Dear Reader, it is our pleasure to present to you Proceedings of the 2013 Federated Conference on Computer Science and Information Systems (FedCSIS), which took place in Kraków, Poland, on September 8–11, 2013. Each of the papers, found in this volume, was refereed by at least two referees and the acceptance rate of full papers was approximately 43%.

FedCSIS was organized by the Polish Information Processing Society (Mazowsze Chapter), AGH University of Mining and Metalurgy, Wrocław University of Economics and Systems Research Institute Polish Academy of Sciences. FedCSIS was organized in technical cooperation with: IEEE Region 8, Computer Society Chapter Poland, Gdańsk Computer Society Chapter, Poland, Polish Chapter of the IEEE Computational Intelligence Society (CIS), ACM Special Interest Group on Applied Computing, Łódź ACM Chapter, SERSC: Science & Engineering Research Support soCiety, Informatics Europe, Asociación de Técnicos de Informática, Committee of the Computer Science of the Polish Academy of Sciences, The Polish Association for Information Systems, Polish Society for Business Informatics and Polish Chamber of Commerce for High Technology. Furthermore, the 8th International Symposium Advances in Artificial Intelligence and Applications (AAIA'13) was organized in technical cooperation with: IEEE SMC Technical Committee on Computational Collective Intelligence, International Rough Set Society, International Fuzzy Systems Association, Romanian Association for Artificial Intelligence, and Polish Neural Networks Society.

FedCSIS consisted of the following events:

- **AAIA'13—8th International Symposium Advances in Artificial Intelligence and Applications**
  - AIMA'13—3rd International Workshop on Artificial Intelligence in Medical Applications
  - ASIR'13—3rd International Workshop on Advances in Semantic Information Retrieval
  - WCO'13—6th Workshop on Computational Optimization
- **CSNS—Computer Science & Network Systems**
  - CANA'13—6th Computer Aspects of Numerical Algorithms
  - MMAP'13—6th International Symposium on Multimedia Applications and Processing
- **ECRM—Education, Curricula & Research Methods**
  - DS-RAIT'13—Doctoral Symposium on Recent Advances in Information Technology
  - ISEC'13—Information Systems Education & Curricula Workshop
- **iNetSApp—Innovative Network Systems and Applications**
  - WSN'13—2nd International Conference on Wireless Sensor Networks
  - SoFAST-WS'13—2nd International Symposium on Frontiers in Network Applications, Network Systems and Web Services
- **IT4MBS—Information Technology for Management, Business & Society**
  - ABICT'13—4th International Workshop on Advances in Business ICT
  - Agent Day'13
  - AITM'13—11th Conference on Advanced Information Technologies for Management
  - IT4L'13—2nd Workshop on Information Technologies for Logistics
  - KAM'13—19th Conference on Knowledge Acquisition and Management
  - TAMoCo'13—Techniques and Applications for Mobile Commerce
- **SSD&A—Software Systems Development & Applications**
  - ATSE'13—4th International Workshop Automating Test Case Design, Selection and Evaluation
  - IWCPS'13—International Workshop on Cyber-Physical Systems
  - PBDA'13—Performance of Business Database Applications
  - WAPL'13—4th Workshop on Advances in Programming Languages

Each of these events had its own Organizing and Program Committee. We would like to express our warmest gratitude to members of all of them for their hard work attracting and later refereeing 420 submissions.

FedCSIS was organized under the auspices of Prof. Barbara Kudrycka, Minister of Science and Higher Education, dr Michał Boni, Minister of Administration and Digitization, Prof. Michał Kleiber, President of Polish Academy of Sciences, Marek Sowa, Marshal of Małopolska and Prof. Jacek Majchrowski, Mayor of Kraków. It was sponsored by Ministry of Science and Higher Eduction and Intel.

Maria Ganzha, *Conference Co-Chair, Systems Research Institute Polish Academy of Sciences, Warsaw, Poland, and Gdańsk University, Gdańsk, Poland*

Leszek Maciaszek, *Conference Co-Chair, Wrocław University of Economics, Wrocław, Poland and Macquarie University, Sydney, Australia*

Marcin Paprzycki, *Conference Co-Chair, Systems Research Institute Polish Academy of Sciences, Warsaw and Management Academy, Warsaw, Poland*

***Abstract*—Operational processes leave trails in the information systems supporting them. Such event data are the starting point for process mining – an emerging scientific discipline relating modeled and observed behavior. The relevance of process mining is increasing as more and more event data become available. The increasing volume of such data ("Big Data") provides both opportunities and challenges for process mining. In this paper we focus on two particular types of process mining: *process discovery* (learning a process model from example behavior recorded in an event log) and *conformance checking* (diagnosing and quantifying discrepancies between observed behavior and modeled behavior). These tasks become challenging when there are hundreds or even thousands of different activities and millions of cases. Typically, process mining algorithms are linear in the number of cases and exponential in the number of different activities. This paper proposes a very general divide-and-conquer approach that decomposes the event log based on a partitioning of activities. Unlike existing approaches, this paper does not assume a particular process representation (e.g., Petri nets or BPMN) and allows for various decomposition strategies (e.g., SESE- or passage-based decomposition). Moreover, the generic divide-and-conquer approach reveals the core requirements for decomposing process discovery and conformance checking problems.**

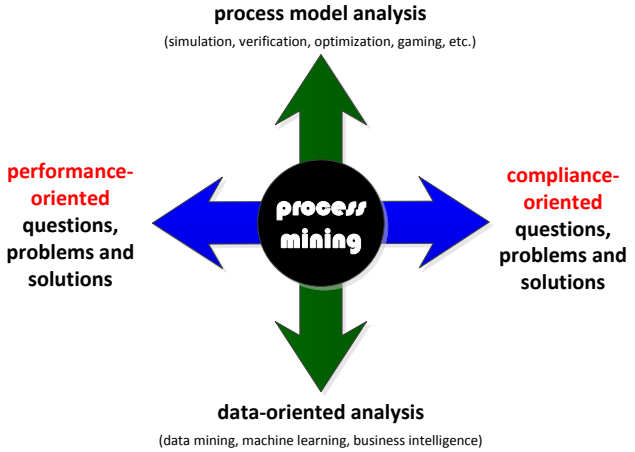

Fig. 1. Process mining is on the interface between process model analysis and data-oriented analysis and can be used to answer a variety of performance and compliance-related questions.

I. Introduction

RECENTLY, *process mining* emerged as a new scientific discipline on the interface between process models and event data [1]. Conventional *Business Process Management* (BPM) [2] and *Workflow Management* (WfM) [3] approaches and tools are mostly model-driven with little consideration for event data. *Data Mining* (DM) [4], *Business Intelligence* (BI), and *Machine Learning* (ML) [5] focus on data without considering end-to-end process models. Process mining aims to bridge the gap between BPM and WfM on the one hand and DM, BI, and ML on the other hand (cf. Figure 1).

The practical relevance of process mining is increasing as more and more event data become available (cf. the recent attention for "Big Data"). Process mining techniques aim to *discover, monitor and improve real processes by extracting knowledge from event logs*. The two most prominent process mining tasks are: (i) *process discovery*: learning a process model from example behavior recorded in an event log, and (ii) *conformance checking*: diagnosing and quantifying discrepancies between observed behavior and modeled behavior.

Starting point for any process mining task is an *event log*. Each *event* in such a log refers to an *activity* (i.e., a well-defined step in some process) and is related to a particular *case* (i.e., a *process instance*). The events belonging to a case are ordered, and can be seen as one "run" of the process. Such a run is often referred to as a *trace*. It is important to note that an event log contains only example behavior, i.e., we cannot assume that all possible runs have been observed.

Lion's share of process mining research has been devoted to process discovery [1]. Here the challenge is to turn a multiset of example traces (observed cases) into a process model. Process representations allowing for concurrency and choice, e.g., Petri nets, BPMN models, UML activity diagrams, or EPCs, are preferred over low-level notations such as finite state machines of hidden Markov models [1].

Given a process model (discovered or made by hand) and an event log one can try to *align modeled and observed behavior*. An alignment relates a trace in a event log to its corresponding path in the model. If there is not a direct match, the trace is aligned with the closest or most likely path. Such alignments can be used to answer *performance-oriented* and *compliance-oriented* questions (cf. Figure 1). Alignments can be used to show how often paths are taken and activities are being executed. Moreover, events often bear a timestamp which

978-83-60810-53-8/$25.00

can be used to compute flow times, waiting times, service times, etc. For example, alignments can be used to highlight bottlenecks in the process model. Similarly, alignments can be used to show where model and event log disagree. This is commonly referred to as *conformance checking*.

The incredible growth of event data is also posing new challenges [6]. As event logs grow, process mining techniques need to become more efficient and highly scalable. Moreover, torrents of event data need to be distributed over multiple databases and large process mining problems need to be distributed over a network of computers. Several approaches have been described in literature [7], [8], [9], [10], [11] (also see the related work described in Section VII). In this paper, we describe a *generic divide-and-conquer approach* based on a (valid) *partitioning* of the activities in sets. The activity sets should overlap if there is a direct dependency. We will illustrate the divide-and-conquer approach for the two main process mining tasks:

- For conformance checking, we decompose the process model into smaller partly overlapping submodels using projection. The event log is decomposed into sublogs, also using projection. Any trace that fits into the overall model also fits all submodels. The reverse only holds if the partitioning is *valid*. Metrics such as the fraction of fitting cases can be computed by checking the conformance of the submodels.
- To decompose process discovery, we first create an activity partitioning, i.e., we split the set of activities into a collection of partly overlapping activity sets. For each activity set, we project the log onto a sublog and discover a submodel for it. The different submodels can be merged to create an overall process model. Again it is guaranteed that all traces in the event log that fit into the overall model also fit into the submodels and vice versa.

Unlike existing papers [7], [8], [9], [10], [11], we abstract from a concrete process representation and do not select a particular decomposition strategy. Instead we focus on the core requirements to enable decomposition.

The remainder is organized as follows. Section II introduces preliminaries ranging from multisets to event logs. Section III provides abstract high-level definitions for process discovery and conformance checking. Section IV shows that any process mining problem can be decomposed trivially, but with a possible loss of precision. Section V shows that exact results can be obtained (not just bounds) if the activity partitioning is valid. Section VI discusses possible strategies to obtain valid (or otherwise suitable) activity partitionings. Related work is described in Section VII. Section VIII concludes the paper.

II. PRELIMINARIES

Before describing the two main process mining tasks and the ways in which these tasks can be distributed, we introduce some basic notations to reason about event logs and process models.

A. Multisets, Sequences and Projection

Multisets are used to represent the state of a Petri net and to describe event logs where the same trace may appear multiple times.

$\mathcal{B}(A)$ is the set of all multisets over some set A. For some multiset $b \in \mathcal{B}(A)$, $b(a)$ denotes the number of times element $a \in A$ appears in b. Some examples: $b_1 = [\,]$, $b_2 = [x, x, y]$, $b_3 = [x, y, z]$, $b_4 = [x, x, y, x, y, z]$, $b_5 = [x^3, y^2, z]$ are multisets over $A = \{x, y, z\}$. b_1 is the empty multiset, b_2 and b_3 both consist of three elements, and $b_4 = b_5$, i.e., the ordering of elements is irrelevant and a more compact notation may be used for repeating elements.

The standard set operators can be extended to multisets, e.g., $z \in b_3$, $b_2 \uplus b_3 = b_4$, $b_5 \setminus b_2 = b_3$, $|b_5| = 6$, etc. Bags are compared in the usual manner, i.e., $b_2 \leq b_4$ and $b_2 \not\leq b_3$. $\{a \in b\}$ denotes the set with all elements a for which $b(a) \geq 1$. $[f(a) \mid a \in b]$ denotes the multiset where element $f(a)$ appears $\sum_{x \in b | f(x) = f(a)} b(x)$ times.

$\mathcal{P}(X)$ is the powerset of X, i.e., $Y \in \mathcal{P}(X)$ if $Y \subseteq X$.

$\sigma = \langle a_1, a_2, \ldots, a_n \rangle \in X^*$ denotes a sequence over X. $|\sigma| = n$ is its length. $a \in \sigma$ if and only if $a \in \{a_1, a_2, \ldots, a_n\}$. $\langle\,\rangle$ is the empty sequence.

Projection is defined for sequences and sets or bags of sequences.

Definition 1 (Projection): Let $\sigma \in X^*$ and $Y \subseteq X$. $\sigma{\restriction_Y}$ is the projection of σ on Y, i.e., all elements in $X \setminus Y$ are removed (e.g., $\langle x, y, z, x, y, z \rangle{\restriction_{\{x,y\}}} = \langle x, y, x, y \rangle$). Projection is generalized to sets and bags. If $s \in \mathcal{P}(X^*)$, then $s{\restriction_Y} = \{\sigma{\restriction_Y} \mid \sigma \in s\}$ If $b \in \mathcal{B}(X^*)$, then $b{\restriction_Y} = [\sigma{\restriction_Y} \mid \sigma \in b]$. In the latter case frequencies are respected, e.g., $[\langle x, y, z, y \rangle^{10}, \langle z, y, z, y \rangle^5]{\restriction_{\{x,y\}}} = [\langle x, y, y \rangle^{10}, \langle y, y \rangle^5]$.

Without proof we mention some basic properties for sequences and projections.

Lemma 1 (Projection Properties): Let $\sigma \in X^*$, $Y \subseteq X$, $s \in \mathcal{P}(X^*)$, and $b \in \mathcal{B}(X^*)$.

- $\sigma \in s \;\Rightarrow\; \sigma{\restriction_Y} \in s{\restriction_Y}$,
- $\sigma \in b \;\Rightarrow\; \sigma{\restriction_Y} \in b{\restriction_Y}$,
- $\sigma \in s{\restriction_Y} \;\Leftrightarrow\; \exists_{\sigma' \in s}\ \sigma = \sigma'{\restriction_Y}$,
- $\sigma \in b{\restriction_Y} \;\Leftrightarrow\; \exists_{\sigma' \in b}\ \sigma = \sigma'{\restriction_Y}$, and
- for any $\sigma_1 \in {X_1}^*$ and $\sigma_2 \in {X_2}^*$: ${\sigma_1}{\restriction_{X_2}} = {\sigma_2}{\restriction_{X_1}} \;\Leftrightarrow\; \exists_{\sigma_3 \in (X_1 \cup X_2)^*}\ {\sigma_3}{\restriction_{X_1}} = \sigma_1 \;\wedge {\sigma_3}{\restriction_{X_2}} = \sigma_2$.

B. Activities, Traces, Event Logs, and Models

Event logs serve as the starting point for process mining. An event log is a multiset of traces. Each trace describes the life-cycle of a particular case (i.e., a process instance) in terms of the activities executed. Process models are represented as sets of traces. As indicated earlier, we avoid restricting ourselves to a specific process notation. However, we will show some Petri nets and a BPMN model for illustration purposes.

Definition 2 (Universe of Activities, Universe of Traces): $\mathcal{A}$ is the universe of *activities*, i.e., the set of all possible and relevant activities. Other activities cannot be observed (or are

abstracted from). Elements of $\mathcal{A}$ may have *attributes*, e.g., costs, resource information, duration information, etc. A *trace* $\sigma \in \mathcal{A}^*$ is a sequence of activities found in an event log or corresponding to a run of some process model. $\mathcal{U} = \mathcal{A}^*$ is the universe of all possible traces over $\mathcal{A}$.

We assume that an activity is identified by attributes relevant for learning, i.e., irrelevant attributes are removed and attribute values may be coarsened. $|\mathcal{A}|$ is the number of unique activities. Process models with hundreds of activities (or more) tend to be unreadable. In the remainder we will refer to activities using a single letter (e.g. a), however, an activity could also be $decide(gold, manager, reject)$ to represent a decision to reject a gold customer's request by a manager.

In a process model a specific trace $\sigma \in \mathcal{U}$ is possible or not. Hence, a model can be characterized by its set of allowed traces.

Definition 3 (Process Model): A *process model* M is a non-empty collection of traces, i.e., $M \in \mathcal{P}(\mathcal{U})$ and $M \neq \emptyset$.

$A_M = \bigcup_{\sigma \in M} \{a \in \sigma\}$ is the set of activities possible in M. Figure 2 shows a process model M using the Business Process Model and Notation (BPMN) [12]. For this paper the representation itself is irrelevant. Trace $\langle a, b, d, e, f, c, d, g \rangle$ is one of the infinitely many possible traces of M.

An event log is a multiset of *sample* traces from a known or unknown process. The same trace can appear multiple times in the log. Moreover, the event log contains only example behavior. Often only few of the possible traces are observed [1].

Definition 4 (Event Log): An *event log* $L \in \mathcal{B}(\mathcal{U})$ is a multiset of observed traces.

$A_L = \bigcup_{\sigma \in L} \{a \in \sigma\}$ is the set of activities occurring in L. Note that projection (see Definition 1) is defined for both models and event logs.

$L = [\langle a, b, d, e, g \rangle^5, \langle a, c, d, e, h \rangle^4, \langle a, b, d, e, f, c, d, e, g \rangle]$ is an event log containing 10 traces that could have been generated by the BPMN model in Figure 2, e.g., five cases followed the path $\langle a, b, d, e, g \rangle$.

III. Process Discovery and Conformance Checking

In the introduction we already informally introduced the two main process mining tasks: *process discovery* (learning a model from a collection of example behaviors) and *conformance checking* (identifying mismatches between observed and modeled behavior). Using definitions 3 and 4 we can now formalize these notions at a high abstraction level.

Definition 5 (Process Discovery Technique): A process discovery technique $disc \in \mathcal{B}(\mathcal{U}) \rightarrow \mathcal{P}(\mathcal{U})$ is a function that produces a process model $disc(L) \in \mathcal{P}(\mathcal{U})$ for any event log $L \in \mathcal{B}(\mathcal{U})$.

Given an event log $L = [\langle a, c \rangle^5, \langle a, b, c \rangle^4, \langle a, b, b, b, b, c \rangle]$, the discovery technique may discover the process model that always starts with activity a, followed by zero or more b activities, and always ends with a c activity: $disc(L) = \{\langle a, c \rangle, \langle a, b, c \rangle, \langle a, b, b, c \rangle, \ldots\}$.

An example of a discovery algorithm is the α algorithm [13] that produces a Petri net based on the patterns identified in the event log. Many discovery techniques have been proposed in literature [14], [13], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24] and are supported by open source tools such as ProM and commercial tools such as Disco (Fluxicon), Perceptive Process Mining (also known as Futura Reflect), ARIS Process Performance Manager (Software AG), QPR ProcessAnalyzer, Interstage Process Discovery (Fujitsu), Discovery Analyst (StereoLOGIC), and XMAnalyzer (XMPro). It is impossible to provide an complete overview of all techniques here. Very different approaches can be followed, e.g., using heuristics [19], [23], inductive logic programming [20], state-based regions [14], [18], [22], language-based regions [16], [24], and genetic algorithms [21].

There are four quality dimensions for comparing model and log: (1) *fitness*, (2) *simplicity*, (3) *precision*, and (4) *generalization* [1]. A model with good *fitness* allows for most of the behavior seen in the event log. A model has a perfect fitness if all traces in the log can be replayed by the model from beginning to end. The *simplest* model that can explain the behavior seen in the log is the best model. This principle is known as Occam's Razor. Fitness and simplicity alone are not sufficient to judge the quality of a discovered process model. For example, it is very easy to construct an extremely simple Petri net ("flower model") that is able to replay all traces in an event log (but also any other event log referring to the same set of activities). Similarly, it is undesirable to have a model that only allows for the exact behavior seen in the event log. Remember that the log contains only example behavior and that many traces that are possible may not have been observed yet. A model is *precise* if it does not allow for "too much" behavior. Clearly, the "flower model" lacks precision. A model that is not precise is "underfitting". Underfitting is the problem that the model over-generalizes the example behavior in the log (i.e., the model allows for behaviors very different from what was seen in the log). At the same time, the model should generalize and not restrict behavior to just the examples seen in the log. A model that does not *generalize* is "overfitting". Overfitting is the problem that a very specific model is generated whereas it is obvious that the log only holds example behavior (i.e., the model explains the particular sample log, but there is a high probability that the model is unable to explain the next batch of cases).

We often focus on fitness, e.g., event log $L = [\langle a, b, d, e, g \rangle^5, \langle a, c, d, e, h \rangle^4, \langle a, b, d, e, f, c, d, e, g \rangle]$ is perfectly fitting model M described in Figure 2.

Definition 6 (Conformance Checking Technique): A conformance checking technique $check \in (\mathcal{B}(\mathcal{U}) \times \mathcal{P}(\mathcal{U})) \rightarrow \mathcal{D}$ is a function that computes conformance diagnostics $check(L, M) \in \mathcal{D}$ (e.g., fitness or precision metrics) given an event log $L \in \mathcal{B}(\mathcal{U})$ and process model $M \in \mathcal{P}(\mathcal{U})$. $\mathcal{D}$ is the set of all possible diagnoses (e.g., a fitness value between 0 and 1) and depends on the metric chosen.

As indicated, we will often focus on fitness. Hence, we introduce some functions characterizing fitness.

Definition 7 (Conformance Checking Functions): Given an event log $L \in \mathcal{B}(\mathcal{U})$ and process model $M \in \mathcal{P}(\mathcal{U})$, we define the following functions:

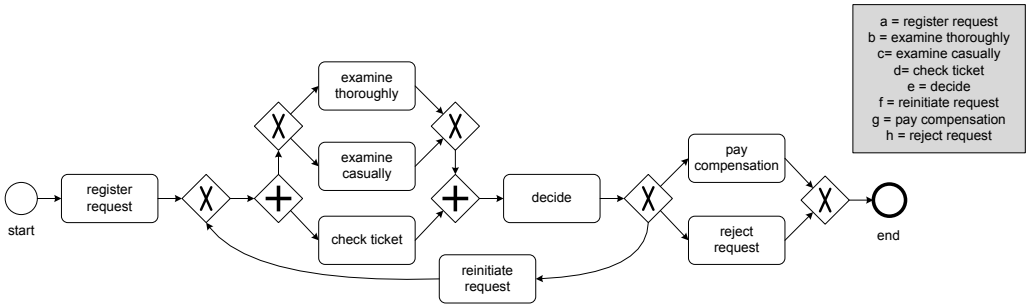

Fig. 2. A process model $M = \{\langle a,b,d,e,g\rangle, \langle a,c,d,e,g\rangle, \langle a,d,b,e,g\rangle, \langle a,d,c,e,g\rangle, \langle a,b,d,e,h\rangle, \langle a,c,d,e,h\rangle, \langle a,d,b,e,h\rangle, \langle a,d,c,e,h\rangle, \langle a,b,d,e,f,c,d,e,g\rangle, \langle a,c,d,e,f,b,d,e,h\rangle, \ldots\}$ expressed in terms of BPMN.

- $\mathit{fit}(L,M) = [\sigma \in L \mid \sigma \in M]$ is the multiset of fitting traces,
- $\mathit{nofit}(L,M) = [\sigma \in L \mid \sigma \notin M]$ is the multiset of non-fitting traces,
- $check_{pft}(L,M) = \frac{|\mathit{fit}(L,M)|}{|L|}$ is the fraction of traces in the event log perfectly fitting the model,
- $check_{bpf}(L,M) = (\mathit{fit}(L,M) = L)$ is a boolean function returning true if all traces in the event log fit.

Note that $\mathit{fit}(L,M) \uplus \mathit{nofit}(L,M) = L$. Clearly, $check_{pft}(L,M)$ and $check_{bpf}(L,M)$ are conformance checking functions in the spirit of Definition 6.

Simply counting the fraction of fitting cases is often too simplistic. Typically, one is interested in conformance metrics at the event level. For example, Petri-net based conformance checking approaches [25] may count the number of missing and remaining tokens during replay. Many conformance checking techniques have been proposed [26], [27], [28], [29], [30], [31], [20], [32], [33], [25], [34]. The alignment-based approach described in [26], [27] is much more sophisticated and provides much better diagnostics than simple metrics such as $check_{pft}(L,M)$. To illustrate the notion of alignments, let us consider the non-fitting trace $\langle a,b,c,e,g\rangle$ and process model M depicted in Figure 2. An optimal alignment is:

$$\gamma_1 = \left|\begin{array}{c|c|c|c|c|c} a & b & c & \gg & e & g \\ a & b & \gg & d & e & g \end{array}\right|$$

The $\gg$ symbols indicate the problems. The third column shows a "move on log only" $(c, \gg)$ indicating that the observed c event cannot be matched with a move of the model. The fourth column shows a "move on model only" $(\gg, d)$ indicating that the necessary execution of d in the model cannot be matched with an event in the log. All other columns refer to "synchronous moves", i.e., model and log agree. Alignment γ_1 has lowest costs assuming equal costs to all non-synchronous moves, i.e., simply count the number of $\gg$ symbols. A non-optimal alignment is:

$$\gamma_2 = \left|\begin{array}{c|c|c|c|c|c|c|c|c|c} a & b & \gg & \gg & \gg & c & \gg & e & g \\ a & b & d & e & f & c & d & e & g \end{array}\right|$$

Alignment γ_2 has four non-synchronous moves, i.e., double the number of non-synchronous moves compared to γ_1. Therefore, it is not optimal and not considered during analysis.

The alignment-based approach is very flexible because it can deal with arbitrary cost functions and any model representation. For example, one can associate costs to activities that are executed too late or by the wrong person. Alignments can also be used for computing precision and generalization [26], [33]. However, the approach can be rather time consuming. Therefore, the efficiency gains obtained through decomposition can be considerable for larger processes.

For simplicity we will focus in the remainder on the fraction of perfectly fitting traces $check_{pft}(L,M)$. However, as illustrated by the results in [7], we can use our decomposition approach also for more sophisticated alignment-based approaches.

IV. Decomposing Models and Logs

As events logs and process models grow in size, process mining may become a time consuming activity. Conformance checking may become intractable when many different traces need to be aligned with a model that allows for an exponential (or even infinite) number of traces. Event logs may contain millions of events. Finding the best alignment may require solving many optimization problems or repeated state-space explorations. In worst case, a state-space exploration of the model is needed per event. When using genetic process mining, one needs to check the fitness of every individual model in every generation. As a result, millions of conformance checks may be required. For each conformance check, the whole event log needs to be traversed.

For process discovery there are similar problems. Now the model is not given and the challenge is to find a model that scores good with respect to different objectives, e.g., fitness, simplicity, precision, and generalization. Depending on the representational bias, there may be infinitely many candidate models.

Given these challenges, we are interested in reducing the time needed for process mining tasks by decomposing the associated event log. In this section, we show that it is possible to decompose any process mining problem by *partitioning the set of activities*.

Definition 8 (Activity Partitioning): $P = \{A_1, A_2, \ldots, A_n\}$ is an *activity partitioning* of a set A if $A = \bigcup_{1 \leq i \leq n} A_i$. The activity sets may overlap. $\tilde{A}_i = A_i \cap \bigcup_{j \neq i} A_j$ are all activities that A_i shares with other activity sets. $A_i^I = A_i \setminus \tilde{A}_i$

are the internal activities of A_i. $\overline{A}_i = A \setminus (A_i^I) = \bigcup_{j \neq i} A_j$ are the non-internal activities of A_i.

Note that $\overline{A}_i \cap A_i = \tilde{A}_i$. A possible activity partitioning for the activities used in Figure 2 is $P = \{\{a, b, c, d, e, f\}, \{e, f, g, h\}\}$. Note that both activity sets in P share activities e and f.

Given an activity partitioning P, activity set $A \in P$, trace $\sigma \in \mathcal{U}$, model $M \in \mathcal{P}(\mathcal{U})$, and event log $L \in \mathcal{B}(\mathcal{U})$, we define the following terms:

- $\sigma{\restriction_A}$ is a *subtrace* of σ,
- $M{\restriction_A} \in \mathcal{P}(\mathcal{U})$ is a *submodel* of M, and
- $L{\restriction_A} \in \mathcal{B}(\mathcal{U})$ is a *sublog* of L.

Given an activity partitioning P consisting of n activity sets, we can partition the overall model into n submodels and the overall event log into n sublogs.[1]

It is easy to see that any trace that fits the overall model also fits any submodel (use the first property of Lemma 1). The reverse does not need to hold in case the behavior of one submodel may depend on internal behavior of another submodel. Nevertheless, we can compute bounds for conformance and use this insight for decomposed process discovery.

Definition 9 (Alternative Conformance Functions): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model, $P = \{A_1, A_2, \ldots, A_n\}$ an activity partitioning of A_M, and $L \in \mathcal{B}(\mathcal{U})$ an event log. We define variants of the functions in Definition 7 that only use submodels and sublogs.

- $\mathit{fit}^P(L, M) = [\sigma \in L \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}]$,
- $\mathit{check}^P_{pft}(L, M) = \frac{|\mathit{fit}^P(L,M)|}{|L|}$, and
- $\mathit{check}^P_{bpf}(L, M) = (\mathit{fit}^P(L, M) = L)$.

Theorem 1 (Conformance Bounds): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model and $P = \{A_1, A_2, \ldots, A_n\}$ an activity partitioning of A_M. For any event log $L \in \mathcal{B}(\mathcal{U})$:

- $\mathit{fit}(L, M) \leq \mathit{fit}^P(L, M)$,
- $\mathit{check}_{pft}(L, M) \leq \mathit{check}^P_{pft}(L, M)$, and
- $\mathit{check}_{bpf}(L, M) \Rightarrow \mathit{check}^P_{bpf}(L, M)$.

Proof: Let $\sigma \in \mathit{fit}(L, M)$, i.e., $\sigma \in L$ and $\sigma \in M$. Using Lemma 1 we can deduce that $\sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}$ for any i. Hence, $\sigma \in \mathit{fit}^P(L, M)$. This proves that $\mathit{fit}(L, M) \leq \mathit{fit}^P(L, M)$. The two other statements follow directly from this. ■

Consider activity partitioning $P = \{A_1, A_2\}$ with $A_1 = \{a, b, c, d, e, f\}$, and $A_2 = \{e, f, g, h\}$ for model M in Figure 2 and $L = [\langle a, b, d, e, g\rangle^5, \langle a, c, d, e, h\rangle^4, \langle a, b, d, e, f, c, d, e, g\rangle]$. $M{\restriction_{A_1}} = \{\langle a, b, d, e\rangle, \langle a, c, d, e\rangle, \langle a, d, b, e\rangle, \langle a, d, c, e\rangle, \langle a, b, d, e, f, c, d, e\rangle, \langle a, c, d, e, f, b, d, e\rangle, \ldots\}$ and $M{\restriction_{A_2}} = \{\langle e, g\rangle, \langle e, h\rangle, \langle e, f, e, g\rangle, \langle e, f, e, h\rangle, \ldots\}$. $L{\restriction_{A_1}} = [\langle a, b, d, e\rangle^5, \langle a, c, d, e\rangle^4, \langle a, b, d, e, f, c, d, e\rangle]$ and $L{\restriction_{A_2}} = [\langle e, g\rangle^5, \langle e, h\rangle^4, \langle e, f, e, g\rangle]$. $\mathit{fit}(L, M) = \mathit{fit}^P(L, M) = L$, i.e., all traces fit into the overall model and all submodels. Hence, $\mathit{check}_{pft}(L, M) = \mathit{check}^P_{pft}(L, M) = 1$, and $\mathit{check}_{bpf}(L, M) = \mathit{check}^P_{bpf}(L, M) = \mathit{true}$.

[1]Note that we use the term "partition" in a loose manner. As indicated before, activity sets may overlap and hence submodels and sublogs can also overlap in terms of events/activities.

V. Valid Activity Partitioning

Consider the following four event logs each containing 100 traces: $L_1 = [\langle a, c, d\rangle^{50}, \langle b, c, e\rangle^{50}]$, $L_2 = [\langle a, c, d\rangle^{25}, \langle a, c, e\rangle^{25}, \langle b, c, d\rangle^{25}, \langle b, c, e\rangle^{25}]$, $L_3 = [\langle a, c, d\rangle^{49}, \langle a, c, e\rangle^{1}, \langle b, c, d\rangle^{1}, \langle b, c, e\rangle^{49}]$, and $L_4 = [\langle a, c, d\rangle^{25}, \langle d, c, a\rangle^{25}, \langle b, c, e\rangle^{25}, \langle e, c, b\rangle^{25}]$. Also consider the process models $M_1 = \{\langle a, c, d\rangle, \langle b, c, e\rangle\}$ and $M_2 = \{\langle a, c, d\rangle, \langle a, c, e\rangle, \langle b, c, d\rangle, \langle b, c, e\rangle\}$. Figure 3 shows both models in terms of a Petri net. M_1 is the model *with* places p_1 and p_2 and M_2 is the model *without* these places. Note that the Petri net is just shown for illustration purposes. None of the definitions or results in this paper depends on a particular representation (see Definition 3).

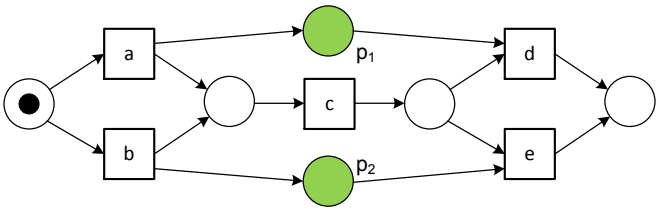

Fig. 3. Two Petri nets used to illustrate valid activity partitioning. $M_1 = \{\langle a, c, d\rangle, \langle b, c, e\rangle\}$ is the model with places p_1 and p_2 and $M_2 = \{\langle a, c, d\rangle, \langle a, c, e\rangle, \langle b, c, d\rangle, \langle b, c, e\rangle\}$ is the model without these places.

Given these three event logs and two process models, we can compute the following fractions of fitting traces:

$\mathit{check}_{pft}(L_1, M_1) = 1$	$\mathit{check}_{pft}(L_1, M_2) = 1$
$\mathit{check}_{pft}(L_2, M_1) = 0.50$	$\mathit{check}_{pft}(L_2, M_2) = 1$
$\mathit{check}_{pft}(L_3, M_1) = 0.98$	$\mathit{check}_{pft}(L_3, M_2) = 1$
$\mathit{check}_{pft}(L_4, M_1) = 0.50$	$\mathit{check}_{pft}(L_4, M_2) = 0.50$

Consider now the activity partitioning $P = \{A_1, A_2\}$ with $A_1 = \{a, b, c\}$ and $A_2 = \{c, d, e\}$. Using this partitioning more events logs will perfectly fit the individual submodels:

$\mathit{check}^P_{pft}(L_1, M_1) = 1$	$\mathit{check}^P_{pft}(L_1, M_2) = 1$
$\mathit{check}^P_{pft}(L_2, M_1) = 1$	$\mathit{check}^P_{pft}(L_2, M_2) = 1$
$\mathit{check}^P_{pft}(L_3, M_1) = 1$	$\mathit{check}^P_{pft}(L_3, M_2) = 1$
$\mathit{check}^P_{pft}(L_4, M_1) = 0.50$	$\mathit{check}^P_{pft}(L_4, M_2) = 0.50$

This illustrates that in general $\mathit{check}_{pft}(L, M) \leq \mathit{check}^P_{pft}(L, M)$, but both values do not need to be the same, e.g., $\mathit{check}_{pft}(L_2, M_1) \neq \mathit{check}^P_{pft}(L_2, M_1)$. In this case the difference is caused by the dependency between the two choices in M_1 which is not "communicated" via the activities in $A_1 \cap A_2 = \{c\}$. This example triggers the question when $\mathit{check}_{pft}(L, M) = \mathit{check}^P_{pft}(L, M)$, or more precisely, what properties must activity partitioning P have such that $\mathit{fit}(L, M) = \mathit{fit}^P(L, M)$?

An activity partitioning is *valid* if the "internal behavior" of one set of activities A_i does not depend on the internals of

another activity set A_j. It other words: the activity sets need to synchronize on non-local phenomena.

Definition 10 (Valid Activity Partitioning): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model with activities A_M and $P = \{A_1, A_2, \ldots, A_n\}$ an activity partitioning of the set A_M. P is *valid* for M if and only if $M = \{\sigma \in {A_M}^* \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\}$.

Activity partitioning $P = \{A_1, A_2\}$ with $A_1 = \{a, b, c\}$ and $A_2 = \{c, d, e\}$ is valid for M_2 but not for M_1. Note that $\langle a, c, e\rangle{\restriction_{A_1}} = \langle a, c\rangle \in M_1{\restriction_{A_1}}$ and $\langle a, c, e\rangle{\restriction_{A_2}} = \langle c, e\rangle \in M_1{\restriction_{A_2}}$, but $\langle a, c, e\rangle \notin M_1$.

The following theorem shows that a valid activity partitioning allows us to compute conformance per submodel without loosing precision, i.e., we get exact values rather than bounds.

Theorem 2 (Conformance Checking Can Be Decomposed): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model and $P = \{A_1, A_2, \ldots, A_n\}$ a valid activity partitioning of A_M. For any event log $L \in \mathcal{B}(\mathcal{U})$:

- $\mathit{fit}(L, M) = \mathit{fit}^P(L, M)$,
- $\mathit{check}_{pft}(L, M) = \mathit{check}^P_{pft}(L, M)$, and
- $\mathit{check}_{bpf}(L, M) = \mathit{check}^P_{bpf}(L, M)$.

Proof: $\mathit{fit}(L, M) = [\sigma \in L \mid \sigma \in M] = [\sigma \in L \mid \sigma \in \{\sigma' \in {A_M}^* \mid \forall_{1 \leq i \leq n}\ \sigma'{\restriction_{A_i}} \in M{\restriction_{A_i}}\}] = [\sigma \in L \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}] = \mathit{fit}^P(L, M)$. This proves the first statement. The two other statements follow directly from this. ■

Theorem 2 shows that conformance checking can be decomposed. Next we show that also discovery can be decomposed. Here we only have an event log to start with. However, while constructing the overall model we can simply assume independence and thus ensure a valid activity partitioning.

Corollary 1 (Process Discovery Can Be Decomposed): Let $L \in \mathcal{B}(\mathcal{U})$ be an event log and $P = \{A_1, A_2, \ldots, A_n\}$ an activity partitioning of A_L. Let $\mathit{disc} \in \mathcal{B}(\mathcal{U}) \rightarrow \mathcal{P}(\mathcal{U})$ be a discovery algorithm used to obtain the submodels $M_i = \mathit{disc}(L{\restriction_{A_i}})$ with $i \in \{1, \ldots, n\}$. $M = \{\sigma \in U \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M_i\}$ is the overall model constructed by merging the discovered submodels.

- P is a valid activity partitioning for M,
- $\mathit{fit}(L, M) = \mathit{fit}^P(L, M)$,
- $\mathit{check}_{pft}(L, M) = \mathit{check}^P_{pft}(L, M)$, and
- $\mathit{check}_{bpf}(L, M) = \mathit{check}^P_{bpf}(L, M)$.

By applying the construction of Corollary 1 we can decompose process discovery. If all the sublogs fit perfectly, then the overall event log will also fit the overall model perfectly. However, if activity sets are not overlapping sufficiently, the model may be underfitting (too general).

One may try to relax the validity requirement. For example, by considering one activity set A_i and its complete environment $\overline{A_i}$.

Definition 11 (Weakly Valid Activity Partitioning): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model with activities A_M and $P = \{A_1, A_2, \ldots, A_n\}$ an activity partitioning of the set A_M. P is *weakly valid* if and only if $M = \{\sigma \in {A_M}^* \mid \exists_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}} \wedge \sigma{\restriction_{\overline{A_i}}} \in M{\restriction_{\overline{A_i}}}\}$.

Clearly, any valid activity partitioning is also weakly valid. If $\sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}$ and $\sigma{\restriction_{\overline{A_i}}} \in M{\restriction_{\overline{A_i}}}$, then we can apply Lemma 1 to show that $\sigma{\restriction_{A_j}} \in M{\restriction_{A_j}}$ for $j \neq i$. The reverse does not hold. Consider for example $M = \{\langle a, b, d, e, g\rangle, \langle a, c, d, f, g\rangle$ and $P = \{A_1, A_2, A_3, A_4\}$ with $A_1 = \{a, b, c\}$, $A_2 = \{b, c, d\}$, $A_3 = \{d, e, f\}$, and $A_4 = \{e, f, g\}$. $P = \{A_1, A_2, A_3, A_4\}$ is not a valid activity partitioning because the traces $\langle a, c, d, e, g\rangle$ and $\langle a, b, d, f, g\rangle$ are not in M. However, P is weakly valid. This example also shows that Theorem 2 in general does not hold for weakly valid activity partitionings.

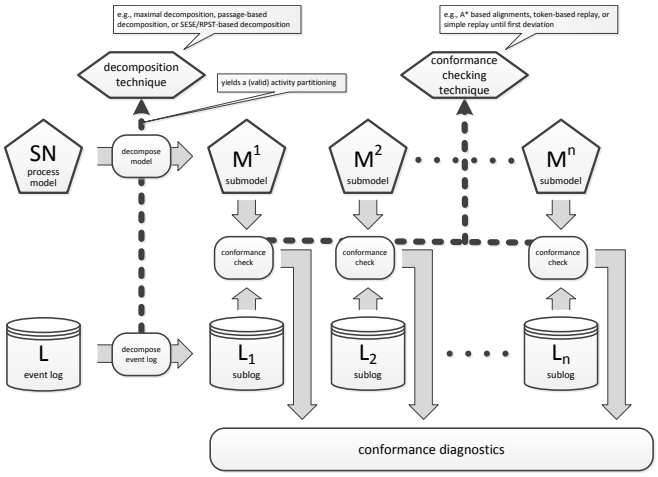

Fig. 4. Overview of decomposed conformance checking showing the configurable elements of the approach: (a) the *decomposition technique* yielding the activity partitioning that is used to split the overall model and event log, and (b) the *conformance checking technique* used to analyze the individual models and sublogs.

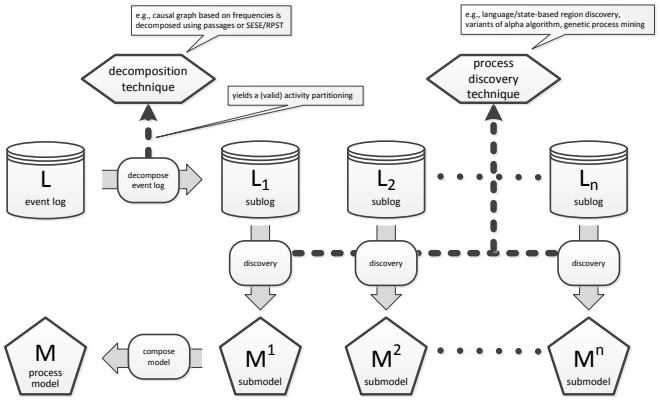

Fig. 5. Overview of decomposed process discovery showing the configurable elements of the approach: (a) the *decomposition technique* yielding the activity partitioning that is the basis for creating sublogs and (b) the *process discovery technique* used to infer submodels from sublogs.

Figures 4 and 5 summarize the overall approach proposed in this paper. Moreover, these figures point out the configurable elements. For conformance checking we need to find an activity partitioning P and a conformance checking technique

$check \in (\mathcal{B}(\mathcal{U}) \times \mathcal{P}(\mathcal{U})) \rightarrow \mathcal{D}$ (see Definition 6). For process discovery we need to find an activity partitioning P (based on only the event log since there is no initial model) and a process discovery technique $disc \in \mathcal{B}(\mathcal{U}) \rightarrow \mathcal{P}(\mathcal{U})$ (see Definition 5).

VI. Finding a (Valid) Activity Partitioning

Theorems 1 and 2 are very general, but stand or fall with a suitable activity partitioning. Consider the following two extreme activity partitionings for an activity set A: $P_{one} = \{A\}$ (just one activity set containing all activities) and $P_{all} = \{\{a\} \mid a \in A\}$ (one activity set per activity). Both are not very useful. P_{one} does not decompose the problem, i.e., there is still one big task. P_{all} decomposes the set of activities into singleton activity sets. P_{all} considers all activities in isolation, hence conformance checking and discovery are only considering frequencies of activities and not their order. For conformance checking P_{all} is typically not valid and decomposed discovery using P_{all} will most likely result in a severely underfitting model.

For conformance checking we can exploit the structure of the process model when searching for a (valid) activity partitioning. For example, the process model (e.g., a Petri net) can be decomposed using the so-called Refined Process Structure Tree (RPST) [35], [36] as shown in [10], [9]. The RPST allows for the construction of a hierarchy of SESE (Single-Exit-Single-Entry) components. Slicing the SESE at the desired level of granularity corresponds to a decomposition of the graph [9] that can be used for process mining.

In [7] an algorithm providing the so-called "maximal decomposition" of a Petri net is given. The construction of the maximal decomposition is based on partitioning the edges. Each edge will end up in precisely one submodel. Edges are taken together if they are connected through a place, through an internal transition (invisible action), or through multiple transitions having the same label. The algorithm iterates until no edges need to joined. Any labeled Petri net has a unique maximal decomposition and this decomposition defines a valid activity partitioning.

The notion of "passages" defined in [8], [37] provides an alternative approach to decompose a Petri net. A passage is a pair of two non-empty sets of activities (X, Y) such that the set of direct successors of X is Y and the set of direct predecessors of Y is X. As shown in [8], any Petri net can be partitioned using passages such that all edges sharing a source vertex or sink vertex are in the same set. This is done to ensure that splits and joins are not decomposed. Note that passages do not necessarily aim at high cohesion and low coupling. Nevertheless, they define a valid activity partitioning.

For discovery we cannot exploit the structure of the model to ensure the validity or suitability of an activity partitioning. Therefore, often an intermediate step is used [7]. For example, one can mine for frequent item sets to find activities that often happen together. Another, probably better performing, approach is to first create a *causal graph* (A, R) where A is the set of activities and $R \subseteq A \times A$ is a relation on A. The interpretation of $(a_1, a_2) \in R$ is that there is a "causal relation" between a_1 and a_2. Most process mining algorithms already build such a graph in a preprocessing step. For example, the α algorithm [13], the heuristic miner [23], and the fuzzy miner [38] scan the event log to see how many times a_1 is followed by a_2. If this occurs above a certain threshold, then it is assumed that $(a_1, a_2) \in R$. Even for large logs it is relatively easy to construct a causal graph (linear in the size of the event log). Moreover, counting the frequencies used to determine a causal graph can be distributed easily by partitioning the cases in the log. Also sampling (determining the graph based on representative examples) may be used to further reduce computation time.

Given a causal graph, one can view decomposition as a graph partitioning problem [39], [40], [41], [42]. There are various approaches to partition the graph such that certain constraints are satisfied while optimizing particular metrics. For example, in [42] a vertex-cut based graph partitioning algorithm is proposed ensuring the balance of the resulting partitions while simultaneously minimizing the number of vertices that are cut (and thus replicated).

Some of the notions in graph partitioning are related to "cohesion and coupling" in software development [43]. Cohesion is the degree to which the elements of a module belong together. Coupling is the degree to which each module relies on the other modules. Typically, one aims at "high cohesion" and "low coupling". In terms of our problem this means that we would like to have activity sets that consist of closely related activities whereas the overlap between the different activity sets is as small as possible while still respecting the causalities.

Definition 10 also suggests to investigate correlations between activity sets. An activity set $A_i \in P$ may be influenced through $\tilde{A}_i = A_i \cap \bigcup_{j \neq i} A_j$ but not through $\overline{A}_i \setminus A_i$. The goal is to find suitable "milestone activities", i.e., shared activities "decoupling" two activity sets.

The ideas mentioned above have only been explored superficially, but nicely illustrate that there are many promising directions for future research.

Interestingly, we can merge activity sets without jeopardizing validity. This allows us to decompose process mining problems at different levels of granularity or to provide a "tree view" on the process and its conformance.

Theorem 3 (Hierarchy Preserves Validity): Let $M \in \mathcal{P}(\mathcal{U})$ be a process model and $P = \{A_1, A_2, \ldots, A_n\}$ a valid activity partitioning of A_M with $n \geq 2$. Activity partitioning $P' = \{A_1 \cup A_2, A_3 \ldots, A_n\}$ is also valid.

Proof: Since P is valid $M = \{\sigma \in {A_M}^* \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\}$. We need to prove: $\{\sigma \in {A_M}^* \mid \sigma{\restriction_{A_1 \cup A_2}} \in M{\restriction_{A_1 \cup A_2}} \wedge \forall_{3 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\} = M$. $\sigma{\restriction_{A_1 \cup A_2}} \in M{\restriction_{A_1 \cup A_2}}$ implies that $\sigma{\restriction_{A_1}} \in M{\restriction_{A_1}}$ and $\sigma{\restriction_{A_2}} \in M{\restriction_{A_2}}$ (Lemma 1). Hence, $\{\sigma \in {A_M}^* \mid \sigma{\restriction_{A_1 \cup A_2}} \in M{\restriction_{A_1 \cup A_2}} \wedge \forall_{3 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\} \subseteq \{\sigma \in {A_M}^* \mid \forall_{1 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\} = M$. Moreover, for any $\sigma \in M$, $\sigma{\restriction_{A_1 \cup A_2}} \in M{\restriction_{A_1 \cup A_2}} \wedge \forall_{3 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}$ trivially holds. The observation that $M \subseteq \{\sigma \in {A_M}^* \mid \sigma{\restriction_{A_1 \cup A_2}} \in M{\restriction_{A_1 \cup A_2}} \wedge \forall_{3 \leq i \leq n}\ \sigma{\restriction_{A_i}} \in M{\restriction_{A_i}}\} \subseteq M$ completes the proof. ■

Theorem 3 can be applied iteratively. Hence, any combination of activity sets originating from a valid activity partitioning yields another valid activity partitioning. This allows us to coarsen any valid activity partitioning. Note that if $P = \{A_1, A_2, \ldots, A_n\}$ is not valid, then $P' = \{A_1 \cup A_2, A_3 \ldots, A_n\}$

may still be valid. Therefore, we can try to merge problematic activity sets in order to get a valid activity partitioning and better (i.e., more precise) process mining results. For example, when we are using alignments as described in [26], [27] we can diagnose the activity sets that disagree. We can also give preference to alignments that to not disagree on the interface of different activity sets. Last but no least, we can create a hierarchy of conformance/discovery results, similar to a dendrogram in hierarchical clustering.

VII. Related Work

For an introduction to process mining we refer to [1]. For an overview of best practices and challenges, we refer to the Process Mining Manifesto [44]. Also note the availability of open source tools such as ProM and commercial tools such as Disco (Fluxicon), Perceptive Process Mining (also known as Futura Reflect), ARIS Process Performance Manager (Software AG), QPR ProcessAnalyzer, Interstage Process Discovery (Fujitsu), Discovery Analyst (StereoLOGIC), and XMAnalyzer (XMPro).

The goal of this paper is to decompose challenging process discovery and conformance checking problems into smaller problems [6]. Therefore, we first review some of the techniques available for process discovery and conformance checking.

Process discovery, i.e., discovering a process model from a multiset of example traces, is a very challenging problem and various discovery techniques have been proposed [14], [13], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24]. Many of these techniques use Petri nets during the discovery process and/or to represent the discovered model. It is impossible to provide an complete overview of all techniques here. Very different approaches are used, e.g., heuristics [19], [23], inductive logic programming [20], state-based regions [14], [18], [22], language-based regions [16], [24], and genetic algorithms [21]. Classical synthesis techniques based on regions [45] cannot be applied directly because the event log contains only example behavior. For state-based regions one first needs to create an automaton as described in [14]. Moreover, when constructing the regions, one should avoid overfitting. Language-based regions seem good candidates for discovering transition-bordered Petri nets that can serve as submodels [16], [24]. Unfortunately, these techniques still have problems dealing with infrequent/incomplete behavior.

There are four competing quality criteria when comparing modeled behavior and recorded behavior: fitness, simplicity, precision, and generalization [1]. In this paper, we focused on fitness, but also precision and generalization can also be investigated per submodel. Various conformance checking techniques have been proposed in recent years [26], [27], [28], [29], [30], [31], [20], [32], [33], [25], [34]. Conformance checking can be used to evaluate the quality of discovered processes but can also be used for auditing purposes [46]. Most of the techniques mentioned can be combined with our decomposition approach. The most challenging part is to aggregate the metrics per model fragment and sublog into metrics for the overall model and log. We consider the approach described in [27] to be most promising as it constructs an optimal alignment given an arbitrary cost function. This alignment can be used for computing precision and generalization [26], [33]. However, the approach can be rather time consuming. Therefore, the efficiency gains obtained through decomposition can be considerable for larger processes with many activities and possible subnets.

Little work has been done on the decomposition and distribution of process mining problems [6], [7]. In [47] MapReduce is used to scale event correlation as a preprocessing step for process mining. In [48] an approach is described to distribute genetic process mining over multiple computers. In this approach candidate models are distributed and in a similar fashion also the log can be distributed. However, individual models are not partitioned over multiple nodes. Therefore, the approach in this paper is complementary. Moreover, unlike [48], the decomposition approach in this paper is not restricted to genetic process mining.

More related are the divide-and-conquer techniques presented in [49]. In [49] it is shown that region-based synthesis can be done at the level of synchronized State Machine Components (SMCs). Also a heuristic is given to partition the causal dependency graph into overlapping sets of events that are used to construct sets of SMCs. In this paper we provide a different (more local) partitioning of the problem and, unlike [49] which focuses specifically on state-based region mining, we decouple the decomposition approach from the actual conformance checking and process discovery approaches.

Also related is the work on conformance checking of proclets [50]. Proclets can be used to define so-called artifact centric processes, i.e., processes that are not monolithic but that are composed of smaller interacting processes (called proclets). In [50] it is shown that conformance checking can be done per proclet by projecting the event log onto a single proclet while considering interface transitions in the surrounding proclets.

Several approaches have been proposed to distribute the verification of Petri net properties, e.g., by partitioning the state space using a hash function [51] or by modularizing the state space using localized strongly connected components [52]. These techniques do not consider event logs and cannot be applied to process mining.

Most data mining techniques can be distributed [53], e.g., distributed classification, distributed clustering, and distributed association rule mining [54]. These techniques often partition the input data and cannot be used for the discovery of Petri nets.

This paper generalizes the results presented in [7], [8], [9], [10], [11] to arbitrary decompositions (Petri-net based or not). In [8], [55], [11] it is shown that so-called “passages” [37] can be used to decompose both process discovery and conformance checking problems. In [10], [9] it is shown that so-called SESE (Single-Exit-Single-Entry) components obtained through the Refined Process Structure Tree (RPST) [35], [36] can be used to decompose conformance checking problems. These papers use a particular particular decomposition strategy. However, as shown in [7], there are many ways to decompose process mining problems.

The results in [7] are general but only apply to Petri nets. This paper further generalizes the divide and conquer approach beyond Petri nets. This allows us to simplify the presentation

and clearly show the key requirements for decomposing both process discovery and conformance checking problems.

VIII. Conclusion

In this paper we provided a high-level view on the decomposition of process mining tasks. Both conformance checking and process discovery problems can be divided into smaller problems that can be distributed over multiple computers. Moreover, due to the exponential nature of most process mining techniques, the time needed to solve "many smaller problems" is less than the time needed to solve "one big problem". Therefore, decomposition is useful even if the smaller tasks are done on a single computer. Moreover, decomposing process mining problems is not just interesting from a performance point of view. Decompositions can also be used to pinpoint the most problematic parts of the process (also in terms of performance) and provide localized diagnostics. This also helps us to better understand the limitations of existing conformance checking and process discovery techniques.

In this paper we discussed a very general divide-and-conquer approach without focusing on a particular representation or decomposition strategy. Nevertheless, it provided new and interesting insights with respect to the essential requirements of more concrete approaches. The paper also provides pointers to approaches using Petri nets as a representational bias and SESEs [10], [9], passages [8], [11], or maximal decompositions [7] as a decomposition strategy. It is clear that these are merely examples of the broad spectrum of possible techniques to decompose process mining problems. Given the incredible growth of event data, there is an urgent need to explore and investigate the entire spectrum in more detail.

Acknowledgements

This work was supported by the Basic Research Program of the National Research University Higher School of Economics (HSE). The author would like to thank Eric Verbeek, Jorge Munoz-Gama and Joseph Carmona for their joint work on decomposing Petri nets for process mining (e.g., using passages and SESEs).

***Abstract*—Nonnegative Matrix Factorization (NMF) is one of the most promising techniques to reduce the dimensionality of the data. This presentation compares the method with other popular matrix decomposition approaches for various pattern analysis tasks. Among others, NMF has been also widely applied for clustering and latent feature extraction. Several types of the objective functions have been used for NMF in the literature. Instead of minimizing the common Euclidean Distance (EucD) error, we review an alternative method that maximizes the correntropy similarity measure to produce the factorization. Correntropy is an entropy-based criterion defined as a nonlinear similarity measure. Following the discussion of maximization of the correntropy function, we use it to cluster document data set and compare the clustering performance with the EucD-based NMF. Our approach was applied and illustrated for the clustering of documents in the 20-Newsgroups data set. The comparison is illustrated with 20-Newsgroups data set. The results show that our approach produces per average better clustering compared with other methods which use EucD as an objective function.**

***Keywords*—Nonnegative Matrix Factorization; Correntropy; Principal Component Analyis; Face recognition**

I. Introduction

The ever-increasing amount of data recorded, stored and processed worldwide necessitates the development of new representations and is becoming a major task for data analysis research [1, 2, 3, 4, 17, and 18]. Dimensionality reduction of the data is a technique that describes each multidimensional data sample with a small number of coefficients that are the sample's coordinates in a new, particular to this dataset, feature space. Often dimensionality reduction is accomplished by finding factorizations of a matrix representing the dataset. Most widely-known methods are Principal Component Analysis (PCA), Independent Component Analysis (ICA) and Singular Value Decomposition (SVD). Recently defined Nonnegative Matrix Factorization (NMF) approach also has been successfully applied in pattern recognition. It is an unsupervised learning method that also reduces the dimensionality of the data. It has also been used for several applications [5-8, 14-16, 19, 20].

Matrix factorization methods treat the data as an $m \times n$ matrix in which every column represents a data sample.

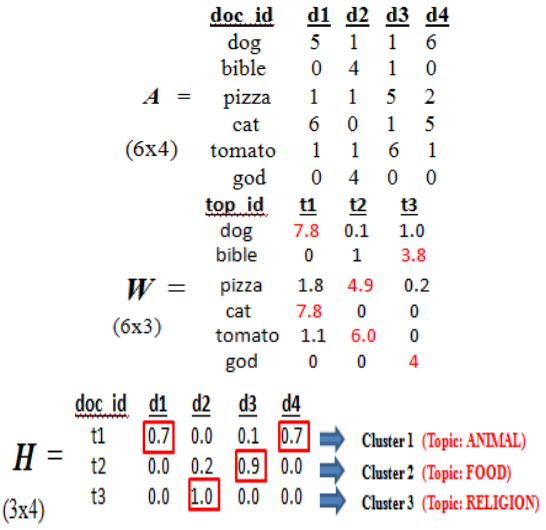

Figure 1. A small document-term matrix and its nonnegative factorization. Indicated are terms that are most important for each topic and assignments of documents into topics (clusters).

This matrix is approximated by a product of two rank k matrices, as follows:

$$A \approx WH,$$

where A is the data matrix, W is the $m \times k$ matrix of basis vectors and H is a $k \times n$ matrix that gives the coordinates of samples in the feature space. We can think of the factorization as of a decomposition of the j-th sample (j-th column of A, $A_{:j}$) into a linear combination of features given by columns of W:

$$A_{:j} = \sum_i W_{:i} H_{ij}.$$

For instance, consider a small artificial data set of documents shown in Figure 1. The documents are encoded in the bag-of-words format. Here, A is a 6×4 data matrix formed by 4 documents, 6 words of interest, and 3 topics. The topics are ANIMAL (d1 and d4), RELIGION (d2) an d FOOD (d4). Once the factorization is computed we can cluster the documents [14]. It can be accomplished by assigning each document to the topic that contributes the

most to its nonnegative representation (has the largest entry in the matrix H). The matrices W and H that form a nonnegative factorization are shown in Figure 1. We have indicated the most important words for each topic and demonstrated the cluster memberships.

II. NONNEGATIVE MATRIX FACTORIZATION (NMF)

The intuitive definition of matrix factorization asks to find two matrices, W and H, whose product approximates a given matrix. Specific matrix factorization schemes are differentiated by the error function used to describe the quality of the approximation and by the constraints imposed on the elements of W and H. The family of nonnegative factorizations imposes that elements of W and H be nonnegative. A necessary prerequisite is that the data matrix A must also contain nonnegative elements only. Fortunately, this is often the case. In example documents in a bag-of-words format or images are non-negative. Application areas for NMF include face recognition, bioinformatics, text mining and audio (speech) processing [2, 3, 6-8, 14, 19]. Clustering task is also one of the main topics for NMF and it has been extensively applied and discussed in the literature [6, 8, 14-16].

Nonnegative factorizations are motivated by their enhanced interpretability. When subtraction is forbidden no cancelations occur in the topic (cluster) definitions and meanings can be deduced, as in the example shown in Figure 1. Indeed, for many applications subtraction is not meaningful. However, except for NMF, other matrix factorization methods generally allow the subtraction of values. These values can be faces, audio or gene expression levels according to application areas. But in these cases, basis values (for instance images for face recognition) are not physically intuitive.

Typically, in NMF the factorization objective is the Euclidean distance between the elements of A and the elements of WH (i.e. the Frobenius norm of the difference $A - WH$). This measure is well-known and often used in the literature. However, other distance (or similarity) measures can be used, and they will often produce different factorizations. In example, calculations derived from the Kullback-Leibler divergence have often been studied in the literature [1-4, 9, and 14]. Often the loss function is chosen to match a specific application domain. In [7], authors used the Itakura-Saito (IS) divergence as an objective function and in [5] authors used the β-divergence.

In [1-4], authors used a distance measure based on the Kullback-Leibler divergence. The measure $D_s(u_j, w_i)$ is a symmetric divergence of u_j with respect w_i given by [2]:

$$D_s(u_j, w_i) = D(u_j||w_i) + D(u_j||w_i),$$

where:

$$D(x||z) = \sum_l \frac{x(l)}{\|x\|_1} \log\left(\frac{x(l)\|z\|_1}{z(l)\|x\|_1}\right).$$

Another distance measure suitable for the NMF is the correntropy function, described in details in Section III.

Extensions of the NMF methodology involve imposing other constraints on the matrices W and H, such as sparseness or orthogonality. Bayesian approaches and other conditions for factorization have also been considered [3, 8].

The typical algorithm used to compute the NMF factorization with the Euclidean distance measure begins with W and H randomly initialized. It then uses the multiplicative update rules to minimize the error function [1,4]:

$$\mathrm{H_{ij}} \leftarrow \mathrm{H_{ij}} \frac{(\mathrm{W^T A})_{\mathrm{ij}}}{(\mathrm{W^T WH})_{\mathrm{ij}}}$$

$$\mathrm{W_{ij}} \leftarrow \mathrm{W_{ij}} \frac{(\mathrm{AH^T})_{\mathrm{ij}}}{(\mathrm{WHH^T})_{\mathrm{ij}}}$$

The rules ensure that at each iteration the error function does not increase, while the matrices W and H stay non-negative. The rules are applied iteratively until convergence.

Faster converging alternatives to the multiplicative updates, that have been proposed for the NMF include the projected gradient descent (PGD) and the alternating least squares (ALS) algorithm [2, 16].

III. CORRENTROPY SIMILARITY MEASURE

We have recently proposed to use the correntropy similarity measure as an objective function for nonnegative matrix factorization [26, 27]. The correntropy is a localized similarity measure between two random variables that was proposed in [9-12, 14]. It can be used as a cost function for NMF. We use it to calculate the element-wise similarity between the matrix A and its factorization:

$$Corr(A, WH) = \sum_{\mathrm{i,j}} \exp\left(\frac{-\left(A_{ij} - (WH)_{ij}\right)^2}{2\sigma^2}\right) \quad (1)$$

where σ is a parameter of the correntropy similarity measure. We note that for NMF we need to minimize the negative of correntropy since it is a similarity and not a distance measure [14].

It can easily be seen from eq. 1 that $Corr(A, WH)$ is always bounded and nonnegative. Moreover, the correntropy saturates when the disagreement between elements of A and its factorization WH is large. This property is important. It makes correntropy insensitive to outliers, because errors for badly approximated elements have less influence on the factorization. We illustrate correntropy as the error surface in Figure 2. It shows the errors for a single element of $1 + Loss(A, WH)$. We can change the shape of the function and control the level of saturation by adjusting the parameter σ. When σ is large little saturation occurs. Lowering σ causes that more and more elements of the difference $A - WH$ saturate and are treated as outliers.

IV. EXEMPLARY APPLICATIONS OF NMF

A. Document Clustering with NMF

For the first real life example we report the result of a comparison between quality of NMF factorizations based on the Euclidean distance and based on correntropy [14, 26]. The evaluation analyses the quality of clusters computed from factorizations. We have used the 20-newsgroups data set, which is one of the popular benchmarks used for clustering and classification of the text data. It has approximately 11,000 documents taken from 20 different newsgroups pertaining to various subjects.

After the factorization process, we obtain W and H. H can be used to group the data (A) into r clusters by choosing the largest value of each column in H.

The 20 newsgroups data contains ground-truth document labels which can be used to evaluate the quality of the clustering. We evaluate the clustering performance with the entropy measure. Total entropy for a set of clusters is calculated as the weighted mean of the entropies of each cluster weighted by the size of each cluster. Firstly, we calculate the distribution of the data for each cluster. For class j we compute p_{ij}, the probability that a member of cluster i belongs to class j as $p_{ij} = m_{ij}/m_i$, where m_i is the number of objects in cluster i and m_{ij} is the number of objects of class j in cluster i. Entropy of each cluster i is defined as:

$$e_i = -\sum_{j=1}^{L} p_{ij} log_2(p_{ij}),$$

where L is the number of classes. Entropy of the full data set as the sum of the entropies of each cluster i weighted by the size of each cluster:

$$e = \sum_{i=1}^{K} \frac{m_i}{m} e_i$$

where K is the number of clusters and m is the total number of data points [24].

Table 1 shows the entropy values of *NMF-PGD (EucD)* and *NMF-Corr* approaches for 20-Newsgroups data set. We graph these values (*NMF-PGD (EucD)* and *NMF-Corr (for* $\sigma = 1$, $\sigma = 0.5$ and $\sigma = 0.01$)) in Figure 3. Here, "k" denotes the assumed number of clusters and equals to the ranks of W, H. We change it from 2 to 20 to track the clustering performance. We show all entropy values in Figure 3, but for brevity we only illustrate 10 data points in Table 1. Since lower entropy values indicate better clustering performance, it can be seen from Table 1 and Figure 3, that *NMF-Corr* ($\sigma = 0.5$) demonstrates superior clustering performance than *NMF-PGD (EucD)* for every evaluated number of clusters.

Experiments and comparative results between NMF-PGD (EucD) and NMF-Corr show that NMF-Corr ($\sigma = 0.5$) has better clustering performance than NMF-PGD (EucD). Therefore, we can conclude that correntropy-based

Table 1. Entropy of 20-Newsgroups data set with NMF-PGD (EucD) and NMF-Corr.

Number of Clusters (k)	NMF-PGD (EucD)	NMF-Corr *(σ = 1)*	**NMF-Corr *(σ = 0.5)***	NMF-Corr *(σ = 0.01)*
r = 2	3.84	3.86	**3.85**	4.30
r = 3	3.86	3.79	**3.58**	4.27
r = 4	3.78	3.49	**3.50**	4.27
r = 5	3.74	3.60	**3.38**	4.24
r = 6	3.49	3.36	**3.30**	4.23
r = 7	3.44	3.28	**3.26**	4.20
r = 8	3.30	3.26	**2.94**	4.19
r = 9	3.30	3.34	**3.13**	4.18
r = 10	3.16	3.23	**2.93**	4.20

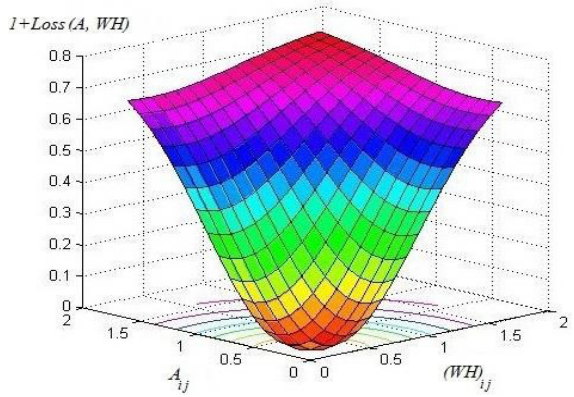

Figure 2. Correntropy objective function 1+Loss(A,WH) with σ=0.5,m=n=1.

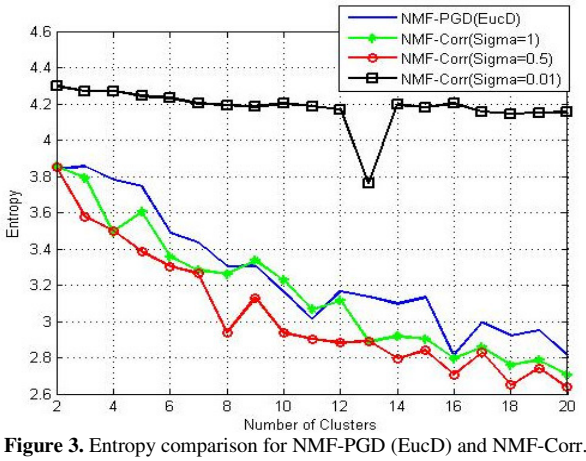

Figure 3. Entropy comparison for NMF-PGD (EucD) and NMF-Corr.

NMF ($for\ \sigma = 0.5$) has comparatively better clustering performance vs. EucD-based NMF for the evaluated data set. However, NMF-Corr does not show improved performance for $\sigma = 1$ and specifically worst performance for $\sigma = 0.01$. This can be seen from Figure 3 and Table 1. Also, the deterioration of clustering results for σ values below 0.5 requires further studies. One additional question

is whether this dependence on σ value is a property of the method or else whether it lies in the properties of the data for which experiments have been conducted. This will warrant further studies.

B. Occluded Face Recognition Using NMF

In the second example we report the results of an application of NMF to the problem of occluded face recognition [26].

Face recognition is one of the well-studied real life problems. Several methods have been defined and applied for this task. Above mentioned methods and Neural Networks (NN) have been studied to recognize face images [1, 19-26]. In fact, faces are not clear for daily life, because some obstacles can be in front of the face. These obstacles can be scarf, glasses, hats or some occlusion on the face. Therefore, occluded face recognition is important area in pattern analysis. There are many studies in the literature for occluded face recognition task, especially using PCA and NMF [19-26].

In this section, we evaluate the recognition performance of occluded face images on ORL face data set. We have compared PCA, NMF and correntropy based NMF (NMF-Corr) formulations by evaluating quality of recognition rates computed from factorizations. The ORL data consists of 40 persons, each photographed in 10 different poses. The data set was partitioned into two equal parts for training and testing. We have resized face images from original 112x92 pixels to 56x46 pixels for efficient computation.

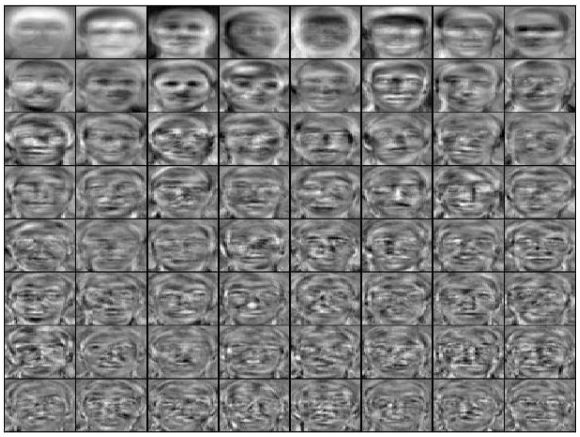
Face recognition in the NMF and NMF-Corr linear subspace is performed by first computing the pseudo-inverse of the W matrix as $W^+ = W^T(WW^T)^{-1}$. Then, all samples were encoded using this pseudo inverse. Finally, we have used 1 nearest-neighbor (1-NN) classifier for the recognition process.

In order to generate occluded faces, we have used randomly located black patches for both training and testing face images. In this way we test the robustness of the compared dimensionality reduction methods to noise on both training and testing data. Each patch covers from 10% to %50 of the face image at a random location. Sample patched face images can be seen from Figure 4.

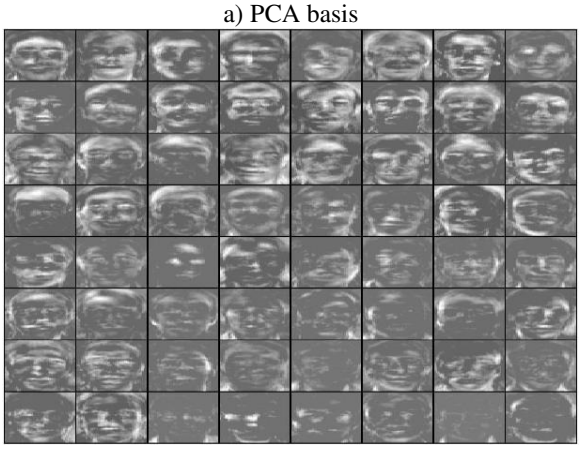
Recognition results have been obtained by running each method (PCA, NMF and NMF-Corr) 10 times, and then average recognition rate has been calculated.

NMF-Corr and NMF algorithms were run with the random initial matrices W and H. For NMF-Corr, we set stopping criteria at most 1000 iterations and relative tolerance 10^{-4}. PCA, NMF and NMF-Corr basis images has been shown in Figure 5, respectively.

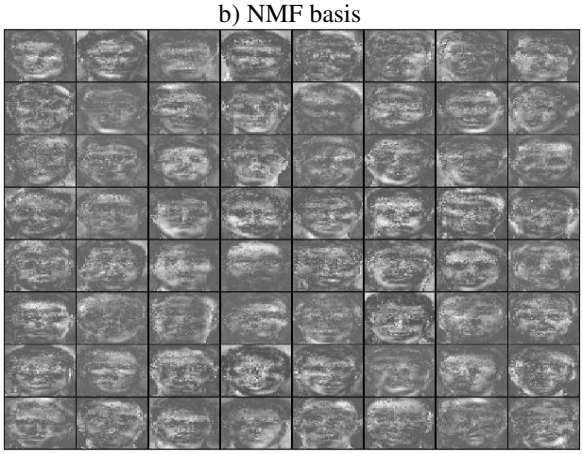
Figure 4 Randomly located occluded face samples from ORL face dataset with 10%, 20%, 30%, 40% and 50% patch sizes (From left to right).



a) PCA basis



b) NMF basis



c) NMF-Corr basis

Figure 5. Basis images of PCA, NMF and NMF-Corr for 64 grids.

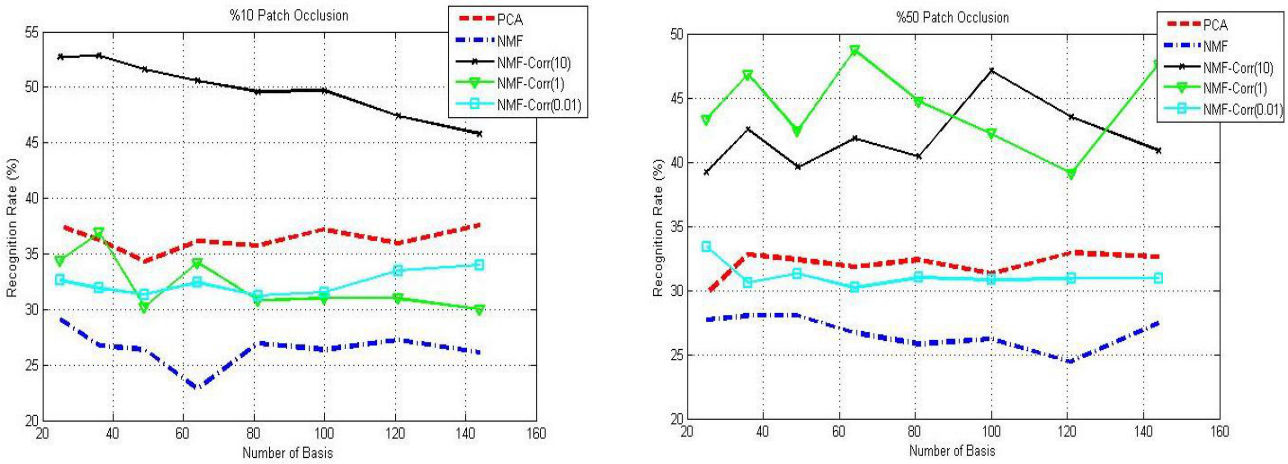


Figure 6. Recognition rates (%) versus number of basis images for 10% and 50% patch occlusions (On the legend, values in paranthesis indicate the corresponding σ parameter for NMF-Corr).

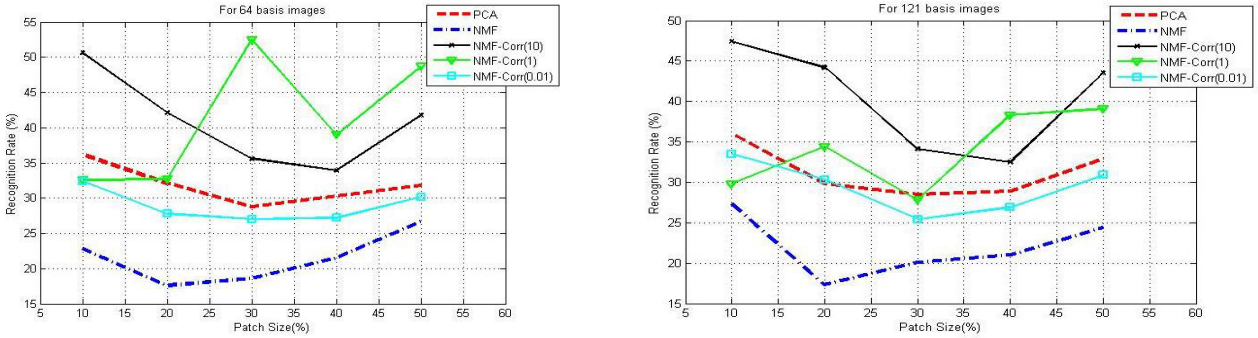

Figure 7. Recognition rates (%) versus patch sizes (%) of face images for 64 and 121 basis images.

For brevity we only illustrate for 10% and 50% occlusions in Figure 6, for different number of basis images. It can be easily seen that NMF-Corr with $\sigma = 10$ demonstrates superior recognition performance than NMF and PCA. Therefore, NMF-Corr with $\sigma = 10$ has the best accuracy. (In the case of 50% patch occlusion, generally $\sigma = 1$ has better accuracy than $\sigma = 10$). Recognition rate plots versus patch occlusion sizes have been also calculated for 25, 36, 49, 64, 81, 100, 121 and 144. Again, we only demonstrate for 64 and 121 basis in Figure 7 for brevity. Here, NMF-Corr has the best recognition rate for all patch sizes. Additionally, it can be seen from Figure 7, the graphic lines are u-shaped, because training and testing parts have been done with occluded face images.

V. CONCLUSION

In this contribution we have first introduced the topic of nonnegative matrix factorization and reviewed its major applications and implementations. The NMF factorizes a given data matrix into a product of two matrices that contain nonnegative elements only. Subtraction is forbidden which enhances sparsity of the patterns that are found in the data. This leads to a better interpretability of the factorization.

The usefulness of nonnegative factorizations was demonstrated using two real-life tasks: document clustering and occluded face recognition. Moreover the demonstrations used correntropy, a novel similarity measure that enhances the robustness to outliers. Experiments on both datasets have shown that using the correntropy criterion has led to better cluster purity and recognition rates than NMF and PCA.

8th International Symposium
Advances in Artificial Intelligence and Applications

THE AAIA'13 will bring researchers, developers, practitioners, and users to present their latest research, results, and ideas in all areas of artificial intelligence. We hope that theory and successful applications presented at the AAIA'13 will be of interest to researchers and practitioners who want to know about both theoretical advances and latest applied developments in Artificial Intelligence. As such AAIA'13 will provide a forum for the exchange of ideas between theoreticians and practitioners to address the important issues.

Papers related to theories, methodologies, and applications in science and technology in this theme are especially solicited. Topics covering industrial issues/applications and academic research are included, but not limited to:

-
- Knowledge Management
- Decision Support Systems
- Approximate Reasoning
- Fuzzy Modeling and Control
- Data Mining
- Web Mining
- Machine Learning
- Combining Multiple Knowledge Sources in an Integrated Intelligent System
- Neural Networks
- Evolutionary Computation
- Nature Inspired Methods
- Natural Language Processing
- Image Processing and Interpreting
- Applications in Bioinformatics
- Hybrid Intelligent Systems
- Granular Computing
- Architectures of Intelligent Systems
- Robotics
- Real-world Applications of Intelligent Systems
- Rough Sets

***Abstract*—This paper presents an approach for underdetermined blind source separation that can be applied even if the number of sources is unknown. Moreover, the proposed approach is applicable in the case of separating I+3 sources from I mixtures without additive noise. This situation is more challenging and suitable to practical real world problems. Also, the sparsity conditions are not imposed unlike to those employed by some conventional approaches. Firstly, the number of source signals are estimated followed by the estimation of the mixing matrix based on the use of short time Fourier transform and rough-fuzzy clustering. Then, source signals are normalized and recovered using modified Lin's projected gradient algorithm with modified Armijo rule. The simulation results show that the proposed approach can separate I+3 source signals from I mixed signals, and it has superior evaluation performance compared to conventional approaches.**

***Keywords*—Underdetermined Blind Source Separation; Rough Fuzzy clustering; Short Time Fourier transform; Lin's Projected Gradient; Armijo rule**

I. Introduction

BLIND Signal Separation (or Blind Source Separation, BSS) has received a great deal of attention in the fields of digital communication systems, speech processing, medical imaging, water marking, biomedical engineering, and data mining [3]-[7] in recent years in combination with artificial neural networks, information theory, and computer science applications. Blindness or blind separation means that no or very little information is known about the source signals or the mixing system [1].

The objective of BSS is to extract original source signals using only the information gathered from observed signals with no or very limited knowledge about the source signals or the mixing system. The approaches developed by researchers in the last few years can be classified into two methodologies, namely over-determined BSS and underdetermined BSS, according to the number of source signals and observable mixed signals [20]. BSS that has fewer sensors or observable mixed signals than source signals is called underdetermined BSS while a BSS that has more sensors than sources is called over-determined BSS, Underdetermined BSS is challenging and is more realistic in practical situations. However, most approaches for BSS rarely involve underdetermined BSS cases. The classical independent component analysis (ICA) approach fails to solve underdetermined BSS problems [10]. Moreover in many practical problems, there are a large number of source signals but a few numbers of sensors that means the underdetermined case. Another major difficulty of ICA is that the mixing matrix and the magnitude of original source signals cannot be estimated due to its ambiguities and that the order, sign, and the variances of the independent components cannot be determined [2].

Most of the current traditional BSS methods assume that the source signals are as statistically independent as possible given the observed data and that the mixing matrix is of full column rank. In many real-world situations, however, this hypothesis is not valid. Consequently, recovering the source signals by multiplying the observable data mixtures by the pseudo inverse of the mixing matrix cannot be used. This makes recovering the source signals a very challenging task [8]. In practical terms, the over-determined mixture assumption does not always hold (e.g., in radio communications the probability of receiving more sources than sensors increases with increase of reception bandwidth), thus it is necessary to solve the problem of underdetermined blind source separation (UBSS) [9].

Nonnegative Matrix Factorization (NMF) has been widely applied to BSS problems. However, the separation results are sensitive to the initialization of parameters, also the additive parts by NMF are not necessarily localized, and consequently the solution is not unique. Avoiding the subjectivity of choosing parameters, we use general matrix factorization (GMF), which completely relaxes the non-negativity constraints from its factors with the Alternative Least Squares (ALS) method as an initialization to the

Email. ossama_alshabrawy87@yahoo.com

source signals instead of random initial values. GMF is a generalization of the well-known NMF where the NMF is constrained by non-negativity on all its factors, is not necessarily localize, has low convergence and, does not provide a unique solution in some cases without additive constraints and parameters. However, GMF has no constraints of non-negativity and is fast convergent with the ALS method used for initialization and improvement.

The motivation of this research is to separate sparse, and super and sub-Gaussian signals in the underdetermined case with an unknown number of source signals without resorting to any sparsity conditions, and to increase the performance of the separation.

The rest of the paper is organized as follows. Section II formulates the problem. In Section III, we introduce an overview, background, and the basic concepts of Projected Gradient and GMF, alternative least square, and rough fuzzy clustering. In Section IV, we present the details of the proposed approach. In section V, we show the analysis of typical experiments and the results obtained by different BSS methods, where the simulation results show the effectiveness and high performance of the proposed algorithm. Finally, a short conclusion and future work are presented in Section 6.

II. Problem Statement

The problem considered in this paper is an underdetermined instantaneous BSS with an unknown number of source signals but without background noise, which can be mathematically formulated as follows:

Assume that for I unobservable components $X(t) = tr[X_1(t), X_2(t), ..., X_J(t)]$, where J is the number of source signals, and *X(t)* is a zero-mean vector. The available sensor vector $Y(t) = tr[Y_1(t), Y_2(t), ..., Y_I(t)]$, where I is the number of sensors and *tr* is the transpose of the vector, is given by

$$Y(t) = AX(t).$$

Here $A \in R^{I \times J}$ is a non-singular and unobservable matrix and has a non-zero determinant, and the rank of A is I. $X \in R^{J \times T}$, $Y \in R^{I \times T}$. t=0,….,T-1 are the sampling instant time points.

III. Preliminary Topics

This section provides a brief explanation of the basic technologies used in this paper including projected gradient and GMF, alternative least squares, and rough fuzzy clustering.

A. Projected Gradient and General Matrix Factorization

GMF is a generalization of NMF where there are no nonnegative constraints on all of the factors [12] and is the focus of a great deal of attention in Mathematics and Computer Science. NMF has been widely used in many areas including BSS [11], [13], [14]. However, the solution is not unique since NMF is non-convex programming, and in most algorithms it frequently converges to local optima. Unlike NMF, GMF is convergent and has good local optima avoidance when initialized with ALS. In this paper, GMF is regarded as a good tool for solving the problem of UBSS. The novelty in this paper is that GMF is to solve the UBSS problem for the first time.

The basic GMF decomposition model for BSS is as follows:

$$Y = AX \qquad (1)$$

where, $Y \in R_{\pm}^{I \times T}$ represents the observable mixtures, $A \in R_{\pm}^{I \times J}$ is the mixing matrix, and $X \in R_{\pm}^{J \times T}$ is the source signals matrix. Hence, Y, A, and X have both signs unlike NMF where Y, A, and X are non-negative. For BSS, I is the number of mixtures or sensors, T is the number of sample time points, and J is the number of sources. With only the data observable mixtures (Y) as the only known variable, the mixing matrix A and the source signals X are estimated using Equation (2).

We will use the projected gradient based update rules in GMF. These updates take the following generalized form of iterative rules [11]:

$$X^{(n+1)} = X^{(n)} - \alpha_X P_X \qquad (2)$$

$$A^{(n+1)} = A^{(n)} - \alpha_A P_A \qquad (3)$$

where P_A and P_X are the descent directions, and α_A and α_x are the learning rates, of A and X respectively.

The projected gradient algorithms for GMF are based on the alternating minimization technique which can be written in the matrix form as follows:

$$\min_{x_{ij}} Cost(Y \,||\, AX) = \frac{1}{2}||Y - AX||_F^2 \qquad (4)$$

$$\min_{a_{ij}} Cost(Y^T \,||\, X^T A^T) = \frac{1}{2}||Y^T - X^T A^T||_F^2 \qquad (5)$$

Basically, the matrix A is assumed to be full rank. Consequently, this provides the existence of a unique solution $X^* \in R^{J \times T}$. The gradient matrix for A and X is given by the following equations:

$$Grad_X(X) = \nabla_X Cost(Y \,||\, AX) = A^T(AX - Y) \qquad (6)$$

$$Grad_A(A) = \nabla_A Cost(Y^T \,||\, X^T A^T) = (AX - Y)X^T \qquad (7)$$

One of the projected gradients based approaches, and will be applied in this paper in a modified version, is Lin's projected gradient algorithm [15]. Lin's projected gradient (LPG) algorithm can be induced by the iterative formulas (2) and (3) with P_A and P_X expressed by the equations (6) and (7). Moreover, the projection on the subspace of non-negative real numbers is not considered.

B. Alternative least squares (ALS)

The minimization of cost function in equations (4) and (5) which represent the standard squared Euclidean distance can be formulated as follows:

$$\begin{aligned} Cost(Y \parallel AX) &= \frac{1}{2}\|Y - AX\|_F^2 \\ &= \frac{1}{2} tr(Y - AX)(Y - AX) \end{aligned} \tag{8}$$

where *tr* stands for the transpose of the matrix. The above cost function can be alternately minimized with respect to the two factors A and X [11]. Moreover, each time during the optimization process of one factor while keeping the other one fixed [18],[19] and finding the stationary or critical points, which are obtained by equating the gradients to zero. This corresponds to the following two minimization problems:

$$\begin{aligned} &A^{(k+1)} = \min_A \|Y - AX^{(k)}\|_F^2, \text{ and} \\ &X^{(k+1)} = \min_X \|Y^T - X^T[A^{(k+1)}]^T\|_F^2 \end{aligned} \tag{9}$$

The gradients after equating them by zero according to the Karush-Kuhn-Tucker (KKT) optimality conditions are:

$$\frac{\partial D_F(Y \parallel AX)}{\partial a_{ij}} = [-YX^T + AXX^T]_{ij} = 0,$$

$$\frac{\partial D_F(Y \parallel AX)}{\partial x_{ij}} = [-A^T Y + A^T AX]_{ij} \; \forall ij. \tag{10}$$

Consequently,

$$A = YX^T(XX^T)^{-1} \text{ and, } X = (A^T A)^{-1} A^T Y. \tag{11}$$

This method will be used as an initialization in our proposed system.

C. Rough fuzzy clustering

In fuzzy c-means (FCM) algorithm developed by Dunn in 1973, improved by Bezdek in 1981, and is the best known method for fuzzy clustering, based on optimizing objective function, the concept of traditional k-means clustering algorithm is extended which for each data point a degree of membership or membership function $\zeta_{ij} \in [0,1]$ of clusters is calculated.

$$\zeta_{ij} = \frac{1}{\sum_{j=1}^{c} \left(\frac{d_{ik}}{d_{jk}} \right)^{2/\delta - 1}} \tag{12}$$

, where δ is the degree of fuzziness.

In contrast to fuzzy clustering, in rough c-means (RCM), the concept of k-means is extended by considering each cluster as an interval or rough set Y [16]. It is characterized by the lower approximation $\underline{BY}$ and the upper approximations $\overline{BY}$ with the following properties: (i) an object or a sample y_k can be part of at most one lower approximation; (ii) if $y_k \in \underline{BY}$ of cluster X, then simultaneously $y_k \in \overline{BY}$; and (iii) if y_k is not a part of any lower approximation, then it belongs to two or more upper approximations. This permits overlaps between clusters.

A rough–fuzzy c-means algorithm which involves the integration of fuzzy and rough sets has been developed [17]. This allows incorporating the fuzzy membership value ζ_{ij} of a sample y_k to cluster center β_i. Moreover, instead of absolute individual distance d_{ik} from the centroid, the membership to the cluster center β_i is relative to the other centers $\beta_j \; \forall i \neq j$. Consequently, the robustness of the clustering will be enhanced with respect to different choices of the parameters. The centroid β_i of cluster U_i can be determined by the following equation:

$$\beta_i = \begin{cases} Z & \text{if } \overline{BU_i} - \underline{BU_i} \neq \varnothing, \; \underline{BU_i} \neq \varnothing, \\ \dfrac{\sum_{y_k \in (\overline{BU_i} - \underline{BU_i})} y_k}{|\overline{BU_i} - \underline{BU_i}|} & \text{if } \overline{BU_i} - \underline{BU_i} \neq \varnothing, \underline{BU_i} = \varnothing, \\ \dfrac{\sum_{y_k \in (\underline{BY})} y_k}{|\underline{BU_i}|} & \text{otherwise}. \end{cases} \tag{13}$$

where,

$$Z = W_{upper} \frac{\sum_{y_k \in (\overline{BU_i} - \underline{BU_i})} y_k}{|\overline{BU_i} - \underline{BU_i}|} + W_{lower} \frac{\sum_{y_k \in (\underline{BU_i})} y_k}{|\underline{BU_i}|}$$

The algorithm of rough fuzzy c-means is stated below in Algorithm 1.

Algorithm 1 Rough fuzzy c-means clustering

Step1: Assign initial means β_i for c clusters.

Step 2: Compute the fuzzy membership ζ_{ij} for c clusters and N data objects according to equation (12) and Normalize the distances used for fuzzy membership in [0,1].

Step 3: Assign each data object y_k to the lower or upper approximation of cluster pair U_i and U_j.

Step 4: Compute the difference $\zeta_{ik} - \zeta_{jk}$ to cluster centroids β_i and β_j

Step 5: Let ζ_{ik} be maximum and ζ_{jk} be the next to maximum

Step 6: If $abs(\zeta_{ik} - \zeta_{jk})$ is less than some *threshold*

Then,

$y_k \in \overline{BU_i}$ and $y_k \in \overline{BU_i}$ and y_k cannot be a member of any lower approximation,

Else,

$y_k \in \underline{BU_i}$ such that the membership ζ_{ik} is the maximum over c clusters
Step 7: Compute the new centroid for each cluster using equation (13)
Step 8: Repeat Steps 2–7 until convergence or until there are no new assignments.

IV. Proposed UBSS Algorithm

In this section, the proposed approach is presented briefly starting with estimating the mixing matrix knowing only the observable mixtures matrix. Also, a method for GMF gradient-based update rules initialized with ALS is introduced.

A. Mixing matrix estimation based on short time Fourier transform and rough fuzzy clustering

Conventional algorithms estimate the mixing matrix based on clustering algorithms such as the k-means algorithm require that the source signals to be very sparse in the time domain and this is unavailable in many practical real world problems. Other algorithms are based on an assumption that there exist many TF points of single source occupancy (SSO), or require that there exists at least one small region in the TF plain with only a single source and such a TF region must exist for each source. All aforementioned approaches require that for each source there exist many TF points of SSO. However, single source detection (SSD) requires that there exists at least one TF point of SSO and is hence less restrictive than the other approaches [20].

The short time Fourier transform (STFT) of the i^{th} observed signal is defined by the following equation:

$$Y_i^{Fourier}(t,r) = \sum_{l=0}^{\infty} h(l-t) X_i(l) e^{-jrl} \qquad (14)$$

at frame t and frequency bin r where $h(l)$ is a window sequence. In equation (14), $i=1,2,...,I$; $t=0,1,...,T-1$ are the sampling points over the time domain and $r=0,1,...,T-1$ are the sampling points over the frequency domain. The SSD is based on the ratio of the TF transforms and finds a set of TF points where a single source is active for each source. Therefore, for a given $\varepsilon > 0$, a set

$$\chi_F = \left\{ (t,r) \mid \| \mathrm{Im}\left[\frac{Y^S(t,r)}{Y_1^S(t,r)} \right] \|_F < \varepsilon,\ Y_1^S(t,r) \neq 0 \right\} \qquad (15)$$

where, Im[ ] denotes the imaginary part. We can choose any of the mixture instead of Y_1.

During clustering the observable mixtures after incorporating STFT, we need to determine the number of source signals. Since there is an overlap between the data objects, estimating the number of sources require an efficient validity index [21] and can be given by the following equation:

$$V(\beta, c) = Scat(c) + \frac{Sep(c)}{Sep(C_{\max})} \qquad (16)$$

where, β is the cluster centers, c is the number of clusters, and C_{max} is the chosen maximum number of clusters. Here,

$$Scat(c) = \frac{\frac{1}{c}\sum_{i=1}^{c} \| \sigma(\beta_i) \|}{\| \sigma(Y) \|} \qquad (17)$$

Also, the value of *Scat(c)* varies from 0 to 1. The term that represents the separation between clusters is defined by

$$sep(c) = \frac{D_{\max}^2}{D_{\min}^2} \sum_{i=1}^{c} \left(\sum_{j=1}^{c} \| \beta_i - \beta_j \|^2 \right)^{-1} \qquad (18)$$

where,

$D_{\min} = \min_{i \neq j} \| \beta_i - \beta_j \|, D_{\max} = \max_{i,j} \| \beta_i - \beta_j \|$

After clustering, and determining the number of source signals, the ith column vector of A, denoted as $\hat{a}_i$, is estimated as

$$\hat{a}_i = \frac{1}{|\chi_{C_i}|} \sum_{(t,r) \in \chi_{C_i}} \mathrm{Re}[Y^F(t,r)]. \qquad (19)$$

Here $|\chi_{C_i}|$ represents the number of TF points in cluster C_i for $i=1,2,...,J$.

Algorithm 2 Mixing matrix estimation and determining the number of source signals

Input: the observable mixtures $Y = [Y_1, Y_2, \ldots\ldots, Y_I]$
Output: number of source signals, the mixing matrix A

Step1: Calculate STFT Y using equations (14)
Step 2: Calculate χ_F using equation (15)
Step 3: Cluster χ_S using rough fuzzy c-means clustering stated in Algorithm 1 for different number of clusters by choosing C_{min}, C_{max} (i.e. min and max chosen number of clusters, respectively) using equations (16)-(18) and the cluster number that minimizes V is considered to be the optimal value for number of source signals.
Step 4: Determine the TF points and their quantity in each cluster.
Step 5: Calculate the columns of the mixing matrix A using equation (19)

B. Lin's Projected Gradient (LPG) with Armijo rule based GMF

In Lin's projected gradient algorithm the learning rates α_A and α_x are not fixed diagonal matrices in the inner iterations but are scalars. These learning rates are computing by inexact estimation techniques. Lin considered two options to estimate the learning rates. The first option is the Armijo rule along the projective arc of the algorithm proposed by Bertsekas [23]. The value of the learning rate α_x, for every iterative step of the algorithm, is given by:

$$\alpha_x^{(k)} = \rho^{m_k}, \qquad (20)$$

where m^k is the first non-negative integer m for which

$$Cost(Y \| AX^{(k+1)}) - Cost(Y \| AX^{(k)}) \leq \upsilon tr\left\{ \nabla_X Cost(Y \| AX^{(k)})^T \left(X^{(k+1)} - X^{(k)} \right) \right\} \qquad (21)$$

with $\rho \in (0,1) and\ \upsilon \in (0,1)$. The value of the learning rate α_A is computed in a similar way.

The second option is the modified Armijo rule. Lin and More [24] noticed that α_A and α_x might be very similar, and they proposed to start from $\alpha_x^{(k-1)}$ and to increase or decrease the learning rate according to condition (20). Here in this paper LPG algorithm with Armijo rule is extended, different from [11], for general matrix factorization relaxing the non-negativity constraints. Moreover the value of ρ and υ are changed to be $\rho \in (-1,1) and\ \upsilon \in (-1,1)$. The algorithm of the modified LPG algorithm with Armijo rule is listed below in Algorithm 3.

Algorithm 3 Modified LPG based GMF

Input: the observable mixtures Y= [Y1, Y2,……..,Yt], number of components (source signals) J, Maximum number of iterations N, the mixing matrix A estimated from algorithm 2

Output: the estimated source signals X

Step 1: Initialize the matrix X by ALS according to equation (11)

Step 2: set α_x =1

Step 3: Assign $X^{(n+1)} = X^{(n)} - \alpha_X P_X$

Step 4: Repeat 4-10 until the stopping criteria is met

Step 5: If condition in (21) is met, then

Step 6: Repeat steps 5,6 until condition (21) does not hold

Step 7: Assign $\alpha_x = \frac{\alpha_x}{\rho}$

Step 8: Update $X^{(n+1)} = X^{(n)} - \alpha_X P_X$

Step 9: Else

Repeat steps 8,9 until condition (21) is met

Step 10: Set $\alpha_x = \alpha_x \rho$

Step 11: Update $X^{(n+1)} = X^{(n)} - \alpha_X P_X$

The source signals are then rescaled and normalized

V. Experiments and Simulation

In this section, the effectiveness of the proposed approach will be discussed by comparing results of experiments and stimulations. Experiments and simulations were performed on synthetically generated signals using the proposed approach and other conventional approaches. In the simulations, sparse, super- and sub-Gaussian signals were separated from the underdetermined mixtures in the challenging case where the true number of source signals is unknown.

