse structure and unique integration	-				
Typical user interfaces	+				
Needs a lot of resources in various part of time			+	+	
Big data analysis					
Mobile BI	+	+			
In memory BI					
Self service BI	+				

If we have most common architecture of transactional systems and they are hosted on-premise we have to elaborate the solution for the indicated issues.

One of the solutions may be an adoption of a hybrid BI environment consisting of:

- the data integration layer which is stored on premise
- the business logic layer stored in the cloud

IV. CONCLUSION

This paper presents the idea of cloud BI system. There are some cases that may inhibit such model of BI software functioning, but author presents how to manage them and what advantages gives combining features of a cloud environment with user expectations regarding BI systems.

Knowledge Acquisition for New Product Development with the Use of an ERP Database

Marcin Relich
University of Zielona Gora,
ul. Licealna 9, 65-216 Zielona Gora, Poland
Email: m.relich@wez.uz.zgora.pl

***Abstract*—Nowadays, a considerable number of enterprises develop new products using an Enterprise Resource Planning (ERP) system. One of the modules of a typical ERP system concerns project management. Functionalities of this module consist of defining resources, company calendars, sequence of project tasks, task duration etc. in order to obtain a project schedule. These parameters can be defined by the employees according to their knowledge, or they can be connected with data from previous completed projects. The paper investigates using an ERP database to identify critical factors, i.e. variables that significantly influence on new product development. Project duration and cost is estimated by a fuzzy neural system that uses data of completed projects stored in an ERP system.**

I. Introduction

THE present information and communication technologies have become one of the most important factors, conditions and chances of the firm development. These technologies enable the collection, presentation, transfer, access and using of enormous amount of data. The data are a potential source of information that in connection with manager skills and experience may influence on the choice of the correct decision. ERP systems help to collect, operate, and store data concerning daily activities of an enterprise (e.g. client orders), as well as the results of previous projects (development of products).

Project success or failure depends on many critical factors, such as the kind of project, access to resources, methods of project management, and environment [1], [2]. The reasons for project failure can be generally considered as a lack of accessibility of resources (e.g. human, financial, raw materials) and changeability of the external environment. Moreover, unstable requirements, lack of well-defined scope, quality of management, and skill of the employees can cause project failure. To reduce project overruns, there are two ways to approach the problem. The first way is to increase the accuracy of the estimates through a better estimation process and the second, to increase the project control.

It is unrealistic to expect very accurate estimates of project effort because of the inherent uncertainty in development projects, and the complex and dynamic interaction of factors that influence on its development. However, even small improvements will be valuable, especially by large-scale projects. More accurate forecasting supports the project managers in planning and monitoring the project, for instance, in project cost, resource allocation, and schedule arrangement.

New product development is connected with uncertainty that includes both internal (e.g. communication in project team, planning techniques, cash flow) and external environments (e.g. social, economic, political, technological conditions). Sources of uncertainty are wide ranging and have a fundamental effect on projects and project management [3]. Uncertainty is an important issue in the support of any decision-making in the process of new product development. Since most companies should estimate project parameters, there is a need to develop an approach that takes into account the imprecise character of data and copes with enormous amount of data. The description of project management and knowledge management in the context of an ERP system, as well as a fuzzy neural system combining the ability for learning and processing inaccurate data is presented in the next section.

II. Background

A. Project management in an ERP system

In recent years, the advancement of information technology in business management processes has placed ERP system as one of the most widely implemented business software in various enterprises. ERP software promises significant benefits to organizations. Some of these benefits include lowering costs, reducing inventories, increasing productivity [4], improving operational efficiency [5], [6], attaining competitive advantage [7], and bettering the reorganization of internal resources [8], [9].

The goal of an ERP based integrated information system is to make the system effective, efficient and user friendly. The performance of software depends on the interaction between the software and users. The primary task of an integrated system is to maintain the data flow of an organization and to reduce the redundancy [10]. ERP is a system for the seamless integration of all the information flowing through the company such as finances, accounting, human resources, supply chain, and customer information [11]. One of the functionalities of an ERP system also includes project management that company can use to develop new products.

The project management functionality comprises the definition of master files and obtaining a project schedule. The definition of master files includes resources that are use in a project, resource calendars, company calendars, time models (blocks), as well as project activities, estimates of activity duration, sequencing (order of activities), milestones. This

978-83-60810-53-8/$25.00

data is the bases to obtain resource allocation, planned cost, network chart, and analyses concerning e.g. original and actual cost.

B. ERP systems from a knowledge perspective

A variety of knowledge management and knowledge integrated manufacturing models have emerged one after another in recent years [12]. These models can be considered in the context of manufacturing or knowledge aspect [13]. The role of manufacturing knowledge is a key strategic resource and it can be presented as the interactive process between manufacturing knowledge and cross-functional activities [14], [15], [16]. Knowledge management may be incorporated into ERP implementation with the use, for instance, a self-sufficient model [17]. In turn, a base to characterize product development and knowledge evolution process can be an integrated knowledge reference system [18].

In the implementation phase, ERP systems have an impact on organizational knowledge (stock of knowledge, distribution, learning processes) [19], as well as on efficiency and flexibility of a knowledge management system [20]. Moreover, business knowledge in the ERP software package to the adopting organization (types of knowledge transferred, resolution of conflicts with existing organizational knowledge, changed knowledge structure) is transferred and internalized from consultants to clients [21], [22]. Knowledge-related ERP systems research mainly concerns the knowledge issues encountered during the system implementation phase or the 'shake-out' period immediately following implementation [23]. The use of an ERP database in the post-implementation phase of ERP system lifecycle is usually obscured. This provides the motivation to develop the approach dedicated for knowledge acquisition in the context of new product development in an enterprise that uses an ERP system.

C. Description of fuzzy neural system

Knowledge acquisition requires some techniques that cope with the description of relationships among data and that solve the problems connected with e.g. classification, regression, and clustering. These techniques include neural networks, fuzzy sets, rough sets, time series analysis, Bayesian networks, decision trees, evolutionary programming and genetic algorithms, Markov modeling, etc.

Fuzzy logic and artificial neural networks are complementary technologies and powerful design techniques that have their strengths and weaknesses [24]. Table I shows a comparison of the properties of these two technologies.

The fuzzy neural system has the advantages of both neural networks (e.g. learning abilities, optimization abilities and connectionist structures) and fuzzy systems (simplicity of incorporating expert knowledge). As a result, it is possible to bring the low-level learning and computational power of neural networks into fuzzy systems and also high-level human like IF-THEN thinking and reasoning of fuzzy systems into neural networks. The fuzzy neural method is rather a way to create a fuzzy model from data by some kind of learning method that is motivated by learning procedures used in neural networks. This substantially reduces development time and cost while improving the accuracy of the resulting fuzzy model. Being able to utilize a neural learning algorithm implies that a fuzzy system with linguistic information in its rule base can be updated or adapted using numerical information to gain an even greater advantage over a neural network that cannot make use of linguistic information and behaves as a black box [25].

The behaviour of a fuzzy neural system can be represented by a set of humanly understandable rules or by a combination of localized basis functions associated with local models, making them an ideal framework to perform nonlinear predictive modelling. Nevertheless, one important consequence of this hybridization between the representational aspect of fuzzy models and the learning mechanism of neural networks is the contrast between readability and performance of the resulting model [25]. The combination of fuzzy systems and neural networks has recently become a popular approach in engineering fields for solving problems in control, identification, prediction, pattern recognition, etc [26], [27], [28]. One well-known structure is the adaptive neuro-fuzzy inference system (ANFIS). ANFIS model is a universal approximator which has the non-linear modelling and forecasting function.

III. Method for estimating project duration and cost

The proposed method is dedicated for new product development in an enterprise that uses an ERP system. New product development is often connected with the superficial changes in design and/or functionality of past products. Thus, data of completed projects can be used to identify relationships between the parameters of past projects and their durations and costs. The method consists of the following stages:

1) extracting data (parameters of past projects) from an ERP system;
2) identification of critical factors that significantly influence on new product development;
3) learning ANFIS in order to obtain rule base;
4) estimating duration and cost of new product development;
5) loading data (estimate of project duration and cost) to an ERP system (module project management).

The presented methodology concerns the estimation of project duration and cost in the different phases of new product development (see Fig. 1). In each of these phases, the critical factors (parameters of an ERP database) that significantly influence on new product development are sought.

Database of an ERP system comprises an enormous number of parameters that can be considered as potential variables to identify the duration and cost of project phases. The second stage in the above-presented procedure concerns the identification of critical factors that influence on the project duration and cost, and indirect on new product development. If the relationship between a variable and the project duration and cost is significant (greater than a level defined by the user), then the variable is considered as the critical factor. The

TABLE I
PROPERTIES OF NEURAL NETWORKS AND FUZZY SYSTEMS

Skills	Type	Fuzzy Systems	Neural Networks

	Flexibility	High	Low

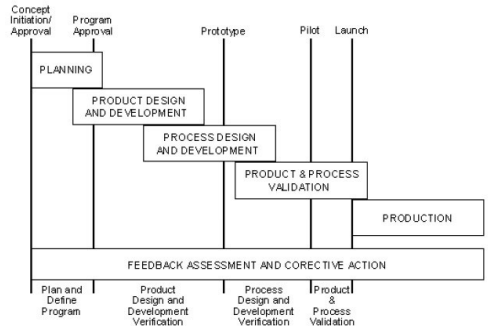

Fig. 1. New product planning phases
Source: [29]

variables are chosen according to the user's experience and can be as follows: a number of human resource (in person-hour), machine-hour, raw material, and activities in a project phase, as well as financial means, delay in client's payment and material delivery by suppliers, quality of material (number of complaints), time of machine inspection, absenteeism during project implementation, project team members, and project manager.