The parameter inputs of the modified LPG algorithm are the observable mixtures matrix Y, and the mixing matrix A obtained from algorithm 2. We choose the maximum number of iterations to be only 25 iterations. We investigate the performance of the proposed UBSS approach in the above mentioned cases by comparing its results with the results of approaches in Khor (2006) [22], Kim and Yoo (2009) [20], Xiang and Peng (2010) [8]. Here, the simulation of the separation of sparse and Gaussian signals is provided followed by some discussion. Then, the cases of a variety of sparse, non-sparse, and super- and sub-Gaussian signals are stated.

A. Sparse and Gaussian signals

The separation of J synthetic Gaussian and sparse signals from I=3 mixtures was performed in the time domain for J=4, 5, and 6 source signals. In this simulation, the mixing matrix was estimated using algorithm 2. The proposed approach was compared to the abovementioned algorithms. The simulation settings were as follows. Synthetic sparse signals were generated by generating 5000 Gaussian samples using the *randn* command of Matlab and substituting 80% of the samples chosen randomly by zeros for each source. The results show that the proposed approach can separate I+3 source signals from I mixtures, unlike the previous approaches. This is confirmed in the next simulations. The analysis aims at comparing mainly the reconstruction index Signal-to-Interference Ratio (SIR) to evaluate the performance of the proposed approach. Given original source signals X and its estimations $\hat{X}$ obtained by the proposed approach, SIR in decibels is defined as

$$SIR = -10\log\left(\frac{\| \hat{X}_i - X_i \|_F^2}{\| X_i \|_F^2}\right), \quad i = 1,2,....,J \qquad (15)$$

Fig. 1 illustrates the averaged SIRs when the number of the sources increases from 4 to 6 signals.

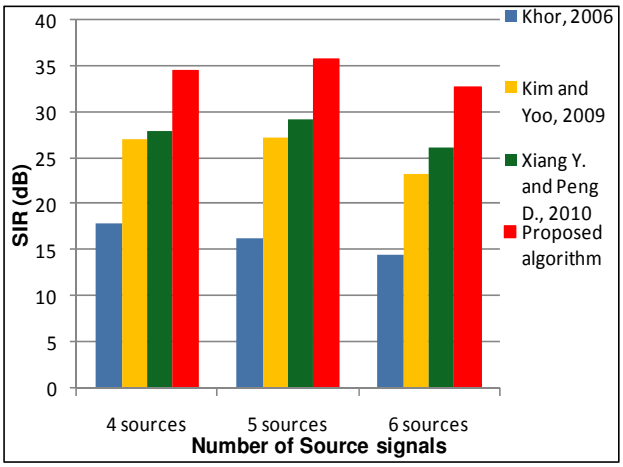

Fig. 1. performance estimation of the source signals according to the number of sources from 3 observable mixtures (in case of Sparse and Gaussian sources).

B. Synthetic signals

We investigated the effectiveness of the proposed UBSS approach by comparing with the methods mentioned above. We chose the number of mixtures to be only 2 and the number of sources to be 5 in order to prove that the proposed algorithm can separate I+3 source signals from I mixtures. The mixture signals that we perform our experiments on are mixed by the following randomly generated mixing matrix:

$$\begin{bmatrix} 0.5377 & -2.2588 & 0.3188 & -0.4336 & 3.5784 \\ 1.8339 & 0.8622 & -1.3077 & 0.3426 & 2.7694 \end{bmatrix}$$

The mixing matrix was once again estimated using algorithm 2. The true and estimated values of A are shown in Table 1. The six source signals, two observable mixtures, and estimated source signals are plotted in Fig. 2. The number of sampling time points is 10,000. The simulation results of the proposed approach in addition to those of the five different UBSS methods are shown in Fig.4. The performance of the source recovery method can be evaluated by Eqs. (15) and (16).

$$SNR = \frac{1}{J}\sum_i 10\log\left(\frac{\| X_i \|_F^2}{\| \hat{X}_i - X_i \|_F^2}\right) \qquad (16)$$

Where J is the number of sources and $\|.\|_F^2$ is the Frobenius norm. The efficiency of the separation results is good when $SNR \geq 25$ [10].

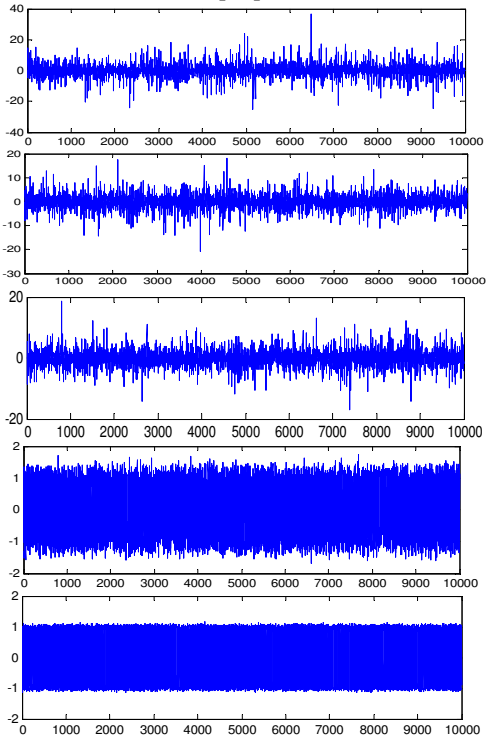

Fig. 2. (a) Source signals

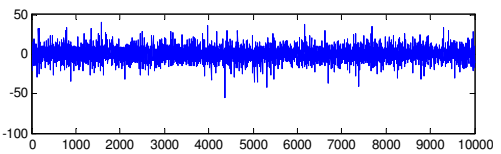

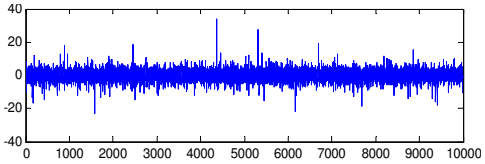

Fig. 2. (b) Observable mixtures

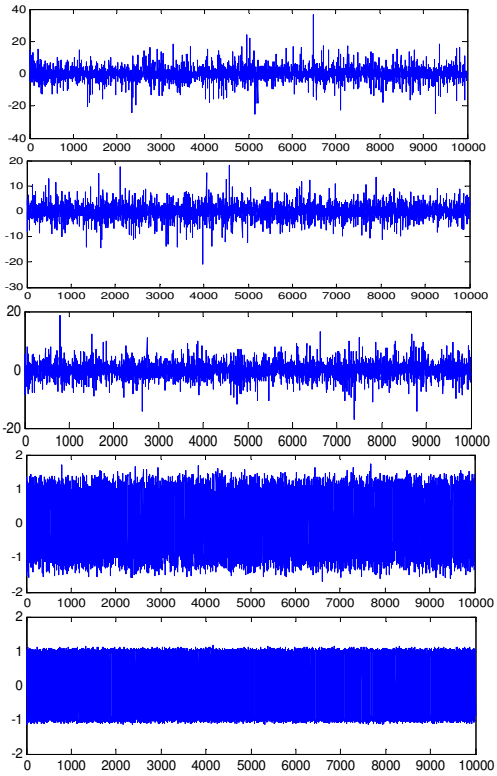

Fig. 2. (c) Estimated source signals

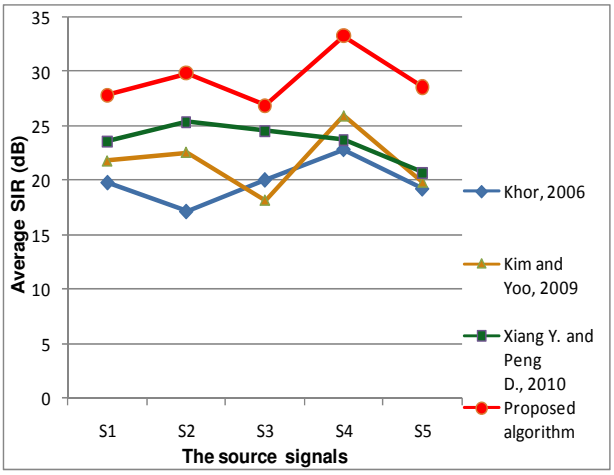

Fig. 3. Performance estimation of the source signals from 2 observable mixtures.

We note from Fig. 3 that the proposed approach achieves about 5.7 dB higher SIR for J=5 sources with only two mixtures than the highest performance algorithm among the other three approaches. Another comparison of the proposed approach with the other five approaches is presented using

the following examples with 2 observable mixtures where X_i is the chosen source signal shown in Fig. 4.

Example 1. $X=\{X_1, X_2, X_5\}$

Example2. $X=\{X_1, X_2, X_3, X_5\}$

Example 3. $X=\{X_1, X_2, X_3, X_4, X_5\}$

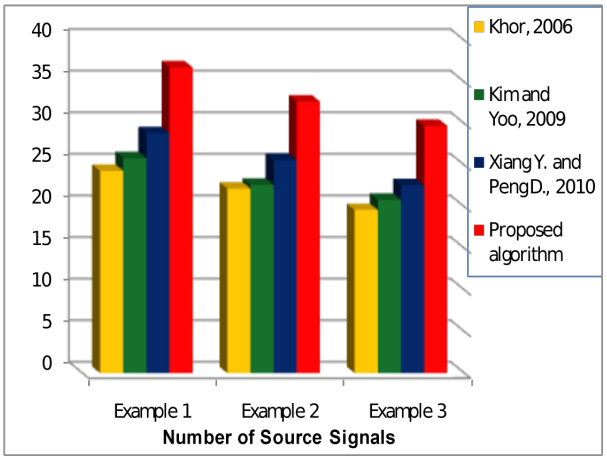

Fig. 4. Performance estimation of Examples 1–3 from 2 observable mixtures.

From the results in Figs. 3and 4, we can conclude that the separation performance of the proposed approach is very high, has faster convergence, and can separate I+3 source signals from I mixed signals.

II. Conclusion

In this paper, we addressed the problem of underdetermined blind source separation with the challenging case that the true number of source signals is unknown. A new two-step approach for optimum estimation of the source signals without additive noise. In this approach, STFT is combined with rough fuzzy c-means clustering to estimate the mixing matrix and determine the number of source signals. Then the source signals are estimated by a modified LPG algorithm with Armijo rule based general matrix factorization. Simulation experiments demonstrated the validity and superior performance of the proposed approach.

***Abstract*—The Multiple Pheromone Ant Clustering Algorithm (MPACA) models the collective behaviour of ants to find clusters in data and to assign objects to the most appropriate class. It is an ant colony optimisation approach that uses pheromones to mark paths linking objects that are similar and potentially members of the same cluster or class. Its novelty is in the way it uses separate pheromones for each descriptive attribute of the object rather than a single pheromone representing the whole object. Ants that encounter other ants frequently enough can combine the attribute values they are detecting, which enables the MPACA to learn influential variable interactions. This paper applies the model to real-world data from two domains. One is logistics, focusing on resource allocation rather than the more traditional vehicle-routing problem. The other is mental-health risk assessment. The task for the MPACA in each domain was to predict class membership where the classes for the logistics domain were the levels of demand on haulage company resources and the mental-health classes were levels of suicide risk. Results on these noisy real-world data were promising, demonstrating the ability of the MPACA to find patterns in the data with accuracy comparable to more traditional linear regression models.**

I. Introduction

CLUSTERING is the task of partitioning data sets into categories of common likeness. It can be a complex problem to unravel because the boundaries between classes are often ambiguous and non-linear. If the data set has high dimensionality, it can be extremely difficult to understand the inherent structure and exploit it with an appropriate clustering algorithm. This has led to a large variety of approaches seeking to optimise cluster analysis, including ones modelled on insect behaviour.

This paper investigates how computer models of ants can help humans sort data into meaningful classes using cluster analysis. A brief review of relevant ant models is provided before explaining how the MPACA works. The main aim of the paper is to show how it can provide meaningful results with real-world data and examples from transport logistics and health are used. The paper concludes with a discussion of the model, its effectiveness, and how it can be applied to additional data sets.

II. Background

Swarm intelligence (SI) is the phenomenon whereby intelligent behaviour emerges from the interactions of numerous separate entities with low-level cognitive capacities [1], [4], [5], [6]. There are many examples in the insect world but the focus of this paper is on ants and specifically ant colony optimisation (ACO). Two ant behaviours have fuelled many of the computer models, one for sorting larvae or corposes and the other foraging for food. The so-called Basic Model (BM) [8] comes from the sorting of ant bodies into piles and is often referenced as the Standard Ant Clustering Algorithm (SACA). It works by assessing the similarity of bodies with others in the same location. In contrast, ant foraging depends on laying down pheromone trails that guide other ants towards objects in which they are interested. It is used to optimise paths between objects, either to link similar ones or to find the shortest paths. The MPACA is based on this type of ACO algorithm.

Using scents or pheromone to form paths is a form of stigmergy, where information is placed in the environment for communication purposes [7], [24]. Shorter paths have ants returning to them more quickly and the pheromone is less affected by evaporation. Together, these phenomena attract ants to locations containing objects with similar attributes and are the driving forces for cluster formation. For the MPACA model applied to real-world domains in this paper, objects are placed within a multidimensional graph space, as others have done [20], [26]. Its main innovation is by having multiple pheromones that distinguish ants within colonies rather than more normally between them [10]. The next section summarises the latest version of the MPACA, which was introduced as a clustering algorithm in [41] and applied to some standard data sets. The goal of this paper is to show how the MPACA can be used to learn class assignations and be applied to noisy, diverse real-world data in the domains of mental-health risk assessment and predicting resource requirements for logistics companies.

III. Overview of the MPACA

The Multiple Pheromone Ant Clustering Algorithm, MPACA, is not unique by having many different pheromones laid down on trails for objects. However, no previous models attach a specific pheromone to each particular value of every descriptive attribute of an object. Pheromones encourage other ants to follow them via a scent. In the MPACA model, each pheromone type indicates paths towards a specific feature value in the given search space. It is applicable to multiple dimensions and can accommodate both discrete and continu-

978-83-60810-53-8/$25.00

ous data of any type. Ordinal dimensions are used to set up the hyperdimensional problem space but are first normalised to help prevent bias due to types of distributions. The values are measured in the number of standard deviations (SD) from the mean, z, where

$$z = \frac{(x - \mu)}{SD}, \tag{1}$$

x, is the original value and μ, is the mean.

The values of each object along the dimensions of the hyperdimensional space determine its location in the graph and objects are linked by edges to all other objects if the Euclidean distance is within a parameterised maximum. Non-ordinal features are not part of the hyperdimensional space but still participate in learning by having ants leave pheromone traces along the edges corresponding to these features and their particular values. Ants are then placed on every object, with each ant assigned to one attribute and responding to the particular value the object has for that attribute. The ant's own attribute value becomes the distinctive pheromone it deposits, which it lays whenever leaving an object with a matching value and which it follows if laid by another ant. The upshot is that there will be as many pheromones in the domain as there are distinct attribute values, including nominal features and ordinal dimensions.

Learning takes place by ants following trails matching their own feature value and depositing pheromone from objects if they also have that value. Paths from an object are chosen stochastically based on the amount of matching pheromone compared to the alternatives. The resulting stigmergy means objects with similar feature values will have higher levels of pheromone connecting them because ants will be depositing in both directions along the path compared to ants travelling along edges with different values at each end. Also, the evaporation of pheromone means longer paths tend to have lower levels of pheromone.

The MPACA has a mechanism for ants to learn feature combinations or interactions that might be important for cluster analysis and classification. Pheromone trails for different feature values can draw ants into the same locations if they regularly co-occur with the same objects. If the encounters between the ants exceed a parameterised threshold, the ants will combine each other's features which means they will now only respond to objects having both features. It enables ants to detect feature combinations and thus to pick up non-linear interactions.

Merging colonies is similarly driven by the frequency of ant encounters. Both feature and colony merges are operationalised by recording ant meetings. These take place when an ant, which we will call the "focus" ant for referential clarity, has reached an object and only if its feature set matches that of the object because this means it is in an area of interest to it. The "encounters" data structure of the focus ant is updated at this point by finding all other ants within the vicinity that are also in an area of interest to them, which is the case if they are in deposit mode on a path away from the object that has the focus ant on it or are coming towards the object. If the number of encounters for the focus ant go above a threshold for colony or feature merging (they have different thresholds), then the focus ant updates its feature and colony properties accordingly. The thresholds have to be exceeded within a certain time span. The time span is measured in the number of steps, where each cycle of the system moves an ant one step along an edge and encounters recorded on a step that goes outside the time window are removed.

A. MPACA parameters

Although the general idea and philosophy of the MPACA has been described, much of the detail resides with how it is parameterised. This will be summarised here so that the actual values used when applying the model to the data can be understood.

- **Edges joining objects** Only ordinal dimensions are used to set up the hyperdimensional problem space. They are normalised as already explained by Equation 1. This gives the same units to all dimensions in the hyperdimensional space and object values are likewise normalised so that they can be placed in their appropriate location in the space. The resulting graph, G, has a vertex, v, for every object and all objects are connected to other objects by an edge, e, but only if is is within a distance parameter, d: relationships between objects further apart are therefore ignored.
- **Step size** The granularity for measuring differences between objects depends on how small the steps are along the edges. The assumption was made that plus or minus 2 SDs from the mean covers most population values on that dimension except the outliers. A step size of 0.1 SDs gives 40 steps along each dimension, which is enough for meaningful distinctions between objects.
- **Pheromone deposition, evaporation, and path choice** Pheromone is laid by ants when they leave an object with matching values and the same parameterised amount, ph, is laid for all ants and all features. A percentage is removed from paths by evaporation on each step and a maximum amount, $ph.max$, prevents paths increasing levels of pheromone indefinitely, which would overwhelm the influence of other paths.
  A residual parameter r, determines the percentage of total matching pheromone on all edges that is placed on each of them by default. It adds uncertainty by allowing ants to go down paths with little or no scent and explore new areas. Given N potential paths from a vertex with pheromone scent s on the first step of each path, where s is the pheromone matching the features of the ant, the probability of selecting a particular path, p, is given by
  $$P(p) = \frac{(s+r)}{\sum_{i=1}^{N} s_i + (r \times N)}.$$
- **Detection range for continuous dimensions** Ants responding to a dimension of an object (e.g. length) are given a range around the exact value of their "home"

object (the one they are placed on at the start and that defines their feature value). They respond to any value within this range, which is based on the step size for the dimension.

- **Ant complement**
  The ant complement, ac, determines how many ants are placed on each feature of an object at the start. It defines the population size and influences sensitivity of cluster analysis by increasing encounters between ants. Greater computational load is an inevitable consequence and the balance will depend on the density of objects and dimensionality of space.
- **Merging thresholds**
  The colony threshold, ct, determines when the population density of ants is high enough to trigger the ant joining a colony. The feature threshold, ft, is linked to the number of times a particular feature has been seen in other ants. Both are driven by ant encounters. On each encounter, the ant records the following information of the other ant: the ant identifier (id), the colony id, the carried feature id, the timestep, and a boolean flag holding the deposit mode of the encountered ant at that time stamp. This is put into the*AntSeenRecord*, within the *AntSeenList*. The size of the list structure is kept in check by the time stamp which is placed on it. On exceeding the time-window parameter, this encounter is removed.
- **Time-window**
  The time window, tw, defines the maximum number of steps that can be remembered for ant encounters. It helps prevent over-fitting and enables the ACO model to learn new patterns over time if the domain structure changes.
- **Visibility** The number of steps within which an ant encounter is counted. Any ant within this distance of the ant whose encounters are being calculated (the focus ant in the earlier description) becomes eligible for being recorded as an encounter.

B. Ant movement

Ants move one step at a time and each movement is recorded as one timestep for the whole system. The path or edge to follow is chosen as a probabilistic function of the strength of matching pheromone on the first step of each edge leading from the vertex: the higher the strength, the more likely the path will be chosen, which distinguishes it from [7]. This mechanism does not require any foresight about the potential vertices that can be visited, and has the single restriction that ants cannot go back along an edge they have just traversed.

C. The MPACA Algorithm

Require: Graph space with connecting edges and ants assigned to each feature.
while ($Termination\ not\ met$) **do**
  for ($Each\ ant\ in\ antlist$) **do**
    Increment $StepNumber$ against all encounters in AntSeenList by one
    if ($StepNumber > threshold$) **then**
      Remove encounter from AntSeenList
    end if
    if ($Ant\ at\ vertex$) **then**
      Update $AntSeenList$ counts;
      if ($Ant\ features\ match\ object$) **then**
        Activate pheromone deposition mode;
        Process $AntSeenList$ for colony and feature merging
      else
        Deactivate pheromone deposition mode;
      end if
      Choose next edge stochastically taking pheromone values into account;
    end if
    $EdgeTraversal \leftarrow EdgeTraversal - 1$;
    if ($Ant\ in\ deposition\ mode$) **then**
      deposit pheromone for each feature;
    end if
  end for
  if ($Stopping\ criterion\ reached$) **then**
    Output cluster definitions;
  else
    Perform system wide evaporation;
  end if
end while

In the MPACA, each step of the ants is a single time interval so edges which are n steps long will take n timesteps to traverse. The MPACA terminates when ants reach a stable dynamic equilibrium in the colonies they form. This is indicated by a consistent number of colonies and a stable population number in each one.

IV. Evaluation and results

The main aim of this paper is to determine the potential of the MPACA for analysing diverse real-world data sets. Two example domains have been chosen, mental-health risk assessment and hub-and-spoke logistics. The domains have extremely high dimensions (over 200 for the mental-health one) and extremely high numbers of cases (many millions for the logistics domain). These present serious challenges for the tractability of the MPACA but the rewards are high. If the MPACA can form accurate clusters, these will have ant populations that represent a detailed analysis of the relative importance of features and feature combinations required for cluster membership.

In each domain, one of the authors is creating a cognitive model of decision making based on human expertise [42], [43] [44]. The aim is to use it within an Intelligent Knowledge-Based System that helps end users optimise their decisions based on the input information and by exploiting mathematical analysis of the underlying database. The MPACA can provide a useful alternative method that analyses the ant population demographics in each colony to form rules about class membership that can complement the cognitive model. The Ant-Miner algorithm [27] and its derivatives have shown how this approach can work and provide data representations that are

more comprehensible to users. The main loop of the Ant-Miner algorithm consists of three key steps: rule construction, rule pruning, and pheromone updating. Results show that Ant-Miner has good classification performance on test data sets and the ability to constrain the number of rules required [27], [28]. The MPACA rules would be constructed from a detailed understanding of how ant features and their combinations differ within the learned classes.

A. Application of the MPACA to hub-and-spoke logistics networks

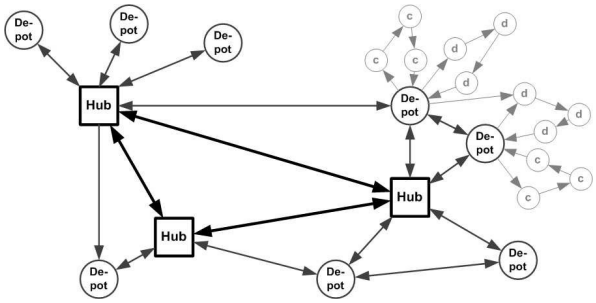

Fig. 1. Transportation in a multiple hub-and-spoke logistics system.

Hub-and-spoke logistics networks have a standard modus operandus [45]. They consist of a number of haulage depots which collect and deliver shipments to and from one or more central hubs. Figure 1 shows a simplified diagram of these activities for a network with 3 hubs and 8 depots. In reality, the networks are much larger than this, with over 100 depots feeding the main hub for the one used to evaluate the MPACA in this paper. The idea is that a depot takes its own customers' shipments to the hub and brings back shipments from any of the other depots that require delivery to the depot's assigned delivery area.

The problem depots have is predicting how many shipments will be at the hub by the end of the day that they are required to deliver. If they take too many lorries to the hub, they will have wasted space on the return trip; if they take too few, they will have to leave shipments behind with costly penalties if the network has to deploy alternative resources to deliver them. In short, if depots could be informed early in the day about the total demand (number of shipments) they will have in the day, this will help decision making to optimise their resources.

Clearly some form of automated analysis is required to enable decision makers in a hub-and-spoke model make sense of the available information [46] and companies have been investing in information technology to this effect [47]. It is a key subject of the EU FP7 co-funded project ADVANCE [48], where various machine learning approaches are being studied with regard to their appropriateness for providing reliable predictions. The MPACA will be applied to the same data to compare the performance of ACO with more traditional machine learning.

Field work conducted for ADVANCE shows that fluctuations in the numbers of shipments (pallets, in this domain) have

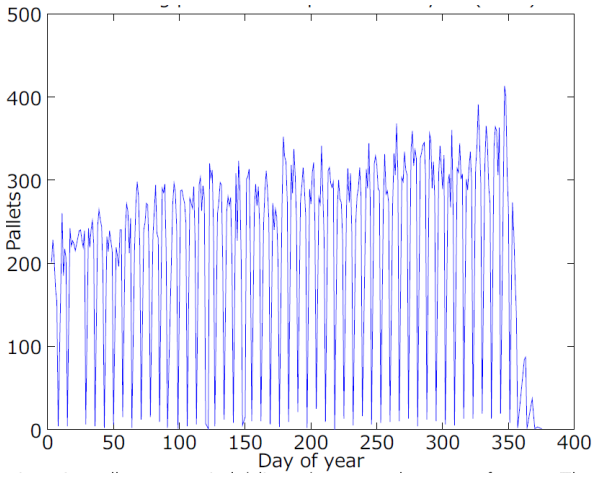

Fig. 2. Fluctuations in the number of pallets each day for a specific depot in the ADVANCE project (the regular very low troughs represent the weekends).

a deleterious impact on operational performance (Figure 2). Such peaks and troughs may appear over the whole network, where the total number of shipments passing through a hub varies widely, as well as on a local level where individual depots experience large changes in numbers from day to day even though the overall network numbers may remain stable. Interviews with depot managers revealed a desire for knowing whether they would have more than or less than the expected number of shipments on a particular day. They could then gear up for additional resources or offer to take on other depots' shipments if spare capacity was likely. To explore the potential of the MPACA in supporting hub-and-spoke decision making, the first step was to find out how well it could predict whether the demand was above or below the mean and compare this with the machine learning program chosen for ADVANCE [40].

1) Predicting shipments: The machine learning program used to compare with the MPACA consists of two main processes: select the most appropriate attributes for a depot and then learn the accompanying linear regression model for predicting the number of shipments or total demand at the end of the day [40]. The attributes used to predict demand include the known current demand (what has already been committed to the hub) and a number of other variables to do with stages of shipment orders, when they were made, and so on. These numbers obviously change as the day progresses so models were learned for separate time points. In fact, a separate regression model was learned for each depot at selected times of each day for each day of the week.

The attribute-selection process picked out 15 of the most influential variables from sixty potential ones and these were used to learn the regression model. The same ones, including the known end-of-day demand, were used by the MPACA to set up the hyperdimensional graph space. Each object (or day in this domain) was assigned to one of two classes: "above" if the known demand was above the mean and "below"

TABLE I
PARAMETER SETTINGS FOR THE MPACA. THE START VALUE IS THE ONE SET AT THE BEGINNING OF LEARNING AND THE MEAN AND STANDARD DEVIATION (SD) ARE THE AVERAGE VALUES AS THESE PARAMETERS WERE MANUALLY VARIED OVER THE 13 TRAINING CYCLES

Parameter	start	mean	SD
Max Edge Length	7	8.4	1.6
Step size	0.1	0.1	0
Phereomone evaporation	0.01	0.05	0
Pheromone deposition	100	100	0
Detection range	2	2	0
Ant complement	1	1.3	0.5
Feature merging threshold	5	5	0
Time window	55	63	8
Visibility	4	4	0

otherwise. At the start of learning, the ants were assigned to the colony matching the class of their starting object. The ants then moved around the graph according to the algorithm described earlier until they had formed population clusters,

Testing was conducted by putting the unknown objects into the hypergraph but with the known-demand dimension removed. In other words, the outcome information about these unknown objects was not included in the domain. They were assigned to the colony that had the nearest centroid (multidimensional mean), measured as the Euclidean distance from the object to that point. This provided the MPACA with the ability to predict whether the demand was going to be greater than or less than normal for the day depending on whether it was in the colony for total known demand above the mean or below the mean. The method differs from the MPACA's origins in cluster analysis [41] by exploiting known outcomes through supervised learning: the actual number of shipments required for delivery is made part of the hyperdimensional space for learning and then removed when classifying unknown cases.

2) Results: Four depots were tested at two different times of the day, 12.00 and 15.00, on a Wednesday. The mean number of shipments for the depots was around 100 (which equates to between two and three lorry loads). Thirteen separate training and testing cycles were conducted for the MPACA and the results were compared with the machine-learning regression model using precision, which is the percentage of outcomes and predictions agreeing with each other with respect to the total sample size of predictions. The sample for each depot consisted of 206 days and these were randomly divided into two equal sets for training and testing.

Table I shows the parameter settings at the beginning and end of learning, where the parameters are in the same order as described in Section III-A. Automated search was not conducted over the parameter space so these are manual settings based on estimates of the optimal initial settings. The mean and SD show that little variation was used to improve the results but this is mainly due to each cycle being set manually. It is likely that a hill-climbing parameter search would produce better results but it is computationally extremely time-consuming and requires optimising the MPACA experimental code.

TABLE II
RESULTS FOR PREDICTING WHETHER DEMAND WILL BE ABOVE OR BELOW THE AVERAGE FOR THAT DAY FOR FOUR DEPOTS AT TWO TIMES. ML GIVES THE MACHINE-LEARNING REGRESSION MODEL PREDICTION AND THE MPACA PRECISION IS ITS MEAN FOR 13 LEARNING AND TESTING CYCLES. THE FINAL STANDARD DEVIATION (SD) COLUMN GIVES THE SD OF THE MEAN ACROSS THE CYCLES.

		Precision		
Depot	**Time**	**ML**	**MPACA**	**SD**
2	12:00	79	68	0.01
3	12:00	83	68	0.01
5	12:00	60	72	0.01
7	12:00	77	74	0.01
2	15:00	74	74	0.02
3	15:00	75	79	0.01
5	15:00	52	80	0.02
7	15:00	65	78	0.00
MPACA mean		71	74	0.01

Table II compares the prediction precision of the MPACA with the machine-learning regresson program produced by ADVANCE [40]. These are preliminary results that are designed to provide an indication of the MPACA's potential for application to real-world data and clearly there are many more sophisticated ways of testing it. Nevertheless, the outcome is promising, with the MPACA having a mean precision equal to the standard regression method. The variation for which of the two models is better for a particular depot and time is probably due to using categorical outcomes where outcome demands only marginally above or below the mean are equally weighted with those having much larger deviations.

B. Mental health risk assessment

The mental-health risk-assessment data relates to the development of the Galatean Risk and Safety Tool, GRiST [49]. GRiST helps mental-health practitioners assess patients' risks of suicide, self-harm, harm to others, self-neglect, and vulnerability. It is based on the assessment knowledge of multidisciplinary practitioners working in all areas of mental health and was designed to disseminate their expertise to services where people did not have a specialist mental-health training.

The MPACA will be tested on the suicide risk data collected by GRiST. The input patient information consists of 138 individual items of information or patient cues. Each of these patient vectors has a clinical risk evaluation given to it by the assessor and the database contains more than 50,000 patient records. However, the data varies in its completeness because the circumstances of assessment often mean only some areas are of interest at any particular time. Therefore, clinical judgements are not based on full vectors, and may have less than 50 per cent of the values present. The output risk judgements are along a sliding scale from 0 (minimum risk) to 10 (maximum risk), which means there are no output classes for categorical assignment. Instead, the judgements map to fuzzy risk labels such as minimum, low, medium, high, and maximum.

The aim of analysing the GRiST suicide data is to determine whether input data can predict clinical judgements accurately.

TABLE III
PARAMETER SETTINGS FOR THE MPACA AS APPLIED TO THE GRIST DATASET. THE START VALUE IS THE ONE SET AT THE BEGINNING OF LEARNING AND THE MEAN AND STANDARD DEVIATION (SD) ARE THE AVERAGE VALUES OVER THE 49 TRAINING CYCLES

Parameter	start	mean	SD
Max Edge Length	9	9.77	0.79
Step size	0.1	0.1	0
Phereomone evaporation	0.005	0.018	0.014
Pheromone deposition	100	148.9	50.51
Detection range	1	1.39	0.49
Ant complement	1	1.45	0.51
Feature merging threshold	5	5	0
Time window	50	53	5.18
Visibility	4	4	0

If so, then the decision support system can provide advice to assessors based on the clinical consensus of the several thousand expert mental-health practitioners who provided the judgements in its database.

The most important pragmatic objective for GRiST predictions is to minimise the numbers of patients who are placed in either the high-risk category when they are low risk or placed in the low-risk category when they are high risk. To test the ability of the MPACA for doing this, two classes of patients were extracted: those with clinical judgements below 4 and those with judgements above 6 on an integer scale from 0 to 10.

Random-forest classification [50] was one of the most successful methods applied to the GRiST data. Its precision for predicting a judgement within plus or minus one of the clinician's judgement was 87%. This was based on 25 of the most important variables and where missing variables had imputed values. For testing the potential of the MPACA, the task was made considerably easier by predicting the most important errors: patients stated to be high risk when they were low or vice versa. However, it was based on a smaller sample using only 13 independent variables and there was no necessity to handle missing data.

The same learning and testing approach was used for the MPACA on the risk data as for the logistics data. A sample of 232 cases were used that were randomly split into 50% training and 50% test cases. The training objects were placed in the hyperdimensional space of 13 variables where the training cases also had the known clinical judgement given as an extra dimension. Ants were placed on each object and if the object was in one of the categories to learn, because the clinical-judgement value was below 4 or above 6, then the ants were assigned to the colony associated with that object. After completion of learning, the test cases were added to the hyperdimensional graph but with the clinical judgement dimension removed. Objects were assigned to the class that had the nearest centroid, as for the logistics domain.

Table III displays the initial parameter values for the 49 cycles of training and testing. Once again, the manual manipulation of parameters from the start value to improve classification did not alter them very much, demonstrated by the very low standard deviation across the 49 cycles. Improvements are obviously possible if automated optimisation was used but these preliminary results show the potential for the MPACA to learn risk judgements. The mean precision, where the MPACA predictions correctly placed test objects into the low clinical risk or high clinical risk categories, was 91.2% with a standard deviation of 0.01. Although this looks like a very good result, it was made easier by only trying to detect gross errors where high and low risks are confused. Attempting to predict the exact judgement between 0 and 10 would obviously be harder but enough encouragement has been given with these initial results to make it worth pursuing.

V. CONCLUSION

This paper has described a new Ant Colony Clustering model called the Multi-Pheromone Ant Clustering Algorithm, MPACA. It was introduced in [41] as a clustering method and was tested on three data sets from the Machine Learning Repository [3]: the Iris, Wine, and Wisconsin Breast Cancer data. This paper gave an overview of the latest incarnation of the MPACA including a detailed description of the algorithm and its parameters. It is unique by having a pheromone for every attribute value of the objects in the domain space. The ants are able to link similar features of objects, to combine the features they detect depending on the frequency with which they meet other ants with the same features, and to form colonies based on local ant population densities. Together, these enable ants to learn the feature profile for different clusters and for mapping colony membership onto those clusters. Where this paper differs from the earlier one is by extending the model to classification learning as well as cluster analysis. In other words, it shows how the MPACA can be adapted for supervised learning and that it should perhaps be renamed a classification/clustering algorithm. Secondly, the paper explored how useful and effective the approach might be when applied to noisy and heterogeneous real-world data sets. These create interesting problems and this paper conducts experiments that determine whether innovations of the MPACA translate into useful outcomes.

Two data sets were used, one for logistics and one for mental health. The structure, dimensionality, and classification objectives differed widely between the two sets but the results show that the MPACA can induce and utilise patterns to produce helpful classification advice. A more stringent test was given to the algorithm for the logistics domain than the mental-health one and the application to both domains could be improved. For the logistics data, having classification decisions based on such broad categories as either above or below the mean does not provide the most interesting output to end users. They need to know how large is the deviation from the mean. In fact, the most important information is whether there will be a peak or trough in demand and the MPACA could easily be adapted to test for these by redefining classes into those where the demand exceeds a given threshold value above or below the mean. This is rather like its application to the mental-health risk data where high and low risk patients were being discriminated. Of course, this leaves patients with

judgements in between these classes without a colony and it would be useful to predict their category as well.

The machine learning regression approach in each domain predicts the actual values of outputs, not just class membership, which makes it more informative. Further work on the MPACA will be on how to translate the colony memberships into a similar prediction. Even with the crude assignment mechanism used in this paper, where unknown objects were classified in the class associated with the colony having the nearest multidimensional mean (centroid), it is possible to translate the relative distances from colonies into the degree of membership in the colony. The more membership in a class above or below the mean, the higher the difference between the predicted demand and the mean.

The most productive way of immediately improving the classification output of the MPACA is by using more sophisticated assignments of unknown objects to classes after learning. Methods currently under investigation include variants of nearest-neighbour analysis where the number of ants from different colonies is calculated for all nodes within a given radius of the object to be classified. The relative proportions of colony populations can be translated into a probability of class membership using a simple Bayes equation. Alternatively, sophisticated probability density functions could be used as input to the Bayesian probability calculations.

There are many avenues requiring exploration for the MPACA model itself, both with the general mechanism and its parameterisation. At the time of writing, there are problems with merging colonies because domains with multiple clusters eventually merge into just two. Somewhere in the learning and merging process, an optimal configuration will have been achieved but it is not easy to know when; some form of dynamic equilibrium should happen and it should also be detectable so that it is clear when learning has reached an optimum end point.

Parameters are an important influence on the model's operation and more needs to be discovered about how they exert their influence so that performance can be improved. The current method is slow and cumbersome, requiring manual setting of parameters, observation of performance, and a new run with adjusted parameters in accordance with conclusions from the observations. A hill-climbing approach where parameters are systematically adjusted to reduce classification errors after learning is the obvious next step. The problem is that ACO methods are computationally expensive and time consuming, requiring careful optimisation of the MPACA code to generate the necessary execution speed.

An important guideline to remember for future research on the MPACA is to avoid chasing performance optimisation without understanding how it is being achieved. Otherwise the particular qualities of the MPACA could be lost or diluted, with improvements failing to come from the metaphor that has motivated the research in the first place.

***Abstract*—In partial approximation spaces with Pawlakian approximation pairs, three partial membership functions are generated. These fuzzy functions rely on the lower and upper approximations of a set. They provide special type of fuzziness on the universe: all of them are partial functions and derived from the observed data relatively to available knowledge about the objects of the universe. With the help of these functions, three new approximation pairs are generated and so new approximation spaces appear effectively. Using not Pawlakian approximation pairs gives a special insight into the nature of general set approximations, and so new models of necessity and possibility can be given.**

I. Introduction

SET approximations were invented by Pawlak in the early 1980's which is known as rough set theory [1], [2], [3]. Its general scheme may be outlined as follows. Let a beforehand predefined family of subsets of the universe of objects be given. It is called the base system from which definable sets may be derived. Next, so-called lower and upper approximations can be formed with the help of definable sets via beforehand fixed rules in order to approximate any sets in the universe.

The starting point of rough set theory is a nonempty *finite* set U of objects and an equivalence relation ε on U [3]. The equivalence classes are called ε-elementary sets.

Definable sets are any unions of ε-elementary sets. Any set $S \subseteq U$ can be naturally approximated by the lower and upper ε-approximations of S which are denoted by $\underline{\varepsilon}$ and $\overline{\varepsilon}$, respectively. The former is the union of all ε-elementary sets which are the subsets of S, whereas the latter is the union of all ε-elementary sets which have a nonempty intersection with S.

A number of studies deal with the relationship between rough set theory and fuzzy set theory [4], [5], [6], [7], [8]. A detailed discussion of their connections and differences can be found, e.g., in [9], [10], [11].

There are many possibilities to establish a relationship between them [12], [13], [14], [15].

Just until now it has been generally accepted that the two theories are related but distinct and complementary to each other. Recently, however, Chakraborty has proposed a common ground relying on the *classical rough membership function* [16].

The classical rough membership function quantifies the degree of the relative overlap between a set $S \subseteq U$ and an ε-elementary set [10].[1] As usual, it is defined by

$$\mu_S^{\varepsilon}(u) = \frac{|[u]_{\varepsilon} \cap S|}{|[u]_{\varepsilon}|},$$

where $|\cdot|$ is the cardinality of a set, and $[u]_{\varepsilon}$ denotes the ε-elementary set to which a $u \in U$ belongs.

Hence, we just obtain a fuzzy membership function $\mu_S^{\varepsilon} : U \to [0,1]$ with

$$\begin{aligned} \mu_S^{\varepsilon}(u) &= 1 \text{ if and only if } [u]_{\varepsilon} \subseteq S; \\ \mu_S^{\varepsilon}(u) &> 0 \text{ if and only if } [u]_{\varepsilon} \cap S \neq \emptyset; \\ \mu_S^{\varepsilon}(u) &= 0 \text{ if and only if } [u]_{\varepsilon} \cap S = \emptyset. \end{aligned}$$

Thus, the rough membership function can be seen as a fuzzyfication of rough approximation, and μ_S^{ε} is a fuzzy subset of U induced by S.

One of the main features of μ_S^{ε} is that it relies on the system of base sets, the system of equivalence classes. In other words, *rough membership functions are generated by our knowledge* (appearing, e.g., in an information system). This is a distinctive feature of rough membership functions in contrast with fuzzy membership functions [18]. Furthermore, following from the definition of μ_S^{ε}, there are many constraints on the values of rough membership functions [12], [20], [21].

An important observation is that the Pawlakian lower and upper approximation pair can be reconstructed by employing the rough membership function. The well-known formulae are the following:

$$\begin{aligned} \underline{\varepsilon}(S) &= \{u \in U \mid \mu_S^{\varepsilon}(u) = 1\}, \\ \overline{\varepsilon}(S) &= \{u \in U \mid \mu_S^{\varepsilon}(u) > 0\}. \end{aligned}$$

In the terminology of fuzzy set theory, the lower and upper approximations $\underline{\varepsilon}$ and $\overline{\varepsilon}$ are the *core* and the *support* of the fuzzy set μ_S^{ε}, respectively.

Nevertheless, Pawlakian set approximation has some very strong theoretical requirements:

- the system of base sets are total, i.e., their union gives back the universe;
- base sets are pairwise disjoint.

[1] Note that the notion of a classical rough membership function was explicitly introduced by Pawlak and Skowron in [10]. Nevertheless, it had been used and studied earlier by many authors. For more historical remarks, see [17]. Moreover, such a coefficient has already been considered by Łukasiewicz in 1913 [18], [19].

978-83-60810-53-8/$25.00

In many cases, however, our knowledge does not fulfill these requirements:

- The partition shows the limit of our knowledge about the objects of the universe in the sense that two objects are indistinguishable if they belong to the same base set. On the other hand, it makes explicit our knowledge because we do distinguish two objects belonging to different base sets. Giving up the requirement of the pairwise disjoint property, the so–called *covering–based rough set theory* is obtained [22], [23], [24], [25], [26], [27].
- The universe may involve some objects without any information, i.e., base sets are not total. For instance, information systems often contain $NULL$ values. In the papers [28], [29], the authors give a very general system of the set approximation giving up both the pairwise disjoint property and the covering of the universe. It is called the (general) *partial approximation framework*.

In this paper, the above procedure is transferred to a partial set approximation context:

1) First, in a partial approximation space with a Pawlakian approximation pair, three *partial* membership functions are defined in the style of the classical rough membership function.
2) Then, three approximation pairs are generated with the help of partial membership functions. The question is whether these approximation pairs meet (at least) the minimum requirements of approximation pairs, i.e., these pairs actually form approximation pairs in partial approximation spaces.

The rest of the paper consists of three parts. In Section 2, the basic notions and notations of partial approximation spaces are summarized. In Section 3, three approximation pairs are generated as outlined above, and it is shown that they meet the minimum requirements prescribed for approximation pairs in partial approximation spaces. Section 4 consist of some remarks on the logical application of partial membership functions.

II. Partial approximation of sets

A. Basic notions and notations

Let U be a nonempty finite set and $\mathfrak{B} \subseteq 2^U$ be a nonempty family of nonempty subsets of U. U is the *universe of objects*, $\mathfrak{B}$ is the *base system* and its members are $\mathfrak{B}$-*sets* or *base sets* [30], [29], [31], [32], [33].

If $B \in \mathfrak{B}$ is a union of a family of sets $\mathfrak{B}' \subseteq \mathfrak{B} \setminus \{B\}$, B is called *reducible* in $\mathfrak{B}$, otherwise B is *irreducible* in $\mathfrak{B}$.

A base system $\mathfrak{B}$ is *single–layered* if every base set is irreducible, and *one–layered* if the base sets are pairwise disjoint. Of course, a one–layered base system is single–layered. From any base systems, single–layered and one–layered base systems can be constructed [31].

By formulae, a base system $\mathfrak{B}$ is single–layered, if

$$\forall B \in \mathfrak{B}\ \ \forall \mathfrak{B}' \subseteq \mathfrak{B} \setminus \{B\}\, (B \cap \bigcup \mathfrak{B}' \neq B),$$

and one–layered, if

$$\forall B \in \mathfrak{B}\ \ \forall \mathfrak{B}' \subseteq \mathfrak{B} \setminus \{B\}\, (B \cap \bigcup \mathfrak{B}' = \emptyset).$$

Informally, a base system $\mathfrak{B}$ is single–layered if every nonempty union of base sets has at least one member which belongs to exactly one base set, whereas $\mathfrak{B}$ is one–layered if all members of every nonempty union of base sets belong to exactly one base set.

During the approximation process, a family of sets $\mathfrak{D}_{\mathfrak{B}} \subseteq 2^U$ are applied. In the most general case, it is supposed only just that

1) $\mathfrak{D}_{\mathfrak{B}}$ is an extension of $\mathfrak{B}$, i.e., $\mathfrak{B} \subseteq \mathfrak{D}_{\mathfrak{B}}$;
2) $\emptyset \in \mathfrak{D}_{\mathfrak{B}}$.

Let $\mathsf{l}, \mathsf{u} : 2^U \to 2^U$ be an ordered pair of mappings and denoted it by $\langle \mathsf{l}, \mathsf{u} \rangle$.

The intended meaning of l and u is to express the lower and upper approximations of any subsets of U. Hence, it is called an *approximation pair*. The next definition specifies its *minimum requirements*.

Definition 1. An approximation pair $\langle \mathsf{l}, \mathsf{u} \rangle$ is a *weak approximation pair* if

(C0) $\mathsf{l}(2^U), \mathsf{u}(2^U) \subseteq \mathfrak{D}_{\mathfrak{B}}$ (*definability* of l and u);
(C1) l and u are monotone, i.e. for all $S_1, S_2 \in 2^U$ if $S_1 \subseteq S_2$ then $\mathsf{l}(S_1) \subseteq \mathsf{l}(S_2)$ and $\mathsf{u}(S_1) \subseteq \mathsf{u}(S_2)$ (*monotonicity* of l and u);
(C2) $\mathsf{u}(\emptyset) = \emptyset$ (*normality* of u);
(C3) if $S \subseteq U$, then $\mathsf{l}(S) \subseteq \mathsf{u}(S)$ (*weak approximation property*).

Clearly, l and u are many-to-one and $\mathsf{u}(2^U) \neq \mathsf{l}(2^U) \subseteq \mathfrak{D}_{\mathfrak{B}}$ in general.

Informally, definable sets represent our available knowledge about the the objects of the universe. They can be though of as *tools*, in more detail, base sets as *primary tools* and definable sets as *derived tools*. An approximation pair prescribes the *utilization* of tools in approximation processes.

It is reasonable that base sets as primary tools are exactly approximated from "lower side". In classical rough set theory, however, definable sets are exactly approximated from "lower side" as well.

Definition 2. A weak approximation pair $\langle \mathsf{l}, \mathsf{u} \rangle$ is

(C4) *granular* if $B \in \mathfrak{B}$, then $\mathsf{l}(B) = B$ (l is *granular*),
(C5) *standard* if $D \in \mathfrak{D}_{\mathfrak{B}}$, then $\mathsf{l}(D) = D$ (l is *standard*).

Of course, if l is standard, the granularity of l also holds.

The following proposition summarizes some simple consequences of the minimum requirements *(C0)–(C3)* in Definition 1 and the conditions *(C4)–(C5)* in Definition 2.

Proposition 1. *Let $\langle \mathsf{l}, \mathsf{u} \rangle$ be a weak approximation pair on U.*

1) $\mathsf{l}(\emptyset) = \emptyset$ *(normality of* l*).*
2) l *is idempotent, i.e.,* $\mathsf{l}(\mathsf{l}(S)) = \mathsf{l}(S)$ *for all* $S \in 2^U$*, and* $\mathsf{l}(2^U) = \mathfrak{D}_{\mathfrak{B}}$ *if and only if* l *is standard.*

3) a) *If* $\mathsf{l}(S) = S$*, then* $S \in \mathfrak{D}_{\mathfrak{B}}$.
   b) *Let* l *be standard. Then,* $\mathsf{l}(S) = S$ *if and only if* $S \in \mathfrak{D}_{\mathfrak{B}}$.
4) a) *If* $\mathsf{l}(U) = \bigcup \mathfrak{D}_{\mathfrak{B}}$*, then* $\bigcup \mathfrak{D}_{\mathfrak{B}} \in \mathfrak{D}_{\mathfrak{B}}$.
   b) *Let* l *be standard. Then,* $\mathsf{l}(U) = \bigcup \mathfrak{D}_{\mathfrak{B}}$ *if and only if* $\bigcup \mathfrak{D}_{\mathfrak{B}} \in \mathfrak{D}_{\mathfrak{B}}$.

The next definition deals with the question how lower and upper approximations relate to the approximated sets.

Definition 3. A weak approximation pair $\langle \mathsf{l}, \mathsf{u} \rangle$ is

(C6) lower semi–strong if $\mathsf{l}(S) \subseteq S$ for all $S \in 2^U$ (i.e., l is contractive);
(C7) upper semi–strong if $S \subseteq \mathsf{u}(S)$ for all $S \in 2^U$ (i.e., u is extensive);
(C8) strong if it is lower and upper semi–strong, i.e., each subset $S \in 2^U$ is bounded by $\mathsf{l}(S)$ and $\mathsf{u}(S)$: $\mathsf{l}(S) \subseteq S \subseteq \mathsf{u}(S)$.

Proposition 2.

1) *If* $\langle \mathsf{l}, \mathsf{u} \rangle$ *is an upper semi–strong approximation pair on* U*, then* $\mathsf{u}(U) = U$ *(co–normality of* u*).*
2) *If* $\langle \mathsf{l}, \mathsf{u} \rangle$ *is an upper semi–strong approximation pair on* U *and* l *is standard, then* $\mathsf{l}(U) = U$ *(co–normality of* l*).*

Based on the foregoing, a general set–theoretic partial approximation framework can be defined as follows.

Definition 4. The ordered 5–tuple $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}, \mathsf{l}, \mathsf{u} \rangle$ whose components are defined as before, is called a *(general) approximation space*.

Definition 5. $\mathsf{GAS}(U)$ is a *(general) total approximation space* or simply *total*, if $\mathfrak{B}$ covers the universe, i.e., $\bigcup \mathfrak{B} = U$, otherwise $\mathsf{GAS}(U)$ is a *(general) partial approximation space* or simply *partial*.

Definition 6. $\mathsf{GAS}(U)$ *relies on Pawlakian base*, if $\mathfrak{B}$ is a partition of U.

Corollary 1. $\mathsf{GAS}(U)$ *relies on Pawlakian base if and only if its base system is total and one–layered.*

Definition 7. The general approximation space $\mathsf{GAS}(U)$ is a *weak/standard/lower semi–strong/upper semi–strong/strong approximation space*, if the approximation pair $\langle \mathsf{l}, \mathsf{u} \rangle$ is weak/ standard/lower semi–strong/upper semi–strong/strong, respectively.

B. Exactness in general approximation spaces

In classical rough set theory, the notions of "crisp" and "definable" are inherently one and the same. In general approximation spaces, however, they can be differentiated.

Definition 8. Let $\mathsf{GAS}(U)$ be a weak approximation space and $S \subseteq U$.
S is *crisp*, if $\mathsf{l}(S) = \mathsf{u}(S)$, otherwise
S is *rough*.

If a set is crisp, its lower and upper approximations coincide with the approximated set only in strong approximation spaces. Furthermore, a crisp set is necessarily definable only in strong approximation spaces as well. However, it can easily be shown that a definable set is not necessarily crisp even in strong approximation spaces ([33], Example 8). Consequently, in general approximations spaces, the notions of "crisp" and "definability" are generally not synonymous to each other.

C. General approximation spaces with Pawlakian approximation pairs

Definition 9. $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}, \mathsf{l}, \mathsf{u} \rangle$ is a *approximation space with a Pawlakian approximation pair*, if

1) U is a finite nonempty set;
2) $\mathfrak{D}_{\mathfrak{B}}$ is *strict finite union type*, i.e., it is given by the following inductive definition:
   a) $\emptyset \in \mathfrak{D}_{\mathfrak{B}}$;
   b) $\mathfrak{B} \subseteq \mathfrak{D}_{\mathfrak{B}}$;
   c) if $B_1, B_2 \in \mathfrak{B}$, then $B_1 \cup B_2 \in \mathfrak{D}_{\mathfrak{B}}$;
3) $\langle \mathsf{l}, \mathsf{u} \rangle$ is a *Pawlakian approximation pair*, i.e.,
   a) $\mathsf{l}(S) = \bigcup \mathbb{L}(S)$, where $\mathbb{L}(S) = \{B \in \mathfrak{B} \mid B \subseteq S\}$;
   b) $\mathsf{u}(S) = \bigcup \mathbb{U}(S)$, where $\mathbb{U}(S) = \{B \in \mathfrak{B} \mid B \cap S \neq \emptyset\}$.

Proposition 3. *Let* $\mathsf{GAS}(U)$ *be an approximation space with a Pawlakian approximation pair.*

1) $\mathsf{GAS}(U)$ *is a standard lower semi–strong approximation space.*
2) $\mathsf{GAS}(U)$ *is an upper semi–strong approximation space if and only if* $\mathfrak{B}$ *covers the universe.*

Definition 10. Let $\mathsf{GAS}(U)$ be an approximation space with a Pawlakian approximation pair and $S \subseteq U$. Then

$$\mathsf{b}(S) = \bigcup (\mathbb{U}(S) \setminus \mathbb{L}(S))$$

is called the *boundary* of S.

Clearly, $\mathsf{b}(S) \subseteq \mathsf{u}(S)$ for all $S \subseteq U$.

Corollary 2. *Let* $\mathsf{GAS}(U)$ *be an approximation space with a Pawlakian approximation pair.*

1) *In general,* $\mathsf{u}(S) \setminus \mathsf{l}(S) \subseteq \mathsf{b}(S)$ *for any* $S \subseteq U$.
2) *If* $S \subseteq U$*,*

$$\mathsf{b}(S) = \mathsf{u}(S) \setminus \mathsf{l}(S) \Leftrightarrow \mathsf{b}(S) \cap \mathsf{l}(S) = \emptyset.$$

Proof:

1) $u \in \mathsf{u}(S) \setminus \mathsf{l}(S)$

$$\begin{aligned} &\Leftrightarrow \quad u \in \bigcup \mathbb{U}(S) \wedge u \notin \bigcup \mathbb{L}(S) \\ &\Leftrightarrow \quad \exists B \in \mathfrak{B}\,(u \in B \wedge B \in \mathbb{U}(S) \wedge B \notin \mathbb{L}(S)) \\ &\Leftrightarrow \quad \exists B \in \mathfrak{B}\,(u \in B \wedge B \in \mathbb{U}(S) \setminus \mathbb{L}(S)) \\ &\Rightarrow \quad u \in \bigcup (\mathbb{U}(S) \setminus \mathbb{L}(S)) = \mathsf{b}(S) \end{aligned}$$

2) ($\Rightarrow$) $\mathsf{b}(S) \cap \mathsf{l}(S) = (\mathsf{u}(S) \setminus \mathsf{l}(S)) \cap \mathsf{l}(S) = \emptyset$.
   ($\Leftarrow$) $\mathsf{b}(S)$

$$\begin{aligned} &= (\mathsf{b}(S) \cap \mathsf{l}(S)) \cup (\mathsf{b}(S) \cap (\mathsf{l}(S))^c) \\ &= \mathsf{b}(S) \cap (\mathsf{l}(S))^c \\ &\subseteq \mathsf{u}(S) \cap (\mathsf{l}(S))^c = \mathsf{u}(S) \setminus \mathsf{l}(S), \end{aligned}$$

which are compared to (1), we get

$$\mathsf{b}(S) = \mathsf{u}(S) \setminus \mathsf{l}(S).$$

■

III. Fuzziness in partial approximation spaces with Pawlakian approximation pairs

Let $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}, \mathsf{l}, \mathsf{u} \rangle$ be a partial approximation space with a Pawlakian approximation pair. In other words, $\mathsf{GAS}(U)$ is an approximation space with a Pawlakian approximation pair and $\bigcup \mathfrak{B} \subseteq U$.

A. Partial membership functions

If $u \in U$, let $\mathcal{N}_{\mathfrak{B}}(u) = \{B \in \mathfrak{B} \mid u \in B\}$. The family of sets $\mathcal{N}_{\mathfrak{B}}(u)$ may be called the *(reflexive) neighborhood system* of u with respect to the base system $\mathfrak{B}$ [34], and its members are called the *neighborhoods* of u.

Three different partial membership functions are defined in $\mathsf{GAS}(U)$ as follows [32], [35], [36], [38], [20].

Definition 11. Let $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}, \mathsf{l}, \mathsf{u} \rangle$ be a partial approximation space with a Pawlakian approximation pair and $S \subseteq U$.

$\mu_S^o, \mu_S^a, \mu_S^p : U \to [0,1]$ are *optimistic/average/pessimistic partial membership functions*, respectively, if

$$\mu_S^o(u) = \begin{cases} \mathsf{max}\left\{ \frac{|B \cap S|}{|B|} \mid B \in \mathcal{N}_{\mathfrak{B}}(u) \right\}, & \text{if } u \in \bigcup \mathfrak{B}; \\ \mathsf{undefined}, & \text{otherwise;} \end{cases}$$

$$\mu_S^a(u) = \begin{cases} \mathsf{avg}\left\{ \frac{|B \cap S|}{|B|} \mid B \in \mathcal{N}_{\mathfrak{B}}(u) \right\}, & \text{if } u \in \bigcup \mathfrak{B}; \\ \mathsf{undefined}, & \text{otherwise;} \end{cases}$$

$$\mu_S^p(u) = \begin{cases} \mathsf{min}\left\{ \frac{|B \cap S|}{|B|} \mid B \in \mathcal{N}_{\mathfrak{B}}(u) \right\}, & \text{if } u \in \bigcup \mathfrak{B}; \\ \mathsf{undefined}, & \text{otherwise.} \end{cases}$$

Remark 1. For the sake of brevity, we will use the symbol "*" in order to denote a member of $\{o, a, p\}$.

In Definition 11, each partial membership function μ_S^* forms a special type of fuzziness on U which is induced by the base system $\mathfrak{B}$, i.e., our available knowledge (primary tools) about the objects of the universe.

An important feature of each μ_S^* is that it is a *partial* function. Clearly, if $\bigcup \mathfrak{B} \subsetneqq U$, $\mu_S^*(u)$ is undefinable for all $u \in U \setminus \bigcup \mathfrak{B}$. In other words, $\mathtt{dom}\ \mu_S^* = \bigcup \mathfrak{B} \subsetneqq U$.[2]

The following statements can easily be checked.

Proposition 4. *Let $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}, \mathsf{l}, \mathsf{u} \rangle$ be a partial approximation space with a Pawlakian approximation pair. Then, for any $S \subseteq U$ and $u \in U$*

1) $\mu_S^o(u) = 1$ *if and only if*

$$\exists B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \subseteq S) \text{ (i.e., } \mathcal{N}_{\mathfrak{B}}(u) \cap \mathbb{L}(S) \neq \emptyset);$$

2) $\mu_S^a(u) = 1$, $\mu_S^p(u) = 1$ *if and only if*

$$\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \subseteq S) \text{ (i.e., } \mathcal{N}_{\mathfrak{B}}(u) \subseteq \mathbb{L}(S));$$

3) $\mu_S^o(u) > 0$, $\mu_S^a(u) > 0$ *if and only if*

$$\exists B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \cap S \neq \emptyset) \text{ (i.e., } \mathcal{N}_{\mathfrak{B}}(u) \cap \mathbb{U}(S) \neq \emptyset);$$

4) $\mu_S^p(u) > 0$ *if and only if*

$$\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \cap S \neq \emptyset) \text{ (i.e., } \mathcal{N}_{\mathfrak{B}}(u) \subseteq \mathbb{U}(S));$$

5) $\mu_S^o(u), \mu_S^a(u) = 0$ *if and only if*

$$\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \cap S = \emptyset) \text{ (i.e., } \mathcal{N}_{\mathfrak{B}}(u) \cap \mathbb{U}(S) = \emptyset).$$

6) $\mu_S^p(u) = 0$ *if and only if*

$$\exists B \in \mathcal{N}_{\mathfrak{B}}(u)\, (B \cap S = \emptyset).$$

Proposition 4 implies the following statements.

Corollary 3. *Let $\mathsf{GAS}(U)$ be a partial approximation space with a Pawlakian approximation pair. Then, for the optimistic partial membership function μ_S^o,*

1) $\mu_S^o(u) = 1$ *if and only if* $u \in \mathsf{l}(S)$,
2) $\mu_S^o(u) > 0$ *if and only if* $u \in \mathsf{u}(S)$,
3) $0 < \mu_S^o(u) < 1$ *if and only if* $u \in \mathsf{u}(S) \setminus \mathsf{l}(S)$,
4) $\mu_S^o(u) = 0$ *if and only if* $u \in \bigcup \mathfrak{B} \setminus \mathsf{u}(S)$,

for any $S \subseteq U$ and $u \in U$.

Corollary 4. *Let $\mathsf{GAS}(U)$ be a partial approximation space with a Pawlakian approximation pair. Then, for the average partial membership function μ_S^a,*

1) *if* $\mu_S^a(u) = 1$, *then* $u \in \mathsf{l}(S)$,
2) $\mu_S^a(u) > 0$ *if and only if* $u \in \mathsf{u}(S)$,
3) *if* $u \in \mathsf{u}(S) \setminus \mathsf{l}(S)$, *then* $0 < \mu_S^a(u) < 1$,
4) $\mu_S^a(u) = 0$ *if and only if* $u \in \bigcup \mathfrak{B} \setminus \mathsf{u}(S)$,

for any $S \subseteq U$ and $u \in U$.

Corollary 5. *Let $\mathsf{GAS}(U)$ be a partial approximation space with a Pawlakian approximation pair. Then, for the pessimistic partial membership function μ_S^p,*

1) *if* $\mu_S^p(u) = 1$ *then* $u \in \mathsf{l}(S)$,
2) *if* $\mu_S^p(u) > 0$, *then* $u \in \mathsf{u}(S)$,
3) *if* $\mu_S^p(u) > 0$ *and* $u \notin \mathsf{l}(S)$,

   then $u \in \mathsf{u}(S)$ *and* $\mu_S^p(u) < 1$,
4) *if* $u \in \bigcup \mathfrak{B} \setminus \mathsf{u}(S)$, *then* $\mu_S^p(u) = 0$.

for any $S \subseteq U$ and $u \in U$.

The different notions of *necessity* and *possibility* can be found in the definitions of partial membership functions μ_S^*.

The values $\mu_S^*(u)$ ($u \in U$) of the partial membership functions defined above informally mean the following.

The case of optimistic partial membership function:

1) if $\mu_S^o(u) = 1$, i.e., u has at least one neighborhood inside S, u can certainly be classified as belonging to S in an optimistic sense;

[2] $\mathtt{dom}\ f$ denotes the domain of the map f.

2) if $\mu_S^o(u) > 0$, i.e., u has at least one neighborhood wholly or partly inside S, u can possibly be classified as belonging to S in an optimistic sense;
3) if $0 < \mu_S^o(u) < 1$, i.e., u does not have any neighborhood inside S but has at least one neighborhood partly inside and partly outside S, u cannot be classified as either belonging to S or does not belonging to S in an optimistic sense.

The case of the average partial membership function:

1) if $\mu_S^a(u) = 1$, i.e., all neighborhoods of u are inside S, u can certainly be classified as belonging to S in average approach;
2) if $\mu_S^a(u) > 0$, i.e., u has at least one neighborhood wholly or partly inside S, u can possibly be classified as belonging to S in average approach;
3) if $0 < \mu_S^a(u) < 1$, i.e., u has a neighborhood not inside S and has at least one neighborhood wholly or partly inside S, u cannot be classified as either belonging to S or does not belonging to S in average approach.

The case of pessimistic partial membership function:

1) if $\mu_S^p(u) = 1$, i.e., all neighborhoods of u are inside S, u can certainly be classified as belonging to S in a pessimistic sense;
2) if $\mu_S^p(u) > 0$, i.e., all neighborhoods of u are wholly or partly inside S, u can possibly classified as belonging to S in a pessimistic sense;
3) if $0 < \mu_S^p(u) < 1$, i.e., u has a neighborhood not inside S and all neighborhoods of u are wholly or partly inside S, u cannot be classified as either belonging to S or does not belonging to S in a pessimistic sense.

Last, for all three partial membership functions,

$$\mu_S^*(u) = \mathsf{undefined}$$

indicates that we do not have any information about u. Consequently, defining membership degree for u should be meaningless with respect to our knowledge about the objects of the universe.

In classical rough set theory, lower and upper approximations and the boundary can be reconstructed setting out from the membership function. In a fuzzy context, the reconstruction can be carried out by means of `core` and `support` of membership functions in a standard way.

As usual, for the partial membership function μ_S^*, the `core` and `support` are the following:

$$\begin{aligned}\mathtt{core}(\mu_S^*) &= \{u \in U \mid \mu_S^*(u) = 1\};\\ \mathtt{support}(\mu_S^*) &= \{u \in U \mid \mu_S^*(u) > 0\}.\end{aligned}$$

Now, $\mathsf{l}^*, \mathsf{u}^* : 2^U \to 2^U$ approximation pair may be defined as usual:

$$\begin{aligned}\mathsf{l}^*(S) &= \mathtt{core}(\mu_S^*) = \{u \in U \mid \mu_S^*(u) = 1\},\\ \mathsf{u}^*(S) &= \mathtt{support}(\mu_S^*) = \{u \in U \mid \mu_S^*(u) > 0\}.\end{aligned}$$

1) The case of optimistic partial membership functions: In the case of the optimistic partial membership function μ_S^o, the *optimistic lower and upper approximation pair* is the following:

$$\begin{aligned}\mathsf{l}^o(S) &= \mathtt{core}(\mu_S^o) = \{u \in U \mid \mu_S^o(u) = 1\}\\ &= \{u \in \mathsf{l}(S) \mid \exists B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq S)\}\\ &= \mathsf{l}(S)\end{aligned}$$

by Corollary 3 (1), and

$$\begin{aligned}\mathsf{u}^o(S) &= \mathtt{support}(\mu_S^o) = \{u \in U \mid \mu_S^o(u) > 0\}\\ &= \{u \in \mathsf{u}(S) \mid \exists B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \cap S \neq \emptyset)\}\\ &= \mathsf{u}(S)\end{aligned}$$

by Corollary 3 (2).

Informally, $\mathsf{l}^o(S)$ is a collection of such $u \in U$ which has at least one neighborhood included in S, and $\mathsf{l}^o(S) = \mathsf{l}(S)$. $\mathsf{u}^o(S)$ is a collection of such $u \in U$ which has at least one neighborhood having nonempty intersection with S, and $\mathsf{u}^o(S) = \mathsf{u}(S)$.

In other words, in the case of optimistic partial membership function μ_S^o, we get back the Pawlakian approximation pair $\langle \mathsf{l}, \mathsf{u}\rangle$. It implies that $\langle \mathsf{l}^o, \mathsf{u}^o\rangle$ meets the minimum requirements *(C0)–(C3)* and the conditions *(C4)–(C5)*.

2) The case of average partial membership functions: In the case of the average partial membership function μ_S^o, the *average lower and upper approximation pair* is the following:

$$\begin{aligned}\mathsf{l}^a(S) &= \mathtt{core}(\mu_S^a) = \{u \in U \mid \mu_S^a(u) = 1\}\\ &= \{u \in U \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq S)\}\\ &\subseteq \mathsf{l}(S)\end{aligned}$$

by Corollary 4 (1), and

$$\begin{aligned}\mathsf{u}^a(S) &= \mathtt{support}(\mu_S^a) = \{u \in U \mid \mu_S^a(u) > 0\}\\ &= \{u \in \mathsf{u}(S) \mid \exists B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \cap S \neq \emptyset)\}\\ &= \mathsf{u}(S)\end{aligned}$$

by Corollary 4 (2).

Informally, $\mathsf{l}^a(S)$ is a collection of such a $u \in U$ whose all neighborhoods included in S, and $\mathsf{l}^a(S) \subseteq \mathsf{l}(S)$. $\mathsf{u}^a(S)$ is a collection of such a $u \in U$ which has at least one neighborhood having nonempty intersection with S, and $\mathsf{u}^a(S) = \mathsf{u}(S)$.

That is, in the case of average partial membership function μ_S^a, we get back the upper Pawlakian approximation map, but the Pawlakian lower approximation map has already changed.

Proposition 5. $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}^a, \mathsf{l}^a, \mathsf{u}^a\rangle$ *is a weak general approximation space provided that* $\mathfrak{D}_1 \setminus \mathfrak{D}_2 \in \mathfrak{D}_{\mathfrak{B}}^a$ *(*$\mathfrak{D}_1, \mathfrak{D}_2 \in \mathfrak{D}_{\mathfrak{B}}$*).*

Proof:

(C0)–(C2) They are straightforward.

(C3) If $u \in \mathsf{l}^a(S)$, then $\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq S)$, and so $\exists B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \cap S \neq \emptyset)$, i.e., $u \in \mathsf{u}^a(S)$.

■

3) The case of pessimistic partial membership functions: In the case of the pessimistic partial membership function μ_S^p, the *pessimistic lower and upper approximation pair* is the following:

$$\begin{aligned} \mathsf{l}^p(S) &= \mathtt{core}(\mu_S^p) = \{u \in U \mid \mu_S^p(u) = 1\} \\ &= \{u \in U \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq S)\} \\ &\subseteq \mathsf{l}(S) \end{aligned}$$

by Corollary 5 (1), and

$$\begin{aligned} \mathsf{u}^p(S) &= \mathtt{support}(\mu_S^p) = \{u \in U \mid \mu_S^p(u) > 0\} \\ &= \{u \in U \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \cap S \neq \emptyset)\} \\ &\subseteq \mathsf{u}(S) \end{aligned}$$

by Corollary 5 (2).

Informally, $\mathsf{l}^p(S)$ is a collection of such $u \in U$ whose all neighborhoods included in S, and $\mathsf{l}^p(S) \subseteq \mathsf{l}(S)$. $\mathsf{u}^p(S)$ is a collection of such $u \in U$ whose all neighborhoods having nonempty intersection with S, and $\mathsf{u}^p(S) \subseteq \mathsf{u}(S)$.

In the case of pessimistic partial membership function μ_S^p, both lower and upper Pawlakian approximation maps have changed.

Proposition 6. $\mathsf{GAS}(U) = \langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}^p, \mathsf{l}^p, \mathsf{u}^p \rangle$ *is a weak general approximation space provided that* $\mathfrak{D}_1 \setminus \mathfrak{D}_2 \in \mathfrak{D}_{\mathfrak{B}}^p$ *(*$\mathfrak{D}_1, \mathfrak{D}_2 \in \mathfrak{D}_{\mathfrak{B}}$*).*

Proof:

(C0)–(C2) They are straightforward.

(C3) If $u \in \mathsf{l}^p(S)$, then $\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq S)$, and so $\forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \cap S \neq \emptyset)$, i.e., $u \in \mathsf{u}^p(S)$.

■

The next proposition deals with the conditions *(C4)–(C5)* of average and pessimistic approximation pairs.

Proposition 7. *Let* $\langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}^a, \mathsf{l}^a, \mathsf{u}^a \rangle$ *and* $\langle U, \mathfrak{B}, \mathfrak{D}_{\mathfrak{B}}^p, \mathsf{l}^p, \mathsf{u}^p \rangle$ *be weak approximation spaces whose components are defined as above.*

If the base system $\mathfrak{B}$ *is one–layered,* $\mathfrak{D}_{\mathfrak{B}}^{\mathfrak{a}} = \mathfrak{D}_{\mathfrak{B}}^p = \mathfrak{D}_{\mathfrak{B}}$ *and the weak approximation pairs* $\langle \mathsf{l}^a, \mathsf{u}^a \rangle$ *and* $\langle \mathsf{l}^p, \mathsf{u}^p \rangle$ *are standard, i.e.,* $\mathsf{l}^a(D) = D$ *and* $\mathsf{l}^p(D) = D$ *for all* $D \in \mathfrak{D}_{\mathfrak{B}}$.

Proof:

Since l is standard, $\mathsf{l}^a(D) \subseteq \mathsf{l}(D) = D$ for all $D \in \mathfrak{D}_{\mathfrak{B}}$.

On the other hand, $\mathfrak{B}$ is one–layered, and so every definable set $D \in \mathfrak{D}_{\mathfrak{B}}$ is a finite union of pairwise disjoint base sets, e.g., $D = B_1 \cup \cdots \cup B_n$, where B_i's are pairwise disjoint. Moreover, for every $u \in D$ there exists exactly one $i \in \{1, 2, \ldots, n\}$ in such a way that $\mathcal{N}_{\mathfrak{B}}(u) = \{B_i\}$.

Hence, we get for all $D \in \mathfrak{D}_{\mathfrak{B}}$,

$$\begin{aligned} \mathsf{l}^a(D) &= \{u \in U \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq D)\} \\ &\supseteq \{u \in D \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq D)\} \\ &= \{u \in B_1 \cup \cdots \cup B_n \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq D)\} \\ &= \{u \in B_1 \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq D)\} \\ &\quad \cup \cdots \cup \{u \in B_n \mid \forall B \in \mathcal{N}_{\mathfrak{B}}(u)\,(B \subseteq D)\} \\ &= B_1 \cup \cdots \cup B_n = D. \end{aligned}$$

Therefore, $\mathsf{l}^a(D) = D$.

The standard property of l^p can be proved similarly.

■

IV. Some remarks on the logical applications

In the previous sections, first, three partial membership functions have been defined in partial approximation spaces with Pawlakian approximation pairs, then three approximation pairs have been generated with the help of them. It has been shown that, among others, they meet the minimum requirements prescribed for approximation pairs in partial approximation spaces, i.e., they actually form approximation pairs.

Optimistic, average and pessimistic partial membership functions have already been studied by the second author from the logical point of view in [38], [32]. It turned out that they are in connection with *decision–theoretic rough set models* (DTRS) which can be considered as the probabilistic extensions of algebraic rough set models [37].

Optimistic, average and pessimistic partial membership functions may serve as a bases of the semantics of a partial first–order logic. In the paper [35], the semantic system of a partial first–order logic with three different types of partial membership functions is presented. The proposed logical system gives an exact possibility to introduce different semantic notions of logical consequence relations which can be used in order to make clear the consequences of our decisions.

V. Conclusion and future work

In this paper, having defined three partial membership functions, three approximation pairs have been generated in partial approximation spaces with Pawlakian approximation pairs. We have investigated how these pairs meet the requirements prescribed for approximation pairs in partial approximation spaces. As a result, in this way we have constructed two not Pawlakian approximation pairs.

In the future, it should be worth performing similar investigations in partial approximation spaces setting out from *arbitrary* approximation pairs, in particular, which have been obtained in this paper.

***Absrtact*—Texture is considered as one of the most crucial image features used commonly in computer vision. It is important source of information about image content, especially for single-band images. In this paper we present the results of research carried out to assess the usefulness of selected textural features of different groups in panchromatic very high resolution (VHR) satellite image classification. The study is based on images obtained from EROS A satellite. The aim of our tests was to estimate and compare the accuracy of main land cover types classification, with a particular focus on determining usefulness of textural features based on multifractal formalism.**

Presented research confirmed that it is possible to use the textural features as efficient global descriptors of VHR satellite image content. It was also prove that multifractal parameters should be considered as valuable textural features in the context of land cover classification.

I. Introduction

TEXTURE as a primary factor of visual perception is a necessary feature of image description. It is usually easy to recognize texture, but it is more difficult to define it, because texture, in contrast to colour, is not determined by a single point, but involve neighbouring area and can be related to a direction or a scale. It was created large spectrum of parameters, due to a lot of possible textural descriptors, to help to extract information about texture (also in the context of satellite images [1]). Textural characteristic can be calculated based on the entire image (global features), fragments of this image delineated by segmentation results or small clusters of pixels formed by moving windows [2], [3], [4]. Different texture analysis techniques, such as Markovian analysis (including Haralick measures), spatial autocorrelation, multi-scale autoregressive models, wavelet transforms or fractals have been successfully used to describe the content of the images [2], [3], [5]. They are considered especially important in case of single-band images, like medical ones.

This work was supported by Polish Natonal Science Centre (NCN) and the Ministry of Science and Higher Education (MNiSW) through grant NN 526 1568 40.

The textural analysis becomes also an important component of the process of information extraction from satellite images, especially in Object-Based Image Analysis approach where textural features supplement the set of typical characteristics obtained from histogram features and image objects' shape. However, it is even more valuable tool when single-band panchromatic images of very high spatial resolution are considered. Textural analysis may facilitate information extraction from such images by enabling the automatic classification of their content. It is also especially important from the content-based image retrieval (CBIR) point of view. Due to the increase of high resolution remote sensing imagery, the developments in this direction are particularly desirable.

In our work we propose multifractal formalism, as a generalization of the fractal geometry, in order to more complete analyze the texture of satellite images [6]. In our previous study [7] we compared efficiency of selected textural features as global content-based descriptors of panchromatic WorldView2 Very High Resolution satellite images. We wanted to investigate how accurately remotely sensed image can be automatically classified to the broad land cover types such as agriculture, urban areas, water bodies, and forest, based on textural information derived from the entire image. We were able to construct decision trees capable for very accurate classification of images from our test image database into these main landuse categories. The research proved that degree of multifractality can be considered as important global image characteristic.

However, tested WorldView2 images were characterised by very homogeneous landuse – over 90% of the image was in the dominating landuse category – and high radiometric quality. In case of the present study we applied the same methodology of analysis to panchromatic EROS A satellite images. This is also a VHR sensor, although older then WorldView2 and acquiring images with a little bit lower spatial resolution (2 m in case of EROS A vs. 0.5 m in case of WorldView2) and higher level of noise. Moreover, images in our EROS A test image database are not such homogeneous regarding the landuse of imaged terrain – the dominat-

ing landuse category covers over 50% of the image. Our previous work [6] showed that selected multifractal parameters can be used as features describing the content of these images. The aim of the present study is to compare their efficiency with other textural parameters. We also intend to carry out experiment to determine the parameters most appropriate as classification features.

II. Data

The test data used in the experiment are the same like used in [6] and consist of two partially overlapping EROS-A scenes (panchromatic high-resolution images, ground resolution – 2 m) of Krakow area (south Poland) acquired on 10th and 15th October 2007. Images were acquired using similar pointing angles (29 and 27.5 degrees) and ground sample distances (2.20 and 2.15 m respectively). The images were orthorectified using orbital model.

We created our testing image database from the 512x512 pixel orthoimage tiles. To make more image tiles available for the study, the ortophotomaps were cut into tiles twice. The second set of tiles was cut with the origin of tiles shifted 256 pixels east and 256 pixels north. Every image in the created database was labeled according to its prevailing land cover category (agriculture, forest, urban), based on photo interpretation done in other studies for the purpose of landscape ecological research. Only images where dominating land cover class covered over 50% of imaged area were used for analysis.

The final database consisted from following sets of images:

- Image set EROS1 – 262 image tiles cut from Scene 1 (agriculture – 199, urban – 40, forest - 23);
- Image set EROS1s – 259 image tiles cut from Scene 1 with shifted origins (agriculture – 204, urban – 35, forest - 20);
- Image set EROS2 – 344 image tiles cut from Scene 2 (agriculture – 298, urban – 25, forest - 21);
- Image set EROS2s – 349 image tiles cut from Scene 1 with shifted origins (agriculture – 308, urban – 24, forest – 17).

III. Methods

The analytical approach adopted in the study is the same as in [7].

A. Textural parameters

Chosen global textural characteristics were calculated for every image chip. As the result every image in the database was described by 295 attributes, which may be grouped into 9 attribute groups (AG):

- AG1: the label (land cover class);
- AG2: four histogram-based characteristics (mean, variance, skewness and kurtosis);
- AG3: six multifractal parameters ($\Delta^{SUM,}$ Δ^{MAX}, Δ^{BCD}, Δ_p^{SUM}, Δ_p^{MAX}, Δ_p^{BCD}); Δ stands for the degree of multifractality and Δ_p for the degree of multifractality for $q > 0$; SUM, MAX and BCD are three different measure types (measure SUM takes sum of pixel values on a given box; measure MAX choses maximum value of pixels in a given box; measure BCD takes deviation of gray levels in a box) [8], [6].
- AG4: 220 co-occurrence matrix-based parameters [9], [10]: angular second moment, contrast, correlation, sum of squares, inverse difference moment, sum average, sum variance, sum entropy, entropy, difference variance, difference entropy; these parameters were computed 20 times, for (d,0), (0,d), (d,d), (d,-d) where the distance d can take values of 1, 2, 3, 4, and 5;
- AG5: 20 run length matrix-based parameters [9], [11]: run length nonuniformity, gray level nonuniformity, long run emphasis moment, short run emphasis inverse moment, fraction of image in runs; these parameters were computed 4 times (for vertical, horizontal, 45-degree and 135-degree directions);
- AG6: 5 absolute gradient-based parameters [9]: mean absolute gradient, variance of absolute gradient, skewness of absolute gradient, kurtosis of absolute gradient, percentage of pixels with nonzero gradient;
- AG7: 5 autoregressive model parameters [12], [13]: θ_1, θ_2, θ_3, θ_4, σ;
- AG8: 20 parameters derived from wavelet analysis [14], [15], [16];
- AG9: fractal dimension determined by using differential boxing-counting (DBC) method [17].

Features from attribute groups AG4 – AG8 were obtained using MaZda software [16]. Histogram-based features, multifractal parameters and fractal dimension were calculated in MatLab.

B. Fractal Dimension and Multifractal Parameters

There are several methods for estimating a fractal dimension (FD) in an image [18], [19]. In the most commonly used Box-Counting methods fractal dimension is calculated by covering an object with boxes of varying size l and is given by the relation:

$$D_F = \lim_{l \to 0} \frac{\ln N(l)}{\ln 1/l} \qquad (1)$$

where $N(l)$ denotes the number of boxes of size l needed to cover considered object. Methods differ mainly in the ways they approximate the quantity $N(l)$. Most of them are applied to images that must be turned into binary images.

In our work we calculate fractal dimension by using differential box-counting (DBC) method [20], [17]. This

method, proposed by Sarkar and Chaudhuri [20], allows working directly on grey-scale images and thus the binarization process is avoided.

In DBC algorithm an image of size $M \times M$ is considered as a three-dimensional spatial surface, where (x,y) denotes pixel position and the third coordinate (z) denotes pixel gray level. The (x,y) plane is partitioned into grids of size $s \times s$, where $M/2 \geqslant s > 1$ and s is an integer. On each grid there is a column of boxes of size $s \times s \times s'$,where s' is the height of each box, $G/s' = M/s$, and G is the total number of gray levels. Let the minimum and maximum gray level of the image in (i,j)-th grid fall into the kth and lth boxes, respectively [20]. Then the contribution of $N(l)$ in the pixel (i,j) of the grid is $n_l(i,j)=l-k+1$. Taking contributions from all grids, we have

$$N(l)=\sum_{i,j} n_l(i,j) \tag{2}$$

Then $N(l)$ is computed to different values of l. Finally, the fractal dimension D_F is estimated from the least square linear fit of log $(N(l))$ against log $(1/l)$ (see Equation 1). It is worth noting that presented DBC methods was compared with other four methods proposed by Peleg [21], Pentland [22], Gangepain and Roques-Carmes [23], and Keller et al. [24], respectively. The DBC method was considered as a better method, as was also supported by the other investigation [25]. Moreover, some modifications of DBC method have been lately proposed [26].

In our research we also consider one of the multifractal functions: generalized dimensions, D_q, as well quantitative parameter strictly connected with this function. The generalized dimensions D_q are calculated as a function of a continuous index q, where $-\infty < q < \infty$ (e.g., see [27], figure 3.1). Index q can be compared to a microscope for exploring different regions of the considered image.

As for FD estimation, many methods exist to obtain the multifractal functions [20]. Here, the Box-Counting based moment method has been applied [28]. In the first step of analysis an image is divided into boxes of size $\delta \times \delta$. Next, for each box following multifractal measure is calculated:

$$\mu_i(\delta)=\frac{p_i(\delta)}{\sum_{i=1}^{N(\delta)} p_i(\delta)}, \tag{3}$$

where $i = 1, ..., N(\delta) = 2^n$ labels the individual boxes of size δ. Here $p_i(\delta)$ denotes three different measures [29], [8]:

$$p_i^{\mathrm{SUM}}(\delta)=\sum_{(k,l)\in\Omega_i} g(k,l) \tag{4}$$

$$p_i^{\mathrm{MAX}}(\delta)=\max_{(k,l)\in\Omega_i} g(k,l) \tag{5}$$

$$p_i^{\mathrm{BCD}}(\delta)=\max_{(k,l)\in\Omega_i} |d(k,l)| \tag{6}$$

where $g(k,l)$ is a gray-scale intensity at point (k,l), Ω_i is a set of all pixels (k,l) in the ith box and $d(k,l)$ denotes the deviation of gray levels in box i.

In the next step of our analysis, a weighted summation is performed over all boxes in a particular grid returning the partition function of order q, i.e.

$$\chi(q,\delta)=\sum_{i=1}^{N(\delta)} (\mu_i(\delta))^q \tag{7}$$

which scales with the box length $\delta \to 0$ and $N(\delta) \to \infty$ according to:

$$\chi(q,\delta) \propto \delta^{D_q(q-1)} \tag{8}$$

From the Equation (8) we obtain generalized dimensions [30]

$$D_q=\lim_{\delta\to 0}\frac{\log(\chi(q,\delta))}{(q-1)\log(\delta)} \tag{9}$$

The difference of the maximum and minimum dimension D_q, associated with the least dense and the most dense regions in the considered measure, is given by

$$\Delta = D_{-\infty} - D_{+\infty} \tag{10}$$

and can be regarded as a degree of multifractality (e.g., [31], [27]). The degree of multifractality Δ is a measure of complexity of considered data; higher values of Δ inform us about greater non homogeneity on image and suggest that different fractals are needed for its full description. In particular, for monofractal scaling the degree of multifractality equals zero.

Finally, as a result of multifractal analysis performed for each image we obtain the following set of six parameters: the degree of multifractality (Δ) for measure SUM (Δ^{SUM}), MAX (Δ^{MAX}) and BCD (Δ^{BCD}), as well the degree of multifractality for positive values of index q (Δ_p^{SUM}, Δ_p^{MAX} and Δ_p^{BCD}). Presented parameters state quantitative and global characteristics used to compare complexity of images.

C. Classification

The decision (classification) tree approach was used for classification. We decided to use this method as it has good computational efficiency and the obtained tree can be presented as a set of easily interpretable rules. It has also been already successfully applied for the semantic labeling of satellite images [32], [33].

In our study, the classification was done using See5 software (Rel. 2.07). The software generates decision trees based on C5.0 algorithm, improved commercial version of well-known C4.5 [24].

Classification was done based on different sets of features (classification features sets, CFS):

- CFS1: all classification features (AG2 – AG9);
- CFS2: all classification features apart from histogram-based ones (AG3 – AG9);
- CFS3: co-occurrence matrix-based features (AG4);
- CFS4: co-occurrence matrix-based and histogram-based features (AG2 and AG4);
- CFS5: run length matrix-based features (AG5);
- CFS6: run length matrix-based and histogram-based features (AG2 and AG5);
- CFS7: absolute gradient-based features (AG6);
- CFS8: absolute gradient-based and histogram-based features (AG2 and AG6);
- CFS9: autoregressive model parameters (AG7);
- CFS10: autoregressive model parameters and histogram-based features (AG2 and AG7);
- CFS11: parameters derived from wavelet analysis (AG8);
- CFS12: parameters derived from wavelet analysis and histogram-based features (AG2 and AG8);
- CFS13: fractal dimension and histogram-based features (AG2 and AG9);
- CFS14: histogram-based features (AG2);
- CFS15: multifractal parameters (AG3);
- CFS16: multifractal parameters and histogram-based features (AG2 and AG3);

Such approach enabled us both, to evaluate the individual performance of each group of textural characteristics (used alone and together with histogram-based features) and to assess the usefulness of combining of features from different groups.

Five approaches with different pruning and thresholding options as well as with or without winnowing of attributes were used for every set of classification features. Boosting with ten trials was used in every classification run.

In the area where satellite scenes overlap, existed some number of 'twin' tiles covering exactly the same area. To eliminate the possibility of using them as training and test data at the same time, in our study we have used the image data sets as shown in Table I.

The average overall classification accuracy was calculated for each classification approach and each set of tested classification features (CFS). The lowest of five classification errors was then assigned as a measure of classification quality for particular tested set of attributes.

TABLE I.
TRAINING AND TEST DATA SETS

	Training data set	Test data set
Classification 1	EROS1	EROS2s
Classification 2	EROS2s	EROS1
Classification 3	EROS1 and EROS2s	EROS1s and EROS2

IV. RESULTS AND DISCUSSION

The results of classification tests are shown in Table II. The best results for each of classification tests gave the classification accuracies in the range from 94 to 96 percent. In two classification tests the best results were obtained when all calculated textural parameters were included in classification feature set. However, in Classification 2 the best result was achieved using the classification feature set consisted only of absolute gradient-based and histogram-based features (CFS8). This kind of textural features is also the best one, when looking into the performance of particular texture attribute groups. This result is surprising as in the previous study for WorlView2 images [7], this attribute group gave rather poor results when compared to other ones. It should be noticed however, that the achieved level of accuracy was quite similar (93 – 95% in case of EROS A and 93% in case of WorldView2). The performance of other textural characteristics was much worse in the actual study. It is especially the case of autoregressive model parameters (CFS9), which performance for EROS A images classification can be pointed as the worst one. For WorldView2 images this group of attributes was between the best ones [7].

The results presented in Table II show that, in general, the classification performance increases when textural features are combined with histogram-based ones. This conclusion is consistent with the results of our previous studies [6], [7].

Multifractal parameters used together with histogram-based features gave the second-best result for Classification 2. However, in the two other tests their performance was rather average.

When features from all attribute groups are combined (CFS1 and CFS2) the classification tree built may be quite complex as many of available features can be used in classification process. In the classification method used in our study, the number of features used for classification may be reduced by using the winnowing approach. We compared the results of the overall accuracy achieved for both options (without winnowing and winnowed) in Table III.

It should be noted, that for two of three tests the classification performance of winnowed set is comparable to the full one and still better then performance of any other classification features set. In these cases the final set of winnowed attributes is the same and consists of two co-occurrence matrix-based parameters, multifractal parameter and skewness of absolute gradient. This result is very similar to achieved for WorldViev2 images, where also the result based on three winnowed parameters was better then any of the results of particular attribute groups [7]. In case of that study the set of winnowed attributes consisted of multifractal parameter (Δ_p-$^{MAX.}$) skewness of absolute gradient and the feature derived from autoregressive model (σ).

TABLE II.
CLASSIFICATION RESULTS

Classification 1		**Classification 2**		**Classification 3**	
Classification feature set	Overall clasification error [%]	Classification feature set	Overall clasification error [%]	Classification feature set	Overall clasification error [%]
CFS 1	5.5	CFS 8	5.8	CFS 2	3.8
CFS 2	5.5	CFS 16	6.9	CFS 1	4.4
CFS 8	7.0	CFS 7	9.3	CFS 3	4.9

Classification 3	3.8	4.7	(5, 5) Contrast Δ_p^{SUM} S(1, 0) Difference Variance skewness of absolute gradient

V. CONCLUSIONS

The aims of the presented study were twofold: (i) to test the usefulness of the selected textural parameters as classification features of panchromatic VHR satellite images and (ii) to compare the efficiency of the multifractal parameters (which we propose for more complete description of the texture of remote sensing images) and other textural features in the context of land cover classification. The present study of EROS A satellite images was a continuation of the research done previously for WorldView2 data [7]. Some results confirmed, but partially the results of this research differ from the earlier ones.

In both studies we prove that for VHR satellite images it is possible to use the textural features as efficient global descriptors of image content. The observed in this study increase in classification accuracy when textural features are supplemented by histogram-based ones was also present in the results of our earlier experiments [6], [7]. Similarly, we noticed earlier the possibility of successful reduction of classification features. It is worth noting, that in both our experiments we were able to reduce the number of classification features from 295 to 3 or 4 with very limited (or even negli-

gible) impact on the overall classification accuracy. This is very important, as calculating of textural parameters for VHR satellite images is very computationally expensive.

When comparing the classification efficiency of different groups of textural parameters, in the present study the best results were obtained for absolute gradient-based features. In the WorldView2 experiment done previously the best accuracy was achieved for multifractal parameters. It is interesting that in the case of the absolute gradient group the level of error obtained in both research is quite similar and for other kinds of textural features the errors are much higher for EROS A classification. In our opinion there are at least two possible sources of such results and much lower value of classification accuracy achieved for EROS A images in general (96.2% comparing to 99.6% for WorldView2).

First of all, the differences are present in the input images themselves. The WorldView2 images have higher spatial resolution (0.5 vs. 2.0 m) and are considered as better radiometrically. The higher level of noise potentially present in EROS A data may deteriorate the quality of textural measures derived from images. It is possible that absolute gradient-based features are less sensitive to the noise present in the imagery.

The second source of differences in the results may be in a different image content. In case of WorldView2 data used in previous experiment, the images were almost entirely (at least in 90%) covered by single land cover class. In present study the EROS A images were labeled based on the prevailing land cover category defined as covering over 50% of imaged area. This could result in much higher complexity of image content, and in turn, in lower classification accuracies.

Both possibilities should be taken into account during further research. Some noise may be added to WorldView2 images, as well as more homogenous EROS A images (or WV2 images of the areas having more complex land cover) may be used.

Presented research prove that for VHR satellite images multifractal parameters should be considered as valuable textural features. Based on this features the second-best classification result was obtained in the one of the three performed tests. For two other tests the multifractal feature (Δ_p^{SUM}) was in the set of the four winnowed attributes, enabling very efficient classification approach. It should be stressed that similar result was obtained also in previous WorldView2 experiment. In both cases, the very limited (and very efficient) sets of textural parameters were chosen by winnowing, containing the multifractal parameter (although not the same one) and the skewness of absolute gradient feature. However, the importance of these parameters for classification of VHR satellite images indicated in reported studies should be proven during further research extended for other VHR satellite sensors and images of different areas.

***Abstract*—The formalization of fuzzy sets in terms of corresponding membership functions is already available in machine-verified mathematical knowledge base. We show how it can be extended to provide the development of fuzzy numbers fully benefitting from the existing framework. The flexibility which is offered by automated proof-assistants allowed us to overcome some initial difficulties. Although fuzziness stems from the same background as rough set theory, i.e. incomplete or imprecise information, both formal approaches are substantially different.**

I. Introduction

DURING the past decades, mathematics would evolve from the pen-and-paper model in the direction of use of computers. As fuzzy set theory proposed by Zadeh offered new mathematical insight for the real data in the world of uncertain or incomplete information, dealing mainly with those contained in digital archives, it is not surprising that similar methods will be used in order to obtain the properties of objects within the theory itself. The original approach to fuzzy numbers met some criticism and various ways of improvement were offered as yet. But usually computers serve as an assistant offering calculations – why not to benefit from their more artificial intelligence strength? We try to address some issues concerned with the digitization of this specific fragment of fuzzy set theory, representing a path to fuzzy numbers, so it can be considered as a case study in a knowledge management, being a work on fuzzy sets in the same time.

The paper is organized as follows. The next section is devoted specifically to the situation in the area of computer-checked formalization of mathematics and contains a brief primer to formal fuzzy sets; in the third we gave an example of the proof to show how it looks like; fourth is devoted to the connection of our work with classical and the rough set theory. The other two sections explain specific issues we met during our work while the final brings some concluding remarks and the plans for future work.

II. A Formal Primer of Fuzzy Sets

We were surprised that within the rough set theory the notion of a rough set is not formally chosen as unique. On the one hand, it is a class of abstraction with respect to the rough equality, on the other – the pair of approximation operators. As both theories have much in common, we expected the same from fuzzy sets. But – the membership function itself can be just treated as a fuzzy set. Obviously, there is something unclear with the domain vs. support of a function (as what we call 'fuzzy sets' in fact is a fuzzy subset), but it is not that dangerous. As the author developed the formalization of rough sets, he could make the decision of how much of the existing apparatus should be used also in this case. Eventually all relational structure framework [3] was dropped as completely useless here. We could take the Cartesian product of the original set and the corresponding function, but it is enough to deal only with the latter one.

"Computer certification" is a relatively new term describing the process of the formalization via rewriting the text in a specific manner, usually in a rigorous language. Now this idea, although rather old (taking Peano, Whitehead and Russell as protagonists), gradually obtains a new life. As the tools evolved, the new paradigm was established: computers can potentially serve as a kind of oracle to check if the text is really correct. And then, the formalization is not *l'art pour l'art,* but it extends perspectives of knowledge reusing. The problem with computer-driven formalization is that it draws the attention of researchers somewhere at the intersection of mathematics and computer science, and if the complexity of the tools will be too high, only software engineers will be attracted and all the usefulness for an ordinary mathematician will be lost. But here, at this border, where there are the origins of MKM – Mathematical Knowledge Management, the place of fuzzy sets can be also. To give more or less formal definition, according to Wiedijk [9], *the formalization* can be seen presently as "the translation into a formal (i.e. rigorous) language so computers check this for correctness."

In this era of digital information anyone is free to choose his own way; to quote V. Voevodsky, Fields Medal winner's words: "Eventually I became convinced that the most interesting and important directions in current mathematics are the ones related to the transition into a new era which will be characterized by the widespread use of automated tools for proof construction and verification". If we take into account famous Four Colour Theorem, automated tools can really enable making some significant part of proofs, so hard to discuss with this opinion.

Among many available systems which serve as a proof-assistant we have chosen Mizar. The Mizar system [4] consists of three parts – the formal language, the software, and the database. The latter, called Mizar Mathematical Library (MML for short) established in 1989 is considered one of the largest repositories of computer checked mathematical knowledge. The basic item in the MML is called a Mizar article. It reflects roughly a structure of an ordinary paper, being considered at two main layers – the declarative one, where definitions and

978-83-60810-53-8/$25.00

theorems are stated and the other one – proofs. Naturally, although the latter is the larger, the earlier needs some additional care.

As lattice theory and functional analysis are the most developed disciplines within the MML, further codification of fuzzy numbers, including their lattice-theoretic flavour, looks very promising. As a by-product, apart of readability of the Mizar language, also presentation of the source which is accessible by ordinary mathematicians and pure HTML form with clickable links to notions and theorems are available after the acceptance of the development into the library. As far as we know, this is the first attempt to formalize fuzzy sets in such extent using any popular computerized proof assistant.

Recall that a fuzzy set A over a universe X is a set defined as

$$A = \{(x, \mu_A) : x \in X\},$$

where $\mu_A \in [0, 1]$ is membership degree of x in A. Because the notions in the MML make a natural hierarchy (as the base set theory is Tarski-Grothendieck, which is close to ordinary Zermelo-Fraenkel axiomatics, accepted by most mathematicians): functions $\rightarrow$ relations = subsets of Cartesian product $\rightarrow$ sets, so it is a relation. Zadeh's approach assumes furthermore that μ_A is a function, extending a characteristic function χ_A. So, for arbitrary point x of the set A, the pair (x, μ_A) can be replaced just by the value of the membership function $\mu_A(x)$, which is in fact, formally speaking, the pair under consideration. Then all operations can be viewed as operations on functions, which appeared to be pretty natural in the set-theoretic background taken in the MML as the base. All basic formalized definitions and theorems can be tracked under the address http://mizar.org.

```
definition let C be non empty set;
  mode Membership_Func of C is
    [.0,1.]-valued Function of C,REAL;
end;
```

The aforementioned definition introduces membership function just as a function from given non-empty set into a subset of the set of all real numbers, and the values belong to the unit interval. Of course, `Membership_Func` is not uniquely determined for C – the keyword `mode` starts the shorthand for a type in Mizar, that is, in fact C variable can be read from the corresponding function rather than vice versa.

```
definition let C be non empty set;
  mode FuzzySet of C is Membership_Func of C;
end;
```

We collected translations of selected formalized notions in Table I. As we can read from this table, there are standard operations of fuzzy sets available, usually taken componentwise (note that `F.x` stands for the value of the function F on an argument x). Note that the Mizar repository extensively uses a difference between functions and partial functions; (`Function of X, Y` and `PartFunc of X, Y` in Mizar formalism); because in case of partial functions only the inclusion of the domain in the set X is required, hence the earlier type expands to the latter automatically.

TABLE I
FORMALIZED NOTIONS AND THEIR FORMAL TRANSLATIONS

The notion	Formal counterpart
the membership function	`Membership_Func of C`
fuzzy set	`FuzzySet of C`
$\chi_A(x)$	`chi(A,X).x`
α-set	`alpha-set C`
supp C	`support C`
$F \cap G$	`min (F,G)`
$F \cup G$	`max (F,G)`
cF	`1_minus F`

III. AN ILLUSTRATIVE EXAMPLE OF THE PROOF

In this section we focus on the example of formalized theorem about level sets. Before we start, we explain some plain ASCII symbols which will be used as all Mizar articles have the limitation of using only this narrow set of codes (but automated translation enables to use ordinary mathematical notations, usually based on LaTeX). `>=` stands for $\geq$, `c=` is set-theoretic inclusion, `"` means counterimage or the converse of the relation (including function); `in` stands for $\in$. Of course, `[.a,b.]` is a interval of real numbers a and b. `dom` denotes a domain of a function [4]. It appeared to be pretty feasible, because we could formalize natural properties in a rather compact way, as shown below [2]:

```
definition let C be non empty set;
           let F be FuzzySet of C;
           let a be Real;
  func a-cut F -> Subset of C equals
    { x where x is Element of C : F.x >= a };
end;
```

One can easily notice near one-to-one correspondence with the well-known definition of α-cuts (or level sets):

$$A_\alpha = \{x \in X : \mu_A(x) \geq \alpha\}$$

As it is the counterimage of the interval $[\alpha, 1]$, we can prove the following theorem:

```
theorem AlphaCut1:
  for F being FuzzySet of C,
      alpha being Real holds
    alpha-cut F = F " ([. alpha, 1 .])
  proof
    let F be FuzzySet of C,
        alpha be Real;
    thus alpha-cut F c= F " ([. alpha, 1 .])
    proof
      let x be element;
      assume x in alpha-cut F; then
      consider y being Element of C such that
A1:   x = y & F.y >= alpha;
      x in C by A1; then
A2:   x in dom F by FUNCT_2:def 1; then
      F.y in [. 0, 1 .] by A1,PARTFUN1:4; then
      0 <= F.y & F.y <= 1 by XXREAL_1:1; then
      F.y in [. alpha, 1 .] by XXREAL_1:1,A1;
      hence thesis by A1,FUNCT_1:def 7,A2;
    end;
    :: the other inclusion omitted
  end;
```

IV. Rough and Fuzzy Formal Approaches

In the usual informal mathematical jargon it is easy to say that e.g., two objects are identical up to the isomorphism, formal language has to deal somehow with it. In the fuzzy set theory this can be noticed at the very beginning – some people treat fuzzy sets as the pair of the set and corresponding membership function. Fuzzy sets are subsets of ordinary sets; as we can take membership function just as χ of ordinary sets, it clearly shows the feasibility of this approach. Of course, it is impossible then, at least without any additional preparing work, to find the common bottom ground for ordinary sets and fuzzy sets; however all sets can be made fuzzy in view of the simple lemma cited below:

```
theorem
  for C being non empty set holds
    chi(C,C) is FuzzySet of C;
```

Although two widely-known views (rough and fuzzy approaches) for incomplete or imprecise information have much in common in principle, there are essential differences between both of them [10]. In fuzzy sets, every element has its own membership measure. In rough approach, the degree of membership is rather calculated from the set as a whole, so it is pretty close to Bayes' probability theory, as we quote this below.

```
definition let A be finite Tolerance_Space;
           let X be Subset of A;
  func MemberFunc (X, A) ->
    Function of the carrier of A, REAL means
  for x being Element of A holds  it.x =
  card (X /\ Class (the InternalRel of A,x)) /
    (card Class (the InternalRel of A,x));
end;
```

Paradoxically, even the notion of the rough set was defined in two ways, as pairs of the lower and the upper approximations of a set (in the sense of Iwiński), and as classes of abstraction with respect to given reflexive, symmetric, and transitive binary relation (original Pawlak's approach). MML reflects both approaches, concentrating on the properties of approximation operators and various types of binary relations generalizing equivalence relations.

V. Some "Easy" Problems

Virtually any mathematician uses a formal language; as engineers have also a higher math course in his curriculum, it shouldn't be a big problem to validate facts formally. But if we claim the proof is correct, some natural questions arise: the correctness with respect to which assumptions? What about foundations? If it comes to machine, what are properties of the checker? The original de Bruijn's dream was to have a small checker with the transparent kernel. Most of contemporary proof assistants are rather far from this requirement. Although a theorem can look easy, formal mathematics can bring some unpredictable problems; it is enough to mention e.g. Kepler's conjecture about the densest sphere packing (a part of Hilbert's 18th problem) or Jordan curve theorem that any simple closed curve cuts the plane into two disjoint areas. Intuitively, they are nearly trivial and understandable virtually for any human being. However, even at the very foundational level of used logic (constructive proofs do not claim the law of excluded middle) we can find some unexpected difficulties. Especially important example in our fuzzy context is the so-called glueing lemma – the proof of a simple fact about pasting some continuous functions together to make e.g. triangular (or trapezoidal) fuzzy set, intuitively trivial, draws some surprising dependencies.

It is rather hard to approximate the real complexity of a proof; one of the most popular measures is the de Bruijn factor, i.e. the ratio between the formal translation of the mathematical paper and the original (usually after packing the source and corresponding LaTeX file). Although it is claimed to be about 4 in the case of the Mizar library, in our case is about six (i.e. formal proofs are six times longer than their informal counterparts). Such relatively high number is caused by technical calculations in the process of glueing continuous functions.

VI. Towards Fuzzy Numbers

As all Mizar types should have non-empty denotation, it would force us to define both triangular and trapezoidal fuzzy sets. The natural definition is usually written as conditional definition of parts of the function. We used intervals `[.a,b.]` and `AffineMaps` to save some work (e.g., affine maps are proven to be continuous, one-to-one, and monotone real maps under underlying assumptions). The operator `+*` glues two functions if their domains are disjoint; if not, then the ordering of glueing counts.

```
definition let a,b,c be Real;
  assume a < b & b < c;
  func TriangularFS (a,b,c) -> FuzzySet of REAL
    equals
    AffineMap (0,0)
   +* (AffineMap (1/(b-a),-a/(b-a)) | [.a,b.])
   +* (AffineMap (-1/(c-b),c/(c-b)) | ].b,c.]);
end;
```

The assumptions on the ordering of real variables a, b, c are unnecessary here and will be removed; we kept this as needed to prove the continuity of this fuzzy set afterwards. It is worth mentioning here that the proof of correctness of the above definition is 40 lines long – surprisingly long comparing to the popular (of course, false) opinion that definitions don't need proofs. Continuity of this triangular fuzzy set needed much more lines in our Mizar script (90 lines in case of one-point glueing).

Remembering that a fuzzy number is a convex, normalized fuzzy set on the real line $\mathbb{R}$, with exactly one $x \in \mathbb{R}$ such that $\mu_A(x) = 1$ and μ_A is at least segmentally continuous, we defined it as the Mizar type:

```
  mode FuzzyNumber is f-convex continuous
    strictly-normalized FuzzySet of REAL;
```

As all types are constructed as radix types with added optional adjectives, the generalization, especially that automated-

driven (by cutting the adjectives in the assumptions), is possible and quite frequently used. Some of the adjectives are a little bit stronger that others, with the quoted below as example:

```
definition let C be non empty set;
           let F be FuzzySet of C;
  attr F is strictly-normalized means :SNDef:
    ex x being Element of C st
    F.x = 1  &  for y being Element of C st
      F.y = 1 holds y = x;
end;
```

Observe that this adjective means that a fuzzy set is also normalized in normal sense. Due to automatic clustering of attributes after *registering* this quite natural and easy property any additional reference won't be needed.

```
registration let C be non empty set;
  cluster strictly-normalized ->
    normalized for FuzzySet of C;
end;
```

In our opinion, we made some significant progress on the certification of fuzzy sets and numbers, but our primary aim was to get the formal net of notions correct and reusable and we hope to benefit from it in our future work.

VII. Conclusion and Further Work

The primary aim of using computers in the process of the formalization was to provide its undoubtful correctness. One can argue however that also careful human review should do the same work. The famous exception is the publication of the proof of the Kepler conjecture by Hales in "Annals of Mathematics"; referees cannot be fully sure of the correctness of computer programs and tedious, extremely long computer-driven calculations. But things are different when it comes to program themselves; hardly readable, looking like computer code, proof of Four Color Theorem is verified formally; it sheds some new light for the verification of program libraries – e.g. there is significant progress made with the computer certification of Java or C libraries or even compilers themselves. But here readability is of minor interest; also proofs and the content itself are rather routine. Once the topic is formalized in the machine-understandable language, automated provers can be applied to obtain new results automatically. Based on computer-certified content, further automatic semantical investigations can be made [5], as, for example, extracting lemmas, annotating technical proofs or investigating direct corollaries, automated translation, and fast unification. Furthermore, MML is a subject of continuous changes called *revisions* which can be the result of software upgrades, generalizations, theory merging, introducing new language constructions etc. Also the original first formal approach for fuzzy sets which is dated back to 2001 [6], was thoroughly revised by the author to improve its reuse (e.g., a fuzzy set was primarily defined as the Cartesian product of the set C and the image of the membership function applied to C).

Computer certification of proofs seems to be an emerging trend and some corresponding issues can be raised. We are assured that there are some visible pros of our approach, as for example, automated removal of repetitions, and also the need of writing a sort of preliminary section vanishes in the Mizar code. The type system enables us to search for possible generalizations (including a kind of reverse mathematics at the very end); the use of automated knowledge discovery tools is much easier due to internal information exchange format, which at the same time offers direct translations for a number of formats (e.g, close to the English-like human-oriented language), not limited to the Mizar source code. There are of course drawbacks we should remember of: first of all, the syntax. The Mizar language, although pretty close to natural language, is still an artificial language. Of course, main problem with the formalization is making proper formal background – lemmas and theorems – which can be really time-consuming, hence the stress on reusability of available knowledge.

We argue that the formalization itself can be very fruitful and creative as long as it extends the horizons of the research and make new results possible. Furthermore, the more the database larger is, the formalization can be more feasible. Even if the formalized content concerning fuzzy sets is not that big as of now (there is only about 9000 lines of Mizar code on fuzzy sets comparing with 2.5 million of lines in the whole MML), the basics are already done, and it can serve both as a good starting point for further development, including rough-fuzzy hybridization, as well as from translated existing content we can try to obtain new results. Regardless of the gains of the availability of the topic to majority of popular proof assistants one can ask a question of assurance of the correctness of the proofs; Urban's [8] tools translating Mizar language into the input of first-order theorem-provers or XML interface providing information exchange between various math-assistants are already in use, so not only proof-checkers other than the Mizar verifier can analyze it, but additionally it can allow for some "dirty work" to be done by computer.

***Abstract*—Truly, heart is successor to the brain in being the most significant vital organ in the body of a human. Heart, being a magnificent pump, has his performance orchestrated via a group of valves and highly sophisticated neural control. While the kinetics of the heart is accompanied by sound production, sound waves produced, by the heart, are reliable diagnostic tools to check heart activity. Chronologically, several data sets have been put forward to sneak on the heart performance and lead to medical intervention whenever necessary. The heart sounds data set, utilized in this paper, provides researchers with abundance of sound signals that was classified using different classification algorithms; decision tree, rotation forest, random forest are few to mention. This paper proposes an approach based on local transfer function classifier as a new model of neural networks for heart valve diseases detection. In order to achieve this objective, and to increase the efficiency of the predication model, boolean reasoning discretization algorithm is introduced to discretion the heart signal data set, then the rough set reduction technique is applied to find all reducts of the data which contains the minimal subset of attributes that are associated with a class label for classification. Then, the rough sets dependency rules are generated directly from all generated reducts. Rough confusion matrix is used to evaluate the performance of the predicted reducts and classes. Finally, a local transfer function classifier was employed to evaluate the ability of the selected descriptors for discrimination whether they represent healthy or unhealthy. The experimental results obtained, show that the overall accuracy offered by the employed local transfer function classifier was high compared with other techniques including decision table, rotation forest, random forest, and NBtree.**

I. Introduction

HEART sounds automated diagnosis in recent years became very important to determine condition of the patient (healthy or unhealthy) and determine type of the disease (valvular disease or not), since heart diseases are identified by sounds produced by the heart [1], [9]. Most of heart valve diseases have an effect on the heart sound of patients [2]. Operation of auscultation of heart sounds by the Stethoscope require a professional person to recognize the sounds then detect whether the subject is patient or not and also can detect the type of the heart disease in patients [3], [5]. Junior physicians can't easy detect type of heart disease from the it sound. Using artificial intelligent tools for remote classification of heart sound signal is a useful technique to avoid the needing to the experience physician and expensive equipments such as Echocardiography (ECG), Magnetic Resonance Imaging, (MRI), etc., which used to recognize heart diseases in accurate manner than heart auscultation. In [1] a different classification algorithms using support vector machine (SVM) with different parameters have been applied to find the best classification accuracy. But due to the high number of features, $100 features$, the classification accuracy could be enhanced if irrelevant and noisy features are removed. Discretization or feature selection or both should be prior the classification operation by most of the classification techniques which could lowers the classification performance and accuracy under many conditions [4]. The discretization method should be a supervised manner to satisfy nature of the classification problem, then feature selection method should be applied after the discretization, that demonstrates the dependence on such method for producing an appropriate results, the successful performance of the two pre-processing steps mean successful classification results. Finally a classification technique should be applied to perform the class label, disease type, prediction. Every classification technique has its own strong and weak points [5]. The most important preprocessing step is the feature reduction of the input data set. The data set contain features that are considered as noisy or irrelevant features, these features could have a negative impact on the classification accuracy of the instances, patients. Feature reduction methods are either feature extraction or feature selection method. Feature extraction method applies operation on the original features and extracts a lower number of features that carries the same characteristics. Feature selection methods has two advantages, the first advantage is rank and select the most important features, where if only a subset of features with the highest rank are used in classification, high classification accuracy could be achieved. The extracted heart sound data are three different data sets, each of 100 features where they are slitted into six different parts. The first data set is required to classify

978-83-60810-53-8/$25.00

whether the heart of the patients are normal or not. The second and third data set are required for the detection of the heart valve disease. The heart valve diseases under investigation in this paper are aortic stenosis *AS*, aortic regurgitation *AR*, mitral stenosis *MS* and mitral regurgitation *MR*. This disease classification is performed in two steps where the first step is applied on the second data set for determining the type of the systolic murmur which means *AS* or *MR*, and the second step is applied on the third data set of a diastolic murmur diseases which means *AR* or *MS*. The second advantage of feature selection method is to determine which stage of the heart sound could have the greatest indication to heart valve disease in the case of each murmur type. The four stages of a heart sound are the first heart signal *S*1, the systolic period, the second heart signal and the diastolic period [1].

This paper proposes an approach based on local transfer function classifier as a new model of neural networks for heart valve diseases detection. In order to achieve a good detection, and to increase the efficiency of the predication model, boolean reasoning discretization algorithm is introduced to discretion the heart signal data set, then the rough set reduction technique is applied to find all reducts of the data which contains the minimal subset of attributes that are associated with a class label for classification. Then, the rough sets dependency rules are generated directly from all generated reducts. Rough confusion matrix is used to evaluate the performance of the predicted reducts and classes. Finally, a local transfer function classifier was employed to evaluate the ability of the selected descriptors for discrimination whether they represent healthy or unhealthy.

The rest of this paper is structured as follows: Section II gives a brief introduction of the heart signals data collection and its characteristics. Section III shows an overview of rough set approach to features selection and reduction methods. The proposed approach is given in section IV. The experimental results and conclusions are presented in Section V and VI respectively.

II. Heart sound signals Data Set and its features

A lot of researches have been applied on heart sound for the detection of heart valve disease. Features are extracted from the heart sound signal into a data set that is composed of 100 features. Then, a classification algorithm is applied on such data set for detection of heart valve disease. Features are extracted in three phases, segmentation [6] [7], transformation and extraction. These extracted features represent the four stages of a heart signal which are *S*1 signal, systolic period, *S*2 signal and diastolic period as shown in figure 1. These features are divided into six groups as follows: (1) **att0:att3** are the standard deviation of all heart sounds, *S*1, *S*2 and average heart rate; (2) **att4:att11** represents signal *S*1; (3) **att12:att35** represents the systolic period; (4) **att36:att43** represents signal *S*2; (5) **att44:att91** represents the diastolic period, and (6) **att92:att99** the four stages of a heart signals are passed from four band-pass frequency filters. The energy of each output is calculated to form these last 8 features.

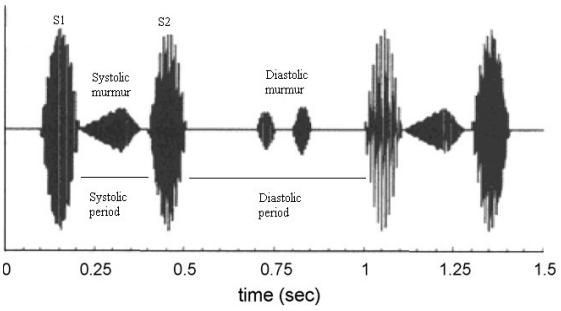

Fig. 1. Heart signal: systolic period and diastolic period [1]

III. Preliminaries

This section provides a brief explanation of the basic framework of rough sets and local transfer function neural network classifier, along with some of the key basic concepts.

A. Rough sets

Rough set theory [17], [16], [15], [14] is a fairly new intelligent technique for managing uncertainty that has can be used for the discovery of data dependencies, evaluation of the importance of attributes, discovery of patterns in data, reduction of attributes, and the extraction of rules from databases. Such rules have the potential to reveal new patterns in the data and can also collectively function as a classifier for unseen data sets. Unlike other computational intelligence techniques, rough set analysis requires no external parameters and uses only the information present in the given data. One of the interesting features of rough sets theory is that it can tell whether the data is complete or not based on the data itself. If the data is incomplete, it suggests more information about the objects to be collected in order to build a good classification model. On the other hand, if the data is complete, rough sets can determine the minimum data needed for classification. This property of rough sets is important for applications where domain knowledge is limited or data collection is very expensive/laborious because it makes sure the data collected is just good enough to build a good classification model without sacrificing the accuracy of the classification model or wasting time and effort to gather extra information about the objects [17], [16], [15], [14].

In rough set theory, data is collected in a table, called a decision table (DT). Rows of the decision table correspond to objects, and columns correspond to attributes. In the data set, we assume that the set of examples with a class label to indicate the class to which each example belongs are given. We call the class label the decision attributes, and the rest of the attributes the condition attributes. Rough sets theory defines three regions based on the equivalent classes induced by the attribute values: *lower approximation*, *upper approximation* and *boundary*. Lower approximation contains all the objects, which are classified surely based on the data collected, and upper approximation contains all the objects which can be classified probably, while the boundary is the difference between the

upper approximation and the lower approximation. So, we can define a rough set as any set defined through its lower and upper approximations. On the other hand, indiscernibility notion is fundamental to rough sets theory. Informally, two objects in a decision table are indiscernible if one cannot distinguish between them on the basis of a given set of attributes. Hence, indiscernibility is a function of the set of attributes under consideration. For each set of attributes we can thus define a binary indiscernibility relation, which is a collection of pairs of objects that are indiscernible to each other. An indiscernibility relation partitions the set of cases or objects into a number of equivalence classes. An equivalence class of a particular object is simply the collection of objects that are indiscernible to the object in question.

B. Local transfer function neural network classifier

A new model based on artificial neural network, called Local transfer function classifier produces encouraging results for many data sets, it is virtually the same architecture as Radial Basis Function Neural Network (RBFNN), its used in supervised learning [13].

Let the training set be composed of N pairs of the form: $(X^{(i)}, c^{(i)})$, where $X^{(i)} = \left[x_1^{(i)}, x_2^{(i)}, ..., x_n^{(i)}\right]$ is the i-th input pattern belonging to the $c^{(i)}$-th class $(c^{(i)} = 1, 2, ..., k)$. Vectors $X^{(i)}$ can be treated as points in the n-dimensional space X. Close neighborhood of the point $X^{(i)}$ should belong to the same class as $X^{(i)}$, therefore the space X can be divided into finite number of *decision regions*-areas of the same value of classification.

IV. THE PROPOSED HEART VALVE DISEASES ANALYSIS

One way to construct a simple model computed from data, easier to understand and having good predictive power, is to create a set of minimal number of rules. Some condition values may be unnecessary in a decision rule produced directly from the data set. Such values can then be eliminated to create a more comprehensible minimal rule preserving essential information. The proposed heart valve diseases detection approach is comprised of the following three fundamental building phases: (1) Pre-processing including a Discretiztion of the attributes; (2) Generate the reducts with minimal number of attributes along with significant of the attributes; (3) Rule generation for the classification: generate a list of rules, compute the overall accuracy of the generated rules; this phase utilizes the rules generated from the previous phase to predict the classification accuracy. These three phases are described in detail in the following section along with the steps involved and the characteristic features for each process. Fig. 2 illustrates the general architecture of the proposed of heart valve disease analysis.

A. Pre-processing phase: Rough Discretization process

When dealing with attributes in concept image classification, it is obvious that they may have varying degree of importance in the problem being considered, importance can be pre-assumed using auxiliary knowledge about the problem,

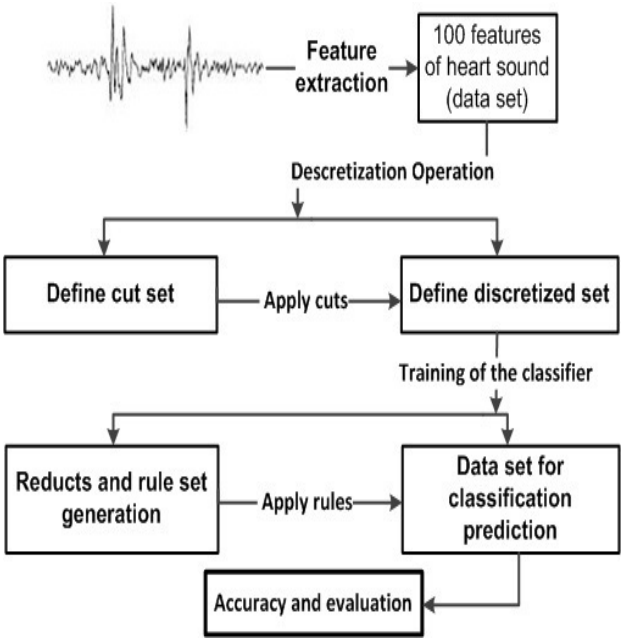

Fig. 2. The general architecture of the proposed of heart valve disease analysis

properly chosen weights. However, in the case of using the rough set approach to concept classification, it avoids any additional information aside from what is included in the information table itself. Basically, the rough set approach tries to determine from the data available in the information table whether all the attributes are of the same strength and, if not, how they differ in respect of the classifier power. Therefore, some strategies for discretization of real valued features must be used when we need to apply learning strategies for data classification (*e.g.*, equal width and equal frequency intervals). It has been shown that the quality of learning algorithm is dependent on this strategy, which has been used for real-valued data discritization [10].

Many classification algorithms such as rough set theory, require that training data contain only discretized feature values. Otherwise, too many equivalent classes will be produced and the algorithms will be over sensitive to noise. To use such an algorithm when there are numeric-valued features, all numeric values must first be converted into discrete values - a process called discretization[11]. This process is performed by dividing the values of a continuous attributes into a small number of intervals, where each interval is mapped to a discrete categorical, nominal, symbolic symbol. Discretization can significantly influence the effectiveness of a classification algorithm.

Medical data sets contains continues and discrete valued data in real world data set. The discretization process divides the attributes value into intervals[12]. The discretization based on RS and Boolean Reasoning (RSBR) shows the best results in the case of heart valve disease data set. In the discretization of a decision table $S = (U, A \bigcap \{d\})$, where U is a non-empty

finite set of objects and A is a non-empty finite set of attributes. And $V_a = [x_a, x_a)$ is an interval of real values x_a, w_a in attribute a. The required is to a partition P_a of V_a for any $a \in A$. Any partition of V_a is defined by a sequence of the so-called cuts $x_1 < x_2 < .. < x_k$ from V_a. The main steps of the RSBR discretization algorithm are provided in algorithm 1.

Algorithm 1 RSBR discretization algorithm

Input: Information system table (S) with real valued attribute A_{ij} and n is the number of intervales for each attribute.
Output: Information table (ST) with discretized real valued attribute

1: **for** $A_{ij} \in S$ **do**
2: Define a set of boolean variables as follows:

$$B = \{\sum_{i=1}^{n} C_{ai}, \sum_{i=1}^{n} C_{bi} \sum_{i=1}^{n} C_{ci}, ..., \sum_{i=1}^{n} C_{ni}\} \quad (1)$$

3: **end for**
Where $\sum_{i=1}^{n} C_{ai}$ correspond to a set of interval defined on the variables of attributes a
4: Create a new information table S_{new} by using the set of intervals C_{ai}
5: Find the minimal subset of C_{ai} that discerns all the objects in the decision class D using the following formula:

$$\Upsilon^u = \wedge\{\Phi(i,j) : d(x_i \neq d(x_j))\} \quad (2)$$

Where $\Phi(i,j)$ is the number of minimal cuts that must be used to discern two different instances x_i and x_j in the information table.

B. Reducts with minimal number of attributes process

Reduct is an important concept in rough sets theory and data reduction is a main application of rough set theory in pattern recognition and data mining. As it has been proven that finding the minimal reduct of an information system is a NP hard problem [10].

The computation of the reducts from a decision table is a way of selecting relevant features [18]. It is a global method in the sense that the resultant reducts represent the minimal sets of features which are necessary to maintain the same classification accuracy given by the original and complete set of attributes. A straight manner for selecting relevant features is to assign a measure of relevance to each attribute and choose the attributes with higher values. Based on the reduct system, we generate the list of rules that will be used for building the classifier model for the new objects. In decision tables, there often exist conditional attributes that do not provide any additional information about the objects. So, we should remove those attributes since it reduces complexity and cost of decision process [18]. A decision table may have more than one reduct. Anyone of them can be used to replace the original table. Finding all the reducts from a decision table is NP-complete. Fortunately, in applications, it is usually not necessary to find all of them. Few of them are sufficient. A natural question is, which reducts are the best. The selection depends on the optimality criterion associated with the attribute. If it is possible to assign a cost function to attributes, then the selection can be naturally based on the combined minimum cost criteria. In the absence of an attribute cost function, the only source of information to select the reduct is the content of the table.

We present a reduct algorithm based on the entropy information measure introduced in [18]. Algorithm-2 shows the main steps of the reduct algorithm.

Algorithm 2 Reduct-based on entropy algorithm

Input: Rough Sets Decision System (RSDS)
Output: One reduct of RSDS

1: $\forall a \in A$ compute the equivalence relation
2: $\phi \leftarrow reduct$;
3: **for** $a_i \in A - reduct$ **do**
4: Compute $H_i = H(a_i \mid reduct)$ {Where H_i is the information quantity of the attribute set, R is a equivalence relation matrix}

$$H = -\frac{1}{n}\sum_{i=1}^{n} log\lambda_i \quad (3)$$

$$\lambda_i = \frac{|[x_i]R|}{n} \quad (4)$$

5: **end for**
6: Compute the significance of attribute a (SIG) in attribute set A using the following equations:

$$SIG(a,A) = H(A) - H(A-a) \quad (5)$$

$$H(a|reduct) = \max(SIG(a_i, reduct)) \quad (6)$$

7: Select attribute which satisfies Equation(20)
8: **if** $H(a|reduct) > 0$ **then**
9: $reduct \cup a \longrightarrow reduct$
10: **end if**
11: Go to Step 3

C. Rule generation for the classification process

The generated reducts are used to generate decision rules. The decision rule, at its left side, is a combination of values of attributes such that the set of (almost) all objects matching this combination have the decision value given at the rule's rough side. The rule derived from reducts can be used to classify the data. The set of rules is referred to as a classifier and can be used to classify new and unseen data. The main steps of the rule generation and classification algorithm are provided in Algorithm 3 (cf. [18]).

V. Experimental results and discussions

A. The heart sound signals data set characteristics

Cardiac disorders of heart diseases in the proposed approach were applied on three different data set of cardiac disorders

Algorithm 3 Rule generation for the classification

Input: reduct sets $R_{final} = \{r_1 \cup r_2 \cup .... \cup r_n\}$
Output: Set of rules

```
for each reduct r do
    for each correspondence object x do
        Contract the decision rule (c1 = v1 ∧ c2 = v2 ∧ .... ∧ cn = vn) ⟶ d = u
        Scan the reduct r over an object x
        Construct (ci, 1 ≤ i ≤ n)
        for every c ∈ C do
            Assign the value v to the correspondence attribute a
        end for
        Construct a decision attribute d
        Assign the value u to the correspondence decision attribute d
    end for
end for
```

with different number of instances in every class. The first data set is healthy and unhealthy persons "$HS-H-U$" contains 70 instances, where 38 instances represent healthy persons and the other 32 instances represents unhealthy patients. The second data set represents 84 instances systolic diseases such that 41 instances aortic stenosis and 43 instances mitral regurgitation "$HS-AS-MR$". Finally the third data "$HS-AR-MS$" set represents 76 instances diastolic diseases, it consists of 38 instances aortic regurgitation and 38 instances mitral stenosis.

TABLE I
MINIMAL REDUCT SETS OF THE THREE DATA SETS

Data type	Reduct sets
$HS-H-U$	att0, att2, att33, att87, att93, att96
$HS-AS-MR$	att0, att2, att31, att87, att89, att99
$HS-AR-MS$	att1, att4, att12, att35, att37

Table I shows the generated reducts that contains minimal number of attributes. While Table II, III, and IV show the generated rules set of the three data sets of heart valve disease signals. As an explanation for some of rules, should be first clearing some terms, "att3" is feature of standard deviation of all heart sounds, S1, S2 and average heart rate, "att36" is feature of signal S2, "att92 and att96" are represent the four stage of the heart signal. If att36= 0.15405 and att92=0.06865 and att3=0.32355 then this patient is normal, about 16 cases match this rule. If att96=0.04485 and att3=0.32355 and att92=0.06865 then this patient is up normal, about 8 cases match this rule.

B. Results analysis and discussion

In this approach, local transfer function neural network classifier (LTF-C) has been applied on three types of heart valve murmurs data sets. It shows the highest classification results as shown by figures 3,4 and 5. The best classification in the three data sets is achieved by LTF-C classifier, comes

TABLE II
GENERATED RULES FOR THE $HS-H-U$ DATA SET

Matches	Decision rules	Class

RandomForest	78.57	78.00	76.00
RotationForest	80.00	73.00	84.00

VI. CONCLUSIONS AND FUTURE WORKS

The heart sounds data set, utilized in this paper, provides researchers with abundance of sound signals that was classified using different classification algorithms; decision tree, rotation forest, random forest are few to mention. Such algorithms were of disputable performance if compared with the classification algorithm adopted in this paper, i.e., the ”local transfer function neural network classifier (LTF-C)”. Discretization of analogue heart sounds was a preparatory step to apply LTF-C classification technique. Consequently, discretized data were classified into several domains and Rough Confusion Matrix was used to produce reducts out of them. The purpose of such data manipulation is to reach a state of subjecting features to discernability, so classes of distinct features can fuel proper decision for a cardiologist, to which class of cardiac disorder this patient belongs. Classes were meant to touch upon crucial cardiac diseases and to aid in diagnosis and prognosis as well. The LTF-C achieved a high accuracy classification compared with other machine learning techniques such as Decomposition Tree, NBTree, Decision Table, RandomForest in addition to RotationForest.

Abstract- This paper presents an approach for controlling collision avoidance among a group of moving multi-agents such that they are not able to communicate with each other and hence, cannot share information. The basics and key features of our collision control algorithm are discussed to include practical examinations. Our approach is based on multi-agent systems and help moving agents to pursue their goals using collision free routes. In terms of validating our solution, we plan to apply into a configuration set of agents located in our experimental space. We also explain our solution algorithm that we have developed, along with the examination that we subjected it to, as well as sketching some of the most important challenges that remain to be addresses in our future researches.

Keywords- Multi-agents; Moving agents; Agents collision control; Intelligent agents; Agents decision making system.

I. INTRODUCTION

In one class of mobile robotics research heralded by [1], sets of rules are used for collision avoidance. Rules correspond to sensing abilities of the mobile robots. Assuming that each robot has abilities to detect collisions and can measure the distance to a colliding robot and its velocity in the forward direction of the avoiding robot, the following two rules are used. In these rules, the robot can know the location of the colliding robot by using sensors for detecting collisions and can judge whether it is approaching or leaving by measuring its velocity. At first, the robot will attempt to apply the rules without communications. If the rules do not apply because of an environmental restriction, the robot stops and starts communicating to determine a way out of the deadlock.

(1) If the colliding robot is located in front and near and it is approaching, then avoid it from the left.

(2) If the colliding robot is located in front and near and it is departing, then stop locomotion for predetermined time duration.

When rules are not applicable, in another class of mobile robotics research, collision avoidance is a negotiated activity between pairs of robots that have potential collisions. During the message exchange of warning and its reply, priorities of each robot are reported to each other. Mobile Robot 1 detects the collision, and after it takes into account the priorities, it determines if it is reasonable for robot 1 to avoid collision due to high priority. If robot 2 detects the collision, reverse processes are executed. If the priority of robot 2 is found to be higher than robot 1 as a result of negotiation, robot 1 sends to robot 2 a declaration to proceed instead of a command to wait for robot 1. Then, robot 2 moves to avoid collision and sends a command to restart to robot1. Alternatively, the coordination algorithm is useful when groups of robots move in opposite directions and while navigating or when a specific region is a target for many robots, in particular [9]. The main goal in the coordination algorithm is that it forces robots to wait while the other robots continue to move to their target, and then allows the remaining robots to move. Consequently, with this coordination, the congestion problem will be decreased, and at the same time, the percentage of reaching robots to their target will be increased. We used a version of this priority scheme in an earlier paper [6].
There have been several attempts to use human behavior as inspiration. Human inspired methodology is summarized in the following three steps [8].

(1) Keep your direction and velocity of motion if there is minor possibility of a collision.

(2) Else, if a major possibility of a collision exists, and there are no ways to manoeuver around it; then, stop to let the other person to continue to move in their direction and velocity,

(3) Else, if a possibility of a collision exists, and there is a way to manoeuver around it; then Change your direction of movement with slightly changing speed to around the other person, and joining back to your original path of motion.

The strategy proposed in this paper is also largely human inspired and it can be applied to robots in crowded environments. We begin by an outline of conditions and premises in section 2. We then examine a magnified scenario of encounters between a pair of individuals in collision sites in section 3. Spiral orbits as a strategy for collision aversion is discussed in section 4. Experimental results are discussed in section 5 followed by conclusions in section 6.

II. CONDITIONS AND PREMISES

There are several terms and conditions that need to be considered in regards to developing a suitable strategy that is able to avert collisions among multiple moving agents as they move toward their goals located in a site. There are two entities available on our two dimensional space; agents and goals.

Below, we outline the most important features that are directly and indirectly pertinent for elaborating our solution.

(1) Agents can be located at arbitrary position on our feasible two dimensional spaces. There are limitations on their numbers; however, the total number of agents at any cycle of experiment will not exceed the total number of goals. Our experimental space, has the following default criteria: $EC = \{EC_1, EC_2, \dots, EC_i\}$, $EC_i = \{A_i, G_j\}, A_i = \{a_1, a_2, \dots, a_i\}, G_j = \{g_1, g_2, \dots, g_j\}, \{\forall(i,j) \in \mathbb{N} \mid (i \in A, j \in G) : i \geq j\}$, where EC, A_i and G_j present experimental cycles, agents and goal respectively.

(2) There is a one to one correspondence between agent groups and the goal collection, which means that each goal will be assigned to a unique, single agent. As a matter of course, each agent maintains its goal during cycles of experimentation. This is captures in the mapping$f: X \to Y$,
where set X indicates the agent set and Y represents the goal set; $f(A_i) = G_i$.

(3) Each agent starts moving at any time during the experiment. $T = \{\Delta t_{a_1}, \Delta t_{a_2}, \dots, \Delta t_{a_i}\}$; $\forall(\Delta t_{a_{i-1}}, \Delta t_{a_i}) \in T, \Delta t_{a_{i-1}} \neq \Delta t_{a_i}$, where Δt_{a_i} , is the start time for a_i. In other words, there is no common time for each agent to start moving toward its goal within experiment cycles.

(4) All agents are assumed to have the same uniform size and shape as pointed out in many other sources such as [2], [5], [11].

(5) Each agent has its own distinctive communication protocol; however they are all use the same collision control method to handle collision sites, if occurred. As a matter of fact, as opposed to those who employ a method of communications among multiple moving agents for their verifications, such as [2], [5], we assumed that agents do not have any connection to each other and hence are not able to disseminate information among themselves during a period of experiment.

(6) Moving toward goals is not necessarily bounded on a straight path, which means, each agent is able to select a route with any speed based on the situation.

(7) Goals can be located at any arbitrary location in two-dimensional space; however, they cannot be relocated and changed their positions during each cycle of an experiment. Agents know their exact location as well as their goal locations; $a_i = \{c_{(x,y)_i}, g_{(x',y')_i}\}$ where $c_{(x,y)_i}$is the coordinate of the agent and $g_{(x',y')_i}$ is the coordinate of the goal location. Each agent is capable of calculating its location and also its corresponding goal location at any needed time during each experimental cycle. An effectual way to achieve this goal is to equip agents with a vision sensor device which is already demonstrated in former publications such as optical motion planning mapping in [7], [10], or motion sensor themselves that are presented in [4], [3] and [12].

III. COLLISION SITE

Each agent is able to recognize a limit site (i.e., a region) located in front of its vision sensor, which is computed by $vs = \int_0^\theta \int_0^r dS = \int_0^\theta \int_0^r \tilde{r} d\tilde{r} d\tilde{\theta} = \int_0^\theta \frac{1}{2} r^2 \theta$, and based on that, it decides and determines the best possible path toward its goal at any time. In this formula, r and θ denote maximum vision depth and vision range angle for each agent vision sensor, respectively. We define a collision site form, if an agent detects another agent in its vision site range. In such situations, orientations of those agents participating to form collision sites are not taken into account. Figure 1 shows a prototypical collision site.

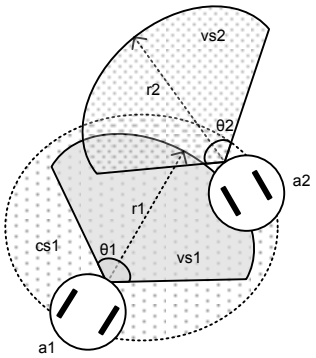

Fig 1. a_1 detects a_2 on its vision site (vs_1), and hence collision site (cs_1) is formed

All agents that are forming such collision sites will use our solution as a potential collision control strategy to enter and exit those sites. The process of handling a collision site consists of two phases. The first phase is forming a distance set $cs_i = \{D_j a_{j(x,y)_j}, D_k a_{k(x,y)_k}, \dots\}$, where $D_j a_{j(x,y)_j}$, indicates distance between a_j and a_i. The second phase is to form the smallest circular area that contains the agent that has the nearest distance from a_i where both agents located on the perimeter of it. For instance, a_i, forms $(x-l)^2 + (y-k)^2 = r^2$, where x, y, l, k, and r, are coordinates for a_i and a_j respectively, if $\forall(a_j, a_k) \in cs_i$, $D_j a_{j(x,y)_j} < D_k a_{k(x,y)_k}$. a_i, then starts moving toward a temporary expansion spiral route computed by $r = pe^{q\theta}$, where e indicates the base of natural logarithms, and p and q are parametric positive real constant values respectively, as polar coordinates, (r, θ), shown as $\overrightarrow{VR_1}$ route, in Figure 2, around a virtual collision site circle formed by a_i and a_j. We present our general path finder solution along with relative formulas in next section.

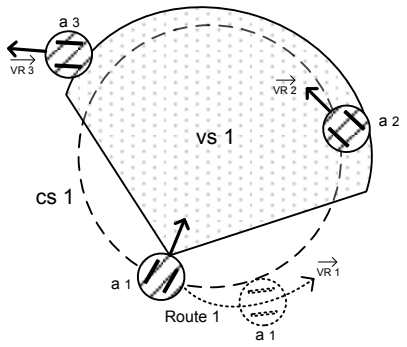

Fig 2. Collision site formed between a_1, a_2, and a_3, once a_1 detected a_2, and a_3 on its vision site. a_1 hence, starts moving on $\overrightarrow{VR_1}$ route

IV. COLLISION AVOIDENCE USING VIRTUAL EXPANSION SPIRAL ORBIT SOLUTION

In this paper, we concentrated on developing a strategy, which is capable of preventing a group of agents to strike each other while moving toward their goals. In order to achieve our objective, we developed an algorithm that each agent in our experimental space uses to determine the safest, short route at each decision making cycle. This consists of two general strategies that will be used in each presumed situation. The path finder algorithm determines a straight line connecting path as the shortest route toward agent goal during the times that agent is not causing or participating in formation of collision sites. The algorithm, however, will determine an expanding spiral path as a temporary route when the agent is still located in the collision site, in terms of preventing potential collisions among moving agents in our two dimensional space. Robots follow those temporary routes until exiting from those collision sites successfully. By analogy, this is a virtual, pivoting dance step between two agents in the collision sites. State diagram in Figure 3 demonstrates general strategies that we used in our route finder algorithm solution.

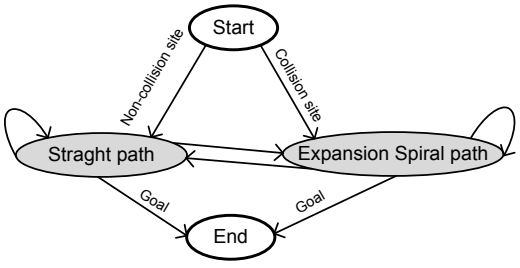

Fig 3. State graph of our path finder solution

Our path finder algorithm including collision avoidance solution inside is shown in Algorithm 1.

Algorithm 1. Path finder algorithm

1. Initialize your current location.
2. Initialize your assigned goal location.
3. Recognize and analyze around yourself by using your vision sensor to determine your current status.
4. If distance from your goal is 0, then end. ($d_{a_i} = 0$).
5. If collision site detected, then jump to step 9.
6. Adjust your direction toward your goal.
7. Move toward goal for one scale.
8. Jump to step 3.
9. Form a group of all agents that are in your vision site, virtually.
10. Calculate distance to each agent from your current coordinates.
11. Form a circle virtually crossing between you and the nearest agent in your vision site.
12. Move toward expansion spiral path around nearest virtual circle, formed in previous step for one scale.
13. Jump to step 3.

We assumed two sets in our two dimension experimental space; $A = \{a_1, a_2, \dots, a_i\}$, and $G = \{g_1, g_2, \dots, g_i\}$, where A, and G are agents and goals set, respectively. Agents know their assigned goal initially, $\forall a_i \in A, \exists g_i \in G, (a_i, g_i) \in I$, where I indicates a one to one correspondence pairs between agent set and goal set. Initially, each agent knows its exact coordinates along with its assigned goal location at the beginning of experimental cycle. $T_0 = \{a_{1(a_{1(x,y)_1}, g_{1(x',y')_1})}, a_{2(a_{2(x,y)_2}, g_{2(x',y')_2})}, \dots, a_{i(a_{i(x,y)_i}, g_{i(x',y')_i})}\}$ Agents start moving toward their goals at random times. Each agent a_i, at the beginning of the process of movement; Δt_{a_i}, a_i evaluates the environment around by analysing data obtained from its vision sensor. This strategy helps them to determine their situation and hence adjust their path accordingly. For instance, a_i is able to analyze the surface of $vs_i = \int_0^{\theta_i} \frac{1}{2} {r_i}^2 \theta$, as its vision site, captured from its vision sensor at any arbitrary time during movement toward its goal. $\bigcap_{p=1}^{m} vs_p = \emptyset \implies cs = 0$, indicates that there is no agent participating to form any collision site and hence a_i concludes to move toward its goal through by $y = y_1 + [(y'_1 - y_1) / (x'_1 - x_1)] \cdot (x - x_1)$, where (x_1, y_1) and (x'_1, y'_1) denote the position of a sample agent and goal on two dimension space respectively. $\exists (a_i, a_j) \in A, (vs_i \cap vs_j) \neq \emptyset \implies cs \neq \emptyset$, however, indicates there is at least one collision site for a_i, and hence it should alter its path through a temporal expansion spiral route. Those agents are located in collision site; follow these temporary spiral routes, until exiting from those sites. During the process of moving out from collision sites, agents continue analysing their environment around to detect any new agents into their current collision sites and hence, form a new temporary path based on the agent that maintains the nearest distance from them, in order to adjust their route, as it expressed in the collision site section.

V. EXPERIMENTAL RESULTS

The presented path finder algorithm, explained in the previous section, was implemented and tested with an experimental scenario. In this section, we illustrate and examine our algorithm along with the relative results and analysis. In this experiment, our system is used to plan avoiding collision among a group of 6 agents moving toward

their goals, in our two dimensional experiment space. They are not able to communicate with to one another during the experiment; however, they are all using the same strategy to find and correct their path into their goals. This scenario is formed by arranging agents and goals in space, randomly, with considering assigning the farthest possible goals in terms of distances, to agents. This type of distributing agents and goals on the experimental site, leads to increasing the possibility of facing agents to more into collision sites, and hence, using our collision avoidance strategy as much as it possible. Figure 4 shows the positions of agents and goals on our experimental space.

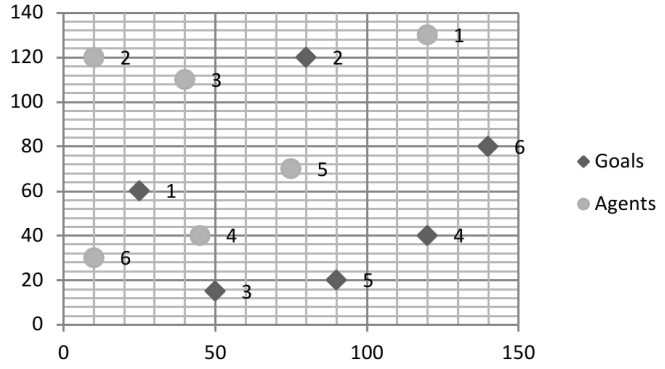

Fig 4. Agents and goals distribution on experimental site

Each agent is assigned a unique number in order to be recognized by other agents during the experiment. In addition, there is a one to one correspondence relationship between agents and goals. In other words, each agent in agent set is assigned the same number goal in goal set. During the cycle of experiment, we collected many key features such as, the times of start moving toward goals by agents, as well as the times of reaching goals, along with the total number of collision sites and virtual circles that each agent is face during the experiment, shown in the following Table 1.

TABLE 1.
RESULTS TABLE OF AGENTS MOVEMENT TOWARD THEIR GOALS

(a_i,g_i)	ΔTa_i	cs_i	vc_i	ΔTg_i
(1,1)	0	7	5	196
(2,2)	2	9	8	314
(3,3)	4	4	2	88
(4,4)	6	8	6	264
(5,5)	8	5	3	165
(6,6)	10	6	5	211

We also collected the times of entering and exiting collision sites for each agent, during the experiment, as shown in the Table 2.

Results depicted in Table 2, show significant differences for ΔT_g , for agents that encountered a larger number of collision sites. In other words, each collision site, based on its situation, and the total number of agents that participate in forming it, can potentially cause a significant delay for agents to reach their goals. This is because, agents that are located in collision sites, change their normal behaviour to choose their paths based on following the shortest possible routes, to a temporary paths which forms based on other agents participating to a same collision site, in order to handle, and hence, exiting from them. We observed no collisions among agents meaning they were able to reach their goals successfully, during the experiment.

VI. CONCLUSIONS

In this paper, we proposed a solution to prevent collision among a group of moving agents toward their specific goals. Our demonstrated algorithm is able to analyse the information gathered by equipped vision sensors, in order to decide the best possible route, in terms of safety and collision avoidance during the time of attempting to reach to their goals. We assumed our agents are not able to communicate and hence do not share details of their environment among one another. Our solution, thus, is able to help our agents to decide and routing toward their goals independently.

Our approach is able to control collision among moving agents into their goals successfully, however, using it, causes agents to have a significant delay before reaching their goals. These delays, depend of the total number of collision sites that each agent involves during the time of pursuing goals can substantially increase the cost of time. Future works includes optimizing our solution, in terms of minimizing the cost of time needed for agents to handle and exit collision sites.

***Abstract*—We present ant colony optimisation approach, enriched with a novel self-adaptation mechanism, applied to solve DIVERSUM Problem that consits of generating a small diversified entity summarisation in a knowledge graph. The recently proposed DIVERSUM problem is viewed in this paper in a novel way as a NP-hard combinatorial optimisation problem. The presented preliminary experimental results indicate superiority of this approach to the previously proposed solutions to the DIVERSUM problem.**

***Index Terms*—Ant Colony Optimisation, Diversified Entity Summarisation, Max Sum Dispersion, Semantic Knowledge Graphs**

I. Introduction

TRADITIONAL optimisation techniques and optimisation methods are related to different types of problems. Some of them deal with constraint handling by using penalty methods, however, they often get stuck in local optima. Moreover, they usually need knowledge of first/second order derivatives of objective functions and constraints.

Hence one looks for more sophisticated methods, especially in cases when: Search space is discrete, discontinuous, non-convex, etc. or objective functions and constraints are non-differentiable or computationally expensive.

If we look at the branch of computer science, called *computational intelligence* then we find here 3 main divisions: nature inspired algorithms, fuzzy logic systems, neural networks.

In the last quarter of the previous century a dozen or more different optimisation algorithms have been proposed that are nature-based methods. One can list some of them: genetic, or more general – evolutionary algorithms, that are based on the Darwin's theory of evolution, swarm optimisation techniques, that copy the swarm intelligence, and they include: ant colony systems, particle swarm optimisation; and simulated annealing methods, that is based on the process of steel production; generalised extremal optimisation, that is based on point-wise equilibrium phenomenon, [1], in which the evolution happens step-wise in contrast to the Darwin continuous evolution, and many more methods.

In this paper we present application of the Ant Colony Optimisation (ACO) approach (Section II), to solve the DIVERSUM problem, i.e. a recently [2] introduced hard optimisation problem of Diversified Entity Summarisation on Knowledge Graphs (Section III). The DIVERSUM problem consists in selecting a small set S of arcs incident to a node x in a knowledge graph so that S gives a good "summary" of the node x. In this paper we present a diversity-aware objective measure so that the DIVERSUM problem is viewed as a combinatorial optimisation problem that is NP-hard.

Then, we report preliminary experimental results (Section IV) run on real data that illustrate the applicability of the presented ACO optimisation technique on the DIVERSUM problem and show that the peformance is higher compared with some previous solutions to the problem.

Ant Colony Optimisation approach was described in [3] and subsequently in a large number of publications. A more recent examples are [4] and [5] where also its application to a hard computational problem such as TSP was presented.

The problem of Diversified Entity Summarisation on Knowledge Graphs has been recently described and studied in [2]. In this paper, we study this problem from the optimisation perspective as optimising a properly defined diversity-aware objective function (Section III-C).

A. Contributions

The contributions of this paper include:

- novel self-adaptation mechanism for one of the parameters of ant colony optimisation algorithm, presented in Section II-G
- formulating the DIVERSUM problem as a combinatorial optimisation one, via defining a novel objective function (Section III-C)
- application of ant colony optimisation approach to such defined optimisation problem (Section III)
- promising preliminary experimental results on real data (Section IV)

II. Ant Colony Optimisation Algorithm

Ant System (AS), has been proposed by M. Dorigo in 1992, is a nature-based heuristic which tackles a range class of the real-life optimisation problems by information cooperation (i.e. *pheromone trials* evolution) inside a set $A = \{a_1, a_2, \ldots, a_{\mathfrak{m}}\}$ of $\mathfrak{m} \geq 1$ abstract agents called *ants*.

AS algorithm is an iterative method in which the three main rules are repeated sequentially:

- *Neighbour Choosing Rule* (AS-NCR) – which defines the probability of adding a new element to the solution being constructed,
- *Solution Construction Rule* (AS-SCR) – which stands for a process of constructing a complete solution for an input problem (AS-NCR is used inside),
- *Pheromone Update Rule* (AS-PUR) – which determines how the ants exchanges local information to build a global description of a space being under optimisation process.

One extra rule is often added, namely:

- *Pheromone Evaporation Rule (AS-PER)* – which defines quantity of evaporation (loss) of global information written down in pheromone trials.

Ant System heuristic schema:

while (stop condition is false) **do**
  for every ant a_i **do**
    construct solution with AS-SCR (AS-NCR inside)
      for every ant a_i **do**
      update pheromone trails with AS-PUR
  evaporate pheromone trials with AS-PER

Let us list the main components of the Ant System.

A. Neighbour Choosing Rule

Neighbour Choosing Rule is based on the probability of adding to constructed solution a new element x_j, just after x_i is previously added, is equal to

$$p_{i,j} = \frac{(\tau_{i,j})^{\alpha}(\eta_{i,j})^{\beta}}{\sum_{k \in \Theta}(\tau_{i,k})^{\alpha}(\eta_{i,k})^{\beta}}$$

where Θ is a set of indexes of all actually reachable elements and:

- $\tau_{i,j}$ – is pheromone trail value connected with an action of choosing element x_j just after an element x_i is chosen,
- $\eta_{i,j}$ – is heuristic value connected with an action of choosing element x_j just after an element x_i is chosen (this coefficient is defined within an input problem),
- α, β – are parameters that control the relative weight of pheromone trail and heuristic value; they need to be adapted.

One of the results of our paper is to define and implement a self-adaptation algorithm for the parameter α; here we assume $\beta = 0$.

B. Pheromone Update Rule

In Pheromone Update Rule for ant a_k the following action is executed

$$\tau_{i,j} \leftarrow (1-\rho)\,\tau_{i,j} + \Delta_k$$

where Δ_k is a value of fixed function of solution quality, and the following Pheromone Evaporation Rule has been already incorporated

$$\tau_{i,j} \leftarrow (1-\rho)\,\tau_{i,j}$$

where ρ is a fixed evaporation coefficient.

In our paper we are generalise the Ant System in the form of a *Discrete Ant System*. In its heuristic we face with a collective work, performed by a discrete number of objects and with the use of a discrete number of functions (tools), that may possess only a discrete number of different values. In this way the set of information collection by individuals - ants in order to construct individual solutions by the use of global knowledge of $\mathfrak{m}$ ants from the set A, is finite, as well. Now we define the optimisation problem for a simple ant system.

By an *optimisation problem* we understand a given quadruple $(\Sigma, \mathcal{R}, \Delta, \|\cdot\|)$, where:

- $\Sigma = \{x_1, x_2, \ldots, x_{\mathfrak{n}}\}$ – is a finite set of $\mathfrak{n}$ indexed *objects* (symbols),
- $\mathcal{R} \subset \Sigma^*$ – is a finite set of $\mathfrak{r}$ indexed *solutions* (words),
- $\Delta : \Sigma^* \to \{0,1\}$ – is a *solution acceptance function* such, that

$$\Delta(\omega) = \begin{cases} 1, & \text{if } \exists\left(\omega' \in \Sigma^*, \omega'' \in \mathcal{R}\right)\left(\omega \circ \omega' = \omega''\right) \\ 0, & \text{in other case} \end{cases}$$

- $\|\cdot\| : \mathcal{R} \to \mathbb{R}_+ \cup \{0\}$ – is a *solution quality function*, where we deal here with the minimisation problem for the quality function.

Notice that this definition of the optimisation problem is suitable for a wide range of real-world computation problems including NP-hard combinatorial problems. For example in the traveling salesman problem (TSP) the set Σ contains all labels of vertices of the graph under consideration and $\mathcal{R}$ is the set of all permutations of Σ. In a discrete knapsack problem, on the other hand, Σ is the set of all objects to be put into knapsack, while $\mathcal{R}$ is the set of words-solutions representing filling methods of the knapsack, taking into account all combinations and constrains put on the number of objects.

The solution $\omega^* \in \mathcal{R}$ is an *optimal* one if

$$\forall\,(1 \leq i \leq \mathfrak{r})\,(\|\omega_i\| \geq \|\omega^*\|)$$

Let $\mathcal{R}^* \subset \mathcal{R}$ denote the set of all optimal solutions. Our task in the optimisation problem $(\Sigma, \mathcal{R}, \Delta, \|\cdot\|)$ is to find any optimal solution $\omega^* \in \mathcal{R}^*$.

C. Pheromone Trail: Basic Variant

The value of saturation of pheromone trail left by an ant is upper bounded by $\tau_{max} \in \mathbb{N}_+$. We assume that

$$\mathbb{H} = \{1, 2, \ldots, \tau_{max}\}$$

is a *set of possible values* of saturation of pheromone trail. Then $F \in \mathbb{H}^{\mathfrak{n}}$ is a column vector of size $\mathfrak{n}$, which defines the *saturation level* of pheromone trail, where $F[i]$ is a value connected with an ant's possibility of choosing an object x_i. Next

$$\mathcal{F} = \{F_1, F_2, \ldots, F_{\mathfrak{f}}\}$$

is a finite set of all possible indexed vectors of saturation level. Notice that

$$\mathfrak{f} = (\tau_{max})^{\mathfrak{n}}$$

In our DAS algorithm we introduce a new object the matrix $H \in \mathbb{H}^{\mathfrak{n}\times\mathfrak{n}}$ of size $\mathfrak{n} \times \mathfrak{n}$, which determines the *saturation level* of pheromone trail, where $H[i, j]$ is a value connected with an ant's moving action from an object x_i to an object x_j. Thus

$$\mathcal{H} = \{H_1, H_2, \ldots, H_{\mathfrak{h}}\}$$

is a finite set of all possible indexed matrices of saturation level. Similarly

$$\mathfrak{h} = (\tau_{max})^{\mathfrak{n}^2}$$

D. Pheromone Trail – Probabilistic

Now let $\widehat{\mathbb{H}}$ be a set of discrete probabilistic values over set $\mathbb{H}$ of all possible values of saturation of pheromone trail, namely

$$\widehat{\mathbb{H}} = \left\{ \frac{a}{b} : a \in \{1, 2, \ldots, \tau_{max}\}, b \in \{1, 2, \ldots, \mathfrak{n} \cdot \tau_{max}\} \right\}.$$

where $0 < \frac{a}{b} \leq 1$. Then, we define the following *reduction function* Ω for the column vectors of set $\mathcal{F}$ where $\mathcal{F} \times \mathcal{R} \times \mathbb{R}_+ \to \widehat{\mathbb{H}}^{\mathfrak{n}}$ and $\Omega(F, \omega, \alpha) = \widehat{F}$ is a stochastic column vector, that according to the rule

$$\widehat{F}[i] = \begin{cases} \dfrac{F[i]^{\alpha}}{\sum\limits_{\{j:\Delta(\omega x_j)=1\}} F[j]^{\alpha}} & \text{if} \quad \Delta(\omega x_i) = 1 \\ 0 & \text{in other case} \end{cases}, \tag{1}$$

for α being a coefficient which describes an individual behavior of a single ant.

E. Neighbour Choosing Rule

The action of Neighbour Choosing Rule is governed by the nondeterministic function, called here $NCR : \mathcal{F} \times \Sigma^* \to \Sigma$ which at given $F \in \mathcal{F}$ and actually constructed word $\sigma \in \Sigma^*$ assume values x_i with the probability given by Eq.(1). It can be formulated as follows:

Remark 1. For any column vector $F \in \mathcal{F}$ and any word $\sigma \in \Sigma^*$ and arbitrary symbol $x \in \Sigma$ the following takes place

$$Pr(NCR(F, \sigma) = x) \in (0, 1), \text{ if } \Delta(\omega x) = 1, \text{and} \tag{2}$$

$$Pr(NCR(F, \sigma) = x) = 0 \text{ in other cases}.$$

This is the basis of the next nondeterministic evolution mechanism in DAS, related to the solution construction rule *SCR*, where $SCR : \mathcal{F} \times \mathcal{H} \to \mathcal{R}$. This rule is the composition of a sequence of independent events generated by a multiple application of the mechanism NCR, unless an internal stop condition is meet. In the reality after the initiation of the algorithm and the formation of the first element of the word-solution, according to the column vector F and

$$\omega \leftarrow NCR(F, \varepsilon), \tag{3}$$

at some i-th stage of the iteration process we obtain a word $\omega = x_{l_1}, x_{l_2}, \ldots, x_{l_i}$, say, then as the result of the l_i-th column vector of the matrix H, denoted here by $H[l_i, \cdot]$, we determine the next element

$$x_{l_{i+1}} \leftarrow NCR(H[l_i, \cdot], \omega) \tag{4}$$

with the probability given by the property of the rule NCR. Then we add the next symbol xl_{i+1} at the end of the word ω, i.e.

$$\omega \leftarrow \omega x_{l_{i+1}}. \tag{5}$$

From this description we can formulate the following remark concerning the probabilistic nature of SCR.

Remark 2. For any column vector $F \in \mathcal{F}$, an arbitrary matrix $H \in \mathcal{H}$ and a word-solution $\omega \in \mathcal{R}$ of the form $\omega = x_{l_1}, x_{l_2}, \ldots, x_{l_r}$, the following is true:

$$Pr(SCR(F, H) = \omega) =$$

$$= Pr(NCR(F, \varepsilon) = x_{l_1}) \cdot \prod_{i=1}^{r-1} Pr(NCR(H[l_i, \cdot], x_{l_1}, x_{l_2}, \ldots, x_{l_i}), \tag{6}$$

which means, by Remark 1, that

$$Pr(SCR(F, H) = \omega) \in (0, 1). \tag{7}$$

The last statement has a fundamental meaning for our nondeterministic algorithm: each word-solution $\omega \in \mathcal{R}$, and by this each optimal word-solution from $\mathcal{R}^* \subset \mathcal{R}$ may be obtained with a positive probability, as a result of the application of the SCR rule in an arbitrary pheromone structure F and H. To these, rather static, mechanisms NCR and SCR we are adding a dynamic one that is related with the actualisation of the pheromone intensity on the trails, governed by the rule PUR. In this way we are introducing a dynamic exchange of information.

The PUR mechanism has two components: short range and long range, and is deterministic. They act on elements of the sets $\mathcal{F}$ and $\mathcal{H}$. We are adding (increasing) some amount of pheromone, by the application of two operators

$$\text{inc}_{\mathcal{F}} : \mathcal{F} \times \mathcal{R} \to \mathcal{F}, \& \ \text{inc}_{\mathcal{H}} : \mathcal{H} \times \mathcal{R} \to \mathcal{H}, \tag{8}$$

and we are decreasing the amount of pheromone by the application of two next operators

$$\text{dec}_{\mathcal{H}} : \mathcal{H} \times \mathcal{R} \to \mathcal{H}, \& \ \text{dec}_{\mathcal{H}} : \mathcal{H} \times \mathcal{R} \to \mathcal{H}. \tag{9}$$

If $\omega = x_{l_1}, x_{l_2}, ..., x_{l_r}$ is a word-solution, then the action of $\mathrm{inc}_{\mathcal{F}}$ on the vector F is

$$F[l_1] \leftarrow min(\tau_{max}, F[l_1]+1)$$

and the action of $\mathrm{dec}_{\mathcal{F}}$ is

$$F[l_1] \leftarrow max(1, F[l_1]-1),$$

on the vector element with the index l_1, being the index of the first element of the solution ω.

The application of two other operators $\mathrm{dec}_{\mathcal{H}}$ and $\mathrm{dec}_{\mathcal{H}}$ is governed by two formula:

$$H[l_i, l_{i+1}] \leftarrow min(\tau_{max}, H[l_i, l_{i+1}]+1), \&$$
$$H[l_i, l_{i+1}] \leftarrow (max(1, H[l_i, l_{i+1}-1]-1)$$

respectively, for all elements $H[l_i, l_{i+1}]$ of the matrix H, where $i = 1, 2, ..., r$ is the subsequent index of the symbols of the solution ω.

F. Theoretic model of DAS

Now we describe the theoretical model of DAS for the single ant, because of its simplicity. The extension for a set of ants is rather of technical nature, because of the sequential character of the algorithm in a loop.

By a state of an ant at time t we understand a quadruple

$$(F_{(t)}, H_{(t)}, \omega_{(t)}, \omega^*_{(t)})$$

where all objects, but the last one, have been already introduced and the index (t) means that it is their actual values at time t. The last object is the historical value of the best word-solution obtained till the moment t.

From the previous considerations we may form the following obvious proposition.

Proposition 1.

A. A state of the ant at time $t+1$ depends on the state of the ant at time t, only.

B. The set of all possible states of the ant is finite.

Now we may introduce an algebraic model of an DAS algorithm evolution for a single ant, where:

- $\widehat{U}_{(t)} \in [0,1]^{\mathfrak{s}}$ – is a column stochastic vector of size $\mathfrak{s}$ such, that $\widehat{U}_{(t)}[i]$ determines a value of probability of a chance that an ant state in moment t is s_i,
- $\widehat{T} \in [0,1]^{\mathfrak{s}\times\mathfrak{s}}$– is a column stochastic matrix of size $\mathfrak{s}\times\mathfrak{s}$ such, that $\widehat{T}[i,j]$ determines a value of probability of a chance that an ant changes its state from s_i to s_j.

Therefore

$$\widehat{U}_{(t)}\widehat{T} = \widehat{U}_{(t+1)} \tag{10}$$

gives a probabilistic evolution of an ant state between moments t and $t+1$. In general if $\widehat{U}_{(0)}$ is an initial distribution of probability of an ant start state, then

$$\widehat{U}_{(i)} = \widehat{U}_{(0)}\widehat{T}^i \tag{11}$$

describes ant state at moments $i = 1, 2, 3, \ldots$. Hence we formulate the next proposition.

Proposition 2.

Evolution process of a single ant in our theoretical model of DAS is a Markovian chain.

The method how to fill the matrix $\widehat{T}$ is described in [6], [7]. The question of the convergence has been solved positively as well, by the application of the convergence theorem formulated for the case of evolutionary algorithms in [8]. In fact we may formulate the result on the so-called pointwise convergence of the DAS, by enlarging the space Σ^* and adding a super-state composed of all states in which the last elements are undistinguishable by the solution quality function.

G. Self-adaptation of α parameter

For the purpose of numerical experiments presented in the article, we introduced a new mechanism for self-adaptation of α parameter occurring in the equation determining the probability of obtaining by a single ant a solution $\omega \in \mathcal{R}$ (see the equation at the beginning of Section II-E and Eq.1). The mechanism is based on the notion of radius variation of α parameter which is further denoted by γ. For practical reasons (arithmetic capabilities of computer's CPU) we aim to reduce γ possible values by $0 \leq \gamma < max$, where *max* is some fixed constant. Then, value of α parameter at time t is in range from 1.0 to $1.0+\gamma$ (strengthening the pheromone trace) or from $\frac{1.0}{1.0+\gamma}$ to 1.0 (reducing the pheromone trace).

Initially (time $t = 0$) condition $\gamma = 0.0$ is satisfied, thus α parameter is equal to 1.0 (neutral state). In each subsequent iteration $t > 0$ we increment γ radius by $\frac{1}{N}$, where N is the size of the ant nest. Next α^* is value of α coefficient which was previously used while currently best result ω^* was found. Further α self-adaptation mechanism is in accordance with the following rules:

- if $|\alpha - \alpha^*| \leq \frac{1}{N}$ holds, then α value is reset randomly with uniform probability in the range from 1.0 to $1.0+\gamma$ or form $\frac{1.0}{1.0+\gamma}$ to 1.0,
- if $|\alpha - \alpha^*| > \frac{1}{N}$ holds, then α value is reset to $\frac{\alpha+\alpha^*}{2}$ (bisection scheme).

Finally, if solution ω found at time t is better than solution so far the best ω^*, γ is again set at 0.0.

The above mechanism of self-adaptation of α parameter can be limited in the space of discrete values. Thus, all of the properties of Discrete Ant Algorithm introduced before, including most significant pointwise convergence, are sustained.

III. Application to Entity Summarisation

In this section, we demonstrate the application of the described optimisation technique on an interesting NP-hard optimisation problem concerning entity summarisation on semantic knowledge graphs that was recently proposed in [2].

A. Semantic Knowledge Graphs

A semantic knowledge graph (henceforth denoted as KG) is a quite novel format for represented semantic data. Knowledge graphs can be automatically or semi-automatically constructed in a process of "knowledge harvesting" from large corpora of text documents e.g. from the WWW, with use of advanced open-domain information extraction technology. There are

existing large datasets in such formats, e.g. DBpedia [9] or YAGO [10]

Basicly, KG constists of: fact graph and ontology.

The fact graph is a directed multi-graph where

- each node represents some entity (e.g. musician, actor, politician etc.) from some domain (e.g. art, movies, politics, etc.), e.g. "Fryderyk Chopin"
- each directed arc represents some "fact" concerning the entities being its ends, e.g. "Fryderyk Chopin is composer". Such facts are commonly represented as so called RDF-triples, that consist of subject, predicate and object, that is often denoted in the relational form: `predicate(subject, object)` (e.g. `is(Fryderyk Chopin, composer)`.

The ontology represents type hierarchy of the entities, i.e. each entity is connected to type node(s) in the ontology by special arcs like "type", etc.

B. Entity Summarisation

[2] studies a problem of entity summarisation in KG, i.e. given an entity (to be summarised) x, knowledge graph G and (small) $k \in N^+$ (a limit on number of facts in the summary) to select a set S of facts concerning the entity x that make a concise "summary" of x. In graph terms the problem consists in selecting a small set of "representative" arcs incident with x in the graph.

Since a node in a large KG (like DBpedia or YAGO) can easily have degree of 100 or higher, and the typical value of k is around 10, it naturally leads to a hard optimisation problem of how to select "the best" facts to the summary.

C. Novel Diversity-aware quality measure of entity summary

A good summary should select the most *important* facts concerning the entity. Furthermore, as observed and experimentally confirmed in [2], a desired summary would be *diversified* i.e. contain facts that concern various *aspects* of the entity being summarised.

This would be stated as a combinatorial optimisation problem via a properly defined bi-criteria objective function obj that takes into account 1) importance of facts, 2) mutual "dissimilarity" between facts.

More precisely, the problem can be defined as: out of the (given) set D of all facts concerning the entity, select a subset S of (up to) k facts so that the following measure is maximised:

$$obj(S) = (k-1)\sum_{d\in S} imp(d) + 2\delta \sum_{d_1 \neq d_2 \in S} diss(d_1, d_2)$$

where $imp : D \to Q^+$ is a "importance" weight of a fact and $diss : D^2 \to Q^+$ is represents pairwise "dissimilarity" of two facts and δ is a parameter to balance between the two criteria of "importance" and "dissimilarity" (to be tuned experimentally). We assume that imp is an increasing function of importance and $diss$ is an increasing function of dissimilarity of facts.

E.g. given entity "Albert Einstein" and two facts concerning this entity: d_1= `hasWonPrize(Albert Einstein, Nobel Prize)` and d_2 = `hasWonPrize(Albert Einstein, Mateucci Medal)` it seems reasonable that d_1 is more important than d_2. In addition, given a fact d_3=`hasChild(Albert Einstein, Evelyn Einstein)` it seems reasonable that $diss(d_1, d_2)$ is lower than $diss(d_1, d_3)$, etc.[1].

The imp and $diss$ functions can be computed based on structural and statistical properties of the underlying knowledge graph. In this paper we assume that the values of the functions are computed externally and we do not focus on this issue.[2]

The factors of $(k-1)$ and 2 are used in the formula to reflect the fact that there are $k(k-1)/2$ possible pairs of a k-element set.

The problem of optimising the obj function defined above is NP-hard (i.e. it can be reduced from MaxSumDispersion NP-hard optimisation problem). If the $diss$ function was a metric, one would adapt the existing 2-approximation algorithm for the MaxSumDispersion problem to this problem.

In the next section, we experimentally apply the ACO optimisation method described in Section II to solve hard optimisation problem defined here. This is additionally justified by the fact that $diss$ function is not necessarily a metric what excludes the applicability of some known approximation algorithms for the MaxSumDispersion problem.

TABLE I
ENTITIES SELECTED FOR EVALUATION.

Entity	Number of facts	Number of predicates
Albert Einstein	32	10
John Wayne	135	12
Denzel Washington	34	7
Robert Mitchum	61	5

IV. EXPERIMENTS

To study practical properties of the described approach we used YAGO2 semantic knowledge database [10] as the underlying knowledge graph. We run the experiments on a sample of entities representing some known people. Some of them, that represent actors, were earlier used for evaluation in [2] and some (e.g. "Albert Einstein") are new. Table I presents selected entities with number of facts assigned. Also number of unique predicates per entity is shown in third column. One can see that the number of facts varies much between entities but for each of them is much higher than 12. This implies that applying a brute force approach of considering all possible 12-element subsets of incident arcs (facts) would be of prohibitive time complexity.

For each fact of an entity we calculated its importance weight and for each pair of facts we calculated dissimilarity. Weights and dissimilarities were later used in $obj(S)$.

A weight of a fact is given by normalised weight of an object (ending of an edge). We applied undirected random

[1]All the mentioned examples are real and taken from the YAGO dataset

[2]The detailed description of how to compute imp and $diss$ functions and other concepts concerning diversified entity summarisation measure mentioned above are out of scope of this publication and deserves a separate publiction that is currently under preparation.

walk (with probability of getting back to the entity set to 0.15) over graph of facts. From this we obtained global weights of entities. In the next step we took facts (with associated endings = objects) associated to a studied entity and scaled weights in a way to fit in range $[0,1]$. At the end, the most important fact assigned to the entity has weight 1.0 and the least important $\varepsilon(\approx 0)$.

A dissimilarity of two facts associated with an entity was calculated using information about types of the entity. Using information about neighbourhood in hierarchy of types we measure how often both facts occur in similar entities. By similar we understand these of close types. Applied method returns dissimilarities always in range $[0,1]$.

A. Preliminary Results

Figure 1 presents sample results ($k=7$) of our method for $\delta = 0.0$ (diversity oblivious variant) and $\delta = 10.0$ (diversity aware variant) in comparison to the results of diversity aware algorithm from [2]. Although we show full results only for single entity ("Denzel Washington") outcomes for other entities have similar properties. Facts shown on different images were placed to resemble their similarity. One should note that since the time of writing [2] the YAGO2 database has been substantially updated and that could slightly influence final results. However we can see that in Diversum image and in image for $\delta = 10.0$ some facts are equal e.g. `directed(D.Wash., The Great Debaters)`, `influences(D.Wash., Noah Sife)`. Correspondence between other facts can also be found e.g. a fact `actedin(D.Wash., DJ Vu)` was replaced with fact `actedin(D.Wash., The preacher's wife)`, information about birth date and children were replaced with place of birth, wife and gender. Similar correspondence can be found between facts `hasWonPrize(D.Wash., Academy Award for Best Actor)` and `hasWonPrize(D.Wash., Tony Award)`.

Additional remarks can be stated after comparison of images for $\delta = 0.0$ and $\delta = 10.0$. One can see that for $\delta = 0.0$ facts connected to acting career dominate summarisation. Information about influence, wife and birth place was replaced with further information about movies that Denzel Washington acted in.

To measure overall quality of obtained summarisations we used Wikipedia info-boxes. Our method is based on this used in [2]. Let $S(e)$ (where $|S(e)| = k$) denote set of facts in summarisation of an entity e and $W(e)$ denote set of facts that can be found in info-box on corresponding Wikipedia pages. Let $f_1 \rhd f_2$ mean that f_1 is equal or more specific fact than f_2 and f_2 can be inferred from f_1. For example: the fact that someone is an actor can be inferred from the fact that he played in some specific movie. $Recall'$ is then defined as:

$$Recall'(e) = \frac{|\{f : f \in W(e) \wedge \exists_{f' \in S(e)} f' \rhd f\}|}{|W(e)|}$$

Tables II and III present comparison of our method to results of Diversum and Precis [2]. $Recall'$ measure for $obj(S)$ with $\delta = 0/1/10$ and for Diversum and Precis is shown. Table II contains results for $k=7$ and Table III for $k=12$. One can see that our approach performs much better than Precis which seems to be the weakest one. The second worst approach is $obj(S)$ with $\delta = 0$ what shows how important diversity is. Diversum algorithm is much better and its results are comparable to our method with $\delta = 1$. When δ is set to 10 and diversity is high quality is the best according to the measure. Overall results are promising but need to be verified in further experiments on more entities.

Authors of $Recall'$ assumed that info-boxes have size of about 7-12. This is not necessary true in our case e.g. for "Albert Einstein" there is 54 facts. Therefore we suggest

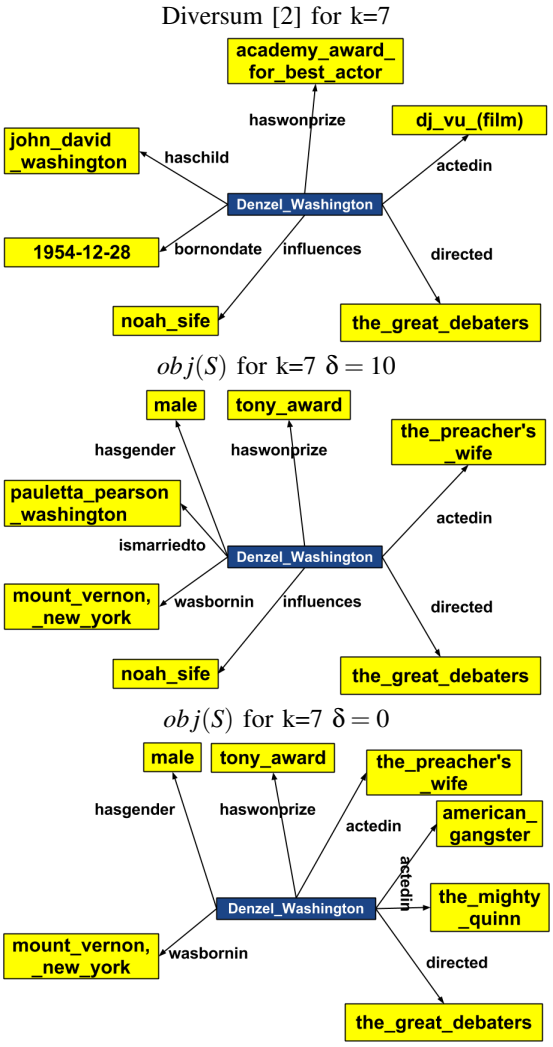

Fig. 1. Comparison of results for "Denzel Washington".

TABLE II
COMPARISON OF $Recall'$ FOR $k=7$.

Entity	δ=0	δ=1	δ=10	Div.	Prec.
J. Wayne	0.31	0.38	0.31	0.29	0.06
D. Wash.	0.50	0.50	0.67	0.60	0.20
R. Mitch.	0.30	0.50	0.50	0.50	0.25
mean:	0.37	0.46	0.49	0.46	0.17

TABLE III
COMPARISON OF *Recall'* FOR $k = 12$.

Entity	δ=0	δ=1	δ=10	Div.	Prec.
J. Wayne	0.46	0.54	0.54	0.42	0.59
D. Wash.	0.50	0.67	0.67	0.60	0.20
R. Mitch.	0.30	0.50	0.50	0.50	0.25
mean:	0.42	0.57	0.57	0.51	0.35

TABLE IV
DIFFERENT MEASURES FOR "D. WASHINGTON" $k = 7$.

δ	*Recall'*	*Recall*	*Precision*	F_1
0	0.50	0.43	0.71	0.54
1	0.50	0.43	0.57	0.49
10	0.67	0.57	0.57	0.57

modified measures:

$$Recall(e) = \frac{|\{f : f \in W(e) \wedge \exists_{f' \in S(e)} f' \rhd f\}|}{|S(e)|}$$

$$Precision(e) = \frac{|\{f' : f' \in S(e) \wedge \exists_{f \in W(e)} f' \rhd f\}|}{|S(e)|}$$

Precision says how many facts out of returned k infer facts from info-box. *Recall* measures how many facts in info-box can be derived from summarisation or in different words: what fraction of facts we covered out of k possible to cover. As long as single fact from summarisation can infer one or zero facts in info-box, what is a specific property of considered data, *Recall* is limited to 1.0.

One should note that Wikipedia info-boxes contain some types of facts that are not included in YAGO2. Therefore we decided to update sets $S(e)$ in a way to keep only this facts that can be connected to facts in knowledge base according to relation $\rhd$.

Sample comparison of different measures for entity "Denzel Washington" can be found in Table IV. For this entity there is only 6 facts from Wikipedia info-box included into $S(e)$ therefore $Recall < Recall'$. Recall that parameter δ controls diversity of results. For $\delta = 0.0$ only weights are taken into account and dissimilarities are omitted. For $\delta = 1.0$ we expect results balanced in weight and diversity and for $\delta = 10.0$ we expect highly diversified results. One can note that *Precision* is very high for $\delta = 0$. The reason is that from every fact "acted in movie" we can infer that "D. Washington" is an actor. From practical point of view it would be enough to include single fact of such type. This situation points out vulnerability of this measure.

Tables V and VI presents average values of four entities from Table I of measures for $k = 7$ and $k = 12$. An analysis shows that both *Recall* and *Recall'* increase when δ increases. It means that for higher values of δ more facts from info-boxes is covered. *Precision* is the highest for $\delta = 0$. The reason of this behaviour was explained earlier (in context of "Denzel Washington" entity). The highest values of F_1 were obtained for $\delta = 10$ and at the end this value seem to be the best option.

TABLE V
AVERAGE (FOUR ENTITIES) MEASURES FOR $k = 7$.

δ	*Recall'*	*Recall*	*Precision*	F_1
0	0.30	0.50	0.75	0.59
1	0.36	0.61	0.68	0.64
10	0.39	0.61	0.68	0.64

TABLE VI
AVERAGE (FOUR ENTITIES) MEASURES FOR $k = 12$.

δ	*Recall'*	*Recall*	*Precision*	F_1
0	0.34	0.36	0.77	0.46
1	0.46	0.46	0.73	0.55
10	0.46	0.46	0.73	0.55

To study deeper the influence of a parameter δ in $obj(S)$ we performed three experiments for different values (0.0, 1.0, 10.0) of this parameter. Tables VII and VIII compare selected facts for different values of parameter δ. Each column says what fraction of facts is common for results with two different values of δ e.g. second column ("1 vs. 0") says how many facts is retained when $\delta = 0.0$ is changed to $\delta = 1.0$. The Table VII presents results for $k = 7$ and Table VIII for $k = 12$. Additionally Figure 2 visually compares second columns from tables.

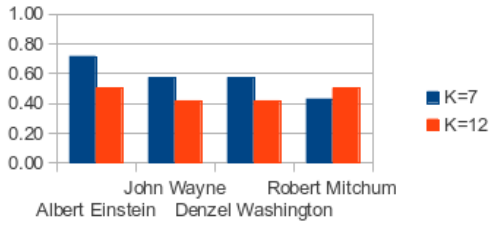

Fig. 2. Fraction of facts shared for $\delta = 0.0$ and $\delta = 10.0$.

TABLE VII
COMMON FACTS FOR DIFFERENT VALUES OF δ (K=7).

Entity / δ	1 vs. 0	10 vs. 0	10 vs. 1
A. Einstein	0.71	0.71	1.00
J. Wayne	0.57	0.57	0.57
D. Wash.	0.57	0.57	0.71
R. Mitchum	0.43	0.43	0.57
mean:	0.57	0.57	0.71
std:	0.12	0.12	0.20

TABLE VIII
COMMON FACTS FOR DIFFERENT VALUES OF δ (K=12).

Entity / δ	1 vs. 0	10 vs. 0	10 vs. 1
A. Einstein	0.50	0.50	0.92
J. Wayne	0.50	0.42	0.75
D. Wash.	0.50	0.42	0.92
R. Mitchum	0.50	0.50	1.00
mean:	0.50	0.46	0.90
std:	0.00	0.05	0.10

An analysis of Tables VII and VIII and Figure 2 leads to several remarks. At first, when δ is changed from 0.0 to 1.0 or 10.0 about half of facts is retained. It holds both for $k = 7$ and $k = 12$. However facts selected for $\delta = 1.0$ and $\delta = 10.0$ differs much e.g. about 30% facts differs for $k = 7$ and about 10% for $k = 12$. The difference in behaviour can be explained by small differences between top facts.

What is more, one can see that there are entities that are resistant to changes of δ. Figure 3 presents comparison of facts shared between situations $\delta = 1.0$ vs. $\delta = 10.0$ for $k = 7$ and $k = 12$. One can see that for "Albert Einstein" all facts are retained. By checking Table VII one can also see that for this entity adding information on dissimilarity ($\delta \neq 0$) changed results much less than for the others.

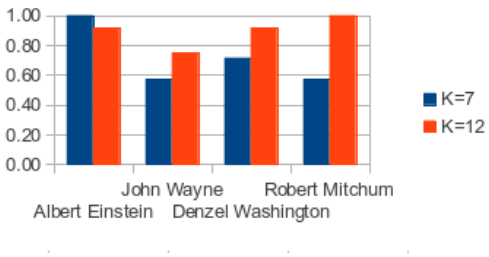

Fig. 3. Fraction of facts shared for $\delta = 1.0$ and $\delta = 10.0$.

V. Conclusions

Results obtained at current level of advance of our project are very promising. In all cases our results were not worse than these described in [2]. Most importantly, the preliminary results indicate appropriate tuning of the δ parameter in the newly proposed solution quality measure makes it possible to beat the performance of the previously proposed diversity-aware algorithm (DIVERSUM) presented in [2]. Anyways, further experiments and evaluations need to be done to confirm this, including user-based evaluations.

Also the issue of tuning the δ parameter should be separately studied as well as theoretical properties of the proposed measure.

In future work it would be also interesting to experimentaly compare the performance of the presented optimisation technique, especially the influence of the novel self-adaptation mechanism, with some other existing sub-optimal approaches, e.g. approximation algorithms for the Max Sum Dispersion problem and other NP-hard optimisation problems.

***Abstract*—In the article we present a comparison of the classification algorithms focused on labeling Fire&Rescue incidents with threats appearing at the emergency scene. Each of the incidents is reported in a database and characterized by a set of quantitative attributes and by natural language descriptions of the cause, the scene and the course of actions undergone by firefighters. The training set for our experiments was manually labeled by the Fire Service commanders after deeper analysis of the emergency description. We also introduce a modified version of Explicit Semantic Analysis method and demonstrate how it can be employed for automatic labeling of the incident reports. The task we are trying to accomplish belongs to the multi-label classification problems. Its practical purpose is to support the commanders at a emergency scene and improve the analytics on the data collected by Polish State Fire Service.**

***Keywords*-Domain Knowledge, Multi-label Classification, Explicit Semantic Analysis, Fire Services**

I. Introduction

THE MAIN goal of Fire Services activity at the fire ground is elimination or neutralisation of arisen threats. Therefore, the core of the Fire&Rescue (F&R) action is to adequately recognize possible dangers for the involved people and properties. A specific emergency generates specific threats. It implies that if we posses a description of the emergency we could predict dangers, or more precisely threats, related to the actual emergency.

The recognition of the threats at the fire ground is only a part of activities that should be performed at the beginning of a F&R action. No less important is the recognition of threatened individuals or objects. Together, those two tasks play a pivotal role in planning of the further actions at the emergency scene.

The task of recognition and categorization of threats is formalized in the tactic of German Fire Service [1]. After arriving at a fire ground or an emergency scene German commanders have to evaluate and recognise the appearing threats. In order to do this systematically and not to miss any of the threats, they have to fulfill the Threats Matrix (in German – Gefahrenmatrix) [1]. The Threats Matrix helps to identify the threats emerging at the scene and the threatened objects. The columns of the matrix represent threats, and the rows represent objects which can be threatened. The Table I depicts the Threats Matrix.

TABLE I
The Threats Matrix used by German commanders. Legend: A1 – Fear, A2 – Toxic smoke, A3 – Radiation, A4 – Fire spreading, C – Chemical substances, E1 – Collapse, E2 – Electricity, E3 – Disease or injury, E4 – Explosion

Threat/object	A1	A2	A3	A4	C	E1	E2	E3	E4
People (ME)									
Animals (T)									
Environment (U)	–					–	–	–	
Property (S)	–	–						–	
Rescuers (MA)									
Equipment (G)	–	–						–	

In German language, column names are chosen so that they can be easily remembered. In order to help to memorize all threats by commanders, German threats' names were taken to form the following pattern: AAAA-C-EEEE *Angstreaktion, Atemgifte, Atomare Strahlung, Ausbreitung, Chemische Stoffe, Einsturz, Elektrizität, Erkrankung, Explosion*. The sign '–' in the table indicates, that this threat in general does not apply to this object. At the background of filled Threats Matrix, German commanders define the Threat Focus and organize their actions accordingly.

If we could create a computer system which can recognize threats at the fire ground, we would effectively support the commanders in doing their duty. Moreover, our previous research [2], [3], [4] show that analytics performed in abstract spaces, such as Threats Matrix allows to reduce significantly the number of dimensions without loosing the information about complexity of the real phenomena. Unfortunately, the Polish Fire Services do not use the method of filling the Threats Matrix at the incident scene. Therefore Polish Incident Data Reporting System called EWID lacks of this information. In the previous work [4] we labeled incidents with threats manually. The reports from EWID database were analysed and labeled by extramural students of The Main School of Fire Service with commanding experience. We selected only commanders having at least seven years experience in commanding. They were involved as *experts – practitioners* in labeling real action reports from the EWID system.

We created a special system to support manual labeling the reports. The labeling process consists of two main phases:

978-83-60810-53-8/$25.00

tutorial phase and *labeling phase*. The tutorial phase was focused on introducing the Threats Matrix and the layout of EWID incident reports to the experts. It was divided into three consecutive parts. In the first part, experts were introduced to the format and purpose of the Threats Matrix. In the second part, some examples of filled Threats Matrices were presented and discussed with the experts. In the third part, experts received an exemplary EWID report together with a Threats Matrix describing this report. The labeling phase consisted of many evaluation stages. At every stage the experts were provided with a single EWID report. On the ground of the information about the incident described in the report, they were asked to evaluate threats which appeared during the reported incident and to complete its Threats Matrix. Every expert was asked to label at least 100 EWID reports. Every report description was labeled by only one expert. In total, we collected 406 labeled incident descriptions.

The presented method has very serious shortcomings – it is not scalable. If we need more labeled reports we need more commanders. Up to now approximately 7 million reports have been collected In the EWID database. Moreover, every day 1 500 new reports are submitted into the system. It is obvious that such a number of incidents is not manually manageable by people.

This article is devoted to prediction methods from Machine Learning which can be used to label the incidents automatically. We use the 406 labeled incidents as a data set to train and evaluate our classification algorithms. We analyse different data representation and different multi-label classification methods in order to find the best one.

The remaining of the paper is structured as follows. In Section II we describe our data set which was used as an input in our experiments. In Section III we present our method of the analysis focused on determining the best classification algorithm and data representation. Section IV contains the results of the conducted experiments. The article is concluded with the interpretation and a summary of the research results, as well as a discussion on perspectives for the future research.

II. Description of the Data

Our data set consists of 291 683 F&R reports. They contain information about the incidents responded by Fire Service, from the years 1992 to 2011. The data concerns the incidents which happened in Warsaw City and its surroundings. In this data set 136 856 reports represent fires, 123 139 local threats and 31 688 where false alarms.

Each of the reports consists of an attribute section and a natural language description part. The attribute section contains 506 attributes describing all types of incidents. However, depending on category of the incident, the number of attributes that take values different than zero varies from 120 to 180 for a report. Most of the attributes are boolean (True/False) type but there are also numerical values (i.e. fire area, amount of water used).

The natural language description (NL) part is an extension to the attribute part. It was designed to store information, which can not be represented in a form of a set of attributes. Unfortunately there is no clear regulation what should be written in the NL part. Therefore, in this part a full spectrum of information, from detailed information including time coordinates, to the very general and brief descriptions can be found. The simple statistics reveal that NL part contains approximately three sentences that describe the situation at the fire ground, actions undertaken and weather conditions. Figure II depicts the idea of a report representation in EWID database.

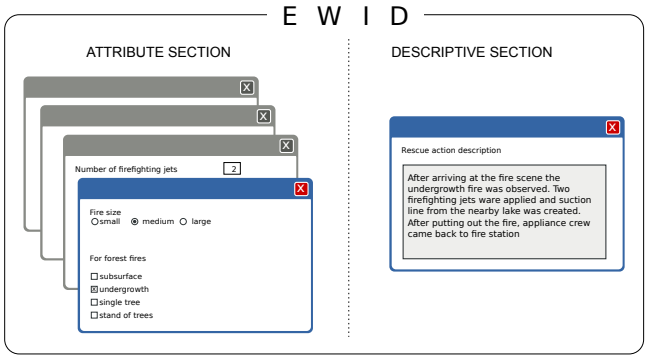

Fig. 1. Representation of a report in EWID database.

In factual aspects, the data stored in the EWID contain information about persons, objects involved in the incident and methods used to eliminate the arisen threats.

In our experiments we used a subset of this data set. For the process of labeling (assigning threats) the incidents by domain experts, we selected only the reports representing fires of residential buildings. This subset of the data consisted of 31 556 reports. From this set 406 reports were labeled by the experts. We used these reports in our experiments described in Section III.

III. Method

The labeling methodology was briefly presented in Section I and is broadly discussed in [4]. In this section we present several approaches to automated labeling of the reports.

In this research we pay a special attention to two aspects of the task: finding an appropriate classification algorithm and selecting a good input data representation. The first approach can be divided into two groups: classifiers which operate on incident features and classifiers which operate on features of the threats. The set of possible representations for the second task consists of: structured part only (SP), NL part only (NLP), structured part plus bag-of-words of descriptions of object (SP-OD), structured part bag-of-words and NL part transformed to the LSA space (SP-OD-LSA). In the next subsections we describe the utilized methods in detail. All the performance evaluation experiments were conducted on a training set of 285 incidents and a test set consisting of 122 incidents.

A. Classification on Structured Part Only

As was mentioned in section II the structured of part EWID database is represented by 506 attributes. However, for our subset of 406 incidents many of them have zero values for each of the incidents. Therefore, we removed those attributes from our subset. We also removed semantically irrelevant attributes, such as ID of a fire station. As a result we obtained an information system with 208 attributes, from which 24 were numeric and 184 were of a boolean type. The prediction targets were sets of combinations of threats and threatened objects (the risks). The set of the possible risks was created as a Cartesian product of threats and objects from the Threats Matrix. Such a representation constituted an input for our classifiers.

Our first experiment was focused on determining the best classifier for a given representation. In this experiment we used the whole set (406 cases) and 5 folds cross-validation technique to evaluate the efficiency of different classifiers. We tested: Naive-Bayes (NB), Classification Tree, Support Vectors Machine (SVM), Clark Niblett induction algorithm (CN2) and Random Forrest. We used Matthew correlation coefficient (MCC)[1] to evaluate the efficiency of the selected classifiers. Table II depicts the comparison of the results.

TABLE II
COMPARISON OF THE CLASSIFIERS. AUC – AREA UNDER CURVE, MCC – MATTHEW CORRELATION COEFFICIENT, SVM – SUPPORT VECTORS MACHINE, CN2 – CLARK NIBLETT INDUCTION ALGORITHM.

Method	AUC	F1-score	MCC
Naive Bayes	0.76	0.61	0.33
Classification Tree	0.71	0.53	0.26
SVM	0.75	0.46	0.27
CN2 rules	0.76	0.50	0.31
Random Forest	0.71	0.45	0.20

According to the criteria (MCC measure) presented in Table II the Naive-Bayes classifier obtained the best results and was selected as a representative for the rest of the experiments. Next, we used training and test methodology to compare the current methods with other approaches. The classifier was trained and tested separately for each of the decisions classes. Then we calculated some performance measures i.e. precision, recall, F1-score in two way: for each of the incidents and for each of the decision classes.

B. Classification on Structured and Object Description Parts

We repeated the experiment described in Section III-A extending the incident representation by the *object description* attribute. The attribute is an extension to the *object type* attribute and contains information such as: storey or room of the building where fire occurred, trash localization (inside, outside in the case of a trash fire), etc. This attribute stores the information in natural language form. In order to use this part as a feature vector we transformed it into the bag-of-words representation. We created Term-Document-Matrix (TDM) to transform the NL attribute into a feature vector. However, in order to reduce the number of dimensions, we firstly lemmatized the descriptions using the Morfologik software [5]. As a result of lemmatization we obtained 1 029 unigrams in bag-of-words representation. Then we repeated the experiments described in Section III-A and calculated the performance measures.

[1]http://en.wikipedia.org/wiki/Matthews_correlation_coefficient

C. Classification on Structured Object Description and NL Part

In this experiment we extended the incidents representation by the entire NL part. The difference between this approach and the one presented in Section III-B is that, we are not limited to the object description attribute only. We used the whole description of the incidents stored in the NL part.

As in the case of object description we lemmatized the textual data and created Term Document Matrix. The TDM revealed that the number of unique words equals 1 277. It our opinion the direct representation of NL part throughout term vector is to exhaustive due to the fact that TDM is a sparse matrix. In order to reduce the number of dimensions and increase the separation of the incidents we use the Latent Semantic Analysis method [6]. After conversion of the TDM into LSA space we obtain 85 dimensions. We calculate the number of dimensions finding the first position in the descending sequence of singular values where their sum, divided by the sum of all values, meets or exceeds the 0.5 share value. Next in order to obtain categorical arguments we discretized the attributes of incidents represented in the LSA space. After discretization, each of the LSA attributes had tree values: -1, 0 or 1. Then, we repeated the experiments described in Section III-A.

D. Classification Based on Features of the Threats

In this experiment we change our approach to the labeling task. Instead of training a classifier to recognize which attribute values should the incident have in order to be labeled with a given threat, we try to learn the features of the possible risks. In other words, we learn which features of the incidents most adequately represent the given risk.