A large number of independent variables in a large data set can present two major problems. Firstly, too many variables result in long training times when the model is built. Secondly, large number of observations and variables tend to retain redundant information through multicollinearity leading to unreliable models. Some of the variables present in historical data are needed for some problems and some variables for others. Often, different variables may carry the same information [30].

A variable reduction method can be based on principal component analysis that is used as a dimension reduction technique for linearly mapping high dimensional data onto a lower dimension with minimal loss of information. The variable reduction is not the main issue in this research and it is not further considered.

The third stage in the proposed methodology concerns obtaining rule base with the use of ANFIS. The identification of rules and the initial parameters of membership function of fuzzy sets are obtained with the use of e.g. grid partition, fuzzy c-mean, or subtractive clustering. The learning stage requires the declaration of optimisation weights method (e.g. backpropagation algorithm) and stop criterion (e.g. error value or the number of iteration). After learning phase, the testing data are led to input of system to compare the results with target. Next section presents an example concerning the use of the above procedure.

IV. EXAMPLE OF PROJECT DURATION AND COST ASSESSMENT

The output variables contain the duration (d_i in months) and cost (c_i in monetary unit - m.u.) of the *j*-th phase in project *i*. In turn, the input variables include:

- h_{ji} - number of human resource in the *j*-th phase of project *i* (person-hour);
- a_{ji} - number of activities in the *j*-th phase of project *i*;
- s_{ji} - number of subcontractors in the *j*-th phase of project *i*;
- tm_{ji} - number of project team members in the *j*-th phase of project *i*.

Table II presents data of eight past projects (development of products) for product design phase that has been applied to the proposed approach.

Calculation has been generated with the use of ANFIS tool that is Matlab software. The application of fuzzy-neural system requires the declaration of input variables and parameters connected with ANFIS, e.g. defuzzification method. Figure 2 presents two ANFIS, for the duration and cost of project phase, respectively.

After the declaration of input variables in fuzzy neural system, the initial parameters of membership functions of fuzzy sets are estimated. As a result, the structure of fuzzy neural system is determined. In next stage, the fuzzy neural system is learnt according to e.g. backpropagation algorithm, and consequently, the shape of membership function is determined (Fig. 3).

The rules can be presented for decision maker in descriptive form. The example of fuzzy rules for the duration and cost is presented in Fig. 4.

To eliminate too strictly function adjustment to data and to increase the estimation quality, the data set is divided into

TABLE II
PROJECT VARIABLES FOR PRODUCT DESIGN PHASE

Variable	P_1	P_2	P_3	P_4	P_5	P_6	P_7	P_8
Human resource	500	400	350	450	600	400	650	500
Number of activities	25	22	20	25	28	22	25	20
Number of subcontractors	3	4	4	5	6	4	5	5
Number of team members	8	7	6	8	12	10	12	10
Duration	14	12	10	15	16	15	15	15
Cost	380	320	320	400	500	420	650	600

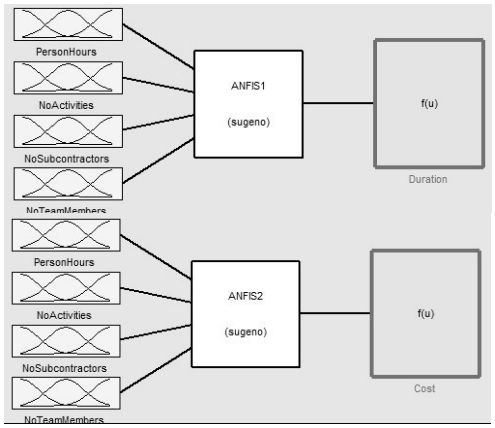

Fig. 2. Specification of fuzzy neural system

learning (P_1-P_6) and testing set (P_7-P_8). The learning phase requires the declaration of method of weights optimisation, and stop criterion (e.g. error value or the number of iteration). After learning phase, the testing data are led to input of system to compare the error between different models. Mean square error (MSE) for various models are presented in Table III. It is noteworthy that the least error in testing set for the duration has been generated with the use of average. It can be connected with a low level of variance for the duration of project design phase. In turn, the least error for the cost has been generated with the use of ANFIS with subtractive clustering method.

The membership functions and rules are a basis to evaluate the duration and cost of an actual project. Let us assume that for the actual project are considered the following values: number of person hours equal 475, number of activities equal 24, number of subcontractors equal 11, and number of team members equal 9. Thus, the duration equals 16.4 months and cost of project phase equals 440 m.u. (see Fig. 5).

There is also possibility to conduct what-if analysis. For instance, if a number of subcontractors will be increased to 20, then the project will be decrease to 13.7 months (see Fig. 6).

The above-presented analysis is conducted for each phase of project and the obtained estimates can be used to evaluate cash flow, working capital, financial reserves, product launch, and other critical factors of an enterprise activity.

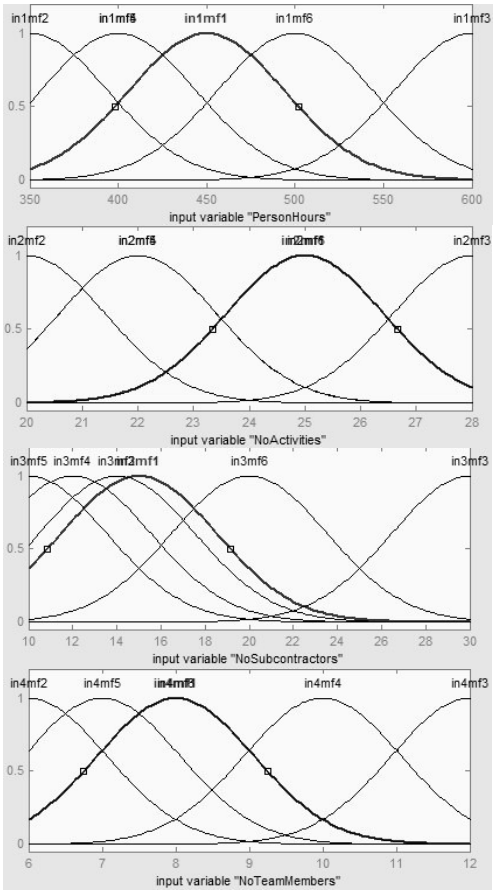

Fig. 3. Membership function for input variables

TABLE III
COMPARISON OF MSE FOR DIFFERENT MODELS

Model	Duration	Cost
Average	1.78	236.32
Linear model	4.16	309.85
ANFIS - grid partition	12.87	564.63
ANFIS - subtractive clustering	2.99	96.10

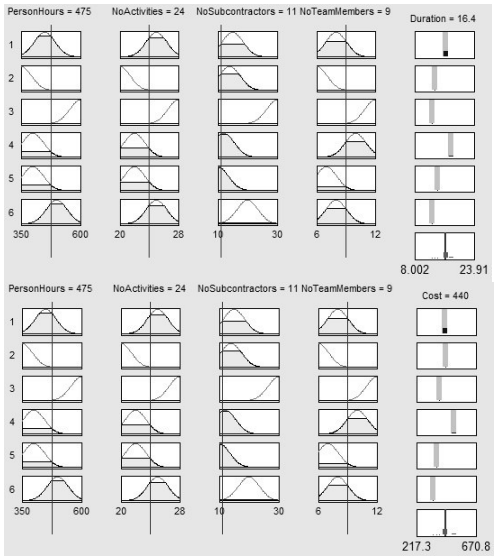

Fig. 5. Estimation of project duration and cost

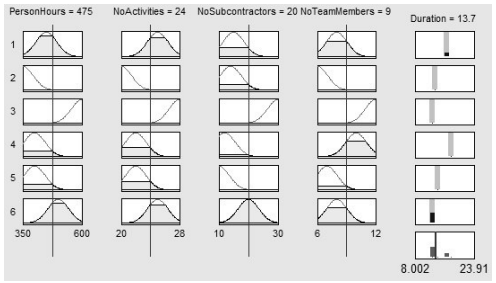

Fig. 6. Project duration for additional subcontractors

V. CONCLUSION

The capabilities of an enterprise to create, share and utilize knowledge effectively are today regarded as one of the key drivers of competitive advantage for industrial enterprises. Competition in quality, design, cost of new products, and time their launching into the market has increased with new competitors having established segments and, in some cases, with change in competitive tools. This forces more frequent and larger-scale changes in contemporary companies, also changes in the use of new information technologies. One of the technologies concerns a fuzzy neural system that is used in this paper to evaluate the project duration and cost.

More exact identification of project duration and cost enables more precision of cash flow planning and finally, decreases the risk of lack of liquidity. If in the enterprise is a database of past projects, then there is the possibility to gather additional information in the form of conditional rules. The application of the proposed approach encounters some difficulties, among other things, by the collecting enough amounts of data of the past similar projects. Moreover, the lack of uniform rules that concern the development of fuzzy neural systems may cause an acceptance problem for the decision-makers. However, the presented approach seems to have the promising properties for acquiring information from an ERP system.

Further research focuses on the development of the presented approach towards searching a set of key performance indicators according to their influence on the success of completed projects. Moreover, future research will be aimed at verifying the proposed approach in a real world to test its practicality.