The risks are defined as a Cartesian product of threats and objects from the Threats Matrix and are represented by a concatenation of a threat and an abbreviation of an object name (i.e. E1_ME). We decided to utilize the Explicit Semantic Analysis method [7] to devise the new representation of the risks in order to facilitate the labeling.

Explicit Semantic Analysis (ESA) proposed in [7] is a method for automatic tagging of textual data with predefined concepts. It utilizes natural language definitions of concepts from an external knowledge base, such as an encyclopedia or an ontology, which are matched against documents to find the best associations. The definitions of concepts are regarded as a regular collection of texts, with each description treated as a separate document. The model structure imposed by ESA can be interpreted as a one layer neural network [8] with L input nodes corresponding to terms and K output nodes

corresponding to concepts. The associations between terms and concepts have numerical weights. Figure 2 depicts the idea of ESA in a form of a neural network.

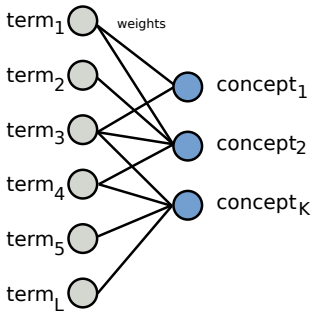

Fig. 2. Representation of the ESA as a neural network.

The implementations of ESA described in [7], [9] use external resources (e.g., an ontology, Wikipedia) which contain the definitions of concepts. In our case there are no external sources of knowledge which can serve as definitions of the risks, therefore we modified the primary idea of ESA and we created *self-defined ESA*. We aggregated the NL parts of incident descriptions from the training set by the assigned risks. In particular, all descriptions of incidents which were labeled with the same risk were concatenated into one document. We repeated this operation for consecutive threats obtaining as many documents as there were threats. Next, we created a Term-Document-Matrix where columns represent the risks and rows represent the terms. The intersection of a column and a row represents an association between a term and a risk. Then, for each incident description in the test set we iterate through the terms, obtain and sum the values of associations to the consecutive risks. The risks for which the sum of the associations is higher than zero constitute a bag-of-risks for a given incident.

For the sake of clarity, we formalize this approach. Let $\mathcal{T}$ be a set consisting of M incidents from the training set, $\mathcal{T} = \{I_1, \ldots, I_i, \ldots, I_M\}$ and $\mathcal{T}'$ is a set consisting of J incidents from test set $\mathcal{T}' = \{I'_1, \ldots, I'_i, \ldots, I'_J\}$. Let $\mathcal{R} = \{r_1, \ldots, r_k, \ldots, r_K\}$ be a set of risks at a fire ground defined as $\mathcal{R} \subseteq \mathcal{H} \times \mathcal{O}$, where $\mathcal{H}$ is a set of the threats from the Threats Matrix and $\mathcal{O}$ is a set of the objects from the Threat Matrix (see Table I). Moreover, let us assume that there were identified L unigrams (e.g. words, stems) $W = \langle w_1, \ldots, w_i, \ldots, w_L \rangle$ from the descriptions of incidents in the training set (NL part of the EWID database). Any incident I_i in the set $\mathcal{T}$ can be represented by a vector of features $I_i = \langle E_i, U_i \rangle$, where $E_i = \langle e_1, \ldots, e_j, \ldots, e_L \rangle \in \mathbb{R}^L$ is a bag-of-words representation of the incident I_i and $U_i = \langle u_1, \ldots, u_k, \ldots, u_K \rangle \in \{0,1\}^K$ represents risks assigned by the experts to the I_i. Each coordinate e_i expresses a value of some relatedness measure for i-th term in vocabulary (w_i), relative to the given E_i. The coordinate $u_k = 1$ if the risk r_k was assigned to the incident I_i by the experts. Respectively, any incident I'_i from the test set is represented by a vector of features $I'_i = \langle E'_i, U'_i \rangle$. However each coordinate of U'_i equals 0 because the incidents from the test set were not labeled by the experts.

We can now define the description of a risk r_k. The description D_{r_k} for risk the r_k is a sum of all bag-of-words representations of incidents in $\mathcal{T}$ where $u_k = 1$

$$D_{r_k} = \sum_{i:u_k=1} E_i \tag{1}$$

Next, all the D_{r_k} from set $\mathcal{D}$ (set of all designations) were converted to the Term-Document-Matrix (TDM), where columns are labeled by descriptions, rows by terms from vocabulary W and the coordinates d_i represent relatedness measure for i-th term in vocabulary (w_i), relative to the given D_{r_k}. The measure used by us to calculate d_i is the *tf-idf* (term frequency-inverse document frequency) index (see [10]) defined as:

$$d_i = tf_{i,k} \times idf_i = \frac{n_{k,i}}{\sum_{j=1}^{L} n_{k,j}} \times \log \frac{|D|}{|\{D_{r_k} : w_i \in D_{r_k}\}|}, \tag{2}$$

where $n_{k,i}$ is the number of occurrences of the term w_i in the description D_{r_k}, $|D|$ is the cardinality of $\mathcal{D}$ which equals K, and $|\{D_{r_k} : w_i \in D_{r_k}\}|$ is the number of the descriptions where the term w_i appears.

Next, the TDM representation of the risks descriptions can be used as an inverted index that maps terms into lists of risks. Each row of TDM expresses an association of the given term from W to K risk descriptions. The inverted index is utilized as a semantic interpreter to assign the risk into incidents from the set $\mathcal{T}'$. Given an incident description E'_i, it iterates over terms from the description, retrieves the corresponding entries and merges them into a weighted vector of risks that represent the given incident.

Let $E'_i = \langle e'_1, \ldots, e'_j, \ldots, e'_L \rangle$ be a bag-of-words representation of the description of incident I'_i from the set $\mathcal{T}'$. Let $inv_{i,k}$ be an inverted index entry for e'_i. It quantifies the strength of association of the term w_i to a risk r_k. For convenience, all the weights $inv_{i,k}$ can be arranged in a sparse matrix structure with L rows and K columns, denoted by INV, such that $INV[i,k] = inv_{i,k}$ for any pair (i,k).

Next we can create a new representation U_i^{INV} of incident I'_i from the test set as a sum of values from the TDM of terms which appear in E'_i:

$$U_k = \sum_{i:e'_i \neq 0} e'_i \times inv_{i,k} = W_i * INV[\cdot, k]. \tag{3}$$

In the above equation $*$ is the standard dot product and $INV[\cdot, k]$ indicates k-th column of the sparse matrix INV. This new representation will be called a *bag-of-risks* of an incident I_i.

The new representation of incident I'_i can be now definded as $I''_i = \langle E'_i, U''_i \rangle$ where U''_i is created as follows $U''_i = \langle u''_1, \ldots, u''_k, \ldots, u''_K \rangle \in \{0,1\}$ $u_k^{INV} > 0 \Rightarrow u''_k = 1$.

For practical reasons it may also be useful to represent the incidents only by the most relevant risks. In such a case, the association weights can be used to rank the risks and to select only the top risks from the ranked list. Therefore, we changed the rule $u_k^{INV} > 0 \Rightarrow u_k'' = 1$ into $u_k^{INV} > var \Rightarrow u_k'' = 1$ where var is some threshold.

IV. Results of the Experiments

In Table III we summarized the results obtained in the experiments. We calculated the performance measures separately for each of the consecutive incidents from the test set, and then we calculated the average for each of the methods. The number of assigned risks for the ESA was set to five with the highest score.

TABLE III
THE PERFORMANCE COMPARISON FOR THE CLASSIFICATIONS METHODS.

Method	Precision	Recall	F1-score
SP	0.68	0.64	0.61
SP-OD	0.45	0.50	0.43
SP-OD-LSA	0.43	0.51	0.43
ESA NLP	0.48	0.70	0.54

The second summarization (see Table IV) compares the performance of different classification methods, according to the risks from Threats Matrix. In this table we also presented the number of the incidents in the training ($\#\mathcal{T}$) and test ($\#\mathcal{T}'$) sets, which were labeled by a given threat.

Figure 3 outlines the comparison of versatility of the methods. We compare the classification methods according to the number of different risks which were at least once properly assigned to an incident.

The practical usefulness and the importance of the results presented in the Tables and Figure 3 is more broadly discussed in Section V.

V. Discussion of the Results

The obtained results revealed that for the maximization of F1-score for a given document we should choose the method which is based on the attribute section only and the classification algorithm (SP). This method achieved very good performance – F1-score reach the value 0.61 (see Table III). However the value of recall is lower than value obtained by ESA NLP approach. That means the best scoring method does not detect the full spectrum of risks.

The intuition is confirmed by the results from Table IV. We observed that if we calculate the F1-score according to the risks, the SP method is classified as the second best. Table IV also reveals the reason for this situation. The SP approach achieves a very good performance for the risks which are assigned very often to the incidents. As an example may serve the risks: A1_ME (86% of incidents labeled in the training set and 88% in the test set), A2_MA (85% and 89%, respectively), A2_ME (88% and 84% of incidents). For these risks the SP method achieves scores 0.86, 0.81 and 0.83, respectively. However, for the risks which were rarely assigned to the incidents the SP methods fails to achieve good performance.

TABLE IV
THE PERFORMANCE COMPARISON (F1-SCORE) OF THE CLASSIFICATIONS METHODS RELATIVE TO THE RISKS. $\#\mathcal{T}$ – NUMBER OF INCIDENTS IN TRAINING SET LABELED BY THE GIVEN RISK, $\#\mathcal{T}'$ – NUMBER OF INCIDENTS IN TEST SET LABELED BY THE GIVEN RISK. THE RISKS ARE DEFINED AS A CARTESIAN PRODUCT OF THREATS AND OBJECTS FROM THE THREATS MATRIX AND ARE REPRESENTED BY A CONCATENATION OF AN ABBREVIATION OF A THREAT AND AN OBJECT NAME (I.E. E1_ME: CALLAPSE_PEOPLE).

Risk	$\#\mathcal{T}$	$\#\mathcal{T}'$	SP	SP-OD	SP-OD-LSA	ESA NL
A1_MA	99	46	0.38	0.49	0.54	0.45
A1_ME	245	107	0.86	0.71	0.69	0.82
A1_T	27	5	–	0.10	0.06	0.07
A2_MA	242	108	0.81	0.64	0.65	0.84
A2_ME	251	103	0.83	0.64	0.70	0.84
A2_S	8	6	0.29	–	0.11	0.22
A2_T	36	8	0.05	0.14	0.06	0.14
A2_U	57	28	0.39	0.37	0.37	0.30
A4_G	3	4	–	–	–	0.08
A4_MA	15	7	0.30	0.32	0.14	0.22
A4_ME	18	9	0.27	0.27	0.15	0.17
A4_S	20	13	–	0.38	0.05	–
A4_T	1	1	–	–	–	0.13
E1_MA	6	3	–	–	0.50	0.11
E1_ME	3	1	–	–	–	–
E2_MA	29	13	0.11	–	0.11	0.31
E2_ME	14	6	–	–	0.13	0.24
E2_S	9	1	–	–	–	0.15
E3_G	3	1	–	–	–	0.12
E3_MA	9	13	–	–	0.10	0.50
E3_ME	2	7	–	–	–	0.12
E4_MA	3	4	–	–	–	–
E4_ME	2	1	–	–	–	–
E4_S	5	2	–	–	–	–
Average F1-score			0.179	0.169	0.181	0.243

Figure 3 compares the versatility of the methods. It depicts the spectrum of risks used by different methods. It illustrates that for the method SP and SP-OD only 10 out of 24 risks could be successfully assigned. The extension of the information by the NL part of the EWID database increases the spectrum of the utilized risks. The SP-OD-LSA method successfully assigned 15 out of 24 risks. However, the most versatile method is ESA NL which is able to properly assign 19 out of 24 risks. We may conclude that the attribute section lacks information related to very rare risks. Only the extension by the NL part allows labeling the incidents with these risks.

The conducted experiments proved that there is a potential in ESA method even for short texts and even in a situation when there are no descriptions available for the concepts in a form of external knowledge base (compare the experiments with long text and an external ontology [7], [9], [11]). However, it should be stated that the descriptions stored in the NL part of EWID database are very specific. In the future work the method should be tested against some more general texts like blogs or news.

The future work should also concentrate on methods for improving ESA. Results of our preliminary experiments suggest that a properly adjusted weights in the inverted index

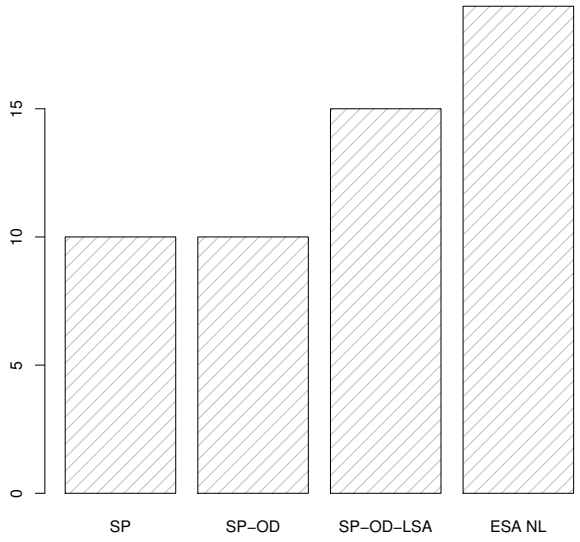

Fig. 3. The comparison of versatility of the methods. Y-axis represents the number of different risks which were at least once properly assigned to an incident.

used by ESA can increase the average F1-score by more than 100%. Therefore, in our research we will focus on finding an appropriate algorithm for updating ESA on for this set.

The experiments also reveal that different risks have different best scoring methods. Therefore, we also consider utilization an ensemble approach in order to assemble a multi-classifier algorithm [12].

***Abstract*—The advance of high-throughput techniques, such as gene microarrays and protein chips have a major impact on contemporary biology and medicine. Due to the high-dimensionality and complexity of the data, it is impossible to analyze it manually. Therefore machine learning techniques play an important role in dealing with such data. In this paper we propose to use a one-class approach to classifying microarrays. Unlike canonical classifiers, these models rely only on objects coming from single class distributions. They distinguish observations coming from the given class from any other possible states of the object, that were unseen during the classification step. While having less information to dichotomize between classes, one-class models can easily learn the specific properties of a given dataset and are robust to difficulties embedded in the nature of the data. We show, that using one-class support vector machines can give as good results as canonical multi-class classifiers, while allowing to deal with imbalanced distribution and unexpected noise in the data. To cope with high dimensionality of the feature space, we propose to form an ensemble, based on Random Subspace and prune it with the usage of diversity measure. Experimental investigations, carried on public datasets, prove the usefulness of the proposed approach.**

***Index Terms*—machine learning, one-class classification, multiple classifier systems, classifier ensembles, bioinformatics, microarray analysis, high dimensionality.**

I. Introduction

CONTEMPORARY high-throughput technologies produce massive volumes of biomedical data. Transcriptional research and profiling, with the usage of microarray technologies are powerful tools to gain a deep insight into the pathogenesis of complex diseases that plague modern society, such as cancer. Recent works on cancer profiling showed without a doubt, that gene expression patters can be used for high-quality cancer subtype recognition [1] - leukemias [2], melanoma [3], breast cancer [4] or prostate cancer [5] to name a few.

Identifying cancer properties, based on their distinct expression profiles may provide necessary information for a breakthrough, that is required for patient-tailored therapy. Currently there are no distinct rules on how individuals respond to chemotherapy and existing chemotherapies have in most cases severe side-effects with varying medical efficiency.

Due to massive amounts of data generated by microarray experiments and their high complexity and dimensionality, one requires a decision support system to extract the meaningful information from them. Machine learning is widely used for this task [6], with two distinct areas - unsupervised [7] and supervised learning [8]. In this paper we will focus on the latter one.

Supervised machine learning is a promising approach for analyzing microarray results in context of predicting patients outcome. Support Vector Machines are among the most popular classifiers used for this task [9]. Multiple Classifier Systems [10], or classifier ensembles, have gained an significant attention of the bioinformatics community in recent years. Random Forest [11] and Rotation Forest [12] ensembles have displayed an excellent classification accuracy for small-sample, high dimensionality microarray datasets, outperforming single-model approaches.

Another important issue is the problem of curse of dimensionality. Microarray data suffer from a relatively small number of objects, in comparison to the feature space dimensionality, often reaching several thousands. This causes difficulties for machine learning algorithms, reducing their performance and increasing their computational complexity. Among this data flood a major number of parameters possess small discriminative power and is irrelevant to the classification process, which makes feature selection a crucial step in microarray analysis [13].

Although there are many applications of machine learning-based decision support systems in bioinformatics, there are still many unresolved problems, such as:

- How to integrate heterogeneous data sources to achieve better insight into the mechanism behind complex diseases?
- How to organize, store, analyze and visualize high-dimensionality data obtained from the biomedical data flood?
- How to deal with the problem of high-dimensionality, small sample size, which strongly affects the classification performance and may lead to overfitting, poor generalization and unstable predictors?
- How to cope with difficulties embedded in the nature of microarray data, such as noise or class imbalance, as canonical machine learning classifiers cannot cope with them easily?

In this paper the last two issues are addressed.

978-83-60810-53-8/$25.00

We propose to analyze microarray data with the usage of one-class classifiers, instead of commonly applied binary ones. Up to author's knowledge this is the first work on applying one-class ensembles and one-class classification in general, to the microarray classification.

To cope with the high dimensionality problem we apply an ensemble approach, based on Random Subspaces [14]. By decomposing the feature space we at the same time reduce the overall computational complexity of the classification model and assure initial diversity among the pool of individual classifiers in the committee. A diversity-based pruning method is applied to discard redundant classifiers and to chose mutually complementary one-class predictors. Experiments, based on a set of publicly available microarray datasets, show that the proposed approach maintains a good classification accuracy, while displaying an improved robustness to atypical data distribution and prevalent noise.

II. One-class classification

The aim of one-class classification (OCC) is to recognize one specific class from the more broad set of classes (e.g., selecting horses from all animals). The given class is known as target class ω_t, while the remaining are denoted as outliers ω_O. During the learning only examples target class (known also as positive examples) are being presented to learner, while it is assumed that during the exploitation phase new, unseen objects from other classes may appear.

OCC problems are common in the real world where positive examples are widely available but negative ones are hard, expensive or even impossible to gather [15]. Let us consider an engine. It is a quite easy and cheap to collect data about its normal work. Collecting observations about failures it is expensive and sometimes impossible, because in this case we would have to spoil the engine.

Such approach is very useful as well for many practical cases especially when the target class is "stable" and outlier one is "unstable". To explain this motivation let us consider a computer security problem as spam filtering or intrusion detection (IDS/IPS) [16].

Among several types of classifiers dedicated to OCC, the most popular is one concentrating on estimation of a closed boundary for given data, assuming that such a boundary will describe sufficiently the target class [17]. The main aim of those methods is to find the optimal size of the volume enclosing given training points. Too small size could lead to overfitting the model, while too big size might lead to extensive acceptance of outliers into the target class. Those methods rely strongly on the distance between objects [18]. Boundary methods require smaller number of objects to properly estimate the decision criterion, which makes them a perfect tool for applications suffering from a small sample size,such as microarrays classification. The well-known boundary methods are one-class support vector machine (OCSVM) [19] and support vector data description (SVDD) [20]. In this work we will use the former one.

A. One-class support vector machine

One-class SVM classifier (OCSVM) [19] can deal with datasets containing only patterns from one target class. OCSVM classification aims at discriminating one class of target samples from all other ones. It consists of learning the minimum volume contour that encloses most of the data in a given dataset. Its original application is the outlier detection finding data that differ from most of the data within a dataset.

Let $\chi = \{x_1, x_2, ..., x_m\}$ be a given dataset in $\mathbb{R}^d$. Each x_j is a feature vector describing an object. OCSVM use the training data to learn a function $f_\chi : \mathbb{R}^d \mapsto \mathbb{R}$ such that most of the data in χ belong to the set $\mathcal{R}_\chi = \{x \in \mathbb{R}^d; f_\chi(x \geqslant 0)\}$ while the volume of $\mathcal{R}_\chi$ is minimal. This problem is known as $MinimalVolumeSet$ (MVS) estimation. Membership of x to $\mathcal{R}_\chi$ indicates whether this estimated volume is overall similar to χ or not. Therefore when considering a M-class recognition problem we have to learn M membership functions f_{χ_i} - one for each class.

OCSVM uses the following approach to estimate the MVS. A kernel function $k(\cdot,\cdot) : \mathbb{R}^d \times \mathbb{R}^d \mapsto \mathbb{R}$. In our research we use a Gaussian Radial Basis Function(RBF) kernel :

$$k(x, x') = exp[- \parallel x - x' \parallel^2 /2\sigma^2], \tag{1}$$

where x' is the object after mapping to a hypersphere, $\| \cdot \|$ denotes the Euclidean norm in $\mathbb{R}^d$. The kernel induces a new, artificial feature space $\mathcal{H}$ by the usage of mapping $\phi : \mathbb{R}^d \mapsto \mathcal{H}$ dened by $\phi(x) \triangleq k(x, \cdot)$. It has been shown that $\mathcal{H}$ reproduces kernel Hilbert spaces of given functions, with dot product denoted as $\langle \cdot, \cdot \rangle_\mathcal{H}$. The reproducing kernel property implies that:

$$\langle \phi(x), \phi(x') \rangle_\mathcal{H} = \langle k(x, \cdot), k(x', \cdot) \rangle_\mathcal{H} = k(x, x'), \tag{2}$$

which makes the evaluation of $k(x, x')$ a linear operation in $\mathcal{H}$, while it is a nonlinear operation in $\mathbb{R}^d$.

Considering the RBF:

$$\parallel \phi(x) \parallel^2_\mathcal{H} \triangleq \langle \phi(x), \phi(x) \rangle_\mathcal{H} = k(x, x) = 1. \tag{3}$$

From this one may assume that all the data mapped into $\mathcal{H}$ are located on the hypersphere with radius equal to one, centered onto the origin of $\mathcal{H}$, which is denoted $S_{(o,R=1)}$. The OCSVM determines in $\mathcal{H}$ the hyperplane $\mathcal{W}$ that separates most of the data from the $S_{(o,R=1)}$, while at the same time maximizing the distance from it. This practically implements the solution to the MVS estimation problem.

Let:

$$\mathcal{W} = \{h(\cdot) \in \mathcal{H}; \langle h(\cdot), w(\cdot) \rangle_\chi - \rho = 0\}, \tag{4}$$

where parameters $w(\cdot)$ and ρ are the results of the following optimization problem

$$\min_{w,\xi,\rho} \frac{1}{2} \parallel w(\cdot) \parallel^2_\mathcal{H} + \frac{1}{vm} \sum_{j=1}^{m} \xi_j - \rho, \tag{5}$$

subject to (for $j = 1, ..., m$)

$$\langle w(\cdot), k(x_j, \cdot) \rangle_\chi \geqslant \rho - \xi_j, \tag{6}$$

where $\xi_j \geqslant 0$, v is a control parameter for the fraction of the data that are allowed to be located on the wrong side of the $\mathcal{W}$ (outliers which do not belong to the $\mathcal{R}_\chi$) and ξ_j are slack variables.

It can be shown that a solution to Eq. (5,6) can be expressed by the following:

$$w(\cdot) = \sum_{j=1}^{m} \alpha_j k(x_j, \cdot), \tag{7}$$

where α_j comes from the dual optimization problem

$$\min_{\alpha} \frac{1}{2} \sum_{j,j'=1}^{m} \alpha_j \alpha_{j'} k(x_j, x_{j'}), \tag{8}$$

subject to $0 \leq \alpha_j \leq \frac{1}{vm}, \sum_j \alpha_j = 1$.

The OCSVM decision function $f_\chi(x)$ is given as follows:

$$f_\chi(x) = \sum_{j}^{m} \alpha_j k(x_j, x) - \rho, \tag{9}$$

where the value of ρ is calculated from knowing that $f_\chi(x_j) = 0$ for those $x_j \in \chi$ that verify both $\alpha_j \neq 0$ and $\alpha_j \neq \frac{1}{vm}$. Objects from χ that satisfies those conditions are located onto a decision boundary.

III. Proposed approach

In this paper we propose to use a one-class classification approach to microarray analysis. Let us list the main features and advantages of the proposed approach:

1) We utilize one of the classes as the target concept ω_T and the remaining one as outliers. In case of imbalanced dataset the minority class is considered as the target concept, while in case of balanced distributions we chose the more numerous class. This is motivated by the fact, that while sacrificing the additional information about the second class, we gain a classifier that is able to adjust itself to the specificity of the given class and is more robust to difficulties that may be encountered, such as class imbalance or in-class noise.
2) The high dimensionality of the feature space is difficult to handle for one-class boundary classifiers. It significantly increases their complexity, the training and execution times and lead to a much more difficult optimization task (and hence to a degradation of the recognition quality). To cope with this problem we propose to use a Random Subspace ensemble to decompose the feature space into smaller competence areas and build an ensemble of simpler one-class models.
3) As Random Subspace may lead to creation of similar classifiers, or classifiers with low discriminative power, a pruning procedure is beneficial, as it may discard irrelevant predictors. We use a diversity-based method, which uses a criterion optimized for OCC task.

A. Dealing with the high dimensionality problem

The one-class boundary compute a distance between the object x and the estimated boundary, which encloses the target class ω_T. This allows to apply fusion methods, that are based on the discrete output (returned class label) of the individual classifiers - such as the voting methods. However, to apply more sophisticated fusion methods, which assume the continuous outputs of each of the individuals, the support of an object x for a given class is required.

We propose to use the following heuristic support function produced on the basis of a distance:

$$F(x, \omega_T) = \frac{1}{c_1} exp(-d(x|\omega_T)/c_2), \tag{10}$$

which models a Gaussian distribution around the classifier, where $d(x|\omega_T)$ is a distance (Euclidean distance is used) from the evaluated object to the support vectors describing the target concept, c_1 is the normalization constant and c_2 is the scale parameter. Parameters c_1 and c_2 should be fitted to the target class distribution.

Estimating this mapping for high dimension is very complex and requires a significant computational power and time. To cope with this difficulty we propose to use a Random Subspace method to partition the dataset into many subspaces of smaller dimensionality. Each base classifier is trained on a new subset, which is highly smaller than the original feature space size. This boosts the training time, while applying ensemble principles makes sure that despite using weaker predictors, we still get a satisfying accuracy [21].

B. Pruning the ensemble

As Random Subspace may produce classifiers of different level of individual quality and diversity, a classifier section step is most beneficial to forming an one-class ensemble. Multiple Classifier Systems, in order to work properly, must consist of predictors of at the same time high accuracy and diversity. Only mutually complementary classifiers may lead to an improvement over using a single-model approach. Diversity is one of the most popular measures for this task. It may be applied to one-class classifiers, but after modifications, that take into consideration the nature of the OCC problem [22]. For this application an one-class entropy measure [23] is used.

Let's assume that the highest ensemble diversity for a given object $x_j \in X$ is displayed by $[R/2]$ of the ensemble votes with the same value (ω_T or ω_O) and remaining R - $[R/2]$ with the other value. If all votes returned identical response the ensemble cannot be considered as a diverse one. Let us denote by $r(x_j)$ the number of one-class classifiers that correctly recognize the object x_j. Assuming there are N objects in the training set, one may use entropy to measure the diversity using the presented concept:

$$E_{oc}(\Pi^r) = \frac{1}{N} \sum_{j=1}^{N} \frac{1}{(R - [R/2])} \min\{r(x_j), R - r(x_j)\}. \tag{11}$$

where Π^r is the considered pool of classifiers.

TABLE I
STATISTICS OF THE DATASETS USED IN THE EXPERIMENTS.

dataset	samples (class 1 / class 2)	features
Breast Cancer	78 (34 / 44)	24481
Breast Cancer - noise	78 (34 / 44)	24481
Central Nervous System	60 (21 / 39)	7129
Colon Tumor	62 (22 / 40)	6500
Lung Cancer	181 (31 / 150)	12533

This is a non-pairwise (global) diversity measure, which take values from [0,1]. 0 corresponds to identical ensemble and 1 corresponds to the highest possible diversity.

C. Fusion method

As a fusion method we use a one-class mean vote, which combines binary output labels of one-class classifiers. It can be written as:

$$y_{mv}(x) = \frac{1}{L}\sum_{k}[(P_k(x|\omega_T) \geq \theta_k)], \qquad (12)$$

where $[(\cdot)]$ is the *Iverson brackets* and θ_k is threshold for the target class. When a threshold equal to 0.5 is applied this rule transforms into a majority vote for binary problems.

IV. EXPERIMENTAL INVESTIGATIONS

In this section we evaluate the proposed one-class ensemble on the basis of datasets available at [1], whose details are given in Table I. Four different datasets were used and additional, fifth one, was generated. It was based on the Breast Cancer dataset. To test the performance of classifiers in difficult scenarios we have affected 25% of objects with Gaussian noise, thus creating in-class outliers in the data.

As base classifier we have used an OCSVM with RBF kernel [24].

To put the obtained results into context we have tested the performance of multi-class classifiers used for this task - single SVM (trained with RBF kernel and SMO procedure), Random Forest (consisting of 100 decision trees) and Rotation Forest (consisting of 100 decision trees). Additionally we show the performance of a single OCSVM and the proposed ensemble without the pruning step.

Results are based on leave-one-out cross-validation (LOOCV).

All experiments were carried out in the R environment [25], with classification algorithms taken from the dedicated packages, thus ensuring that the results achieved the best possible efficiency and that the performance was not decreased by a bad implementation. The Friedman ranking test [26] was done for comparison over multiple benchmark datasets.

Firstly the parameters for the proposed pruned one-class ensemble are examined. We test the correlations between the accuracy and size of the subspaces / number of classifiers in the pool. For analyzing the optimal number of the classifiers, a subspace size equal to 0.2 was used. Then, when the size was selected, the subspace size parameter was investigated.

[1] http://datam.i2r.a-star.edu.sg/datasets/krbd/

One should note that these results are prior to the pruning phase - which firther improves the accuracy while reducing the number of classifiers in the pool. Results are presented in Fig 1 - 5.

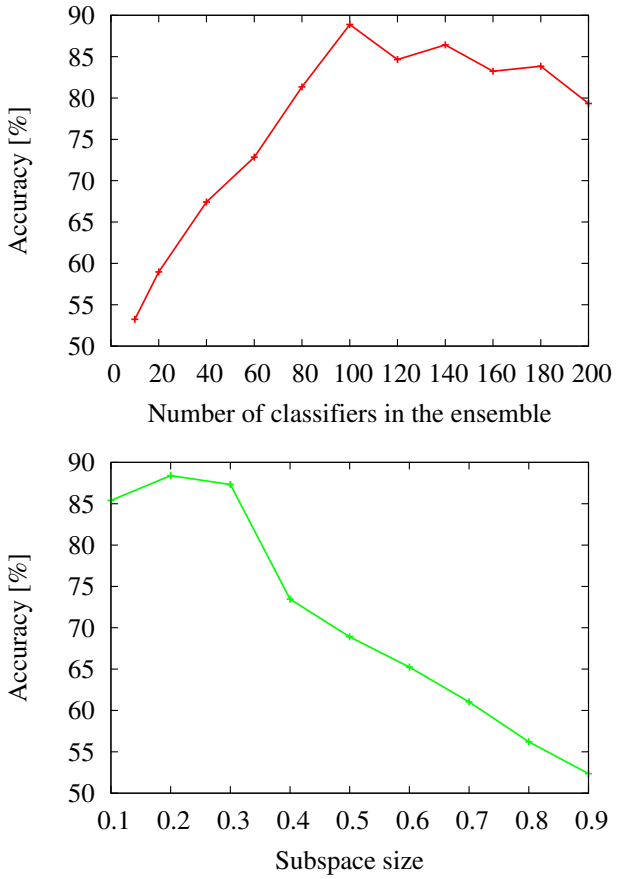

Fig. 1. Correlation between the accuracy and size of the pool of individual classifiers (*top*) and between the accuracy and size of the feature subspaces (*bottom*) for the Breast Cancer dataset.

The established optimal settings are then used for the second stage of the experimental investigation - comparison with other classification methods. Results with respect to sensitivity and specificity, are given in Tab. II.

Analyzing the results of parameter settings for one-class models shows us, that there are some common properties regardless the analyzed dataset. The optimal size of the ensemble was around 100-120 classifiers, built on a small subspaces (consisting of 10% - 20% of features). This allowed to maintain high diversity of the ensemble and allowed for a pruning procedure to select valuable classifiers with mutually complementary areas of competence. Additionally smaller size of the subspaces allowed for training less complex OCSVMs, which in turn prevented them for too overfitted decision boundary.

From the results one may clearly see, that in case of standard microarray datasets the proposed approach returns both specificity and sensitivity similar to those of the state-of-

the-art multi-class models. However in case of noisy (dataset no. 2) and imbalanced (datasets no. 4 and no. 5) our proposed approach is able to outperform significantly the standard classifiers. This happens due to the nature of OCC models - as they are able to learn the distinct properties of the target class, they are able to cope with in-class difficulties.

V. CONCLUSIONS

In this paper a novel approach for microarray analysis, based on an ensemble of one-class support vector machines, was presented. To deal with the problem of high dimensionality, which may cause difficulties for one-class model, a Random Subspace method was applied. This, combined with a diversity-based pruning step, allowed for an effective classifier, returning similar performance as state-of-the-art multi-class methods. The strong points of the proposed method were revealed when dealing with noisy and imbalanced data. In such a case the proposed combined one-class classifier displayed superior quality over its competitors.

The proposed approach may be an attractive tool for bioinformatics decision support systems, in which we deal with uncertain, noisy data or data coming from uneven distributions.

***Abstract*—Spam detection based on flow–level statistics is a new approach in anti–spam techniques. The approach reduces number of collected data but still can obtain relative good results in a spam detection task. The main problems in the approach are selection of flow–level features that describe spam and detection of discrimination rules. In this work, flow–level model of spam is presented. The model describes spam subclasses and brings information about major features of a spam detection task. The model is the base for decision trees that detect spam. The analysis of detectors, which was learned from data collected from different mail servers, results in the universal spam description consists of the most significant features. Flows described by selected features and collected on Broadband Remote Access Server were analysed by an ensemble of created classifiers. The ensemble detected major sources of spam among senders IP addresses.**

***Index Terms*—Spam detection, Flow analysis, Anomaly detection**

I. Introduction

RAPID development of the Internet and associated services induced growth of the desired bandwidth for their execution. Customers expect their Internet Service Providers (IS) to provide a flexible, fully secured access to the Internet. Requirements related to privacy and confidentiality increasingly important. The political environment inside European Union is discussing adjustment of law regulations to market needs. ISPs have to consider Quality of Service (QoS), security, Service Level Agreement (SLA) among others committed to privacy guarantee. This is one of the reasons for development of methods used for monitoring and analysis of traffic in the ISP's core network.

Two approaches are interesting from the perspective of multi–gigabit stream: packet header analysis and flow analysis. Both techniques do not use information contained in payload, which is very important from data reduction and privacy point of view. Additionally, the hash function can be executed on IP addresses to guarantee higher data protection. In some cases, data does not need to be stored. A good example is the statistical detection of Distributed Denial of Service (DDoS) attacks [1] and solutions developed on Field Programmable Gate Array (FPGA) cards [2]. Moreover, such limited data were successful used in an Internet traffic classification task [3].

The packet header analysis is focused processing of headers. The flow analysis is focused on sets of headers determined by a source, a destination IP, source and destination port, timestamps, etc. depending on parameters used to define a flow. The flow analysis enables more compact data reduction. IP Flow Information Export (IPFIX) [4] and NetFlow [5] are well known standards. The equivalent given by Juniper is named J-flow.

Regardless of what was an object of analysis (headers or flows), methods are based on a language that describes analysed events. Usually components of the language are values from packet headers, statistical values such as the average time, the maximal, or the minimal size of packets. Wide lists of defined primitives for flow analysis and honeypot detection are given in [6] and [7] respectively.

In all cases, the following schema is used:

1) select observed parameters $[(m_1, \ldots, m_n) \subset \{M\}]$ (metric),
2) capture values for the parameters $[m_1 \leftarrow .09, m_2 \leftarrow 11, \ldots, m_n \leftarrow false]$ (measurement),
3) calculate features $[f_1 \leftarrow m_1 * m_4, f_2 \leftarrow m_3 + m_5, \ldots]$(features),
4) determine logical relationships between features [if $(f_1 > f_2)$ then action$_1$ else action$_2$](decision).

One of the most important issues in the presented schema is a selection of features. The features that describe spam can be used to create its detection rules. In this paper, flow–level parameters $\{m\}$ selected by Žádník [8] as a subset of the set $\{M\}$ defined in [6] are used create a primary model of spam. In collected spam records, well–separate subclasses are detected (Section II-A). The comparison of subclasses defines important discriminants (Section II-B) that can be used to determine separation rules between spam and the rest of the flows (Section II-C).

Created model was trained and tested on separate data but collected from the same mail server. Therefore, a new data set was created and the most significant features were calculated once again on new data (Section III-A). Both sets of features were compared (Section III-B) and the comparison resulted in a universal set of features (Section III-C).

The final model was checked with Broadband Remote Access Server (BRAS) data (Section IV-A). Decision trees created on the base of both learning sets were used to detect

978-83-60810-53-8/$25.00

spam among BRAS data (Section IV-B). The classification resulted in detection of main sources of spam (Section IV-C).

Conclusions from all tests are presented in Section V.

II. Spam model

The spam model is based on flows collected by Žádník and Michlovský [8]. The flows are defined by by NetFlow protocol that contains:

- source IP address,
- destination IP address,
- IP protocol,
- source port,
- destination port,
- IP type of service.

The NetFlow version 9 allows the user to collect additional features. The features collected in the flows are a subset of features presented in [6].

The authors collected data from the SMTP server hosting mailboxes the Liberouter project group. The data set contains over 58 thousand records described by 64 features and divided into several classes. Among classes, two describe spam. The first class *dnsbl* contains flows from IP address mentioned on DNS black lists. The second class *y_spam* consists of flows that have been successfully received and marked as spam by SpamAssassin.

In the case of the *dnsbl* class flows were labelled because of a source IP address. All flows send from the denied addresses are labelled as spam. For the second class *y_spam*, the labelling process is more complex. The flows are labelled in the off–line mode. The IP addresses and the time of arrival for the flow are compared with the SpamAssassin logs. If a mail with the same source IP address and the destination IP address was marked as spam then all flows with a similar time of arrival are labelled as spam.

The described division of spam is a consequence of used methodology and cannot be used as a framework of the model without any doubt. In the following section, the statistical methodology that creates spam subclasses is presented.

A. Detection of subclasses

Spam subclasses are created in two steps. Firstly, a clustering method is used to detect inner clusters. Next, a decision tree is created to find discrimination rules.

1) Clustering: The predefined spam subclasses *dnsbl* and *y_spam* are a consequence of used methodology. It should not be assumed that this division has a statistical base. Therefore, a new division is created using k–means clustering [9].

In the analysis, all members of *dnsbl* and *y_spam* are treated as a single class *spam*. The class consists of almost 54 thousand records.

A number of spam subclasses is unknown. Therefore, various values of k coefficient from the range $k \in [2, 25]$ are tested. The results of subsequent tests are compared in v–fold cross–validation process. In such test, random samples are drawn v times. Summary indices of the accuracy of the prediction are computed over the v replications. In the described case, the value v is fixed as 10.

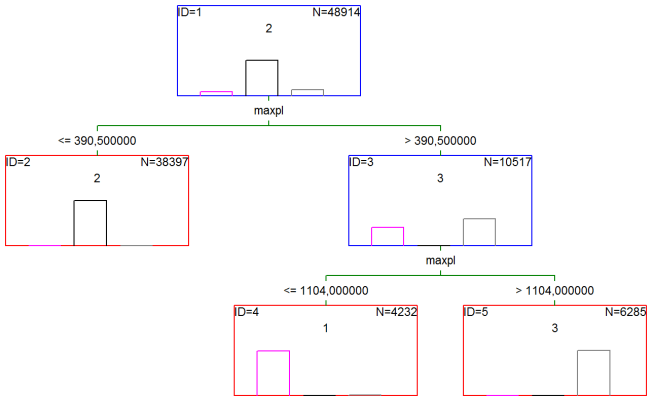

Fig. 1. The classification tree that divides spam into subclasses

A classification error calculated among cross–validation probes was smallest for division into four classes. In such case, the obtained error was 8 percent. However, one of the created classes has a relatively small cardinal number (632 records, which is about 1.3 percent of spam).

Significant differences between cardinal numbers of classes determine *a priori* probability used in a classification task. Members of classes with small *a priori* probability are classified as members of numerous classes to reduce the risk of misclassification.

To avoid future problems the number of classes was reduced to three. The cross–validation classification error increased over 8 percent, which is still an acceptable level. The smallest class was eliminated and the new distribution is more reasonable. The biggest class 2 contains 78.5 percent of record when classes 3 and 1 contain 12.9 and 8.6 percent respectively.

2) Separation rules: The second step of modelling creates discrimination rules between subclasses created during the clustering process. This task is done using a C&RT tree [10]. Such tree is not a very advanced classifier but creates clear decision rules.

The classification accuracy was over 99 percent. That proves a good division of spam into subclasses. Detailed information about classification errors is given in Table I.

TABLE I
THE MISCLASSIFICATION MATRIX FOR SUBCLASSES OF SPAM

	Observed 1	Observed 2	Observed 3
Predicted 1	4206	2	24
Predicted 2	1	38396	0
Predicted 3	6		6279

However, not the accuracy of classifier but the simplicity of created rules is the point to stress in this case. The classifier uses a single feature **maxpl**, which is the maximal length of a packet. The structure of classification tree is given in Figure 1.

Reasons for selection of **maxpl** as the most important discrimination factor are given in the next section.

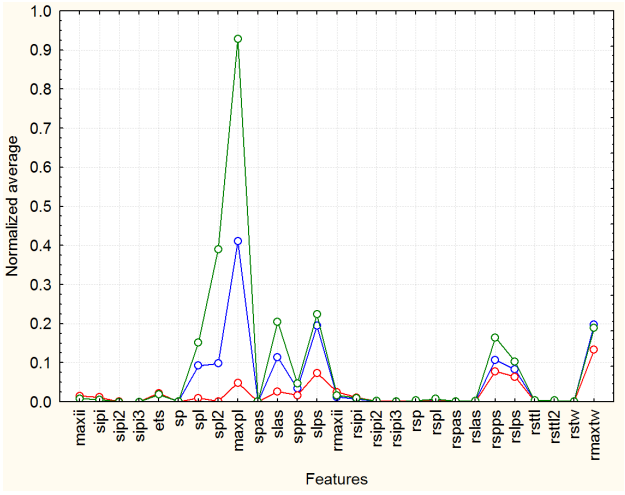

Fig. 2. Normalised average values of the most important spam features calculated separately for subclasses

B. Description of spam subclasses

A classification tree selects features because of the Gini coefficient [11] that is a measure of statistical dispersion. The feature significance is computed by summing over all nodes in the tree the drop in node impurity. The results are expressing relative to the largest sum found over all predictors where the largest sum gets 100 points. Details are given in [10].

The maximal length of package as the feature with major statistical dispersion should differ significantly among classes. It is proved by an analysis of normalised average of features for all three subclasses (presented in Figure 2). The differences between normalised average values calculated for separate subclasses are most significant for this feature. On the same basis, a set of important discriminants may be defined as:

spl Average package length,
spl2 Variation of package length,
maxpl Maximal package length,
slas Average length of package having the ACK flag,
slps Average length of package having the PUSH flag,
rspps Number of packages having the PUSH flag in response,
rslps Average length of package having the PUSH flag in response,
rmaxtw Maximal size of the response TCP window.

All mentioned features (except **rmaxtw**) take highest values for the subclass number 3 and the lowest for the subclass number 2. The subclass number 1 is somewhere between.

The presented analysis is limited to the normalised averages. More information is given by a probability density function. The function that was calculated for selected features (separately for all subclasses) is presented in Figure 3.

The presented normal distribution functions are determined by the following formula

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \qquad (1)$$

TABLE II
THE DISTRIBUTION OF *dnsbl* AND *y_spam* GROUPS AMONG SPAM SUBCLASSES

	dnsbl [%]	*y_spam* [%]
Subclass 1	2.9	97.1
Subclass 2	98.3	1.7
Subclass 3	0.0	100.0

where μ is the mean and σ is the standard deviation. Both values are estimated on the base of values of a feature in the given subclass.

The distribution for the feature **maxpl** presented in 3(b) shows once again that the maximal length of packets is a good discriminant of subclasses. The feature gives three well–separate distributions.

Finally, an analysis of distribution of groups *dnsbl* and *y_spam* among calculated subclasses is presented. The analysis shows that the subclass 2, which has the lowest values of analysed features, consists of spam sent by IP addresses from DNS black lists. In this case, the analysis confirms division of original data between spam detected by blacklists and a spam analyser. However, spam in the *y_spam* group, which contains spam detected by SpamAssassin, is not a solid group and its members split between subclasses 2 and 3. Details are given in Table II.

C. Spam subclasses in classification task

In section II-A, the decision tree was presented as a source of discrimination rules. The tree, which separates spam subclasses, brings the description of the most significant spam discriminants.

The features are used to create a similar tree that separate spam from the rest of network traffic. The tree separates known spam subclasses (1–3) from flows without spam. This new class, labelled as 0, consists of records accepted by SpamAssassin as well as outgoing traffic. The class consists of about 4 thousand of records, which is significant less than number of spam records (54 thousand).

The created tree is given in Figure 4. The tree uses the **rslps** feature that describes the average length of package having the PUSH flag in response.

TABLE III
THE CLASSIFICATION MATRIX FOR THE CLASSIFICATION TREE THAT SEPARATES SPAM SUBCLASSES FROM THE REST OF TRAFFIC

	Class 0	Class 1	Class 2	Class 3
Predicted 0	2920	2	0	282
Predicted 1	242	4169	2	0
Predicted 2	86	1	38396	0
Predicted 3	924	41	0	6021

The classes 1 to 3 are covered with a false positive error. A part of valid traffic is recognised as spam. The error is not equally distributed among classes. The error is minimal for the class 2 where it is only 0.2 percent. For classes 1 and 3

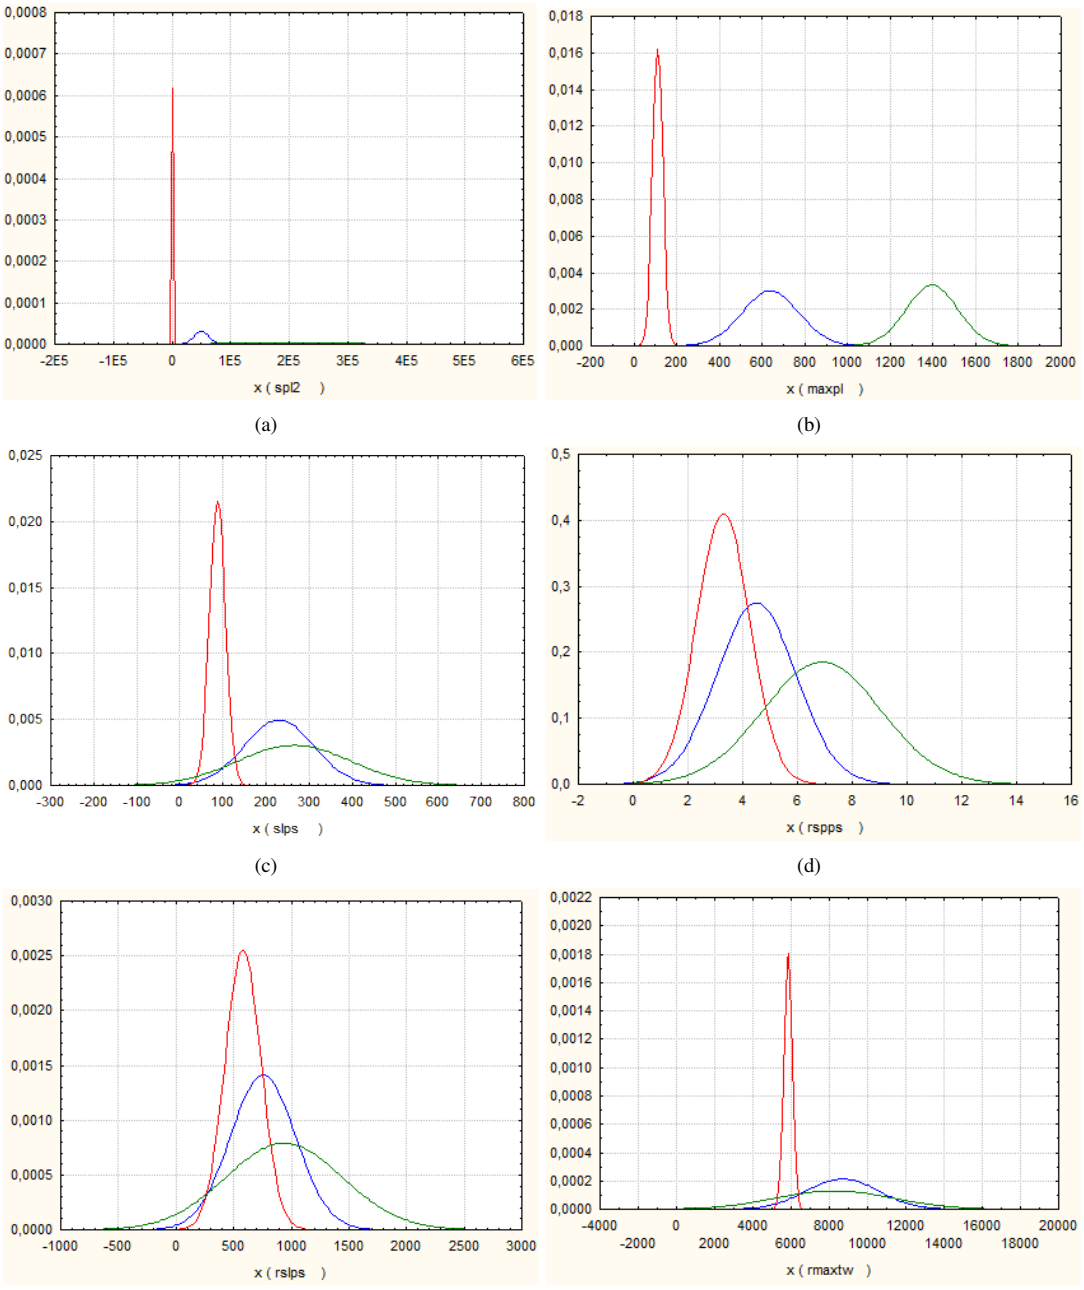

Fig. 3. Probability density calculated for the most characteristic spam features

it is 5.5 and 13.8 percent respectively. Details are given in Table III.

The total accuracy of the tree is 97 percent. When spam is treated as a single class, the accuracy is a slightly lower and the classification tree creates seven rules instead of three.

Similar results, for the same data set but described by different features, are presented in [12] (over 95 percent) where the Principal Component Analysis (PCA) was used to reduce number of features and in [8] (about 96 percent) where 64 features were used.

Although the accurate rate is higher than in cited works, a high error (about 30 percent) in classification of class 0 can be observed. This class is corresponding to the flows without spam. Obviously, this is the most important class since the classifier has to avoid misclassifying non–spam flows with spam flows. The high false positive ratio makes the binary classifier useless, but the classifier that recognises spam subclasses can be still used as a filter.

In the described example, there are three different cases. The first case concerns separation of valid traffic (class 0) and

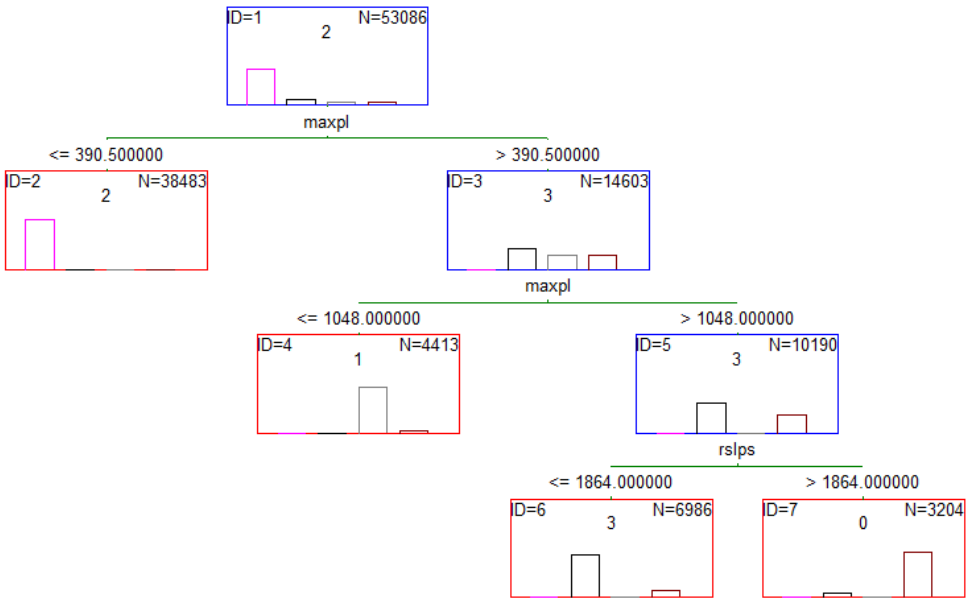

Fig. 4. The classification tree that separates spam subclasses from the rest of traffic

spam from blocked DNS addresses (class 2). In this case, the tree is an adequate tool to separate classes. The second case concerns the class 1. Nearly all members of this class are recognised correctly. However, some flows without spam are also classified as members. This class requires future analysis of false positive. The last case is focused on the class 3. Misclassifications are noticed between this class and the class 0. A more powerful classifier is needed to separate these classes.

III. Model verification

The results of analysis presented in Section II were verified with separate data. Significance of features determined on Žádník's data was validated by comparison with features calculated on Warsaw University of Technology mail server called Alpha.

A. Alpha

The described spam model was created on the base of NetFlow records collected by Žádník. For validation, a new set of NetFlow records was collected at Warsaw University of Technology. The set originates from the mail server called Alpha and consists of NetFlow records described by the same collection of features as Žádník's set. Data was collected through one working week. Over 42 thousand NetFlow records were collected. Among them 589 were labelled as spam.

This ratio between spam and non–spam data is completely different from the data discussed before. Here, the number of non–spam data is lower than the spam data. Therefore, the model was created on a dataset that is not very similar to the dataset collected from the Alpha.

Using the same method as for the Žádník's set (section II-C) a classifier based on a classification tree was created. The classifier separates spam from the rest of flows. The accuracy for both classifiers is very similar (about 97 percent). However, the disparate distribution of classes in the Alpha set results in much lower observed error (about 3 percent) in classification of class 0.

The created classification trees have different structures and splits are based on different features. Therefore, a set of features chose on the base of analysis of the Žádník's set should be verified.

B. Verification of features

Two decision trees that separate spam from the rest of traffic were created. The first one was trained on data from the Žádník's set, the second one on data collected from the Alpha server.

In the training process, the Gini coefficients were calculated. Therefore, the same approach that was used before to evaluate features describing spam can be applied once again to evaluate importance of features. The importance was calculated for all features proposed in [8].

An importance ranking on a 0–100 scale for each feature was created separately for each set. Figure 5 presents calculated significance of features.

The significant correlation between sets cannot be detected. There are several possible reasons for the difference between features selected by different classifiers.

The first reason may lie in the method. When a classification tree is created, the algorithm focuses on the most important features. Third–rate features may be different in various solutions.

The second reason lies in difference between the contents of discussed sets. As an example the feature **spas**, which describes the number of packages having ACK the flag set

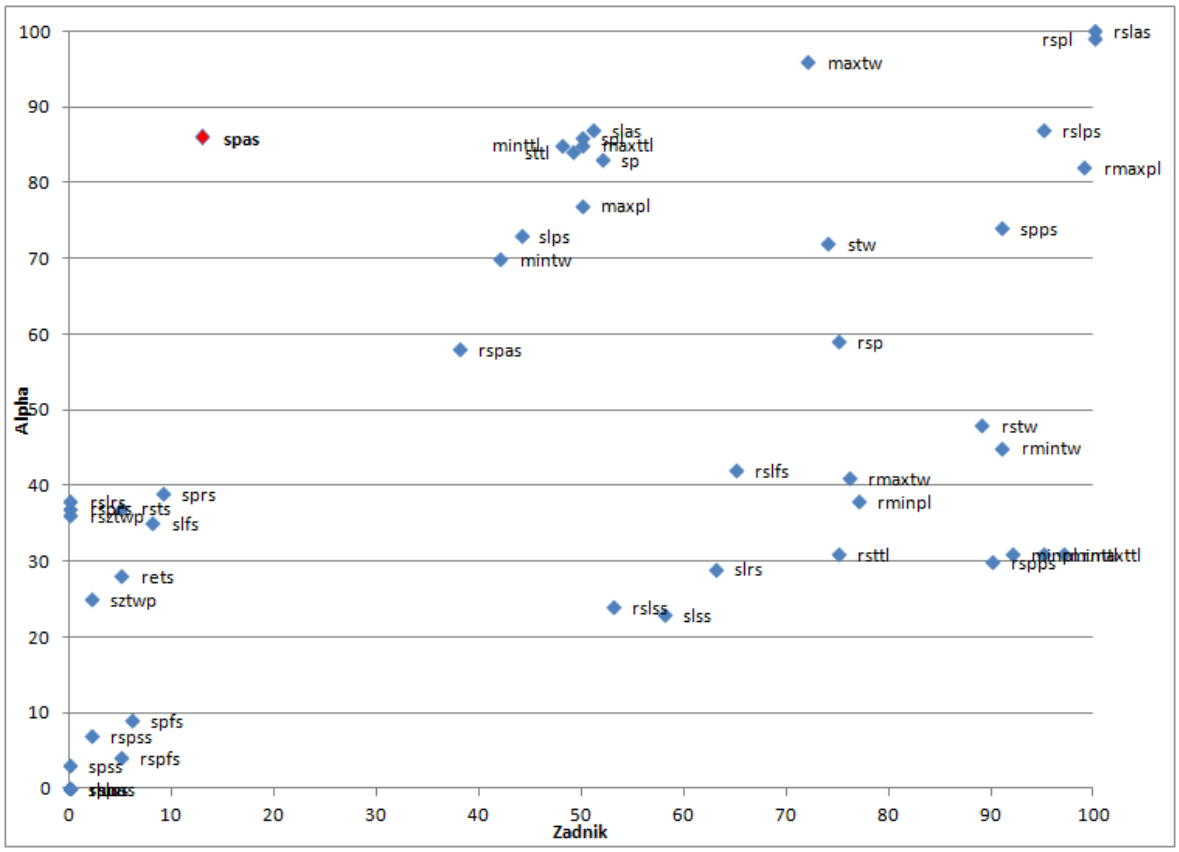

Fig. 5. Significance of features for both data sets: Žádník and Alpha

will be discussed. The feature is quite important for the classifier created on the Alpha set whereas of little importance for classifier created on the Žádník's set. The observation is highlighted in Figure 5.

The ACK flag is used to acknowledge the successful receipt of packets. Therefore, it should be turned on in almost all packages. The only exception is the first package sent in an exchange. In a transaction, the total number of packages with the ACK flag should be the total number of packages sent by a sender minus one. In practice, packages can be resend or missed and exceptions to the rule can be observed.

For discussed sets, the relation between the total number of packages (**sp**) and the total number of packages with the ACK flag (**spas**) in a flow was estimated using the method of least squares [13]. Results are presented in Figure 6.

For data collected on the Alpha server, (Figure 6(b)) the relation is similar to the ideal one:

$$\textbf{spas} = \ \textbf{sp} - 0.6. \tag{2}$$

Meanwhile, in the Žádník's set (Figure 6(a)), the relation is farther from the ideal:

$$\textbf{spas} = 0.9 \ \times \ \textbf{sp} - 9.4. \tag{3}$$

Such differences may influence features evaluation.

C. Universal features

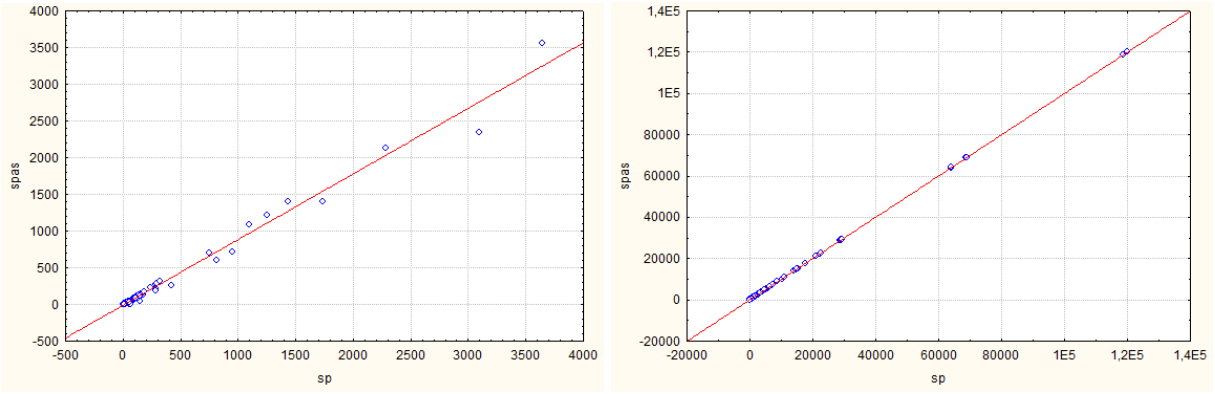
Despite the differences in importance of features evaluated on the base of data from different sources there is a small number of features such as **rslas** or **rspl** significant for both classifiers. However, their number is not enough to create a universal set of features. Therefore, the following method was used to create such set.

Each feature f calculated for a flow from source to designation has its equivalent rf calculated for a response. It is assumed, in the described method, that if a feature is added to the universal set then a response equivalent will be also added and vice versa.

The significance of features is evaluated on the base of Gini coefficients calculated during the decision tree creation. The evaluation functions g_A and g_Z are calculated from the Alpha and the Žádník's sets respectively. Each feature should be evaluated on the base of both evaluations. The presented assumptions result in the following evaluation function

$$g(f) = \frac{\max(g_A(f), g_A(rf)) + \max(g_Z(f), g_Z(rf))}{2}. \tag{4}$$

Because the range of evaluation functions g_A and g_Z is $[0, 100]$ it is reasonable to assume that significant features should at least achieve the level of 50 points.



(a) (b)

Fig. 6. The relation between the total number of packages and the total number of packages with the ACK flag calculated for the Žádník 6(a) and the Alpha 6(b) sets

TABLE IV
THE MOST SIGNIFICANT FEATURES DESCRIBING SPAM

Rank	Name	Description
100,0	slas	Average length of package having the ACK flag
99,5	spl	Average package length
91,0	slps	Average length of package having the PUSH flag
90,5	maxpl	Maximum package length
84,0	maxtw	Maximum TCP window size
82,5	spps	Count of packages having the PUSH flag
73,0	stw	Average TCP window size
68,0	mintw	Minimum TCP window size
67,5	maxttl	Maximum TTL
67,0	sp	Packages count
66,5	minttl	Minimum TTL
66,5	sttl	Average TTL

Among features, twelve have the evaluation result greater than 50 points. The most significant features are collected in Table IV. Information about direction of traffic is skipped. It is assumed that mentioned features should be calculated for both directions. That gives 24 features.

IV. Model application

The model was applied on data collected from a Broadband Remote Access Server (BRAS). On the base of learning data, an ensemble of classifiers was created and used to detect main sources of spam.

A. BRAS

Data was collected from a Broadband Remote Access Server (BRAS). Firstly, a probe that contains full headers was created. In eight seconds, almost 50 million PCAP packages were captured. From the packages payload was removed. The total size of remaining headers was 4.44 GB. Among all packages, 29.5 thousand were transferred by STMP protocol. That produced 407 NetFlow records. The ratio of collected records to the size of created file forced a different approach.

The second set was calculated in a reduced form. Because of huge size of collected PCAP headers NetFlows record were captured instead. Each record was described by 12 features including minimum, maximum, and average size of package, and binary information about flags occurrence. 176 thousand records were captured. The total size of collected NetFlow records was 18 MB.

Collected records was analysed by a spam detector to get out information about sources of spam.

B. Detector

The classifiers that detect spam were created on the base of two learning sets: Alpha and Žádník. Both sets were divided into learning and testing sets. The cardinal number of the training set was similar to the cardinal number of the learning set. Moreover, the proportion of spam to the rest data was similar in the learning and the testing sets, although the proportion of spam in the Žádník's set and the Alpha set are different.

It was mentioned before that a single tree should not be used as a detector. Instead, detector was projected as an ensemble of trees. Each tree was trained on the learning set and validated on the training set.

Each classifier from the ensemble recognises two classes: spam and background traffic. Before, the subclasses of spam were considered to determine the spam model. However, for the final user a determination of the spam subclass is not such important as a detection of spam. Therefore, the binary classification is performed.

The classes are labelled by 1 and -1 respectively. The classifier C_i that returns a decision y_i is described by the s_i coefficient that is the accuracy of discrimination between spam and the background. The final classification decision is the sign of a weighted sum given by the formula:

$$y = \operatorname{sgn}\sum_{i=1}^{n} \frac{s_i}{\sum_{j=1}^{n} s_j} y_i, \tag{5}$$

where n is the number of classifiers in the ensemble.

The detector can return 0 what means that the decision is uncertain.

C. Detection of spammers

The created detector was used to detect spam among flows collected from the BRAS. Over 60 trees trained on various subsets of the universal features set were used to create the detector defined by (5). In the result, 934 records from 176 thousand records were labelled as spam.

In the next step, sources of spam were localised. Records from the captured data came from 64088 unique IP addresses. Among them, 359 have sent at least one record labelled as spam. Most of them (211 addresses) sent just one record labelled as spam, but the record holder sent 221 spam records.

It is hard to assume that each sender from this set is a spammer. Therefore, a spammer was defined as a source of at least 10 spam records. This limitation results in seven main spam senders. Together they sent 46 percent of records labelled as spam. The main spammers can be easy blocked, which results in a significant reduction of spam.

V. Conclusions

In this work, the approach to detect main sources of spam in collected network traffic is presented.

Firstly, flow–level model of spam is created. The model describes spam subclasses and brings information about major features for a spam detection task. The presented model was verified on separate data. The verification resulted in a universal set of features.

The universal set consists of features that should be collected from a network in the form of NetFlow records. Among features are length of packages, information about window size, information about flags etc.

Selected features from the universal set were collected on Broadband Remote Access Server. Next, the detector, which was an ensemble of decision trees learned on various datasets, was created. The detector showed main source of spam among senders of collected flows. An elimination of detected spammers will reduce a number of spam by over 45 percent.

It should be noticed that the spam traffic properties will be changing over time and model will need to be retrained. The traffic properties can be also different in case of intensive spam attack. However, a regular collection of learning records from a network should resolve the first problem. Additionally, special learning sets that simulate intensive attacks can be used to improve model.

Gradually modifications of the model can be easy done by addition of new classifiers to the detector represented by equation (5) (although the total number of classifiers should be limited to avoid the drift learning problem).

Moreover, the detector based on decision trees can be implemented as a network probe. A software solution can be implemented as an nProbe [14] plug–in, but a hardware solution is also possible if the decision algorithm will be implemented on FPGA card.

***Abstract*—Binary classifiers are grouped into an ensemble to solve multi–class problems. One of proposed ensemble structure is a directed acyclic graph. In this structure, a classifier is created for each pair of classes. The number of classifiers can be reduced if groups of classes will be separated instead of individual classes. The proposed method is based on the similarity of classes defined as a distance between classes. For near classes the structure of DAG stays immutable. For the distant classes more than one is separated with a single classifier. In this paper, the proposed method is tested in variants based on various metrics. For the tests, several datasets from UCI repository was used and the results were compared with published works. The tests proved that grouping of radial basis functions into such ensemble reduces the classification cost and the recognition accuracy is not reduced significantly.**

***Index Terms*—Classification, Radial Basis Function, Directed Acyclic Graph, Support Vector Machines**

I. Introduction

RADIAL Basis Functions (RBF) can be used both as multi–class and binary classifiers. Binary RBF classifiers are useful, still improved linear models in a nonlinear subspace [1], [2] and can be used to create an ensemble of classifiers to solve multi–class problems. Such approach was confirmed by research on Support Vector Machines [3]. In fact, there is equivalence between a decision rule created by an SVM with radial kernels and radial networks [4]. Therefore, an ensemble of classifiers can be created for binary RBF classifiers as well as in the case of SVM equivalents.

Although one–step solutions were proposed [5], [6] to solve multi–class tasks by an SVM, they are not efficient [7]. An alternative solution is creation of an ensemble. Main approach to create an ensemble are discussed in [7], [8].

Proposed approaches are One–Against–All (one class is compared against the rest) [9], One–Against–One (a classifier is created for each pair of classes) [10], Error-Correcting Output Codes (class binarisation in order to enhance generalisation ability) [11], and several methods based on graph structures [12], [13].

Among several graph ensemble fusion methods can be used to solve multi–class problems using binary RBF classifiers [14] one of the most popular strategy is grouping SVM classifiers into a directed acyclic graphs (DAG) [13].

In the case of an n-classes problem a tree implementation requires $n-1$ classifiers and the average decision process uses $n-1/2$ classifiers. A DAG ensemble needs $n(n-1)/2$ classifiers to solve the same problem. However, only $n-1$ classifiers is used in the classification process and obtained results are usually better [15], [16].

In the work [17], the method for reduction of number of classifiers in a DAG structure was presented. The proposed method is based on a class similarity. Similar classes are grouped and separated from diametrical different classes as a whole group. In this case, a number of used classifiers is reduced. The method was projected for linear classifiers and verified on a single recognition task. The similarity calculated in the work was a derivative of the Euclidean metric. The algorithm was tested on a single recognition task.

This work is based on the algorithm proposed in [17]. However, several improvements with respect to the previously published works have been done. The algorithm has been tested on a wider set of classification problems. Researches on new problems resulted in modifications of the algorithm. The most important modification was done in limitation rules presented in Section II-C.

The algorithm was a basis for several models based on various definitions of similarity. The following metrics are used in modelling: the Euclidean, the Chebyshev, the Manhattan, the Minkowski, and the Pearson.

Models are verified on various datasets from UCI repository. Therefore, results can be compared with others works and the results of the modified algorithm were compared with results of RBF classifiers grouped into a DAG ensemble.

II. Reduced DAG ensemble

A. DAG ensemble

A directed acyclic graph G, which is described by the set of vertices $V(G)$ and the set of edges $E(G)$, can be declared as an ensemble of binary classifiers.

The vertices are grouped in layers. The first layer contains a single vertex – the root. Each subsequent layer has one more vertex. The last layer consists of n vertices where n is the number of recognised classes.

Each vertex from any layer except the last one has connections with two vertices from the next layer. Vertices on the last layer are leaves. Each leaf from $L(G)$ is connected with a final classification decision (one of the recognised classes). The rest of vertices $V(G)\backslash L(G)$ contains binary classifiers. The decision of the classifier defines which connected vertex

978-83-60810-53-8/$25.00

will be activated next. If a leaf is activated a final decision is determined by a class connected with the leaf.

A vertex is also identified with a group of classes that can be achieved from the vertex. Each vertex can be declared as a root of sub–DAG. Such root represents a group of classes collected on the last layer of the sub–DAG. If $v \in V(G)$ is the root of the sub–DAG G_v then $L(G_v) \subseteq L(G)$ determines classes identified with the vertex.

Sub-DAGs can be also used to determine classifiers. A vertex $v \in V(G) \backslash L(G)$ has two successors v_i and v_j. The successors are identified with classes connected to $L(G_{v_i})$ and $L(G_{v_j})$ respectively. Therefore, the binary classifier in the vertex v divides dataspace between two groups of separable classes from sets $L(G_{v_i})$ and $L(G_{v_j})$.

The aim of the proposed method is to eliminate some of vertices from layers. Then an activated vertex can lie on a layer further than the next one. The example of reduced structure is presented in Figure 1. The elimination of vertices shortens the average classification time. However, not each vertex can be eliminated without a significant reduction of the accuracy ratio. Therefore, the selection of eliminated vertices will be based on similarity between classes.

B. Similarity

A similarity between classes is estimated on the base of a distance. The distance between classes $d(C_X, C_Y)$ depends on the distance between elements of those classes $d(x, y)$ and can be defined as the distance between nearest, furthest elements or as the average distance between all pair of elements. However, mentioned above distances are very time-consuming. Instead, the distance may be approximated as the distance between centroids (the centres of gravity for the classes)

$$d(C_X, C_Y) = d\left(\frac{1}{n_{C_X}} \sum_{x \in C_X} x, \frac{1}{n_{C_Y}} \sum_{y \in C_Y} y\right). \quad (1)$$

The equation (1) can be also used to calculate a distance between groups of classes. If a group is an union of classes $C_X = \bigcup_{i=1}^{k} C_i$ then all members of classes C_i, where $i = 1 \ldots k$, are treated as members of C_X. The distance between such groups can be calculated as (1).

The distance between an individual elements of the data space $d(x, y)$ depends on the selected metric. Usually it is the Euclidean metric

$$d(x, y) = \sqrt{\sum_{i=1}^{n} (x_i - y_i)^2}. \quad (2)$$

However, if the recognised elements are described by some specific features it is sometime better to select a different measure.

Two potential candidates are Manhattan and Chebyshev metrics. The Manhattan distance

$$d(x, y) = \sum_{i=1}^{n} |x_i - y_i| \quad (3)$$

should be calculated when individual features are independent, but their sum may be treated as a rational measure of the similarity. In the Chebyshev distance

$$d(x, y) = \max_{i \in \{1, \ldots, n\}} |x_i - y_i| \quad (4)$$

the similarity will depend on the maximal difference among features.

In the tests, two more metrics were used.

The Minkowski metric is a parameterised metric that becomes the Euclidean metric for $k = 2$.

$$d(x, y) = \left(\sum_{i=1}^{n} |x_i - y_i|^k\right)^{\frac{1}{k}}. \quad (5)$$

In this work $k = 3$ was used.

The Pearson metric bases on the Pearson product–moment correlation coefficient r_{xy} and presents inverse correlation between data vectors

$$d(x, y) = 1 - r_{xy}. \quad (6)$$

C. Creation of structure

The graph for the n–classes classification task has n layers where the last layer contains leaves labelled as recognised classes. The algorithm starts with the set $V(G)$ of n leaves. Therefore initially $V(G) = L(G)$.

In each step a pair of the vertices v_i and v_j is selected. The selected vertices are roots of DAGs with nearest groups of classes on the last layers $L(G_i)$ and $L(G_j)$.

$$(v_i, v_j) = \arg \min_{v_i, v_j \in V(G)} d(L(G_i), L(G_j)). \quad (7)$$

In this and the following equations, the notation $L(G_i)$ means all classes from the last layer (leaves) of the DAG with root in the vertex v_i. Therefore the distance $d(L(G_i), L(G_j))$ can be calculated as a distance between group of classes (1).

The new vertex v_k is added to the graph G. The vertices v_i and v_j are now its successors. The new graph G is given by the set of vertices

$$V(G) = \{v_k\} \cup V(G) \quad (8)$$

and the set of edges

$$E(G) = \{(v_k, v_i), (v_k, v_j))\} \cup E(G). \quad (9)$$

It is easy to observe that groups $L(G_i)$ and $L(G_j))$, determined by vertices v_i and v_j, may be still the nearest groups in the graph G. Moreover, the created group $L(G_k)$ is the union of groups $L(G_i)$ and $L(G_j)$ and consequently the union may be selected as the nearest with one of groups determined by the successors. Such situations should be avoided. Therefore, the set of vertices that are taken into consideration in the equation (7) should be limited by the following rules.

Under the second rule, that eliminates problem with the same pair selected again, the two vertices v_i and v_j can be joined if and only if the union of classes represented by them is not a subset represented by any existed vertex

$$\forall(v_k \in V(G))L(G_i) \cup L(G_j) \nsubseteq L(G_k). \tag{10}$$

The rule (10) is modification of the rule presented in [18]. The previous rule assumed that $L(G_i) \cup L(G_j) \neq L(G_k)$, however then the algorithm was not convergent for some datasets.

Under the first rule, that eliminates problem of joining successors with a predecessor, the two vertices v_i and v_j can be joined if and only if the set of classes represented by one of them is not a subset of the other

$$C(G_i) \nsubseteq C(G_j) \wedge C(G_j) \nsubseteq C(G_i). \tag{11}$$

Both conditions (11) and (10) can be used to create a limited set of allowed pairs of vertices

$$\begin{aligned} S_P &= \{(v_i, v_j) : v_i, v_j \in V(G) \\ &\wedge \ L(G_i) \nsubseteq L(G_j) \wedge L(G_j) \nsubseteq L(G_i) \\ &\wedge \ \forall(v_k \in V(G))L(G_k) \neq L(G_i) \cup L(G_j)\}. \end{aligned} \tag{12}$$

Moreover, the common part of classes is ignored when the distance is calculated and the final form of the formula (7) is

$$(v_i, v_j) = \arg \min_{(v_i,v_j)\in S_P} d(L(G_i)\backslash L(G_i \cap G_j), L_j \backslash L(G_i \cap G_j)), \tag{13}$$

where

$$L(G_i \cap G_j) = L(G_i) \cap L(G_j). \tag{14}$$

In each step of the algorithm, the two allowed vertices v_i, v_j are joined. The algorithm stops when no join can be made

$$\forall(v_i \in S_G)\exists(v_j \in S_G)L(G_i) \subseteq L(G_j) \vee L(G_j) \subseteq L(G_i). \tag{15}$$

D. Classification

The classification process starts in the root of DAG ensemble and finishes in a vertex from the last layer.

In the DAG ensemble, each classifier rejects one from the recognised classes. Therefore, if the vertex v_i is a root of a DAG with the last layer consists of vertices $L(G_i)$ then the vertex v_j, which is next in the classification path, is connected with classes defined by the following rule

$$L(G_j) = L(G_i) \setminus \{v_k\} \wedge v_k \in L(G_i). \tag{16}$$

In the reduced ensemble, the number of classification steps can be reduced, because a classifier can reject more than one class in one step and the rule (16) is replaced by

$$L(G_j) = L(G_i) \setminus V_k \wedge V_k \subset L(G_i). \tag{17}$$

When a vertex $v \in V(G)\backslash L(G)$ has two successors v_i and v_j, identified with classes connected to vertices $L(G_i)$ and $L(G_j)$ respectively, then the binary classifier in the vertex v divides dataspaces between two groups of separate classes $L(G_i) \setminus (L(G_i) \cap L(G_j)))$ and $L(G_j) \setminus (L(G_i) \cap L(G_j)$.

E. Time reduction

Three main elements that describe costs of the created classifiers are the construction time, the learning time, and the classification time.

The first element is a construction of the ensemble. In the case of a DAG, this element can be omitted. However, it is an important part of the presented method (described in Section II-C. If the cost of the ensemble creation is significant then potential reduction of the learning time can be balanced by a cost of the new element.

At the first glance, the learning time should be shorter in a reduced structure. However, a reduction of classifiers in the ensemble does not necessarily have to result in a reduction of the learning time. All classifiers in a DAG structure present the One–Against–One approach. Meanwhile, at least several classifiers in the reduced structure split dataspace between a class and a group of classes. It was proved that One–Against–One approach can results in lower costs than One–Against–All approach [8]. Therefore, the learning time can be longer for the reduced structure.

Considering pessimistic assumptions on the building time and the learning time, we should remember that the most important cost in the classifier evaluation is the classification time. The reduced structure has definitely lower classification costs that DAG.

In the n–classes recognition time, a DAG structure needs $n-1$ binary classifiers to assign the analysed case to one of recognised classes. If C is a set of analysed cases and C_i is a subset of cases assigned to the class labelled with i then the classification time for the set C is calculated as

$$\sum_{i=1}^{n} |C_i| * (n-1) * t = |C|(n-1) * t, \tag{18}$$

where t is the binary classification time, which should be equal for all binary classifiers from the ensemble.

In the case of the reduced structure, the same set C is defined as the union of cases $\hat{C}_i$ assigned to the class labelled with i by the new classifier. The number of binary classifiers used in the classification depends on the final classification decision and can be calculated as $d_i - 1$, where d_i describes number of vertices on the path from the root to the leaf assigned to the class labelled with i. Therefore, $d_i \leq n$.

The classification time for the set C is calculated as

$$\sum_{i=1}^{n} |\hat{C}_i| * (d_i - 1) * t. \tag{19}$$

From $d_i \leq n$ and $\sum_{i=1}^{n} \hat{C}_i = C = \sum_{i=1}^{n} C_i$ we know that

$$\sum_{i=1}^{n} |\hat{C}_i| * (d_i - 1) * t \leq \sum_{i=1}^{n} |\hat{C}_i| * (n-1) * t \leq |C|(n-1) * t. \tag{20}$$

Therefore, the classification time for the reduced structure is lower if at least one case from an analysed set belongs to the class with a reduced classification path.

III. Results and Discussion

In this work, four sets from UCI repository were used. Letter Image Recognition Data (Letter), Optical Recognition of Handwritten Digits (Optdigits), Glass Identification Database (Glass), and Wine recognition data (Wine).

Optdigits	3823	1797	10	64

In the case of Optdigits dataset and Letters relations between the training sets and the testing sets proposed in the reference works [15] and [16] had been used. However, in the case of datasets Wine and Glass solutions proposed in the reference works had been tested by the cross validation method. Therefore, the validation performance was measured by training 70 percent of the training set and testing the other 30 percent of the training set in these cases. Details on the sets are given in Table I.

The computational experiments for this section were done on an Intel Core i5–2500 with 8 GB of RAM.

All the problems were tested using RBF kernels. The accuracy rate was estimated using different kernel parameters γ and cost parameters C where $C = \{2^0, 2^1, \ldots, 2^{12}\}$ and $\gamma = \{2^{-12}, 2^{-11}, \ldots, 2^4\}$. The selection of parameters values is the most time–consuming part of the process. 221 tests must be done to check all pairs of parameters for one metric. On the testing computer, the test series lasted from few seconds to three hours depending on a dataset. Therefore, some proposals should be made to reduce the computation time.

Table II presents the accuracy ratio obtained by using different metrics. Results are very similar and any of metrics cannot be chosen as the best one. However, it can be observed that the Chebyshev and the Manhattan metrics gave worse results. The Minkowski metric, which had been gotten with $k = 3$, resulted in the accuracy similar as the Euclidean metric. In fact, the calculations can be limited to Euclidean and Pearson metrics to cover all of the best results.

The accuracy ratio obtained by the proposed method was compared with RBF classifiers ordered in the DAG structures, presented in works [15] and [16]. The detailed results including used parameters are presented in Table III.

The results of three compared approaches cannot be compared directly because works [15] and [16] covers different data set. Therefore, the proposed method should be compared with each work separately. The average accuracy ratio calculated among datasets discussed in the works is always minimal better for the proposed method.

The results of the proposed method were compared with two more state-of-the art algorithms: One–Against–All and One–Against–One methods. The average accuracy calculated for all data sets was 92.22 percent for the One–Against–One method, 91.92 percent for the One–Against–All method and 92.35 for the proposed method. Details on results and configuration are give in Table IV. The averages are very similar and any method cannot be pointed as the best one.

The most important aspect in the comparison is reduction of created vertices in the DAG structure. The number of vertices used to solve the Optdigits and Letter problems was reduced to 42 and 66 percent of vertices from the DAG structures. The proposed method reduced the number of RBF classifiers that has to be trained. Additionally, the average classification time will be shorter, because of reduction of decision paths. Two examples for Optdigits are shown in Figure 1.

Each graph has leaves marked with circles and vertices with classifiers marked with diamonds. Inside the diamonds two groups of classes are noticed. The classifier inside the vertex divides the data space between members of both groups.

The reduction of the average classification time is clearly visible in the case of the class zero. The class can be selected after three classification steps instead of nine as in the case of non–reduced DAG structure. In the proposed method, only two classes from the last layer are classified in nine steps.

The created graphs have the same number of vertices. However, the structures are different. First, numbers of vertices on layers are different. Moreover, different nearest classes were selected in the first step of the algorithm. For the Chebyshev metric, nearest classes are 1 and 8, whereas for the Euclidean metric the nearest classes are 3 and 9. The differences in the structure results in differences in the accuracy presented in Table II.

The ensembles created in the Letter problem is too complex to present a comparison between several graphs. However, the graph created using the Euclidean metric is presented in Figure 2. The letter 'L' can be recognised in 9 steps. 20 steps are needed to recognise such letters as 'K', 'G', 'Q', 'R', 'B', 'S', and 'Z'. Meanwhile the DAG structure needs 25 classifiers to recognise any letter. Therefore, both average and pessimistic costs are much lower in the proposed solution.

In the case of Glass problem, the reduction ratio is smaller. This is connected with the smaller number of recognised classes. In the Wine problem, a number of vertices cannot be reduced. However the algorithm determines the order of classifiers in the DAG. As it was shown in Table III, the determined order allows the ensemble to obtain the best result.

The method results in reduction of the classification time. In Table V, the learning time and the classification time obtained by DAG classifiers are compared with the time obtained by the proposed method. Additionally, the graph structure building time is presented in the case of the method from this work.

The proposed method reduces the classification time for complex tasks. Although, the classification time for various methods given in second has only an approximate character, the difference between methods bases on strong theoretical bases (Section II-E).

TABLE II
THE ACCURACY RATIO OBTAINED BY USING DIFFERENT METRICS. THE BEST RESULTS ARE EMPHASISED.

Dataset	Chebyshev	Euclidean	Manhattan	Pearson	Minkowski
Wine	98.86	**99.44**	**99.44**	**99.44**	**99.44**

Letter	298.62	92.80	0.05	214.00	37.02
Optdigits	15.47	1.81	0.00	1.75	1.06

IV. CONCLUSION

In this work, the algorithm based on primary works [17], [18] was modified and used to create several models of RBF ensembles. The structures of created ensemble are reduced directed acyclic graphs. The method reduces a number of created classifiers. The classifiers, which discriminate distant classes, are replaced by the classifiers, which separate groups of classes. A theoretical estimation shows that the new structure should reduce the classification time in comparison to the DAG structure.

The algorithm was tested on four sets from UCI repository. The obtained results were compared with published results. The accuracy ratio obtained by proposed method is similar to presented in works [15] and [16]. Also results obtained by two state-of-the art algorithms One–Against–All and One–Against–One are nearly identical. The proposed algorithm should be also compared with other methods such as ECOC and Decision Template tested in [19], [20], but its main advantages is not the highest accuracy, but the significant reduction of the number of classifiers in the DAG structure.

The number of created classifiers was reduced to 42 and 66 percent of classifier from the DAG structure in some complex recognition tasks. The reduction of classifiers results in the reduction of the classification time.

***Abstract*—This article presents a recommender system based on rough mereology for predicting Ozone concentration in Kuwait through testing the data gathered from Al-Jahra station. The proposed recommender system consists of three phases; namely pre-processing, classification, and recommendation phases. To evaluate the performance of the presented recommender system, fifteen parameters were used. Those parameters were developed and validated between Jan. 2006 and Sept. 2010. The obtained results demonstrated the effectiveness and the reliability of the proposed recommender system.**

***Index Terms*—recommender system, rough mereology, air pollution, ground-level Ozone**

I. Introduction

INDUSTRIALIZATION, technical growth and over population in urban areas of Kuwait have resulted in increased air pollution [1], [2]. This has deteriorated the quality of fresh air. Toxic air pollutants in close proximity to populate areas can have adverse health effects. In this respect, surface Ozone can become a serious problem in the urban areas of Kuwait - if it frequently occurs in sufficient concentration to threaten human health and environment [3].

Ground-level Ozone (O3) is formed by chemical reactions between nitrogen oxides (NOx) and volatile organic compounds (VOC) in the presence of heat and sunlight. It is difficult to exactly define the formation and destruction mechanism of Ozone. This is because Ozone is an extremely reactive pollutant and can be scavenged by its precursors [2], [4]. As a result, the area of air pollution forecasting through empirical methods has gained importance with the availability of sufficient data. Earlier forecasting models were based on simple empirical data correlations, but the availability of a large amount of information has resulted in development of complex air pollution simulations for forecasting [2], [5]. Management of public warning strategies for Ozone levels in densely populated areas require accurate forecasts of ambient levels. Although Ozone prediction models exist or have been proposed at several cities [6]–[9], [16], [17], they have not been assessed in realistic conditions.

Recently, there has been an increase in air pollution in urban areas of Kuwait. This is the result of rapid industrialization, technical growth and over population. In the past, it has been observed that toxic air pollutants in close proximity of populated areas can have adverse health effects. Ozone is one such pollutant that can become a serious problem in urban areas of Kuwait if it occurs in sufficient concentration. Thus, accurate forecasting of surface Ozone is required as it can help with successful implementation of public warning strategies during episodic days in Kuwait.

This article presents a recommender system based on rough mereology for predicting Ozone concentration in Kuwait through testing the data gathered from Al-Jahra station. The proposed system firstly maps the Ozone dataset into a normalized dataset of ground-level Ozone predictions. Then, rough mereology and rough inclusion techniques are applied for clustering and classifying the normalized Ozone dataset into sets of granules with different radius. Voting by objects approach is subsequently applied in order to select the optimized granules. Finally, normalized rating matrix is acquired, then the predicted ground-level Ozone is recommended. To evaluate the performance of the presented recommender system, fifteen parameters were used. Those parameters were developed and validated between Jan. 2006 and Sept. 2010. The initial three years of data are used to develop the predicting models and the remaining data is used for testing and verifying these models.

The rest of this article is organized as follows. Section II presents the basic concept of rough mereology. Section III describes the different phases of the proposed recommender system; namely pre-processing, classification, and recommendation phases. Section IV introduces experimental results via firstly discussing the tested dataset in addition to the details of

978-83-60810-53-8/$25.00

the applied Air Quality Index (AQI), then presenting statistical analysis of the obtained experimental results. Finally, Section V presents and discusses conclusions.

II. Rough Mereology: An Overview

Rough mereology proposed by Lesniewski in [10] as the theory of concept. The relation of mereology is a part of relation, e.g. x mereology y means x is a part of y. According to Polkowski [11], the mereology relation described in equation (1), where $\pi(u, w)$ is a partial relation (proper part) and $ing(u, w)$ is ingredient relation means an improper part.

$$ing(u, w) \Leftrightarrow \pi(u, w) \ or \ u = w \tag{1}$$

$\mu(x, y, r)$ means rough mereology relation x is part of y at least degree r, also described as shown in equation (2).

$$\mu(x, y, r) = sim_{\delta}(x, y, r) \Leftrightarrow \rho(x, y) \leq (1 - r) \tag{2}$$

Computing the indiscernibility relation to get the object can be done using rough inclusion, which is of less complexity time than the indiscernibility relation computed by rough set technique. Rough inclusion from metric according to Polkowski in [11] computed by the Euclidean metric space or Manhattan space, where,

$$\mu_h(x, y, r) \Leftrightarrow \rho(x, y) \leq 1 - r \tag{3}$$

Then, the indiscernibility relation Ind can be computed as shown in equation (4).

$$Ind(x, y) = \frac{|IND(x, y)|}{|A|} \tag{4}$$

Then, equation (2) becomes equations (5) and (6).

$$\mu_h(x, y, r) \Leftrightarrow Ind(x, y) \geq r \tag{5}$$

$$IND(x, y) = a \in A : a(x) = a(y) \tag{6}$$

Where, a is an attribute(s) in an information system A, and $|A|$ is the cardinality of a set A.

III. The proposed recommender system

The proposed Ozone recommender system tested for ground-level Ozone data collected at Al-Jahra city in Kuwait during the time from January/2006 to September/2010. The architecture of the proposed system consists of three phases; namely pre-processing, classification, and recommendation phases.

A. Pre-processing Phase

In this phase, the proposed recommender system receives the ground-level Ozone data as an input, then it generates a normalized rating matrix. As shown in equation (7) with X representing the original value, the input data were mapped into a normalized dataset of the range [0,1], where the values 0 and 1, represent the smallest and the largest values in each dataset attribute, respectively.

$$Normalized = \frac{X - min.value}{max.value - min.value} \tag{7}$$

B. Classification Phase

In this phase, the proposed recommender system receives the normalized Ozone dataset generated from the pre-processing phase. Rough mereology and rough inclusion approaches were applied in order to produce rough inclusion table that reflects similarity degree among parameters. Then, the granulation mechanism that reflects a given set of inclusion data into collection of granules will be applied via voting by training objects in order to produce the optimal similarity measurement.

1) Ground-level Ozone Clustering: In this phase, the granular computing formalized within the theory of rough mereology - as proposed by Polkowski; as an application of the idea of a granular reflection of data and of classifiers induced from it [5] is used to classify the normalized data into group of similar data according to the definition of rough mereology. In this section, a brief description of the theory of rough mereology and rough inclusion will be presented.

2) Rough Mereology: Indiscernibility relations in rough set theory represents the core problem in this theory that it takes a long of time to get the classification of data. Rough mereology theory used the flexible similarity relations, which allow for huge data to be classified. The similarity relations that will be used must be satisfy properties are MON, ID, EXT. Rough inclusion technique satisfy their three properties of similarity relations; namely Monotonic (MON), Identity (ID), Extreme, or proportionality (EXT) [5].

- (MON) if similarity (x, y, 1) then for each z, from similarity (z, x, r) it follows that similarity (z, y, r).
- (ID) similarity (x, x, 1) for each x.
- (EXT) if similarity (x, y, r) and $s \leq r$ then similarity (x, y, s).

3) Rough Inclusion: Rough Inclusion is a technique that uses the Reduced Hamming Distance [11] equation to compute the similarity between vector u and v, where u represents a user and v represents an item, as shown in equation (8) [5], where, $IND(u, v) = \{a \in A : a(u) = a(v)\}$, and $|A|$ denotes the cardinality of set A.

$$ind(u, v) = \frac{|IND(u, v)|}{|A|} \tag{8}$$

After applying equation (8) on the normalized rating matrix, similarity table is produced by using rough inclusion approach. The proposed recommender system classifies the attributes of the dataset using *Gödel* t-norm technique [6], as shown in equation (9).

$$T_{min}(a, b) = min\{a, b\} \tag{9}$$

The granulation mechanism reflects a given inclusion data into collection of granules, each granule has a fixed granule radius value r, where $r \in$ the interval [0,1] [7]. Accordingly, the proposed recommender approach applies the voting by training objects to produce prediction/recommendation regarding the ground-level Ozone.

4) Voting by Training Objects: Voting by objects stage takes as an input the list of similarity measure tables for each radius resulted from the clustering stage and computes the accuracy rate for each radius as shown in equation (10). Then, the optimum radius that represent the largest accuracy measure is selected. This stage is divided into two steps: 1) accuracy measure computation, which uses equation (10) to compute the accuracy for each table representing the similarity measure at radius r and 2) optimization step, where the table containing the largest accuracy measure at radius r is selected, so the radius r called the optimum radius r_{opt}.

$$Accuracyrate = (\frac{T}{N}) * 100 \tag{10}$$

Where, T is the rate of number of valid tuples and N is the total number of tuples in each row.

Let a is an attribute, u is a test object, v is a training object, and ϵ is a selected number in an interval $[0, 0.1]$ taken every 0.01. So, the final value of ϵ is taken according to the equation of the factor, shown in equation (11).

$$q_a(u, v) = \frac{|a(u) - a(v)|}{diam(a)} \tag{11}$$

Where, diam(a) is computed as shown in equation (12).

$$diam(a) = Max(a) - Min(a) \tag{12}$$

and $a(u)$ can be computed as follows:

$$a(u) = \begin{cases} min & \text{if } u < min, \\ max & \text{if } u > max, \\ u & \text{if } otherwise \end{cases}$$

For each selected ϵ, $sel_u(c, t) = \frac{\sum w_u(v,t)}{sizeofc}$ is computed, where c is the decision category, t is selected t-norm, and $w_u(v, t) = ind_\epsilon(u, v)$. Then, u is assigned to the category with maximal $sel_u(c, t)$. The end value of ϵ is selected when $q_a(u, v) < \epsilon$. Based on the optimum radius selected from the voting by object stage, rules are generated from the rough inclusion table of selected optimum radius.

C. Recommendation Phase

In this phase the system receives the testing Ozone dataset as an input, then it outputs a recommendation/prediction value of ground-level Ozone as shown in equation (13) according to the formula that used to recommendation/prediction in collaborative filtering technique.

$$prediction = \frac{\sum_i \frac{w_{u,i} - mean}{\sigma_u} \times w_{a,u}}{\sum_i w_{a,u}} \times \sigma_a + mean \tag{13}$$

Where, $w_{u,i}$ is the Pearson's correlation coefficient shown in equation (14).

$$w_{a,u} = \frac{\sum_{i=1}^{m} (r_{a,i} - mean) \times (r_{u,i} - mean)}{\sigma_a \times \sigma_u} \tag{14}$$

IV. Experimental analysis and discussion

A. Dataset

The study used hourly air pollutants data from January 2006 through September 2010 gathered by the Environmental Monitoring Information System of Kuwait (eMISK, working under the Environment Public Authority of Kuwait). The data were collected from Al-Jahra fixed surface station. The initial three years of data was used to develop the forecasting models and the remaining data was used for testing and verifying these models. Table I represents the generated rules of Al-Jahra dataset.

B. Air Quality Index (AQI)

The Air Quality Index (AQI) is a key tool for making information about outdoor air quality as easy to find and understand as weather forecasts. It is an index for reporting daily air quality via updating how healthy or unhealthy the air is. Equation (15) shows the AQI conversion formula for the ground-level Ozone.

$$AQI = \frac{I_{HI} - I_{LO}}{BP_{HI} - BP_{LO}} \times (C_{O3} - BP_{LO} + I_{LO}) \tag{15}$$

Where, I_{HI} is the index value at the upper limit of the AQI category, I_{LO} is the index value at the lower limit of the AQI category, BP_{HI} is the break-point concentration at upper limit of the AQI category, BP_{LO} is the break-point concentration at lower limit of the AQI category, and C_{O3} refers to 1-hour Ozone concentration. Also, depending on the value of the Ozone concentration C_{O3}, the values of the I_{HI}, I_{LO}, BP_{HI}, and BP_{LO} parameters are being identified. For example, if the detected value of the C_{O3} is within the range [0.00, 0.059], then the values of the I_{HI}, I_{LO}, BP_{HI}, and BP_{LO} parameters will be 50.00, 0.00, 0.059, and 0.00, respectively [12]. The AQI is considered a standard measurement that runs from 0 to 500, where the higher the AQI value, the greater the level of air pollution and the greater the health concern [13].

C. Statistical Analysis

Evaluating the recommendation quality of the proposed recommender system is mainly based on statistical precision

TABLE I
RULE GENERATION TABLE OF AL-JAHRA DATASET

Rule	Description	Accuracy
Rule(1)	if SO2 is healthy then Ozone is healthy	79.1087

and decision supporting precision measurement methods [14]. Statistical precision measurement method adopts the MAE (Mean Absolute Error) in order to measure the recommendation quality [15]. MAE is a commonly used recommendation quality measurement method. MAE calculates the irrelevance between the recommendation value predicted by the recommender system and the actual evaluation value. Each pair of interest predicted rank is represented as $< p_i, q_i >$, where p_i is the system predicted value and q_i is the user evaluation value. Based on the entire set of $< p_i, q_i >$ pairs, MAE calculates the absolute error value $|p_i - q_i|$ and the sum of all the absolute error value. Then, the average value is calculated. Small MAE values represent a good recommendation quality indicators. The predicted values of rating sets can be represented as $p_1, p_2, ..., p_N$ and the corresponding actual testing rating set can be represented as $q_1, q_2, ..., q_N$. The MAE can be defined as shown in equation (16).

$$MAE = \frac{\sum_{i=1}^{N} |p_i - q_i|}{N} \tag{16}$$

Based on experimental results, the ground-level Ozone depends on the values of NO, (NO2, CO), Wind direction degree, and Industrial temperature. Figure 1 depicts the monthly actual values, predicted values by the proposed recommender system, and the mean absolute error (MAE) of the ground-level Ozone in Kuwait (AL-Jahra city station) during the time from January-2009 to September-2010. As shown in figure 1, the curve presenting the values of ground-level Ozone predicted by the proposed recommender system has a similar behavior as the curve presenting the actual values of the ground-level Ozone dataset. Also, both curves existed in the healthy region of the O3 value, which is less than 0.165. For the MAE curve, it almost matches the predicted curve for the months (10/2009, and 11/2009) as the data readings gathered in the tested dataset during those months was zeros, the MAE curve may be in some points drawn over the actual values of the ground-level Ozone dataset because the actual dataset attribute's has sparsity problem and the rough mereology classifier predict this value as the lowest value in this attribute.

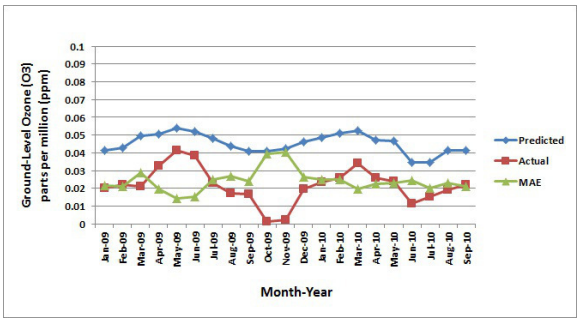

Fig. 1. Monthly values of actual, predicted, and MAE values of ground-level Ozone in Kuwait (AL-Jahra) [Jan-2009 to Sept-2010]

V. Conclusions

In this article, based on ground-level Ozone concentration data gathered from Al-Jahra station in Kuwait, a rough mereology based recommender system was presented for the prediction of ground-level Ozone pollution. The obtained results demonstrate the effectiveness and the reliability of the proposed recommender system. Resulted experimental values of ground-level Ozone predicted by the proposed recommender system showed similar behavior as the actual tested values of the ground-level Ozone dataset. Also, both experimentally resulted and actual dataset values existed in the healthy region of the O3 value, which is less than 0.165 ppm according to the reference AQI.

***Abstract*—Dropping out of school is one of the most complex and crucial problems in education, causing social, economic, political, academic and financial losses. In order to contribute to solve the situation, this paper presents the potentials of an intelligent, robust and innovative system, developed for the prediction of risk groups of student dropout, using a Fuzzy-ARTMAP Neural Network, one of the techniques of artificial intelligence, with possibility of continued learning. This study was conducted under the Federal Institute of Education, Science and Technology of Mato Grosso, with students of the Colleges of Technology in Automation and Industrial Control, Control Works, Internet Systems, Computer Networks and Executive Secretary. The results showed that the proposed system is satisfactory, with global accuracy superior to 76% and significant degree of reliability, making possible the early identification, even in the first term of the course, the group of students likely to drop out.**

I. Introduction

HISTORICALLY, school dropout is one of the most complex and crucial problems in education, causing social, economic, political, academic and financial damage to all the people involved in the educational process, from the students to the governmental and promotional agences that long for efficient strategies to reduce the indexes of school dropout, since the measures adopted up to now did not have the desired effect.

In relation to higher education, school dropout is an international problem. Although its indexes show considerable variations among different nations, they show that in fact school dropout is present and strikes more and more a higher number of higher educational institutes (HEI) worldwide.

It is worth mentioning the United States - USA, with a dropout rate in colleges and universities of around 40%, representing a decline in the index of students graduated in higher education. Conversely, China and India empower higher education, increasing the conclusion index. Between these extremes lies Brazil, presenting a mean dropout index of about 20%.

Even taking into account all the differences and specificities of the (HEI) of different nations, the difficult task of solving the evasion problem is still common ground between them.

From this perspective, prevention and intervention programs are developed and structured taking into account the results of researches that identify the possible causes that generate the phenomenon of evasion. However, such measures could be more fruitful if there was prior knowledge of the students prone to evasion. And, for this, the development of methods, instruments or systems capable of previously making this identification is necessary.

To meet this need an intelligent, ambitious and innovative system was developed, for the prediction of risk groups of student dropout in presential higher education courses [1], using artificial intelligence techniques, the Fuzzy ARTMAP Neural Network [2-4]. This network has a structure in which the training is carried out in a supervised and self-organized way, with the possibility of continued learning [2].

This paper aims at presenting and making the developed intelligent system available as a possibility of identifying, in a proactive, continued and accurately the students of the traditional presential education, prone to evasion in higher education. And also to disseminate their fruitful results that contributed to the development of prevention and intervention programs, in order to improve retention of those students identified in the institution [1].

II. ART and FUZZY ARTMAP Neural Networks

The Artificial Neural Networks (ANN) [5] are computational tools that emulate the human brain and learn with the experience, trying to model and simulate its learning process, organizing its neurons in such a way that they will be capable of processing the information.

The ART network systems are able to solve the “stability-plasticity” dilemma. They are plastic because they are able to learn to adapt to a changing environment and, at the same time, preserve their previously learned knowledge while maintaining their ability to learn new patterns, therefore they are stable.

The basic structure of an ART neural network consists of two subsystems of attention and orientation, where some elements such as: two layers of neurons (F1 and F2) and their synaptic weights (Wij amd Vji), the module parameter vigilance (ρ) and the module reset are arranged and inter-linked.

Briefly, the process of classification of an ART network consists of four phases [6]:

978-83-60810-53-8/$25.00

- Recognition: recognizes the stimuli produced in layer F2 and selects the category of higher value after calculating the function choice.

- Comparison: through the vigilance parameter, tests the similarity between the input vector and the prototype vector, whether allowing or not the inclusion of the pattern input in the category. If the vigilance parameter is not met, the input vector is stored in another neuron.

- Search: for every new input vector, searches for a neuron in layer F2 to represent it.

- Training: the training only starts after the conclusion of the search process, it can occur quickly or slowly.

The Fuzzy ART neural network [7] uses the theory of the fuzzy sets, employing the minimum operator (^) AND Fuzzy, enabling the treatment of patterns of binary and analogical input, in an interval [0, 1], and increasing the generalization ability of the network.

In the Fuzzy ARTMAP model, two ART modules are interlinked through an inter-ART module, called Field Map. This module has a self-regulatory mechanism called match tracking that seeks for "marriages" or combinations among the categories of ARTa and ARTb modules, aiming to increase the generalization level and reduce the network error [2].

The architecture of the Fuzzy-ARTMAP neural network, has been designed to conduct supervised learning in an environment or set of multidimensional data. When the Fuzzy-ARTMAP network is used in a learning problem situation, it is trained until it can classify correctly all the training data.

The mathematical development and the algorithms for the processing of a Fuzzy-ART and Fuzz-ARTMAP neural network are found, respectively in [7] and [8], and applied in [9].

III. Methodology

This study was conducted under the Federal Institute of Education, Science and Technology of Mato Grosso - IFMT. The universe of interest are the students enrolled in the Colleges of Technology (CT) in Automation and Industrial Control, Control Works, Internet Systems, Computer Networks and Executive Secretary at IFMT, attending presential courses in the morning, afternoon and evening. The choice is justified in view of the high dropout rates, verified by previous statistical studies, noting that CT Automation and Industrial Control, reached a dropout rate of 62.46% from 2004 to 2010 [1].

In the implementation and pilot test of the intelligent system proposed, the neural network was fed with data belonging to all the students enrolled in the CT, from 2004 to 2009, making a total of 1650 samples for the training phase, constituting the basis historical data. For diagnosis 499 samples, of data from the students enrolled in 2010 and 2011 were used [1].

The database for prediction of the risk group prone to evasion consists of the students' characteristics such as demographic factors, and factors internal and external to the school. These characteristics were lifted from data from the selection processes at IFMT, the Q-Selection, which stores the answers of the socioeconomic questionnaire filled by the students on the day they enroll for the selection examination and the Q-Academic, system of integrated academic management, where all the academic history of the IFMT students is concentrated [1].

The input vector of the Fuzzy ARTMAP neural network is composed by 16 parameters considered as significant for the school dropout prediction and the output of the network constituted by two classes, evasion and non-evasion. The input-output vector pairs are represented in the binary coding, being the input vector composed by 41bits and, the expected response represented by 1 bit. A summary of the input and output variables of the neural network can be visualized in Table I.

IV. Fuzzy ARTMAP Neural System Proposed for the Evasion Prediction

The data that involve the study about evasion, are sometimes, complex, subjective, non-linear, inter-related and keep in themselves the specificities inherent to the different levels of teaching, courses and institutions that one can analyze, thus choosing ANN, as among its potentialities there is the possibility of processing problems where complex and unknown relations are involved among different sets of data and, also adjust the relations of non-linearity between the input and outup variables [1]. More specifically, the Fuzzy ARTMAP network, where the training is carried out in a supervised and self-organized way, with possibility of continued learning, as implemented in [10]. Its application potential aims at solving several problems of classification and of approach of non-linear functions and showing prompt reply.

The input of the Fuzzy ARTMAP network proposed is represented by vector a (input of the module ARTa) and its

TABLE I. Composition of input and output vectors

	Characteristics of the Subvectors of a and y			
	Position	***Name***	***Abbreviation***	***Size***
Variable of the Input Vector (a) of the Network	a_1	Gender	Gen	1 bit
	a_2	Age Group	Ag	3 bits
	a_3	Ethnicity	Etn	3 bits
	a_4	Marital Status	MSt	3 bits
	a_5	People/House	P/H	3 bits
	a_6	Family Income	FI	3 bits
	a_7	Has a Computer	Comp	1 bit
	a_8	Parents' Education	PE	3 bits
	a_9	School of Origin	SO	3 bits
	a_{10}	Self-Evaluation	SEv	3 bits
	a_{11}	Where From	WF	1 bit
	a_{12}	Dist. School-Residence	DistSR	3 bits
	a_{13}	Means of Transport	MT	3 bits
	a_{14}	Work	Wk	3 bits
	a_{15}	Study Shift	SS	2 bits
	a_{16}	Students/Classroom	S/C	3 bits
Output Vector (y)	y	Non-Evasion	NEv	1 bit
		Evasion	Ev	

desired output, in the training phase, represented by vector b (input of the module ARTb), being these ones described in the following way:

$\boldsymbol{a} = [\boldsymbol{a}_1\ \boldsymbol{a}_2\ \boldsymbol{a}_3\ \ldots\ \boldsymbol{a}_{16}]$

$\boldsymbol{b} = [\ b\ ]$, where: $\boldsymbol{b}$ = "0" ou "1"

The subvectors $\boldsymbol{a}_1\ \boldsymbol{a}_2\ \boldsymbol{a}_3\ \ldots\ \boldsymbol{a}_{16}$ of the vector a (Table I) are lines vectors which contain the binary representation of the students' characteristics. Each bit corresponds to one component of the corresponding vector.

The network output is represented by the activity layer vector F2 (y) and provides answers in the binary coding with 1 bit, being that code "1" corresponds to students' evasion and code "0" to non-evasion, defined as follows:

y = [y] (Fuzzy ARTMAP network output)

The model proposed in this study consists of an intelligent system (flowchart shown in Fig. 1) for the study of students' evasion in the IFMT, using an Fuzzy ARTMAP Neural network [2-4], Logic Fuzzy and/or Dempster-Shafer's Theory of Evidence - TDS.

The information of the database is pre-processed and converted into a binary database. The essentially binary conception is considerably worthwhile, because the neural network presents a more efficient behavior (prompt and better quality of answers) and allows the extraction of knowledge in a continuous way (continued training), seeking for a better adaptation to the conditions of the institution and improvement with time.

In the phase of the neural analysis, if the answer is negative in relation to evasion, no action is adopted; just the register of the mentioned information is performed. If the answer of evasion is positive, the following step corresponds to a better discrimination about the quality of information (fine analysis) based on the use of Fuzzy module and/or of the Dempster-Shafer's Theory of Evidence. Later, solutions that aim to revert students' evasion will be proposed (proactive action).

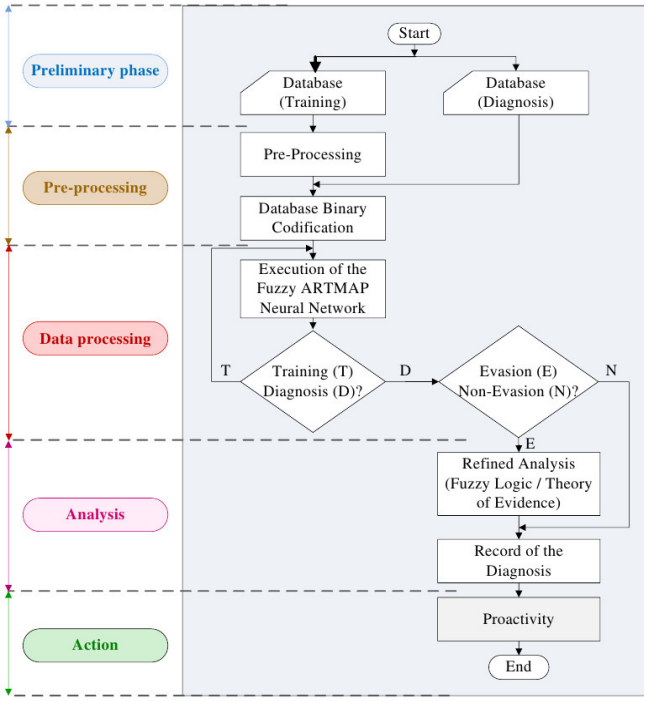

Fig. 1 Flowchart of the structure and sequence of development of the neural system proposed to perform the prediction of the evasion group risk

V. Application and Analysis of the Results

The intelligent system, using a Fuzzy ARTMAP, Neural Network proposed to make the prediction of the risk group of students prone to evasion, was implemented and tested with a database composed by 1.650 rows and 42 columns in the training phase of the network. In the validation and diagnosis phase of the network a sample with 499 lines and 41 columns was used, about 30% of the training samples. Each line represents the inputs standard vector and its corresponding desired output, in the training. The data of the columns from 1 to 41 represent the attributes correspondent to vector a, input of the module ARTa. In column 42 are represent the desired outputs, vector b (input of the module ARTb) of the Fuzzy ARTMAP neural network.

The parameters used in the database processing are specified in Table II.

After the network training five simulations were performed, based on data for the diagnosis, for the validation of the model proposed, being that, in one of them the samples were processed in a naturally way and the other in a randomized way.

The results of the processing were compared and analyzed, using a criterion, called "voting criterion" [7], "0" or "1" of higher incidence for each of the inputs. The result of higher incidence constitutes the output of the neural network.

Later, comparing the output from the network with the real situation of each sample of the group of students analyzed, it was possible to investigate the coincidence of the evasion ("1") and non-evasion ("0") among the samples processed and the reality.

After concluding the phases of the processing of database through an Fuzzy ARTMAP Neural Network and respective analyses necessary to the understanding of the behavior in relation to students' evasion and non-evasion, the results were compiled and, briefly, shown in Table III.

TABLE II. Specification of the Parameters: Fuzzy ARTMAP Network

Parameters and References Values	
Parameters	***Values***
Choice parameter ($\alpha > 0$)	0.001
Training rate ($\beta \in [0,1]$)	1.0
Vigilance parameter module ART_a ($\rho_a \in [0,1]$)	0.2
Increasing in the vigilance parameter ρ_a (ε)	0.05
Vigilance prameter module ART_b ($\rho_b \in [0,1]$)	0.999
Vigilance parameter module inter-ART_{ab} ($\rho_{ab} \in [0,1]$)	0.7
Vigilance parameter in the match tracking ($\rho_{amat} \in [0,1]$)	0.75

TABLE III. QUANTITATIVE AND PERCEPTUAL RESULTS OF THE DIAGNOSIS OF SCHOOL EVASION PREDICTION

Diagnosis of School Evasion	Quantitative and Percentages Values: Output of Network					
	Evasion		*Non-Evasion*		*Total of Samples*	
	Number	*%*	*Number*	*%*	*Number*	*%*
Samples	90	100	409	100	499	100
Corrects	88	97.8	295	72.1	383	76.7
Errs	2	2.2	114	27.9	116	23.3

The reading, interpretation and data analysis in Table III show that: of 499 samples, 90 of them corresponded to the evaded students and, 409 students who had concluded or attending a course, that is, not-evading. The proposed system identified 88 evasion possibilities and ignored 2, with a margin of success of 97.8%. Among the 409 samples of non-evasion, the Fuzzy ARTMAP network proposed recognized 295 samples in this situation and did not hit the target in 114, getting it right in 72.1% of the cases. It reached the global accuracy of 76.7%, finding correctly 383 samples of a total of 499.

The quantitative results of the previous diagnosis of the students with possibility of evasion can be perceived, more clearly in the graphs of Fig. 2.

Considering the experiment done and consistency of the results obtained, it can be inferred that the intelligent system, using Fuzzy ARTMAP, neural network proposed to identify the students prone to evasion, is a model with a significant degree of reliability and expresses accurately the situation in which the students analyzed are.

VI. CONCLUSION

This study presented an innovative method to identify, in a proactive, continued and accurate way, the students considered to belong to the risk group of school dropout, using Fuzzy ARTMAP neural network.

The analysis of the results showed that the proposed system is satisfactory, with global accuracy superior to 76%, and with a significant degree of reliability, making possible the early identification, even in the first term of the course, the group of students likely to drop out. The anticipated identification of this group of students enables the institutional education, alongside the multidisciplinary team to adopt strategic, proactive and individualized measures with the aim of reducing or even mitigating the students' evasion.

***Abstract*—In this paper, we investigate the problem of quality analysis of clustering results using semantic annotations given by experts. We propose a novel approach to construction of evaluation measure, which is based on the Minimal Description Length (MDL) principle. In fact this proposed measure, called SEE (Semantic Evaluation by Exploration), is an improvement of the existing evaluation methods such as Rand Index or Normalized Mutual Information. It fixes some of weaknesses of the original methods. We illustrate the proposed evaluation method on the freely accessible biomedical research articles from Pubmed Central (PMC). Many articles from Pubmed Central are annotated by the experts using Medical Subject Headings (MeSH) thesaurus. This paper is a part of the research on designing and developing a dialog-based semantic search engine for SONCA system[1] which is a part of the SYNAT project[2]. We compare different semantic techniques for search result clustering using the proposed measure.**

I. Introduction

CLUSTERING can be understood as an unsupervised data mining task for finding groups of points that are close to each other within the cluster and far from the rest of clusters. Intuitively, the greater the similarity (or homogeneity) within a cluster, and the greater the difference between groups, the "better" the clustering. Clustering is a widely studied data mining problem in the text domains, particularly in segmentation, classification, collaborative filtering, visualization, document organization, and semantic indexing.

It is a fundamental problem of unsupervised learning approaches that there is no generally accepted "ground truth". As clustering searches for previously unknown cluster structures in the data, it is not known a priori which clusters should be identified. This means that experimental evaluation is faced with enormous challenges. While synthetically generated data is very helpful in providing an exact comparison measure, it might not reflect the characteristics of real world data.

In recent publications, labeled data, usually used to evaluate the performance of classifiers, i.e. supervised learning algorithms, is used as a substitute [18], [6], [1]. While this provides the possibility of measuring the performance of clustering algorithms, the base assumption that clusters reflect the class structure is not necessarily valid.

[1]Search based on ONtologies and Compound Analytics

[2]Interdisciplinary System for Interactive Scientific and Scientific-Technical Information (www.synat.pl)

Some approaches therefore resort to the help of domain experts in judging the quality of the result [2], [7], [6]. When domain experts are available, which is clearly not always the case, they provide very realistic insights into the usefulness of a clustering result. Still, this insight is necessarily subjective and not reproducible by other researchers. Moreover, there is not sufficient basis for comparison, as the clusters that have not been detected are unknown to the domain expert.

There have been several suggestions for a measure of similarity between two clusterings. Such a measure can be used to compare how well different data clustering algorithms perform on a set of data. These measures are usually tied to the type of criterion being considered in evaluating the quality of a clustering method [10].

The goal of clustering is to assign objects to subsets which are coherent internally, but are dissimilar to each other. These goals are usually explicitly formulated as *internal criteria of clustering quality*. The word "internal" highlights the fact that they are based on object similarity expressed in the original feature space. Usually it may not necessarily be clear whether modeling assumptions in the underlying model (feature space and e.g. the notion of distance between objects) are valid. Hence, one may ask to validate or evaluate a clustering in a specific application, using feedback from users or experts. When a "gold standard" clustering is provided by experts, one may compare it with the result from a clustering algorithm. This approach is an *external criterion of clustering quality*.

The problem becomes even more complicated in evaluation of text clustering with respect to semantic similarity, whose definition is not precise and highly contextual. As the number of results is typically huge, it is not possible to manually analyze the quality of different algorithms or even different runs of the same algorithm.

The remainder of this paper is structured as follows. In Section II we present some basic notions and problem statement. This is followed by an overview of external clustering evaluation methods in Section III. In Section IV we present the basic semantic evaluation techniques and propose a novel evaluation method based on exploration of expert's tags which is the fundamental contribution of this paper. After this we use the proposed evaluation method to analyze the search result clustering algorithms over the document collection publish by PubMed. An analysis of the methods result representation and their interpretability is presented in Section V, followed by some conclusions and lessons learned in Section VI.

II. PROBLEM STATEMENT

A hard clustering algorithm is any algorithm that assigns a set of objects (e.g. documents) to disjoint groups (called clusters). A soft clustering relaxes the condition on target clusters being disjoint and allows them to overlap. Clustering evaluation measures[15], [10] proposed in the literature can be categorized as either *internal criteria of quality* or *external criteria of quality*.

An *internal criterion* is any measure of "goodness" defined in terms of object similarity. These criteria usually encompass two requirements – that of attaining high intracluster similarity of objects and high dissimilarity of objects in different clusters.

External criteria on the other hand compare a given clustering with information provided by experts. Typically in the literature it is assumed that both the clustering provided by studied algorithm and the clustering provided by experts are hard clusterings. We believe that the requirement that expert knowledge is described in terms of a hard clustering is overly restrictive. In typical applications in text mining, one faces datasets which are manually labeled by experts, but with each document being assigned a set of tags. We can think of such tags as of soft clusters. In this paper we aim to provide measures of external evaluation criteria that relax both conditions on the clustering and expert clusterings being partitions (hard clusterings).

In what follows, our focus is on clustering of documents, hence we will occasionally use terms "object" and "document" interchangeably. We stress that the notion of Semantic Explorative Evaluation (SEE) introduced in this paper is a general framework which can be used to evaluate clustering of objects of an arbitrary type.

Typically in the literature it is assumed that the input data to clustering evaluation can be described in a form similar to Table I, i.e. with exactly one valid cluster C_i and exactly one valid expert cluster E_j for each document.

We will relax this condition to allow comparison of soft clustering and a set of expert tags assigned to each document, thus allowing input data as in Table II.

III. OVERVIEW OF CLUSTERING EVALUATION METHODS

In this section we briefly review external evaluation criteria typically used in clustering evaluation. We assume that two partitions (hard clusterings) of objects are given: one by an algorithm, and another one provided by domain experts. Most external evaluation criteria can be naturally grouped in two groups:

- *Pair-counting measures*, which are defined on a 2×2 contingency matrix that summarizes similarity of pairs of objects w.r.t. both clusterings (see Table III):
  If there are k objects in the dataset, then
  $$a + b + c + d = \binom{k}{2}$$
  A typical measure that can be expressed in terms of these numbers is
  $$\textit{Rand Index} = \frac{a+d}{a+b+c+d}.$$
  However, there is a multitude of different variants of other similar measures. Pfitzner et al.[15] provide an overview of 43 measures that all fit into this scheme.
- *Information-theoretic measures* on the other hand compare distributions of $c(D)$ and $e(D)$, which denote respectively the cluster and the expert label (which induces a partition) assigned to a document D drawn randomly from the dataset. These measures can be expressed in terms of joint distribution of $\langle c(D), e(D)\rangle$, i.e. simply by counting objects belonging to each pair $\langle C_i, E_j\rangle$ as shown in Table IV. Numbers in brackets denote expected values of counts assuming independence of $c(D)$ and $e(D)$. Information-theoretic measures thus aim to to measure the degree of dependence between these two. An example such

TABLE III. ALL PAIR-COUNTING MEASURES CAN BE SUMMARIZED IN TERMS OF NUMBERS a, b, c, d IN THIS TABLE.

Pairs of documents		Same cluster? True	Same cluster? False
Same expert tag?	True	a	b
	False	c	d

TABLE IV. INFORMATION-THEORETIC MEASURES ARE DEFINED IN TERMS OF CONTINGENCY TABLE SHOWN HERE (FOLLOWING EXAMPLE IN TABLE I).

	C_1	C_2	C_3	Total
E_1	1	0	0	1
E_2	0	0	1	1
E_3	0	1	1	2
E_4	1	1	0	2
	2	2	2	

measure is *mutual information* I between $c(D)$ and $e(D)$, where

$$I(X,Y) = \sum_x \sum_y p(x,y) \log \left(\frac{p(x,y)}{p(x)p(y)} \right).$$

A measure typically used in clustering evaluation is *Normalized Mutual Information*[10], though [15] reviews 13 different measures, all defined quite similarly.

Purity is a measure occasionally used as an external evaluation criterion. While it is not strictly an information-theoretic measure, it can be also expressed in terms of table IV.

IV. SEMANTIC EVALUATION METHODS FOR SOFT CLUSTERING

We stress two limitations of measures proposed in the literature and briefly reviewed thus far:

- The first limitation, already mentioned in the previous section, is the typical assumption that both the clustering algorithm and the experts provide partitions. We will show how all measures mentioned (whether directly or indirectly) in the previous section can be naturally extended to the case of comparing a soft clustering with expert knowledge expressed in terms of multiple tag assignment. In the first part of this section we will briefly review our proposed solution to this problem, described earlier in [12].
- A more important limitation, though, is that neither of these measures described so far resemble the thought process that the expert himself would undergo if he was faced with the task of manually evaluating a clustering. In the second part of this section we will describe a novel method of semantic evaluation that addresses this issue.
  This is the fundamental contribution of this paper.
- The third problem, that we address further in the paper, is that of comparing different clusterings.
- Finally, methods mentioned so far do not allow us to compare different clusters of a single clustering.

A. Comparing set covers.

Previous works by other authors on this problem include [3] (Fuzzy Clustering Mutual Information) and [8] (comparing set covers).

In this section we consider two types of measures defined earlier separately.

TABLE V. PAIR-COUNTING MEASURES CAN BE NATURALLY DEFINED FOR SOFT COVERS IF WE SUBSTITUTE *hard membership* (SEE TABLE III) BY THE NOTION OF *similarity*.

Pairs of documents		Cluster-similar? True	Cluster-similar? False
Expert-similar?	True	a	b
	False	c	d

TABLE VI. INFORMATION-THEORETIC MEASURES CAN BE DEFINED IF WE CAN DESCRIBE THE JOINT DISTRIBUTION OF CLUSTERS AND EXPERT LABELS (SEE EXAMPLE IN TABLE II).

	C_1	C_2	C_3
Cosmonaut	0.139	0.083	0
astronaut	0.083	0	0
moon	0.139	0	0
car	0.056	0.125	0.125
truck	0	0.042	0.208

First we describe how to extend a pair-counting measure of similarity of two partitions to a measure of similarity of set covers. Pair-counting measures only pose a tiny problem. Looking at table III, we see that for soft clusterings, rows and columns are not well defined. In order to fully characterize a pair of documents $\langle d_i, d_j \rangle$, we proposed in [12] to define notions of cluster-similarity and expert-similarity for documents and base pair-counting measures on table V. This approach naturally extends any pair-counting measure, with the focus of our prior experiments on Rand Index [16]. We defined very simple notions of similarity: we considered two documents d_i, d_j θ-expert-similar, if $\frac{|e(d_i) \cap e(d_j)|}{|e(d_i) \cup e(d_j)|} \geq \theta$, and we defined θ-cluster-similarity in the same way. This approach allows us to effortlessly apply each of the 43 pair-counting measures reviewed by Pfitzner[15].

Information-theoretic measures can be extended by counting a given document in multiple cells of Table IV whenever the document is in multiple clusters and/or multiple tags are assigned to the document. If we wish to assign an overall equal weight to each document, instead of raw counts, one may further assume that the contribution of a document is inversely proportional to the number of cells that it contributes to. This has a straightforward probabilistic interpretation. The original measures, like $I(c(D), e(D))$ are defined for deterministic functions c and e and a random document D. In the proposed extension, c and e are also random variables, with $c(d)$ uniformly distributed across clusters containing document d, and $e(d)$ uniformly distributed across tags assigned to document d. Original formulas themselves, like $I(c(D), e(D))$ remain unchanged. This approach is illustrated in Table VI.

B. Semantic Explorative Evaluation

We have mentioned that the calculation of neither of the measures reviewed so far resembles human reasoning. We propose a different approach to the problem of semantic evaluation.

If an expert faced the problem of manual inspection of clustering results, he would try to explain (describe) the contents of clusters in his own words (i.e. in terms of expert tags). In essence, a cluster should be valid for an expert if the expert can briefly explain its contents. The expert would find

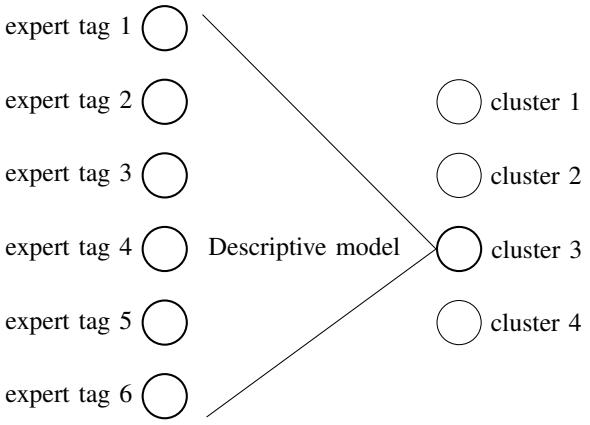

Fig. 2. For each cluster (e.g. cluster 3), we build a model describing the contents of this cluster in terms of expert tags. A measure of complexity of the resulting model thus corresponds to semantic validity of the cluster.

a set of clusters valid if he could provide a short explanation for each cluster.

In order to define a measure of semantic validity which is based on this reasoning, we need to specify three things:

- description of clusters in terms of expert concepts (i.e. a model family),
- define the length of such an explanation so that we know if it is short,
- a penalty incurred if a cluster is indescribable in terms of expert concepts,
- define the aggregate measure, so that we can evaluate a set of clusters.

We specify these three ingredients as follows:

- The explanation or description of a cluster is in essence a model of the cluster in terms of expert tags. Any classification algorithm provides such a model. The exact choice of the classifier is of secondary importance as long as the same procedure is consistently used to evaluate different clusterings. In our experiments, the classifier of choice is a decision tree with no pruning, with splits defined greedily using Gini index.
- By appealing to Minimum Description Length principle, one may then define a measure of validity of a fixed cluster as the complexity of the model describing the cluster. The measure of model complexity that we use is the average depth of the resulting tree.
- For simplicity we omit a penalty for indescribable clusters at this point, although we guarantee during tree construction that resulting leaves in descision trees contain either objects from the same decision class or objects that are indiscernible given the information about expert tags alone.
- We define the measure of validity of a clustering as the average validity of clusters.

The pseudocode of the presented idea is presented below in Algorithm 1.

Algorithm 1: SEE – Semantic Explorative Evaluation.

Input:
- $\mathbf{C} = \{C[i,j] : i = 1,\ldots,k \text{ and } j = 1,\ldots,n\}$: the document–cluster assignment matrix.
- $\mathbf{E} = \{E[i,j] : i = 1,\ldots,k \text{ and } j = 1,\ldots,m\}$: the expert–cluster assignment matrix.
- L: a decision tree construction algorithm.

Output: m: the average mean depth of decision trees describing clusters.

for $j = 1,\ldots,n$ **do**
  Construct a decision table
  $$H_j := \left[E; [C_{1,j},\ldots,C_{k,j}]^T\right]$$
  // H_j is the decision table constructed from the matrix $\mathbf{E}$ augmented with the j-th column of matrix $\mathbf{C}$ at the end as the decision variable.
  $T_j := L(H_j)$;
  // Construct the decision tree T_j by applying algorithm L on decision table H_j.
  $m_j = \text{MeanDepth}(T_j)$
end
Return $m = \frac{m_1+\ldots+m_n}{n}$;

C. Semantic Explorative Evaluation: Example

In this Section we demonstrate the proposed evaluation method (presented above in Algorithm 1) on the example introduced in Table II.

This table summarizes a small text corpus consisting of just 6 documents. Half of these documents, forming cluster C_2, concern vehicles: cars and trucks, whereas the other half concerns cosmonauts and moon: these documents form cluster C_1. Cluster C_1 is the easiest one to explain for the expert: he associates either the concept 'cosmonaut' or 'astronaut' with each document from this cluster. Document d_1 concerns a lunar rover and is an interesting "outlier" that needs to be explicitly excluded from cluster C_3 by the expert: the branch on attribute "moon" in decision tree describing cluster C_3 explicitly addresses this case.

The constructed decision trees T_1, T_2, T_3 for clusters C_1, C_2, C_3 are presented in Fig. 3, Fig. 5 and Fig. 4, respectively. According to those trees, cluster C_3 seems to be "hardest" to explain by the expert. Hence the average depth or weighted average depth of the decision tree T_3 are also higher than for T_1.

Depths of decision trees describing clusters C_1, C_2, C_3 are $1\frac{2}{3}$, 2 and $2\frac{1}{4}$, respectively. Thus SEE of the clustering equals approximately 1.97.

Doc.	Expert Tag					decision
	Cosm.	astron.	moon	car	truck	C_1
d_1	1		1	1		1
d_2		1	1			1
d_3	1					1
d_4				1	1	
d_5				1		
d_6					1	

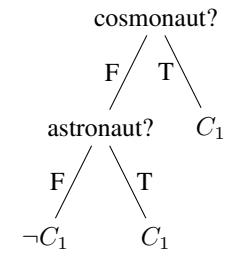

Fig. 3. The decision table H_1 (above) and the decision tree describing cluster C_1 constructed from H_1. Cluster C_1 is the easiest for the expert to explain.

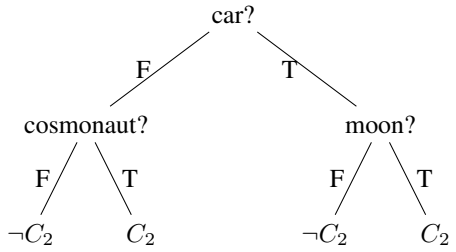

Fig. 4. Cluster C_2 is not easily describable in expert terms.

D. Randomization

The last problem we aim to address is that of comparing different clusterings. With all evaluation methods, either reviewed or introduced in this article, we face the same issue when we aim to compare different clusterings: we lack an explanation why one clustering may be better than the other one. In this section, we introduce a trick which allows us to isolate a specific sub-problem solved by a clustering algorithm, to which we can assign a measure of quality that is easily interpretable.

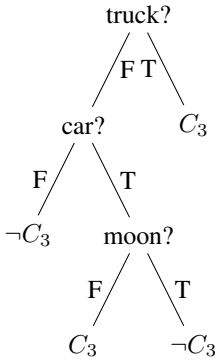

Fig. 5. Cluster C_3 does not contain document d_1, which concerns a very specific type of a car – a moon rover. This outlier forces the expert to provide a longer explanation to explicitly "remove" this object.

In what follows, we will think of a clustering algorithm as of a procedure that solves two sub-problems. For hard clustering these are:

- Determining the structure of clusters, i.e. the number of clusters and the number of documents belonging to each cluster.
- The assignment of documents to clusters, while preserving constraints on the structure.

For soft clustering, these two sub-problems are:

- Determining the structure of clusters is actually determining the number of clusters K as well as the joint (rather than the marginal) distribution of the number of documents in each cluster.
- Instead of assigning documents to clusters, an algorithm assigns documents to each of the 2^K possible partitions.

In what follows, we will focus on measuring the quality of a clustering algorithm w.r.t. the second sub-problem, while ignoring the first sub-problem. The idea is to randomize the assignment of documents to clusters while keeping the structure of clusters fixed and calculate the value of m for such randomized assignments so as to determine a meaningful "basis" or benchmark for comparison. Each measure m can thus be transformed into an m-quantile measure, which basically says how often a clustering algorithm outperforms a random assignment, while solving the second sub-problem.

V. The results of experiments

The following experiments are the continuation of our previous studies in [13], [11], [12], although in this work they merely serve as an illustration of the discussed and introduced measures.

A. Experiment Set-Up

We have applied the model-based semantic evaluation measure introduced in this paper to study clusterings induced by different document representations (lexical, semantic and structural) and using different algorithms. The document repository in our study is a subset of PubMed Central Open Access Subset[17].

TABLE VII. An example of tags assigned to the paper: "PubMed Central: The GenBank of the published literature." by Roberts R. J. ([17])

heading	subheading
Internet	
MEDLINE	economics
Periodicals as Topic	economics
Publishing	economics

The majority of documents in PubMed Central are tagged by human experts using headings and (optionally) accompanying subheadings (qualifiers) from a MeSH controlled vocabulary [20]. A single document is typically tagged by 10 to 18 heading-subheading pairs. The example of tagged document is shown in Table VII

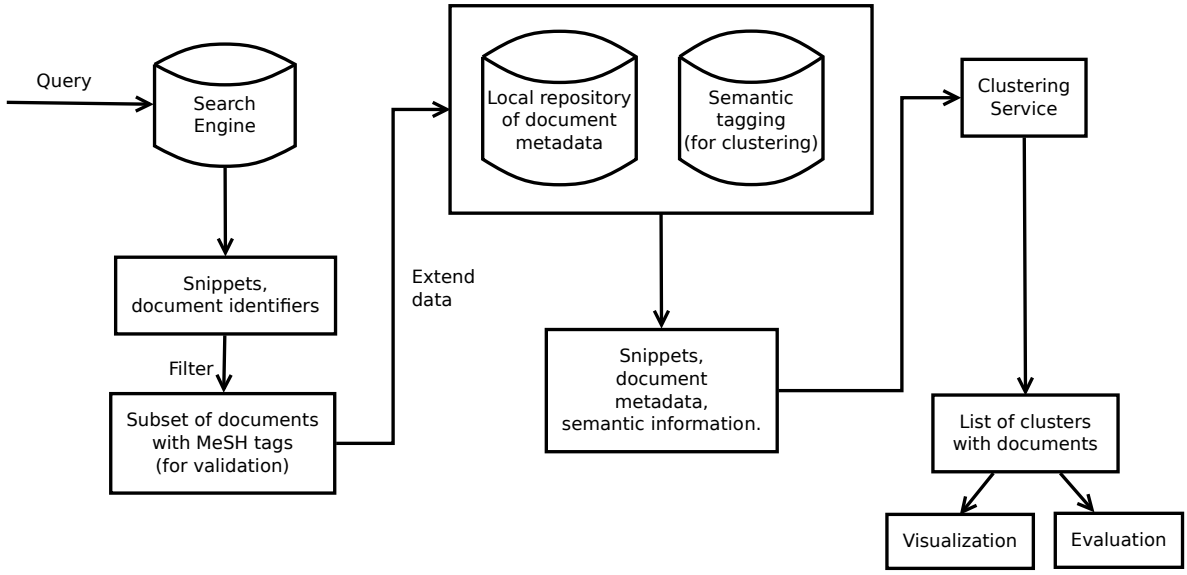

Fig. 6. Experiment diagram.

There are approximately 25000 subject headings and 83 subheadings. There is a rich structural information accompanying headings: each heading is a node of (at least one) tree and is accompanied by further information (e.g. allowable qualifiers, annotation, etc.). Currently we do not use this information, but in some experiments we use a hierarchy of qualifiers[3] by exchanging a given qualifier by its (at most two) topmost ancestors or roots.

TABLE VIII. THE NUMBERS OF POSSIBLE TAGS IN PUBMED CENTRAL OPEN ACCESS SUBSET[17]

source	**possible tags**	**expert tags assigned to example document**
headings	~ 25000	Internet, MEDLINE, Periodicals as Topic, Publishing
subheadings	83	economics
subheading roots	23	organization & administration

The choice of expert tags determines how precisely we wish to interpret expert opinion. In experiments that we describe in this paper, we interpreted subheadings as the expert tags.

The diagram of our experiments is shown in Figure 6. An experiment path (from querying to search result clustering) consists of three stages:

- Search and filter documents matching to a query. Search result is a list of *snippets* and document identifiers. Usually more than 200 documents are returned for a single query. The result set is then truncated to the top 200 most relevant (in terms of TF-IDF) documents.
- Extend representations of snippets and documents by *citations* and/or *semantically similar concepts* from MeSH ontology (these MeSH terms were automatically assigned by an algorithm[19], whereas MeSH subheadings used for evaluation were manually assigned by human experts).
- Cluster document search results.

In our experiments, we worked with three clustering algorithms: K-Means[9], Lingo[14] and Hierarchical Clustering[4].

In order to perform evaluation (and choose parameters of clustering algorithms) one needs a set of search queries that reflect actual user usage patterns. We extracted a subset of most frequent one-term queries from the daily log previously investigated by Herskovic et al. in [5] and retrieved relevant documents from PubMed Central Open Access Subset.

Roughly one fourth of these result sets was used for initial fine-tuning of parameters, whereas the remaining 71 queries were further used in evaluation.

B. Experiment results

We need to stress that we used subheadings as the source of expert tags used for semantic evaluation. There are only 83 possible subheadings in MeSH vocabulary, hence the granularity of information provided for evaluation is very limited. We have not applied pruning to resulting decision trees (the goal of algorithm Algorithm 1 is merely to provide a description, not a model for inference), and the resulting decision trees are somewhat deep, as can be seen from Figure 7.

Nevertheless, as we can see from Figure 8, the m-quantile measure is usually below 0.5 (SEE-quantile value 0.5 corresponds to a random document-to-cluster assignment). Furthermore, result sets for different queries visibly differ in how "hard" they are to cluster: m-quantile measures of different algorithms are significantly correlated. Figure 7 should not be directly interpreted in this way due to different structure of result sets corresponding to different queries (e.g. different number of documents).

[3] http://www.nlm.nih.gov/mesh/subhierarchy.html

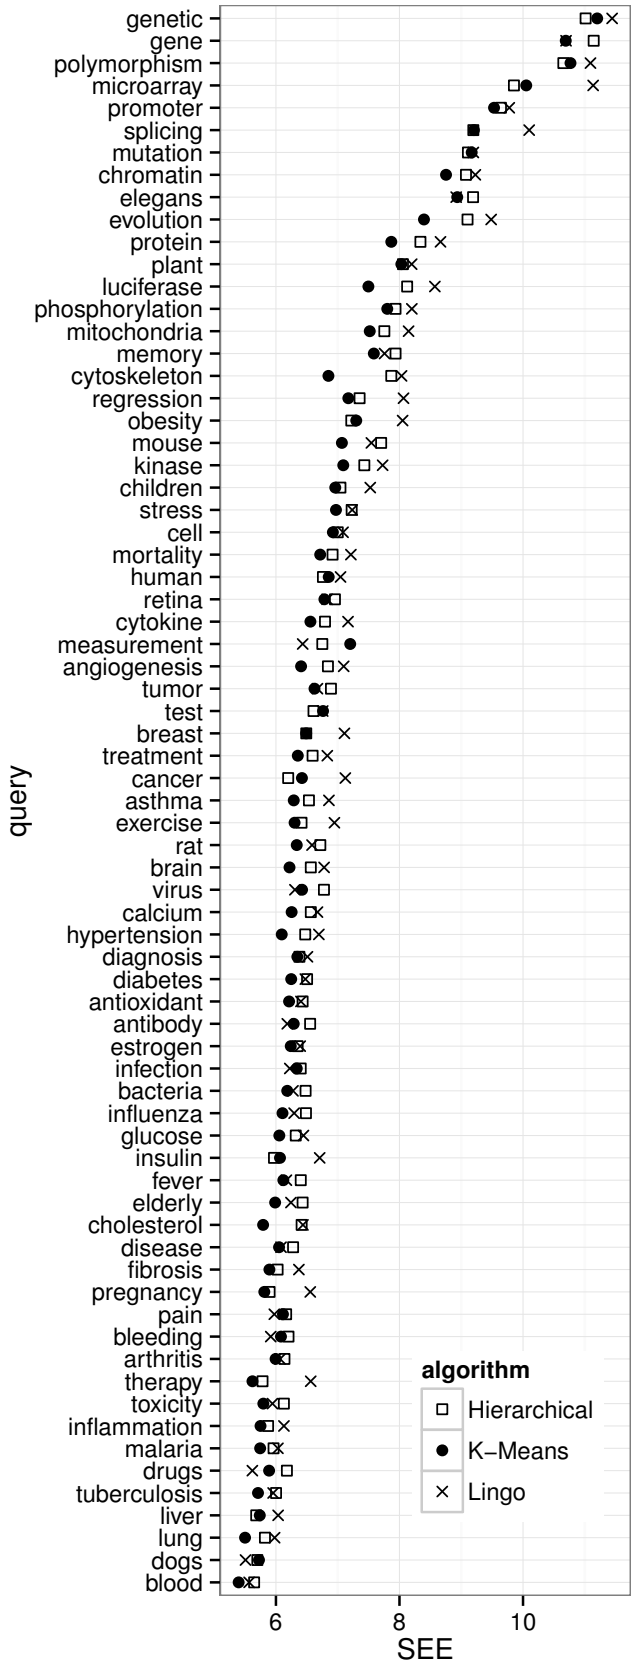

Fig. 7. Average tree depth for different result sets and clustering algorithms.

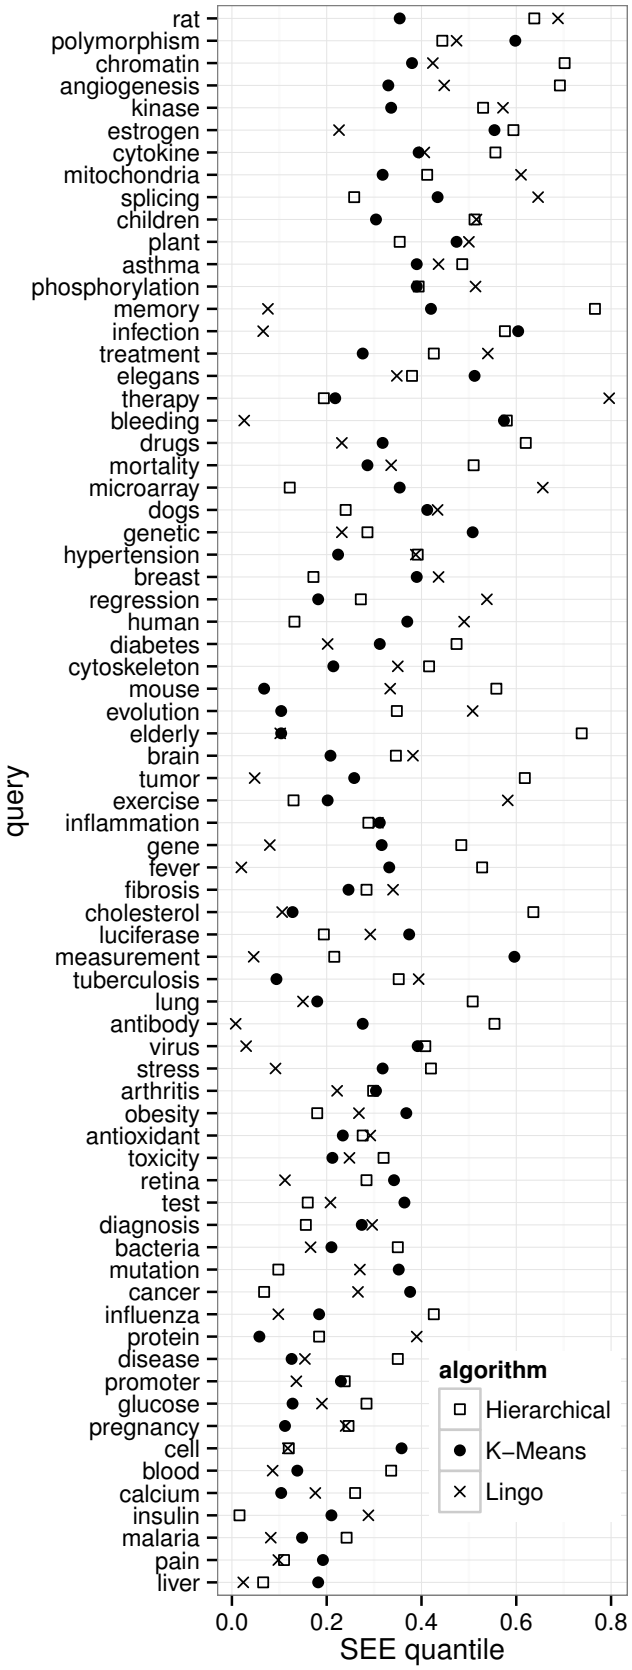

Fig. 8. SEE-quantile measure for different clusterings and queries.

VI. Conclusions and future plans

In this paper we have introduced a novel paradigm of semantic evaluation. Unlike traditional approaches, which are either measures counting pairs of objects or are variations of information theoretic approaches, our proposed procedure resembles the process of human perception, as it is based on a model describing the clustering in terms of expert knowledge. We proposed a specific implementation of this evaluation measure (i.e. a choice of the underlying model structure and optimization framework) and further demonstrated its application to online results clustering evaluation problem. We have observed that even if we only used information about MeSH subheadings assigned to documents as the source of information for evaluation, for most result sets in our experiments clusterings performed better than random assignments of documents to clusters. Furthermore, we have observed that some result sets are inherently harder to cluster than others, and the performance of analyzed clustering algorithms is usually correlated.

***Abstract*—The combination of game theory and data mining opens new directions and opportunities for developing novel methods for extraction of knowledge among multiple collaborative agents. This paper extends on this combination, and motivated by the work of Nix and Kantarcioglu employs the Vickrey-Clarke-Groves (VCG) mechanism to achieve privacy-preserving collaborative classification. Specifically, in addition to encouraging multiple agents to share data truthfully, we facilitate preservation of privacy. In our model, privacy is accomplished by allowing the parties to supply a controlled amount of perturbed data, instead of randomised data, so long as this perturbation does not harm the overall result of classification. The critical point which determines when this perturbation is harmful is given by the VCG mechanism. Our experiment on real data confirms the potential of the theoretical model, in the sense that VCG mechanism can balance the tradeoff between privacy preservation and good data mining results.**

I. Introduction

DATA mining provides a range of useful tools for data manipulation and extraction of meaningful information from large data sets, that can improve our lives. For example, collaboration among hospitals and other healthcare institutions by providing the medical record sets, and thus creating a large database, can lead to better and more reliable research results. In a different scenario, markets can share their data related to the customers' shopping preferences, in order to make future product deals and offers that will increase the income. Furthermore, cooperation in international level among governments, by merging intelligence data sets, might result in strengthening the security against terrorism. However, in all cases it is important to ensure that sensitive information must remain hidden and not be disclosed.

This paper addresses the problem of privacy preserving collaborative data mining, motivated by a paper by Nix and Kantarcioglu [1]. A brief description of the setting is as follows: a number of participants, also called agents, jointly supply their individual data sets in order to perform a data mining task and extract information from the large database that is formed. As the trustworthiness of the agents is not guaranteed, it is necessary to add incentives for good behaviour. One approach is to have penalising strategies that will prevent inappropriate behaviour. However, game theory offers a solution with positive incentives. Our work, as in [1], employs a method from a branch of game theory, called mechanism design. More specifically, we use the Vickrey-Clarke-Groves (VCG) mechanism, in which the payoff of each agent contains the agent's contribution to the 'community'. Thus, if an agent's contribution harms the overall result, this agent will be charged and hence receive low payoff. Following the setting of [1] we also choose the data mining task to be classification. However, in contrast to [1], for simulation of an agent who supplies falsified data we modify the complete data set of the agent through a controlled amount of perturbation, rather than random perturbation of certain percentage of the data. Furthermore, apart from complete randomization of the data, which corresponds to the action of an agent who lies or an agent who aims for the maximum possible privacy, we also include small deviation from the true data. The latter action models an agent who wishes to preserve the privacy of his data without damaging the overall result. We show that this strategy results in information gain while keeping the agent's data private.

This work has been supported by the Engineering and Physical Science Research Council (EPSRC) of UK, under the grant EP/J020389

II. Related work

The combination of data mining and game theory in a collaborative environment has opened a new direction for research. Halpern and Teague [2] address the problem of secret sharing and multi-party computation, under the assumption that the agents are rational, rather that being good or bad. They show that there exists a randomised secret sharing scheme in which the agents reach a Nash equilibrium that overcomes the iterated deletion of weakly-dominated strategies. In [3] Abraham at al. extend the work of [2], by introducing the notion of k-resilient equilibrium, which is similar to the Nash equilibrium, but instead of tolerating deviation from one player, it tolerates deviations by coalitions with at most k members. Examination and analysis of the multi-party computation, and specifically of the secure sum computation problem under a game theoretic framework can be found in [4]. In many scenarios, in order to simulate real world situations the involved parties are divided into good or bad.

978-83-60810-53-8/$25.00

However, under a game theoretic framework this approach is often replaced by settings where the participants are assumed to be rational, whose aim is to maximise their gain. In this context, the authors of [5] introduce the notion of rational secure computation and show that the ballot-box can be used to securely compute any function. Although security is an important issue to be addressed, the behaviour of the participants must also be examined. Thus, in order to discourage improper behaviour, [4], [6], [7] introduce penalising methods. In particular, assuming semi-honest players, [6] is concerned with the problems that arise in a sovereign information sharing setting. The goal is to ensure that the participants learn the result from the task on the shared information, without gaining any knowledge about the shared data. This is achieved by using an auditing device that will repeatedly check the players' actions, penalising inappropriate behaviour. Punishing strategies against malicious players is also examined in [7], in a setting which includes verification of the results, in addition to the information sharing. A different approach to punishing policies in order to achieve good behaviour is the use of VCG mechanism [1], [8]. In [8] this particular mechanism is employed for regression learning and in [1] for classification.

III. Mechanism Design

Mechanism design is a branch of game theory concerned with the problem of social welfare [9]–[11]. The setting involves a set of I agents, each one having their own private preferences on a set of alternatives, and a principal, whose role is to ensure that the rules of the mechanism will be followed. The aim of the mechanism is to help the agents make a collective choice that is beneficial for all. Formally, a mechanism is a collection of strategy sets $S_1, \ldots, S_I$ and an outcome function $g : S_1 \times \ldots \times S_I \to X$, where X is a set of possible alternatives. Each alternative is associated with a utility function $u_i(x)$ (known also as payoff), which denotes the gain of agent i when alternative x is chosen. As different alternatives lead to different payoffs, clearly each agent has a different preference on the alternatives. In order to model the distinctiveness of the agent's preferences, we associate each agent with a type θ_i, $i = 1, \ldots, I$. An important point is that the preference, and hence the type of each agent is private information and hence θ_i is known only to agent i. For this reason, in the game theoretic context, we are in an environment of incomplete information.

Once the agents have decided upon the preferences and their type has been determined, they report types $\hat{\theta}_i$, which might or might not coincide with θ_i (direct revelation mechanism). After $\hat{\theta}_i$ has been announced from all agents, the mechanism selects the collective choice to be

$$k^*(\hat{\theta}) = \arg\max_{k \in K} \sum_i v_i(k, \hat{\theta}_i),$$

where K is the set of possible choices, $\hat{\theta} = (\hat{\theta}_1, \ldots, \hat{\theta}_I)$ and $v_i(k, \hat{\theta}_i)$ is the valuation of agent i on the choice k, when his reported type is $\hat{\theta}_i$.

A. The Vickrey-Clarke-Groves Mechanism

The Vickrey-Clarke-Groves mechanism (denoted by VCG) is a mechanism where the utility function has the following quasi-linear form:

$$u_i(x, \theta_i) = v_i\big(k^*(\hat{\theta}), \theta_i\big) + t_i,$$

where $v_i\big(k^*(\hat{\theta}), \theta_i\big)$ is agent i's valuation on the choice $k^*(\hat{\theta})$ when his type is θ_i. The term t_i denotes the payment rule and in this particular mechanism has the form:

$$t_i = \sum_{j \neq i} v_j\big(k^*(\hat{\theta}), \hat{\theta}_j\big) + h_i(\hat{\theta}_{-i}),$$

where $\hat{\theta}_{-i} = (\hat{\theta}_1, \ldots, \hat{\theta}_{i-1}, \hat{\theta}_{i+1}, \ldots, \hat{\theta}_I)$. In general, h_i is an arbitrary function, but in the case of VCG mechanism is equal to the following:

$$h_i(\hat{\theta}_{-i}) = -\sum_{j \neq i} v_j\big(k^*_{-i}(\hat{\theta}_{-i}), \hat{\theta}_j\big),$$

where $k^*_{-i}(\hat{\theta}_{-i})$ is the social choice which has resulted from a mechanism with all agents excluding agent i. This particular formula for the function h_i is called the pivotal or Clarke mechanism and reflects the contribution of agent i to the community. The utility function has the final form:

$$u_i(x, \theta_i) = v_i\big(k^*(\hat{\theta}), \theta_i\big) + \\ + \Big(\sum_{j \neq i} v_j\big(k^*(\hat{\theta}), \hat{\theta}_j\big) - \sum_{j \neq i} v_j\big(k^*_{-i}(\hat{\theta}_{-i}), \hat{\theta}_j\big)\Big) \quad (1)$$

If $k^*(\hat{\theta}) = k^*_{-i}(\hat{\theta}_{-i})$, which means that the reported type of agent i does not change the social choice, then $t_i = 0$ and hence, i is not charged. If $k^*(\hat{\theta}) \neq k^*_{-i}(\hat{\theta}_{-i})$, which means that agent i's type changes the social choice (agent i is pivotal), then $t_i < 0$. By allowing the payment rule t_i to be negative, it is possible to have a mechanism with the following properties:

1. *ex post* efficient: the social welfare is maximised
2. incentive compatible: for all agents, true revelation of their type, i.e. $\hat{\theta}_i = \theta_i$, $\forall i \in I$ is a dominant strategy.

IV. Our Scheme

Motivated by the work of Nix and Kantarcioglu in [1] we advance the potential of applying VCG mechanism in order to achieve privacy preserving collaborative classification. To comply with the game theoretic scenario, we assume a set of I agents, each one possessing a data set d_i, under the assumption that the pairwise intersection of these sets is empty. All agents share the same strategy set:

$$S_1 = \ldots = S_I = \{\texttt{true}, \texttt{perturbed}, \texttt{randomised}\},$$

where `true`, `perturbed` and `randomised` correspond to an agent providing true, perturbed and randomised data, accordingly. The set X of alternatives consists of the classification results. As explained in a previous section, the outcome of the mechanism, or in other words the collective choice, is that particular alternative which maximises the social welfare. In our scenario this is translated to achieving good classification

results. As classification is a supervised mining task, this alternative corresponds to the accuracy of the classification, which measures the performance of the classifier. Following the notation of [1] we denote the classification accuracy on a data set d by $acc(d)$. However, the lack of trust among the agents requires the introduction of privacy notions.

In our model, privacy is preserved by adding noise to the data values (perturbation). Although there are techniques to determine the distribution [12] and even to recover the true data from the noise [13], our experiment makes use of real data sets that do not have any particular trend, and thus those suggested methods for data recovery lead to poor results. For a clearer understanding of why this game theoretic approach succeeds, apart from the data perturbation, we also include complete randomization of the data, by replacing the true value with a random one. This random value is chosen from the interval formed by the minimum and maximum values of the attribute to be randomised. More formally, if x_i is the true value then the randomised value is $\tilde{x_i} = t_i$, where $t_i \in [\min \texttt{attribute\_value}, \max \texttt{attribute\_value}]$. Regarding the perturbation, the method we use depends on the type of the data. For numeric attributes we have $x_i' = x_i + r_i$, where r_i is chosen randomly from $[-a, a]$. If the attribute is of nominal type, then we use the AddNoise filter of the data mining toolset WEKA [14].

After the agents have decided on their preferences, their type is determined. The different types that we consider are: `per`, `rand`, `true`, where `per` describes an agent who provides perturbed data, `rand` corresponds to an agent who randomises the data and `true` represents an agent who is truthful. As all agents ideally prefer the extraction of information from true data, we regard their true type to be `true`, which corresponds to the accuracy of the classification on the union of the data sets $\bigcup_{i \epsilon I} d_i$ when all data is true. However, when an agent reports his type, the reported type $\hat{\theta}_i$ might not be the same as the true type θ_i.

An important feature of the mechanism design concept is a trusted third party who acts as the authority that imposes the rules. This is the role of the mediator, who will perform the mining task and distribute the payoffs to each agent. If the mediator knew the true (private) type of the agents, then he could decide the outcome of the mechanism and distribute payoffs to the agents according to their types. However, as the types are private the particular form of the Clarke mechanism serves as an incentive for the agents to reveal the true type, and thus lead to a fair payoff distribution by the mediator. Rewriting the payoff function (1) using the accuracy, agent i obtains the payoff:

$$u_i = acc(d) + \big(acc(\hat{d}) - acc(\hat{d}_{-i})\big), \tag{2}$$

with $d = \bigcup_{i \epsilon I} d_i$ being the union of the true data sets d_i, $\hat{d} = \bigcup_{i \epsilon I} \hat{d}_i$ is the union of the reported data sets $\hat{d}_i$ supplied by the agents and finally $\hat{d}_{-i} = \bigcup_{j \neq i} \hat{d}_j$, $i, j \in I$ corresponds to the data set formed from all data sets apart from the data of agent i. The expression

$$acc(\hat{d}) - acc(\hat{d}_{-i}) \tag{3}$$

calculates the loss or gain that agent i poses to the overall outcome, in other words his contribution. Using the result of (3) as a reference point, we can determine whether the agent wishes to mask his data in order to keep it private, or his aim is to harm the 'community' by providing falsified data. More specifically, if the modification of his data results in classification accuracy that leads to (3) having a negative value, then his behaviour is considered harmful. However, if from the modification we obtain accuracy that keeps (3) non negative, then we infer that agent i's intention is to preserve the privacy of his data without harming the overall outcome of the classification. Clearly, in an ideal situation agents would provide the true data and thus obtain high classification accuracy. However, as privacy is also required, the experimental results in the next section demonstrate that a controlled amount of perturbation results in both high accuracy levels and hiding of the data.

A. Measuring Privacy

Since the preservation of privacy is equally significant to the extraction of information, truth telling is not a necessarily desired strategy. On the other hand, complete falsification results in poor information gain. Perturbation of the data is a reasonable compromise, but what is the limit of the perturbation range before reaches complete randomisation, and subsequently diminishes the information gain? The answer lies in the term $acc(\hat{d}_{-i})$ of (2) which indicates the accuracy that can be achieved using data sets from all agents except agent i. As long as the expression (3) remains non negative, the perturbation of agent i's data causes insignificant reduction to the accuracy. If (3) becomes negative, then this is an indication that the perturbed data of agent i harms the overall accuracy and hence, agent i must obtain low payoff.

We suggest the following three different ways to measure privacy:

With respect to the distance from the true values:

$$\text{privacy} = \frac{|\text{perturbed value} - \text{true value}|}{|\text{randomised value} - \text{true value}|}$$

With respect to the range of the attribute values:

$$\text{privacy} = \frac{|\text{perturbed value} - \text{true value}|}{|\text{max value} - \text{min value}|}$$

With respect to the accuracy:

$$\text{privacy} = \frac{|\text{accuracy(perturbed data)} - \text{accuracy(true data)}|}{|\text{accuracy(randomised data)} - \text{accuracy(true data)}|}$$

Although in all cases the highest privacy is desirable, expression (3) poses a bound in the privacy that can be achieved without decreasing the agent's payoff.

V. Experimental Results

In support of the aforementioned model, this section presents our experimental results. The data set we used relates to the Civil War events in Africa, and was obtained from the Armed Conflict Location & Event Dataset [15]. For all data mining operations we used the toolset WEKA [14]. In particular, for the classification we applied the LibSVM to perform classification using the support vector machine method. Without loss of generality, we assumed that there are three agents with the following attributes:

Agent 1: {`year`, `source`}
Agent 2: {`actor1`, `actor2`}
Agent 3: {`latitude`, `longitude`}

All agents supply modified data, which can be either perturbed or randomised. We consider a small amount of perturbation for the attributes held by agents 1 and 2. In order to understand the sensitivity of the overall classification performance in terms of the amount of perturbation, we perform simulation study for a wide range of perturbation values while keeping the amount of perturbation on the data supplied by agents 1 and 2 fixed. We also study the classification performance when agent 3 completely randomises his attributes in order to understand the tradeoff between the privacy and the performance. The reason we choose agent 3 for greater modification of the data is due to his attributes `latitude`, `longitude` consisting of a wide range of real numbers. Moreover, the attributes of agent 3 form convex sets consisting of real numbers in the range of $[\min \texttt{latitude}, \max \texttt{latitude}]$ for the `latitude`, and $[\min \texttt{latitude}, \max \texttt{latitude}]$ for the `longitude`. Hence, the perturbed values also fall within these convex sets.

Let x_i denote the true value of an attribute and x'_i be the corresponding modified value. For perturbation of the numeric attributes, and particularly for the `year` attribute, we have that $x'_i = x_i + r_i$, with $r_i \in \{-1, 0, 1\}$. We perturbed both `latitude` and `longitude` as $x'_i = x_i + r_i$, with $r_i \in [-a, a]$. In our experiments we considered a range of perturbation as characterised by $a = 0.5, 1, 1.5, 2, 2.5, 3$. The nominal attributes (i.e. `source`, `actor1`, `actor2`) are perturbed using the AddNoise WEKA filter, with the noise parameter being 10%. For the randomisation of `latitude` and `longitude` $x'_i = t_i$, where t_i is drawn uniformly at random from $[\min \texttt{latitude}, \max \texttt{latitude}]$ and $[\min \texttt{longitude}, \max \texttt{longitude}]$, respectively. In order to prevent overfitting we applied the 0.632 Bootstrap method [16] with 200 bootstrap samples, each one having the same size as the training set.

Figure 1(a) depicts the overall accuracy for four cases when the perturbation parameter a takes the aforementioned values (a) all agents provide true data (legend $-+-$), (b) all agents perturb the data (legend $-o-$), (c) agent 1 and 2 supply perturbed data and agent 3 provides randomised data (legend $-*-$) and (d) the classification is performed on the perturbed data of agents 1 and 2 only (legend $-\diamond-$). A closer look at these accuracies (Figure 1(b)) shows that between the ideal accuracy (which is achieved when all agents provide the true data) and a higher level of privacy (achieved when the data is perturbed), there is an interval where these two desired but contradictory properties are in balance. This interval lies between the accuracy of the classification on the true data and the output of (3), which is the accuracy that is achieved without the contribution of agent 3. Clearly, when agent 3 randomises, the resulting accuracy is significantly diminished.

Figures 2(a) and 2(b) depict the contribution (corresponding to the outcome of (3)) and payoff of agent 3. For a better understanding of these results, both figures present the charges and payoff, respectively, that result from the supply of perturbed data from agents 1 and 2, and true data from agent 3 (legend $-\diamond-$). As this situation offers the maximum payoff to agent 3, when he introduces perturbation in his data the charges increase and his payoff decreases. Perturbation of up to $a = 2$ (i.e., 2^0 of perturbation) results in high payoff, and at the same time the data is concealed, as 2^0 latitude is equal to 222km. Furthermore, both Figure 2(a) and 2(b) show that randomisation is not a beneficial approach due to very low payoff.

Regarding the privacy, Figure 3 shows the three different ways of measuring it. Clearly, the maximum privacy is achieved when the data is completely randomised. However, as randomisation results in poor classification accuracy, the actual maximum privacy that can be attained is represented by the line denoted by 'max-privacy-'. In all three subfigures, this line marks the critical point which separates the privacy with positive classification results from the privacy with undesirable classification results. Finally, Figure 4 presents a 3D overview of the relation among the perturbation, the accuracy and the privacy, for the three different privacy measures. The square on the figures denotes the critical point (as can also be seen in the intersection of those two curves in Figure 1(b)) where we have the maximum privacy while the accuracy of the classification is high and the perturbation of agent 3 is not harmful.

VI. Conclusions

This work examined the problem of collaborative data mining using tools from game theory, while being able to offer data privacy to individual agents. In particular, motivated by [1] we used the Vickrey-Clarke-Groves mechanism in order to offer incentives that will prompt the agents to follow the rules. The behaviours that we considered are `true`, `per`, `rand`, corresponding to agent providing true, perturbed and randomised data. Our experiment showed that indeed the use of the VCG mechanism leads to high accuracy of the data mining task, while preserving the privacy of the data by allowing the agents to supply perturbed data. The key point of the VCG mechanism is that the gain of each agent includes the agent's contribution. Hence, the agent can perturb the data, as long as his contribution does not harm the overall result.

dotRL: A platform for rapid Reinforcement Learning methods development and validation

Bartosz Papis, Paweł Wawrzyński
Institute of Control and Computation Engineering, Warsaw University of Technology

***Abstract*—This paper introduces dotRL, a platform that enables fast implementation and testing of Reinforcement Learning algorithms against diverse environments. dotRL has been written under .NET framework and its main characteristics include: (i) adding a new learning algorithm or environment to the platform only requires implementing a simple interface, from then on it is ready to be coupled with other environments and algorithms, (ii) a set of tools is included that aid running and reporting experiments, (iii) a set of benchmark environments is included, with as demanding as Octopus-Arm and Half-Cheetah, (iv) the platform is available for instantaneous download, compilation, and execution, without libraries from different sources.**

***Index Terms*—Reinforcement learning, evaluation platform, software engineering**

I. Introduction

IN THE area of Reinforcement Learning (RL) [1] algorithms are developed that learn reactive policies for sequential decision making and control. Research in RL is based on the paradigm of *micro–worlds*: ideas are tested and demonstrated with the use of decision-making and control problems that can be defined analytically and reimplemented by others. This has forced researchers to spend a lot of time developing their experimental platforms. In order to help others and enable fair comparison of the ideas, many researchers have published their platforms: RL-Glue [2], PyBrain [3], CLSquare [4], RLT [5], PIQLE [6], lipbqrl [7], MDP Toolkit [8], MMLF [9], or QCON [10]. The general design principles for RL platforms were analysed in [11].

The purpose of this paper is to introduce another platform, dotRL, for development of RL algorithms. Although the platforms reduce the space for yet another project, it also demonstrates that a researcher developing a new idea in RL or a student getting familiar with this field still prefers writing their own platform from scratch instead of using an existing one. That is why the main principle that we adopted when designing our platform was as follows: the user should spend as little time as possible installing, getting familiar with the platform, and writing code, before they are ready to run their own agent or environment.

A. Related work

Perhaps the oldest and best-known RL platform is RL-Glue [2]. It dates back to 1996 through a project by Rich Sutton and Juan Carlos Santamaria called RL-Interface. RL-Glue has been a protocol specified by annual RL competition workshops held at ICML and NIPS. RL-Glue is basically a text communication protocol over sockets, between agents and environments. Reinforcement learning toolbox (RLT) [5] is a flexible platform for development learning algorithm in various scenarios: MDP, POMDP, and imitation learning. The price of this flexibility is the complexity of this platform and difficulty of its use. Libpgrl [7] focuses on planning and reinforcement learning in a distributed environment. Maja machine learning framework (MMLF) [9] supports not only RL but also model-based learning and direct policy search. It enables automated experimentation with the use of XML configuration files. PyBrain [3] is a general machine learning library, that also includes RL, but focuses on neural networks. Object-oriented platforms written in Java include PIQLE [6], RLPark [12], and Teachingbox [13]. Another platform, YORLL [14], is written in C++.

B. Requirements and basic assumptions

The dotRL platform is designed to minimize the time spent by its user on technical and infrastructural details. The user should focus almost all of their effort on dealing with purely scientific issues. In order to meet this requirement, the design of dotRL is based on the following assumptions and characteristics:

1) Altogether, dotRL is a *solution* written under .NET 4.5 framework, Windows operating system, and Visual Studio 2010. As a result, further development of dotRL may be based on all the tools provided with Visual Studio and .NET technology.
2) Having been downloaded and opened with Visual Studio, it is ready to be compiled and run.
3) In order to add a new agent or a new environment to the platform, one only needs to implement a class with an appropriate interface. After compilation, the platform alone is able to couple this new entity to other environments or agents.
4) Each agent and environment is designed for one particular *problem type*. The problem type defines the types of state and action spaces. They may be continuous (i.e., contain vectors of reals), discrete (contain vectors of integers), and possibly others.
5) A set of tools is provided with dotRL that enables launching many learning runs with the same setting and getting logs almost directly insertable to a scientific paper. Tools for implementing agents, such as neural networks, are also included.
6) A set of exemplary agents and environments are provided with the platform. Those include as complex en-

978-83-60810-53-8/$25.00

vironments as Octopus-Arm [15], [16] and Half-Cheetah [17], [18].

7) The platform is fully compatible with RL-Glue [2].

To our knowledge, the platform presented in this paper is the first full-featured platform written under .NET, and the first one in which adding a new agent or environment only requires implementing a single class. Especially this last feature is helpful in rapid development and validation of new algorithms.

The aforementioned notion of problem types is based on the following observation: An agent is usually applicable, without modification only to environments with compatible state and action space types. No one really implements a learning algorithm that, in the same form, is applicable to several problem types. It is possible to do so, but almost always means that the agent will do something completely different for different versions of environment it deals with at the moment.

Additional contribution of this work is RL-Glue codec for .NET platform.

dotRL is an open source software under BSD license and hosted on *sourceforge.net* [19]. We welcome anyone to contribute to the project.

C. Organization of the paper

The remaining part of the paper is organized as follows. Sec. II presents an overview of the user interface, sec. III defines basic modules and components of the dotRL platform. Another subsection presents the interaction protocol between an agent and an environment that the platform supports. Sec. IV explains how to use a new component (agent or environment) with the platform. Sec. V elaborates on integration of dotRL with the RL-Glue protocol. Sec. VI concludes the paper and indicates directions of future development of the platform.

II. User interface

Typical usage scenario of the dotRL solution, when the user wants to test an existing agent on an existing environment consists of the following steps:

1) Click the “Experiment” menu item from the “New” menu,
2) Choose an environment from the list of available environments,
3) Choose an agent from the list of available agents compatible with the chosen environment,
4) Configure parameters of the chosen environment and agent
5) Configure reporting parameters,
6) Configure experiment parameters (i.e. number of episodes, maximum number of steps in one episode),
7) Click “OK” when finished configuring the experiment,
8) Click “Background learning” or “Real time learning”,
9) Click “Present policy” and/or view the created report file.

The user can modify parameters of the ongoing experiment. Details on extending the platform’s set of components (agents or environments) are provided in Section IV. An example view of the application during configuration of an experiment is presented in Figure 1. Running experiment is presented in Figure 3, and a screen presenting functionality allowing more than one simultaneous experiments to run is shown in Figure 4.

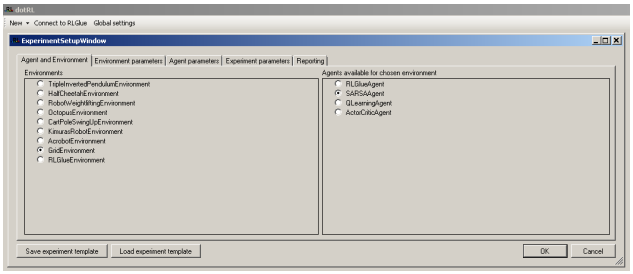

Fig. 1. Experiment configuration.

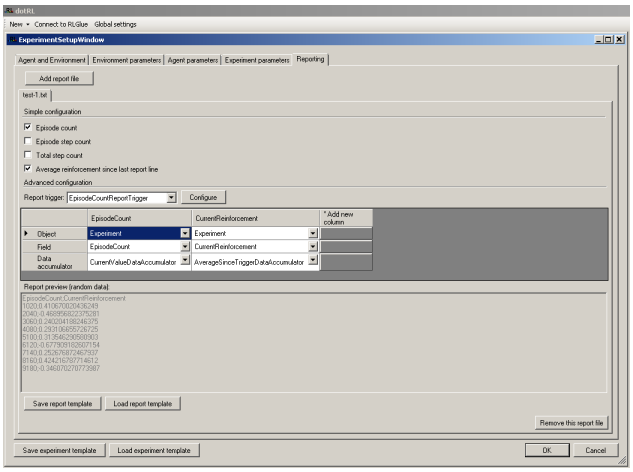

Fig. 2. Reporting configuration.

To configure the reporting parameters “Add report file” button in “Reporting” tab needs to be clicked. Then, the user can either choose to use simple configuration and choose from the standard set of report columns, or to configure their own report:

1) For each report file tab:
   a) Choose one of *report triggers*
   b) Click “Add new column” for each desired column in the output file
   c) Choose one of available data sources and a way to accumulate their values

ReportTrigger and *DataSource* objects are explained in detail in Section III-C. An example view of the application during reporting configuration is presented in Figure 2.

For interacting with RL-Glue one of these two actions must be taken:

- Choose the *RLGlueAgent* or *RLGlueEnvironment* in the component choice window after choosing to create new experiment
- Start an RL-Glue experiment to connect to RL-Glue core.

Integration with RL-Glue components is explained in detail in Section V.

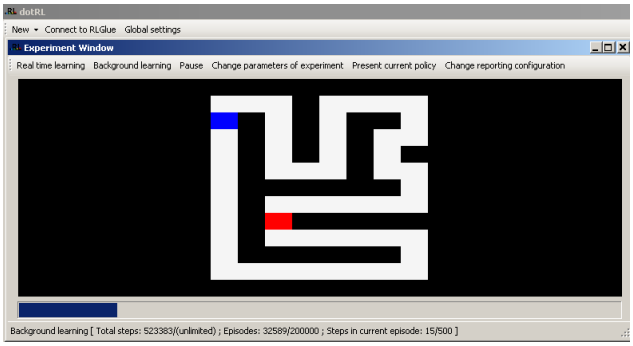

Fig. 3. An example experiment.

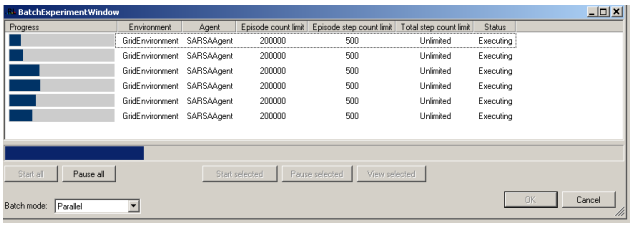

Fig. 4. An example batch experiment.

III. dotRL components

This section presents the *domain model* [20] of the dotRL solution. Section III-A presents the set of core entities which reflect key notions of an RL experiment. Section III-B presents how these components interact with each other during an experiment.

A. Classes

Learning algorithms, called *Agents* in RL are represented as subclasses of the *Agent<TStateSpaceType, TActionSpaceType>* base class. Problems to solve by these algorithms, called *Environments* in RL are represented as subclasses of the *Environment<TStateSpaceType, TActionSpaceType>* base class. Environments can have continuous or discrete state transition function and they accept real or integer vectors as actions. This divides them into four groups, three of which are commonly addressed, and which we call *problem types*: continuous state & continuous action, continuous state & discrete action, discrete state & discrete action. Each agent and environment is dedicated to one problem type and this is made explicit in dotRL in the form of generic parameters of *Agent* and *Environment* base classes. Interaction between an agent and an environment is called *Experiment*. This whole design is modelled with classes presented in Figure 5.

Agent represents the class hierarchy of all agents implemented in dotRL, with *Agent<TStateSpaceType, TActionSpaceType>* (in Figure 5 generic arguments are omitted for clarity) being their base class. Agent's responsibility is to decide which *Action* to take in given *Environment*'s *State*, and to improve its policy with received *Sample*s. Details on how to implement an agent are provided in Section IV.

Similarly, *Environment* represents the hierarchy of classes which represent RL problems to be solved by the *Agent*s. The class *Environment<TStateSpaceType, TActionSpaceType>* (in Figure 5 generic arguments are omitted for clarity) is the base class for any environment implemented in dotRL. Environment's responsibility is to simulate a designed behaviour, reacting to given *Action*s by changing it's *State* and providing a *Reinforcement*. Unlike some other solutions (like PyBrain [3]) we do not divide responsibility of modelling a behavior and assigning reinforcement between two separate objects. Theoretically, it would lead to a more accurate domain model and it is a valuable idea, but it makes development more time-consuming and this opposes our requirements. Different rewarding policies can be easily implemented using environment's parameters.

The *Experiment* models a key notion in RL research — an experiment, i.e. a continuous interaction between an *Agent* and an *Environment*. Experiment's resposibilities are: controlling the course of an experiment (i.e. informing about begining and ending of an episode, evaluating finish conditions) and passing information between an agent and an environment (*State*s, *Action*s, *Sample*s and *Reinforcement*s), and passing information to classes resposible for reporting functionality.

State<TStateSpaceType>, *Action<TActionSpaceType>* and *Reinforcement* (again, generic parameters omitted for clarity in Figure 5) are simple wrapper classes for vectors and numbers to make RL domain notions explicit in the code — they are not essential, but they make the design clear and explicit, and improve implementation's readability.

EnvironmentDescription<TStateSpaceType, TActionSpaceType> (again, generic parameters omitted for clarity in Figure 5) is a class containing information about the structure of an environment. The details about its contents are provided in Section IV.

Presentation class provides a root for hierarchy of classes that are used to visualize the state of the environment. Its responsibility is to draw a visualization of a given state on a given canvas object (.NET's *System.Drawing.Graphics*). It is used only when user chooses "Policy presentation" mode in the user interface.

Sample represents a smallest piece of information in a RL experiment. Sample consists of:

- *PreviousState*: a state in which the *Environment* was.
- *Action*: an action taken by the *Agent* for state *PreviousState*.
- *CurrentState*: a resulting state after taking action *Action* in state *PreviousState*.
- *Reinforcement*: a reinforcement received after taking action *Action* in state *PreviousState*.

The use of *sample*s allows the implementation of an agent to be stateless — no information needs to be stored between calls to various agent's methods (such as *EpisodeStarted*, *GetAction*, etc.). More details are available in Section IV.

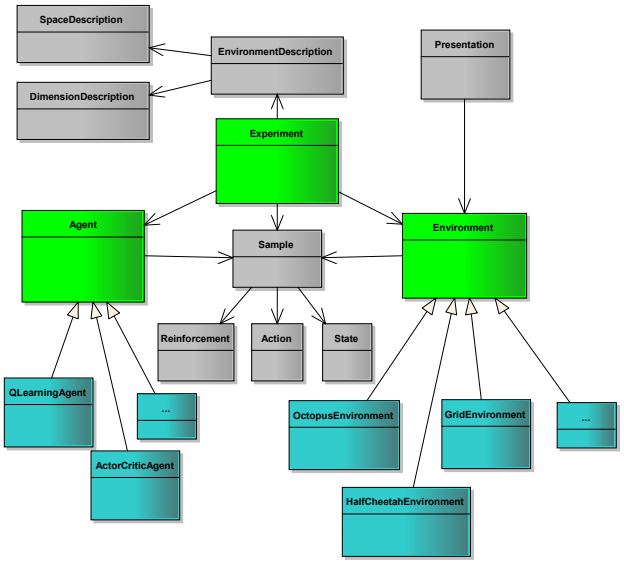

Fig. 5. dotRL main components. Green classes represent core components essential to implement the concept of RL experiment. Gray classes are useful utility classes which represent minor concepts. Blue classes represent a place for user's activity: they are concrete implementations of agent's and environment's behaviors. Ordinary arrow represents association, filled arrow represents inheritance.

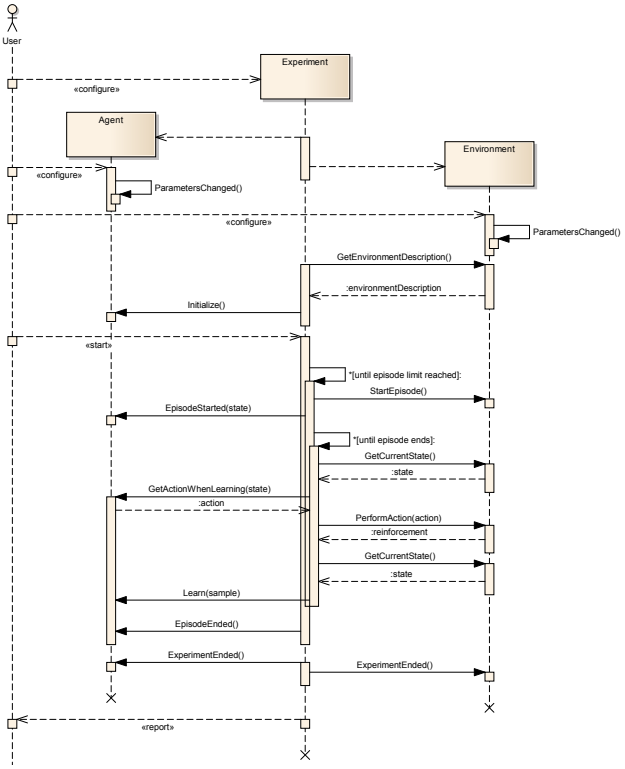

Fig. 6. dotRL interaction scenario. After user initiates a new experiment the platform's core components exchange data in a way typical for an RL experiment.

B. Operation sequence

We propose to adopt a simple interaction scenario based on explicit interfaces. Many existing RL platforms use typical setting in which subsequent method calls (*episode start*, *step*, *episode end*) implicitly rely on each other, forcing agent's implementation to be a state machine. This is not always the most convenient way, and such interface does not follow readable code guidelines [20]. The proposed sequence of method calls between components during an experiment is presented in Figure 6.

After the user initiates a new experiment instances of chosen classes are being automatically created: a subclass of the *Agent<TStateSpaceType, TActionSpaceType>* base class and a subclass of the *Environment<TStateSpaceType, TActionSpaceType>* base class (generic arguments are omitted for clarity in Figure 6). First, the user configures the parameters of the experiment (i.e. number of episodes, number of steps in each episode), agent and environment. Then, after experiment passes the information about the environment to the agent, a loop common to all RL experiments is being started. Each episode consists of a sequence of repeatedly executed steps:

1) The current state of the environment is retrieved by calling the *GetCurrentState* method.
2) If the current state is terminal or the current episode should end because of its duration limit, agent's *EpisodeEnded* method is called, and a new episode is started by calling *StartEpisode* environment's method and *EpisodeStarted* agent's method.
3) Agent's action for current state is retrieved with call to the *GetActionWhenLearning* method.
4) The *Environment* is informed what action it should execute via call to the *PerformAction* method.
5) The reinforcement and the new current state are retrieved from the *Environment* as return values from the *PeformAction* and *GetCurrentState* methods.
6) The *Agent* is informed about the consequences of executed action via call to the *Learn* method.

If the user wishes only to see how the agent behaves without changing it's policy they can choose "Policy presentation" mode. In this mode, another copy of the environment is used and agent's *GetActionWhenNotLearning* method is used (opposed to *GetActionWhenLearning*) so there is no interference with the learning process (provided that the implementation of *GetActionWhenNotLearning* is correct and truly does not influence the learning process).

C. Reporting

A valuable functionality of dotRL is provided by the reporting mechanisms. When configuring an experiment the user can setup multiple output log files. This is done through three useful notions: *ReportTrigger*, *DataSource* and *DataAccumulator*. A report trigger is a class that decides when to write a line to the output file. Lots of report triggers have already been implemented, such as: *TotalStepCountReportTrigger* which causes emiting a log file line at configured intervals of steps in an experiment, *EpisodeCountReportTrigger* which causes emiting a log file line at configured intervals of episodes in the whole expermient.

DataSource consists of an object and it's field, which's value

will be reported to the output file. There are three main objects which provide data: Experiment, Agent and Environment. The experiment provides typical experiment information, like the number of steps executed so far, or the reinforcement received by the agent. Data exposed by the agent and the environment depends on the creator of these components. Any useful piece of data can be accessed by the reporting functionality as easy, as marking any component's field with *ReportedValue* attribute. An example is provided in *QLearningAgent* which exposes it's *td* field, containing recently computed temporal-difference value.

DataAccumulator allow some simple manipulations on the data read from data sources. The most common are *no-op* data accumulator (*CurrentValueDataAccumulator*) which just outputs the returned value and *AverageSinceTriggerDataAccumulator* which accumulates the data between each report file line and calculates average.

D. Implemented components

Currently, the following components are implemented in dotRL:

- Environments:
  - *Cart-Pole Swing Up* [21]
  - *Double Inverted Pendulum on a Cart* [22]
  - *Acrobot* [23]
  - *Robot weightlifting* [24]
  - *Kimura's Robot* [25]
  - *Half Cheetah* [17]
  - *Octopus Arm* [16]
  - *Coffee task* [26]
  - *Grid*
- Agents:
  - *Actor-Critic* [27]
  - *Actor-Critic with Experience Replay* [17]
  - *Q-Learning* [28]
  - *SARSA* [29]

IV. Adding new components

We focus our design to make adding new agents and environments as simple as possible. This allows a researcher to spend most of his time on substantial work instead of dealing with technical details. Developing a new agent or a new environment is most straightforward: one needs just to subclass the *Agent*<*TStateSpaceType, TActionSpaceType*> class or the *Environment*<*TStateSpaceType, TActionSpaceType*> class, respectively. The *TStateSpaceType* and *TActionSpaceType* generic arguments need to be set to types corresponding to desired problem type (for example: setting $TStateSpaceType = double, TActionSpaceType = int$ allows creation of a continuous state & discrete action agent/environment).

Each component, once implemented, will appear automatically in the user interface. If additionally a subclass of the *Presenter* class is supplied, the environment's state will be visualized in the experiment's window. Otherwise the default presenter will be used, which just prints raw state and reinforcement information. The implementation of *Experiment*<*TStateSpaceType, TActionSpaceType*> (green component in Figure 5) is provided by the dotRL platform, and is fully configurable through the user interface.

Another convenience is automatic handling of component's parameters. Every *Agent* or *Environment* can have any of its fields or properties (doesn't matter whether private, protected, public, static or instance related) marked with one of *Parameter* or *NumericParameter* attributes. Such fields will appear in a configuration dialog window before starting each experiment, allowing the user to tune the component's behavior. Also, if any component uses another component (for example one wants to implement an environment similar to an existing one, and reuses the latter as a part of the new one) its parameters will be also handled automatically.

A. Adding a new environment

Subclassing the *Environment*<*TStateSpaceType, TActionSpaceType*> class requires implementing the following methods (for clarity, generic arguments have been omitted):

- EnvironmentDescription *GetEnvironmentDescription*(): called to retrieve information about the environment
- void *StartEpisode*(): called when a new episode begins
- Reinforcement *PerformAction*(Action action): called to execute action and retrieve reinforcement

The first method is called to transfer information about the structure of the problem to the agent. Usually agents require information about the problem's state, action and reinforcement spaces. Such information is stored in *EnvironmentDescription*<*TStateSpaceType, TActionSpaceType*> class, which has two instances of *SpaceDescription*<*TSpaceType*> classes (one for state space and one for action space) and one instance of *DimensionDescription*<*TSpaceType*> class for describing the reinforcement space. *SpaceDescription*<*TSpaceType*> consists of *DimensionDescription*<*TSpaceType*> instance for each described dimension. *DimensionDescription*<*TSpaceType*> contains: minimum value, maximum value, average value and standard deviation.

Not all of these fields are always used. Typically, state space information contains:

- Minimum value for each state variable.
- Maximum value for each state variable.
- Average value for each state variable.
- StandardDeviation of each state variable.

Action space information:

- Minimum value for each action dimension.
- Maximum value for each action dimension.

Information about the reinforcement:

- Minimum reinforcement value.
- Maximum reinforcement value.

Despite the typical setting, all values are optional but the environment should provide as much information as possible, to allow cooperation with agents that need it.

Typical behavior of the *StartEpisode* method is to initialize environment's state (to some predefined state, probably dependent on parameters or to a random state).

The last method, *PerformAction* is typical to RL environment implementations: it usually performs a simulation step, evaluating the consequences of the given *action* (calculating environment's next state) and returns a reinforcement associated with this *action* in its current state.

Technically, these methods should be implemented in the paradigm of a *stateful* protocol — environment should keep track of its current state. To facilitate this and for efficiency, the *Environment<TStateSpaceType, TActionSpaceType>* base classes exposes a protected mutable *CurrentState* property. As long as it is used by *StartEpisode* and *PerformAction* methods one needs not to bother about implementing the *GetCurrentState* method.

Additionally these methods can optionally be overriden:

- State *GetCurrentState*(): called to retrieve environment's current state
- void *ParametersChanged*(): called after user changes environment's parameters
- void *ExperimentEnded*(): called after the user closes the experiment window

The default implementation of the first method returns the *CurrentState* property as an immutable object. The default implementations of the two remaining methods do nothing.

Environment class must contain a parameterless constructor.

B. Adding a new agent

Subclassing the *Agent<TStateSpaceType, TActionSpaceType>* class requires implementing the following methods (for clarity, generic arguments have been omitted):

- void *ExperimentStarted*(EnvironmentDescription environmentDescription): called to pass the information about the environment to the agent
- Action *GetActionWhenNotLearning*: called to retrieve agent's decision about an action to take in the given *state*, when presenting current policy
- Action *GetActionWhenLearning*(State state): called to retrieve agent's decision about an action to take in the given *state*, during learning
- void *Learn*(Sample sample): called to inform the agent about a state, action that took place and the resulting next state and reinforcement

The first method is called before the start of the experiment, so the agent could prepare its internal structures accordingly to the structure of the environment(e.g., dimensions of the state, and action spaces).

The *GetActionWhenNotLearning* should return the action according to agent's current policy for the given *state*, not affected by agent's exploration policy, and in way not to interfere with agent's internal state related to learning.

The third method, *GetActionWhenLearning* should return the action according to current agent's policy for the given *state* which can be distorted for exploration. Also in this method agent can calculate or remember some additional quantities which will be needed in the *Learn* method. It is guaranteed that a call to *Learn* method will always follow a previous call to *GetActionWhenLearning*.

The *Learn* method, typical to RL agent implementations, is used to transfer experience to the agent. Agent can, for example accumulate this experience, or improve its policy at once.

Technically these methods should be implemented in the paradigm of a *stateless* protocol. Subsequent calls to *GetActionWhenLearning* or *Learn* should not be explicitly dependent. Of course, there should be an implicit dependency between these calls and calls to the *Learn* method through the agent's policy and some internal variables used for learning. Also, the *action* returned by the *GetActionWhenLearning* method will be present in a *sample* given to a subsequent *Learn* call.

The *GetActionWhenNotLearning* method should act in a completely transparent way — no assumptions should be made about the moment of its execution, as user can switch to "Policy presentation" mode at any time. The environment will remain unaffected, as in "Policy presentation" mode its copy is being used.

Similarly to environments' base class, the base class for agents exposes a mutable protected *Action* property to be modified in place for efficiency, and returned from *GetAction* as an immutable version.

Additionally these methods can optionally be overriden:

- void *EpisodeStarted*(State state): called when episode starts
- void *EpisodeEnded*(): called when episode ends
- void *ExperimentEnded*(): called after the user closes the experiment window

The default implementations of these methods do nothing.

Agent class must contain a parameterless constructor.

C. Adding a new presenter

Subclassing the *Presenter* base class is optional, however it allows a researcher to evaluate environment's behavior visually. Usually environments represent some imaginable object, or they are related to a real-world object. Having them drawn and being able to observe their dynamics makes it easier to verify their implementation, and to analyze agent's behavior. To implement a presenter one needs to:

- subclass the *Presenter* base class and implement the *Draw* method,
- provide a constructor taking one argument of type of the environment to visualize.

The *Draw* method should draw the visualization of environment's current state to the canvas held by the *Graphics* object, exposed by the *Presenter* base class. *Draw* implementation should use drawing functions also provided by the *Presenter*

base class, as they scale the drawing appropriately to window's dimensions and aspect ratio. Presenter implementations should hold the reference to the visualized environment for themselves. Implementation of a presenter can be designed to visualize more than one environment — it just needs to provide one constructor for each visualized environment. This is useful when one environment is derived from another one.

V. Integration

A. Integration with RL-Glue

In RL research field there are many agents and environments available, however they are implemented in different platforms and languages. This problem is taken care of by the RL-Glue protocol [2]. dotRL supports it, to give its users access to the vast set of agents and environments already implemented and compatible with RL-Glue.

Generally, interaction between two integrated platforms (or components from different solutions) relies on one of them managing the course of an experiment and the other acting passively as one of experiment components: an agent or an environment. This gives two options of integrating dotRL with RL-Glue components:

1) *dotRL* manages the course of an experiment employing a RL-Glue agent or environment.
2) *dotRL* acts as RL-Glue component: an agent or an environment, while RL-Glue manages the course of the experiment.

dotRL allows both scenarios: the user can instantiate a component (agent or environment) alone, and configure it to connect to a RL-Glue server application, or user can open an ordinary experiment window chosing a special agent (*RLGlueAgent*) or environment (*RLGlueEnvironment*) type which act as proxies and encapsulate RL-Glue network communication details. Example of the first scenario is presented in Figures 7 and 8. Some other platforms, like Teachingbox [13] also provide integration with RL-Glue, but dotRL is the only platform known to the authors which allows both integration scenarios.

B. Integration with other applications

Integrating dotRL with other platforms, or single-component applications is easy thanks to the mechanisms provided by the .NET framework. For example:

- C/C++ code, compiled to a *DLL* library is easily accessible from .NET through the *Platform Invoke Services* (*P/Invoke*) or *It Just Works* (*IJW*).
- Python code can be accessed with solutions like *IronPython* [30] which provide Python virtual machine implementation in .NET.
- Because *Matlab* gives access to its API through DLL interface, it also possible to run *Matlab* scripts using *P/Invoke* mechanism. *Matlab*'s COM interface can also be used.
- Interaction with *XML* based communication (e.g. configuration of the Octopus-Arm environment [15], [16]) is easy to develop thanks to provided tools ranging from simple *XML* stream processors (*XmlReader* and *XmlWriter*) to powerful *LINQ to XML* which allows comfortable operating on *XML* documents in an elegant and concise way.
- Network communication is also supported with easy to use highlevel classes and libraries like *WCF* (*Windows Communication Foundation*).

In any of these cases, user is required only to implement a wrapper class managing the interoperability using one of described mechanisms as a subclass of the *Agent* or *Environment* base class.

C. Comparison with RL-Glue

Although RL-Glue and dotRL are different types of solutions, some of their merits can be compared:

- RL-Glue being a network protocol is fully platform independent, whereas dotRL can work only on platforms with existing .NET framework implementation. However, the number of platforms which support .NET is becoming bigger. Thanks to the *MONO* project [31], .NET is supported not only on Windows, but also most Unix-like systems, MacOS X, and even Android (full list of supported systems can be found in [32]).
- RL-Glue is however tied to the infrastructure: *BigEndian* convention is obligatory[1], and there are fixed sizes of basic data types. dotRL is completely infrastructure ignorant, as long as .NET Framework is supported.
- RL-Glue, being a handcrafted protocol is not feasible for extensibility (e.g. hard-coded order of elements in *TaskSpec*). dotRL is easily extensible by design.
- In both solutions adding new components requires at minimum writing only one class required to implement one simple interface.
- RL-Glue does not offer a standard way to turn off policy improvement. dotRL handles this case via "policy presentation" mode.
- In RL-Glue reporting and visualization must be managed by the user on their own (however, see *RL-Viz* project mentioned below). dotRL offers easily extensible reporting and presentation frameworks with convenient GUI.