***Abstract*—Competence management systems are an important addition to knowledge management systems. Competencies can be processed, during the identification, assessment and acquisition processes, because there is a certain set of tools used to test competencies and estimate their levels. In this paper, we focused on the analysis of the concept of Dynamic Competence Management System. The system takes into account competence changes caused by the efflux of time and competence diffusion process in project group.**

I. Introduction

THE management and control of knowledge and skills, and more recently the management of firms' competencies have turned out to be essential factors of industrial processes' performance and part of a strategic objective of human capital management [2]. In studies related to knowledge management, managing competencies is becoming a crucial research problem [22]. On one, hand it is being analysed from the point of view of an educational organisation in which we focus on transparent description of a student's achievements in a form of their competencies and their levels described [15]. On the other hand, we analyse competencies in companies. According to [26] *intellectual capital=competence x commitment*. Competence profile of an employee should allow us to make the right decisions regarding training, assigning to a project or even recruiting. Moreover, the knowledge about the competencies is produced and transformed by identification, assessment and acquisition processes [25]. Competencies can be processed because there is a certain set of tools used to test competencies and estimate their levels (e.g. http://www.inspeo.com, http://www.matchinglab.com, http://www.actonomy.com/) and methodology to competence assessment [14]. Moreover, the process of competence computing should be understood as enabling the use of competence databases for inference and combination of competencies for different functions and processes, not as a reductionist account of competencies to numeric models [6].

Large enterprises are characteristic of several features that cause difficulties in managing competencies of their employees. The first feature is a high personnel rotation on different positions. Second one is related to the lack of standardised system approach regarding saving and storing information about competencies. The competencies themselves change in a dynamic way, employees thanks to trainings or being members of some projects are developing and/or achieving new competencies. Additionally, we have to factor in a constant obsolescence of knowledge, which affects the competencies achieved by certain employee. Luckily this process is being avoided by implementing Life Long Learning policy. Organisations constantly approach the question of what employees are needed for certain projects, so that its rate success will be as high as possible thanks to certain set of competencies.

This paper will describe the concept of Dynamic Competencies Management System (DCMS) which will help in better processing of the dynamic nature of competencies. There are several reasons to create and maintain the DCMS in the organization [4]: (1) they can provide identification of the skills, knowledge, behaviours and capabilities, needed to meet current and future personnel selection needs, (2) they can focus the individual and group development plans to eliminate the gap between the competencies requested by a project, job role, or enterprise strategy and those available. The existing systems to not support dynamic aspects of competence management enough. Systems focused on providing the tools for recording competence profiles and use them to select the employees to the project.

The first part will include an overview of literature related with competencies management in a typical organisation. Next, the components and functions of the DCMS will be defined. After that we will clear up the concepts related to the DCMS and its relation. The next part will showcase dif-

The part of this work was supported by Project „Platforma Informatyczna TEWI", nr. POIG.02.03.00-00-028/09,

ferent approaches regarding modelling the dynamic nature of competencies. At the end, the social network approach to dynamic nature of competencies modelling will be discussed.

II. Competence in the Organization

According to [10] the competence is a observable or measurable ability of an actor to perform a necessary action(s) in given a context(s) to achieve a specific outcome(s). The competence information (competence profile) is a data about a competence that may be aggregated for communication among individuals, organizations, and public administrations. The more detail discussion about competence notion can be found in [5] or [16]. The history and background of standardization in this area and research project are covered in [7].

Generally speaking the competencies in the organization are placed on unit (organizational), collective (team) or individual level [17]. The typical related competencies are presented on Tabele I.

TABLE I. TYPICAL COMPETENCIES IN ORGANISATION (BASED ON [13])

Unit Competence	Collective Competence	Individual Competence
- Knowledge Landscape - Knowledge Assets - Information Sharing - Push/Pull Power Balance - Synergy Creation	- Knowledge Sharing - Cultural Integration - Resources Utilization - Innovation - Management/ Leadership	- Result Orientation - Role Commitment - Continuous Learning - Networking - Creativity

Based on the [8] we can defined what qualities and capabilities the competent person or team require:

1. The domain knowledge empirical, scientific or a blend of both;
2. The experience of application (knowing what works) in different contexts;
3. The drive and motivation to achieve the goals and strive for betterment/excellence;
4. The ability to adapt to changing circumstances and demands by creating new know-how;
5. The ability to perform the requisite tasks efficiently and minimise wastage of physical and virtual resources;
6. The ability to sense what is desired and consistently deliver that at a high quality to the satisfaction of the end client.

While creating a IT system that will allow for competencies processing we must take into account the nature of competencies. The main medium for competencies caring is human, its work and personal development affects the parameters of given competence. Competencies are considered as an union of different components. Thanks to literature analysis (e.g. [7], [20], [21]) we can distinguish some components like: knowledge, skills, experience, etc. The important issue is the question of whether competence is a binary quality or not. According to [7] in natural language, and in other domains such as law and biology, competence is seen as binary, someone is either competent or not. In the educational domain, however, the competence can be graded on a scale, and that it can have degrees or "dimensions".

Competence can get gradually stronger, in a situation where surroundings affect and stimulate its components. For example, we acquire new skills in a training session or while working (e.g. software developers programming everyday). Competence (its level) can also degrade. The most common reason for it is not using the given competence in everyday work. The other is thanks to technology progress which makes the components of competence outdated. We can distinguish different relations between competencies which affect the interaction between them. Increasing competence in a certain competence group (e.g. communication) can affect the increase of other competencies (e.g. sales of products). Next issues regarding competence processing in an organisation start to show up when we take a look from a company's perspective. From the company's point of view, certain competencies are created only by combining the competencies of a greater number of employees. The complexity of these combined competencies is too great for a single person to obtain this kind of competence.

III. Dynamic Competencies Management System Definition

Based on literature analysis we can specify the following functions of the Dynamic Competence Management System (DCMS): employment planning, recruitment, trainings, raising work efficiency, personal development, managing key competencies. The literature current thinking is that competence management can be organized according to four kinds of mutual related processes [1]: competence identification, competence assessment, competence acquisition, competence knowledge usage.

Currently in Competence Management Systems, the analysis of changes happening in competencies by time is much confined. Employee, while working in a project group, develops his/her soft competencies and acquires experience and knowledge that later result in hard competencies. At the same time, some competencies (when not used) can decline. This process leads to a rapid obsolescence of employee's competencies profile. From the point of view of organisation, the process of managing competencies is dynamic because indicators comprising certain competencies constantly change thanks to employee's and its surroundings actions in the organisation. Building the DCMS is a complex process. The problem lies in a complex nature of competencies. Just like knowledge, competencies are created in human mind and are manifested by doing intellectual or manual operations correctly.

The core components of typical DCMS are [4]: competence model management, departments management, job roles management, learning object management, employees management, projects management. This functions allow to the competence knowledge model manipulation for insert-

ing, updating and deleting ontology data – knowledge model mapping on competence. The system also support functions for creating, updating and deleting a relationship between two competencies, a job assignment and an association between a learning materials and a competence [4].

Typical tasks of module of competencies processing system include (based on [4]):

- Finding competencies gaps between the existing and the desirable employee's competencies according to the position that he/she occupies, the related function is skill gap analysis for a future position (succession planning),
- Aggregation of individual competencies to the group's level - it is allows to estimated the average organization's/department's/team's proficiency level. This function calculates the average level of proficiency possessed by the employees for all competencies in the competence model for a specific department.
- Estimating the costs of acquiring competencies - it gives employee possessed proficiency level and the corresponding cots (e.g. time duration) for every competence since he/she was hired. The function 'optimizing the process of competencies transfer' is looking for minimal cost. In some cases we need to invest in employee by using function find learning materials for employee/project.
- Building projects groups - is a function that finds an employee who is an expert for a given competence on required level related to the project requirements (find best fit employees for project' function). If there is still no employee, then the system searches for an expert for other competencies (and comparing employees abilities), which are related somehow to base competence.

Practical problems to solve:

1. Discussion and analysis of competencies nature to determine the methods of analysing and estimating them for a certain employee.
2. Proposal methods for manipulating the structures of competencies.
3. Proposal methods for building the competencies profile for given employee.

Corresponding research problems:

1. Mathematical methods of processing and describing competencies.
2. Describing knowledge with a model (e.g. OWL ontology) regarding the acquisition of competencies.
3. Modelling the environment of competencies acquisition (social networks, viruses, network game theory).
4. Modelling and optimising network models of competencies.

IV. System nomenclature

To define the Dynamic Competencies Management System (DCMS) we need to establish axioms related to building the system:

A. Organisation

Has a global objective which is maintaining a position on the market. It is possible only by developing owned core competencies. Core competencies are competencies which are unique for the company and help to build a competitive advantage. Currently, in a dynamically changing environment, competitive advantage is not only decided by the fact of owning this kind of competencies but also their high levels. In a knowledge-based economy, employees (and their competencies) and intangible resources of the organisation (e.g. patents) are the main elements of its assets. The key to correct operation of organisation is to effectively manage the process of transferring knowledge which will use its assets in the most effective way.

B. HR Department

A department in organisation responsible for competencies audit and management. The work of HR department is based on using dynamic competencies management system.

C. Knowledge worker

Knowledge worker thanks to intelligent operations takes part in project's tasks assigned to him/her. Knowledge worker enhances his/her competencies by taking part in projects and cooperating with other employees (which are willing to share knowledge and they have higher competencies), attending training and self-study. Knowledge worker is described by competence profile which includes: possessed knowledge, competencies and their levels. Moreover, every knowledge worker is also described by his/her individual objectives, cognitive and social characteristics.

Worker has different roles assigned in different projects. Assigning a role requires to possess a certain set of competencies (set of competencies) on a certain level. By assigning a certain position to a worker his minimal competencies are being described.

D. Project

Conducted by knowledge workers. Each worker has a role in the project. Project is being created to solve a certain task, which is composed from sub-tasks. The condition for conducting a task (sub-task) is to have the required competencies on a certain level. Project always involves working in a group with other knowledge workers.

E. Competencies bank

It is distinguishing for every company. It contains a set of all competencies in an organisation (both possessed competencies and those planned to obtain). All competencies are related to each other and they form up a competencies network in a company. Each competence has a certain accumulated level for an organisation. The strategic purpose of organisation's operation is to achieve a desired level for each competence placed in competencies network. Every competency is described by description, and related descriptors (see Table II.)

TABLE II. EXAMPLE OF EVALUATION MATRIX FOR *COMMUNICATIVENESS* COMPETENCE (BASED ON INSPEO.COM SYSTEM)

Competence name	Communicativeness
Definition	Transfer to other information in a clear and understandable way, as well as listening and clarification to what others are saying to us.
Descriptors (1-5 Likert scale):	A. He/she speaks in an understandable way A.1: He/she is expressed in a vague and difficult to understand. No form of communication adapted to the situation and audience whatsoever. A.2: Sometimes he/she has problems with the formulation of clear and concise expression, even in standard situations. A.3: He/she speaks in a clear, concise, and keeps the topic of conversation. A.4: Even in the case of complex issues and in new or challenging situations (time pressure, challenging the audience), is expressed clearly and precisely. Adjusts the way of expression to the situation and audience. A.5: He/she is expressed in a understood manner, even on specialized topics. Communicate to the other their knowledge on how to communicate effectively. Creates and implements the rules of good communication practices. B. He/she ensures that the message was understood by the public … C. Encourages others to share their opinions … D He listens to speeches of his callers / listeners … E Knows the rules of proper written communication … F. It strengthens and validates their content through body language (posture, gestures, facial expressions, distance) …

F. Competencies network

A graph structure showing relations between competencies. Adding new competence to the network requires to make a relation with a competence already existing in the network. Usually it may involve creating new competencies to maintain/create relations with competencies that are already in existence. All competencies in the network must be connected.

G. Competencies catalogue

Description of positions, including competencies and their minimum level required to work on certain positions.

H. Competencies audit

A process that focuses on establishing what competencies and on what level, from the competencies bank, a certain employee possesses. Competencies audit is conducted by completing different psychometric tests, chats with a qualified assessor or an outside certificate that can confirm competencies.

I. Process of acquiring competencies

Process of acquiring competencies consists of different kinds and types of knowledge (ability) transfer to achieve a certain knowledge/experience for an employee and thus allows for achieving good results and reactions regarding certain competence. The transfer occurs between employees or between employees and dedicated systems.

J. Knowledge status

Set of certain areas of knowledge, measured with special equipment, that are included in the certain competence.

K. Core competencies

A set of competencies which are essential for an organisation to work.

L. Organisation graph

Shows relations between workers that occur in certain organisation. It changes over time.

Typical organization is composed of many different departments. In the context of competency management HR department is the most important, because it is responsible for storing information about the competences of employees in the competencies bank in form of the competence profiles. It also performs regular audits of competence, which provides the information necessary to update the employee's competency profile. Audit examines different areas of competence of the employee's knowledge and determine their constitution (knowledge status). All profiles are stored in the bank's responsibility. The structure of competence bank is a graph structure mapping network of competencies. HR department also manages a catalogue of competencies, which is used when hiring new employees.

When the project is coming up the HR helps is project stuff based on an analysis of the project required competencies and the competencies already possessed by the individual employees. When deciding on the allocation of staff to the project , the one must also take into account the organizational structure of the company, expressed as a organisation graph.

In addition, the HR department supports and manages the process of competencies acquiring. In this process, the key issue is to ensure an adequate level of the core competencies in the organization and the desire to cover the competence of the entire competencies network.

V. DISCUSSION OF THE DYNAMIC COMPETENCIES MODEL

In previous sections of the article it was discussed that the competence of a person changes and is subjected to many factors. Thus, the competence should be considered as a dynamic system that depends on many factors, mainly related to time. The competence of a person can be acquired in the process of training or strengthen during work which requires using this competence. Moreover, the competence can be transferred from others while working collaboratively. The competence of a person can also decline while he or she is not actively using it for certain period of time. The pace in which the competence is acquired, strengthen, transferred or declining usually is non-linear and dependent on many fac-

tors, like the nature of competence, its structure, context, current state and individual qualities of a person.

Like any dynamic system the competence can be represented by the set of its states variables values. State variables represent different pieces of a person's competence, like pieces of knowledge, information and skills, thus the competence can be seen as the function of several time-based arguments, such as:

- Time of training (acquiring).
- Time of working actively using competence (strengthening).
- Time of inactivity (decline).
- Time of team work/problem solving (transfer).

The proposed model should reflecting the structure of the competence and represent it as a set containing skills and knowledge existing in a certain domain. The model should be aware of context of competence and be able to reflect relations existing between them (ex. composition, similarity, etc.). There are many researches on this subject that propose well elaborated models [3], [29]. These approaches usually focus on providing exact models of different professional domains for human resource description or training planning. The intention of this model is to extend regular competence model by adding fuzzy measures describing the level at which a person mastered certain competence. The description of personal competence will use fuzzy representation of set to precisely show the "strength" of every element of competence by setting quantitative value of degree of membership for every element of the competency set. This approach will allow performing quantitative analysis on personal competences (ex. level of meeting competence requirements by a person, comparison of competence of two people for staffing purposes etc.). There are several works representing this "fuzzy" approach to competence modelling (e.g. [17] ,[27]) but, in turn, they lack the possibility to map complex relationships between competences.

The next step of the work is to elaborate the method for evaluation of the level of competence basing on analysis of a person portfolio (analysis of training history and professional experience in order to assess the value of the level of competence). This analysis will take into account the phenomenon of "learning curves", which assumes non-linear pace of knowledge and skill increase during work and learning process. On the last stage the model for group competence will be elaborated. The model will allow representing competence of the whole organization consisting of many individual professionals. This method will cover topics such as: aggregation of the level of competence, complementarity, competence domain coverage etc.

The competence model assumes fuzzy representation of set to precisely show the "strength" of every element of competence by setting quantitative value of degree of membership for every element of the competency set [17] ,[27]. The model will focus on modelling the process of competence development, which occurs during training and professional work. In the case of the fuzzy competence set this process reflects in rising the degree of membership for the element representing the competence under development [19].

Known studies on this subject assume linear relationship between the increase in the competence strength and the time spent on training. On the other hand, studies in the domain of cognitive science show that the learning process is non-linear and goes according to different "learning curves". Thus, the main goal of this work will be to develop the formal competence extension model, which will take into account the idea of "learning curves" in order to reflect non-linear relationship between time of training and competence strengthening. The formal model of non-linear competence extension will be then used to develop the method for competence extension cost analysis. This method bases on the assumption that extension of personal competence requires effort that takes some time, which can be translated into financial cost by introducing cost factors.

VI. Social Network Approach to Dynamic Competencies Management

Within the organization social networks can be identified, which are related to the flow of information and exchange of knowledge. Studying structures within an organization can be considered in terms of improving the information flow mechanisms and the identification of key members of the organization. Social network analysis methods can be used that make it possible to determine the quantitative parameters of the network, identifying community and relationships within the network structures [28]. This type of research involves both static properties of networks and their evolution over time.

Social networking is also used for measuring competence, which may relate to specific network segments, competence of separate groups and members of the community. While the subject matter of competence is usually considered both static and focused on the analysis of individual units, in this article it relates to the recognition of dynamic problems which can include movement of competence in the organization. That concept includes flow modeling competence within social network using diffusion models derived from the field of epidemiological studies which in recent years have been developed in the direction of social networking and viral marketing [30]. This is used to identify trends related to the prediction the range of diffusion, diffusion models and the identification of network nodes, which should be contacted by an initial infection [9]. The analysis of diffusion processes is based on in epidemiological models, linear model threshold or independent cascades model and branching processes [12].

In the area of competence-oriented modelling, a number of areas can be identified where the diffusion processes take place when acquiring competence. It is therefore a possible

link between the methods of social network analysis to identify key members of the team, whose competence is worth investing. Taking into account the mechanisms of diffusion a flow of competence in an environment can be specified where there is exchange of knowledge among team members and use the multidimensional approach [11]. Competence can be treated as information diffusion processes and can move between team members. The number of contacts between team members is conducive to the flow of competence and invests in workers for whom the identified high communication activity can promote the exchange of information to a greater degree than improving the skills of workers whose social activity is reduced.

The proposed concept of using methods of social network analysis and modelling of adaptation mechanisms of diffusion processes can find a number of applications in the analysis of competences and is reflected in both the theoretical and practical areas related to this topic.

VII. Conclusion

The construction of the system, with implementing the new approach to competence management, requires an in-depth conceptual phase. This article was devoted to this goal. The dynamic aspects of competencies level fluctuating have to be implemented with the proposed models, data structures and system components. The most important observations from the paper are:

- Typical tasks for competencies processing include: finding competencies gaps, aggregation of individual competencies to the group's level, estimating the costs of acquiring competencies, building projects groups
- Competencies bank, catalogue and network are the main elements that store information about competencies of employees in the organization.
- The competence level is changing in time during following situations: training (competence acquiring), active using (competence strengthening), inactivity (competence decline), team work/group problem solving (competence transfer).
- Transfer of competence in the group through the realization of tasks within a project can be analysed using the tools and methods of social network analysis.

***Abstract*–This paper is an attempt to present the concept of organizational transformation with the use of the strategic renewal theory oriented towards organizational learning. It is indicated that enterprise renewal processes constitute the basis for organizational changes enabling evolutionary development towards implementing enterprise learning mechanisms. A new aspect occurring in this presentation is the discussion of the benefits which might be brought for the organization by the use of external resources (outsourcing tools) for the purpose of enhancing renewal processes.**

I. Introduction

IN THE last decades, the dynamics of the turbulence in environmental changes occurs simultaneously with the development of the latest technologies (and in particular along with the considerable acceleration in the development of the digital technologies). Therefore, entrepreneurs are forced to focus their activities on various types of transformations primarily aimed at the organization's keeping pace with the changing environment. One of interesting forms of such transformations of the recent years is the strategic renewal concept [4], [3]. Cognitive components of the strategic renewal concept based on which enterprises strive for transforming into learning organizations are described in the study [14]. The authors additionally point to the possibility to intensify renewal processes by using the knowledge coming from organization's external resources through implementing tools such as outsourcing, and in particular Knowledge Process Outsourcing.