RL-Glue is more popular, and in fact seems a better solution if multiplatform or distributed environment is obligatory. However, dotRL is easier to maintain (no hardcoded assumptions), provides more useful tools for evaluation of new agents (built in extensible reporting framework), visualization of environments (built in extensible visualization framework), and allows easy integration with other solutions (details were provided in sec. V-B). In the context of reporting and visualization it is fair to mention the *RL-Viz* project, however it remains unreleased since 2007 [33].

[1]BigEndian is obligatory in the context of network communication with the RL-Glue Core application. Refer to the RL-Glue Core implementation: "rlBufferWrite" and "rlBufferRead" functions in the "RL_network.c" file.

VI. Conclusions and Future Work

In this paper dotRL — a platform for fast development and validation of reinforcement learning algorithms was introduced. The platform had been designed to minimize the time spent by its user on technical and infrastructural details, as they should focus on purely scientific issues. Seemingly, the platform meets this requirement.

Directions of further development of dotRL include its integration with other platforms. They also encompass enriching the set of agents and environments available within the platform.

An Emotional Learning-inspired Ensemble Classifier (ELiEC)

Mahboobeh Pasrapoor, Urban Bilstrup
School of Information Science, Computer and Electrical Engineering (IDE), Halmstad University

Abstract— In this paper, we suggest an inspired architecture by brain emotional processing for classification applications. The architecture is a type of ensemble classifier and is referred to as 'emotional learning-inspired ensemble classifier' (ELiEC). In this paper, we suggest the weighted k-nearest neighbor classifier as the basic classifier of ELiEC. We evaluate the ELiEC's performance by classifying some benchmark datasets.

I. Introduction

Classification methods have been widely used in the area of science, engineering, industry, business and medicine; they can be used for classification problems e.g., anomaly detection, handwriting recognition, speech recognition and medical diagnosis. Among them, the data driven classification approaches e.g., neural network-based models and neuro-fuzzy-based methods are the most popular methods due to the self-adaptive and high generalization capability. However, they have some significant issues: over fitting, model complexity and the curse of dimensionality, etc. [1]-[5]. Thus, developing new classification models to increase the classification's accuracy while resolving the mentioned issues are an open research topic in data mining. In this paper, a new classification model is suggested that can be considered as an ensemble classification with a different integration mechanism and combination algorithm. The model is an emotionally inspired model and is named 'brain emotional learning-inspired ensemble classifier' (ELiEC).

The rest of this paper is organized as follows: Section II reviews some works in classification and emotional learning–based models. Section III explains the ELiEC's structure. In Section IV, the benchmarks classification data sets are examined by ELiEC and the obtained results compared with other methods. Finally in Section V, we conclude and recommendsome possible future improvements to ElIEC.

II. A Brief Review

A. Related works to Classification methods

Numerous artificial intelligence-based methods have been proposed for classification problems. They can be categorized as: inductive or transductive, statistical-based or non-statistical–based, supervised or unsupervised methods. One popular group is supervised classification methods that include statistical methods (e.g., Naïve Bayes), non-statistical methods (e.g., neural network), instance based learning and support vector machine. Given a set of instances, these algorithms can assign an appropriate label to an unlabeled instance. Among the supervised learning methods, the support vector machine has the best performance in terms of classification accuracy; however, it has high time complexity that is a big issue for online classification applications [2] and [5].

Numerous efforts have been put into developing regularization methods to increase the generalization of supervised classification algorithms and reduce the time complexity of the learning procedure. A good example of the enhanced classification methods is the NFI model (Neuro-Fuzzy Inference Method for Transductive Reasoning) that provides a local model for each instance using a transductive reasoning system. The NFI model outperforms the neural network model in terms of accuracy and time complexity; nevertheless this model is not suitable for high dimensional classification applications [6]. Developing an ensemble-based [4] classifier is a major progress in addressing the misclassification and time complexity issues. The idea of ensemble-based classifiers is inspired by the human decision making process. The main components of an ensemble method are diversity generator and combiner. The former selects appropriate classifiers while the latter combines the classifiers' outputs. The combination mechanisms that have been developed can be divided into two subgroups: meta-combination and weighting methods. Choosing suitable diversity classifiers and combination procedures, the classification accuracy of ensemble-based classifiers outperforms the accuracy of each of the classifiers; however there is no adaptive procedure for choosing the classifiers and the combiner using information of classification problems.

Recently, a novel classification framework with the ability to adaptively tune the classifier's structure has been developed. This model, called meta-cognitive neural network (McNN), encompasses two components: a cognitive component and a meta-cognitive component [1],[5]. In McNN, the first component is a Radial Basis Neural Network and it is responsible for the change and optimization of the structure. The second component plays a role in choosing samples and the effective structure of the learning algorithm, obtaining knowledge from the training data. The McNN model and an extended version of that PBL-McRBFN [5] have shown excellent performance for classification problems.

The ELiEC model is a general purpose classification method that aims to reduce the misclassification rate and time complexity in classification applications. The ELiEC model

978-83-60810-53-8/$25.00

can be categorized as a type of ensemble classifiers that uses Wk-NN as the classifiers.

B. Brain Emotional Learning-based Models

Modeling the brain emotional processing and the memory to develop the artificial intelligence (AI-based) based tools has been an interesting topic in the machine learning research area. The emotionally-inspired AI tools are often referred to as the computational models of emotional learning. A well-known computational model is the amygdala-orbitofrontal system that defines emotional processing on the basis of the limbic system. The assumption of this model is that the limbic system, which consists of thalamus, sensory cortex, amygdala and orbitofrontal cortex, is mainly responsible for emotional learning in mammalian brains [8]. Fig. 1 depicts the connection between amygdala and its components. Fig. 2 describes the amygdala-orbitofrontal subsystem model that consists of four parts that interact with each other to mimic the emotional learning processing [8]. Due to its simple structure, the fundamental framework has been used for developing AI tools for control applications and and nonlinear system prediction. [12]-[17].

One popular emotionally inspired controller is BELBIC[9] that has been proven to overcome uncertainty and complexity issues of other intelligent controllers. Studies [9]-[11] have proved that BELBIC outperforms many other controllers such as PID controller and linear controllers in terms of simplicity, reliability and stability.

The emotionally based prediction models have often been applied for chaotic time series prediction and have also shown improvements in prediction accuracy [12]-[17].

III. EMOTIONAL LEARNING-INSPIRED ENSEMBLE CLASSIFIER (ELIEC)

The brain emotional learning-based ensemble classifier (ELiEC) model has a similar architecture to our two previous modelsBELRFS and BELFIS [13], [15]. The ELiEC model consists of four main parts and imitates the internal connection of the emotional system. The parts of ELiEC are named as : TH, CX, AMYG and ORBI that **are** referred to as THalamous, sensory CorteX, AMYGdala and ORBItofrontal cortex**.** The ELiEC model and the connection between these parts are described in Fig. 3.

For a classification problem, we define the set of training data as $(\mathbf{x}_1,\mathbf{c}^1),...,(\mathbf{x}_i,\mathbf{c}^i)...,(\mathbf{x}_n,\mathbf{c}^n)$, where $\mathbf{x}_i$ is an instance with m features and $\mathbf{c}^i$ determines the label class of $\mathbf{x}_i$. In a multi-class classification problem, we have n classes and the corresponding class of $\mathbf{x}_i$ which can be encoded as $\mathbf{y}^i = \ y_1^i,...,y_2^i,...,y_n^i$. If $\mathbf{c}^i$ is equal with j^{th} class, the value of y_j^i will be equal to one and other values will be zero. Using the following steps we explain how ELiEC classifies each instance in order to minimize the misclassification. The TH part evaluates the features of $\mathbf{x}_i$ and adds several extra features to $\mathbf{x}_i$. The extra features are calculated according to equation (1).

$$\mathbf{th}_i = [\max(\mathbf{x}_i), \text{mean}(\mathbf{x}_i), \min(\mathbf{x}_i)] \quad (1)$$

The CX evaluates the features of $\mathbf{x}_i$ and eliminates redundant features. The CX has a role to select the most informative features and eliminate the redundant features. Thus, the CX receives $\mathbf{x}_i$ with m features and provides $\mathbf{s}_i$ with l features ($l \le m$).

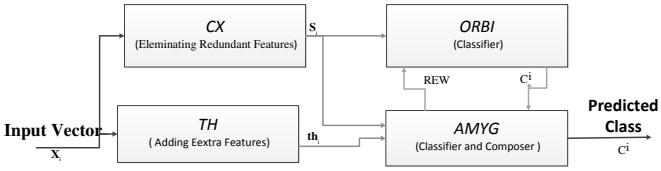

Fig. 3.The architecture of ELiEC.

The AMYG consists of a classifier and a combiner. The classifier that is represented as equation (4) predicts an appropriate class for $\mathbf{x}_i^a$ which is determined as equation (3). The combiner of the AMYG combines the outputs of the AMYG and ORBI to provide the final class as equation (5).

$$\mathbf{x}_i^a = [\mathbf{th}_i, \mathbf{s}_i] \quad (3)$$

$$C_a^i = \mathrm{Class}(\mathbf{x}_i^a) \quad (4)$$

The combiner strategy depends on the type of classification methods. In this paper, the Wk-NN method has been utilized as the classifiers of AMYG and ORBI. The combiner is another Wk-NN and determines the final class of the input vector $\mathbf{x}_i^c$ which is a vector as $\mathbf{x}_i^c = [\mathbf{x}_i^a, \mathbf{x}_i^o, C_a^i, C_o^i]$.

$$C^i = \mathrm{Class}(\mathbf{x}_i^c) \quad (5)$$

The ORBI is another classifier that can be a dependent classifier or independent classifier. For a dependent classifier the ORBI classifies the input vector $\mathbf{x}_i^o = [\mathbf{s}_i, \mathrm{REW}_i]$; while for an independent classifier the input vector is $\mathbf{x}_i^o = \mathbf{s}_i$. Finally, it forwards the classification result $C_o^i = \mathrm{Class}(\mathbf{x}_i^o)$ to AMYG. For the examples of this study an independent classifier is assigned to ORBI.

It should be noted that the classifiers of AMYG and ORBI can be defined on the basis of any supervised classification method, e.g., decision tree, single or multilayer perceptron, and support vector machine, etc. We can also form a meta-ensemble classifier by choosing an ensemble-based classifier for the AMYG and the ORBI.

IV. Weighted K- Nearest Neighbor : A Basic Classifier of ELiEC

Weighted k-nearest neighbor (Wk-NN) is a type of instance-based algorithm that has been widely used as a classification and regression method. For a given training set as: $(\mathbf{x}_1, c^1), ..., (\mathbf{x}_i, c^i) ..., (\mathbf{x}_{N_t}, c^{N_t})$, the Wk-NN determines the class of a test vector, $\mathbf{x}_{\text{test}}$,using the following steps [18]:

1) The Euclidian distance between $\mathbf{x}_{\text{test}}$ and $\mathbf{x}_i$ is calculated, $d_i = \|\mathbf{x}_{\text{test}} - \mathbf{x}_i\|_2$, in which each $\mathbf{x}_i$ is a member of $\mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_{N_t}$, where N_t denotes the number of samples of the training data set.

2) The k minimum values of $\mathbf{d} = \{d_1, d_2, ..., d_{N_t}\}$ are selected as $\mathbf{d}_{\min}$. The $\mathbf{x}_i$ s that are corresponding to $\mathbf{d}_{\min}$ are the k nearest neighbors to $\mathbf{x}_{\text{test}}$ and define the local neighborhoods of the test vector, $\mathbf{x}_{\text{test}}$ [18].

3) The class label of $\mathbf{x}_{\text{test}}$ is chosen from the class labels of the local neighborhoods. Using the weighted k-nearest neighbor (W-kNN), a weight is assigned to each neighbor; the assigned weight is defined according the kernel function $K(.)$.

Any arbitrary function that holds the properties below can be considered as the kernel function [18].

1) For all d , $K(d) \geq 0$.
2) If $d = 0$ then $K(d)$ gets the maximum value.
3) If $d \to \pm\infty$ then $K(d)$ gets the minimum value.

In this paper, the kernel function is defined as (6). Thus, the closer neighbors to $\mathbf{x}_{\text{test}}$ have higher weights on estimating the class label of $\mathbf{x}_{\text{test}}$.

$$K(d) = \frac{\max(\mathbf{d}) - (d_j - \min(\mathbf{d}))}{\max(\mathbf{d})} \quad (6)$$

V. Benchmark Datasets

In this section, we test the ELiEC model to classify several data sets that have obtained from the University of California, Irvine (UCI) machine learning repository [20]. It should be noted that, each data instance has been normalized and the values of the attributes are scaled to the range [0,1]. For each benchmark, the cross validation set has the same size as the training data set. We test the classification model 100 times; however, we present the best results. To present an efficient comparison, we test the ELiEC model for both multiclass and binary class benchmark data sets. We also consider both balanced and imbalanced classification benchmark data sets. The performance of classification models are calculated using the average per class classification accuracy as (7) which is represented as η_a . The parameter n determines the number of classes and η_j indicates the classification accuracy of j class. The test error determines the number of misclassification samples of the test set; the samples of the test data set is determined by N_{test}

$$\eta_a = \frac{1}{N_{\text{test}}} \sum_{j=1}^{n} \eta_j \quad (7)$$

A. Multiclass and Well Balanced Benchmark Data Sets

Iris data set and wine determination are two well-known classification benchmarks that have been categorized under the well balanced and multiclass data sets. Iris data set waobtained from the University of California, Irvine (UCI) machine learning repository [20] and has been examined by several classification methods e.g., NFI, PBL-McRBFN, etc [1],[5],[21],[22]. This data set consists of 150 samples; each sample has 4 attributes named as: sepal length, sepal width, petal length and petal width. Iris data set is a set with multiclassand consists of three classes: iris setosa, iris versicolor and iris virginica [20].

As the first case study, 50 percent of iris data sets are randomly chosen as the training data set; while the rest of the samples are considered as the test data set. Table I compares the number of misclassifications using ELiEC, NFI and MLP. The results indicate that using ELIEC the average number of test errors is equal to 2.2, that is less than the two other methods.

Table I. Comparison of performance classification of BELBEC and other methods for Iris data set with 50% as the training data set and 50% test data set.

Classificati on Model	Specification of results		
	Structure	Test error	The number of training data
BELBEC	15 neighbor	2.2	75
NFI[6]	6.3 neighbor	3.3	75
MLP[6]	12 neuron	4.6	75

Table II. The classification accuracy of BELBEC for the Iris data set with 45 samples as training data and 105 samples test data.

Classificati on Model	Specification of results		
	Structure	The average per class accuracy	The number of training data
BELBEC without normalized	16 neighbor	99.02 %	45
McNN[1]	5 neuron	97.14 %	22
PBL-McRBFN[5]	6 neuron	98.10 %	20
BELBEC	18 neighbor	%96.24	60
McNN[1]	9 neuron	98.49 %	27
PBL-McRBFN[5]	11 neuron	98.69 %	29
ensemple of (OC-SVM) [22]	----	92.00%	----

As the second case, the ELiEC classifies iris set using 45 samples as the training data set..

The wine data set is the second data set that is used to evaluate ELiEC. This data set that is a multiclass and a well-balanced data set; it is obtained from the chemical analysis of some wines that are produced from various cultivars in the same region of Italy. The sample of the data set consists of 13 features and can be categorized into three classes. Table II compares the results of ELIEC and three methods: McNN, PBL-McRBFN and another method types of ensemple classifiers; this model was named OC-SVM that is referred to as one-class support vector machines[22]. In this experiment, we use 60 samples as the training data samples and 118 samples as the test data. It is observable that ELiEC has good results in classification of this well-balanced data set

As was mentioned, the ELiEC is based on W-kNN; thus, we compare the results of ELiEC and W-kNN for classifying the wine data set (see Table II). We also compare the ELiEC and W-kNN to classify wine data with two different structures. As Table III shows, the classification accuracy of ELiEC has no noticeable difference when the total number of neighbors of ELiEC's classifiers is only eight neighbors. However, when we define a lower number of neighbors for Wk-NN, its accuracy has a significant decrease.

Table III. Comparison between WKNN and BELBEC for the wine data set.

Classificati on Model	Specification of results		
	Structure	The average per class accuracy	The number of training data
BeLBeC	18 neighbor	%96.24	60
BeLBeC	8neighbor	%95.27	60
KNN	3 neighbor	%95.40	60
KNN	18neighbor	%91.60	60

B. Binary and Low Dimensional DatabaseLiver Disorders (LD) and PIMA Indian Diabetes are two medical data sets that have been tested by different classification methods. Liver Disorders (LD) is related to a blood test and has 345samples and 6 attributes, respectively. Pima Indians diabetes set is another medical data set and has been provided by the National Institute of Diabetes and Digestive and Kidney Diseases. It is used to diagnostic diabetes. The number of samples and number of attributes are 768 and 8 respectively. Table IV lists the results of ELIEC for the data sets and compares the results with three methods: McNN, PBL-McRBFN and a modification of adapting splitting and selection (AdaSS) [23]. It shows that the results of McNN, PBL-McRBFN and a modification of adapting splitting and selection (AdaSS)are better than the results of ELiEC; however, the ELiEC has a simpler structure than the two other methods.

Table IV. Comparison between different methods to classify the LD and PIMA. The number of training samples is equal to [5]

Classificati on Model	Specification of results		
	Structure	The average per class accuracy	DATA
BELBEC	48neuron	68.4	LD
McNN[1]	68 neurons	71.60	LD
PBL-McRBFN[5]	87 neurons	72.63	LD
BELBEC	100neuron	70.37	PIMA
McNN[1]	193 neurons	77.31	PIMA
PBL-McRBFN[5]	162 neurons	76.67	PIMA
MAD [23]	7 clusters and 5 classifiers	72.010	PIMA

V. CONCLUSION

This paper presents a new ensemble-based classifier that is inspired by the brain emotional network. The architecture is referred to as ELiEC and utilizes W-kNN as the basic classification method. However, the ELIEC differs from other ensemble methods in the way that the classifiers are fed (see Figure 2).

The performance of ELiEC is evaluated by classifying several benchmark data sets. The results indicate a fairly good performance of ELiEC for classification.

As future works, we replace W-kNN with other learning classification methods e.g., the support vector machine to address the time complexity and the curse of dimensionality issues. In addition, a random forest method can be used to form a meta-ensemble classifier.

***Abstract*—In this paper evaluation of a policy-based algorithm for video inputs switching is presented. The term 'data quality' is not trivial for Human-Machine Interaction systems, yet a simple and efficient algorithm is needed for choosing the most valuable video source. This becomes particularly important for systems that support functional decomposition of image processing algorithm, which are designed for non-optimal working environment. In this paper an autonomous input management system is proposed, which consists of a data quality evaluation algorithm and a simple decision algorithm.**

Keywords – Human-Machine Interaction (HMI), Machine Vision, Decision Systems, Distributed Systems, Autonomic Systems

I. Introduction

COMPUTER vision has become a popular information source for computer and robotic systems interacting with humans, however the tests were conducted mostly in laboratory conditions. Real-life applications may cause some challenges as various environmental conditions are taken into account, although some biological mechanisms enable to handle both data aquisition and information processing, which exceed the capabilities of a very complex acquisition subsystems, such as – being able to see in the dark or being able to read and understand a text with the majority of illegible letters. Computer systems are supposed not only to entertain but also to support and protect humans, therefore they should contain more efficient, than the human one, information processing system. Possible future implementaion of these acquisition systems with the application of speech and/or vision include inter alia fire rescue teams supporting systems.

II. Policy-Based Input Switching

It is possible to implement all available acquisition systems and to process all the input information (thermal video, night vision), but in real-life applications it is not efficient because the data streams may be too massive and require high computing power for real-time processing in order to enable embedded system-based implementation. Transmission of multiple video streams to a remote workstation/server is also complicated due to the limited bandwidth, however it is possible to choose one input at a time and transmit it (or process it locally) [1], if the system was able to judge the value of the data input quality of its acquisition subsystems. The quality evaluation could be performed on the basis of static threshold values (e.g. any measure of image noise or edges quality), but in that case it would be just a simple condition. The Policy-Based Input Switching (PIS) becomes especially useful when adjusting/changing the policy for choosing an input depending on circumstances or environment. The proposed PIS conception is not a set of rules and threshold values, but an entire framework offering wrapper functionality (similarly to [2]) for additional modularity and as a foundation for autonomous policy reloading/changing. A semi-autonomous mobile robot designed for a fire team support could enable to change its policy for operating in a particular environment and to change its policy autonomously depending on any transient environment parameters.

III. Subjective Quality Evaluation Procedure

The Subjective Quality Evaluation Procedure (SQEP) is implemented in the core of the PIS framework and is able to decide locally on the active input (as a part of policy algorithm) and on the active policy (as a part of wrapper's autonomous module). Whilst the SQEP is intended to be run locally. It should involve only simple and efficient operations for data input evaluation. In a pilot study basic policy was implemented for choosing the best visual data input out of three available inputs: (1) video stream, (2) night vision, (3) thermography. The exemplary SQEP was implemented to choose between (1) and (2) basing on brightness and noise and then between (1|2) and (3) basing on the width of histogram of (1|2). Fig. 1 shows the value of a quality coefficient calculated for two different acquisition subsystems, acquiring visual information of the same scene and objects and in the same temporal context. Acquisition starts in darkness, and c.a. 128th frame a dim light source is turned on. The light is bright enough to turn off the infrared lighting, but not bright enough for the computer vision camera to acquire data of good quality. It is highly beneficial to have a SQEP procedure implemented in the PIS system, where the algorithm of a policy (and its rules or conditions, parameters and decisions) is intended to be easily replaceable and changable at runtime, without any

978-83-60810-53-8/$25.00

modifications to the inputs and outputs of PIS policy wrapper. The wrapper's functionality is extended to support autonomous policy exchange.

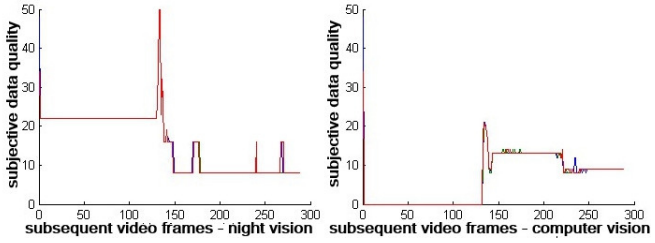

Fig. 1. Compartment of two acquisition subsystems, showing data quality during a change of lighting in the scene.

IV. SQEP for Autonomous Input Management

The main goal of using the proposed framework is to extend the functionality, versatility and robustness of the acquisition subsystems of vision-based mobile robots. It can only be achieved if the outputs of the Acquisition Subsystems and the outputs of PIS system will be developed to become modular and replaceable, so the Subjective Quality Evaluation Procedure (SQEP) should handle the evaluation of all inputs available in the hardware and all possible combinations (subsets) of these inputs and to produce the same set of predefined output variables and data structures. The SQEP should offer not only the possibility of on-demand input switching, but most of all it should perform the input selection procedures autonomously, if there is a better data quality input than the currently processed one. The decision about which input to process should be done locally to prevent transmitting of all data inputs to remote servers and the inputs should be evaluated in a simplest possible way to save the CPU cycles of local/mobile/embedded system. The most important feature of SQEP is the capability of autonomous data quality evaluation. Only one input is being transmitted and the most valuable data input is connected to the Cognitive/Decision System at a time. The coefficients and rules (the algorithm) of input quality evaluation can be changed at runtime by PIS system.

V. PIS for Autonomous Policy Management

The SQEP has proven to be useful, as it is beneficial in order to stay connected to a good data quality input, even in a changing environment. The basic PIS functionality is the possibility to change selection criterions – the policy, such as different environments as a very attractive feature. The most useful feature of PIS system, however, is the possibility to change the selection criteria in runtime (without rewriting the code, compiling, uploading, running). Thus there is no need to interrupt learning/execution or to reset the system's memory/knowledge/execution. The PIS system, in its most sophisticated version is expected to enable changing its policy 'intentionally'. In some cases it has very little effect on a mobile system, but sometimes it may be crucial feature for the accomplishment of the horizontal goal of the system.

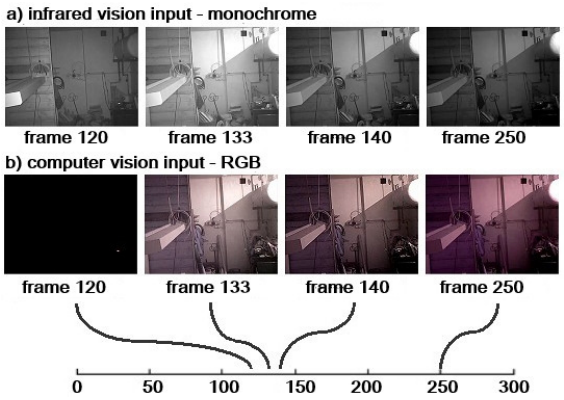

Fig. 2. The exemplary visual data input: darkness (frame 1..127) and with a dim light turned on (frame 128..288). Frames 128..140 are too bright due to the automatic white balance feature.

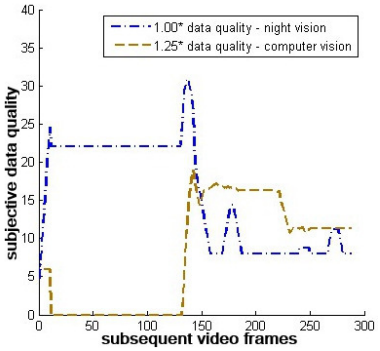

Fig. 3. An exemplary simple data quality coefficient for SQEP system for a policy-based input switching system, during a change of lighting in the scene.

VI. Advantages for HMI Systems, Future Work

Future work will implement inter alia virtual agents [3] and bio-signals. Use of virtual agents would make the system more intuitive. Initial tests were run with the application of the face mimic and the Emotiv EPOC headset. Future work will also involve development of a standalone application (AE) connecting Emotiv EPOC headset with any embedded platform. The work will be advanced by implementing various bio-signals [4]. The proposed control architecture should also be improved in order to reduce appearance of potential control errors, which is a common issue in autonomic systems.

Knowledge-based Named Entity Recognition in Polish

Aleksander Pohl
Jagiellonian University
ul. Łojasiewicza 4, 30-348 Kraków, Poland
Email: aleksander.pohl@uj.edu.pl

***Abstract*—This document describes an algorithm aimed at recognizing Named Entities in Polish text, which is powered by two knowledge sources: the Polish Wikipedia and the Cyc ontology. Besides providing the rough types for the recognized entities, the algorithm links them to the Wikipedia pages and assigns precise semantic types taken from Cyc. The algorithm is verified against manually identified Named Entities in the one-million sub-corpus of the National Corpus of Polish.**

I. Introduction

IN THE recent years the research conducted in the field of Information Extraction (IE) has brought many interesting results. First of all at the end of the twentieth century researchers have overcome the first major obstacle preventing wide-spread adoption of IE systems. Namely, by incorporating weakly supervised methods they were able to quickly adopt systems to new domains, by providing only a handful of training examples. Works of Brin [1] as well as Agichtein and Gravano [2] showed that large-scale information extraction is feasible, provided that we have access to large corpora, WWW in particular.

The ideas from the previous century were developed in two, slightly contradictory directions. First of all the term Open Information Extraction was introduced in works of Banko et al. [3]. This approach towards IE was pushed further in systems such as ReVerb [4] which does very well in the task of relation extraction. The goal of Open IE, much influenced by Information Retrieval is extraction of *all* information found in web-documents. Since it is very hard to build an ontology covering all the phenomena that might be described on the Web, these methods make very minimalistic assumptions about the world. As a result the extracted information is not transformed into some coherent semantic framework, but rather it is assumed that the user will find the relevant information by refining his/her query, the same as in traditional search engines.

The opposite approach towards IE comes from the researchers from the SemanticWeb camp. The primary difference comes from the fact that they are trying to utilize various knowledge-sources, especially taxonomies and ontologies, in order to extract the information available in the textual data and transform them into well established and broadly accepted schemas. In that form the information might be further automatically processed and consumed by intelligent systems. As a result, there are several important problems that have to be resolved, which are absent in Open IE systems. First of all, the concepts that are extracted must be identified within some ontology. The ambiguities also have to be resolved, especially among the relations. That approach is characteristic for the systems such as DBpedia Spotlight [5] and AIDA [6], both utilizing Wikipedia as the reference resource for concept identification. Recently Exner and Nugues [7] showed how relation extraction might be performed combining well known Natural Language Processing (NLP) techniques and DBpedia both as a reference conceptual scheme as well as source of examples used for training relation classifiers.

However if we look at the development of IE methods that are employed for Polish, we will discover that the state of research resembles the state of research in English in mid-nineties. To the best of our knowledge there are only two systems [8], [9] that perform template filling. Both of them employ manually constructed extraction grammars and operate in closed domains – the first one extracts information from mammogram reports and the second from patients' diabetic records. Regarding relation extraction there is only limited research in the field. [10] describes methods for automatic extraction of semantic relations aimed at development of the Polish Wordnet. The described method uses massive amounts of data in order to determine the best location for a new synset in a large semantic network. On the other hand [11] describes an ontology-based method for the extraction of relations form a bibliographical lexicon based on manually defined grammars. The only IE task that is well developed is Named Entity recognition[1], but the methods still rely on manual construction of grammars or tagging of large amounts of data.

As we know from the development of systems aimed at English these bottlenecks might be overcome if appropriate methods are employed. This work is a step in this direction. It presents an algorithm that does not require any manual construction of extraction grammars, nor tagging of large amounts of data. By utilizing Wikipedia link structure and classification of Wikipedia articles into the Cyc ontology [12] the system is able to precisely classify and link the entities to Wikipedia articles. Since there are knowledge-bases such as DBpedia [13] that are based-upon Wikipedia and Cyc is the largest known manually constructed ontology, this opens interesting possibilities for automatic processing of the extracted data by intelligent systems.

[1]The next section contains a detailed description of the available systems.

Locations	82.0	72.0
Organizations	92.0	52.0

II. RELATED WORK

Named entity recognition (NER) is a vast topic. There are many approaches towards it and systems that actually perform NER. To constrain the review of such systems we present only the work on NER in Polish.

The research on NER in Polish starts with the works of Piskorski [14], [15], [16]. These works describe the adaptation of the SProUT platform [17] for Polish and its application in the recognition of entities such as: time, percentage, money, organizations, locations and people.

Applying SProUT to NER requires manual definition of the rules, which in general consist of a pattern/action pairs built upon typed feature structures (TFS). The LHS of a rule matches segments with particular features and the RHS defines the TFS that is produced as the result of that match. Besides basic matching of words and features, the rules allow to use variables and call other rules. As a result the formalism is both expressive and transparent.

The adoption of SProUT for Polish required integration of a morphological analyzer for Polish – Morfeusz [18]. Also gazeteers were used and the morphological variants were produced automatically. The author elaborates on problems that are specific to Slavonic languages, Polish in particular, especially the rich morphology of names as well as problems with name segmentation. This causes serious problems for NER since there are cases where it is impossible to determine the base form of a NE without appealing to data such as verb frame subcategorization, which is usually out of scope of NER. The constructed rules were evaluated on a set of 100 news articles. The values are presented in Table I.

A more elaborate evaluation of this approach is presented in [20], where it is applied in the domain of cadastral information. The described system used a more elaborated entity classification taxonomy consisting of nearly 30 classes. It it also evaluated on a much bigger corpora counting more than 4 thousand entities. The evaluation methodology was more elaborate were exact and partial matches were counted separately. The results of the evaluation are presented in Table II.

A more lightweight approach is presented in works of Graliński et al. [21], [22] and Walas et al. [23]. The authors find SProUT formalism too complex for the tasks of NE translation and anonymization. [21] identifies errors in NE translation as one of the important problems that make the translation hard to understand. What is more 10% of errors in machine translation (MT) are due to invalid processing of named entities. [22] uses NER in task of anonymization of police reports that are used to improve MT. Since the researchers are not allowed to see the names of the suspects, they provide a set of Word macros that are used to remove sensitive data (such as names of people and companies) from the documents. [23] describes NER in the context of a question answering (QA) system.

Each of these systems uses a formalism based on Spejd [24]. The rules are less complex than in SProUT so the results are less precise. For instance in [21], depending on the evaluation scheme the precision varies between 76 to 88%. On the other hand [21] and [23] report that special handling of NEs improves both MT and QA.

Only recently the researchers of Polish NER systems started to use machine learning approach. Marcińczuk at al. [25] describes application of Hidden Markov Models (HMM) for this task, which was restricted to the recognition of names of people and organizations. The authors used HMM with 7 hidden states for each NE type. The transitions between states were modeled by the maximum likelihood over the training data, while tag emissions were generated by n-gram character language models with generalized form of Witten-Bell smoothing [26]. The authors used LingPipe [27] to compute the parameters of the HMM.

The system was trained on a corpus containing stock exchange reports with 670 person mentions and more than 3 thousand company mentions. It was evaluated on the same corpus (using 10-fold cross validation) and on a corpus containing police reports. The vanilla HMM reached 86% for people names and 80% for companies names (F_1 metric) on the stock exchange corpus. In order to improve the precision of the system the authors applied two heuristics: filtering and trimming. The first one imposed some restrictions on the form of the names, the second one stripped preceding and following words if they did not start with an upper case. The first heuristic improved the precision of the method from 63% to 89% with only small reduction of recall. The authors also report the evaluation of the system on the police report corpus. The results were significantly worse (55% F_1 metric), showing that this approach towards NER is highly domain-dependent.

The latest achievement in Polish NER is described in [28]. The authors used Conditional Random Fields (CRF) model [29] to overcome the limitations of HMM model, e.g. ignorance of the right context of the name. They were detecting 5 types of entities: first names, surnames, country names, city names and road names. The developed model incorporated not only statistical data, but also knowlege, e.g. the list of names of peoples positions and titles taken from the Polish WordNet [10]. In general there were 5 types of features that were used to build the model: ortographic, binary-ortographic, WordNet-based, morphological and gazetteer-based.

The model was trained on one corpus (used in the previous works of Marcińczuk et al. [25]) and tested on that corpus following 10-fold cross-validation scheme and on two others corpora (police reports corpus and corpus of economic news). The results on the first corpus substantially outperformed the HMM model, reaching F_1 score of 92.5%. On the other hand the evaluation performed on the two other corpora showed that the drop in performance is significant – the model achieved 67.7% F_1 score on the police reports corpus and 72.3% F_1 on the economic news corpus, meaning that the model fits well to the training data, but causes problems when ported to different (even highly related, like in the case of stock exchange reports and economic news) domains.

The primary difference of the presented algorithm with the already described methods comes from the fact that this algorithm does not require any manual construction of NE recognition rules, nor tagging of the training data. As such it does not require any manual intervention, besides the *selection* of the name types that should be identified. The other difference comes from the fact that this algorithm is tested on the 1-million sub-corpus of the National Corpus of Polish [30], to the best of our knowledge the first such demonstration. This is particularly important, because the corpus contains a variety of language styles and text sources, contains a large number of NEs and allows for a comparison of different algorithms in a unified setting.

III. Entity recognition

The algorithm employed to recognize NEs is an adaptation of the Word Sense Disambiguation (WSD) algorithm described in [31]. That algorithm builds on the Wikipedia Miner disambiguation algorithm described in [32]. The original algorithm of Milne and Witten works as follows. First of all it recognizes occurrences of phrases used in Wikipedia to link to other Wikipedia articles. Since many of these phrases are ambiguous, e.g. *Washington* may refer to a state, a city, a person, a football club, a university and almost four hundred other concepts, the algorithm tries to disambiguate its meaning by employing machine-learning techniques. First of all it computes several features of each candidate target concept:

1) an average weighted *semantic relatedness* with other (unambiguous) concepts
2) a *probability* of the candidate concept
3) a *context goodness*, i.e. a measure showing if the context of the phrase is well defined

The *semantic relatedness* between two concepts[2] in the original algorithm is computed using the Normalized Google Distance (NGD) [33]:

$$sr_G(a,b) = 1 - \frac{log(max(|A|,|B|)) - log(|A \cap B|)}{log(|W|) - log(min(|A|,|B|))} \quad (1)$$

Where:

- $sr_G(a,b)$ – the measure of semantic relatedness between a and b,
- $|A|$ – the size of the set of articles that link to a,
- $|A \cap B|$ – the size of the set of articles that link both to a and b,
- $|W|$ – the number of all articles in Wikipedia.

The weights of the concepts are established according to their semantic relatedness with other concepts and the link probability of phrases they are identified by (e.g. the ratio of the number of phrase occurrences as link to the total number of phrase occurrences).

The *probability* of the candidate concept is computed as the ratio of the number of links with that phrase pointing to that concept to the total number of links containing that phrase.

When the features are computed, the algorithm tries to select the most probable meaning by employing a machine learning algorithm – C4.5 in this case [34]. The algorithm of Milne and Witten uses also Wikipedia link structure to train the classifier. Wikipedia links are used as positive examples for *phrase–concept* pairs. The negative examples are constructed from all the remaining concepts that could be linked via this phrase (i.e. there are links with the same anchor name that point to the other concepts). Since the internal link structure of Wikipedia is very dense, it is easy to generate millions of the training examples.

The primary improvement described in [31] is the usage of a Jaccard coefficient-inspired measure instead of the NGD:

$$sr_J(a,b) = \begin{cases} \frac{1}{1 - log\left(\frac{|A \cap B|}{|A \cup B|}\right)} & |A \cap B| > 0 \\ 0 & a \neq b \wedge |A \cap B| = 0 \\ 1 & a = b \wedge |A \cap B| = 0 \end{cases} \quad (2)$$

Where:

- $|A \cup B|$ – the size of the set of articles that link to a or b

The second improvement is the employment of several additional features that are already used in the original algorithm (but not in the classifier) or are trivial to compute:

- the *rank of the semantic relatedness* of the candidate concept among all the candidate concepts,
- the *rank of the probability* of the candidate concept among all the candidate concepts,
- the *link probability* of the concept.

By employing the different semantic relatedness measure and the additional features the automatically computed performance of the algorithm measured as the weighted precision and recall (F_1) jumped from 84 to 92.4% in the English dataset and from 83 to 91.7% in the Polish dataset. What is more by using the latest Polish Wikipedia dataset[3], it was measured that the performance of the algorithm was further increased to 93.5%.

Direct application of the WSD algorithm results in the identification of phrases that might be (unambiguously) linked to the Wikipedia articles. But its application in Named Entity Recognition requires several adjustments that are covered in the next section.

[2]Although this is not fully accurate, we identify the Wikipedia articles with concepts.

[3]Dump from the 2^{nd} of May 2013.

IV. ENTITY CLASSIFICATION

The regular definition of the Named Entity Recognition task [35] requires that the entities are recognized and *classified* into some well-defined conceptual scheme. Although in the time of MUC conferences [36] it was required that the classification scheme makes fine-grained distinctions allowing for e.g. distinguishing between civil and military objects[4], in recent years, e.g. in the tasks defined in the scope of ACE initiative [37], the conceptual scheme was substantially simplified. ACE 2008 defines 5 general types divided into 31 subtypes. The general types are as follows:

- facility
- geo-political entity
- location
- organization
- person

Similarly in the National Corpus of Polish [30] the following NEs are identified:

- personal names
- geographical names
- names of organizations and institutions
- words related to the above categories
- basic temporal expressions

This simplification of the conceptual scheme stems from the fact that these resources are domain-independent and as such, should make as few ontological assumptions as possible. Especially because in such domain-independent environment it is hard even for people to assign fine-grained classes, let alone force research teams to adopt one „golden" ontology.

But when it comes to the application of the results of IE in some specific domain, such sketchy schemas have limited value. If we wish to conduct intelligence analysis we are not interested in people in general, but those who have important roles in their societies. If we are considering financial investments, we are not interested in organizations „in general", but only those which operate on a specific market, e.g. mining companies. As a result, the more we are concerned with the application of the IE results, the more fine-grained conceptual scheme is needed.

In order to make the results of NEs recognition useful in practical settings, the Cyc ontology [38] is used as the taxonomy of the entities. Although there are alternatives such as YAGO [39] and DBpedia ontology [40], which are directly mapped to Wikipedia, both of them have certain deficiencies making them less useful for automatic processing of the extracted knowledge. Although YAGO's taxonomy is very dense, since its classes were extracted from Wikipedia's category scheme, it lacks features such as well defined disjointness relation. Although its authors have used heuristics to detect inconsistencies, they were error-prone. As a result there are contradictory facts in YAGO, e.g. *Gertrude Stein* is classified both as a *person* and as a *literary work*.

[4]It was assumed that a terrorism activity is targeted only at civil objects, such as churches, shopping centers and railway stations.

TABLE III
THE COVERAGE OF METHODS USED TO CLASSIFY THE ARTICLES IN THE POLISH WIKIPEDIA.

Method	Count (thousand)	Percentage
English Wikipedia [12]	283.9	25.8
Infobox mapping	534.9	48.6
People heuristic	213.1	19.4
Total	**688.6**	**62.6**

On the other hand the DBpedia ontology[5] is rather small (contains less than 400 classes) and lacks coverage. Since the entities are assigned to the classes according to the infoboxes attached to the articles and less than 2 million of articles (out of 4 million) have such infoboxes attached, many of the entities lack their type.

Cyc [38] on the other hand is a long running effort of building an ontology that would allow intelligent systems to perform common-sense inferences. As a result it contains thousands of well defined semantic classes. These classes are not only organized into subsumption relation, but they are also inter-related with disjointness relation. This feature of Cyc makes it particularly useful for ensuring high accuracy of the extracted informations, since inconsistencies in type assignment might be resolved automatically.

Although Wikipedia is not aligned with Cyc in its entirety, in our recent effort [12] we created a classification of more than 2.2 million of the English Wikipedia entities into the Cyc ontology with precision reaching 93%. That mapping was made available in the N-triple format, with links to the English DBpedia[6] and OpenCyc[7]. In order to use that mapping in the Polish Wikipedia the following procedure was employed:

1) The interlingual links from the latest DBpedia[8] were downloaded.
2) The interlingual links were used to establish a mapping between the English and the Polish DBpedia entities.
3) The Cyc types were assigned to the corresponding Polish DBpedia entities.

There were 626 thousand of links in the English DBpedia that were employed in the second step. But since the type assignment covered only 2.2 million of articles (out of 4 million) the number of classified articles in the Polish Wikipedia was 284 thousand. To extend the coverage of the method infoboxes from the Polish Wikipedia were mapped to terms in Cyc and a simple heuristic for people marking all articles with *Urodzeni w* (Eng. *Born in*) and *Zmarli w* (Eng. *Died in*) categories as instances of `Person` class was applied. The first heuristic yielded 535 thousand of classifications and the second 213 thousand. Since the methods were overlapping, the final result was a classification of 689 thousand of Polish Wikipedia articles (out of 1.1 million). The results are summarized in Table III.

[5]`http://dbpedia.org/Ontology`
[6]`http://klon.wzks.uj.edu.pl/wiki-types/`
[7]`http://www.cyc.com/platform/opencyc`
[8]`http://wiki.dbpedia.org/Downloads38`

The second adjustment which was applied to the Wikipedia-based disambiguation algorithm concerned filtering of the entities that were provided as the NER result. Since contents of Wikipedia is encyclopedic, it covers descriptions both of classes and individuals. The WSD algorithm does not make distinction between these types of entities. However, the result of NER should be a discovery of *names*, i.e. proper names (usually) of individual things. We are not expecting from the NER system to annotate occurrences of words such as *woman*, *child* or *man*, because they are instances of common nouns. Yet, the algorithm is able to properly disambiguate these words and its original version produces such results. So the filtering was concerned with rejecting the instances of common nouns and similar expressions from the final result.

In general, making the distinction between classes and individuals is not a trivial task. Since it was not the primary concern of this research, a simple, yet powerful heuristic was employed: for each Wikipedia article the total number of links starting with an uppercase letter and a lowercase letter was counted. If the number of links starting with an uppercase letter was greater or equal to the number of links starting with a lowercase latter, the article was considered as describing an individual. A small test performed on a random sample of 200 entities showed that this heuristic is able to produce distinctions with precision above 90%. This result is very good compared to the results of a similar task of distinguishing between types and instances in the Wikipedia category system [41], where several heuristics were employed, yielding similar precision.

V. Evaluation

The evaluation of the algorithm was performed on the one-million sub-corpus (ONEM) of the National Corpus of Polish [42] with manually annotated named entities [30], [43]. ONEM contains excerpts from many sources: literature, newspapers, the Internet, speech transcripts and other. It contains 3888 excerpts which amount to more than 50 thousand of NEs.

The annotation covered identification of names referring to people, locations, organizations and temporal expressions. Some of these types were subdivided into subtypes. Table IV summarizes the taxonomy of the entities. It should be noted that not only the nominal expressions were annotated, but also all other types of expressions that refer to NEs, adjectives in particular. So in the following expressions *restauracja w **Warszawie*** (Eng. *restaurant in Warsaw*) and ***warszawska** restauracja* (Eng. *Warsaw restaurant*), the boldfaced fragments were annotated as referring to *Warsaw*. These occurrences of NEs are called *relational expressions*.

Although, in general proper names do not follow the principle of compositionality, since their contents might be arbitrary, it was decided that the annotation covers also subordinate names, which are parts of larger units. E.g. in the expression *Dom dziecka w Oruni* (Eng. *Orphanage in Orunia*), the whole expression is annotated as a name of an organization, while *Oruni* is annotated as a name of a location. From the point of view of the evaluation of NER this gives some added value, since algorithms might be rewarded for accurate partial matches within longer expressions.

TABLE IV
The types of entities annotated in ONEM [30].

Type	Subtypes	Description
persName	forename surname addName	given name family name nickname
orgName		an organization
geogName		a geographical entity (excludes geopolitical entities)
placeName	district settlement region country bloc	a district within a city a city or a village a country region a country a bloc of countries
date		at least partially determined date
time		at least partially determined time

TABLE V
The counts of entities annotated in ONEM. Time and date expressions are skipped.

Entity type	Test corpus	Tuning corpus
persName	19619	336
orgName	10914	217
geogName	4001	69
placeName	15432	311
total	**49966**	**933**

Regarding the scope of the evaluation – it did not cover date and time expressions, since the WSD algorithm is not aimed at theses types of expressions. What is more, it is apparent that these expressions are domain independent and can be captured by a well developed grammar or some other NER technique. On the other hand the evaluation included the relational expressions, which are quite hard to spot using traditional NER methods.

During the developement of the algorithm, the ONEM corpus was split into two parts – one containing 100 randomly selected text excerpts, used for the tuning of the algorithm and the other containing 3788 text excerpts. The counts of entities in both of the corpora are given in Table V. The results reported in the next section are based only on the second part of the corpus.

The tuning corpus was used solely for the recognition of the Cyc types that were present in the corpus and for their mapping to the corresponding name types in ONEM. The mapping is summarized in Table VI. The mapping covers only the most general Cyc types. If a more specific Cyc type was assigned to the entity, the appropriate type was selected using the generalization relation (in Cyc called `genls`). Since some of the specific types generalize to more than one of the general types (e.g. a *Country* generalizes both to a *GeopoliticalEntity* and an *Organization*) the first matching type was selected (according to the priority presented in Table VI).

TABLE VI
THE MAPPING BETWEEN ONEM TYPES AND CYC TYPES.

Priority	ONEM type	Cyc type
1	persName	Person HumanGivenName HumanSurname Saint God FictionalCharacter PersonTypeByEthnicity PersonTypeByOccupation
2	placeName	GeopoliticalEntity PopulatedPlace
3	geogName	GeographicalPlace Territory AstronomicalBody Place
4	orgName	Organization

We should noted however that the precise Cyc type was not discarded in that procedure. The mapping was provided in order to compare the results of the algorithm with the coarse-grained annotation from the ONEM corpus. In the applications of the NER algorithm the Cyc types are easily accessible since they are attached to the Wikipedia articles, indentified by the disambiguation algorithm.

VI. RESULTS

The results of the evaluation are given in Table VII. The system was evaluated only against the whole NE units. So if the system recognized a geographical name inside a name of an organization, the result was counted as invalid, even though there was an annotation that captured the geographical name as a subordinate of the organization name. It is because we believed that the non-compositionality of NEs is their primary characteristic and usually only the whole lexical unit should be recognized and annotated. The internal lexical structure of a given NE has only anecdotal value for information extraction. What is more, if more date (such as the location of a given place or an architectural structure) regarding the entity is needed, it can be found in the DBpedia knowledge base.

The table contains the results for exact matches as well as partial matches. An *exact match* is counted as a match which is exactly the same as in the annotation, so any characters such as quotation marks have to be present in the system provided annotation, even though they do not carry much information. A *partial match* is counted for a system-provided annotation which is completely covered by the reference annotation. So this excludes matches that only partly overlap.

The direct comparison with the performance of the other NER systems shows that the primary deficiency of the algorithm is low recall. Although such comparisons should be made with care, since none of the systems described in section II was tested against ONEM corpus.

Overall recall of 41.8% for the exact matches and 48.6% for the partial matches is below expectations for a NER system. It should be noted however that the coverage of the classification of the entities was not complete (only 62.5%),

TABLE VII
THE RESULTS OF THE EVALUATION OF THE KNOWLEDGE-BASED NER ALGORITHM. P - PRECISION, R - RECALL, F_1 - $2 * P * R/(P + R)$

	Exact match			Partial match		
Entity type	**P** [%]	**R** [%]	$\mathbf{F_1}$ [%]	**P** [%]	**R** [%]	$\mathbf{F_1}$ [%]
persName	**95.2**	34.6	50.8	**93.7**	46.6	62.2
orgName	82.7	35.8	50.0	73.3	42.5	53.8
geogName	78.2	34.4	47.8	68.3	37.7	48.6
placeName	91.8	**57.0**	**70.3**	91.5	**58.3**	**71.2**
overall	**90.0**	**41.8**	**57.1**	**86.3**	**48.6**	**62.2**

so we could expect better results if all Wikipedia entities had a type assigned. What is more – the system tries not only to detect the type of the entity, but also to disambiguate it against the Wikipedia articles. As a result, only the entities that have a corresponding entry in Wikipedia might be recognized.

Regarding precision, the algorithm achieves similar results as the other described systems and in some cases (names of people and places) even outperforms the already known methods. Still the performance for organization and geographical names is below our expectations. A manual inspection of the results showed that the low precision might be at least partly a result of the organization – place name distinction used by the annotators.

It is reported [30] e.g. that a name of a country might be treated both as a name of a place and an organization, depending on the context. This causes serious problems for the algorithm, since each entity has only one type assigned. But this seems to cause problems not only for the algorithm, but also for the annotators. E.g. in the sentence ***Amerykańska*** *prasa twierdzi, że mimo oficjalnego poparcia kampanii* ***USA*** *przez rząd* ***Pakistanu***, ... (Eng. ***American*** *press says that despite the official support of the* ***US*** *campaign by the government of* ***Pakistan***, ...), *American* and *Pakistan* are marked as names of places, while *US* is marked as a name of an organization. Such annotation does not seem to be coherent. Suffice it to say that the creators of ACE NER tasks [37] introduced the geopolitical entity type to resolve this kind of problem.

VII. CONCLUSIONS

We presented a knowledge-based algorithm for named entity recognition in Polish texts. It was tested on the one-million manually annotated sub-corpus of the National Corpus of Polish. The results obtained by the algorithm show that this method, although achieving reasonably good precision, has low recall. Definitely a combination of the presented method with grammar-based method would give much better results, since the coverage of this algorithm is limited by the contents found in Wikipedia. What is more, the classification of Wikipedia entities is not complete and further worsens the recall.

On the other hand it should be stressed that the algorithm does not require any manual work, neither in the construction of multi-word grammars, nor in tagging of large amounts of textual data. What is more, the classification scheme based

on the Cyc ontology allows for a direct consumption of the results of the algorithm by intelligent systems. This feature of the algorithm together with the moderately good results show that further research in this direction should be pursued.

***Abstract*—In this article two approaches of Tabu Search in Multi–Skill Resource–Constrained Project Scheduling Problem (MS–RCPSP) have been proposed, based on different neighbourhood generation methods. The first approach assumes swapping resources assigned to pair of tasks, while the second one proposes assigning any resource that could perform given task. Both approaches need to respect the skill constraints. The objective of this paper is to research the usability and robustness of proposed approaches in solving MS–RCPSP. Experiments have been performed using artificially created dataset instances, based on real–world instances, got from Volvo IT and verified by experienced project manager. Presented results show that Tabu Search (TS) based methods are efficient approaches that could be developed in the further work.**

I. Introduction

RESOURCE-Constrained Project Scheduling Problem (RCPSP) is a classical problem (e.g. [3], [11]). Its objective is to assign scarce resources to given tasks to make the project schedule as short / cheap as possible. Because of its combinatorial nature, it is known as NP–hard [1]. It means that it is not possible to find optimal solution in finite, polynomial time. It also suggests using some soft computing methods, which do not always provide optimal solutions, but usually sub–optimal acceptable solutions in reasonable processing time. There are several metaheuristics [12] used for solving RCPSP and its extensions – Evolutionary Algorithms (EA) [4], [6], [7], [9], [15], [22], [26], Simulated Annealing (SA) [2], [5], [14], Ant Colony Optimization (ACO) [16] or Tabu Search (TS) [17], [18], [20], [21], [24]. The last of mentioned methods would be investigated in this paper. We decided to develop TS–based methods because of its relative simplicity in comparison to other metaheuristics. On the other hand, it could be comparably effective to other methods.

RCPSP could be extended by the skills domain to Multi–Skill Resource–Constrained Project Scheduling Problem (MS–RCPSP) [8], [19]. Each task requires given skill in specified familiarity level, while each resource disposes some skills pool. It causes that not every resource can perform every task and the schedule is more difficult to be built.

(MS–)RCPSP is very practical problem. Project managers in significant companies still often need to schedule their projects manually, what is extremely time consuming. Because of human fail-ability, manually scheduling could also cause obtaining infeasible schedule solutions, where not every constraints are satisfied. Providing computer–aided methods could save a lot of time and ensures that every designed constraints would be met. What is also important, automated AI–based methods mentioned earlier could give final solution in minutes, while experienced project manager needs a few hours to prepare a schedule for the same–sized project (with the same number of resources and tasks).

Proposed (MS–)RCPSP definition has been designed in strict cooperation with Volvo IT Department in Wroclaw. Provided requirements, assumptions and constraints have been considered, approved and then included in problem description, what enlarges the practical value of this paper.

The rest of the paper is organised as follows. Section II describes other approaches to solve the (MS–)RCPSP using metaheuristics, especially TS. Section III presents the MS–RCPSP problem statement, while Section IV describes the approaches proposed in this paper. Section V provides conducted experiments of proposed methods in a given dataset. Finally, section VI presents the conclusions of obtained results and suggests some ideas of future work.

II. Related work

To make a structured overview of related work, we divided it into groups of methods. EA–based [4], [6], [7], [9], [15], [22], [26] methods mostly use task–vector representation of an individual. The order in a vector describes the order of tasks' performance in a project. Schedule can be generated in a serial [7], [22], [25], [26] or parallel [12] generation scheme. Because of proposed individuals representation, mostly semi–blind crossover and mutation operators could be applied, like swap [22], [23], [26] or insert [7], [25] mutation and one–point [7], [9], [25], two–point [7], position–based [26] or uniform [15] crossover. Some papers presents more dedicated operators, like peak crossover in [22].

SA–based approaches [2], [5], [14] are also often investigated. In [2] classical precedence–feasible activity list representation with the serial generation scheme is used. The neighbourhood is created by insertion method of regarded task within its last predecessor and the first successor. Cooling scheme assumes annealing of multiple starting solutions. The other approach of generating a neighbourhood is presented in [5], where the new solution in neighbourhood is created randomly, preserving precedence– and resource constraints. In [5] some hybrid of TS and SA has been proposed, where the memory of moves has been added to traditional SA approach.

978-83-60810-53-8/$25.00

The last of mentioned approaches, presented in [14] assumes investigating set of SA–based methods with multiple start, where the initial solution is prepared in various ways, e. g. randomly or using scheduling priority rules.

In TS–based methods [17], [18], [20], [21], [24] several elements can be variously implemented. The neighbourhood can be created by swapping or inserting activities [20] in the task–order list. In [20] the tabu list size is dependent on the number of critical tasks to be scheduled in a project. What is more, several strategies of diversification have been proposed there, while not better solutions have been recently found and strategies of intensification, where a solution with very good quality has been found. In [21] a starting solution is obtained using the minimal slack heuristic rule (MINSLK). The same approach assumes regarding move as an exchange of two activities positions in the activity list and the *difference move* measure is introduced, computed as the difference between solutions which are regarded by given move. An aspiration criterion is also proposed in [21] – if the move is on a tabu list, but produced solution (S) is better than the best (B) found so far, S replaces B. The termination criterion is set as a number of iterations which could not find better solution. Similar starting solution, using priority rule heuristics, is proposed in [17], [18], where classical neighbourhood generation methods have been also proposed: swap and insertion. In an approach presented in [24] classical TS method has been extended by local search procedures, to find better solutions.

Other (MS–)RCPSP heuristic solutions have been included in [12], [13], where local search methods and other population based methods have been also presented, e. g. ACO–based approach, that was also investigated in [16].

III. Problem statement

In MS–RCPSP we assume that project consists of several main elements: tasks, precedence relations, resources and skills. **Tasks** are described by their start and finish dates, duration and skill required to be performed. Tasks are often related by **precedence relations** – some tasks cannot be started before their potential predecessors would not be finished. Analogously, task's successor cannot be started before it's finish date. **Resources** are described by their salary and **skills** pools they own. As it was mentioned earlier, not every resource can perform each task, when given resource does not own skill required by given task. Only one resource can be assigned to given task.

A. Conflicts, solution's feasibility

Furthermore given resource cannot be assigned to more than one task in an overlapping period of time – if such a situation occurs, we defined it as a **conflict** and it has to be resolved. Conflict solving is made by shifting one of conflicted tasks just after the other one in the timeline. Because conflict resolving could disturb the precedence relations constraints, they should be preserved after each conflict resolution. Without resolving conflicts and preserving critical path constraints, produced solutions would be infeasible and could not be regarded as final, correct schedules. Solutions where resource is assigned to task when it does not own required skill in specified level is also regarded as infeasible.

B. Evaluation function

The (MS–)RCPSP objective is to schedule the project as quick or / and cheap as possible. It could be presented as **multi–objective optimization problem**: project schedule's **duration minimization** and project's performance **cost minimization**. Those objectives are generally in opposition. Reducing a project duration could cause enlarging a project's cost and vice versa. That is why, the *happy medium* is often sought – how to reduce the value of first objective, to get larger but still acceptable value of the second objective. In project scheduling problem domain it is often called *time & cost trade–off problem*.

A single project schedule (PS) solution is represented as a resource–to–task assignments vector $A = [a_i^j] : i = 1, 2, ..., t$, $j = 1, 2, ..., r$, where a_i^j represents the assignment of j-resource to i-task, t-number of tasks and r - number of resources.

To evaluate a solution, we proposed weighted, evaluation function:

$$\min f(PS) = w_\tau f_\tau(PS) + (1 - w_\tau) f_c(PS) \tag{1}$$

where: w_τ - weight of duration component, $f_\tau(PS)$ - duration evaluation component, $f_c(PS)$ - cost evaluation component.

Components' weights are applied to tune up the importance of time and/or cost factor in the given project optimization. The duration–aided optimization means setting time weight close to value 1 that automatically reduce the cost weight near zero. Analogously weights in the cost–aided optimization are tuned.

The time component $f_\tau(PS)$ is calculated as follows:

$$f_\tau(PS) = \frac{d_{PS}}{\tau_{max}} \tag{2}$$

where: d_{PS} - duration of schedule PS, τ_{max} - maximal possible duration of schedule PS, computed as the sum of all tasks' duration. The cost component $f_c(PS)$ is defined as follows:

$$f_c(PS) = \frac{\sum_{i=1}^{t} c_i^j}{c_{max} - c_{min}} \tag{3}$$

where: c_i^j - standard cost of performing task i by resource j, c_{min} - minimal schedule cost – a total cost of all tasks assigned to the cheapest resource, c_{max} - maximal schedule cost – a total cost of all tasks assigned to the most expensive resource. c_{max} and c_{min} do not involve skill constraints. It means that c_{min} value could be reached only for non–feasible solution. Analogously to c_{max}.

C. Solution space size

Given number of tasks and number of resources, we can estimate the solution space size, as:

$$SS(t, r) = t! * r^t \tag{4}$$

However, that estimation takes also into account non–feasible solutions, because skill–constraints are not satisfied. To give an example, let's assume $t = 10$ and $r = 5$ – without any precedence relations we get $SS(10, 5) = 3.54 * 10^{13}$ combinations. It is worth mentioning, that each task can be placed only once in schedule, but resources could be assigned more often. An extreme situation occurs if the same one resource would be assigned to perform each task.

Large solution space size makes impossible checking each of the combinations manually. However, space includes also non–feasible solutions that do not satisfy defined conditions. Moreover, given example is a simplification and in real world problems we meet a higher number tasks (about $t = 100$) and resources ($r = 20$) – it gives $SS(100, 20) = 1,19 * 10^{288}$ of all solutions. As solution space is constrained, relatively large and the MS–RCPSP problem is NP–hard it proves the legitimacy of metaheuristics usage.

IV. Proposed approaches

The overall TS approach is to avoid entrainment in cycles by forbidding moves which take the solution, in the next iteration, to point in the solution space previously visited (hence tabu). TS proceeds according to the supposition that there is no point in accepting a new (poor) solution unless it is to avoid a path already investigated. This insures new regions of a problems solution space will be investigated in with the goal of avoiding local minima and ultimately finding the desired solution.

To perform, TS needs some parameters to be set. The neighbourhood size defines the size of neighbourhood, that is created based on currently best solution and from which the better solution is sought. Number of iterations stands how many times the neighbourhood would be generated and sought for better solution (stopping criterion). Tabu list size tells, how many recent swaps should be recorded in the list of forbidden ones. For simplicity in this paper, we decided not to introduce any aspiration criteria for TS in our investigations.

A. Initial solution generation

Initial solution is straightforwardly loaded from a file that contains the project data. The project schedule had been previously prepared using EA with classical crossover (one–point) and mutation (swap–based) operators that satisfies all constraints (precedence, skills and conflicts resolving). Therefore, it could be regarded as a feasible solution. The feasibility of initial solutions has been confirmed and approved by experienced project manager from Volvo IT.

B. Neighbourhood generation

To generate a neighbourhood, a new solution generation method has to be provided. We designed new solution as generated in two general steps: setting assignments to tasks and then build the schedule, respecting precedence constraints and resolve conflicts. We proposed and compared two methods of setting assignments to tasks. The first one bases on the swapping resources within the pair of tasks, while the second approach assumes assigning any resource that is capable of performing given task. Above mentioned rules provide the feasibility of generated solution.

Swap–based neighbourhood (SBN): In this approach potential solution is created in the following way. For given assignment another is sought that enables swapping resources between those assignments. Swapping is possible only if both resources are capable of being assigned to tasks related to chosen assignments – skill constraints are preserved. If no other assignment, which can be used for swapping with given one, is found, new assignment is selected and the procedure of searching *swapping mate* for it is repeated.

Random–based neighbourhood (RBN): A new potential solution, that can be visited by the TS procedure, is created by changing the assignment of given task in following way. List of resources that can perform given task (dispose skill required by task) is obtained and then any different resource than currently assigned is chosen.

Fig.1 presents schematically ways of generating new solutions that can be included into new neighbourhood. OK signs in this figure presents which resources can perform given tasks. In RBN, we consider only one task, for which new resource is sought. In SBN, we need to find two tasks and resources that are capable to swap assignments between them. The *QX.Y* notation describes skills owned by resources or required by particular task to be performed. In provided example task *T1* requires skill *Q2* at proficiency level *2* to be performed. Moreover, resource *R1* owns skill *Q1* at proficiency level equal *3* and skill *Q2* at proficiency level equal *2*. Thus R1 is able to perform *T1*. *R1* is also able to perform task *T4* because *R1* owns skill (*Q1*) required by *T4* (level 1) with higher proficiency level (*3*). Analogously R1 is also capable of performing *T3*.

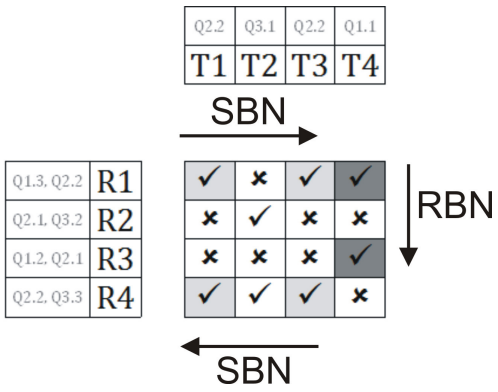

Fig. 1. Illustration of neighbourhood generation methods

Example results of neighbourhood generation methods have been presented in the Fig.2. For SBN only resources for tasks $T1$ and $T3$ could be swapped. Hence, as a result, swapping of mentioned pair of resources assigned to indicated tasks has been performed. For RBN other resource could be assigned to every task. In this example, we decided to change the assignment of $T4$. This example explains the main difference – SBN involves two tasks, while RBN changes assignment of

only one task.

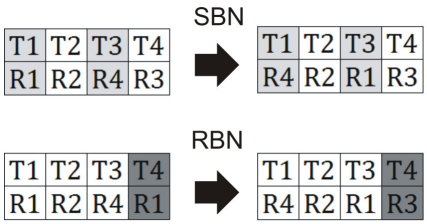

Fig. 2. Example of neighbourhood generation methods

After setting an assignments' vector, the schedule is built in a few steps. First, all tasks have their start time dates set to the project's start date. Then the conflict fixing mutually with the critical path preserving methods are launched, until no conflicts would be found and the schedule could be regarded as a feasible. Neighbourhood generation methods are designed not to allow generating infeasible solutions.

C. Move description

A move describes how the solution B has been created in the base of solution A. In our approach, the move stores the information about task and resource related to assignments that have been changed in neighbourhood generation procedure. In SBN the information about pair of tasks and pair of resources within which the swap has been performed.

Let's see some example: task A has been assigned to resource 1 - *A(1)* and task B has been assigned to resource *B(2)*. After the swap the situation is as follows: *A(2)* and *B(1)*. The information stored in move is as follows: *A(1),B(2)→A(2),B(1)*.

In RBN less information is stored in particular move. It is because this neighbourhood creation method involves only one task. Hence, using previous example, the information stored in a move looks like: *A(1)→A(2)*.

V. Experiments and results

The goal of conducted experiments was to compare two different approaches of creating neighbourhood in TS and investigate whether proposed TS approaches could be used in solving MS–RCPSP in effective way. To evaluate solution – the resulted project schedule – its duration time ([days]) and performance cost ([c.u][1]) were investigated.

A. Dataset

Due to evaluate not only the project schedule duration, but also the cost of the schedule, we cannot use the standard PSPLIB benchmark dataset [10], that does not contain any information about the task performance cost. What is more, PSPLIB dataset instances do not reflect the MS–RCPSP. Hence, we prepared the dataset, containing six project instances, that have been artificially created[2], in a base of real–world instances, got from the Volvo IT Department in Wroclaw.

TABLE I
MS–RCPSP dataset description

Property	D1	D2	D3	D4	D5	D6
Tasks	100	100	100	200	200	200
Resources	20	10	5	40	20	10
Skills	9	9	9	9	9	9
Relations	20	26	22	133	148	129

The dataset summary has been presented in the Table I. There are two groups of created project instances: one contains 100 tasks and the second – 200 tasks. Within the group, project instances are varied by number of available resources and the precedence relationship complexity. It led to create three different project instances both with 100 and 200 tasks. The skill variety has been set up to constant 9 different skill types for each project instance, while any resource can dispose no more than six different skill types. Because of the different resources and relations number, the scheduling complexity for each project is varied.

B. Experiments' set–up

The experiments have been divided into investigating the influence of TS parameters' configurations for project duration and performance cost in three various components' weights in evaluation function: duration optimization (DO: $w_t = 1$), balanced optimization (BO: $w_t = 0.5$) and cost optimization (CO: $w_t = 0$). Each experiment for given parameter configuration has been repeated ten times.

To present the average results in detail, a standard deviation measure should be introduced and applied to each average value. However, to keep the results' presentation clear and simple, we decided not to present it. It is because we have obtained the standard deviation measure values and they generally were not much significant. Only 2 of conducted experiments provided the standard deviation value bigger than 10% of the average.

The processing time of both approaches was varied within the range from about 40 seconds (D1 project instance with neighbourhood size = 10) to about 900 seconds (D6 project instance with neighbourhood size = 45)[3].

C. Experiments' performance

During the experiments, following parameters have been examined: tabu list size and neighbourhood size. Each parameter configuration was ran in both neighbourhood creation methods. Number of iterations has not been investigated. During experiments we noticed that after, in average, 200 iterations, no better solutions have been produced, regardless the remaining parameters' configuration and used dataset instance. Based on that observation, we set up the iterations size as a constant value equal to 250 iterations. Neighbourhood size and tabu list size parameters have been chosen experimentally.

For DO and CO, the best result has been indicated as the one with the smallest value of duration and cost respectively.

[3]Intel Core 2 Duo P8700 (2.53 GHz at each core) and 4 GB memory RAM.

If there was more than one result with the smallest value of time or cost, the one with the smallest value of the second optimization aspect has been chosen as the best. For BO the best result has been obtained based on the smallest value of evaluation function.

D. Results' discussion

Analysing results we can notice that optimization direction (more duration– or more cost–oriented) is related with the neighbourhood creation method. Looking at the Tab.**??** the best results for DO have been found in SBN method part in 5 from 6 dataset instances. On the other hand, the best CO results have been all obtained using RBN. An interesting observation regards the results for BO optimization mode. Project instances consisting 100 tasks have been optimized the best using SBN method, while the best optimization results for project instances consisting 200 tasks have been found in the part of table regarding the RBN.

Analysing the influence of examined TS parameters to obtained results, some following observations could be indicated. Taking into account the influence of the neighbourhood size to the DO results, we can suggest using smaller neighbourhood size values. It is because that the best DO results have been obtained for the $N = 10$ (4 best solutions – *winners*). $N = 20$ and $N = 45$ provided best results only once per each N value parameters' configurations. On the other hand, all best solutions for CO have been found for $N = 45$. It could lead to some general conclusion that enlarging the search space could be beneficial for cost optimization but does not have to help obtaining better solutions, where project duration is the core aspect of optimization. Above mentioned observation could be derived to BO mode but with a respect to a conclusion made in previous paragraph – for BO best solutions of project instances consisting 200 tasks have been obtained for RBN with the $N = 45$. BO results for project instances consisting 100 tasks cannot allow us to make any general conclusions.

We have not found any interesting relationship between the tabu list size and the optimization's robustness, regardless the configuration of remaining parameters, chosen optimization mode or even project instance. We have found 4 best obtained solutions in DO or BO for the $TL = 10$, but that value has not been confirmed in remaining results as potentially good in optimization. It is very difficult to make any general conclusions and assumptions regarding the influence of tabu list size into the potential of optimization.

VI. Conclusions and further work

The best obtained solutions for each dataset instance in every optimization mode have been presented in Tab.II. For each solution a project duration and performance cost has been presented with the description of configuration, for which the solution has been found. The notation for that description is as follows: *neighbourhood creation method (neighbourhood size, tabu list size)*. E.g., SBN(10,15) means that the solution has been obtained for swap–based neighbourhood solution with neighbourhood size equal to 10 and tabu list size set to 15. That summary table briefly summarizes which neighbourhood creation mode is preferred for a given optimization mode.

Obtained results could lead to a conclusion that neighbourhood creation strategy has significant influence on the optimization ability. Using SBN, better solutions in duration optimization were obtained. SBN provided the best duration optimization results in 5 of 6 project instances. On the other hand RBN generally is more effective in cost optimization. Hence, different approaches could be used for different optimization modes. Despite that, end user would have to be always aware of opposite–character of project duration and performance cost objectives, which cause enlarging one aspect where the optimization is focused on the second one.

TABLE II
SUMMARY TABLE – BEST OBTAINED RESULTS IN INVESTIGATED OPTIMIZATION MODES

ID	DO		BO		CO	
	days	cost	days	cost	days	cost
D1	SBN(10,15)		SBN(45,10)		RBN(45,10)	
	32	40656	37	38939	129	30750
D2	RBN(10,10)		SBN(45,7)		RBN(45,10)	
	33	43542	49	34240	179	26444
D3	SBN(10,7)		SBN(20,7)		RBN(45,7)	
	51	40054	61	36100	133	31645
D4	SBN(45,10)		RBN(20,15)		RBN(45,7)	
	92	88720	125	50438	254	46371
D5	SBN(20,15)		RBN(45,10)		RBN(45,10)	
	179	80448	184	54181	481	52425
D6	SBN(10,15)		RBN(45,15)		RBN(45,15)	
	199	97978	222	75996	330	73126

To lift end–user of setting weights in evaluation function, both TS approaches could be merged in Pareto–based related mechanism. Mixing solutions from both approaches and choosing only the best, non–dominated ones could give the end user more flexibility of choosing the most appropriate schedule of proposed solutions pool. Furthermore two interesting future work directions could be indicated: investigating and applying aspiration criteria for both proposed approaches and creating an initial solution in more directed ways. To cope with the second mentioned idea, scheduling priority rules could be applied, while the first of proposed research directions could enhance the proposed method's robustness.

It would be also useful to compare obtained results with simple hill–climbing method – like TS without storing information about moves. It would provide information about the real usability of applying TS for MS–RCPSP.

***Abstract*—In this article some novel scheduling heuristics for Multi–Skill Resource–Constrained Project Scheduling Problem have been proposed and compared to state-of-the-art priority rules, based on task duration, resource salaries and precedence relations. New heuristics stand an aggregation of known methods, but are enhanced by skills domain. The goal of the paper is to investigate, whether evaluated methods can be used as robustness enhancement tools in metaheuristics, mostly evolutionary algorithms. Experiments have been performed using artificially created dataset instances, based on real–world instances. Obtained results prove that such methods stand interesting feature that can be included to more complex methods and increase their robustness.**

I. Introduction

RESOURCE-Constrained Project Scheduling Problem (RCPSP) is one of the most widely described [1], [4], [10], [11], [12] combinatorial problems in the literature. RCPSP describes the problem [4], where the set of predefined tasks and resources are given. The objective of RCPSP is to assign tasks to resources in the way to make the overall project schedule as cheaper and shorter as possible – time & cost optimization. However, there are many constraints that have to be satisfied to make the schedule feasible. Given resource cannot be assigned to more than one task in specified time. Moreover, the precedence relations between tasks have to be obeyed.

The RCPSP can be extended to Multi–Skill RCPSP (MS–RCPSP) [16], where the set of predefined skills pool is given. In MS–RCPSP each task requires some skill in specified level to be performed. Each resource disposes some subset of skills. Hence not every resource can perform every task. The ability of performance specified task has to be checked before the assignment. If specified resource is assigned to given task, even it does not cover required skills, the project schedule become infeasible.

As MS–RCPSP is a combinatorial, NP–hard problem [1], there is no optimal solution that can be found in acceptable, finite time. That is why the soft computing methods are often used, mostly metaheuristics. However, simpler heuristics are often used. Usually they obtain suboptimal solution, but their advantages are different - they are much faster than more complex metaheuristics, like Evolutionary Algorithms (EA) [8], [14] or Ant Colony Optimization [13]. What is more, heuristics provide repeatable results, while the non-deterministic character of metaheuristics can be regarded as one of the most important disadvantage.

Heuristics used to solve the RCPSP and its extensions are called *scheduling priority rules* (SPR) [10]. They are usually related to the main elements that create the problem description - tasks with their precedence relations, resources or skills. In this paper five SPR will be presented and evaluated on proposed dataset: known from the literature, like based on a task duration, a resource salary, and task successors' list size. Some novel approaches are proposed, based on an adjustment between required and available skills.

Proposed SPR could be applied to more complex methods, like metaheuristics, i.e. as a method of generating initial population in EA, to make the search more effective. Furthermore SPR can be combined with the EA–based approaches, constructing hybrid metaheuristics, where those methods could be regarded as a local search methods. The goal of this paper is to investigate whether proposed SPR are effective enough to recommend them to such applications.

The rest of the paper is organised as follows. Section II describes other approaches to solve the (MS)–RCPSP with the SPR paradigm. Section III describes proposed SPR, while Section IV provides experiments made with described approaches, based on proposed dataset. Finally, Section V presents discussion of obtained results, while Section VI provides the conclusions and some ideas of future work.

II. Related work

SPR have been widely investigated in the literature (e.g. [2], [3], [10]). In [2] some standard priority rules has been presented: minimum total slack (MINSLK), minimum late finish time (MINLFT) and minimum processing time (MINPTM). Furthermore some less popular rules have been introduced: maximum number of immediate successors (MAXNIS), maximum remaining work (MAXRWK) and maximum processing time (MAXPTM). Proposed priority rules has been tested on a randomly created dataset. Results have shown that the most sufficient priority rule for proposed dataset is MAXNIS.

In [3] most of above mentioned priority rules have been examined, like MINSLK, MINLFT, MINPTM and MAXPTM. The work–related priority rules has been changed to total work: minimum total work (MINTWRK) and maximum total work (MAXTWRK). The MINPTM and MAXPTM has been

978-83-60810-53-8/$25.00

examined, however they have been called in different ways—shortest operation first and longest operation first, but their meaning is the same to above mentioned. Authors presented some novel heuristics, based on tasks criticality or load balancing factor, which became more suitable for solving RCPSP than standard ones, as it was presented in the results section.

An approach presented in [5] proposes priority rule based on resource availability. After each task is scheduled, the resource availability is computed and it influences on further resource–to–task assignments. An opposite measure for resource availability - moving resource strength (MRS) is introduced. The bigger the MRS value is, the more busy the resource is and the probability of choosing it for further tasks is smaller. MRS is computed locally – for given time window in a project. The MRS is included for most of typical priority rules (LFT, SLK, MTS).

Some researchers also proposed combined approaches, where priority rules are included in EA [11], [17]. In those approaches priority rules are used to generate the initial solution from which the whole initial population could be generated. Other approach [6] proposes using priority rule as a general method of creating the whole schedule from the resource–to–task assignments. Resources are assigned to given tasks and then the schedule is built by adding following tasks in given order, preserving resource– and precedence–constraints. In that approach SPR based on successors definition has been investigated.

The standard notation for scheduling has been presented in [4]. It introduces the formal language for describing the scheduling problem using SPR in comparison to metaheuristics and other more complex methods. It also describes other known priority rules and methods to solve various RCPSPs with different objective functions.

Most of state-of-the-art scheduling priority rules has been tested on the PSPLIB [9] benchmark dataset. The experiments and results have been widely described in [10], [11]. An update of performed evaluation has been performed in [12] and some novel methods have been also proposed there. Moreover, priority rule heuristic methods have been compared to metaheuristics, i. e. genetic algorithms (GA) [7]. Even if GA produces comparative results, priority rule heuristics are indispensable to create initial solution.

Solutions based on priority rules for multi–mode RCPSP (MM–RCPSP) are presented in [15]. MM–RCPSP assumes that task can be performed in several modes while every mode could cause various task's performance cost or its duration. For that problem typical priority rules have been proposed: LFT, SLK, NIS, LPM and SPM. Obtained results could lead to conclusion that LFT and LST priority rules are the most suitable.

III. Scheduling priority rules

A priority rule contains information to construct a list of tasks that ranks all project tasks in a certain order to determine the priorities in which the tasks are assigned to the project schedule. Such a list is constructed in order to assign priorities to tasks based on the following project information:

- task description: information about time or cost estimates of the tasks also determines the task priorities.
- precedence constraint information: information obtained from simple critical path scheduling tools determines the task priorities.
- resource skills information: information about the project resources and skills pools they cover, determines the task priorities.

The constructed list of tasks is then used and tasks are removed one by one from the list and are put in the schedule in the heuristic scheduling process.

Constraints that have to be preserved for each priority rule:

- Resource can be assigned to specified task only if it owns the required skill in required or higher familiarity level.
- If task has predecessors, it cannot be started before the last of predecessors would be finished.
- If a *conflict* occurs during the scheduling the specified task t, it has to be removed by shifting the start time of t just after the finish time of conflict-related task. The *conflict* is defined as a situation, when given resource is assigned to more than one tasks, which are performed in overlapping periods of time.

A. Simple priority rules

We proposed three simple priority rules, where tasks are ordered to be performed by satisfying simple conditions, presented below.

1) Task duration–based: In task duration–based priority rule (TD) tasks are ordered by their duration (ascending or descending). Then resources are assigned to tasks in predefined order. If there is more than one resource that can be assigned to specified task, the cheapest one (with the smallest standard rate) is selected. If there is more than one resource with the smallest standard rate, the first one from the pool is taken to be assigned. The TD bases on MINPTM and MAXPTM state-of-the-art priority rules.

2) Resource salary–based: In resource salary–based priority rule (RS) resources are sorted by their standard rate salary and then are assigned to tasks in an order the tasks were added to the project description. If there is more than one resource with the smallest standard rate, the first one from the pool is taken to be assigned. The tasks' order is taken directly from the dataset instance.

3) Successors' list size–based: In successors' list size–based priority rule (SLS) tasks are sorted by the size of successors' list. Then resources are assigned to tasks in defined order. The SLS bases on the state-of-the-art MAXNIS priority rule. If there is more than one resource that can perform given task, the cheapest one is taken (the same like in TD). If there is still more than one resource, that can be chosen, the first one from the pool is taken.

B. Complex heuristics

Above mentioned methods base on one or maximum two sorting criteria that define the tasks order. However, those methods do not utilize sufficiently the information about the resource load balancing or skills covered by resource and skills required by tasks. Thus we propose novel SPR approaches, based on mentioned aspects.

1) Skill adjustment–based: In skill adjustment–based heuristic (SA) skills are ordered by the adjustment measure (π), compared as a difference between number of tasks requiring specified skill and number of resources owning it and then normalized to [0;1] values. For each skill, the list of tasks that require it in specified level is obtained. If the list size is bigger than one, tasks are sorted by their duration time and the first one from the ordered list is taken to be assigned by the first resource in ordered resource list by standard rate salary. If there is more than one resource than can perform specified task in the same cost, the first one from the list is used.

This priority rule has been extended by one decision to made - whether the adjustment measure should be computed only once where the following skill is taken into consideration or should be computed after each task would be assigned. In extreme, if each task had different required skill, this decision would be useless. However, such situation occurs very rarely. Hence, it was useful to check the importance of that decision in the context of obtained results. This method has been presented as a pseudo–code in the Algorithm 1.

Because the sorting order for π, task duration and resource salary can be ascending or descending and the dynamic adjustment decision had to be included, we proposed four two-state parameters: P_π regards the sorting order of π, P_d concerns task duration sorting order, P_s declares the sorting order for resource salary and the last one - P_a treats whether the dynamic adjustment feature is active or disabled. Each of those parameter can be set to A (ascending for sorting order and active for dynamic adjustment feature) or D (descending sorting order or disabled dynamic adjustment feature).

2) Resource properties – based: In resource properties – based heuristic (RP) resource that should be assigned to specified task is selected by using a complex method, where many conditions are checked. First, only valid resources are obtained – who dispose required skill in specified level. Then the subset of obtained resources is created that contains only resources, who have specified skill in the highest / lowest acceptable level. If there is more than one resource that satisfies above condition, resources are compared by their free time during the project lifetime. The free time is computed for each resource as a difference between the project duration and sum of hours that reflects all tasks assigned to specified resource. If there are still more than one resource that can be assigned, the cheaper / more expensive one is chosen, by comparing their standard rate. If there are more than one resources with the smallest / biggest resource standard rate, the overtime rate is compared. The last comparison stage regards the number of skill types that are owned by resource. Finally, if there is still more than one possibility of choosing resource, the first one from the list (regarding the order from creating the project instance) is taken. The whole RP procedure is shown as a pseudo-code in the Algorithm 2.

Algorithm 1 SA(P_π, P_d, P_s, P_a) priority rule

Require: Defined tasks (T), resources (R), relations and skills
Ensure: Feasible schedule (set of task–to–resource assignments (A)

$Q \leftarrow sortByAdjustmentMeasure(P_\pi)$
for $q \in Q$ **do**
  $T_q \leftarrow tasksWithExpectedSkill(q)$
  $T_q \leftarrow sortByDuration(P_d)$
  for t to T **do**
    for r to R **do**
      if $resourceCanDoTask(r, t)$ **then**
        $R' \leftarrow add(r)$
    $R' \leftarrow sortByStandardRateSalary(P_s)$
    $R' \leftarrow getCheapestResources()$
    $r' \leftarrow getFirst(R')$
    $a_i \leftarrow t(r')$
    $A \leftarrow add(a_i)$
  if $dynamicAdjustment(P_a)$ **then**
    $\pi \leftarrow adjustment()$
    $Q \leftarrow sortByAdjustmentMeasure(\pi)$

In analogy to SA, some parameters have to be included, to determine the sorting order of investigated elements. Hence P_{sl} concerns ordering skills by their level, P_t regards the order of resources by their free time in the project, P_{sr} sorts the resource in the order of their standard rate, P_{or} - the same like previous but regards overtime rate and P_{st} defines the sorting order for number of skills owned by resource.

Algorithm 2 RP($P_{sl}, P_t, P_{sr}, P_{or}, P_{st}$) priority rule

Require: Defined tasks (T), resources (R), relations and skills
Ensure: Feasible schedule (set of task–to–resource assignments (A)

for t to T **do**
  $skill \leftarrow getSkillName(t)$
  for r to R **do**
    if $resourceCanDoTask(r, t)$ **then**
      $R' \leftarrow add(r)$
  $R_{HSL} \leftarrow resourcesOrderedBySkillLevel(skill, P_{sl})$
  if $size(R_{HSL}) > 1$ **then**
    $R_{MFT} \leftarrow resourcesOrderedByFreeTime(P_t)$
    if $size(R_{MFT}) > 1$ **then**
      $R_{MSR} \leftarrow resourcesOrderedByStandardRate(P_{sr})$
      if $size(R_{MSR}) > 1$ **then**
        $R_{MOR} \leftarrow resourcesOrderedByOvertimeRate(P_{or})$
        if $size(R_{MOR}) > 1$ **then**
          $R_{MST} \leftarrow resourcesOrderedBySkillTypes(P_{st})$
          if $size(R_{MST}) > 1$ **then**
            $a_i \leftarrow getFirst(R_{MST})$
          else
            $a_i \leftarrow R_{MST}$
            ...
  $A \leftarrow add(a_i)$

Similarly to SA priority rule, the set of values for parameters in RP priority rule is the same: A – ascending, D – descending.

IV. Experiments and results

The goal of conducted experiments was to investigate whether proposed SPR stand a robust way of solving MS–RCPSP and thus – whether they can be used in combination with EA. To evaluate solution – the resulted project schedule – its duration time ([days]) and performance cost ([c.u][1]) were investigated.

A. Dataset

Because not only the project schedule duration, but also the cost of the schedule should be evaluated, we cannot use the standard PSPLIB benchmark dataset [9], that does not contain any information about the task performance cost. What is more, PSPLIB dataset instances do not reflect the multi–skill model. We propose the dataset containing six project instances that has been artificially created[2], in a base of real–world instances, got from the Volvo IT Department in Wroclaw. The dataset instances have been verified by experienced project manager from mentioned enterprise.

TABLE I
MS–RCPSP dataset description

Property	D1	D2	D3	D4	D5	D6
Tasks	100	100	100	200	200	200
Resources	20	10	5	40	20	10
Skills	9	9	9	9	9	9
Relations	20	26	22	133	148	129

The dataset summary has been presented in the Table I. There are two groups of created project instances: one contains 100 tasks and the second – 200 tasks. Within the group, project instances are varied by number of available resources and the precedence relationship complexity. It led to create three different project instances both with 100 and 200 tasks. The skill variety has been set up to constant 9 different skill types for each project instance. Because of the different resources and relations number, the scheduling complexity for each project was varied.

B. Set-up

For SA priority rule 4 parameters has been investigated – $2^4 = 16$ experiments with different parameters' configurations have been performed (see Tab. III). In RP summary table (see Tab. IV) records containing the same values for each project instance with different parameters' configuration have been filtered out. The number of experiments is equal to the number of parameters' configuration: $2^5 = 32$.

C. Experiments

Experiments have been divided into the following parts. Evaluation of project duration and performance cost (see Table II) for first three priority rules. Furthermore, an evaluation of the same project properties (duration and cost) has been performed for SA (Tab. III) and RP heuristics (Tab. IV).

[1]Currency units

[2]http://www.ii.pwr.wroc.pl/˜myszkowski/scheduling

All experiments have been performed on a personal computer equipped with Intel Core 2 Duo P8700 (2.53 GHz at each core), 4 GB memory RAM and Windows 7 Professional with Service Pack 1. For such configuration, SPR processing times were negligible small (1-3 [s]), thus they were not presented in details in this paper. The experimental environment was provided by the Eclipse IDE and Java programming language. We used some specific libraries[3] to process MS Project files.

We decided to highlight the best obtained results in specified tables (see Tab. II, III, IV). However, as described problem is multi-objective, we highlighted the best duration– and cost oriented optimization results for given project instance. If there were more than one best result for specified objective, that with smaller value of second objective was highlighted as the best one.

D. Results obtained for TD, SLS, RS

The experimental results for TD, SLS and RS has been presented in Table II. Taking into account the consideration of obtained results for evaluation of project duration for TD, SLS and RS, we can see that that the SLS became *a winner* in 5/6 times. Both ascending and descending mode for SLS priority rule got the best results four times. RS priority rule has never obtained the best result, what can be explained by the fact that this rule does not *care about* the duration of the project. It is focused only on the cost aspect.

As RS priority rule became the worst approach for scheduling focused on the duration aspect, it turned out to be the best way when the cost–oriented scheduling mode is required. When the ascending mode for RS priority rule was set, the best results for each project instance was obtained (6/6). However, changing the order of this priority rule from ascending to descending make it the less effective approach. It suggests that this is one of the most performance cost–sensitive SPR.

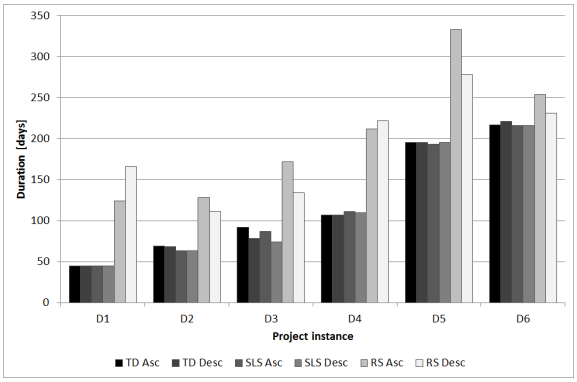

Fig. 1. Project schedule duration for TD, SLS and RS priority rules

Project duration and performance cost results for TD, SLS and RS priority rules have been also illustrated in the Fig. 1 and Fig. 2 respectively. Indicated figures gives as a clue how changing the number of resources in project could influence on the potential of scheduling optimization. The more tasks

are statistically assigned to resource, the longer the project schedule could be.

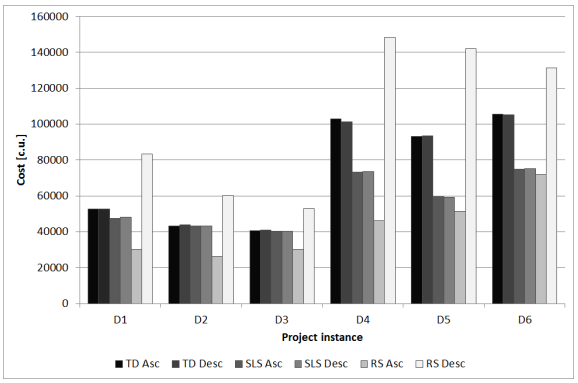

Fig. 2. Project schedule cost for TD, SLS and RS priority rules

E. Results obtained for SA

However duration results obtained for the dataset using SA heuristic are much diversified (see Tab. III), an interesting observation has been made. For 4 from 6 project instances, the best solution was found where the second parameter value, which was reflected to task duration sorting order, had been set to D. In other words - sorting tasks by their descending duration provides the best duration results. What is also interesting, for two remaining project instances the best duration results were obtained when task duration sorting order had been set to ascending, but the skill adjustment order had been set to descending.

The cost–oriented scheduling (see Tab. III) with the use of SA priority rule leads to the conclusion, that cost–related parameter (resource standard rate) is the most important. Moreover, results show that this is the only one parameter that influences to the method's robustness. If cost sorting order is set to ascending, provided results as the best, while changing the parameter to the descending value makes often results even the worst from all of investigated methods. What is also interesting, for all of performed experiments related to evaluating the cost for SA priority rule, only two resulting values were obtained.

What is also worth mentioning, duration optimization results for SA priority rule were significantly worse in comparison to those obtained for duration optimization in TD, SLS, RS and RP priority rules. While the average duration for sample project instance (D1) is equal to 78 for TD, SLS, RS (see Tab.II) or 70 (see Tab.IV) for RP priority rules, the average duration value for the same project instance in SA (see Tab.III) is about two times bigger - 149 days! On the other hand, cost aspect for D1 has been changed from average 52436 [c.u.] (see Tab.II to average 56708 [c.u.] (see Tab.III).

F. Results obtained for RP

As it is presented in the Table IV, ascending skill level criterion generally leads to get better results. Most often the best results has been placed into the parameters' configuration pool consisting skill level criterion ascending and resource availability criterion descending. It could lead to the conclusion that those two parameters influence the heuristic optimization potential the most. However, for the D6 project schedule instance, the best configuration regards ascending skill level criterion and ascending resource availability. On the other hand, for two from six project instances the best duration optimization results were obtained also for descending skill level criterion, while the resource availability criterion still remains descending.

Looking at the cost optimization results (see Tab. IV) the first impression can be made that those results are in opposition to project duration results. It proves the previous assumption that project cost and duration are in opposition. It means: reducing the performance cost leads to enlarging the project duration. The best cost optimization results were obtained when the second parameter – resource availability – has been set to ascending. An interesting fact is that steering remaining parameters does not influence on the final result. However it involves only the parameter configuration, when the skill level criterion is set descending.

Nevertheless the average values for cost optimization in SA is generally smaller than those relevant values for SA, the better optimization results were obtained for SA. The differences in average values come from smaller standard deviation of performance cost values in parameter configurations of RP. Cost obtained for RP are relatively small, but the smallest values were obtained in SA. On the other hand, invalid parameter configuration in SA could lead to increase the performance cost drastically.

TABLE III
PROJECT DURATION AND PERFORMANCE COST FOR SA PRIORITY RULE

V. RESULTS' DISCUSSION

The best obtained results for the duration and cost optimization has been compiled into the Table V. The table shows that SLS priority rule became the most effective in duration optimization for the most analysed project instances. Only for D4 instance the other method turned out to be more robust (TD). While first of proposed complex heuristic (SA) became not sufficient for duration optimization, the RP heuristic resulted well, being mostly equally efficient as SLS.

TABLE V
THE BEST OBTAINED DURATION AND COST INDICATORS.

ID	DO			CO		
	Method	D	C	Method	D	C
D1	SLS-A	45	47530	SA-ADAA	121	30140
D2	SLS-D	63	43221	SA-DDAA	131	26322
D3	SLS-D	74	40286	SA-DAAA	174	30163
D4	TD-D	107	101319	SA-DAAD	212	46132
D5	SLS-A	193	59627	SA-ADAD	329	51495
D6	SLS-A	216	75033	RS-A	254	51986

Beside the duration optimization, the project performance cost optimization has been also examined for each project instance. The cost optimization results are also presented in the Table V. Obtained results are quite interesting: SA methods became the best cost–optimization–oriented. An interesting fact is that for each best SA parameter configuration, the third criterion that reflects resource standard rate, was always set to ascending (A). Results given for RS were comparably good as those obtained by SA (see Tab. II), thus both SA and RS method became the best cost–optimization method for each project instance.

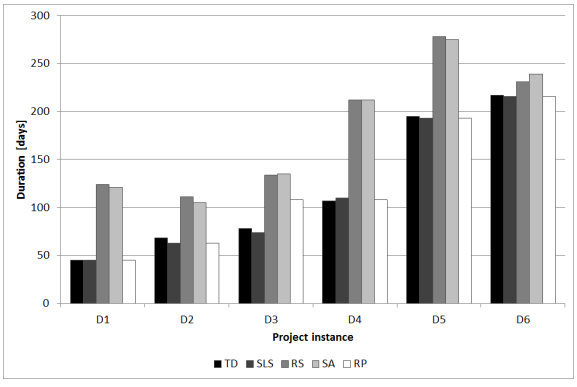

Fig. 3. Summary duration optimization results of examined methods.

The summary of duration and cost optimization for the best parameter configuration has been presented in Fig. 3 (duration optimization) and in Fig. 4 (cost optimization). In these figures

the issue of time/cost trade-off is clearly presented – reducing the project cost makes the performance cost larger and vice versa.

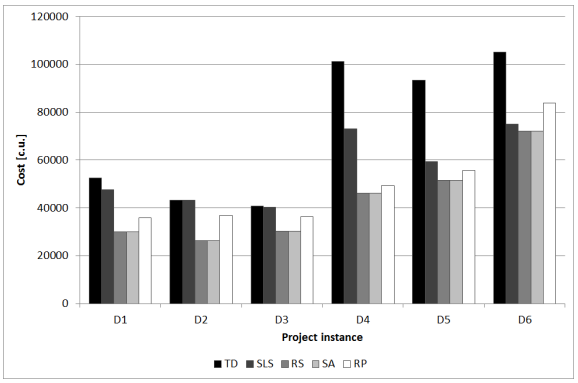

Fig. 4. Summary cost optimization results of examined methods.

Let's analyse the differences between the best duration and cost optimization. While the best project duration for D1 is 45 days, such a schedule would cost 47530 [c.u.], the cheapest project schedule could save about 17000 [c.u.] (37%), but would enlarge the project for 169%. For D2 project instance those indicators are 39% of reducing cost and enlarging the project duration by 108%. For D3 project instance 135% of project duration enlargement could cause saving 25% of budget. An interesting example is D4, where reducing the budget by the half, enlarges the duration about two times. D5 project instance turned out to be the least prone for cost optimization, where only 14% of budget could be saved, with the respect of enlarging the project duration by 70%. The last project instance – D6 – has the smallest potential in duration optimization - only 18% of duration was able to be reduced. Consequently, the potential of performance cost optimization for this instance is also reduced.

VI. Conclusions and Further Work

Before making some more general assumptions and conclusions, an important issue has to be reminded. The best optimization results, both time– or cost– oriented influence on the opposite project property. In other words, best time optimization could cause generate the schedule with unacceptable performance cost. Analogously, reducing the cost could be the reason of enormous enlargement of project duration. As it was presented in tables with detailed results.

The main drawback that can be stated for proposed SPR is that they are much less flexible in obtaining the final solution than other methods, like metaheuristics, especially those population–based. E.g. for EA the set of possible solutions is investigated during the EA *runtime*. Thus they can be compared and the *best compromise* can be found - the solution that is cheaper enough, but with acceptable cost. For SPR we do not have the possibility to find such a medium solution.

On the other hand the computing time of above mentioned methods is negligibly small, using such methods in EA could enlarge its processing times. The decision would have to be made, whether potential increase of robustness and flexibility is worth of enlarging processing time.

Obtained results provide also a conclusion that there is no need to make the priority rules too much complicated. TD, SLS and RS are operating in one or maximum two sorted lists (tasks and / or resources), while in the SA one more sorted list has to be made, based on the skills pool. It enlarges the computing complexity, but does not provides better results.

Furthermore, if cost–oriented scheduling is taken into account, the best results have been obtained using the SA heuristic. However, the results are the same like obtained for RS priority rule. It could lead to conclusion, that also cost–oriented optimization could be made with the usage of simpler priority rules.

Performed experiments showed that using SPR give possibility to get sub-optimal solution of proposed problem. Hence, in a further work proposed methods would be applied to EA as a local search (mutation operator) or as an initial population generator method.

As the fitness function in EA could be weighted by their duration and cost component, specified heuristic could be chosen depending to the weight settings of evaluation function in EA. Directed selection of local search or initial population creation method could enhance the final optimization results.