According to Prahalad and Krishnan, "in the new innovation era, it is the capability of introducing and improving flexible transparent business processes allowing continuous changes in selecting resources R=G in the interest N=1 that will determine the advantage of companies" [12, p. 34] (these principles will be discussed in the further part of the presentation).

For the sake of this idea, organizations should give up storing all needed resources and initiate the implementation of programs for accessing specialized global suppliers, and one of the cheap and effective manners of sharing/using resources is outsourcing.

II. Strategic Renewal in the Context of the Classical Theory of Change

Strategic renewal is an interesting concept of evolutionary development of organizations of the recent years, which refers to various aspects of the enterprise's operation. The foundation of renewal is the theory of change but the renewal itself has not been unambiguously defined to date. It is frequently identified with the theory of change in the relevant literature [3, p. 13]. Among the first who made an attempt at distinguishing change from renewal were R. Agarwal and C. Helfat [1, p. 281]. They defined the notion of renewal as "the process, content and effect of transformation or exchange of the characteristics of organization which have a significant impact on long-term operation perspectives." Following this interpretation, it should be assumed that renewal is a much broader phenomenon than change and refers to the foundations of survival or development of the organization. Change, in turn, is a mere component of renewal [4, p. 33]. Such a viewpoint was adopted also by J. Skalik, who defines strategic renewal as a fundamental change with a broad scope, one being a form of response to fluctuations of the environment and all phenomena inside the organization that decrease its effectiveness level [15, p. 18].

The common plane of change and renewal is their process. While in the case of change its process nature does not arouse doubts, in the case renewal the process aspect is related with elaborating new attributes the significance of which is strategic for the organization [4, p. 35]. However, renewal ought to be understood as a process whereby changes generating qualitatively new bases for implementing modern enterprise development concepts occur.

Both change and renewal are based on a common plane, that is the process. While in the case of change its process nature does not arouse doubts, in the case of renewal the process aspect is related with elaborating new attributes the significance of which is strategic for the organization [4, p. 35]. Renewal ought to be understood as a process whereby changes generating qualitatively new bases for implementing modern enterprise development concepts and innovation occur.

It is indicated that renewal processes cannot be one-time processes in the moment of an organizational crisis but they

978-83-60810-53-8/$25.00

should be continuous processes which systematically renew the enterprise by bringing it to the state of equilibrium and at the same time ensuring its development.

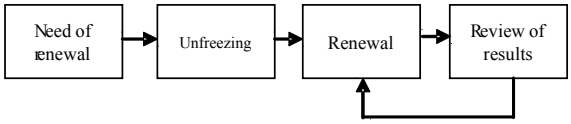

Fig. 1. The model of the infinite renewal process with feedback
Source: own work

In the ideal renewal model presented in Fig. 1, the once initiated renewal process should last infinitely in the organization. After diagnosing the need of renewal (internal impulse) in the enterprise, the permanent unfreezing stage occurs only once and then the organization becomes a plastic body in the constant unfreezing state. The infinite renewal process begins in this stadium, being interrupted only with the review of results.

A significant complementation of the above model is the aspect of renewal initiation. It is maintained that the initiator of the renewal process should be an impulse coming from inside the organization. Only such a stimulus can be strong and effective enough to commence an effective renewal process. The probability of renewal initiation effectiveness by forces coming from the environment of the organization seems to be negligible since each of such actions will be treated as an obligation rather than as one's own action, which has an advantage in the form of significantly weaker resistance forces than in the case of external initiation from the very beginning.

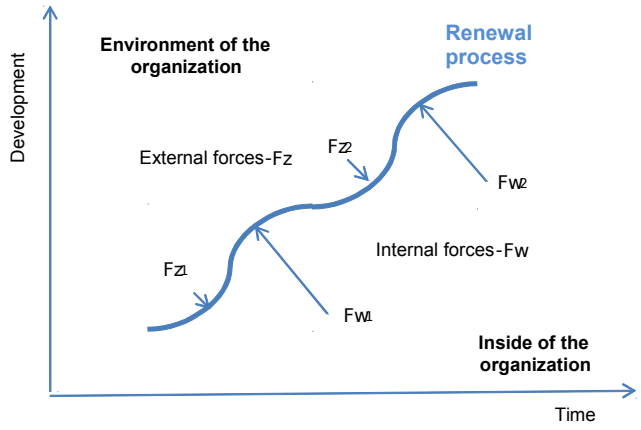

Fig. 2. The renewal process against forces from the inside and the outside of the organization
Source: own work

When discussing the component of the renewal process initiation from inside the organization, it needs to be indicated that such an impulse is possible only when the organization has reached an appropriate organizational maturity level. In enterprises with no or a low organizational maturity level, the renewal impulse will never occur.

Strategic renewal in the presented model (Figure 1 and 2) is a method of continuous and systematic introduction of changes and of formation of the organization without the necessity to defeat change resistance forces every time. At the same time, it introduces a new quality of the organization's operation. Renewal imposed by an internal impulse becomes the property of the organization's members. Introducing innovative solutions seems to be difficult without renewal, and even impossible in numerous cases.

III. Mechanisms of Organizational Learning of Enterprises as the Renewal Process

Information and knowledge are currently the basic resources in the micro- and macro-economic approach. The speed of obtaining information and the ability to learn fast are among the main factors ensuring competitive advantage. The above principles are used by the learning organization concept. Learning organizations broaden their creative capacities such that they can create their future effectively. Working in such organizations involves the continuous knowledge improvement process and the use of experiences rather than mere performance of tasks [14]. A common term for this type of enterprises is an intelligent organization. The basis for the operation of this type of companies is building a community of specialists (knowledge workers) who communicate well with each other and are capable of continuous transformation of the enterprise, its products and themselves for the purpose of satisfying market requirements and challenges formulated by the society. Intangible resources, including in particular knowledge, are most important in such an organization [10, p. 103].

The learning organization concept is a response to the continuously changing environment, technological changes and growth of employee competences and requirements; at the same time, it is closely related to the enterprise innovation strategy, which is possible owing to a properly pursued enterprise renewal process.

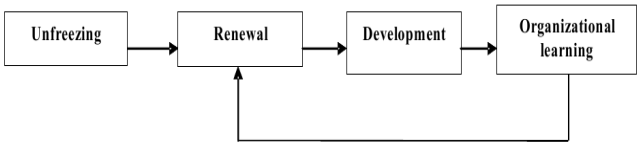

Fig. 3. The renewal process model towards organizational learning.
Source: own work

The learning organization concept and, literally, organizational learning is a natural consequence of strategic renewal.

Innovativeness is a creative process and, like every process of this kind, it begins with an idea, is followed by incubation, and ends with illumination, that is a qualitatively new idea that solves the formulated problem. From the viewpoint of learning organizations, such a process begins with implementing organizational changes, is followed by strategic enterprise renewal, and ends with implementing structural mechanisms of learning organizations (Fig. 4) [6].

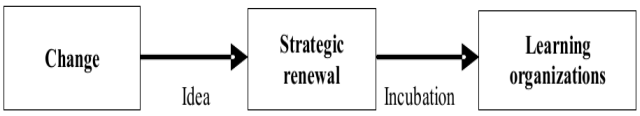

Fig. 4. The implementation model of the organizational learning process – from changes to strategic enterprise renewal. Source: [6]

It needs to be indicated that implementing structural changes in the organization that facilitate the enterprise development towards organizational learning is a component of strategic renewal. Strategic enterprise renewal is a phase of "incubating" organizational development, the effect of which should be qualitative improvement of organizational effectiveness of the enterprise that facilitates information flow management in the organization called synergy or supercompensation effect. The enterprise capacity to implement renewal processes is a necessary condition for the enterprise to be able to build its organizational potential towards organizational learning [6].

IV. Outsourcing Tools – Current Applications and Trends

According to Prahalad and Krishnan [12, pp. 31-31], "the principal significance for firms to be ahead of their competitors is a sense of the achievable and the use of innovations coming from laboratories of institutions operating on the global scale and small new firms… The nature of financial, human and technological resources outgrows the firm and its legal boundaries. Today, resources are global. Attention needs to be focused on access and influence rather than on ownership and control." Prahalad and Krishnan provide the following principles to be followed by the organizations which wish to build competitive advantage:

N = 1 and

R = G.

N=1 states that "value is based on unique, personalized experiences of consumers." That is, even companies serving 100 million consumers need to focus on individuals.

R=G, meanwhile, argues that since no company can hope to satisfy the varied expectations of so many consumers, it must diversify how it operates. "All firms will access resources from a wide variety of other big and small firms—a global ecosystem," write Prahalad and Krishnan. In other words, companies' internal focus should be on gaining access to resources, not necessarily owning them [12, pp. 27-28].

Globalization provides enterprises with easier access to more numerous labor force resources and employment of a greater number of employees with a more specialized education, which contributes to increasing the quality of the provided work and the number of innovations in many cases. Outsourcing and offshoring development results from the fact that more and more organizations strive for improving their competitiveness by relocation of goods and services. Outsourcing and offshoring more and more frequently concern knowledge-based processes aimed at supporting innovative operation of the organization [5, p. 48].

Oshri, Kotlarsky and Willcocks, who have been observing the outsourcing market for years now, notice that various new types of global supply models have been emerging. The major difference between the models lies in:

- whether the function is used by a business unit dependent on the parent company or an external supplier (or jointly by both entities), and
- whether the function is used by the enterprise on-site (in the registered office) or off-site (outside the registered office – in the country where the organization is based (onshore), in a neighboring country (nearshore) or in a distant location (offshore) [9, p. 25].

The ongoing growth in the outsourcing market has major implications for management. Organizations have to develop new capabilities supporting the ever-changing business models in their sourcing engagements. Understanding how and where value is created in sourcing engagements becomes another challenge. Dependency on external partners has increased. Providers of outsourcing services are becoming more aware of clients' growing demand to realize innovation and transformation from outsourcing engagements and they are refocusing their efforts to deliver value to clients by improving their performance management systems and by seeking to extend their offerings [17, pp. 1-2].

One can observe a trend towards outsourcing relationships becoming increasingly managed and leveraged as strategic assets. New forms of sourcing deals are required for collaborative innovation to succeed.

In today's knowledge-based economy, one of the major sources of competitive advantage has been the ability of the firm to transfer external knowledge efficiently and effectively. Knowledge transfer can be defined by as activities of exchanging explicit or tacit knowledge between two agents, during which one agent receive and apply the knowledge provided by the other agent. The agents could be an individual, team/department or an organization. In the literature, knowledge transfer has been given various but related labels such as knowledge sharing, knowledge flows, knowledge acquisition and knowledge mobilization [2, p. 1].

One of the knowledge acquisition options by taking advantage of external resources is using such centers as Knowledge Process Outsourcing. KPO centers are established dynamically worldwide. A trend proving the increasing comprehensiveness of business processes served from Poland is also noticeable. At the same time specialization of many centers increases – consisting in serving more advanced processes (market research, business analyses, etc.). Thus, a "subsector" called knowledge process outsourcing is being slowly formed in Poland. On the global scale, it is characterized by a significantly faster growth than the entire BPO (Business Process Outsourcing) sector, which means a chance for Poland to develop in this area mainly due to the held resources of qualified employees, appropriate communication infrastructure and political stability. Owing to the qualified staff and good academic centers, and not only low labor costs, Poland has been becoming an attractive place for locating this type of projects for a few years now [13, p. 46].

V. Outsourcing of Knowledge as an Accelerator of Changes Towards Enterprise Renewal

Outsourcing as a strategic component of renewal should facilitate organizational learning, and for this purpose the organization deciding to outsource must set clear goals for outsourcing collaboration. Collaboration in a strategic sourcing context is pro-active working together and risk sharing, in flexible integrated ways, to achieve high performance on longer, mutually rewarding commercial goals [17, p. 129].

Whitley and Willcocks suggest four fundamental practices behind effective collaborative innovation [based on 17, pp. 143-144]:

- Leading. Leadership shapes and conditions the environment in which requisite contracting, organizing and behaving can occur. Leadership also changes the approach to risk in order to share and manage down risk and manage in opportunity.
- Contracting. New forms of contracting are required to secure successful collaborative innovation. Such contracts share risk and reward in ways that provide incentives for innovation, collaboration and high performance to achieve common goals.
- Organizing. Organizing for innovation requires more co-managed governance structures and greater multi-functional team working across those organization and people responsible for delivering results. Team working now requires the ability to collaborate within a client organization, between client and supplier and between suppliers in multi-supplier environments.
- Performing. Leading, contracting and organizing in these ways provides incentives to change existing modes of performing and enables collective delivery of superior business outcomes. Collaborative innovation is most effective when it generates high personal, competence-based and motivational trust among the parties. High trust is a key component and shaper of the collaborative, open, learning, adaptive, flexible and interdependent performance style required and open communication that help in knowledge diffusion.

These four elements have a temporal sequence as shown in Figure 5.

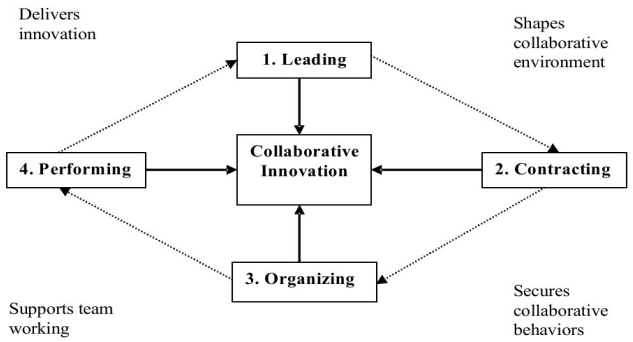

Figure 5. The process of collaborative innovation
Source: [17, p. 144].

Knowledge management in IT outsourcing relationship should enable creation and utilization of intellectual capital, that, in Willcocks opinion, should be generated through the interplay between such essential elements as [9, pp. 111-112]:

- structural capital (that refers to the codified bodies of semipermanent knowledge that can be transferred and the tools that augment the body of knowledge by bringing relevant data or expertise to people),
- human capital (which represents the capabilities of individuals to provide solutions to customers),
- customers capital (that is linked to shared knowledge, or the value of an organization's relationships with the people with whom it does business)
- and social capital (for example: trust, loyalty and reciprocity within a community - the values created from social networks), which helps bring these elements together.

As outsourcing often disrupts and reduces social capital by disembedding people, systems, and institutional knowledge from the client organization more attention should be paid to cultivating social capital. Social capital can have a considerable impact on effective knowledge transfer between outsourcing parties. It allows outsourcing partners reduce cultural barriers, understand common goals and strengthen network stability and ties.

According to the authors, organizations should take advantage of outsourcing such that is supports renewal processes and organizational learning to the highest possible extent. For this purpose, on the one hand, the organization ought to ensure easy access to the required information to both parties to the contract, and on the other hand it should not burden employees with excessive formalization but it needs to stimulate creativity and involvement in activities related to achieving the goals of the outsourcing project/contract.

Concepts such as outsourcing can accelerate renewal process since:

- they contribute to innovation growth when they concern processes related to innovation activities;
- they facilitate the improvement of the quality and effectiveness of processes and services owing to access to better/cheaper resources;
- they enable the introduction to new markets (if the supplier comes from a different country);
- they enable expanding the network of relations – they increase the structural capital of the organization.

From the viewpoint of knowledge management, an attempt might be made to describe outsourcing as [11, p. 394]:

- a manner of acquiring specialized knowledge and skills which the organization does not have;
- a form of stabilization of the knowledge related to the operation of selected areas in the organization (if the organization cannot handle e.g. the fluctuation of the IT staff, outsourcing could in a way secure the organization against a possible loss of critical employees);

- a guarantee of keeping pace with technological development (in this case, the outsourcing contract should provide for appropriate terms and conditions imposing the obligation of continuous development and improvement of services on the service supplier);
- a replacement of the internal know-how with the same type of knowledge from the outside.

Selecting the appropriate sourcing model is one of the critical aspects in the outsourcing planning.

It is worth emphasizing here that the selection of the optimum organization operation model is conditioned on numerous factors, such as: the held intellectual capital, the sector of activities, the phase of the organization's lifecycle, etc. Hence, every organization needs to make an independent decision on which of the operation options can have the most beneficial impact on the enterprise development and monitor on an ongoing basis if the selected model is still optimum in the context of strategic renewal.

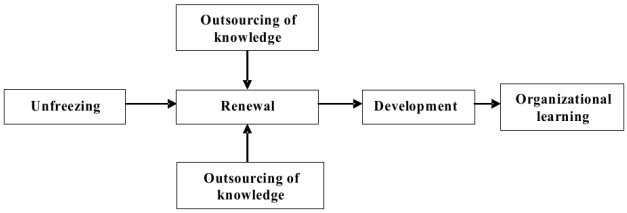

Fig. 6. The universal model of organizational learning through renewal and outsourcing of knowledge
Source: own work

The enterprise deciding on outsourcing ought to make an attempt to build such trust and create conditions facilitating knowledge sharing between employees and suppliers so that the organization's tacit knowledge could be co-created by external companies. It increases the probability that, along with broadening employee knowledge and experience, owing to continuous improvement, the outsourcing process will mature, which in turn will be reflected in the acceleration of organizational renewal processes.

VI. CONCLUSION

The execution of the strategic renewal process initiated inside the organization and pursued based on the exclusive use of internal resources of the enterprise is an appropriate action. However, it is indicated that the quality and thoroughness of renewal can be considerably increased by the application of external resources. In order to obtain the enhancement effect of the discussed process, it is suggested to use an outsourcing tool which has been effective in practice for years. Outsourcing, like many other modern management concepts, is a response of enterprises to the dynamically changing conditions of the environment as well as the new management trends that are being formed. Outsourcing is a complex enterprise management tool and its impact might involve numerous aspects of the enterprise operation.

Outsourcing creates a new type of strong correlations between partners, which do not arise from legal provisions. A successful collaboration cannot be ensured exclusively by contracts. Various unpredictable events might occur during the implementation of the project and therefore it is good when collaboration with the external supplier(s) is based on trust, respect and informal business coexistence principles.

***Abstract*—In this article we explore students' experience with digital educational games. We analyze and discuss the factors which determine a student's perception of the educational benefits of game-based learning. The organization of the research is structured by the main question - how do variables such as player satisfaction, game features (e.g. the perceived quality of the educational content, the design) and enhancement in the player's educational process are interconnected. The study proves that games as an educational tool are assessed very favorably by undergraduate students of business and economics. Moreover game features are correlated with educational benefits and player satisfaction. A player satisfaction is also linked with enhanced learning.**

I. Introduction

SERIOUS games – intended to improve players' learning skills – are regarded to be a more effective educational tool than traditional lecturers when it comes to meeting the needs of the 'digital millennium generation'. The 'virtual generation' ('digital natives') learns differently compared to previous less technologically immersed generations (Pasin & Giroux 2011), although it is arguable that 'differently' means 'better'.