Object Tracking and Video Event Recognition with Fuzzy Semantic Petri Nets

Piotr Szwed* and Mateusz Komorkiewicz*
*AGH University of Science and Technology

Email: {pszwed,komorkie}@agh.edu.pl

***Abstract*—Automated recognition of video events is an important research area in computer vision having many potential applications, e.g. intelligent video surveillance systems or video indexing engines. In this paper we describe components of an event recognition system building up a full processing chain from low-level features extraction to high-level semantic information on detected events. It is comprised of three components: object detection and tracking algorithms, a fuzzy ontology and Fuzzy Semantic Petri Nets (FSPN), a formalism that can be used to specify events and to reason on their occurrence. FSPN are Petri nets coupled with an underlying fuzzy ontology. The ontology stores assertions (facts) concerning object classification and detected relations being an abstraction of the information originating from object tracking algorithms. Fuzzy predicates querying the ontology are used in Petri net transitions guards. Places in FSPN represent scenario steps. Tokens carry information on objects participating in an event and have weights expressing likelihood of an event's step occurrence. Introduced fuzziness allow to cope with imprecise information delivered by image analysis algorithms. We describe the architecture of video event recognition system and show examples of successfully recognized events.**

***Index Terms*—video events, surveillance, fuzzy Petri Nets, fuzzy ontology**

I. Introduction

RECOGNITION of video events is an important research area in computer vision. Developed methods may have many potential applications: intelligent video surveillance, video indexing engines and various systems in which human-computer interactions are based on interpretation of video content.

Automated video event recognition comprise several tasks including detection of objects, intelligent tracking, recognition of compound events or activities and finally reasoning about occurrences of high-level events. Each of them may involve various problems to solve, e.g. how to distinguish real objects from such visual phenomena as shadows or reflexes, how to merge objects that have split into multiple segments, how to maintain objects' identities in case of occlusion, what kind of information is required to describe scene and which formalism should be used to specify events and efficiently detect them. Solutions to these problems are never perfect, each processing step may produce noisy and uncertain data, moreover a mapping between elements of semantic event specifications and low level video features often incorporate vagueness.

This work was supported from the National Centre for Research and Development (NCBiR) under Grant 0128/R/t00/2010/12 and AGH UST under Grant No. 11.11.120.612

In this paper we describe components of a video event recognition system building up a full processing chain from low-level features extraction to high-level semantic information on detected events. A conceptual layout of the systems is shown in Fig. 1. Input video sequence is analyzed with object detection and tracking algorithms. A tracking information is then represented in form of assertions in a more abstract Fuzzy Ontology layer and finally video events are detected with Fuzzy Semantic Petri Nets (FSPN), a specific class of fuzzy Petri nets, which reference terms in an ontology.

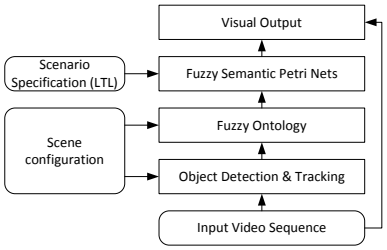

Fig. 1. Conceptual model of the event recognition system

Guards in FPNS are conjunctions of unary or binary predicates examining asserted class membership facts or object relations. Tokens in FSPN are tuples of selected scene objects participating in an event with associated weight factors. Such approach make event scenarios tolerant to classification errors, imprecise measurements and missed subevents or conditions. As transitions are fired, fuzzy weights obtained from guards evaluation are combined with token weights. In consequence, FSPN are not only capable of reasoning about scenario occurrences, but also about their likelihoods. This property is particularly important, as it allows to fine-tune the system operation by appropriately selected thresholds and filter output of less probable scenarios. Another important feature of the proposed approach is that several scenarios, starting at different time points and with different participating objects can be analyzed concurrently.

The paper is organized as follows: the next Section II reports known approaches to event specification and analysis. It is followed by Section III, in which an algorithm used to detect and track objects is briefly described; the next Section IV discusses the fuzzy ontology. FSPN are defined in Section V.

978-83-60810-53-8/$25.00

The detection system implementing the proposed approach is presented in Section VI and finally Section VII gives concluding remarks.

II. Related works

Recognition of video events has been intensively researched over last fifteen years. A large number of approaches is reported in recent surveys: [1] and [2]. Systems for video recognition usually have a layered architecture, e.g. [3], [4], in which lower level layers provide an *abstraction* of meaningful aspects of video sequences, whereas higher level layers are related to formalisms used for *event modeling* and algorithms that detect events based on formal specifications.

Probabilistic state-based methods use models comprised of states and transitions, in which transitions are attributed with probability factors learned from annotated video. During an analysis of an input video sequence a likelihood of a situation is computed. This group include methods based on neural networks [5], Hidden Markov Models, Dynamic Bayesian Networks [6] and stochastic Petri nets [7].

In grammar based methods complex activities are represented by production rules that generate strings of atomic actions. Hence, complex events can be recognized by language parsing techniques [8], [9]. In the review [2] a limitation of these methods as regards concurrent activities was indicated. The criticism seems to be founded in a case, where sequences of single actions are analyzed. However, in a more general setting, e.g. this provided by the Kripke structure [10], each string element is a set of low level events occurring in parallel and in consequence high-level concurrent events can be tracked.

Description based approaches specify events and scenarios using high level languages, either textual [11], or graphical as Situation Graph Trees [4], [12] and Petri nets [7], [13], [14]. The methods falling into this category are considered to be *semantic*, as specifications are prepared by experts, who give meaningful names to events, engaged objects, actions and conditions. Descriptions are often hierarchical: complex events can be expressed as graphs of subevents. Models can also include constraints and knowledge about scene objects, e.g. in [4] they are expressed as formulas of a Fuzzy Metric-Temporal Horn Logic. In some approaches scenarios and their ingredients: types of participating objects and relations are defined as ontologies [15], [16].

Petri Nets (PNs) are applied in the field of event detection in two modes [1]. In the first mode of *object PNs* tokens represent objects, places object states and transitions events of interest. Such approach was applied in surveillance of traffic [13] and people [17]. In the second mode of *plan PNs* places correspond to subevents building up a plan. Presence of a token in a place indicates that a particular event assigned to the place is occurring. The latter approach was applied to parking [18] and more recently people [14] surveillance.

The semantics of Petri nets proposed in this paper is closer to *plan PNs*, as tokens represent combination of objects participating in scenarios. There are, however, some salient differences. 1) In probabilistic PNs discussed in [14] in case of a conflict (e.g. two enabled transitions sharing input place with a single token) only one transition with a higher learned probability would fire, whereas in our model they both can be executed and produce two tokens with weights aggregating the weight of the input token and transition guards. This allows to reason concurrently about scenario alternatives. Moreover, a weak initial likelihood of a scenario branch can be amplified by future events. 2) In our approach all enabled transitions are executed in a single parallel step. Such behavior rather resemble reasoning with Fuzzy Cognitive Maps [19] than the most often utilized interleaving PN semantics. 3) Petri nets modeling scenarios are actually state machines. Their structure is sufficient to construct a Büchi automaton [20] representing a LTL formula.

There are a vast number of tracking algorithms and it would be hard to present all previous works in this field. However there exist two very interesting surveys which give an in-depth view of all methods [21] and [22]. Based on classification proposed in these surveys, the tracking algorithm used in this work can be assigned to a group, which detect objects by background modeling and subtraction. The final tracking is based on kernel tracking methods (region based tracking).

III. Object detection and tracking

The detection and tracking algorithm maintains a set of tracked objects O and updates it after an arrival of a new video frame. Each object has several attributes: a history of its bounding box position and size at current and N-1 previous frames, a unique object ID, information about object type (pedestrian, graffiti, group of objects etc.) and flags denoting object occlusion or information, that object can't be tracked and its position must be estimated.

For each i-th frame the set O is updated with a procedure comprised of the following steps:

A) A background is updated and foreground object segmentation is performed.
B) A set of segments S is extracted, labeled and tracked.
C) Segments S which are similar to objects from O are assigned to them.
D) All segments S which were not assigned to O are submitted to a classification process and detected objects are added to O.
E) Overlapping objects from O are merged.
F) Merged objects from O are split, if they have separate areas.
G) Positions of objects from O, that cannot be tracked by segments, are estimated.

These steps are explained in detail in the next paragraphs:

A. Foreground object segmentation

The method is based on background generation and foreground object detection described in [23]. It consists in creating a binary mask by background substraction and processing it in order to extract connected components (segments) and label them. A single segment can be a group of objects (e.g.

a crowd), single object (e.g. a pedestrian) or part of the object (e.g. a torso). Partitioning may be caused by failures of segmentation algorithm.

B. Segment tracking

Number of segments, their position and size may vary significantly from frame to frame. Segmentation errors can be caused by many factors e.g. camera noise, changes in lighting condition, shadows, occlusion by other objects etc. To make sure that only segments, which are correctly extracted will be used in the next processing stage, a simple tracking mechanism is applied that is based on checking bounding box positions of current and previous segments. If two bounding boxes overlap in two consecutive frames, segments are linked with the *history* relation describing evolution of segments in time. For further analysis only segments, which have clear history based on observation form N previous frames are used.

C. Segments to object assignment

In the next step all segments S detected in a frame i are assigned to objects from previous frame O. Let us introduce a function $h\colon O \times \mathbb{N} \to 2^S$ that defines a mapping between an object o at a frame i and a set of segments. The Algorithm 1 takes at input the sets of objects O and segments S, updates the function h and computes the set of assigned segments S_u.

Algorithm 1

procedure ASSIGN(O, S, i, S_u, h)
  for all $o \in O$ **do**
    for all $s \in S$ **do**
      if $d(o, s) \geq \epsilon$ **then**
        Add segment to an object:
        $h(o, i) \leftarrow h(o, i) \cup \{s\}$
        Add s to the set of used segment S_u:
        $S_u \leftarrow S_u \cup \{s\}$
      end if
    end for
  end for
end procedure

The function d calculates a normalized to $[0, 1]$ similarity between an object o and a segment s considering overlapping of segments in $h(o, i-1)$ and s (bounding boxes or image masks). The threshold ϵ is a small constant, e.g. 0.1.

After executing the procedure new positions and sizes of all objects $O_u = \{o \in O\colon h(o, i) \neq \emptyset\}$ are computed based on position and size of segments assigned to them.

D. Object detection and classification

All segments, which were not assigned to any object ($S_{NA} = S \setminus S_u$) are further analyzed by a set of classifiers. Simple geometrical rules are applied (perspective is compensated) e.g. an adult person should be higher than 160 cm and wider than 40 cm. If a segment with desired properties is detected, a new object is created o_{new} with a unique ID and added to object list $O \leftarrow O \cup \{o_{new}\}$. If an object is divided into several segments, a correct classification is not possible. In this case the system will not detect it on the current frame. As the video sequence is analyzed, it is very likely that in next few frames it will appear not split and the algorithm will be able to detect it. The benefit of this approach is that only very reliable objects are detected, what leads to smaller false detection rate.

E. Object merging

In the next processing step, the algorithm handles cases, when two previously tracked objects merge, e.g. if two pedestrians approach and finally their silhouettes overlap. As it is then impossible to track objects based on the information on segments position and history, the algorithm sets a special flag in the overlapping objects descriptors. From that time their positions are not computed based on the position of segments belonging to them. Instead, a prediction mechanism is used, which is based on information about previous sizes, movement direction and speed. Also a new temporal object is created (so called merged object). Its size and position is updated based on segments which previously belonged to merged objects. Thanks to this, the system is able not only to estimate the object position, but also to keep track of real area occupied by the estimated objects.

F. Object splitting

In the next step it is checked, if previously merged objects are split. Such situation occurs, e.g. when two previously joined pedestrians move away far enough to allow for total separation of segments belonging to each object. In this case, all segments are checked to test, if they resemble an object within a merged group. If appropriate correspondences can be found, the unique IDs are restored based on estimated positions of the original objects. Another scenario is also possible. A person may leave a luggage and start to move away (possible bomb planting scenario). In such case it is possible that an object, which has only one ID starts to split. To cover such situations, a maximum object size is checked and, if it exceeds the maximum allowed object size, the tracking object is removed and classification is rerun for all segments belonging to this object. The largest detected object is given the old ID, all other detected objects are given new unique IDs.

G. Position estimation

In the last step, for all objects, which are marked as lost or impossible to track, i.e. $h(o, i) = \emptyset$, a history of their positions on previous frames is analyzed to compute a mean velocities. Object's velocity is then used to estimate a new position. The object size is not estimated, the last known size is used instead. This estimation method is working well in most cases. It can also cause wrong results, if objects change speed or movement direction during the estimation. To overcome this types of errors, a guard mechanism was introduced. It is based on counting the number of pixels belonging to foreground objects within an estimated bounding box. If it drops below a fixed

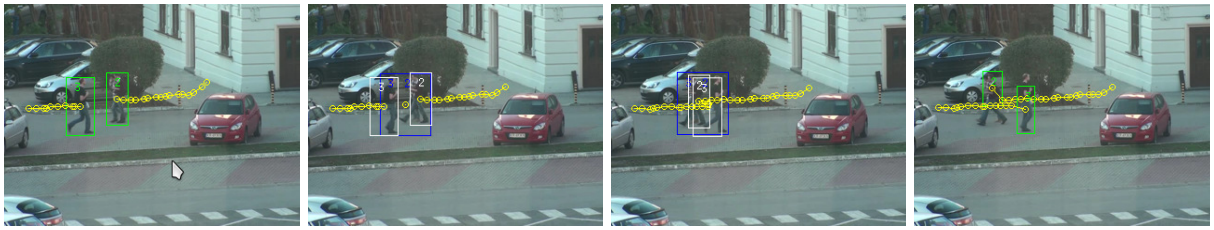

Fig. 2. Sample tracking sequence, green boxes - tracked pedestrians, white boxes - estimated pedestrians positions, blue boxes - group position, yellow circles - trajectories

threshold, it is a signal that the object position is not estimated correctly. In such case the estimated object is removed.

A sample tracking sequence of two passing pedestrians is presented in Figure 2.

IV. Fuzzy ontology

The fuzzy ontology constitute an intermediate layer between information on tracked objects and fuzzy Petri nets. Whereas objects within the tracking model are described with numeric values, like size, distance or speed, the ontology provide a kind of linguistic abstractions, e.g. *a small object*, *objects are close* or *a person is walking*.

There are several benefits of this approach:

- Scenario specifications can be prepared in a more general and meaningful manner, they can be decoupled from the code and implementation details can be hidden .
- It is much easier to customize a recognition system to specific needs and conditions, because the translation between numeric values and linguistic terms is accomplished in isolated and easy to identify functions
- Facts concerning classifications of objects and detected relations are materialized, hence they can be evaluated only once, what generally increases performance.

Ontologies are often described as unions of two layers: terminological (*TBox*) and assertional (*ABox*). The *TBox* defines concepts and types of relation including: taxonomic relations between concepts, *object properties* and *datatype properties*. The *ABox*, in turn, gathers facts about individuals and existent relations. In Description Logic, being a counterpart of ontology languages, concepts and relations can be expressed by means of unary and binary predicates, e.g.: $Person(x)$ – x is a member of the class $Person$, $isWalking(x)$ – a boolean datatype property $isWalking$ of an individual x or $isClose(x, y)$ – an object property between two individuals x and y.

For *fuzzy ontologies* and corresponding Fuzzy Description Logics the ontology relations are extended by adding weights being real numbers from $[0, 1]$. They can be used to express uncertainty, e.g. with respect to class membership or relation occurrence. Formalizations of fuzzy ontology languages including fuzzy classes, roles (object properties) and datatype properties can be found in [24] and [25].

In the case of a fuzzy ontology used with FSPN, its TBox is a stable part, whereas the ABox is updated for each frame. A crucial element of the described approach is that relations in the ABox are practically never fully evaluated. Only their subset that is requested from FSPN is calculated by making calls to plugged in functions (function objects in object-oriented implementation) called *evaluators*. They examine the tracking model and calculate fuzzy weights of predicates. In opposition to approach proposed in [25] evaluators are external entities beyond the ontology. In many cases they have a form of membership functions described by line segments, as in Fig. 3, but they can be also based on other features, as Jaccard metrics applied to object areas (Fig. 4). In this case a bounding box of a detected object is divided into a $n \times m$ grid and each cell is assigned with a probability density p_{ij}. The weight returned by the evaluator is calculated according to the formula: $w = \frac{1}{Z} \sum_{i=1}^{n} \sum_{j=1}^{m} h_{ij} p_{ij}$, where Z is a normalizing constant $Z = \sum_{i=1}^{n} \sum_{j=1}^{m} p_{ij}$ and $h_{ij} = 1$ if a cell (i, j) intersects with an object or 0 in other case. The selection of probability distribution is arbitrary and depends on the type of interaction, e.g. the grid in Fig. 4a was used to calculate intersection values for vertical objects, e.g. walls, whereas the grid in Fig. 4b for horizontal ones, e.g. forbidden zones on a floor.

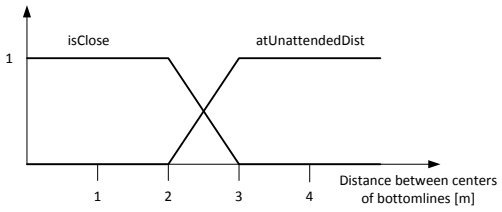

Fig. 3. Membership functions used by *evaluators*

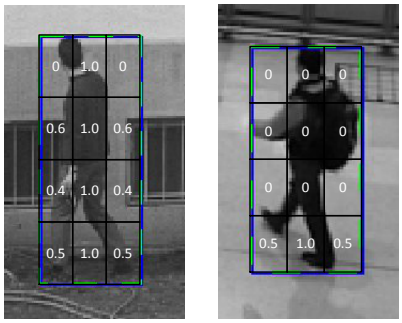
V. Fuzzy Semantic Petri Nets

In this section we define Fuzzy Semantic Petri Nets and describe their behavior. FSPNs are placed at the top of video event recognition stack (Fig. 1 and are responsible for interpretation of low-level events and conditions represented as assertions in a sequence of ABoxes of the coupled fuzzy ontology.

It should be noted, that the presented semantics of FSPN is dedicated to a particular case of state machines, i.e. Petri nets, in which transitions link single places. Such restrictions



a. b.

Fig. 4. Evaluators based on Jaccard metrics.

stems from fact that we use Linear Temporal Logic (LTL) [26], [27] to specify video events. LTL specifications are then transformed to corresponding FSPN structures following the rules for translating them to Büchi automata [20].

Relations between FSPN and LTL are even deeper, an input sequence of ABoxes analyzed by a FSPN can be considered a specific kind of Kripke structure [10], which is defined as a sequence of states $s_0, s_1, s_2, \ldots, s_n, \ldots$ and a function that assigns sets of true propositions P_i to states s_i. In our case a state s_i corresponds to an i-th video frame and a set of propositions P_i to a set of assertions in an i-th ABox of the fuzzy ontology. Hence, detection of a video event can be considered a checking if a model (a sequence of ABoxes) satisfies an LTL formula that is translated to a FSPN.

In the presented approach we generalize and relax the acceptance requirements:

- Instead of Büchi automata, fuzzy Petri nets are used as a tool for scenario analysis. This allows to process concurrently scenarios, in which participate various combinations of objects.
- To manage uncertainty and inexactness of input data, fuzzy predicates returning values from $[0, 1]$ are used. These values are then combined with weights of tokens flowing through a net. Tokens, in turn, represent scenario occurrences. This enables monitoring scenario steps and reasoning about their likelihood.
- Sequences of accepted states strictly defined with LTL formulas can be interleaved with states not satisfying the specified conditions. In such case, the weight determining scenario satisfaction gradually decrease and, after passing a certain threshold, the scenario is rejected by token removal.

A. Definition of Fuzzy Semantic Petri Nets

Formal definition of Fuzzy Semantic Petri Nets is comprised of three concepts: Petri net structure, binding and fuzzy marking. We start with some auxiliary definitions. Unary predicate is defined as a pair (n, v_s) where, n is a predicate name and v_s is a variable name referring to a *subject* of the predicate. Binary predicate is a triple (n, v_s, v_o); the variable v_o is a predicate object. Set of all unary and binary predicates is denoted by $Preds$. By $Vars(p)$ we denote a set of variables appearing in the predicate p. Analogously, for a set $C \subseteq Preds$ we define $Vars(C)$, as $\bigcup_{p \in C} Vars(p)$.

Definition 1 (Petri net structure)**.** Petri net structure PN is a tuple $(P, T, F, Preds, G, L, H)$, where P is a set of places, T is a set of transitions, P and T are satisfying $P \cap T = \emptyset$ and $P \cup T \neq \emptyset$. $F \subseteq P \times T \cup T \times P$ is a set of arcs (flow relation), and $Preds$ is a set of unary and binary predicates. $G\colon T \to 2^{Preds}$ is a guard function that assigns sets of predicates to transitions. $L\colon P \to \mathbb{N} \cup \{0\}$ is a function assigning lower bound to a place; this value defines how long a token should stay in a place to be allowed to leave it. $H\colon P \to \mathbb{N} \cup \{\omega\}$ assigns upper bound to a place. The symbol ω represents infinity.

Following [28] the set of input places for a transition $t \in T$ is denoted as $\bullet t = \{p \in P\colon (p, t) \in F\}$ and the set of output places as $t\bullet = \{p \in P\colon (t, p) \in F\}$

Definition 2 (Binding)**.** Let V be set of variables and I a set of objects. *Binding* b is defined as a partial function from V to I. A variable v *is bound* for a binding b, iff $v \in \operatorname{dom} b$. A set of all bindings is denoted by B.

Let $p \in Preds$ a predicate and $b \in B$ be a binding. Predicate value for a binding $val\colon Preds \times B \to [0, 1]$ is a function that assigns value from the interval $[0, 1]$ to a pair (p, b), $p \in Preds$ and $b \in B$. If $Vars(p) \setminus \mathbf{dom}\, b \neq \emptyset$, then $val(p, b) = 0$.

Definition 3 (Fuzzy marking)**.** A set of fuzzy tokens FT is defined as $FT = B \times \mathbb{R} \times (\mathbb{N} \cup \{0\}) \times (\mathbb{N} \cup \{0\})$. Components of a token tuple $(b, w, c, \tau) \in FT$ are the following: $b \in B$ denotes a binding, $w \in [0, 1]$ is a fuzzy weight, $c \geq 0$ is a counter storing information, how long a token rests in a place and τ is a time stamp. *Fuzzy marking* for a Petri net $PN = (P, T, F, Preds, G)$ is defined as a function that assigns sets of fuzzy tokens to places $FM : P \to 2^{FT}$.

B. Execution

The behavior of FPNs defined in previous section differs from the standard semantics for Petri nets, as they are not intended to focus on concurrency and conflicts, but to perform a kind of fuzzy reasoning and classification of sequences of events.

Single i-th step of execution of a fuzzy Petri Net is comprised of three basic stages:

1) *Firing enabled non-initial transitions and generating new tokens.* During this stage each token-transition pair (t, m), where $t \in T$ and $m = (b, w, c, \tau) \in FM(\bullet t)$ is analyzed. If a guard $G(t)$ references unbound variables, i.e. $Vars(G(t)) \setminus \mathbf{dom}\, b \neq \emptyset$, an attempt is made to create a new binding b' by grounding free variables with ontology individuals; in other case $b' = b$. Then, a weight of the guard is calculated: $w_g = \min\{val(p, b)\colon p \in G\}$ and aggregated with the old token weight: $w' = a\, w_g + (1 - a)w$. If w' is greater than a certain threshold (in experiments 0.2 value was used), a new token $m' = (b', w', c', t')$ is created and put

into the transition's output place $t\bullet$. The current iteration number i is assigned as token timestamp $\tau' = i$ and, if the transition t is a self-loop, the counter is updated: $c' = c + 1$. It should be mentioned, that only self-loop transitions can fire if token counter c does not belong to the interval $[L(\ bullett), H(\bullet t)]$ (see Definition 1).

2) *Removing old tokens.* A transition occurrence performed in the previous stage can be regarded as a triple (m, t, m'), where m is an input token, m' an output token and $t \in T$ a transition. Let C denote a set of such triples, and $w(m)$ a weight of a token. For each input token m a sum of weights of output tokens m' is calculated and subtracted from its weight: $w_{new}(m) = w(m) - \sum_{(m,t,m')\in C} w(m')$. If the value falls below a certain threshold, the token m is removed. Also in this step multiple tokens having the same binding and assigned to the same place are aggregated.
3) *Firing initial transitions.* Finally, new tokens are introduced into the net, by firing initial transitions (i.e. satisfying $\bullet t = \emptyset$). For each initial transition variables appearing in its guard are bound to objects, then the guard value is calculated and used as a weight of new tokens. To avoid analyzing scenarios with low likelihoods, a threshold preventing from creating tokens with small weights is defined. The mechanism is also protected against introducing tokens with a binding already present in the net.

C. Video event specification

We start preparing a specification of a video event by outlining a general scenario in form of Temporal Logic formula, then events appearing in the scenario are refined into conjunctions of low-level events or conditions expressed as predicates. The resulting LTL specification is used in two ways: (1) it is translated into FSPN and (2) predicates are included into TBox of the fuzzy ontology.

To give an example: a high-level video event, in which a person violates a forbidden zone can be expressed in LTL as a sequence of three medium-level events: $init \Rightarrow \Diamond move \Rightarrow \Box violate$, where $init$ defines conditions to start recognition, $move$ denotes a situation, when a person is moving towards a zone and $violate$ a situation, when the person enters the zone. During the refinement step the scenario is transformed into formula (1), which is further translated into FSPN shown in Fig. 5.

$$\begin{aligned} &Person(x) \wedge isWalking(x) \wedge atBorder(x) \wedge Zone(y) \\ &\Rightarrow \Diamond(isWalking(x) \wedge movesTowardsZone(x,y)_{\{8,\infty\}} \\ &\Rightarrow \Box(bottomInZone(x,y))_{\{4,\infty\}} \end{aligned} \quad (1)$$

Fig. 6 shows a FSPN defining a complex event, during which a person leaves unattended luggage. Its scenario (in a narrative form) with accompanied video material was published as a benchmark for PETS 2006 workshop [29]. The event is defined as a sequence of four simple steps: *init* – a still person appears, *separate* – the person puts a luggage on the floor and remains close to it, *leave* – distance between the person and luggage grows above a certain threshold (equal to 3 meters in PETS specification) and finally *remain* – the person disappears and the luggage remains alone.

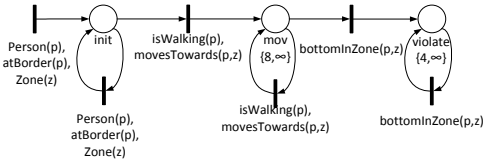


Fig. 5. Fuzzy Semantic Petri Net representing a scenario, in which a person violates a forbidden zone

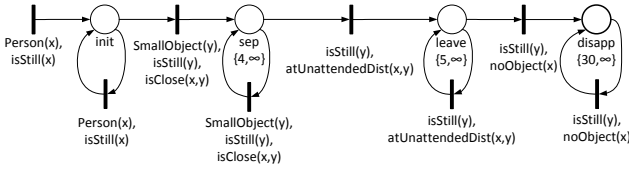

Fig. 6. Fuzzy Semantic Petri Net representing luggage left scenario

A more complex FSPN is presented in Fig. 7. It defines an event of graffiti painting on a wall decomposed into medium level events: a person moves towards a wall, then appears in front of the wall, optionally: a person is widening (what may indicate painting graffiti), then a new object emerges on a wall (but not inside a window) and remains still.

VI. Detection system

In this section we describe a prototype system allowing to test recognition of events based on specifications in FSPN. The system takes at input a video sequence with an XML file defining tracking information. For each frame a list of segments and identified objects is provided. The data originate from tracking algorithms described in Section III. The architecture of the prototype scenario detection system is presented in Fig. 8. Main components are: the *Fuzzy ontology*, a set of *Evaluators* and the *Fuzzy Semantic Petri Net* execution engine. The system is also equipped with GUI providing visual output shown in Fig. 9.

The control flow during a single iteration was marked in Fig. 8 with numbers in circles.

1) After a new frame appears, asserted relations between objects are removed from the ontology, then newly identified objects are added as individuals.
2) In the next step all enabled transitions in concurrently analyzed Petri nets are fired. Preparation of transitions requires calculations of guards and in some cases extensions of bindings.
3) In order to obtain weights of predicates appearing in guards, appropriate queries are made to ontology. If a weight for a predicate was evaluated earlier, it is immediately returned.
4) In other case an *evaluator* assigned to the predicate is called, and returned value is asserted in the ontology as a weight of corresponding fuzzy relation.

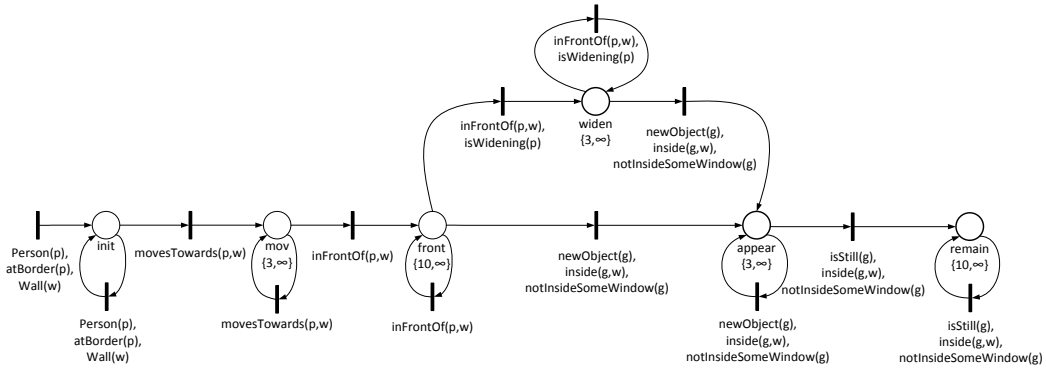

Fig. 7. FSPN representing graffiti painting scenario

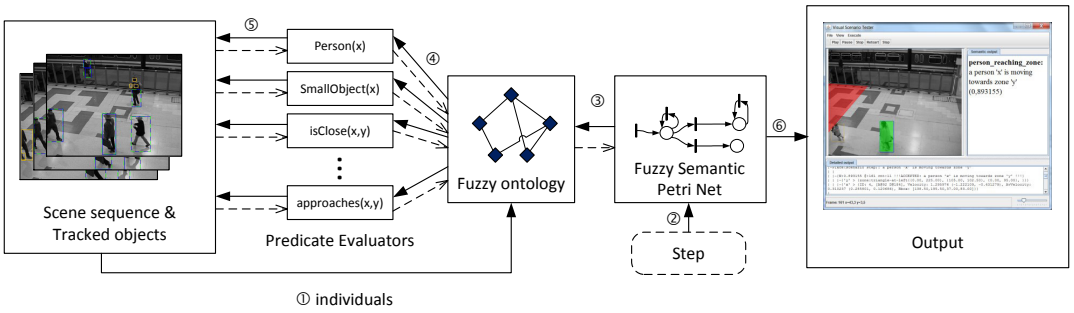

Fig. 8. Architecture of the detection system

5) Evaluators examine the tracking information. As a tracking history covering a number of past frames is kept, evaluators are capable of returning temporal properties, e.g. $newObject(x)$ - an object is considered *new* if it has recently appeared.
6) After the net state is updated, a reached marking is analyzed. If a token stays in a selected place long enough (observed places are defined in FSPN specification) its presence is reported as an important scenario step or a final stage.

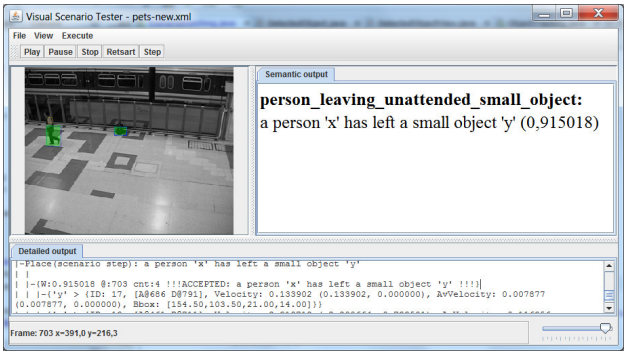

Fig. 9. Visual scenario tester. The displayed video frame and messages correspond to the place *leave* ($isStill(y) \wedge atUnattendedDist(x,y)$) of the FSPN specifying luggage left scenario.

The software is entirely written in Java. Its performance is quite good: for three concurrently analyzed scenarios and a scene with a few tracked objects, a single reasoning iteration, during which the ontology is updated, evaluators are called and multiple transitions in Petri nets are fired, is executed within 0.1ms to 1.6ms (average 0.45 ms) on a Pentium i7 2.2 GHz machine.

The system was successfully tested to recognize a number of events, including these specified in Fig. 5, Fig. 6 and Fig. 7, returning in each case high likelihood value close to 1.0.

Fig. 10 presents visual output corresponding to the steps of the graffiti painting scenario specified by FSPN in Fig. 7. Filled bounding boxes mark objects included into the binding of tokens that reached places (scenario steps), for which semantic messages are displayed.

VII. Conclusions

In this paper we describe components of video events recognition system building a full processing chain: from objects detection and tracking, through transforming tracking information into more abstract representation of Fuzzy Ontology, to reasoning on events occurrences with Fuzzy Semantic Petri Nets.

An advantage of FSPN is their capability of detecting concurrently occurring events, in which participate various combinations of objects, analyze scenario alternatives and their likelihoods. Petri nets state (marking) gives general overview of the situation, of *what's going on*. A presence of a token in a

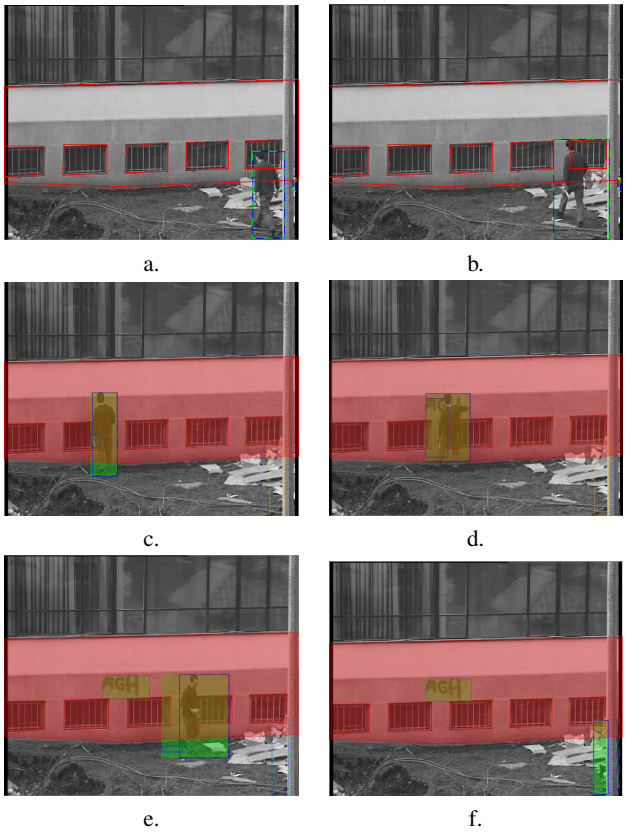

Fig. 10. Recognized steps of a graffiti painting event: a – *init*, b – *move*, c – *front*, d – *widen*, e – *appear*, f – *remain* (scenario completion)

place can be reported as *semantic output*, e.g. to a surveillance system operator.

The proposed scenario detection system is a generic framework, that can be adapted to specific needs by: 1) defining an ontology including classes of objects and relations of interest; 2) implementing evaluators, i.e. functions responsible for calculating values of fuzzy predicates, and plugging them into the framework; 3) configuring scene objects (their types must be defined in the ontology) 4) writing a scenario using in formulas entities (classes and relations) from the ontology.

Collective Belief Revision in Linear Algebra

Satoshi Tojo

Email: tojo@jaist.ac.jp

***Abstract*—Although the logic of belief update has mainly concerned a belief state of one agent thus far, the real world settings require us to implement simultaneous belief changes. Here, however, we need to manage so many indices: agent names, time stamps, and the difference of information. In this paper, we introduce the notation of vectors and matrices for the simultaneous informing action. By this, we show that a matrix can represent a public announcement and/or a consecutive message passing, with the time of the change of belief states properly. A collective belief state multiplied by a communication matrix, including matrices of accessibility in Kripke semantics, becomes a hypercuboid.**

I. Who Knows What at Which Time?

THE authors have tackled legal reasoning system thus far [12], [13], in which one of the main issues is to properly represent *who knows what at which time*. In Fig. 1, we show the informing actions of three agents: judge, lawyer, and the suspected. At the initial stage, the judge sentenced the suspected to be guilty, and at the same time the lawyer pleaded innocent to the judge with a new witness. The judge changed his mind and he was going to sentence the defendant to be innocent, but at the same time the maladjusted defendant insulted the judge in the court, and which badly impressed jury members ...

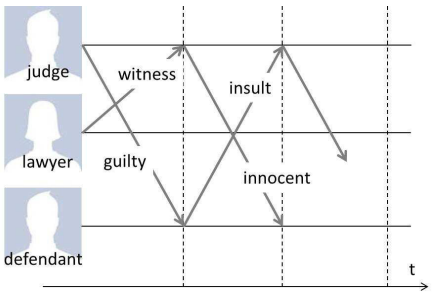

Fig. 1. Informing Agents on Time-axis

Multi-agents communication includes such many factors as agent ID, many messages, and time. In this paper, we introduce vectors and matrices to represent those agents' informing actions collectively, to clarify the complicated relations of those many indices.

II. Preliminaries

First we show the simplest prescription for an informing action; in a similar way to FIPA/ACL [3], we place the precondition in the upper deck and the result in the lower deck.[1]

$$\frac{B_i\varphi}{B_j\varphi}[c_{ij}^{\varphi}] \tag{1}$$

That is, when agent i believes φ ($B_i\varphi$) and there is a communication from i to j (c_{ij}^{φ}), agent j comes to believe φ ($B_j\varphi$). At this stage, there are several issues we need to consider:

- The problem of belief revision; the recipient of information may not believe what was informed of, or he/she may need to change some of what he/she has believed.
- The resultant state should include nested belief states, i.e., both of the sender and the recipient should recognize that the information is shared between them as $B_iB_j\varphi$ and $B_jB_i\varphi$. In addition, if those agents are quite introspective, each of them also possesses $B_iB_i\varphi$ and $\neg B_i\neg\varphi$.[2]

Incidentally, a Kripke frame is such $\mathfrak{M} = \langle \mathcal{W}, \mathcal{R}, \mathcal{V} \rangle$ that $\mathcal{W}$ is a set of possible worlds, $\mathcal{R}$ is the accessibility of belief modal operator B , and $\mathcal{V}$ gives valuation to each φ. Dynamic Epistemic Logic (DEL) [2] presents a change of belief state, restricting accessibility to possible worlds, as:

$$\mathfrak{M}, w \models [\varphi!]\psi \iff \mathfrak{M}^{\varphi!}, w \models \psi. \tag{2}$$

where $R^{\varphi!}$ in $\mathfrak{M}^{\varphi!}$ is:

$$R^{\varphi!}(w) = R(w) \cap \{w' \in W \mid \mathfrak{M}, w' \models \varphi\}.$$

On the contrary, Public Announcement Logic (PAL) [11] masks those contradicting possible worlds, as follows.

$$\mathfrak{M}, w \models [!\varphi]\psi \iff \mathfrak{M}^{[\![\varphi]\!]}, w \models \psi.$$

where in $\mathfrak{M}^{[\![\varphi]\!]}$ let $W_{\uparrow\varphi}$ be the worlds in which φ holds and

$$\mathfrak{M}, w \models \varphi \rightarrow w \in V_{W_{\uparrow\varphi}}(\psi).$$

Note that the significance of these methods is to make formula $[!\varphi]B\varphi$ valid since φ holds in all the accessible possible worlds.

Among various trials to represent agent communication formally [1], [9], [10], Yamada [14] showed a command from i to j as $[!_{(i,j)}\chi]$ where χ is the contents of the command. Kobayashi and Tojo [6], [7] generalized this notion to an informing action, representing the dynamic operator as $[inf_{ij}^{\varphi}]$.

[1] In this paper, we disregard U (uncertain) and U_{if} (uncertain if) operators for simplicity.

[2] In general, belief modality is often implemented with $KD45$, including $B_i\varphi \rightarrow B_iB_i\varphi$ (Axiom 4) and $B_i\varphi \rightarrow \neg B_i\neg\varphi$ (Axiom D), while knowledge modality requires $KT5$ including $K_i\varphi \rightarrow \varphi$ (Axiom T).

978-83-60810-53-8/$25.00

As for linear algebraic representation of belief, Fusaoka [4] used a matrix to show probability of knowledge source. Also, as we have mentioned, Liau [8] represented the network of accessibility in matrix. We combined these works, though we avoid probabilistic point of view and restricted the elements to truth values.

III. Informing Action

The belief modality B_i^t represents the belief state of agent i at time t. As to information φ, the belief states of multiple agents are written collectively in a vector as follows.

$$\begin{pmatrix} B_1^t\varphi \\ B_2^t\varphi \\ \vdots \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ \vdots \end{pmatrix}$$

where $1/0$ are the truth values. Therefore, our specification of belief revision of agent j, with regard to (1), becomes:

$$B_j^{t+1}\varphi = B_j^t\varphi \vee (c_{ij}^{\varphi} \wedge B_i^t\varphi). \tag{3}$$

Here, c_{ij}^{φ} represents the informing action from j to i.

We define the addition and the multiplication of linear algebra as the logical 'or' and the logical 'and', respectively, as follows.

$\wedge$	1	0
1	1	0
0	0	0

$\vee$	1	0
1	1	1
0	1	0

Then, we can generalize (3) to be:

$$B_j^{t+1}\varphi = \bigvee_i (c_{ij}^{\varphi} \wedge B_i^t\varphi), \tag{4}$$

and the dynamic operator becomes such an $n \times n$ matrix that

$$(c_{ij}^{\varphi}) = \begin{pmatrix} 1 & 0 & \cdots \\ 1 & 1 & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix}$$

where n is the number of agents. Its (i, j)-element represents the truth value of c_{ij}^{φ}, that is the existence of informing action from j to i. We assume that diagonal elements c_{ii} $(i = 1, \cdots, n)$ are always true to maintain his/her original knowledge as (3). Now, the collective belief revision becomes:

$$\begin{pmatrix} B_1^{t+1}\varphi \\ B_2^{t+1}\varphi \\ \vdots \end{pmatrix} = (c_{ij}^{\varphi}) \begin{pmatrix} B_1^t\varphi \\ B_2^t\varphi \\ \vdots \end{pmatrix}.$$

Example 1: Let

$$(c_{ij}^{\varphi}) = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \text{ and } \begin{pmatrix} B_1^t\varphi \\ B_2^t\varphi \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

Then,

$$\begin{pmatrix} B_1^{t+1}\varphi \\ B_2^{t+1}\varphi \end{pmatrix} = (c_{ij}^{\varphi}) \begin{pmatrix} B_1^t\varphi \\ B_2^t\varphi \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

Namely, by the informing action from agent 2 to 1, as is $(1, 2)$-element of the matrix, agent 1 comes to know φ. ∎

In the following examples, we highlight our attention with the boxed truth values.

Example 2: Suppose the following three kinds of communication matrices:

$$C_1 = \begin{pmatrix} 1 & \boxed{1} & 0 \\ \boxed{1} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},\ C_2 = \begin{pmatrix} 1 & \boxed{1} & 0 \\ 0 & 1 & 0 \\ 0 & \boxed{1} & 1 \end{pmatrix},\ C_3 = \begin{pmatrix} 1 & \boxed{1} & \boxed{1} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

If there happened a reciprocal and simultaneous communication as to the same information, the matrix becomes symmetric (C_1), that is, agent 2 tells some information to agent 1 (c_{12}) and at the same time so does agent 1 to agent 2 (c_{21}). An agent can announce some information publicly, in which case a certain column is filled with all 1's (the second column of C_2). If multiple different agents tell the same information to a certain agent, then there appear multiple 1's in the same row; if agent 2 and 3 inform the same content to 1, then the situation becomes C_3. ∎

IV. Transitive Communication

Let us consider to connect two communications. Now, we introduce a vector representation for the collective belief state of multiple agents at time t:

$$\boldsymbol{B}^t\varphi = \begin{pmatrix} B_1^t\varphi \\ B_2^t\varphi \\ \vdots \end{pmatrix}.$$

For the time being, we may omit φ unless we need to mention it explicitly. Two consecutive informing actions can be written in the following matrix multiplication.

$$\begin{pmatrix} B_1 \\ B_2 \\ \vdots \end{pmatrix}^{t+2} = \begin{pmatrix} c'_{11} & c'_{12} & \cdots \\ c'_{21} & c'_{22} & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix} \begin{pmatrix} c_{11} & c_{12} & \cdots \\ c_{21} & c_{22} & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix} \begin{pmatrix} B_1 \\ B_2 \\ \vdots \end{pmatrix}^t.$$

A. Associativity

First, we need to prove that communication matrices are associative. Let X and Y be communication matrices and $\boldsymbol{B}^t$ be a collective belief state.

$$(XY)\boldsymbol{B}^t = X(Y\boldsymbol{B}^t).$$

As $XY = \bigvee_k (x_{ik} \wedge y_{kj})$,

$$(XY)\boldsymbol{B}^t = \bigvee_l (\bigvee_k (x_{lk} \wedge y_{kl}) \wedge B_l^t) = \bigvee_l \bigvee_k (x_{lk} \wedge y_{kl} \wedge B_l^t).$$

On the other hand, since $Y\boldsymbol{B}^t = \bigvee_l (y_{kl} \wedge b_l)$,

$$X(Y\boldsymbol{B}^t) = \bigvee_k (x_{lk} \wedge \bigvee_l (y_{kl}) \wedge B_l^t) = \bigvee_k \bigvee_l (x_{lk} \wedge y_{kl} \wedge B_l^t).$$

As the both results meet, Q.E.D.

B. Repetitive communication

Let us consider the case that the same communication matrix is employed repeatedly.

$$\boldsymbol{B}^{t+n} = (c_{ij})^n \boldsymbol{B}^t.$$

Example 3: Suppose

$$C = (c_{ij}) = \begin{pmatrix} 1 & \boxed{1} & 0 \\ 0 & 1 & \boxed{1} \\ 0 & 0 & 1 \end{pmatrix},$$

that is, c_{12} and c_{23} are true, besides self-informing. Then,

$$C^2 = \begin{pmatrix} 1 & 1 & \boxed{1} \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

Namely, agent 3 is reachable from agent 1 in two steps. ∎

Now let $\boldsymbol{B}^t$ be the initial belief state of the community, and let us consider the following sequence.

$$\boldsymbol{B}^{t+1} = C\boldsymbol{B}^t,\ \boldsymbol{B}^{t+2} = C\boldsymbol{B}^{t+1},\ \boldsymbol{B}^{t+3} = C\boldsymbol{B}^{t+2},\ \cdots.$$

Note that the number of 1's in the matrix increases monotonously, since $c_{ii} = 1$ and once an agent believes the proposition (s)he keeps it in his/her recognition. Let $\boldsymbol{B}^*$ be the fixed point such that $\boldsymbol{B}^* = C\boldsymbol{B}^*$. If $\boldsymbol{B}^* = \boldsymbol{B}^{t+k}$, C^k is the transitive closure of the communication graph.

C. Anti-commutativity

As is the case in usual matrix multiplication, communication matrices are not commutative.

Example 4:

$$\begin{pmatrix} 1 & 0 & \boxed{1} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \text{ and } \begin{pmatrix} 1 & 0 & 0 \\ \boxed{1} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

are communication matrices from agent 3 to 1 (left), and that from 1 to 2 (right), respectively. If agent 3 first believes φ, as

$$\begin{pmatrix} 1 & 0 & 0 \\ \boxed{1} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & \boxed{1} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 0 \\ 0 \\ \boxed{1} \end{pmatrix} = \begin{pmatrix} \boxed{1} \\ \boxed{1} \\ 1 \end{pmatrix},$$

agent 2 comes to believe φ. But, when agent 1 does not believe φ, as

$$\begin{pmatrix} 1 & 0 & \boxed{1} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ \boxed{1} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 0 \\ 0 \\ \boxed{1} \end{pmatrix} = \begin{pmatrix} \boxed{1} \\ 0 \\ 1 \end{pmatrix}$$

the first informing action, that is from 1 to 2, results in vain, and thus 2 still remains ignorant of φ. ∎

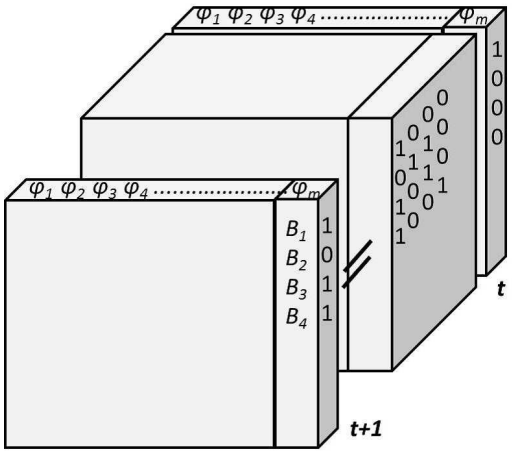

Fig. 2. Multiple Propositions in Informing Action

V. Multiple Information Tensor

Thus far, we have restricted our concern to single information passing. However, we can represent the message passing of multiple information $\varphi_1, \varphi_2, \varphi_3, \cdots, \varphi_m$ as a tensor in Fig. 2.

The flat matrix in the front in Fig. 2 represents the resultant state of informing action. The i-th column is the belief states of the agents as to φ_i and the j-th row is what agent j believes, at time $t+1$. In the similar way, the flat matrix in the behind is that of belief states at time t. The in-between $n \times n \times m$-cuboid is a simultaneous communication, where n is the number of agents and m is the number of information. In order to clarify the relation of elements, we place the contravariant elements as superscripts and the covariant ones as subscripts as a tensor:

$$(B_j^{\varphi})^{t+1} = (c_j^{i,\varphi})(B_i^{\varphi})^t.$$

In Fig. 2, we only have shown the atomic propositions. We can add such composite propositions as $\varphi_1 \vee \varphi_2$ and $\varphi_1 \wedge \varphi_2$ simply in the figure, as these truth values are composed by φ_i's.

VI. Model Updating

A kripke frame for multiple agents is such $\mathfrak{M} = \langle \mathcal{W}, \mathcal{A}, \mathcal{R}_1, \cdots, \mathcal{R}_n, \mathcal{V} \rangle$ that $\mathcal{A}$ is a set of agents and $\mathcal{R}_i$ is the accessibility of belief modal operator B_i.

A belief state of an agent can be represented also in matrix, when we render (i, j)-element as the accessibility from possible world i to j of Kripke semantics [8]. For example,[3]

$$\begin{array}{c} \\ w_1 \\ w_2 \\ w_3 \end{array}\begin{array}{c} \begin{array}{ccc} w_1 & w_2 & w_3 \end{array} \\ \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \end{array} \tag{5}$$

represents $\mathcal{R} = \{w_1 R w_1\ w_1 R w_2,\ w_2 R w_2,\ w_2 R w_3,\ w_3 R w_3\}$ in $\mathcal{W} = \{w_1, w_2, w_3\}$. In this matrix representation, the configuration of truth values directly shows the axioms of modality.

[3]We employ square brackets for the accessibility to distinguish it from the communication matrix.

For example, if the matrix is symmetric, it satisfies axiom of symmetricity (Axiom B). If the diagonal elements are all 1's, it is reflexive (Axiom T), If there is at least one 1 in each row, it satisfies seriality (Axiom D).

A belief change becomes a change in matrix. For example, let $\mathcal{V}(\varphi) = \{w_2, w_3\}$; then matrix (5) cannot satisfy $B_i^t\varphi$ as $\mathfrak{M}, w_1 \not\models B_i^t\varphi$ (for $w_1 R w_1$, $\mathfrak{M}, w_1 \not\models \varphi$). Here, we consider DEL style belief update (2), that is, to cut some of accessibility for an agent to come to believe an informed proposition; namely some 1's in the accessibility matrix at time t are replaced by 0's at $t+1$. In the case of (5), if $(1,1)$-element becomes 0, then $B_i^{t+1}\varphi$.

Since the accessibility with the valuation maps a belief state of a given agent to a truth value:

$$(\mathcal{R}_i, \mathcal{V})\colon B_i^t\varphi \to 1/0,$$

we identify such accessibility matrices with truth values in the following example.

Example 5: Suppose $\mathcal{V}(\varphi) = \{w_2, w_3\}$. A belief vector at time t is:[4]

$$\boldsymbol{B}^t\varphi = (\begin{bmatrix}1&0&0\\1&1&0\\0&0&1\end{bmatrix}, \begin{bmatrix}1&1&0\\1&1&0\\0&0&1\end{bmatrix}, \begin{bmatrix}1&0&0\\1&1&0\\1&0&1\end{bmatrix}, \cdots).$$

After a public announcement of φ from some agent, the revised belief vector becomes:

$$\boldsymbol{B}^{t+1}\varphi = (\begin{bmatrix}0&0&0\\0&1&0\\0&0&1\end{bmatrix}, \begin{bmatrix}0&1&0\\0&1&0\\0&0&1\end{bmatrix}, \begin{bmatrix}0&0&0\\0&1&0\\0&0&1\end{bmatrix}, \cdots). \blacksquare$$

Now, the multiple belief states of agents at time t becomes $(n \times m \times k^2)$-hypercuboid, where n is the number of agents, m is the number of information, and k is the number of possible worlds.[5]

VII. Discussion

In the belief revision of multiple agents, as there are so many indices appears, we have represented them in linear logic. As we have shown, the collective belief state and the communication matrix include more then three indices, those matrices become hypercuboids.

We have shown that the consecutive informing action can be realized by a product of matrices, including the n-th power, with associativity and anti-communtativity. This discussion naturally leads us to the inversion of matrix, as

$$\boldsymbol{B}^t = (c_{ij})^{-1}\boldsymbol{B}^{t+1},$$

being the inversion regarded as belief contraction [5]. However, some communication matrices do not have their inversions, as their rank fails to be n. Furthermore, we cannot give proper semantics for value '-1', or '0' may appear on the diagonal elements in the inversion matrix. We need to recognize that how we can *redo* the revision is difficult problem, especially in Kripke semantics.

In this paper, we evaluated formulae in the same possible world even though time shifts. We are now to intend that we regard the world itself as a temporal state, as:

$$\mathfrak{M}, t \models [c_{ij}^{\varphi}]\psi \iff \mathfrak{M}^{c_{ij}^{\varphi}}, t+1 \models \psi.$$

Now, let us get back to the two issues: belief revision and nested modalities. We could not implement simultaneous arrivals of two different information to one agent, i.e.,

$$B_j^{t+1} := B_j^t \dot{+} \{\varphi\} \dot{+} \{\psi\},$$

regarding B_j^t as a belief set and '$\dot{+}$' as revision operator. Note that how we can revise the belief of each agent is an independent topic from our formalism in this paper, and depends on the preference of revision. Also, it is difficult to send such propositions including modality as $B_j\varphi_2$, which results in the nested belief state. In addition, sending a negative formula also affects how we can revise the accessibility; these would be our common research topics in the community of belief update logic in future.

[4] We show belief vectors in row vectors here just for visibility, although they are intrinsically column vectors.

[5] If we fix the number of atomic propositions to m, then the number of maximal possible worlds becomes $k = 2^m$.

***Abstract*—The paper presents the development of a new system that is used to solve the problem of the recognition of the dermatoglyphic pattern and the understanding of the classification process of the symptoms of Down's syndrome. The method used in the system for diagnosing Down's syndrome in infants is based on the combination of text knowledge found in the scientific literature describing Down's syndrome with the knowledge obtained from the analysis of dermatoglyphic indices characteristic of Down's syndrome with the use of digital pattern recognition techniques. The scientific goal is to design a classifier system that realizes automatic medical diagnosis through the application of an expert system designed on the basis of knowledge included in the scientific text descriptions of the Down's syndrome. One other aim is the application of the pattern recognition algorithms to the analysis of indices present in the images of dermatoglyphic patterns. This approach, similar to the approach used by anthropologists, is realized by the system through the juxtaposition of the knowledge described in the form of expert system rules and the information provided by the appropriate digital equipment, and on the basis of this juxtaposition an arbitrary classification of the investigated patterns is performed.**

I. Introduction

THE present state of knowledge in the discipline of medical pattern recognition allows the extraction of image features using computer methods and data processing algorithms. The results obtained using these methods are presented to an expert who affirms in an arbitral way his understanding of the pattern presented to him as an after-effect of the occurrence of a pathological process and describes it using terms established in the scientific medical literature. In the present state of science and technology development the number of available patterns and the amount of information included in the scientific literature is constantly increasing. It can be assumed with certainty that both of these elements will have a tendency to increase in a hard to predict tempo. The community of medical experts copes with the high increase in information by dividing medical knowledge into many new specializations. The main and basic source of professional knowledge is the knowledge written in the form of natural language sentences. The attempt described in the project is to combine knowledge extracted from scientific medical literature with features extracted and classified by pattern recognition algorithms in the process of analyzing digital images of infants' dermatoglyphic patterns. In its basic form this approach is based on building a hybrid decision support system that comprises an expert system module inferring the occurrence of a genetic disorder on the basis of the results passed from pattern recognition modules that analyze the dermatoglyphic images automatically without the participation of a human expert. The success of this approach may lead to the application of a computer technique to achieve near complete automation of screening tests for the detection of Down's syndrome in infants.

II. The Aim of the Work

The tasks of the recognition and understanding of dermatoglyphic patterns, whose results form the basis for inferring the occurrence of a genetic disorder in infants, are complex issues. The classification of the patterns and the diagnosing of the presence of a genetic disorder on the basis of recognitions is carried out by professional anthropologist. The service of automatic pattern recognition and clinical decision support designed in the form of a telemedical system can perform specialized screening tests of dermatoglyphic data delivered from medical centers that do not employ anthropologists. The data is collected in a non-invasive manner using touch scanners or specialized cameras and then sent to a distant server that is running the telemedical system via the Internet. The uploaded data is then subject to a detailed analysis whose aim is the extraction of features from the collection of images on the basis of which the classification of the case is carried out. It should be emphasized that it is possible to implement and use the designed system with the use of the existing IT infrastructure of local hospitals.

The design of the system involves the following information processing scheme:

1. The analysis of texts containing specialized field knowledge in the form of natural language sentences, arithmetic expressions and arithmetic-logic relations leads to the formulation of conditions which are basis for the conclusion.

978-83-60810-53-8/$25.00

2. The synthesis of partial information contained in the digitally stored image leads to the generation of features that represent characteristic image patterns.

As a result of the proposed scheme application a set of rules for the expert system is obtained, on the basis of which the probability of the occurrence of a genetic disorder in infants is determined. The calculation of the values of premises for the expert system is realized through the determination of the classes of the analyzed patterns of particular dermatoglyphic areas and through the assessment of other features of dermatoglyphs. The values of the conclusions of the expert system that was built on the basis of a text analysis allow for the qualification of the medical case to the group of healthy infants or to the group of infants with a genetic disorder. Undertaking the research topic results from the difficulty in the direct access to the screening tests that are carried out by an anthropology specialist. The proposed decision support system allowing for remote access to these tests overcomes limitations that result from the shortage of employment of specialists in small medical centers. Therefore it brings a new substantial value into social life and helps in the task of improving the accessibility to specialized medical services. It is assumed that the application of the system will improve the effectiveness of the treatment, i.e. the number of complications due to improper treatment of infants with certain genetic defects will decrease and thus the costs of the treatment and the length of hospital care will also decrease. The authors believe that the system will prove particularly useful as a support system for doctors working in small hospitals which do not employ anthropologists and as an automatic system for screening tests of infants performed on a large scale. The device for the analysis of dermatoglyphs will consist of an average desktop computer with a touch scanner or a digital camera attached to it. Depending on the computing capabilities of the workstation, it can serve as an independent unit performing diagnosis or as a terminal used for the acquisition of and for sending data over the Internet and for displaying the results of the analysis.

III. Design of the Medical Decision Support System

The project of the decision support system is of interdisciplinary character as it combines the achievements of modern sciences in the fields of computational intelligence, digital image processing, pattern recognition and the design of expert systems containing medical knowledge. The design proposed by the author assumes the modular architecture of the diagnostic system. Based on the design of dermatoglyphic nomogram [4] the system consists of four main modules. One may distinguish three modules that realize the pattern recognition of medical images. Another superior module in the form of an expert system generates diagnosis on the basis of recognition results that come from pattern recognition modules.

The role of the first of the pattern recognition modules is the classification of fingerprints. Fingerprint classification is one of the fundamental tasks of dermatoglyphic analysis. Several

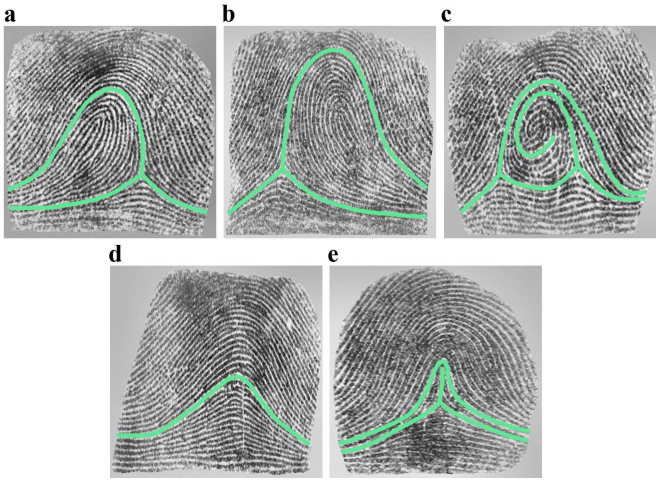

Fig. 1. Classification scheme of fingerprints: (a) left loop (LL); (b) right loop (RL); (c) whorl (W); (d) plain arch (A); (e) tented arch (TA). (The green lines traced on the prints are the type lines, which define the unique skeletons of the patterns.)

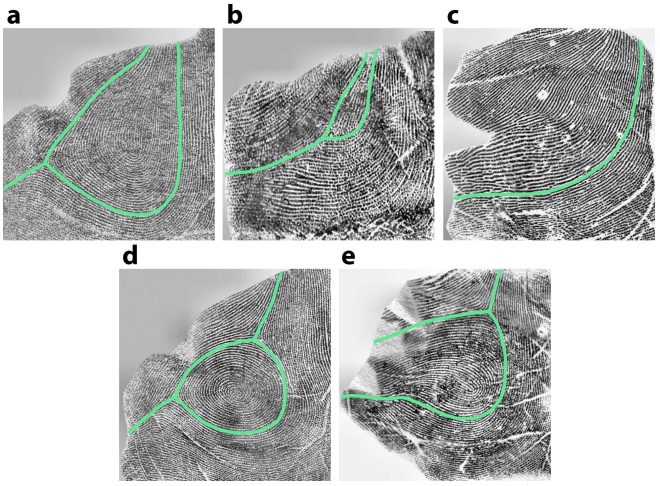

Fig. 2. Classification scheme of the hallucal area of the sole prints: (a) large distal loop (LDL), (b) small distal loop (SDL), (c) tibial arch (TA), (d) whorl (W), (e) tibial loop (TL).

methods of fingerprint classification have been proposed in scientific literature and are used for a variety of applications relating to the analysis of fingerprints [2]. The classification method used in the dermatoglyphic analysis is called Henry's classification method after the name of the originator of this method. It distinguishes between the following five classes of fingerprint patterns: left loop (LL), right loop (RL), whorl (W), plain arch (A) and tented arch (TA) Fig. 1.

The second module performs the classification of patterns of the hallucal area of the sole. A classification scheme of hallucal area patterns includes the following classes: large distal loop (LDL), small distal loop (SDL), tibial arch (TA), whorl (W) and tibial loop (TL) Fig. 2.

Both pattern recognition modules employ the image pro-

cessing algorithms for the segmentation of the background and contrast enhancement of the analyzed images. An important element of enhancement of the local ridge structures of dermatoglyphs is the application of contextual image filtration, which is realized by STFT algorithm [1]. In the classification process, the features extracted from the enhanced images represent the unique properties of the patterns contained within the images. The features used by the classification modules are local ridge flow directions of dermatoglyphic patterns. The classification is accomplished by an ensemble of SVM classifiers that make use of the RBF kernel functions in the learning process and that are trained with the use of the one vs. one voting scheme. Both classification modules recognize the patterns of appropriate dermatoglyphic areas with 90% accuracy ratio.

The third pattern recognition module is used to determine the ATD angle of the right palm print Fig. 3. The value of this angle is determined by the location of digital triradii A and D and the axial triradius t. A reliable and accurate identification of the location of the characteristic points is a complex issue, therefore the algorithm devised for finding these points uses two independent local image descriptors calculated in different ways. The first of these descriptors is an improved variant of the Poincare index [7] that is determined from the ridge flow directions map calculated by the algorithm based on the image pyramid decomposition and PCA [3]. The second of the determined descriptors is a local coherence map calculated from the image texture. For each point of the image containing the analyzed pattern, the values of eigenvectors which create the coherence map are calculated. Eigenvectors are calculated from the confusion matrix that contains the values determined for each image pixel with the use of multiplication of a local image segment centered in pixel (i,j) and the combination of two dimensional Gauss-Hermite moments [7]. The information in the form of the Poincare index and the information in the form of a coherence map are compared for all pixels of the image that contains the dermatoglyphic pattern. The points of the image in which the values of both of these descriptors simultaneously indicate the occurrence of a characteristic point are considered to be the true characteristic points.

The fourth module implemented as an expert system is superior to the modules that carry out the pattern recognition tasks. On the basis of the recognition results that come from pattern recognition modules this module carries out an automatic diagnosis which determines the qualification of the infant to a group of healthy children or to a group of children with Down's syndrome. The basis of the design of an expert system is a dermatoglyphic nomogram. The dermatogram was created on the basis of statistical test results. The statistical test allowed for selecting, from the group of all known dermatoglyphic features that indicate the presence of a genetic disorder, the four most significant features on the basis of which a credible diagnosing of the likelihood of the presence of Down's syndrome in newborns is possible [4].

The premises in the rules of an expert system are the recognized types of patterns of the dermatoglyphic areas that

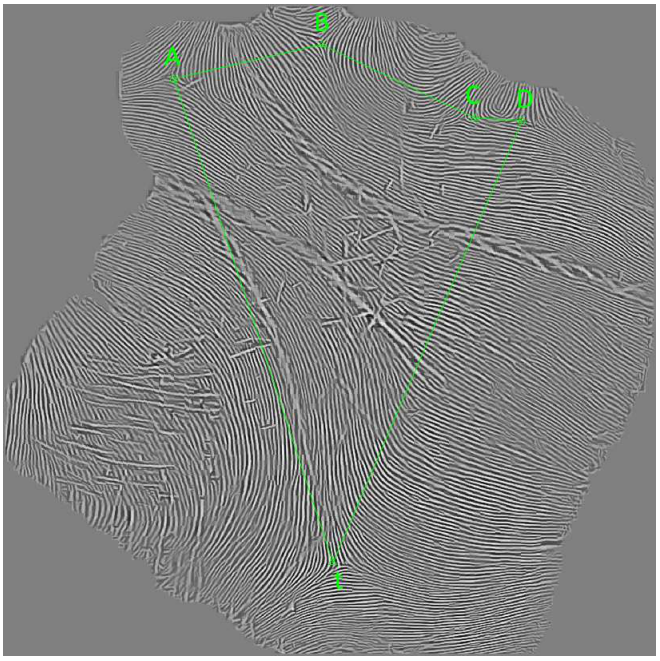

Fig. 3. Singular points of the palm print located with the use of a two stage algorithm that use the improved Poincare index and Gauss-Hermite moments.

contain the four significant features which are: pattern types of index fingers of the left and right hand, pattern type of the hallucal area of the right sole, value of the ATD angle of the right palm. The conclusions of the expert system are diagnostic values determined for diagnostic criterions of the dermatogram that result from the types of dermatoglyphic patterns and from the value of the ATD angle. A combination of these diagnostic criteria values determines the value of the dermatogram diagnostic score and the fact of Down's syndrome occurrence in the newly-born. For the dermatogram 125 possible combinations of patterns exist, which corresponds to the same number of expert system rules.

Table I presents a set of premises and diagnosis results for the rules that correspond to the combination of the recognition of the left and right hand index fingerprints patterns UL - UL (denoting the left loop pattern type on the index finger of the left hand and the right loop pattern type on the index finger of the right hand) and all the possible combinations of the hallucal area of the sole pattern types and the ranges of the ATD angle values.

IV. Results

In the course of the research carried out, components of the system have been designed and implemented. The system will allow for an automatic diagnosis of the occurrence of genetic disorders in infants on the basis of sets of dermatoglyphic images. The system has a modular design. The implementation of the system required the application of numerous computer technologies. The modules responsible for carrying out image processing, feature extraction and pattern recognition tasks

have been implemented with the use of the Matlab and C languages. The database containing dermatoglyphs was designed and implemented with the PostgreSQL database management system. In the database, collections of images are stored along with their descriptions. The diagnostic module in the form of an expert system has been implemented in the Prolog language. The analysis of the collection of images realized by pattern recognition modules allows for the classification of fingerprint patterns [5], for the classification of the hallucal area of the sole patterns [6] and the determination of the value of the ATD angle of the palm print. The outcomes of the classifications and image features calculations are passed to the set of rules of the expert system which on their basis calculates the value of the diagnostic score that determines to which of the three groups the diagnosed infant belongs: healthy infants, infants with Down's syndrome, or infants for whom the value of the diagnostic index does not give a clear answer as to the occurrence of a genetic disorder. The client application implemented in the project is equipped with typical useful capabilities such as enabling users to search and view data. It also provides scientific capabilities allowing for the following: sending requests to the decision support server to perform a dermatoglyphic analysis, the visualization of analysis outcomes in a numerical form and the visualization of the diagnosis results, generated by the explanation facilities of the expert system module in the form of a text description.

V. SUMMARY

The paper presents the architecture of the medical decision support system for the diagnosis of Down's syndrome in infants on the basis of collections of images. The results of the research on the system have reached a high level of advancement. From the technical standpoint, the modules responsible for the pattern classification of the fingerprint and hallucal area of the sole impressions were accomplished. A procedure for the calculation of the ATD angle of the palm has been proposed and implemented. A decision module that determines the diagnostic index value on the basis of the results passed from pattern recognition and image parameters analysis modules has also been implemented. The intention of the authors is an implementation of the system in a form that is useful for public institutions (hospitals, health care institutions, etc.) and for medical universities that use the advisory nature of the diagnostic system to assist in the education of medical students. A client application will be installed in dedicated terminals as a tool that supports the process of infants' diagnosis. A stand-alone application designed for personal computers, having the functionality of the above-mentioned application, is also planned. This software will serve the public as a free to use assistance for those interested in performing a stand-alone diagnosis. After a full implementation of the system, its further development is assumed depending on the degree of extension of the dermatoglyphic database used as a knowledge base. The users of the system (medical doctors, other medical personnel) will be encouraged to upload the data collected in their daily work to the database and thus improve its efficiency and thereby contribute to the development of the system.

***Abstract*—This paper describes a neural system which helps to make the current investment decisions. Some well known financial indicators usually considered by investors are inputs of the system. The basic problem is to select appropriately the indicators which would give the best predictor. Two methods are used and compared: the combination method and the correlation method. To analyze the problem daily quotations of companies included in the Warsaw Stock Exchange Index (WIG20) are used.**

Keywords: Stock exchange, prediction, nonlinear modeling, neural networks, soft computing.

I. Introduction

NEURAL networks [5] are universal approximators [6]. It means that a network with at least one hidden layer is capable of approximating any nonlinear smooth function to an arbitrary accuracy (provided that the number of hidden units is sufficient enough). Multilayer perceptron neural networks are most common. As the practical experience indicates, they can be successfully used in numerous application, including e.g.: pattern recognition [1], [12], numerical methods [2], biomedical engineering [7], optimization [9], fault diagnosis [8], robotics [11], load forecasting in a power system [13] and control algorithms [14], [15]. Neural network can be also used in financial forecasting [4], [16]. Usually, a stock exchange time-series model is trained the role of which is to predict the future price of shares. Although such a "black-box" approach is commonly used in system identification but it is completely different from the classical technical analysis methods [3], [10] popular in banks and in the financial community. In this work neural networks are used for developing an investment strategy. Unlike "black-box" approaches some technical analysis indicators are used as inputs of the system. Investors often consider those indicators before making decisions because they have intuitive interpretation. Because there are various indicators used in the technical analysis, the basic problem to solve is to select the indicators which would give the best predictor.

II. Description of the problem

One of the very interesting investment strategies is based on stock quotes. In some periods the stock quotes stabilize for some time and share price fluctuations are very small. Such a time period is named stagnation. It is not difficult to find such periods on the price chart because the value of the shares should be analyzed from the last 4 weeks (20 market days). From observations of the stock quotes it can be observed that they appear immediately after a period of stagnation followed by a sharp change in the value of shares (either upward or downward). The investment strategies frequently used by investors use the popular technical analysis indicators. The "buy", "sell" and "hold" decisions are made taking into account the values and behavior of selected indicators in periods of stagnation points of interest.

In this paper the investment strategy shortly described above leads to developing a neural network which would be able to serve as the decision support systems. The neural network uses the information represented by the classical technical indicators well understand by the investors. The objective of the neural network is to answer the question whether or not the investor should invest. To analyze the problem daily quotations of the last 10 years of the biggest 20 companies included in the Warsaw Stock Exchange Index (WIG20) are used. This choice was made due to the fact that the stock market of WIG20 is the most liquid, it allows for greater investment in less time.

For determination of important points associated with finding periods of stagnation of stock prices a time window of variable width of 20 days is used, which measures changes in the average value of the shares. It is assumed that the interesting point is when the change in value of the shares is greater than the average change in the time window, while the previous two trading points are characterized by below-average volatility of the window.

Fig. 1 shows the interesting points on the background of the graph of a company's share price. It can be observed that in the periods prior to the occurrence of these points there are periods of stagnation of stock prices, and in the near future from the important points share price rises or falls rapidly.

III. The neural predictor

The set of all points of interest is divided in half: the first part is the training data set for the neural network, the second part is the test data set.

From an analysis of all the points of interest it can be concluded that 93% of those points actually lie before significant changes of stock prices. The interesting points that lie before increases in the shares of companies described as positive points, but those points, followed by the decline in stock prices described as negative points. The analysis of points of interest is shown in Table I.

978-83-60810-53-8/$25.00

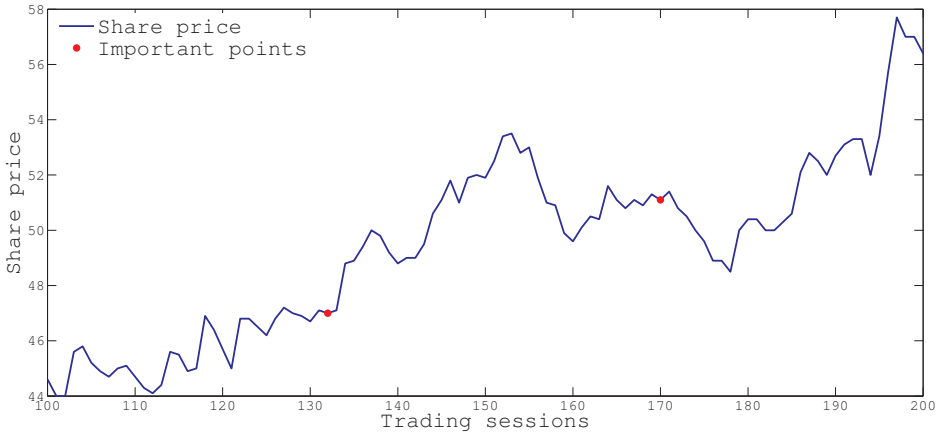

Fig. 1. Interesting points on the background of the graph of a company's share price

TABLE I
ANALYSIS OF A SET OF POINTS OF INTEREST

Data set	Positive points	Sum of all points	Good investments (%)
All data	1187	2251	52.73%
Training data set	582	1126	51.69%
Testing data set	605	1125	53.78%

While analyzing data from a set of points of interest one can identify a strategy that conventionally is called "the trivial strategy". It is based on the fact that if the investor finds an interesting point, he or she invests. The percentage of all positive points in the set of all points of interest is 52.73%. It means that if the investor uses any signal of an interesting situations to invest in the stock market, in 52.73% of such situations he or she would be successful.

It can be argued that "the trivial strategy" is "buy" and "hold". However, the art of investing in the stock market, which is characterized by quickly transfer money between investments so that the whole time money is working in an optimal way.

The task of the intelligent investor and the proposed neural decision support system is to analyze the points of interest, reject the situations that lead to losses, and recognize those that generate profit. In order to analyze the problem considered in the article it is necessary to answer the following questions:

1) Do the indicators proposed by the investors carry the necessary information that allows the choice of the positive points?
2) Are all the indicators proposed by the investors required to make the correct decision?
3) Is it possible to construct a computerized system of investment, which would give the results much better than the trivial strategy?

IV. CREATING A NEURAL NETWORK

A multi-layer perceptron neural network with nonlinear (tanh) hidden neurons and one linear output neuron is used for modeling. Due to the fact that the study is based on finding the correct classification of investment situation, in the output layer of neural network one linear neuron is used. When the network output gives a positive value, the investment situation is recognized as opportunity and the system suggests to invest. Whet the network output gives a negative value, the system suggests to omit the investment. The linear output neuron is chosen, because it can show general suggestion of investing or omitting the investment, but also magnitude of this signal can tell the investor if this investment situation is clear or it is difficult to take a decision. When the system gives a positive value, but this value is close to 0, the investor should be aware of the increased risk of this particular investment. On the other hand, when there is a big output value, it may suggest that the investment situation is clear and the risk is small. The risks is understood as the number of conflicting signals from the analyzed indicators. If a large majority of indicators generates the same signal, the risk of making a wrong decision is small.

The following assumptions are made:

1) All the indicators suggested by the investors are chosen as network inputs.
2) Neural network with different number of hidden nodes are trained and compared.
3) During training the network classification error is calculated for the training data set, the test data sets are used to finally choose the structure of the neural system.

The neural network are trained by means of the Levenberg-Marquardt algorithm. Initial experiments indicate that after 200 iterations of the training procedure the classification error stabilizes and further training does not bring better results. Thus, in all further experiments, the number of training iterations is 200.

Classification accuracy (percentage of hits in a good investment) for different number of hidden nodes is shown in Fig. 2. The network with 15 hidden neurons is finally chosen because it gives classification results better than the results obtained by means of all other networks (the test data set is taken into account). Smaller networks have low approximation abilities whereas bigger networks are overparameterized, they have too many parameters (weights).

The answers to the questions put above (in the previous section) require the study of the influence of the neural network inputs on the classification accuracy. Thus, the above questions are equivalent to the following:

1) Do the neural network input signals allow the classification and selection of positive points?
2) What is the number of inputs that allows the best classification and selection of positive points?
3) Does the best possible network achieves better results than the trivial strategy?

A. Technical analysis indicators used in the investment strategy

When one has a set of interesting points, the next step is to calculate the value of technical analysis indicators for the points. As recommended by investors from the Warsaw Stock Exchange, seven indicators are taken into account: the slow stochastic oscillator %K %D, the Moving Average Convergence-Divergence (MACD), the Commodity Channel Index (CCI), the Relative Strength Index (RSI), the three backward linear regression values for the 5, 10 and 15 days.

1) The slow stochastic oscillator %K %D (the 1^{st} *input):* Stochastic oscillator [3] is commonly used by traders. It tracks the relationship of each closing price to the recent high-low range. The stochastic oscillator consists of two lines: a fast line called %K and a slow line called %D. The first step is to calculate the %K from this equation:

$$\%\text{K} = \frac{C_{tod} - L_n}{H_n - L_n}$$

where C_{tod} – today's close, L_n – the lowest point for the selected number of days, H_n – the highest point for the selected number of days, n – the number of days. The second step is to obtain %D. It is done by smoothing %K over a three-day period:

$$\%\text{D} = \frac{\text{3-day sum of } (C_{tod} - L_n)}{\text{3-day sum of } (H_n - L_n)} \cdot 100$$

Fast stochastic oscillator is very sensitive to the returns on the market, but it leads to many erroneous signals. Many investors use the slow stochastic oscillator, which is less sensitive. The value of %D of fast stochastic oscillator becomes the %K of slow stochastic oscillator and is smoothed by repeating step 2 to obtain the value of %D of slow stochastic oscillator. An example slow stochastic oscillator is demonstrated in Fig. 3. The stochastic lines help identify top and bottom areas when they move above or below their reference lines. The stochastic oscillator gives its best signals when it diverges from prices.

2) Moving Average Convergence-Divergence (the 2^{nd} *input):* The MACD index [3] consists of three Exponential Moving Averages (EMAs). It appears on the charts as two lines whose crossovers give trading signals. The original MACD indicator consists of two lines: a solid line (called the MACD line) and a dashed line (called the signal line). The MACD line is made up of two Exponential Moving Averages. It responds to changes in prices quickly. The signal line is made up of the MACD line smoothed with another Exponential Moving Average. It responds to changes in prices more slowly. Fig. 4 demonstrates an example MACD index. To create MACD one has to:

1) calculate a 12-day EMA of closing prices,
2) calculate a 26-day EMA of closing prices,
3) subtract the 26-day EMA from the 12-day EMA, and plot their difference as a solid line (it is the fast MACD line),
4) calculate a 9-day EMA of the fast line and plot the result as a dashed line (it is the slow Signal line).

When the fast MACD line crosses above the slow signal line, it gives the "buy signal". When the fast line crosses below the slow line, it gives the "sell signal".

3) Commodity Channel Index (the 3^{rd} *input):* The CCI [10] is an oscillator originally developed by Donald Lambert. Since its introduction the indicator has grown in popularity and it is now a very common tool for traders to identify cyclical trends. The CCI was developed to determine overbought and oversold levels. It is done by measuring the relation between price and a moving average (MA), or, more specifically, normal deviations from that average. The value of the CCI is calculated from

$$\text{CCI} = \frac{1}{0.015} \cdot \frac{p_t - \text{SMA}(p_t)}{\sigma(p_t)}$$

where p_t – typical price (average of the maximum price, minimum price and closing price), SMA – the arithmetic moving average, σ – the absolute deviation. Fig. 5 demonstrates an example CCI index.

Possible "sell" signals are:

- the CCI crosses above 100 and has started to curve downwards,
- there is bearish divergence between the CCI and the actual price movement, characterized by downward movement in the CCI while the price of the asset continues to move higher or moves sideways.

Possible "buy" signals are:

- the CCI crosses below -100 and has started to curve upwards,
- there is a bullish divergence between the CCI and the actual price movement, characterized by upward movement in the CCI while the price of the asset continues to move downward or sideways.

4) Relative Strength Index (the 4^{th} *input):* The RSI index [3] measures the strength of any trading vehicle by monitoring

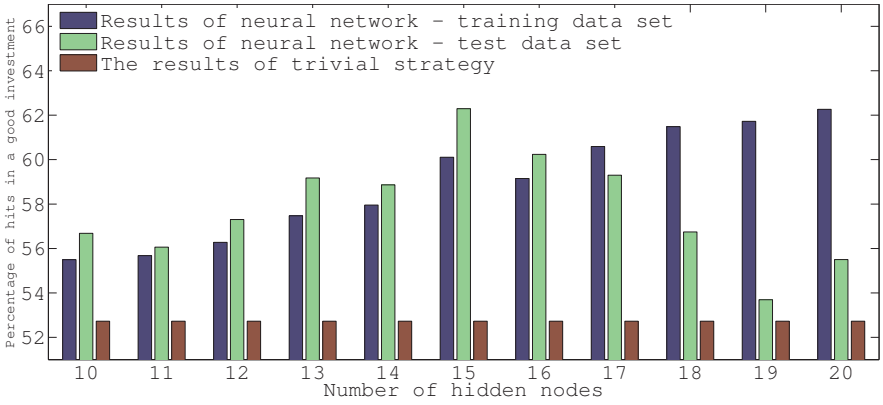

Fig. 2. Testing different structure of neural network

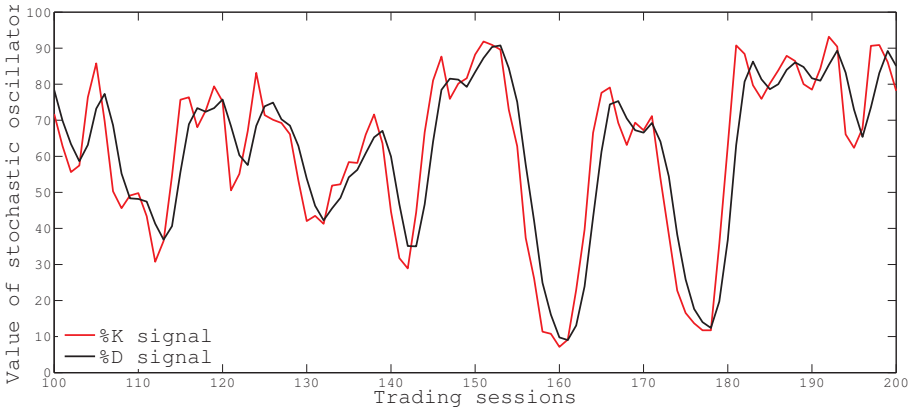

Fig. 3. The example slow stochastic oscillator

changes in its closing prices. It is a leading indicator, it is never a laggard. Its value is

$$\mathrm{RSI} = 100 - \frac{100}{1 - \mathrm{RS}}$$

where

$$\mathrm{RS} = \frac{\text{average of net UP closing changes for n days}}{\text{average of net DOWN closing changes for n days}}$$

The RSI fluctuates between 0 and 100. When RSI reaches a peak and turns down, it identifies a top. When RSI falls and then turns up, it identifies a bottom. Fig. 6 demonstrates an example RSI index.

Divergences between RSI and prices give the strongest "buy" and "sell" signals. They show when the trend is weak and ready to reverse. Horizontal reference lines must cut across the highest peaks and the lowest valleys of RSI. They are often drawn at 30 and 70.

Bullish divergences give "buy" signals. They occur if prices fall to a new low but RSI makes a more shallow bottom than during its previous decline. One buys as soon as RSI turns up from its second bottom. "Buy" signals are strong if the first RSI bottom is below its lower reference line and the second bottom is above the line.

5) Backward linear regressions (the 5^{th}*,* 6^{th} *and* 7^{th} *inputs):* The last information that investors take into account are backward linear regressions. Based on trading behavior in the recent past, investors are trying to guess the future behavior of the market. Three backward linear regressions are taken into account: 5, 10 and 15 days. Investors are interested whether these regressions indicate an increasing or a decreasing trend. The relationships between these trends suggest further course of trading stocks. Fig. 7 shows the example trends of the linear regressions of the corresponding points of interest.

One of the basic rules used by investors is to invest in accordance with the medium-term trend when the linear regressions of 15 and 10 days reference the same trend. Fig. 7 shows two interesting points, one of which meets the above condition. Linear regressions 15 and 10 days for the second point shows the different trends, so there is a signal to omit the investment.

6) Network output – 21 days forward linear regression: All the indicators describing the selected points of interest are enough for investors to make a decision to proceed with the investment or its omission. In the case of neural network modeling the given signal is used which indicates whether the situation related to the point, in fact, is an important investment

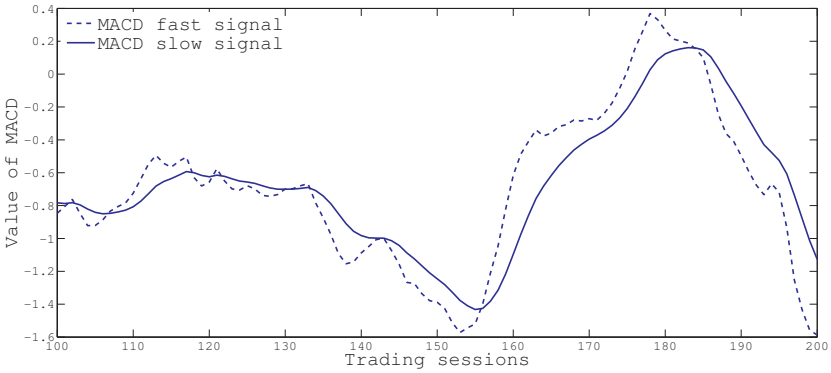

Fig. 4. The example Moving Average Convergence-Divergence (MACD) index

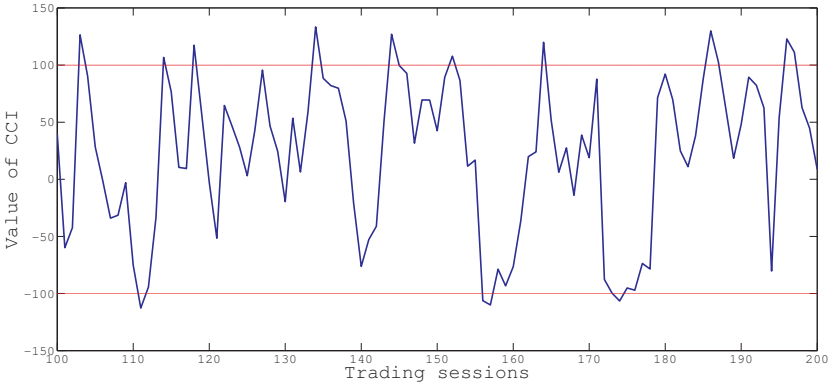

Fig. 5. The example Commodity Channel Index (CCI)

situation (it is possible to make money on it) or not. The investment horizon is also determined by investors and its value is 21 days. The linear regression is used to check if at the relevant time horizon value of the shares is in an uptrend or not. An example of the 21 days forward linear regression is shown in Fig. 8.

V. The Choice of Inputs of the Neural Predictor

The basic problem is therefore the choice of inputs of the neural network and determination how many inputs and how their combination allows to achieve the best results. Two approaches which make it possible to choose the inputs of neural networks are discussed. Those methods were chosen to represent the exemplary approach to solve the problem, but there is a whole class of different approaches that can give different results. In the first method all possible combinations of inputs are considered, neural models are trained, compared, and finally the best model is selected which produces the best results. The second method is based on the elimination of inputs approach, which are most correlated with the rest of the inputs. The numerical results are given only for the test data set, the training data set is used only for training.

A. The combination method

Table II shows the results of the conducted experiments. It is interesting that the best results are achieved with 5 inputs of neural network, which included the stochastic oscillator %K %D, oscillator MACD, RSI index and backward regressions 5 and 10 days. The best result of the neural network for the 5 inputs is 67.42% accurate decisions on positive points. When the neural network suggests that analyzed point of interest is the negative point, the investment decision is the omission of buying the shares. Otherwise, the neural network over 67% of the time classified as a positive point of interest properly. The result is much better than the result of the trivial strategy.

In the case of neural networks operating with all the inputs indicated by the investor, the result is clearly worse but still higher than the result of a trivial strategy. Therefore one can conclude that the two indices that analyze the investors, in fact, do not bring valuable information and even obscure the decision-making situation. It is likely that the CCI indicators and backward linear regression for 15 days carry conflicting information from other indicators, which makes the classifier more was wrong, when all indicators are taken as inputs.

Comparison of the results of the neural network and trivial strategy is shown in Fig. 9. It is worth noting that the neural networks of the worst matched inputs achieve results far worse than trivial strategy and is approximately 40%. It is an experimental proof that a key consideration is the choice of set of inputs, and that from the proposed inputs by investors there are combination which gives very bad results.

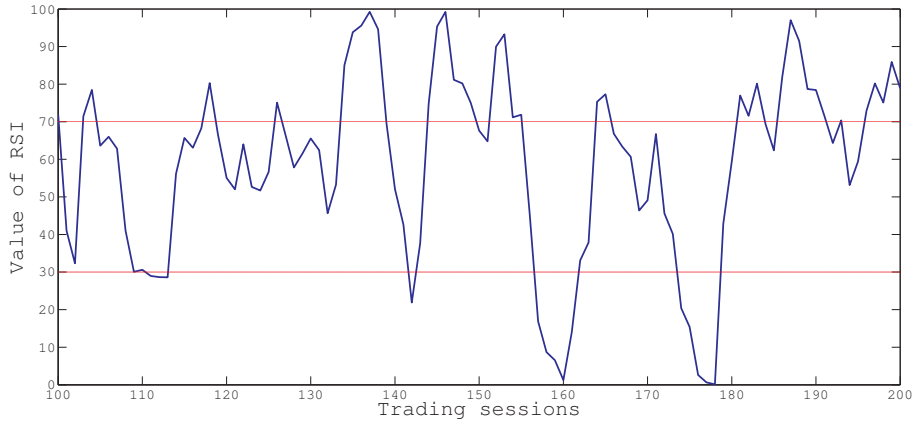

Fig. 6. The example Relative Strength Index (RSI)

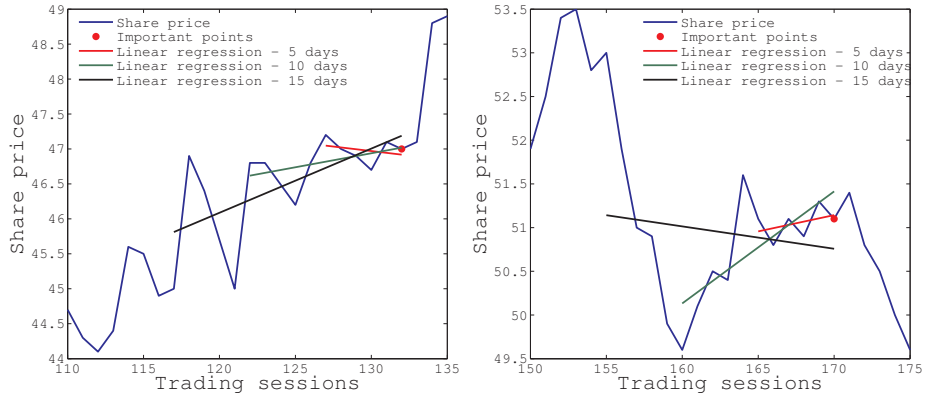

Fig. 7. The backward linear regression for 5, 10 and 15 days

TABLE II
THE RESULTS OF THE NEURAL NETWORK FOR THE BEST COMBINATION OF INPUTS

Number of inputs	Best inputs	Positive points found	Good investments (%)
1	4	312	60.00%
2	2 7	388	60.95%
3	2 4 6	377	63.33%
4	2 5 6 7	368	63.57%
5	1 2 4 5 6	300	67.42%
6	1 2 3 4 5 6	329	65.93%
7	1 2 3 4 5 6 7	377	62.29%

B. The correlation method

Although in the combination method the best result can be found, as many as 1270 neural networks are learned, which takes a lot of time.

The correlation method of selecting the inputs of the neural network consists of eliminating inputs that are most correlated with other inputs. This method is based on the belief that inputs that are correlated with each other can be removed, and the other inputs take over the role of the removed inputs. Following this rule it is sufficient to examine the correlation between all inputs, and then eliminate the ones that carry the most common information with other inputs. The optimal set of inputs for each number of inputs is given in Table III. One may conclude that the achieved results are not optimal. It should be noted, however, that the best combination of inputs determined by this method differs a little from the optimum. The process of elimination gives the best result of the neural network with 5 inputs, which corresponds to the best global result. Selection of inputs is also very similar, because only one indicator is only different.

Computing effort of the second method is much smaller than searching all possible combinations of inputs of neural networks. Fig. 10 shows the results of this method against the results of a trivial strategy. Referring to the results of

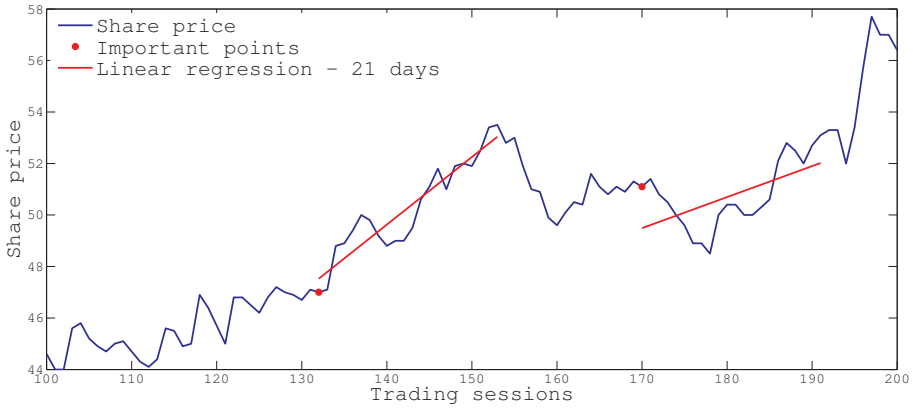

Fig. 8. The output of neural network – 21 days forward linear regression

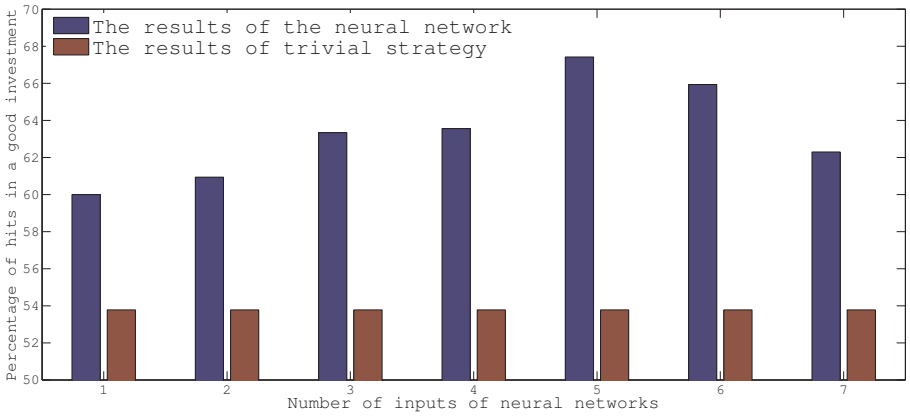

Fig. 9. The percentage of good results depending on the number of inputs of the neural network

TABLE III
THE RESULTS OF NEURAL NETWORK THE LEAST CORRELATED INPUTS COMBINATIONS

Number of inputs	Best inputs	Positive points found	Good investments (%)
2	1 4	338	60.14%
3	1 4 6	303	60.00%
4	1 3 4 6	357	60.61%
5	1 3 4 5 6	279	62.48%
6	1 3 4 5 6 7	373	59.39%
7	1 2 3 4 5 6 7	377	62.29%

the strategy proposed by the investors one must concede that the results obtained by the method of elimination of most correlated inputs are a little better from the results when all indicators are used, as suggested by the investors.

C. Comparison of methods

To compare the two methods used for the selection of neural network inputs it is necessary to look into the results from two perspectives. First, the combination method, of course, gives the best results. The method of eliminating most correlated inputs also brings good results, but it fails to find solutions much better than the approach suggested of investors. Secondly, considering the computational burden necessary to carry out all experiments, one can see the undoubted advantage of the second approach. Both methods brought similar results, so it can be concluded that the impact on the result of the trend predictor is associated with the selection of uncorrelated inputs that carry a consistent information. Fig. 11 shows a comparison of the results of both methods.