The number of publications referring to digital game-based learning has significantly increased in the first decade of the 21-st century (Hwang & Wu 2012). Nowadays the body of literature empirically or theoretically embracing the problems and issues connected with game-based learning is quite significant. Publications which clearly show the direct comparison between the different studies (the aims, participants, main findings), such as Pasin & Giroux (2011) or Wu et al. (2012), are particularly insightful and useful for understanding the scope of research that has been conducted in this field.

Therefore, due to the wide variety of forms (strategic games, solitary games, social games, board games, computer games etc.) the conclusions from different studies about the educational effectiveness of the game are not easily comparable. Most studies argue for the educational effectiveness of games, although different authors set different approaches for conducting their studies. For example Tao at al. (2009) proposed a model developed from the technology acceptance model, the expectation confirmation theory, and the agency theory. Other authors, Lin & Tu (2012) implemented the concept of means-end chain (MEC) to explore the value sought by players. Also in the literature researchers refer to different learning theories (behaviorism, cognitivism, humanism, constructivism) or they do not refer to any theory of learning at all (see – Wu et al 2012). Analysis of game-based learning is even more difficult due to the lack of a clear definition of game features. Games have game mechanics (which includes such elements as points or virtual gifts), game dynamics (e.g. status, reward, individual achievement and self-expression), an immersive environment which includes the rules, the story which outline the theme of the game, the embedded risks and competition (Derryberry 2007, Simões et al. 2013). A game's interactivity, which is the imminent aspect of a digital game (Rouse III 2005) is also difficult to assess and define. (Even as a website feature is difficult to measure due to the incongruence in the actual and the perceived interactivity of the website – Voorveld et al. 2011).

The study presented in this article is an exploratory study. So far business simulation games are not very popular in higher education in Poland and this presumption was confirmed by the empirical study presented below – only three participants of over 100 reported previous game-related experience. Do students perceive games as useful tools in formal education? Do educational games in higher education meet academic standards from the students' point of view? Although we would point out that we do not focus on answering the question whether or not a university's educational program can be substantially based on games, or if the games can replace the academic reading, class discussion and live lectures. We rather see that games can be useful tools for the purpose of introduction and invitation to more in-depth analysis.

II. Research Design

This article presents part of data and analysis conducted as part of a wider research project "e-Education within the social Internet". In the part of the project presented here two simulation games - Trade Ruler Game and Marketing Manager (connected with economic and managerial problems) - were tested for their educational benefits (see Table I).

This work was a part of the project 'Badanie statutowe 614564' Jan Kochanowski Univeristy in Kielce

We understand simulation games as to be games which have an embedded risk of losing or winning, are based on a backstory, and have game mechanics; on the other hand, they embed simulation (see Tao et al. 2012) One of the selected games – Marketing Manger - can be classified as a functional game around the specific topic of business. The other – Trade Ruler Game – can be classified as concept simulation in referring to a specific type of decision making (classification of the management simulation games - Pasin & Giroux 2011). We used games which are not time-consuming and can be completed within one-hour of play. This kind of game increases participants' full attention and motivation for the whole duration of the study. (Very complex games, such as multi-module business simulation games, need much more time and effort to play and therefore bring different challenges for educators).

In the present study we measured the constructs – the navigation of the game, the design, the educational content – as the player's perception-based construct. This means that the participants of the survey answered questions about their feelings and perceptions (e.g. they agree or disagree with the statement "I can easily find information which I need'). Most students played the games as an out of class task and then they filled out the questionnaires. We did not measure the progress which students made playing the games several times – instead we asked them to generally assess their feelings about using this new form of learning. We also did not include in the study data referring to the heterogeneity of the participants such as risk avoidance, general attitude to the university or interest in their studies.

We chose the constructs to measure arbitrarily, agreeing that they are under theorized and often have different meaning in the literature (with the concept of design as a prime example). In this study we wanted to 'capture' the students' general feelings and experience regarding game-based education.

In this empirical study we assumed that the game features – the educational content, the ease of navigation and the design of the game - influence player satisfaction and that satisfaction is linked to the player's enhanced learning (Fig. 1). Therefore the hypotheses are:

H1: The game features - the perceived value of the educational content, the perceived design of the game, and the ease of navigation and playing - enhance player satisfaction

H2: The features of a game and a player satisfaction are linked with the player's educational benefits.

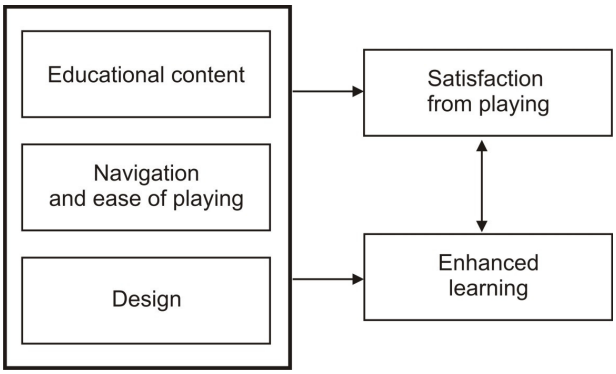

Fig. 1 The framework for empirical research

For this research, a questionnaire was developed to gain students' feedback (see Table II–VIII). The study was conducted in April 2013. A total of 208 filled questionnaires were received, 99% of the respondents were under the age of 25. All of the participants are business and economics students at one of three different Polish universities. In the study:

- for the Trade Ruler Game 106 participants took part - 72% of which were women,
- for the game Marketing Manager – 102 participants took part with the same proportion of women – 72%.

Very few – only three participants stated that they had previous experience with the game-based learning connected with economics or management.

III. Results and Discussion

Tables II-VIII present the main results and the structure of the survey questionnaire. Summarizing the results we can point out that:

1. The students' perception of the game Trade Ruler is affected by the language of the game which is not

TABLE I.
CHARACTERISTICS OF THE GAMES

Trade Ruler Game – available: http://www.nobelprize.org/educational/economics/trade/index.html	This is an educational game available at Nobel Prize official website. The theme of the game is based on the Heckscher-Ohlin trade theory. The player takes the role of the leader of one country and has to make decisions - depending on the country's resources– regarding production and trading with another country. After a few turns the player receives information about the score - calculated on the basis of the welfare of the country as a result of international trading. The language of the game - English
Game Marketing Manager http://www.nbportal.pl/pl/cw/gry/gry_decyzyjne/marketing	The game is available at the educational website of the National Bank of Poland. The task of the player is to choose marketing options for a car company: to decide to buy or not to buy a market research report, choose the client base, establish a delivery chain, etc. The player receives information on how the decisions affect the company's finances in areas such as sales, profits, and costs. A player's score is based on the total number of points given for the correctness of the player's business decisions. The language of the game - Polish

their native language. Almost 40% of the students stated that the game's language was a problem or a significant problem (table II).

2. Students assessed the educational content of the analyzed games very favorably (table III). The majority (over 80%) of the participants claimed that The Trade Ruler Game or Marketing Manager Game helped them to better understand the economic issue in focus (the trading between different countries or basic marketing strategic options).
3. The games analyzed were perceived by the players to be easy to navigate and easy to find the necessary information (table IV). In both games over 90% of the participants found the game easy to play, over 80% found information easily and the majority of the players found their score without problems
4. The design for both games was also well received (table IV). Interactivity was positively assessed by over 80% of informants in both games, graphic design over 55%, with the general quality of The Trade Ruler Game received an average score of 2.8 (on a scale of 1-4) and Marketing Manager Game-3.1.
5. Player satisfaction is high for both games (table VI). The majority – nearly 80% of players ranked their satisfaction at a 3 or 4 in Trade Ruler game (the average being 3.0). In the case of Marketing Manager the percentage was 90% (the average being 3.3).
6. Players perceived the games to be very useful and effective educational tools (table VII). They claimed that the games triggered their interest in economical or marketing issues (over 80% of participants), made learning more effective (over 85% of participants), helped to increased engagement in the subject (over 80%) and linked the learning process to a positive emotion (over 85% of participants).

In order to test the hypotheses we looked for correlation between variables (table VIII) and a weak or moderately positive correlation between some of the variables were found. Below we emphasizes the findings for the moderate positive correlation (R Spearman above 0.33, $p<0.05$).

TABLE II.
THE PLAYERS' ASSESSMENT OF HOW LANGUAGE AFFECTS PLAYING THE GAME

How much of a problem was the use of the English language in "The Trade Ruler" game in your playing of the game?	Not a problem at all	It was a problem	It was a significant problem
N=106	61%	30%	9%

TABLE III.
EDUCATIONAL CONTENT [TRADE/MARKETING MANAGER]

			Strongly disagree			Strongly agree	It's difficult to say	Negative opinion	Positive opinion	Average (1-4)
Code			1	2	3	4	-			
QE1	The game helps me to understand [international exchange with cost-and labor product/marketing management: segmentation]	Trade (N=106)	0.9%	9.4%	44.3%	38.7%	6.6%	10.3%	83.0%	3.3 (n=99)
		Marketing Manager (N=102)	1.0%	5.9%	33.3%	56.9%	2.9%	6.9%	90.2%	3.5 (n=99)
QE2	The game clearly explains [the Heckscher-Ohlin theory/the idea of segmentation and marketing mix]	Trade (N=106)	7.5%	14.2%	38.7%	24.5%	15.1%	21.7%*	63.2%*	2.9 (n=90)
		Trade (without language barrier, n=65)	7.7%	9.2%	33.8%	29.2%	20.0%	16.9%	63.0%	3.1 (n=52)
		Marketing Manager (N=102)	12.7%	42.2%	38.2%	6.9%	0.0%	54.9%*	45.1%*	3.3 (n=95)

Note: students fills two different questionnaires about two games, but to make the presentation of the findings more clear, they are presented in one table. The average is only calculated for participants who ranked the game, and excluded the 'It's difficult to say'. Mark * means that there is a significant difference ($p<0.05$) between the percentage of Trade Ruler users and the percentage of Marketing Manger users in assessing the game positively or negatively

TABLE IV.
NAVIGATION AND EASE OF PLAYING

Code			Strongly disagree			Strongly agree	It's difficult to say	Negative opinion (1-2)	Positive opinion (3-4)	Average (1-4)
			1	2	3	4	-			
QN1	I find this game simple to play	Trade (N=106)	0.9%	3.8%	22.6%	72.6%	0.0%	4.7%	95.2%	3.7 (n=106)
		Marketing Manager (N=102)	1.0%	1.0%	24.5%	71.6%	2.0%	2.0%	96.1%	3.7 (n=100)
QN2	I easily find information which I need	Trade (N=106)	1,9%	15.1%	46.2%	34.0%	2.8%	17.0%	80.2%	3.2 (n=103)
		Marketing Manager (n=102)	2.9%	12.7%	41.2%	41.2%	2.0%	15.6%	82.4%	3.2 (n=100)
QN3	Without any problems and I easily established my score in this game	Trade (N=106)	0.9%	9.4%	26.4%	63.2%	0.0%	10.3%*	89.6%	3.5 (n=106)
		Trade (without language barrier, n=65)	0.0%	9.2%	23.1%	67.7%	0.0%	9.2%	90.8%	
		Marketing Manager (n=102)	1.0%	2.0%	32.4%	57.8%	6.9%	3.0%*	90.2%	3.6 (n=95)

1. Positive perception of the educational content is interlinked with the belief that introducing the games into the university curriculum increases the effectiveness and the engagement of the students.
2. Ease of playing the game is correlated with positive emotions during learning process.
3. The interactivity of the game is linked with the perceived effectiveness of game-based learning, the student's engagement in learning, and positive emotions.
4. Graphic design is correlated with positive emotions during the learning process.
5. Player satisfaction is correlated with interactivity, the design, the perceived total quality of the game, the educational content of the game and the ease of navigation.
6. Player satisfaction is correlated with the perceived effectiveness of learning, the engagement in learning, and positive emotions connected with the learning process.

Therefore the general hypotheses were confirmed. Although there are variables within main constructs which were not interlinked as we presumed.

QS-QL1	0.31	**QS-QL2**	**0.35**
		QS-QL3	**0.38**
		QS-QL4	**0.40**

Note: while both variables have the option 'It's difficult to say' the correlation was calculated using the full scale. If only one variable had the option 'It's difficult to say' the correlation was calculated with the exclusion of answers "It's difficult to say"

IV. CONCLUSIONS

The main conclusions of the study:

- Introducing 'one-hour-play' simulation games into the university curriculum would be connected with positive educational outcomes such as increased student engagement in learning, positive emotions, and the perceived effectiveness of learning. This means that 'one-hour play' games (the games tested were assessed to be simple to play by over 95% of students) - which are more affordable and easier to prepare than very complex multi-modul simulations games - can be useful tools for introducing managerial or economic issues to students.
- Unfortunately – as our survey also showed – very few students have had previous experience in using the games as the part of their courses and games are a neglected educational tool in the Polish universities. Perhaps this is one of the reason why participants of our survey evaluated the games so favorably. Students were very enthusiastic about the games and they assessed them

very highly in different areas, especially their the educational content, simplicity and interactivity.

- Our survey shows there is a positive link between the player satisfaction and perceived enhancement of the learning process. It suggests that when there are two or more different games for evaluation it may be worth focusing more on measuring general satisfaction than on a particular feature of the game.
- The finding emphasis the importance of game design. Interactivity, graphic design and general quality of the game design can influence the player satisfaction.

There are a few limitations for study presented. First of all, the size and the process of choosing the participant sample limit the way in which results of the study can be interpreted and generalized. Also the study did not include some variables which could influence the results including a student's level of achievement at university and learning style. Future studies should extend the scope of analysis.

***Abstract*—Most of the governments and civil society organizations work hardly to promote the disabled people especially blind and deaf persons to join the normal community and practice the regular daily life activities. Indeed, Information Technology with its modern methodologies such as mobile and Cloud computing has an impressive role in enhancing the intercommunication among the people with different disabilities and normal pupils from one side and among the disabled people themselves who have the same or different impairments. However, a few numbers of suggested systems are quite limited for the Arabic Region. Additionally, according to our knowledge, there is no proposed system for connecting the blind and deaf people within direct Arabic language-based conversations. In this paper, we propose a comprehensive framework constructed upon three main modern technologies: mobile devices, Cloud resources and social networks to provide a seamless communication between the blind and deaf people especially for those living in the Arabic countries. Moreover, it is designed to facilitate the communication with normal people through various directions by using recent methodologies such as time-of-flight camera and social networks. The main modules and components of the suggested framework and its possible scenarios are fully analyzed and described.**

***Keywords*—Cloud, Mobile Devices, Social Networks and Blind/Dead people**

I. Introduction

LACK of awareness of the blind/deaf needs could lead to discrimination in a single community. It could also leave many talented blind/deaf people out of productive members of society. In addition, it could have a substantial effect on the educational performance of children. Furthermore, children with hearing loss and deafness, specifically in developing countries, hardly receive any education. Moreover, adults with hearing loss suffer from a much higher unemployment rate [1].

As recently reported by the World Health Organization, 285 million people around the world are visually impaired (39 million are blind and 246 have low vision) [2]. About 80% of all visual impairment around the world could be cured or avoided [2]. However, this is unachievable due to fact that 90% of the 285 million visually impaired people live in developing countries. It is also reported that, 360 million of the worldwide population have disabling hearing loss [1]. In addition, "current production of hearing aids meets less than 10% of global need" [1].

In Egypt, as an example of the developing countries, about 6% of the total Egyptian population is visually impaired [3] and nearly three million people in Egypt suffer from hearing impairment. Nonetheless, there is no a national project on how the government helps those people to be active members in the community. For example, according to the report in [4], the Egyptian government has provided sign language services for News Programs on Television (10 minutes to 7 hours a week). However, there are no current programs or plans to provide subtitles or captions. In addition, the government does not provide any access for Deaf people to get governmental documents in their sign language [4]. Indeed, the blind/deaf communities are still out of the government interests and future plans.

As a matter of fact, social interaction is a life-process and a crucial part of our success in life. It supports independent living, community experiences and relationships. However, social skills are learned by repeated visual observations (e.g. facial expressions, body language) that are translated to cues that help us to develop and understand concepts of social behavior. In other words, vision plays an important role in establishing and maintaining social interactions that is a great challenge for individuals who are visually impaired or blind.

To enrich the social interaction process, recent technologies such as social networking websites and mobile devices have been introduced and used in a wide scale as new means for social communication between people. These services are widely popular in Egypt – a February 2013 survey found that around 13 million out of 32.5 million online Egyptians use Facebook [5]. In addition, in January 2013, MCIT of Egypt [5] reported that the mobile subscribers are 96.11 million and 10.08 million of these subscribers are accessing the Internet through their mobile phones. Meanwhile, there are no real interests or efforts for helping disabled people to get benefit of these technologies to develop their social skills. The main goal of our work in this paper is to introduce a new framework that may help to shorten the distance between the blind/deaf people and the normal life. In other words, the proposed solution should support a seamless communication between blind, deaf and normal people from one side, and facilitate the interconnection between the blind/deaf and daily-based activities from the other side.

In this research paper, we propose an integrated framework to provide a Mobile-Cloud system to help blind and deaf people to gain better social skills for a more successful life. The main goals of the system are:

- Seamless communication between blind and deaf people. This includes ways to (a) detect the face to tell the blind about the identity of the conversation partner, (b) detect

978-83-60810-53-8/$25.00

emotion to tell the blind about his feelings, and (c) detect sign language and convert it to Arabic speech if it exists.

- Social network that can help blind and normal people to communicate with each other. Such network could help blind people to (a) detect certain objects or identify Arabic text, (b) use a social website to communicate with their friends while protecting their privacy, and (c) find and contact the nearest friend in case of critical situations.

The rest of this paper is organized as follows. The related work is discussed in Section 2. Section 3 presents the proposed framework and its involved modules. Section 4 describes the seamless communication between blind and deaf persons. Section 5 demonstrates the roles of social networks for connecting a disabled person to reality. Section 6 shows the possible challenges that may encounter the framework implementation. Finally, Section 6 concludes the presented solution and highlights the future work.

II. RELATED WORK

In this section, we will introduce all related research according to three main bases or technologies that may assist the blinds to have a normal life with regular activities which are: social network, mobile device and Cloud infrastructure. The social network is proposed as an electronic hand that would guide them to the right position or decision. The mobile device is the portable eye that might describe and recognize the objects or people who are naturally invisible for them. Finally, the Cloud infrastructure is the co-brain for processing the captured photos and associated data.

There are several innovative trials to build a particular social network for disabled people in general and for the blind community in particular such as [www.disabilinet.com, www.disabledcommunity.net, audioboo.fm/about/social_blind, and theblinduniverse.com] in which some special features have been added to facilitate the interaction and communication among the involved subscribers including the audio and media contents. These networks may give the disabled and blind people what they wish to connect them with their peers or friends; However, they may lead to (1) isolating the blind people from the normal world, (2) increasing the feeling by their hindrance, consequently fallen in more sociological and depression problems. On the other side, to the best of our knowledge, the popular social networks such as Facebook and Twitter do not provide any particular features for the blind/deaf people for attracting them to their community or helping them to easily participate in regular life with its different activities (e.g. searching jobs) as well as bringing them in a direct relationship with several parties including near friends and families members.