VI. SUMMARY

This paper describes the development of the neural investment strategy system. In order to determine the best set of the model inputs the two methods are compared: the neural networks for all possible combinations of inputs can be evaluated or the elimination method can be used. The first

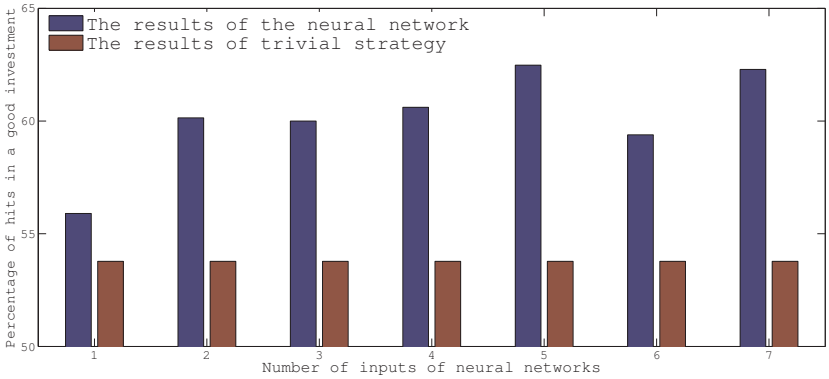

Fig. 10. The percentage of good results in correlation method

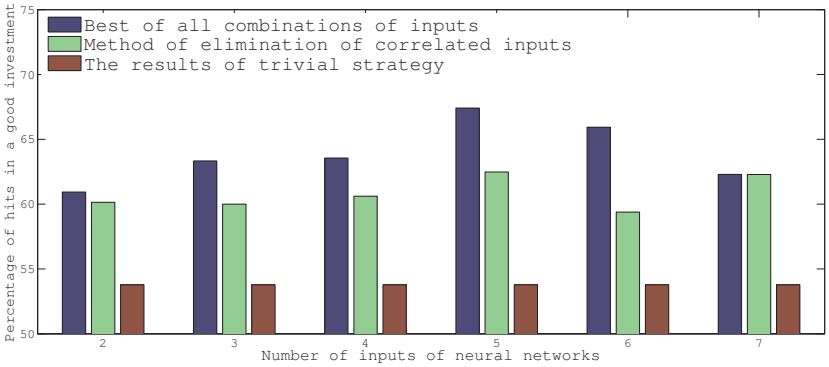

Fig. 11. Comparison of methods for the selection of inputs of neural network

method makes it possible to find the best model, but is very time consuming since as many as 1270 neural networks must be trained. The second method is much more effective and practically gives the neural model of the same accuracy.

It is necessary to emphasize that the discussed investment strategy is based on both the economic knowledge and intuition. The neural predictors are not entirely "black-box" time-series models, but technical analysis indicators are used as the input signals. The obtained experiments shows that the selected indicators make it possible to obtain 62% of investment efficiency. When the number of indicators is reduced, the neural system is able to realize investment decisions of 67% success rate, which indicates that the redundant indicators could give wrong signals to investors.

International Workshop on Artificial Intelligence in Medical Applications

THE workshop on Artificial Intelligence in Medical Applications – AIMA'2013 - provides an interdisciplinary forum for researchers and developers to present and discuss latest advances in research work as well as prototyped or fielded systems of applications of Artificial Intelligence in the wide and heterogenious field of medicine, health care and surgery. The workshop covers the whole range of theoretical and practical aspects, technologies and systems based on Artificial Intelligence in the medical domain and aims to bring together specialists for exchanging ideas and promote fruitful discussions.

The topics of interest include, but are not limited to:

- Artificial Intelligence Techniques in Health Sciences
- Knowledge Management of Medical Data
- Data Mining and Knowledge Discovery in Medicine
- Health Care Information Systems
- Clinical Information Systems
- Agent Oriented Techniques in Medicine
- Medical Image Processing and Techniques
- Medical Expert Systems
- Diagnoses and Therapy Support Systems
- Biomedical Applications
- Applications of AI in Health Care and Surgery Systems
- Machine Learning-based Medical Systems
- Medical Data- and Knowledge Bases
- Neural Networks in Medicine
- Ontology and Medical Information
- Social Aspects of AI in Medicine
- Medical Signal and Image Processing and Techniques

***Abstract*—Liver cancer is one of the major death factors in the world. Transplantation and tumor resection are two main therapies in common clinical practice. Both tasks need image assisted planning and quantitative evaluations. An efficient and effective automatic liver segmentation is required for corresponding quantitative evaluations. Computed Tomography (CT) is highly accurate for liver cancer diagnosis. Manual identification of hepatic lesions done by trained physicians is a time-consuming task and can be subjective depending on the skill, expertise and experience of the physician. Computer aided segmentation of CT images would thus be a great step forward to scientific advancement for medical purposes. The sophisticated hybrid system was proposed in this paper which is capable to segment liver from abdominal CT and detect hepatic lesions automatically. The proposed system based on two different datasets and experimental results show that the proposed system robust, fastest and effectively detect the presence of lesions in the liver, count the distinctly identifiable lesions and compute the area of liver affected as tumors lesion, and provided good quality results, which could segment liver and extract lesions from abdominal CT in less than 0.15 s/slice.**

I. Introduction

THE LIVER cancer is one of the most common internal malignancies worldwide and also one of the leading death causes. Early detection and accurate staging of liver cancer is an important issue in practical radiology. Liver lesions are a wound or injury to body tissues. It is the area of tissue that caused damage because a wounding or disease. Liver lesions refer to those abnormal tissues that are found in the liver. In a CT scan these can be identified by a difference in pixel intensity from that of the liver. Manual segmentation of this CT scans are tedious and prohibitively time-consuming for a clinical setting. Automatic segmentation on the other hand, is a very challenging task, due to various factors, such as liver stretch over 150 slices in a CT image, indefinite shape of the lesions and low intensity contrast between lesions and similar to those of nearby tissues. The irregularity in the liver shape and size between the patients and the similarity with other organs of almost same intensity make automatic liver segmentation difficult [1, 2].

Several studies have developed various algorithms that can be categorized on the degree of automation (fully, semi or interactive) and in two approaches: region-based or contour-based. Region-based segmentation is commonly based on intensity of neighbour pixels. While contour-based segmentation includes geometrical or statistical active shape model. Each of these approaches has its advantages and disadvantages in terms of applicability, suitability, performance, and computational cost [3,4].

Particularly, no one who did not consider above characteristics of the abdominal CT image can meet desirable results on liver segmentation. In addition, the traditional method of getting volume of the liver is to perform a by-hand 2D segmentation of parallel cross-sectional CT slices and to multiply all voxels of the stacked slices by their size while the procedure is often time consuming and non-systematic [5].

Therefore, to address the above mentioned problems, we present fully automatic liver segmentation and detection algorithms in abdominal CT images based on a hybrid approach using an adaptive threshold, morphological operators and Connected Component Labelling algorithm (CCL) to segment liver parenchyma from abdominal CT and Watershed algorithm coupled with Region Growing algorithm to extract lesions from liver parenchyma. The hybrid system is proposed to improve the segmentation performance and time consuming compared with the conventional process. The proposed approach starts with search for suitable abdominal liver CT image from DICOM file, and then this suitable image is passed to a filter to enhance and remove noise, and finally passing to segmentation algorithm to segment the whole liver then passed to hybrid segmentation system to extract hepatic lesions.

978-83-60810-53-8/$25.00

The process of segmentation is done in two phases. The first phase aimed to segment liver parenchyma from abdominal CT, this phase consist of three steps. The first step is to convert CT image into binary image using adaptive threshold that examine the intensity values of the local neighbourhood of each pixel. The second step is to apply multi-scale morphological operators to filter tissues nearby liver, to preserve the liver structure and remove the fragments of other organs. The third step is a CCL algorithm to remove small objects and false positive regions. The second phase aimed to segment and extract lesions from liver parenchyma which is segmented in first phase, in this phase integration between segmentation algorithms was applied to boost and increase the efficiency of segmentation behaviour. Marker-controller watershed algorithm was applied to cluster liver and define ROI, after liver clustered using watershed, an adaptive region growing is integrated with watershed algorithm to increase the performance and accuracy of segmentation. This system was tested on two different datasets. Good results were obtained in terms of quality and less processing time of the segmentation operation.

The reminder of this paper is ordered as follows. Section II discusses the previous work on liver segmentation. Details of the proposed methods and datasets are given in Section III. The proposed system is presented in Section IV. Section V shows the experimental results and analysis. Finally, Conclusion and future work are discussed in Section VI.

II. Previous Work

Several researchers have focused their attention on the use of threshold to segment liver. Massoptier and Casciaro [6] used adaptive thresholding to detect livers and refined the segmentations by graph cut. Campadelli et al. [7] detected livers by using heart segmentation information and then used adaptive thresholding and morphology as an alternative to graph cut to segment livers. Masumoto et al. [8] utilized conventional thresholding in multi-phase images to delineate the liver. Rusko et al. [9] mainly used region-growing with various pre-processing and post-processing steps to segment liver. Extracting regions of interest (ROIs) requires a sharpening filter to stress the regions edges [10]. Kumar and Moni [11] proposed their thresholding and morphological operator based algorithm to segment liver from abdominal CT image slices. Susomboon et al. [12] proposed a hybrid approach consisted of intensity based partition, region-based texture classification, connected component analysis and thresholding for liver segmentation. Massieh et al. [13] proposed an automatic region growing method that incorporates fuzzy c-means clustering algorithm to find the threshold value and modified region growing algorithm to find seed point automatically. However, their approach is very time consuming. In contrast with active shape models, Seghers et al. [14] incorporated both local intensity and local shape models for liver segmentation. Wan Nural and Hans Burkhardt [15] used Integration of Morphology and Graph-based Techniques for liver segmentation. Abdalla et al. [16], proposed new combined approach level set and watershed approach for CT liver segmentation to separate the liver from other organs and obtained overall accuracy of 92%. Shweta and Sumit [17] proposed level set segmentation technique using Variational Level Set Formulation techniques without initialization with various filtering methods. It was found that maximum filter provided the best results on the samples of the segmentation of CT images.

Jeongjin et al. [18] applied two steps of seeded region growing onto level-set speed images to define liver region. Ruchaneewan etal. [19] used intensity-based partition and region-based texture to segment liver. Abdalla et al. [10] Proposed for segment and isolate the liver region of interest using a region growing segmentation approach, and achieved highest performance for contrast stretching filter.

III. Martials and Methods

CT scanning is a diagnostic imaging procedure that uses X-rays in order to present cross-sectional images ("slices") of the body. The proposed system will be work on two different datasets: First dataset has divided into seven categories depends on the tumour type of benign (Cyst (CY), Hemangioma (HG), Hepatic adenoma (HA), and Focal nodular hyperplasia (FNH)) or malignant (hepatocellular carcinoma (HCC), Cholangiocarcinoma (CC), and Metastases (MS)), each of these categories have more than fifteen patients, each patient has more than one hundred slices, and each patient has more than one phases of CT scan (arterial, delayed, portal venous, non-contrast), also this dataset has a report diagnosis for each patient. All images are in JPEG Format selected from DICOM file and have Dimensions 630 x 630 with horizontal and vertical resolution of 72 DPI and bit depth 24 bit. All CT images captured from Radiopaedia web site [19].

For the second dataset, the data is acquired on a GE Discovery ST with the breathing trace provided by a Varian RPM system, and processed by a Varian 4D workstation. Information found in series description DICOM tag [0008,103E], T=0% is end-inhale and T=50% end-exhale. Livers and liver tumours CT images are manually segmented by five expert radiologists. These datasets are provided by Dr. Kevin Cleary at the Imaging Science and Information Systems (ISIS) Center from the Georgetown University Medical Centre [20].

A. Pre-Processing

The main objective of image pre-processing is to enhance, smoothness, remove noise that caused by defects of CT scanner, improve quality and emphasizes certain features of an image so that it makes segmentation or recognition easier and more effective. Filtering is a key pre-processing technique used for various effects including contrast stretching, sharpening and smoothing. In this paper, the effective filtering techniques were evaluated and analysed to modify, smooth the image and to enhance the efficiency of proposed algorithm. Pre-processing of Liver CT's are typically aimed at either improvement of the overall visibility of features or enhancement of a specific sign of malignancy also morphological operators

based algorithm is sensitive to noise, for these reasons pre-processing and filters is very important for liver images.

B. Liver segmentation methods

Segmentation of the liver and hepatic lesions from abdominal CT image is difficult. Therefore, a system is developed to extract liver and lesions automatically with sophisticated hybrid technique. To achieve the segmentation process, the following methods was proposed:

1) Adaptive thresholding Technique

Global thresholding, local adaptive thresholding are used to separate the desirable foreground image objects from the background based on the difference in pixel intensities of each region. Global thresholding uses a fixed threshold for all pixels in the image and therefore works only if the intensity histogram of the input image contains neatly separated peaks corresponding to the desired subject(s) and background(s). Hence, it cannot deal with images containing, a strong illumination gradient. Local adaptive thresholding, on the other hand, selects an individual threshold for each pixel based on the range of intensity values in its mean of local neighbourhood. This allows for thresholding of an image whose global intensity histogram doesn't contain distinctive peaks. Adaptive thresholding is more sophisticated and accommodate changing lighting conditions in the image. This approach is used for finding the local threshold to statistically examine the intensity values of the local neighbourhood of each pixel. This method is simple, fast and less computationally intensive and produces good results for CT liver images.

2) Morphological Operator-based Algorithm

A morphological processing is an obvious choice to refine the segmentation. The main idea of morphological operators is to detect the object forms or shapes from the images based on a set of pre-defined structuring elements. Usually a set of structuring elements (SE) is based on the prior knowledge, and then some morphological operators apply structuring elements to images [21]. Dilation and erosion are the two main morphological processing. Dilation expands objects by a structuring element, filling holes, and connecting disjoint regions. Erosion deletes the small region by a structuring element. Morphological operations based algorithm has several advantages. First it does not need any specific initialization, which makes it possible to design the fully-automatic algorithms. Second it focuses less on the structure of the object of interest. Therefore, it can work well on the liver whose structure varies between different persons.

3) Connected Component Labeling algorithm(CCL)

CCL works by scanning a binary image pixel by pixel (from top to bottom and left to right) in order to identify connected pixel regions [22]. The result of applying an adaptive threshold is a collection of different regions, applying morphological operators to preserve the liver structure and remove the fragments of other organs, but still some regions not interested to be liver will be removed by post-processing approach CCL. The largest region extracted by using CCL, it is used to label the separate regions in CT, yielding a new labelled image. In general, this algorithm is useful to find non-connected objects in images.

C. Lesions segmentation methods

In this phase we used two different methods to extract lesions. Watershed algorithm as edge-based image Segmentation and Region Growing (RG) algorithm as region-based image Segmentation.

1) Watershed Algorithm

Separating lesions from liver image is one of the more difficult processing operations. The watershed transform is often applied to this problem. Watershed image segmentation can be regarded as an image in three dimensions (two spatial coordinates versus intensity). We will use three types of point which "minimum", "catchment basin", and "watershed line" to express a topographic interpretation. Watershed algorithm has an advantage that it is fast speed. While disadvantages of this algorithm is over-segmentation results, to solve this problem used marker-controlled for watershed Segmentation.

The watershed marker finds "catchment basins" and "watershed ridge lines" in an image by treating it as a surface where light pixels are high and dark pixels are low. Segmentation using the watershed marker works better if you can identify, or "mark," foreground objects and background locations. Marker-controlled watershed segmentation follows this basic procedure:

1. Use a smoothing filter to pre-process the original image, then the action can minimize the large numbers of small spatial details.

2. Compute a segmentation function. This is an image whose dark regions are the objects you are trying to segment.

3. Compute foreground markers. These are connected blobs of pixels within each of the objects.

4. Compute background markers. These are pixels that are not part of any object.

5. Modify the segmentation function so that it only has minima at the foreground and background marker locations.

6. Compute the watershed transform of the modified segmentation function.

2) Region Growing Algorithm

The region growing (RG) algorithm is one of the simplest region-based segmentation methods. It performs a segmentation of an image with examine the neighboring pixels of a set of points, known as seed points, and determine whether the pixels could be classified to the cluster of seed point or not [22].The advantages of this algorithm is simplest, can correctly separate the regions of same properties, give good shape matching of its results. The algorithm procedure is as follows.

Step1. Start with a number of clusters and seed points which have been identified from watershed algorithm, cluster called C_1, C_2,...., C_n. And the positions of initial seed points is set as P_1, P_2,....., P_n.

Step2. To compute the difference of pixel value of the initial seed point pi and its neighboring points, if the difference is

smaller than the threshold criterion that define, the neighboring point could be classified into C_i, where i = 1, 2,....,n.

Step3. Recompute the boundary of C_i and set those boundary points as new seed points pi (s). In addition, the mean pixel values of C_i have to be recomputed, respectively.

Step4. Repeat Step 2 and 3 until all pixels in image have been allocated to a suitable cluster.

The mean drawback of RG is initial seed-points. The initial seed-points problem means the different sets of initial seed points cause different segmentation results. This problem reduces the stability of segmentation results from the same image. Furthermore, how many seed points should be initially decided is an important issue because various images have individually suitable segmentation number. These problems will be handled in this paper by integrated RG with watershed algorithm.

IV. Proposed System

The proposed fully automatic technique and methods to segment liver structure and lesions from abdominal CT divided into two phases liver structure segmentation and lesions segmentation. The first phase of liver parenchyma segmentation from abdominal CT is comprised of five fundamental building steps as seen in Figure 1. The first step searches for suitable slices in CT DICOM file because liver intensity distribution is different between slices. Liver parenchyma is the largest abdominal object in middle slices. These slices are suitable for segmentation and give high accuracy.

Pre-processing step: In this step pre-processing algorithm is used before the segmentation phase to enhance contrast, remove noise and emphasize certain features that affect segmentation algorithms and morphology operators.

Adaptive threshold step: In this step CT image is converted into binary image using adaptive threshold method that examines the intensity values of the local neighbourhood of each pixel.

Morphological Operators step: After the CT image is converted into binary image using adaptive threshold, morphological operators will be applied to filter tissues nearby liver, to preserve the liver structure and remove the fragments of other organs.

Connected Component Labeling phase: CCL algorithm is used to remove small objects, false positive regions and focused on liver parenchyma.

The second phase of liver lesions segmentation and extraction aimed to integrate between watershed algorithm and RG to boost and increase the performance of segmentation. Watershed used to segment liver into different regions and solving the problem of over-segmentation using watershed marker. RG used to improve watershed segmentation using the clusters and centroid point for each cluster in watershed as seed point for RG.

V. Experimental Results

Hybrid system was used to segment liver structure from abdominal CT. The reason to do these hybrid methods was that each method as such has problems, which the other method does not have. The proposed hybrid system divided into two phases. In the first phase suitable abdominal CT slice image of a patient with liver lesions was selected from DICOM file. Liver parenchyma is the largest abdominal object in middle slices as shown in Figure 2(a). Pre-processing median filter is used to enhance, remove noise and emphasize certain features that affect segmentation algorithms and morphology operators with 3x3 window as shown in Figure 2(b). After pre-processing stage, the hybrid segmentation based on adaptive threshold algorithm is applied on enhanced abdominal CT as shown in Figure 2(c). The adaptive threshold used the mean of the local intensity distribution to decide whether a pixel belongs to an organ of interest based on its neighboring features. Output is a binary image with the mean of local threshold. This mean of the local area is not suitable as a threshold, because the range of intensity values within a local neighborhood is very small and their mean is close to the value of the center pixel. The quality of adaptive threshold was improved by using static coefficient factor for all slices to increase performance. This method is simple, fast, less computationally intensive and produces good results for all slices.

After applying adaptive threshold, the morphological erosion and dilation operator with the shape and size of structuring element (SE) was used to shrink and remove small regions and extract liver from abdominal CT as shown in Figure 2(d). The experimental results show that the best shape

is diamond with SE size value 4. The shape and size of SE is decided after analyzing many Liver CT's. After applying morphological operators, post-processing CCL is applied on adaptive threshold with 8-connected objects to search for the largest connected region, remove false positive regions and focus on the ROI as shown in Figure 2(e).

In the second phase, after liver parenchyma segmentation passed to watershed to segment liver into distinct regions. Watershed approach combines the edge detection and region growing approaches, producing more stable results and connected boundaries. The main idea in watershed approach is to check whether one point belongs to one minimal, then it merges the point to it. Otherwise, the pixel is considered a boundary between the two minimal. This is done in a binary image using the morphological dilation. A huge number of potential minima of small objects in an image lead to over-segmenting problem. A smoothing filter should be used to eliminate that huge number. The simulation result of this algorithm has an advantage that it is fast speed. At the same time, it has a critical over-segmented problem, to solve this problem we use internal and external marker control to segment objects with closed contours, expressing the boundaries as ridges. Then pass this segmented liver to RG. The RG algorithm is used to improve watershed segmentation using the centroid point for each segmented region from watershed as seed point for RG. The region growing method had basically three problems, the rugged border, seeded point very difficult to assign it automatically for ROI and the leakage problem, but when combined with watershed gives accurate results as shown in Figure 3. The performance and accuracy of the proposed system was evaluated by Similarity Index technique (SI) between automated segmented images and manual segmented images.

The proposed hybrid system applied on 112 patients from different datasets with different hepatic lesions. The overall accuracy obtained is 0.93 for livers segmentation, and the proposed system applied on 860 abdominal CT slices achieved overall accuracy result 0.90. The proposed approach also gives acceptable accuracy of livers segmented with hepatic lesions are 0.94, 0.91, 0.91, 0.93, 0.95, 0.90, and 0.94 for CC, CY, FNH, HG, HA, HCC, and MS respectively as shown in Figure 4. In Figure 5, the proposed system also measures the segmentation accuracy of abdominal CT phases (arterial, delayed, portal venous, and non-contrast) for hepatic lesions. The better segmentation accuracy was achieved in portal venous phase, while arterial phase gives non accurate results in Hepatocelleour Carcinoma. This is because the nature of livers tissue which are ambiguous in this phase.

Comparing the results of proposed system with other previous work on CT liver segmentation from abdominal CT as shown in Table 1. The proposed approach is fast, precise, robust and provides good quality results and there is no meaningful loss of information, which could segment liver and extract lesions from abdominal CT in less than 0.15 s/slice

when implemented in Matlab on PC Intel Core I5, 2.5GHz with 4GBytes of RAM.

VI. Conclusion and Future Work

The presented system for segmentation and liver lesions extraction is able to reliably segment and extract the lesions in the used patient database. Liver segmentation is a complicated process which consists of many steps for segmentation process. Integration between edge-based segmentation and region-based segmentation methods give more reliable and trust segmentation. The experimental results show that it is a robust proposed algorithm and obtained 93% of good extraction for liver from abdominal CT.

In conclusion, our results suggest that ensemble segmentation is effective in segmentation of livers and liver lesions, boosting and increasing the performance of weak segmentation processes.

In future work, we plan to assess the performance using a large dataset to evaluate generalization performance of the algorithm that includes a number of parameters in the feature measurement process, which means it might sensitive to size and characteristics of lesions.

***Abstract*—The diabetic retinopathy disease spreads diabetes on the retina vessels thus they lose blood supply that causes blindness in short time, so early detection of diabetes prevents blindness in more than 50% of cases. The early detection can be achieved by automatic segmentation of retinal blood vessels in retinal images which is two-class classification problem. This paper proposes two improvements in previous approach uses ant colony system for automatic segmentation of retinal blood vessels. The first improvement is done by adding new discriminant feature to the features pool used in classification. The second improvement is done by applying new heuristic function based on probability theory in the ant colony system instead of the old that based on Euclidean distance used before. The results of improvements are promising when applying the improved approach on STARE database of retinal images.**

I. Introduction

THE DIABETIC retinopathy is the most common cause of blindness worldwide since the blindness occurs as a result of retina death due to loss of blood supply by the widely spread diabetes on it [1]. The blindness brings significant costs both to individual and society. There are two types of diabetic retinopathy; the first type is the non-proliferative diabetic retinopathy where the capillaries of retina swell and interfere with normal vision. The second type is the proliferative diabetic retinopathy where the capillaries of retina shut down. In both types, the diabetic retinopathy usually leads to retina revascularization [2]. So the segmentation of blood vessels in retinal images is an important step in treatment of diabetic retinopathy. Also there are many other diseases are often diagnosed based on their changes on reflectivity, bifurcations and tortuosity of retinal blood vessels such as hypertension [3]. Retinal blood vessels segmentation is also the core stage in automated registration of two retinal blood vessels images of a certain patient to follow and diagnose his disease progress at different times [4]. The retinal blood vessels segmentation is a classification problem where each pixel in the field of view of retinal image is classified as vessel-like or non-vessel. The manual segmentation of retinal blood vessels is a long and tedious task which also requires training and skill. So, for the last two decades, the automated retinal blood vessels segmentation attracts a lot of research in the medical image processing area since it's the critical component of circulatory blood vessel analysis systems [5]. The Reliable automated retinal vessel extraction encounters several challenges [6]: "(1) The blood vessels have a wide range of widths from very large (15 pixels) to very small (3 pixels) and diffident bifurcations. (2) Various structures appear in retinal image, including the optic disc, fovea, exudates and pigment epithelium changes, which severely disrupt the automatic vessel extraction. (3) The narrow vessels with various local surroundings may appear as some elongated and disjoint spots, which are usually lost. (4) The vessels intensity contrast is weak and variant and the small vessels especially are overwhelmed by Gaussian-like noises".

This paper proposes two improvements of the previous approach [7] used for automatic segmentation of blood vessels in retinal images based on the ant colony system (ACS) [8]. The improvements are performed in two ways, first adding new discriminant feature to the features pool to be consisted of fifteen features and second applying new heuristic function in ACS. The features pool consists of features that are simple, fast in computation, needn't to be computed at multiple scales or orientations and highly discriminate between vessels and background in retinal images [9]. These features are based on gray-level of the green image of retina, gray-level of computed vessels-enhanced image and Hu moment-invariants [10]. Since the large number of computed features increases the classification complexity, time and reduces its accuracy, so feature selection is an essential step for successful classification because it removes irrelevant features and achieves less complex, more accurate and faster classification. In this paper, the correlation based feature selection heuristic (CFS) [11] is used and it reduced the features set from fifteen to the best four features set. The performance of this improved approach is evaluated on a publicly available STARE database of retinal images [12] for scientific research in terms of the sensitivity, specificity and accuracy. Thus it's the first paper that tests ACS performance on STARE database. The rest of this paper is organized as follows: Section II surveys the previous popular related work. Section III presents scientific background on

978-83-60810-53-8/$25.00

the used features, CFS and ACS. Section IV presents the proposed approach and its improvements. In section V, there are experimental results. Finally in Section VI, conclusions and directions for future research are presented.

II. Related Work

The automatic segmentation methods of retinal blood vessels are categorized into supervised and unsupervised. In this section, short survey of popular retinal blood vessels segmentation methods from two categories is presented. This short survey shows how these methods were developed in the last two decades. For the supervised methods, they depend on pixel classification into vessel class or non vessel class using a classifier previously trained on manually-labelled samples by ophthalmologists from two classes. So these methods depend on pre-classified data which mayn't be available in real life applications. Also there are significant differences between ophthalmologists themselves in delineation of blood vessels. The training makes these methods give better performance than unsupervised methods especially in healthy images. Staal et al. [13] used KNN-classifier with 27-D feature vector based on ridges information. Their method depends on extracting ridges in the image, forming line elements from ridges, assigning each pixel to nearest line to partition image into patches and computing features vector of each pixel based on its line and patch attributes. Then the feature vector reduced to those result in best class separability by sequential forward selection algorithm. Ricci and Pefetti [14] used 3-D feature vector consists of the inverted gray-level of green color plus the two maximum responses of two orthogonal line detectors rotated in twelve angles and their classifier was the support vector machine (SVM). Marin et al. [9] used 7-D feature vector consists of five features encode gray-level variation between pixel and its surroundings plus other two features based on Hu moment-invariants and their classifier was the neural network (NN). Fraz et al. [15] used 9-D feature vector consists of the inverted gray-level of green color, the sum of gradient orientation maps at three scales, sum of tophat transform responses in eight directions using linear structure element, the two maximum responses of two orthogonal line detectors rotated in twelve angles and the four maximum responses of Gabor filter rotated in ten angles at four scales. They used an ensemble classifier from two-hundred bagged and boosted decision trees.

For the unsupervised methods, they are classified into methods based on mathematical morphology, vessel tracking, matched filter, bio-inspired algorithms and active contour. For the methods based on mathematical morphology, they utilize the fact that retinal vessels have morphology of connected piecewise linear segments. The top-hat morphological transformation is widely used in blood vessels segmentation since it estimates the background of retinal image using morphological opening operation and the retinal vessels are better enhanced when subtracting this estimated background from original image. The advantages of mathematical morphology are the speed and noise resistance but its drawback is that it doesn't exploit the known shape of retinal vessel cross-section. Miri and Mahloojifar [16] used the fast discrete Curvelet transform (FDCT) for contrast enhancement and multi-structure morphological transformation for detection of retinal vessels edges. The false positive detections are pruned by morphological opening by reconstruction and length filtering. Fraz et al. [17] extracted the centerlines of retinal vessels using first-order derivative of Gaussian (FODOG) filter rotated in four orientations to detect retinal vessels in all directions. Then the shape and orientation maps of the retinal vessels are produced by applying morphological top-hat transform with linear structuring element at eight directions to emphasis vessels in all possible orientations followed by morphological bit plane slicing of gray-level image. The final vessels tree is reconstructed using detected centrelines and maps of shape and orientation.

For the methods based on vessel tracking, they work at single retinal vessel rather than entire retinal vasculature. Starting with initial set of pixels as seeds that are selected automatically or manually labelled, the trace of a vessel is done based on pixels local information by selecting the next candidate pixel in the retinal vessel from set of pixels that are closed to current pixel under consideration. The main advantage of these methods is providing information about single vessel such as its width, connectivity and branching. Their drawback is the need for good initial set of pixels to trace all retinal vessels or they may be missed especially at bifurcations and crossings. Kelvin et al. [18] initially determine sparse seed points along the vessel boundary and found the optimal contours connecting these points using Dijkstras algorithm. After that, they used cost function incorporates Frangis multiscale vesselness measure, vessel direction consistency, the edge evidence and the spatial and radius smoothness constraints into conventional Livewire framework to efficiently compute optimal vessels medial axes. Delibasis et al. [19] initialized the seeds pixels for vessel tracking using a multiscale vesselness filter and picked a random non-zero pixel as a seed. They utilize a parametric model that exploits the geometric properties of retinal vessel composed of a "stripe" and they defined a measure of match (MoM) which quantifies the similarity between the model and the given image. The vessel tracking is done by identifying the best matching strip with the vessel by using the seed point, strip orientation, strip width and the MoM. This method actively seeks vessel bifurcation, without user intervention.

For the methods based on matched filter, the matched filter is 2-D kernel convolved with the image to search for three features of retinal vessel in the image at unknown position and orientation. These features should be considered when designing a matched filter; (1) intensity profile of cross-section of a retinal vessel is approximated by Gaussian curve so the matched filter has Gaussian profile. (2) The retinal vessel has little curvature so it can be approximated by piecewise linear segments. (3) The retinal vessel diameter decrease as it moves outward from the optic disk. The kernel is rotated in multiple orientations to detect the all vessels in all directions so it takes more computation overhead. The response of matched filter is

high with retinal vessels that have the same standard deviation of Gaussian function modelled by matched filter so it may miss retinal vessels that have different profiles. The illumination variation in background and presence of pathologies increases false positive detections resulted by the matched filter. Al-Rawi et al. [20] applied exhaustive search based optimization on DRIVE retinal images database [13] to find optimal values of matched filter parameters such as size, standard deviation and threshold. Zhang et al [21] extended the matched filter by using two kernels; one based on Gaussian and another based on first derivative of Gaussian (FODOG) to filter out false positive detections resulted by matched filter such as non vessel edges which has high responses to both kernels while vessels has high responses only to the basic Gaussian-profiled matched filter.

For the methods based on bio-inspired algorithms, little work was done used ACS. Cinsdikici and Aydn [22] fused the results of ACS and matched filter using OR operator to construct the final segmentation result. Hooshyar and Khayati [23] used fuzzy ACS where the maximum eigenvalue of Hessian matrix at multiples scales and the maximum response of Gabor filter at multiple orientations are the features of each pixel. Asad et al. [7] used ACS standalone where the features of each pixel are simple because they are based on gray-level variations between it and its surroundings in green color of retinal image and the known Hu moment-invariants. These features don't need to be computed at multiple scales or orientations, so they are fast on computation.

For methods based on active contour, the active contour (snake) is initialized curve moves on the image under internal forces by the curve itself and external forces by the image data. Both types of forces are defined so that the snake fits to a desired feature in the image. The external forces are defined by a human user or supervising process. The active contour are used in edge detection, shape recognition and object tracking. The advantage of active contour for example in shape recognition is that it's independent and self-adapting so it conforms to any shape but its drawback is that it needs to be initialized close to the search target to avoid local minima. Espona et al. [24] initially mapped vessel creases using the multilevel set extrinsic curvature based on structure tensor. Next tracing of the optic nerve circumference is performed to initialize an active contour at the intersection of vessel creases with this circumference. The active contour is deformed influenced by external forces of vessel creases. Al-Diri et al. [25] initially used tramline filter to segment some pixels of likely vessel centerline then the segment growing algorithm initialized multiple vessels segments from these segmented pixels using pairs of active contours. The twins active contours conformed to vessels edges while the bifurcations and crossings are extended using the junction resolution algorithm.

III. Background

A. Features

The features pool consists of the gray-level of green channel of RGB retinal image (*green*), group of five features based on the green gray-level (*f1, f2, f3, f4, f5*), group of eight features based on Hu moment-invariants (*Hu1, Hu2, Hu3, Hu4, Hu5, Hu6, Hu7, Hu8*) and the gray-level of the vessels-enhanced image (*Ive*) [7]. Most of the vessels segmentation approaches extract and use the green color image of RGB retinal image for further processing since it has the best contrast between vessels and background so it's taken as feature. The five gray-level based features group is presented by Marin et al. [9] and its features describe the gray-level variation between vessel pixel and its surrounding. The Hu moment-invariants are best shape descriptors which are invariant to translation, scale and rotation change. So they are used by the second group of eight features to describe vessels have variant widths and angles. The vessels-enhanced image [9] is better enhancing blood vessels while removing the bright retinal structures as optic disc and exudates, so it's used for computing the group of eight Hu moment invariants based features and its gray-level (*Ive*) is the new added feature to the previous features pool as first improvement. These features are simple, better discriminate between vessel and non-vessel classes and needn't be computed at multiple scales or orientations. The features computation is more detailed in [7].

B. Correlation Based Feature Selection Heuristic

It's a heuristic approach for evaluating the worth or merit of a subset of features [11]. The main premise behind this selection method is that the features that are most effective for classification are those that are most highly correlated with the classes (intensifiers and dissipaters), and at the same time are least correlated with other features. The method is therefore used to choose a subset of features that best represent these qualities. The best individual feature based on the following merit metric:

$$M_s = \frac{k r_{cf}}{\sqrt{k + k(k-1) r_{ff}}} \tag{1}$$

where M_s is the heuristic merit of a features subset S containing k features, r_{cf} and r_{ff} are the average feature-class correlation and the average feature-feature inter-correlation respectively. The numerator gives an indication of how predictive a group of features are; the denominator of how much redundancy there's among them.

C. Ant Colony System

The ACS as meta-heuristic searching algorithm was first proposed by Dorigo et al. [8] for solving the travelling sales man problem (TSP). The ACS is based on simulating the foraging behaviour of real ants in nature. In nature when real ants are searching for foods, multiple ants are going out in random paths. As the ant is moving, it deposits a chemical substance which is called pheromone on its moving path for guiding other subsequent ants to its path. As the time goes,

the pheromone is evaporating. So as the path is shorter as its pheromone concentration remains more time and more other ants are attracted to it. Thus the shortest path is the only one which attracts other ants. ACS is more detailed in [7].

IV. PROPOSED APPROACH

After features selection process by CFS heuristic and determining its recommended features set for STARE databases *(f2, f5, Hu1, Ive)*, the proposed approach is applied to retinal images. It consists of four phases; preprocessing, features computation, ACS based segmentation and post-processing. In preprocessing phase, the green channel of RGB retinal image is extracted and its contrast is better enhanced by covering the whole range of intensity [0, 255] since it's a feature*(green)* and it's used in further processing. After that, the central light reflex which runs down the central length of some vessels is removed. In features computation phase, the varying illumination in background is corrected by computing the homogenized background image for better discriminating vessels from background and computing the gray-level based features *(f2, f5)*. Finally, the vessels-enhanced image is computed since its gray-level *(Ive)* is used for computing Hu moment-invariants based feature *(Hu1)* as well as it's selected feature by CFS. In The ACS based segmentation phase, each pixel is classified as vessel or background depending on its pheromone level τ and heuristic function η value. The old heuristic function η was the Euclidean distance between the target pixel and both centers of vessels and background classes in the feature space:

$$\eta = \frac{Euclidean\,distance\,to\,background\,class\,center}{Euclidean\,distance\,to\,vessels\,class\,center} \qquad (2)$$

The class center consists of averages of all selected features by CFS over all training pixels of the database. From the final pheromone map image τ, the vessels are segmented from background by thresholding. In post processing phase, linking of disjoint pixels is performed by setting pixel to 1 if it's surrounded at least by four neighbouring pixels of 1; otherwise it's sat to 0. All small regions have area less than 20 are filtered out. Finally, a median filter of size 3*3 eliminates all remaining isolated noisy pixels. Algorithm (I) shows the proposed approach which is more detailed in [7].

As second improvement, new heuristic function based on probability theory is applied to enhance the performance of proposed approach. The heuristic function is also computed from all training pixels of the database. So for probability calculation, the values of features in the feature space are transformed to specific interval and rounded to the nearest integers inside this interval. The following equation defines the new heuristic function η^*:

$$\eta^* = \frac{P(v/Vessels)}{P(v/Background)} \qquad (3)$$

where *P(v/Vessels)* and *P(v/Background)*are the likelihood of feature value *v* for vessels and background classes respectively.

Algorithm 1 PROPOSED APPROACH

```
/* Preprocessing Phase*/
Extraction of the green channel of retinal image
Linear transformation of its intensity to cover the whole intensity range [0, 255]
Remove of the central light reflex from it.
Computation of its homogenized-background image.
Computation of its vessels-enhanced image.
/* Features Computation Phase*/
for each pixel in the homogenized-background image do
    Compute its gray-level based features (f2,f5)
end for
for each pixel in the vessels-enhanced image do
    Compute its Hu moment-invariants based feature (Hu1)
end for
/* ACS based segmentation */
Initialize ACS parameters and the pheromone map image
Compute the heuristic function based on Eq.3 for each pixel in the image
Apply ACS operation
Threshold the resulted ACS pheromone map image to segment vessels from background
/* Post-processing */
for each pixel in the thresholded image do
    if surrounded by at least four neighboring pixels of 1 then
        Setting it to 1
    else
        Setting it to 0
    end if
end for
for each region in the thresholded image do
    if area is less than 20 then
        Removing it by morphological opening using disk structure element
    end if
end for
Applying median filter of size 3*3 to remove all remaining isolated pixels
```

V. EXPERIMENTAL RESULTS

A. Material

The STARE database, originally collected by Hoover et al. [12], comprises 20 eye fundus color images (ten of them contain pathology) captured with a TopCon TRV-50 fundus camera at 35 degree field of view (FOV). The images were digitalized to 700*605 pixels, 8 bits per color channel and are available in PPM format. The database contains two sets of manual segmentations made by two different observers. The FOV binary mask for each image isn't available, so we create it by hand for each image using MATLAB function named "impoly" which creates an interactive draggable and resizeable polygon on the image to specify the FOV. Also the images aren't divided into separated train and test sets, so the training pixels are selected from the manual segmentations made by the first observer. The segmentation performance of the proposed approach is compared against the segmentations of the second observer as ground truth.

B. Samples Selection

The STARE training set contains 919308 vessels pixels and 5281987 non-vessels (background) inside FOV. These pixels

needed to select samples from them for computation of the best features set using CFS heuristic. Since the ratio of vessel pixels to background pixels in each image and overall images is 1:9 on average, the samples set consists of randomly selected 1000 vessels pixels and 9000 background pixels from each image; there are 20 images give 200000 total samples. The best features set consists of the most repeated features resulted from multiple runs of CFS.

C. Results

Three measures are calculated for evaluating the segmentation performance of recommended features set by CFS with ACS. The first measure is the sensitivity (SN) which is the ratio of well-classified vessels pixels. The second measure is the specificity (SP) which is the ratio of well-classified background pixels. The third measure is the accuracy (ACC) which is the ratio of well-classified vessel and background pixels. Tables I and II show the ACS performance values with the old η and new heuristic function η^* respectively. It's shown from both tables that new heuristic function η^* improves largely the average performance of the ACS especially in sensitivity which increased by about 10% while specificity increased by 1% and accuracy increased by 2%. In the normal images set, the least performance of ACS with the old heuristic function was on image 7 but it's improved when using the new heuristic function; in sensitivity from 0.6608 to 0.9289, in specificity from 0.9005 to 0.9269 and in accuracy from 0.8742 to 0.9271. Also in the abnormal images set the least performance of ACS with the old heuristic function was on image 6 but it's improved when using the new heuristic function; in sensitivity from 0.6472 to 0.8188, in specificity from 0.8883 to 0.9213 and in accuracy from 0.8670 to 0.9122.

Fig.1 and Fig.2 compare between the average performances of ACS with the old η and new heuristic η^* functions with respect to normal and abnormal images in STARE database. It's shown from Fig.1 that ACS with the new heuristic function outperforms ACS with the old heuristic function with respect to normal images by about 13.5% in sensitivity, 1.5% in specificity and 2.7% in accuracy. Also in Fig.2 the ACS with new heuristic function outperforms the ACS with old heuristic function with respect to abnormal images by about 6% in sensitivity, 1% in specificity and 1.4% in accuracy.

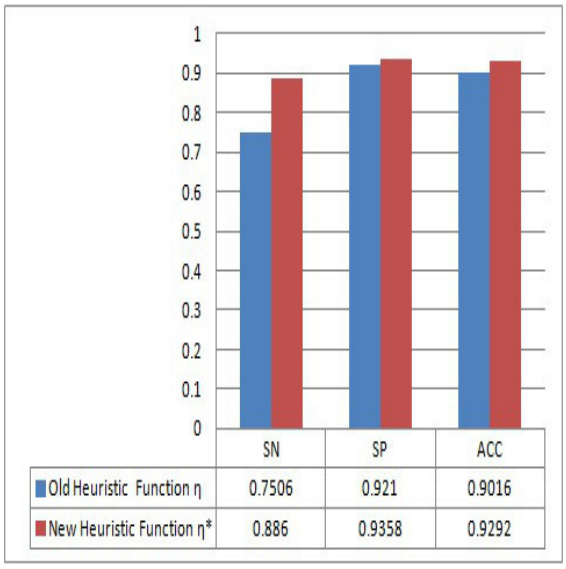

Fig. 1. ACS Performance on Normal Images in STARE

Fig.3 shows how ACS with the new heuristic function outperforms ACS with the old heuristic function in segmenting the small capillaries and bifurcations Fig.3-(d) with fewer false positives Fig.3-(h). So its better to use the new heuristic

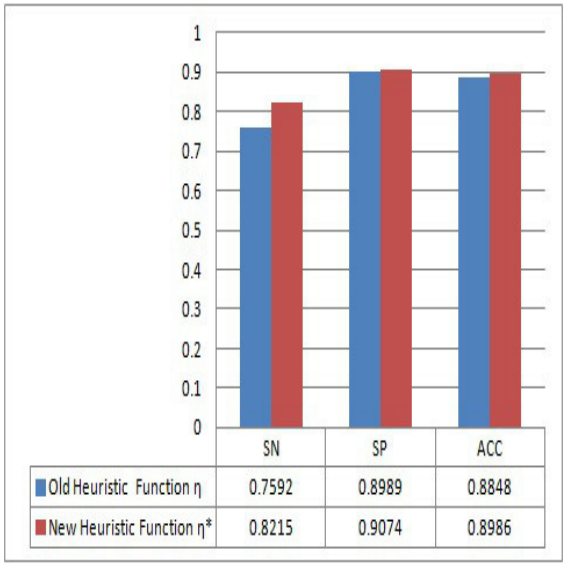

Fig. 2. ACS Performance on Abnormal Images in STARE

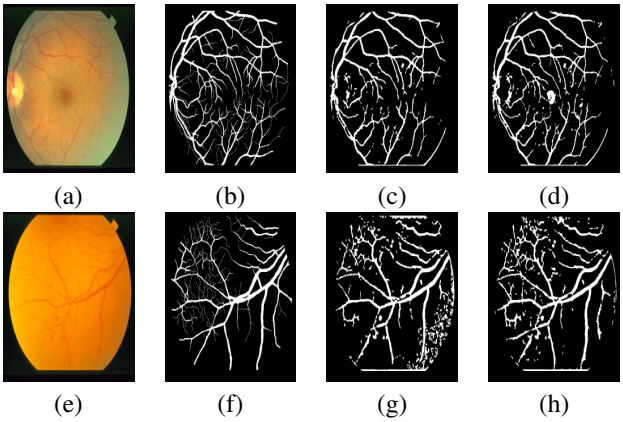

Fig. 3. ACS performance with old and new heuristic functions on normal and abnormal image: (a),(e) retinal image; (b),(f) manual segmentation by second observer; (c),(g) results of ACS with old heuristic function; (d),(h) results of ACS with new heuristic function

function that's based on probability theory instead of the old one that's based on Euclidean distance. Table III shows the performance comparison of the state of art methods as well as the old and improved approaches on SATRE database where the empty cells aren't reported by their authors. Both the old and improved approaches give the best largest sensitivity over the state of art methods. But their values of specificity are the lowest due to high false positives that affected negatively on their accuracies. Although this improved approach gives performance less than performances of state of art methods but its results are promising because they are obtained without learning and using complex features need to be computed at multiple scales and orientations. With respect to the time consumed by this improved approach, for single retinal image the selected four features computation takes on average forty two seconds while the ACS phase takes on average two minutes and forty five seconds on PC with Intel Core-i3 CPU at 2.53 GHz and 3 GB of RAM.

VI. CONCLUSION

The automated extraction of blood vessels in retinal images is an important step in early diagnoses of diabetic retinopathy and prevention of visual loss since diabetic retinopathy leads to retina revascularization. This paper presents an approach for automatic segmentation of blood vessels in retinal images using ACS based on features that are simple, fast in computation, needn't to be computed at multiple scales or orientations and highly discriminate between vessels and background in retinal images. The paper improves the features by adding new discriminant feature which is selected by CFS heuristic within the best features set. The paper also improves the performance of ACS using new heuristic function based on probability theory instead of the old one which is based on Euclidean distance. The paper is the first one that tested ACS performance on STARE database while the other two papers that also perform ACS-based segmentation of retinal images tested on DRIVE database. The improved approach sensitivity is the largest among the state of art methods. Because of simplicity of its used features, it can be more improved in future to give comparable performance to state of art methods especially by focusing on false positives reduction to increase its specificity and accuracy. Also in future it's needed to asses this improved approach performance on other databases of retinal images such as the DRIVE database.

***Abstract*—Gesture recognition may find applications in rehabilitation systems, sign language translation or smart environments. The aim of nowadays science is to improve the recognition systems' efficiency but also to allow the user to perform the gesture in a natural way. The article presents different methods (DTW – Dynamic Time Warping, DDTW - Derivative Dynamic Time Warping, PDTW - Piecewise Dynamic Time Warping) based on Dynamic Time Warping algorithm, which is commonly used for hand gesture recognition using small wearable three-axial inertial sensor. Additionally, different approaches to signal definitions and preprocessing are discussed and tested.**

To verify which of the methods presented is more accurate in case of gesture recognition, database of 2160 simple gestures was collected, and recognition procedure was implemented. The main goal was to compare the efficiency of each method assuming that each person should perform the movement naturally. Obtained results suggest that the most efficient method for the presented problem was the DDTW. The worst recognition performance was achieved with the PDTW method.

I. Introduction

THE recent advance of sensor technologies allows engineers to use smaller and smaller devices capturing human motion. These devices are cameras[1], game controllers, such as Microsoft's Kinect [2] or sensors: inertial [3], [5], [6] or built in data gloves[4]. One of the areas of interest is gesture recognition, which may find its application in game interface design, controlling virtual reality, smart environments but also in biomedical science. For example gesture recognition system may be used as a rehabilitation instrument to improve the sensibility of hands for people recovering from physical accidents or cognitive disabilities [3]. Another application might be an assistive translating system for the deaf people, who use sign languages to communicate [1], [4]. Much research has been done on the topic of gesture recognition, and designers of recognition system should always bear in mind that hand gestures are complicated and the way of performing a gesture varies depending on the person. Solutions presented in the literature using inertial sensor systems reach effectiveness of simple gesture recognition from 69% to 96% for general recognition and from 98% to 99% in recognition of one person's set of gestures [3], [5], [6]. Above solutions, however, assume that all gestures examined are strictly defined or they should be performed in one plane. Our research goal is to compare different variants of widely used for gesture recognition Dynamic Time Warping (DTW) algorithm and conclude which method gives the best results in recognition effectiveness taking into consideration aspects such as: defining the distance between two signals and choosing proper signals for analysis and recognition (acceleration or orientation in space). All tests (in contrast to [3], [5], [6]) are done assuming that a person should do the gesture in a natural way, which implies that a gesture can be performed in 3D space, according to one's preferences and physical conditions. Therefore, small wearable device such as three-axial IMU sensor was considered to collect motion data. Authors based on previous research presented in [7], where information about acceleration and Euler angles in 3-dimensional space of a sensor placed on a forefinger was used to classify the gesture. The aim of this research was to compare different variations of Dynamic Time Warping algorithm (DTW) including Piecewise Dynamic Time Warping (PDTW) and Derivative Dynamic Time Warping (DDTW) in gesture recognition. Moreover, some solutions concerning signal preprocessing leading to the recognition effectiveness improvement are presented.

II. Materials

Authors used database collected for tests described in [7]. Data acquisition was performed using 9 DoF inertial sensor, NEC-TOKIN, Motion Sensor MDP-A3U9S, placed on a volunteer's forefinger (Fig. 1). The small size (20 × 20 × 15 mm) and weight (6g) of the measurement module allowed user to move his hand and to bend the forefinger in natural way. The sensor contains 3-axis accelerometer, magnetometer and gyroscope. The output raw data contain information from each of these 3-axis sensors as well as the angular orientation expressed in Euler angles. Data transfer to the PC was performed via USB wire (sampling rate - 25 Hz). The set of 10 simple gestures was the recognition subject, their scheme is shown on Fig. 2. Similar gestures were also recognized in [3], [5], [6]. The database consisted of 2160 gestures, each in the separate text file, collected during 3 mea-

This work is supported by Ministry of Science and Higher Education in Poland in years 2013-2014

Fig. 1 Measurement module and its attachment to the forefinger. Original picture from [7]

surement sessions. In a single measurement session each of 9 volunteers performed each gesture 8 times.

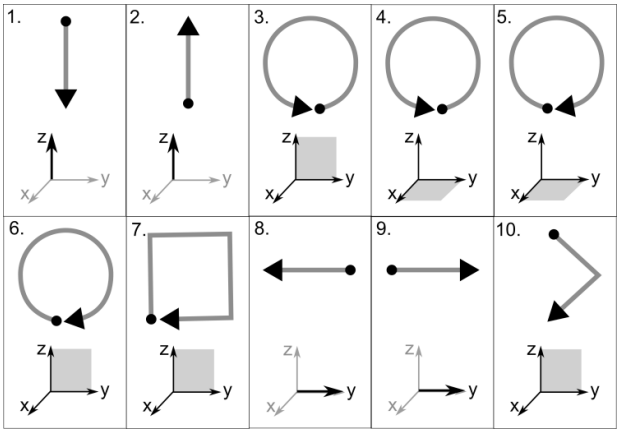

Fig. 2 Schemes of the gestures with coordinate system corresponding to that in measurement module. Main directions and planes of movement were marked.

In view of the fact that the individual gesture performance might vary significantly depending on the time, mood, tiredness or concentration, sessions were held at least one day apart. The database was divided into testing and training sets. 5 of 8 each gesture repetitions performed during measurement sessions were included into the training set, remaining 3 became the testing set. The training set contained 62.5% of all gestures, testing - 37.5%. Contrary to [3] and [6], authors did not assume that during gesture performance palm angular orientation does not change. In gestures made in natural way position changes can be observed, as well as changes of angular orientation. There were no restrictions about the way of gestures performing, what caused that some volunteers performed the same gesture using just one finger, others using the palm and some using whole arm.

III. METHODS

Preprocessing was applied to all measured signals, including mean filtering, signal values scaling to the interval [-1,1] as well as segmentation to obtain data corresponding only to the activity of performing a gesture uniformed for all examined people. Research on the topic of preprocessing was presented in [7] and showed that signal segmentation based on monitoring changes in Euler angles during movement improves the segmentation process.

Basic algorithm used to both determine exemplar set as well as to classify gestures was DTW algorithm (Dynamic Time Warping). This algorithm is commonly used to find the similarity between time series. Such a method was chosen because of the characteristic of collected gesture signals which were usually similar but transformed in time. The signals in our data base were different concerning their length, distribution of peak values and the velocity of performing particular gesture phases. Additionally two transformations of the base algorithm were implemented: Derivative Dynamic Time Warping (DDTW) and Piecewise Dynamic Time Warping (PDTW) [7-11].

A. Dynamic Time Warping (DTW)

DTW algorithm allows to compute the distance between two signals in the following procedure. Assuming there are two gesture signals (given by acceleration or angle signals changing in time): $X = \{x_1, x_2, \dots, x_n\}$, $Y = \{y_1, y_2, \dots, y_m\}$ to align these two sequences using DTW for X and Y we need to define distance matrix *D* containing Euclidian distances between all pairs of points (x_i, y_j).

$$D(i,j) = d(x_i, y_j) \tag{1}$$

where

$$d(x_i, y_j) = |x_i - y_j|$$

Then we define cumulative matrix P recursively:

$$P(1,1) = 0$$
$$P(i,1) = D(i,1) + P(i-1,1)$$
$$P(1,j) = D(1,j) + P(1,j-1)$$

For $i,j>1$

$$P(i,j) = D(i,j) + \min\{P(i-1,j), P(i,j-1), P(i-1,j-1)\} \tag{2}$$

As a result of the DTW algorithm optimal total distance between X and Y after alignment was obtained, which is denoted by $q_{DTW} = P(n,m)$.

B. Derivative Dynamic Time Warping (DDTW)

DDTW algorithm is a variation of basic DTW algorithm. When the two series may have local differences in the Y-axis, it is useful to take into consideration derivative of the signals instead of the signals themselves. First, we calculate the estimate of derivatives of the signal. Then, as before according to equation (1) we construct an *n*-by-*m* matrix D where the (i_{th}, j_{th}) element of the matrix is the distance $d(x_i,y_j)$ between the two points x_i and y_j and finally calculate $q_{DDTW} = P(n,m)$.

C. Piecewise Dynamic Time Warping (PDTW)

PDTW algorithm uses time series transformed to reduced representation. A time series X of length n can be represented by a time series $\overline{X} = \{\overline{x_1}, \overline{x_2}, \dots, \overline{x_N}\}$, where $N<n$ and

the i-th element of $\overline{X}$ can be calculated from the following equation:

$$\bar{x}_i = \sum_{j=\frac{n}{N}(i-1)+1}^{\frac{n}{N}i} x_j \quad (3)$$

This means that data is reduced from n dimensions to N by averaging data in each of N frames. We denote the ratio of the length of the original time series to the length of the reduced representation by the compression rate c.

$$c = \frac{n}{N} \quad (4)$$

If the compression rate is high, it will reduce the time of performing calculations, but it will flatten the signal as well.

D. Different approaches to signal definitions

Since six different signal components (3 acceleration and 3 angle components) might be taken into consideration, same algorithms were used to compare the results of recognition based only on accelerations or only on angles or on both of the values together to show whether information about orientation in space may improve widely used technique based on acceleration analysis. As DTW algorithms compute distance between two signals, it can be used for two one-dimensional signals. However, the signals can be also treated as three-dimensional considering all acceleration or all orientation components. In this case distance matrix *D* (1) was modified and it consisted of distances between two points in three dimensional space defined by:

$$d(x_i, y_j) = \sqrt{(x_{i1} - y_{j1})^2 + (x_{i2} - y_{j2})^2 + (x_{i3} - y_{j3})^2}$$

for $x_i = (x_{i1}, x_{i2}, x_{i3}),\ y_j = (y_{j1}, y_{j2}, y_{j3})$

E. Exemplars

Authors proposed two approaches to the exemplars, that were the basis of gesture recognition: user-dependent and user-independent. In user-dependent approach, using samples from the training set, for each person for each of 10 gestures one gesture was indicated as an exemplar. The gesture from the training set became an exemplar, when it was the most similar to others in terms of one of the warping methods (DTW, DDTW and PDTW). For each warping method one individual (user-dependent) exemplar for every gesture was indicated. Then, taking into account all individual exemplars for each gesture, the one that was the most similar to others became general exemplar used in user-independent recognition. There were different sets of exemplars for acceleration, for angles, for all signals, also for 1D distance function and for 3D distance function.

IV. RESULTS

Gestures classification was performed using the testing set, all described below algorithms: DTW, DDTW and PDTW and corresponding sets of exemplars. Firstly, to recognize gestures authors used all acceleration and Euler angles signals at once. Secondly, to determine which parameter is more important for natural gestures recognition, classification was carried out for them separately. There were also two different approaches used in single parameter recognition:1) distance function in algorithms DTW, DDTW and PDTW was computed separately for each component of the parameter (for x, y and z axis in case of acceleration and for pitch, roll and yaw in case of Euler angles – 1D distance); 2) both acceleration and angles were treated as 3-dimensional signals and the distance in DTW algorithms was calculated like in 3-dimensional space giving one value for all acceleration components and one value for all angles (3D distance). Obtained results were also divided into individual and general cases. Individual are average efficiency values calculated for each person using his or her individual exemplar, general are average efficiency values calculated for everybody using the same general exemplar for each person. Efficiency was calculated as the sum of all correctly recognized gestures divided by the sum of all gestures. Efficiency values for each of the described recognition method are shown in Tab. I and Tab. II.

TABLE I.
CLASSIFICATION RESULTS FOR INDIVIDUAL CASE. GIVEN VALUES ARE RECOGNITION EFFICIENCIES.

Basis for classification	Distance function	DTW	DDTW	PDTW
Acceleration	1D	0,922	0,895	0,923
	3D	0,948	0,947	0,940
Angle	1D	0,757	0,861	0,747
	3D	0,789	0,921	0,784
All signals	1D	0,894	0,937	0,895
	Average	**0,862**	**0,912**	**0,858**

TABLE II.
CLASSIFICATION RESULTS FOR GENERAL CASE. GIVEN VALUES ARE RECOGNITION EFFICIENCIES.

Basis for classification	Distance function	DTW	DDTW	PDTW
Acceleration	1D	0,877	0,785	0,872
	3D	0,854	0,836	0,626
Angle	1D	0,584	0,674	0,579
	3D	0,638	0,822	0,626
All signals	1D	0,794	0,828	0,789
	Average	**0,749**	**0,789**	**0,698**

The PDTW method was conducted for three values of compression rate: 2, 3 and 5. All results for the PDTW method shown in tables above correspond to the compression rate equal to 2. The higher the value of this parameter, the lower recognition efficiency for collected database (the PDTW method might give better results for higher sampling rates or unfiltered signals). It can be observed that the highest value for recognition efficiency for individual case was obtained for classification based on 3-dimensional approach to acceleration signals and distance function – all warping methods lead to the value of 0.94 for this parameter. 3-dime-

sional approach to all other signals brought much better results in comparison to the corresponding methods with 1-dimensional distance function. Taking into account individual and general cases, statistic tests were conducted (at the 95% confidence level), indicating significant differences between results obtained by all described DTW methods. Tests revealed no difference only in one case: comparison of DTW and PDTW with compression rate c = 2 for general case. The most efficient warping method is the DDTW and the highest efficiency rate is also for acceleration signals. However, analyzing the various gestures separately, it appears that in some cases, the analysis of the angles lead to more accurate classification. Results of each gesture recognition efficiency for different basis of classification for the DDTW method are presented on Fig. 3.

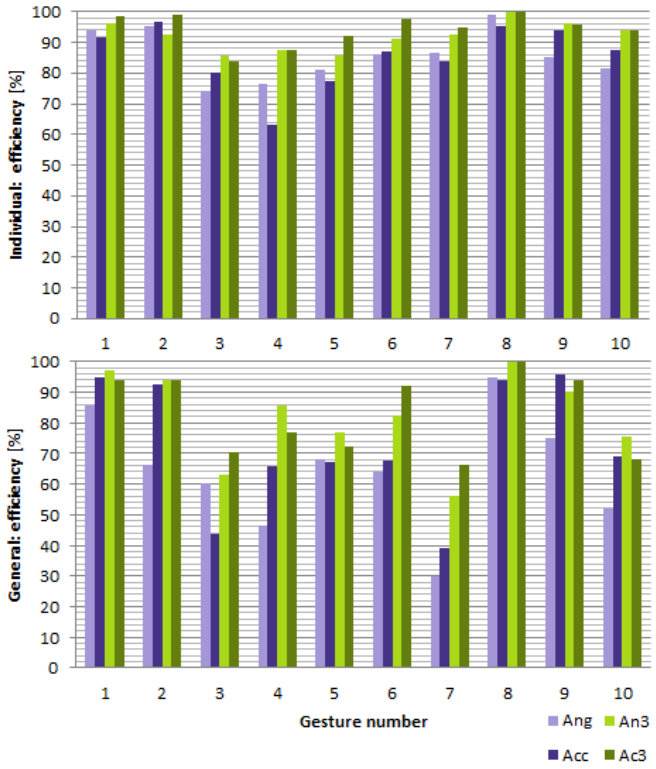

Fig. 3 Each gesture recognition efficiency for individual and general case for different classification basis: Ang – angles, An3 – angles and 3D distance function, Acc – acceleration, Ac3 – acceleration and 3D distance function. DDTW method.

V. Disscusion

Authors proved that recognition of gestures performed in a natural way without any constraints for the examined person is possible using methods based on Dynamic Time Warping Algorithms. Analyzing recognition efficiencies obtained for all DTW methods and taking into account the results of statistic tests which revealed significant differences between methods, it can be stated, that the most efficient method to described application is the DDTW. The worst recognition performance was achieved with the PDTW method. The higher compression rate, the higher reduction of information and the lower efficiency values. The reduction of information that was caused by the PDTW method was a disadvantage in this case, but it can occur that for higher sampling rates it will become an advantage.

Signals collected confirmed the theory that such aspects as time of the day, tiredness, concentration, experience may affect gesture performing which results in lower recognition efficiencies. As these problems are unavoidable, obtaining better results is a matter of algorithms and preprocessing.

Moreover, analyzing Fig. 3 it can be observed that there are gestures which are much better recognized while using angular orientation as a basis of classification. Solution to improve this method to recognize natural gestures would be to combine information about angular orientation and acceleration. Possibly treating the signal as a 6 dimensional (3 acceleration components and 3 angle components) would cause increase of recognition efficiency.

In future, research data base enlarging should be considered to verify the hypothesis which of the methods presented is more accurate in case of general (subject independent) gesture recognition. Another improvement may be creating more general exemplar set containing modeled signals (instead of signals registered by the sensor), which will reduce the influence of between subject variability.

***Abstract*—Clinical Decision Support Systems (CDSSs) need to disseminate expertise in formats that suit different end users and with functionality tuned to the context of assessment. This paper reports research into a method for designing and implementing knowledge structures that facilitate the required flexibility. A psychological model of expertise is represented using a series of formally specified and linked XML trees that capture increasing elements of the model, starting with hierarchical structuring, incorporating reasoning with uncertainty, and ending with delivering the final CDSS. The method was applied to the Galatean Risk and Safety Tool, GRiST, which is a web-based clinical decision support system (www.egrist.org) for assessing mental-health risks. Results of its clinical implementation demonstrate that the method can produce a system that is able to deliver expertise targetted and formatted for specific patient groups, different clinical disciplines, and alternative assessment settings. The approach may be useful for developing other real-world systems using human expertise and is currently being applied to a logistics domain.**

I. Introduction

MANY Clinical Decision Support Systems (CDSSs) with appropriate functionality have been successfully developed in academic institutions but never seen the light of day within healthcare practice. There are two fundamental reasons why these systems are not adopted. One is the failure to integrate with the way organisations and their individual employees work. The other is the inability to communicate information effectively beyond the immediate remit of the CDSS, which is often too narrow in the first place. This paper describes a research approach that attempts to circumvent both problems by developing a CDSS that has flexible requirements and data sharing protocols built into the design process from the very beginning. The CDSS is the Galatean Risk and Safety Tool, GRiST [1], [2], that helps assess and manage risks associated with mental-health problems.

The aim of the research was to design GRiST so that it could disseminate mental-health expertise using appropriate language for the particular type of recipient and in a format commensurate with the variable circumstances of assessment. This is no easy task because it would need to accommodate end users ranging from psychiatrists with years of specialist medical education to carers or charity workers who may have minimal training. In fact, GRiST was later adapted for self-assessments, by patients who do not have any predefined common ground apart from mental-health problems. Assessment contexts were also highly variable because GRiST was intended to be deployed for mental-health patients across the care pathway, from primary care, through secondary care and specialist services, and back to care in the community.

The complexity of health services in general and mental health in particular is one reason why the UK Government had so many problems with its National Programme for Information Technology [3] that was intended to revolutionise information systems and processes within the National Health Service (NHS). When GRiST was available for deployment in 2006, the oft-acknowledged "cinderella" mental-health services were still more paper-based than most in the NHS. GRiST set out to tackle barriers to information technology (IT) and its adoption by a design process dedicated to developing flexible interfaces and delivery formats for heterogeneous users and contexts. The research questions were: (i) how can the knowledge base be presented in the format and language most appropriate for each intended type of user? and (ii) how can the information technology generate flexible interfaces to the knowledge so that they fit with the different contexts of assessment?

The paper will first briefly review the clinical rationale for GRiST before describing the main functionality and underlying philosophy of the system. This will provide the context for the cognitive engineering approach that was used to develop knowledge structures providing risk assessments and advice. Their implementation as a sophisticated set of linked XML trees will be described, showing how they support the full GRiST CDSS and its deployment across health and community settings. Examples of the variety of interfaces and language used will be given along with an evaluation of the clinical implementation and adoption. The paper will end by considering the next steps for the research programme and how these have been facilitated by the knowledge structure design principles.

II. Background

To prevent serious untoward incidents (SUIs) amongst inpatients and in the community, clinicians need new and reliable

978-83-60810-53-8/$25.00

research evidence to help them detect high risk patients and to support risk management decisions. Despite patient safety being central to NHS policy [4], SUIs remain worryingly common [5]–[7]. Identified causes are lack of sufficient, accessible information about patients' risk profiles [5] and poor risk management or care planning [5], [6]. Risk assessment and management are core competencies for mental health clinicians [8], [9], but the two processes are often not properly connected [10].

There is a clear need to improve clinical practice, which was the motivation for GRiST. It is set apart from alternative risk-assessment and management tools by explicitly modelling human expertise within a generic model of psychological classification. This was a fundamental design principle; if GRiST is based on how humans in general organise their knowledge and reason with it, then its expertise will be in a universally accessible format. It enables GRiST to transcend disciplinary specialisms and opens its expertise up to people with no training at all.

GRiST is designed to assist the early detection of multiple risks amongst people with mental health problems, including suicide, self-harm, harm to others, self-neglect, and vulnerability. It records patient data (cues) to provide a precise information profile that supports the risk judgements given by clinicians.

Risk assessment can be formulated as a classification problem where each risk such as suicide or harm to others is a class and the support for each class determines the level of risk. The factors determining which risk gains most support will be the patient cues such as previous risk history, current intention, emotional and mental state, as deemed relevant by the assessor. The classification task is to formulate the support for each risk from the input data and activate appropriate interventions associated with the most supported class.

In GRiST, risk classes are represented by hierarchical knowledge structures or trees called galateas [11], which are used to represent mental-health expertise. The trunk or root node of the tree is the risk. It is deconstructed into subconcepts that are themselves trees until the leaf nodes are reached, representing the input data.

Figure 1 provides a hypothetical illustration of how the galateas represent classes and their support. The data used for input to the tree can be any type but it is then converted into a fuzzy-set membership grade, MG, from 0 to 1. Zero represents no support for the root decision class and 1 represents maximum support, but for this item of information alone; its MG at this point is independent of any other item. The main role of the MGs is in converting from real-world patient data to the model input. This is shown in Figure 1 by the MG row of the datum nodes, which defines a distribution of MGs matching the range of potential input data values. Values above or below the range take the MG associated with the maximum or minimum value respectively; values within the range are found by linear interpolation if they don't match a value specified in the distribution. For example, the "number of attempts" datum in Figure 1 has the value 3, which is 0.6

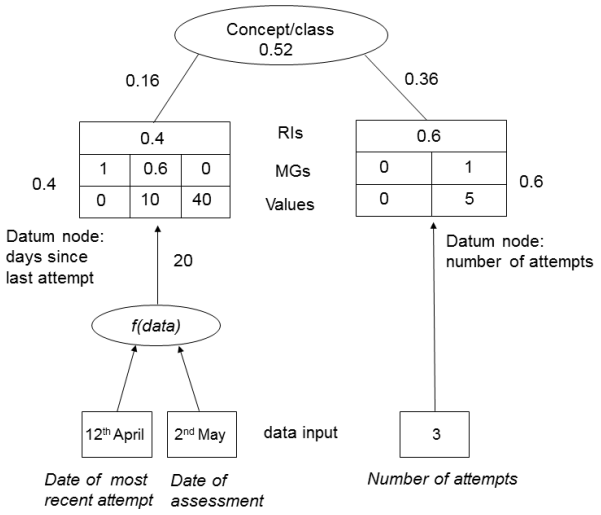

Fig. 1. Hypothetical example of how membership grades (MGs) are processed from patient input data to risk concept. RIs are relative influences, which represent the weights of data and concepts.

along the value range between 0 and 5 and so is assigned an MG that is 0.6 between 0 and 1; i.e. 0.6, as given by the MG outside the box for that datum. For others, such as "days since last attempt", the patient data is passed through a function, *f(data)*, before matching the value-mg distribution: two dates, in this case, which the function uses to generate the number of days between them, 20. Twenty is one-third between 10 and 40 and so is one third along the MG continuum between 0.6 and 0, producing an MG of 0.4, likewise shown outside the datum-node box. The MG is then multiplied by the RI associated with the datum, as shown in the RIs row, to give the MG contribution to the parent concept.

The parent concept MG is the sum of its children contributions, which is how 0.52 is assigned to the concept node in Figure 1. If this concept also had a parent, then the concept would have its own RI and its contribution to the parent would be the product of its RI and MG in the same way that it received its children MGs. The MGs percolate in this manner through to the root node to produce the overall class membership and thus the risk evaluation. Equation 1 formalises the process

$$MG_C = \sum_{i=1}^{n} MG_i RI_{pi} \tag{1}$$

where C is a concept, MG is the membership grade generated at each datum node, i, of the concept, and RI_{pi} is the product of all the RIs along the path, p, from the datum node to the concept.

The focus of this paper is how the hierarchical modelling of expertise translates into an ontology that can drive the GRiST CDSS. The added value of the hierarchy is that it represents the conceptual structure understood by human decision makers when relating influential factors to the decisions taken. There is plenty of evidence for the psychological validity of this

hierarchical knowledge structuring. For example, expert chess players "chunk" positions of chess pieces into hierarchical types of game states [12]. Similar strategies have been shown in other domains such as architecture [13], fault diagnosis [14], and medicine [15]. A review of the evidence [16] concluded that "on balance, it is difficult to dismiss hierarchical organisation as only a construct" (p31) and more recent research has begun to show its neural correlates [17], [18].

The psychological grounding of GRiST is not unique, of course, when it comes to intelligent knowledge-based systems (IKBSs) [19], [20]. However, it uses a generic classification model that represents expertise in a non-specialist format. It can be understood without requiring clinical training and makes it ideal for communicating to heterogeneous users (see [11] for more on the Galatean model rationale).

A. Cognitive engineering and the GRiST ontology

The GRiST approach to constructing decision support systems can be categorised as cognitive engineering because it is the application of cognitive science to IT systems that are intended to help solve real-world problems [21]. For cognitive engineering, models need to encapsulate expertise in a format that can be accessed by the experts and that is commensurate with the inputs and outputs those experts are familiar with in their problem-solving worlds [22]. IKBS Engineers were coming to this conclusion with the idea of situated cognition [23], which argues that thinking cannot be separated from the environment [24], [25]. These environments change and static IKBSs based on a single, giant elicitation exercise are doomed to fail because they will not be flexible enough to evolve or even be maintained easily [26, pg. 767].

There has been a change in tack from psychology to the data itself, with machine learning, data mining, and pattern recognition approaches coming to the fore. In a recent review of artificial intelligence in medicine [27] Peter Szolovits points out that in the early days, "we thought we knew a lot, but had little or no actual data. Today we are inundated with data, but have correspondingly devalued expertise" (pg. 12). The focus is on the machine, how knowledge can be structured for easy processing, and how useful outputs can be induced from the data. It is the same focus that stimulated the rise of ontologies for organising data into shared knowledge bases. Nevertheless, despite Musen's claim that cognitive models do not lead to scalable and maintainable IKBSs [28], "the symbiosis between cognitive science and cognitive engineering shows no sign of abating" [21, pg. 582] and continues to be the case in medicine [29].

The GRiST research tries to bring human and machine closer together using a form of ontology that has an intuitive connection with the knowledge used by mental-health experts. The interface between human and machine ontologies should be a primary focus for knowledge engineering [30], especially for CDSSs based on clinical expertise. The most basic form of ontology is a controlled and extensible vocabulary [31], [32], which means that dictionaries and thesauri would count. These are very familiar to people and emphasises the point that ontologies are not strictly the preserve of machines. Indeed, all sensate beings create some kind of ontology for interacting with their environment [33].

Maintaining the intuitive representation of the GRiST knowledge base meant that the terms should reflect the natural language of human users [34], [35]. This is particularly important in mental-health risk screening because of the diversity of information that relates to risk and the lack of any all-encompassing coding schemes. Where schemes do exist, e.g., ICD-10 [36] and DSM-IV [37], they focus on diagnostic categories for mental disorders such as depression and schizophrenia and do not encompass the diversity of peoples' histories and current behaviour that impact on risk. Attempts to create ontologies within mental health have also focused on diagnoses [38], not risk, and have been aimed at data interoperability rather than formalising expertise and clinical decision making.

The GRiST ontology development was designed to ensure the end product met the needs of its users and organisational settings [39] by extensive iteration between clinicians and the evolving CDSS. The galatean psychological model kept the human-machine interface open and intuitive. It has a precisely specified semantics for hierarchical knowledge, incorporating parameters required for processing uncertainty, and the mathematical functions for propagating them through the hierarchy. This coupling of the ontology with its problem-solving method (classification) helps construct a system that solves real-world tasks [40], but does so by emphasising the fluid relationships of human intuition rather than machine formalisms and logic-based reasoners [41]. The next section explains the method in detail.

III. METHOD

The goal of the methods reported in this paper was to create galatea knowledge structures that were able to evolve with expert consensus and support customised knowledge delivery for a variety of end users accessing it in different contexts. The first problem was how to develop and manage the hiearchical knowledge, which was solved using mind maps.

A. Mind maps

One of the most intuitive aids for note-taking, brainstorming, and generally organising ideas is the mind map [42]. Its layout reflects the goal of representing free-flowing, unconstrained associations of the mind at the same time as structuring knowledge hierarchically; it exactly accords with the knowledge-engineering requirements of GRiST.

There are many mind mapping software programs available. Freemind [43] was chosen because it is: (i) open-source; (ii) available across platforms; (iii) creates node structures that can be easily edited; (iv) enables icons to be incorporated into the nodes; (v) attaches notes to the node without obscuring the structure; and, most importantly, (vi) uses XML directly for representing the mind map rather than it being only an export choice. Its structure-editing role was integrated with the GRiST knowledge-engineering toolkit by creating an XSLT

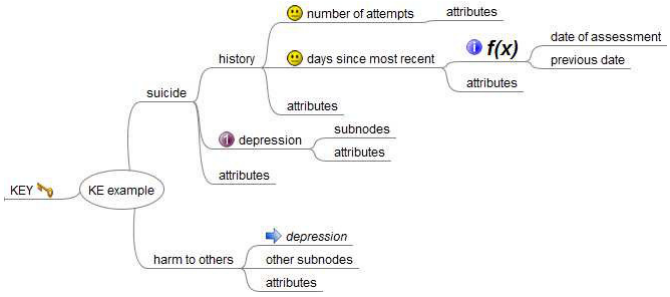

Fig. 2. Hypothetical and simplified mind map of risk assessment expertise

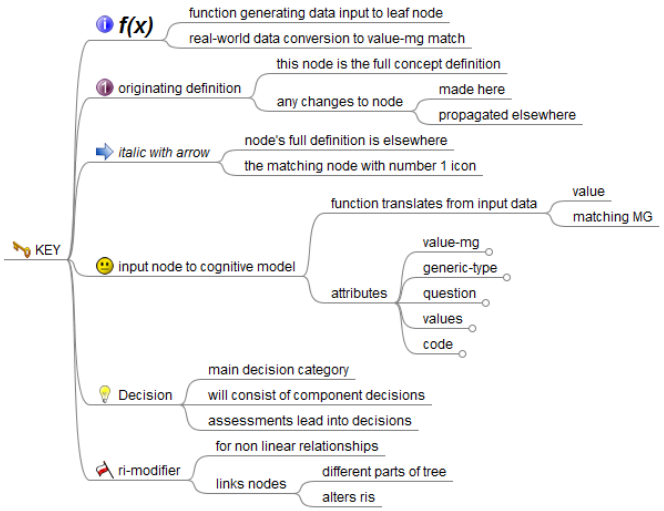

Fig. 3. Expanded key node showing icons that help drive knowledge engineering

document that transformed the Freemind mind map XML into the GRiST structure tree.

A useful resource for helping users control structure changes and also to direct the style sheet is Freemind's icons. Figure 2 shows a simplified example of how Freemind defines the knowledge structure; Figure 3 expands the "Key" node that explains the icons helping control the translation between mind map specification of knowledge structures and the subsequent GRiST XML trees. Many concepts, such as depression, underlie all risks and so are repeated in the knowledge hierarchy. The blue arrow icon enables the mind map to define the full structure in one place. When the style sheet detects the blue arrow, it looks for a node with the same name that has the round number 1 icon associated with it (see Figure 2). The other icons are similarly used to specify aspects of the galatean structure, such as the face, which identifies leaf nodes of the galatea where value-mg distributions are defined. The $f(x)$ node indicates which patient data are required to generate the matching value to the value-mg distribution. This is the case for the time period between the assessment and the most recent suicide attempt, for example, as shown in Figure 1.

Every risk node, both leaf and concept, has a subnode called "attributes", which contains attributes required by the GRiST XML trees. These enable the XSLT conversion document to translate between Freemind mind map format and GRiST XML nodes by making the attributes an explicit structure in Freemind. Otherwise, they would be unrecognised and ignored by Freemind when creating the mind map. The XSLT conversion document looks in the attributes subnode and creates them as well-formed attributes of the output XML tree that is at the root of the GRiST ontology. The next section introduces the GRiST XML trees and their attributes in more detail.

B. GRiST XML tree functionalities, attributes, and relationships

Once the initial knowledge structure has been specified in Freemind, it is translated via the XSLT specification into the GRiST initial XML. The idea is to have a base tree that incorporates the requirements for all patient types and assessment circumstances. It is a kind of "universal" or Everyman tree incorporating every issue for every user. The knowledge-engineering task is to encapsulate the different subtypes with their particular perspectives and priorities within the GRiST XML trees and extract them for delivery within the CDSS.

For GRiST, the subtypes reflect the variety of patient being assessed and the contexts of assessment. Four patient types or *populations* were quickly distinguished as GRiST developed: children and adolescents; working-age adults; older adults; and learning disabilities. Delivering GRiST across assessment contexts also required functional variations that may apply to more than one population (i.e. are not unified with populations) and so needed to be treated separately. Customisations of this type are called services. GRiST is thus tailored along the axes of populations for different assessment trees and services, if it turns out that the functionality needs customising as well as the underlying classification tree; service functionality can be applied to combined subsets of more than one population.

Three objectives were pursued when designing the GRiST XML structures: (i) define the structures of all trees; (ii) instantiate the trees with parameters required for classifying patients according to their particular population; and (iii) generate the specific data structures required for delivering the variety of CDSS functionality for end users. The trees can be summarised as follows (Table I defines the main attributes):

The Super Structure Tree (SST), which contains for all populations, all structural information about nodes and the questions attached to them, with associated values and membership grades. The SST also enumerates all the services that it may be used in with the accompanying more modest functional customisations required across different end users. The SST is the base "Everyman" tree that holds common information across them all as well as information about how to generate the distinctive sub-trees.

The Structure Tree (ST), which contains structural, question, value, and value-mg information for an individual population. It is generated from the SST, and can be conceived of as an SST tailored for one and only one population. Service

TABLE I
EXAMPLES OF ATTRIBUTES USED BY THE GRIST XML SPECIFICATIONS TO DRIVE KNOWLEDGE ENGINEERING TOOLS AND DELIVERY FUNCTIONALITY OF THE CDSS. THE TREES COLUMN IDENTIFIES THE TREES THAT CONTAIN THE ATTRIBUTE.

Attribute	Semantics	Trees
`label`	name of tree node that can vary for populations	all trees
`code`	code for tree node, which is invariant	all trees
`populations="(`*`population-name`*`)"`	different populations of users defined by the tree	SST
`services`	defines services with particular configurations	SST, ST, RIT,
`help="(`*`help text`*`)"`		SST, ST, RIT, QT
`generic="[path to generic node]"`	locates full definition of node	SST, ST, RIT
`generic-type="g"`	repeating nodes with invariant uncertainty parameters	SST, ST, RIT
`generic-type="gd"`	repeating nodes with varying uncertainty parameters	SST, ST, RIT, CAT
`generic-datum="[path to definition of datum]"`	locates full definition of node	SST, ST, RIT
`value-mg="((0 0)(7 1)(10 0.5))"`	association list of values and membership grades	SST, ST, RIT
`level`	prunes tree at different levels of assessor expertise	SST, ST, RIT
`question="`*`question`*	question for collecting item of information	SST, ST, RIT
`values="`*`values`*`"`	defines the type of the item of information	SST, ST, RIT, QT
`layer="n"`	specifies order of initial data collection	SST, ST, RIT, CAT
`filter-q="`*`question`*`"`	question indicating whether subtree is applicable or not	SST, ST, RIT, CAT
`persistent="hard/soft/value"`	carries data forward from previous assessment	SST, ST, RIT, QT
`service`	configures node with given services customisation	SST, ST, RIT, CAT
`prune-for`	removes branch/node for a population	SST
`other attributes ...`	emerging out of knowledge engineering	any

definitions contained in the SST will be carried over to the ST, meaning that customisations defined for a given service type will apply across all populations. The ST is used to generate the RIT corresponding to a population.

The Relative Influence Tree (RIT), which holds the RIs for all nodes. Nodes with generic-type attribute of "gd" are expanded in all locations that point to them because these nodes may have different internal RIs (for concepts) or value-mgs (for datum nodes) in the locations. The RIT structure is generated from the ST and used to elicit and store the RIs.

Together, the ST and RIT are sufficient to specify all the information required for the Galatean psychological model of classification to be instantiated. They provide the complete ontology and problem-solving package and are the end products of the knowledge elicitation stage. However, four more trees are required by the end-user decision support tools. Three are derived from the ST and/or RIT and one is generated by the decision tool during the assessment of decisions, as follows:

The Class Assessment Tree (CAT) is generated from the RIT because it needs the RI attribute. It produces the full galatean tree for classifying objects and so has all nodes fully expanded in all locations, with no paths to separate generic nodes.

The Question Tree (QT) is generated from the RIT and has all the information required to display questions, obtain associated answers, and generate membership grades for the answers.

The Answer Tree (AT) is generated during an assessment by the data-gathering tool, and stores all user-supplied data.

The Landmark Tree (LT) is a tree used for helping assessors to navigate the CAT during assessments. It is a reduced version of the CAT, and will highlight nodes that may be of particular interest or relevance to the current assessment. It is envisaged that this will be derived from the Freemind mind map defining the base structure.

Table I provides examples of attributes that represent data defining the psychological model and its specifications of variations for populations and services. For example, `prune-for="(older working-age)"` means remove this branch of Everyman for older-age and working-age adults but not for any of the other listed populations. Many of the node attributes have an "enhanced" form where they can have different values for the populations of classification trees. This was required to encompass the variety of end-user perspectives that went beyond simply providing different views of the Everyman tree structure but also different representations of the data. For example, the tree node labels for the service-user self-assessment population are different to those seen by the mental-health practitioners assessing services users, as shown for the suicide node label:

```
label="(((service-user) "ending your own
life") ((iapt learning-disabilities older
child-adolescent working-age) "suicide"))"
```

Lisp-like association lists are used to pair the population or service with its customised value. They provide great flexibility for dynamically creating and updating customisations within the SST. They are integral to giving the correct values to the tree transformation procedures that generate the correct trees for each population and service.

Customisation of the same population tree across different service provider contexts is effected by the `services` attribute in the top-level root node of the ST. Each service

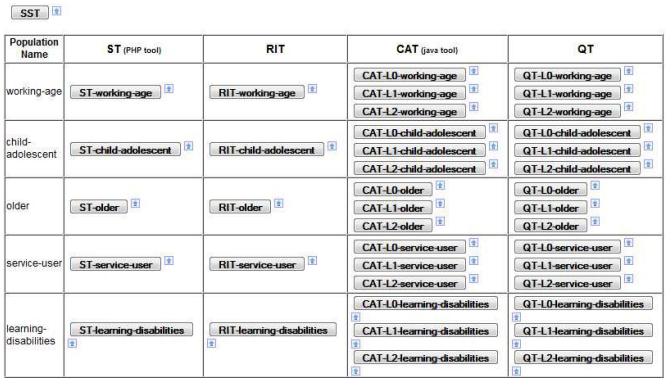

Fig. 4. Screenshot of the admin interface for managing population trees

provider represents a particular set of (minor) customisations/configurations that will be applied to GRiST's question set when conducting an assessment for that service. The top-level root node of the ST will have a:

```
services=
  "((structure
      ((service1 (association list of mods))
       (service2 (association list of mods))
       (...)))
    (rendition
      ((service1 (association list of mods))
       (service2 (association list of mods))
       (...)))"
```

attribute, defining all the services for which customisation/configuration data exists in the ST. Within the `services` attribute, these modifications (abbreviated to mods in the example) are organised as:

Structural modifications: those that involve dynamic (just-in-time) manipulations of the trees in some way prior to their being used to drive a GRiST assessment. Assessment tools will be agnostic of the structural changes, and will therefore not need to perform any additional processing.
Rendition modifications: those that involve dynamic (just-in-time) manipulations of the rendition of the GRiST assessment. Additional coding effort will be required in each assessment tool to realise the rendition manipulations.

The normal behaviour is that in order for a tree node to be amenable to the application of the defined modifications, it needs to "subscribe" to the modifications via a service attribute. For example, `service="rendition"` placed in a node will cause all the service-specified renditions to be applied to that node, such as providing it with a prefix or changing the font to bold, both of which were required for the IAPT service described in the results.

IV. Results

The principle behind managing the different XML trees is to have one single master tree (i.e., the SST) that is used to generate all the other ones. The conversions will be carried out using XSLT in the main and the resulting trees will be labelled so that they can be linked to the particular master tree from which they are derived.

An administrator's interface was provided for uploading, viewing and manipulating the trees (Figure 4). The website automates the derivation of all trees from each SST: namely each population's STs, RITs, and CATs and QTs at various levels (higher level trees pruned at concepts can be used for assessors with greater expertise who can use judgements in place of low-level data). Active trees (i.e. those delivered to end users) need to be marked so that experimental or legacy trees can be made or kept available alongside the current "live" ones for testing before deployment. When the GRiST CDSS is accessed from a patient record system, parameters are passed to the clinical server to indicate which patient assessent is being conducted and what population to invoke.

The success of the methodological approach has been clearly demonstrated over the years by the ability to create new trees suited to particular patient types when requested by mental-health practitioners. The first derivations enable GRiST to cover all age ranges, not just working age, and an additional specialist population was recently added for learning disabilities. Most conclusive was the need to produce a tool for self-assessments that patients could use in the community. This led to the development of myGRiST that exploited the enhanced attribute values to produce variations of nearly all the tree nodes. Not only were different data-collection questions and accompanying help text boxes required but also most tree branch names were changed to ones more suitable for non-clinicians. These substantial variations were all linked to the same common Everyman tree, which meant that clinical and patient answers were always directly comparable: the trees provide a common language and knowledge base despite their multiple manifestations.

The method facilitates a single genotype with a variety of phenotypes. But it also provides different drivers of the end-user CDSS tools. Clinicians tend to be under serious time pressure and want to collect data as efficiently and concisely as possible. This meant their tool was driven by the ST, which keeps class-specific questions separate from generic concepts that are applicable to all classes, and only expands generic concepts once. In other words, it reflects the original mind map with no structural redundancy. On the other hand, the service users conducting self assessments have more time to explore risks dynamically. They wanted less control over the order of access and they also wished to answer generic concepts such as their relationships, current behaviour, living conditions, etc. in the context of whichever risk they were considering. For them, their tool was driven by the CAT, which expands all concepts in all locations to provide full trees for every risk.

The first service customisations were also motivated by time pressures, especially for primary-care practices. Here, the visibility and rendition of risk tree data was needed across all populations (i.e. not limited to only working-age adults). At present, the main service customisation currently in use is for a primary-care service provided to general practitioners called Improving Access to Psychological Therapies (IAPT).

Since mental-health organisations started using the electronic (web service) version of GRiST in 2010, more than 2,000 clinicians have conducted the following number of completed assessments for the different populations and the IAPT service.

working age population: 50,193
children and adolescents population: 4,008
older adults population: 28,188
iapt service: 696

These results are testimony to the knowledge engineering method that facilitated accommodation of different end-user requirements. They also demonstrate the robustness of their implementation, with different populations and services being requested dynamically in real-time.

V. Conclusions

This paper has described a methodology for eliciting, evolving, and delivering complex mental-health expertise using a psychological model of classification. The new research reported here develops GRiST from its initial construction [44], [45] into a fully-fledged knowledge engineering environment that can manage both structure changes and subtle variations in knowledge parameters within an integrated system. The sophisticated application of attributes and XSLT to deliver customised services has been proven by continuous delivery to mental-health practitioners, every hour of every day of every week.

GRiST is generating an accumulating database of patient information that will help parameterise the galatean model underlying the CDSS. The RIs will be learned from the data to provide models of expert consensus that can detect risks more accurately and target appropriate advice. Efficiency of data collection will exploit the latest research on fast and frugal classification [46], [47] where the most important information is identified first and processed very rapidly. More in-depth analysis only needs to take place if the decision-maker remains ambivalent.

New GRiST versions have been requested for forensic services, accident and emergency, and ante-natal clinics. The knowledge engineering methodology means they can be delivered in short timespans because few or no changes are required in end-user applications. Structural information in the GRiST ontology is given by the node nesting but information about the role of the node, both for the psychological classification model and its delivery within a CDSS, is held by attributes. There is no limit to the number of attributes that can be added, which provides great flexibility for amending node behaviours as knowledge engineering progresses.

The disadvantage is that the meaning of attributes has to be recorded outside the XML. Ontology specification languages such as OWL [48] have more power to include semantics and logical relationships but the galatean approach traded flexibility of knowledge structure with the need for a detailed specification document to accompany it. Any tools operating on the XML would need to refer to the specification document and ensure their operations were in full accordance with the definitions. Once this has been achieved, then any changes in the ontology using existing attributes require no further software development.

The GRiST ontology was able to integrate natural language for people with codes more convenient to machines, helping to keep the human-machine interface closely aligned [34], [35]. Now that it has stabilised, it makes more sense to consider translating it into a formal specification language [49]. This would make it easier to validate the tree transformations and embed the rules more formally within the machine specification. An ontology language would also help with the problems of interoperability that are endemic within mental-health services, possibly to a greater extent than in other health areas. There is an inherent difficulty with categorising intangible mental-health constructs but data interchange on more straightforward health and social-care patient data would be beneficial. GRiST is explicit about how this generic information links to risks but mental-health organisations often collect it in other documentation not related to risk. Sharing it has proved problematic and its absence from risk documentation could present a danger to proper care [10].

Whether or not the current GRiST ontology is converted into a language such as OWL, instantiation of the galatean model as a formal specification of mental-health risk expertise has led to assessment tools that have generated considerable interest both in the UK and abroad. The method has applicability to any domain where human expertise can be disseminated within a DSS and where the DSS will be used by people with varying needs, characteristics, and work contexts. Evidence for this is emerging from the logistics domain where the galatean approach is being applied. The expertise and decision context is very different, with the goal being to optimise the use of vehicles for deliveries and collections based on predicting the number of orders. The knowledge trees have already successfully captured expertise that is able to represent alternative perspectives [50] and implementation of the CDSS is currently underway. Irrespective of the particular application domain, whether a CDSS is actually used in the real world depends on how flexible it is in meeting varying user requirements and *modus operandi*; this paper reports a method that should help improve its chances of adoption.

***Abstract*—In the paper, we deal with the problem of automatic determining syntactic complexity of visual stimuli. This problem is important in case of using paintings in eye-tracking based diagnosis and therapy of some kinds of neuropsychological and emotional disorders. Our approach to solving the considered problem is based on the clustering procedure using Self Organizing Feature Maps. The clustering results are compared with the heat maps obtained in the eye-tracking process.**

I. Introduction

ART therapy is based on the idea that the creative process of art making is healing and life enhancing and is a form of nonverbal communication of thoughts and feelings. Like other forms of psychotherapy and counseling, it is used to encourage personal growth, increase self-understanding, and assist in emotional reparation, and has been employed in a wide variety of settings with children, adults, families, and groups. Art therapy supports the belief that all individuals have the capacity to express themselves creatively and that the product is less important than the therapeutic process involved [1]. However, not only art making but also art viewing can have a therapeutic influence. Participating in the arts and viewing the arts have been found to have tremendous therapeutic impact [2]. Ulrich conducted a significant study of psychiatric patients' response to art from an extensive and diverse collection of wall-mounted paintings and prints [3].

Constant research is needed for increasing effectiveness of art diagnosis and therapy. Research in the area of neuroaesthetics is an example of this type of activities. As its name implies, neuroaesthetics is an attempt to combine neurological research with aesthetics by investigating the experience of beauty and appreciation of art on the level of brain functions and mental states. The first approach relies on observation of subjects viewing art samples and inspection of the mechanism of vision, with the aim of inducing general rules about aesthetics. This is the most popular approach to neuroaesthetics proposed by Zeki [12].The second approach aims at establishing the link between certain brain areas and artistic activity. In contrast to approaches focusing on the artistic abilities and creativity, the third approach investigates aesthetic enjoyment through brain-imaging experiments on subjects looking at pictures. A fundamental methodological crux for all these approaches is whether the aesthetic judgments are perceived as bottom-up processes driven by neural primitives or as top-down processes with high-level correlates [4].

Conclusions presented above enable us to hope that the visual art can be an effective tool in the diagnosis and therapy process, for example, in the treatment of some kinds of neuropsychological and emotional disorders. In order to do that, we need research systematizing the methodology of application of the art as a therapeutic tool. The first step of our research has been presented in [11]

II. Syntactic Complexity of Visual Stimuli

As it was mentioned earlier, painting perception is connected with the activity of a number of regions of the brain. A structure of visual stimuli, i.e., its complexity, influences which regions of the brain are activated by visual stimuli (painting), i.e., which cognitive functions (basic or higher) are initiated by the patient. Therefore, an important goal of conducted research is categorization of visual stimuli according to their complexity, i.e., their usefulness for diagnosis or therapy in the treatment of different kinds of neuropsychological and emotional disorders.

Paintings can represent many things and be analyzed on various syntactic and semantic levels [5] (cf. Figure 1). Jaimes and Chang [6] developed an overview structure of these content levels for the indexing of images. Jaimes and Chang's Index Pyramid consists of four syntactic and six semantic levels, where the width of each level gives an indication of the amount of knowledge required to describe the image content on that level. Even though the lower levels consist of upper levels, single levels can be seen as individual parts.

Syntactic levels define the visual elements such as colors and lines and are in close relation to visual perception. Semantic levels are concentrated on visual concepts and they define the meanings of the visual elements and of their arrangements. As can be seen from the Pyramid, semantics can be observed on the general, specific or abstract level. Jörgensen [7] divides painting attributes into three different groups; perceptual, reactive and interpretive attributes. Perceptual attributes are closely related to visual stimuli, e.g. the color "red". Reactive attributes are peoples' personal reactions to paintings, e.g. uncertainty, confusion and liking the image.

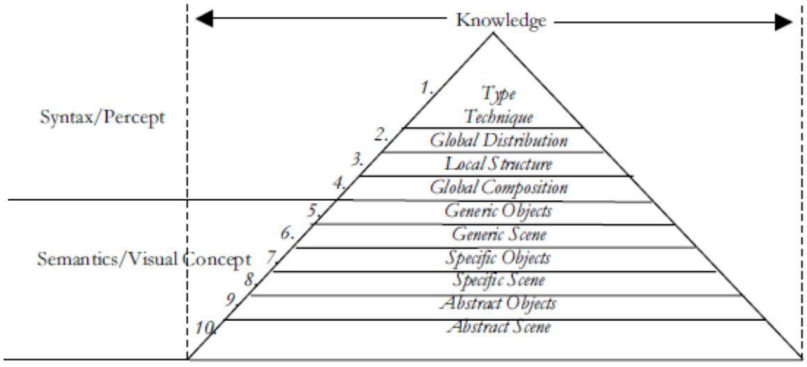

Fig. 1. The ten-level visual structure

Interpretive attributes include features like sentiment, abstract concepts and content elements like action and function.

The image complexity is a sum of syntactic and semantic complexity. At the most basic level, we are interested in the general visual characteristics of the image or the video sequence. Descriptions of the type of image or video sequence or the technique used to produce it are very general, but prove to be of great importance. Images, for example, may be placed in categories such as painting, black and white, color photograph, and drawing [6]. Global distribution aims to classify images or video sequences based on their global content and is measured in terms of low-level perceptual features such as spectral sensitivity (color), and frequency sensitivity (texture). Individual components of the content are not processed at this level. Global distribution features, therefore, may include global color (e.g., dominant color, average, histogram), global texture (e.g., coarseness, directionality, contrast), global shape (e.g. aspect ratio), global motion (e.g. speed, acceleration, and trajectory), camera motion, global deformation (e.g. growing speed), and temporal/spatial dimensions (e.g. spatial area and temporal dimension), among others. In contrast to Global Structure, which does not provide any information about the individual parts of the image or the video sequence, the Local Structure level is concerned with the extraction and characterization of the image's components. At the most basic level, those components result from low-level processing and include elements such as the Dot, Line, Tone, Color, and Texture. At this level, we are interested in the specific arrangement of the basic elements given by the local structure, but the focus is on the Global Composition. In other words, we analyze the image as a whole, but use the basic elements described above (line, circle, etc.) for the analysis.

One of the key goals realized by the observer at the syntactic level is to detect image contours. One common attribute of paintings in a broad array of artistic traditions, starting from the earliest surviving depictions on cave walls, is the use of boundary lines to depict the edges of objects. There are no actual contour lines dividing real objects from their backgrounds in most cases, which raises the question of why contour lines are so ubiquitous and effective in depiction. One theory is that line drawings are a convention that are imposed within a particular culture and passed down through learning [8].

Recapping, image complexity at the syntactic level is the degree of cognitive effort to which the observer is forced by the structure (arrangement) of the painting obtained by means of adequate painting techniques at the level of receiving physical stimuli. The degree of this type of complexity can be determined in terms of uncertainty or redundancy.

III. Procedure

Human eyes are unable to observe the whole image with the equal acuity. The area of acute vision covers a field of less than 1.5° of arc. A standard eye-tracking examination is performed within 50 cm of the screen. An image has a horizontal resolution of 1200 - 1600 pixels. Therefore, the area of acute vision covers a field with a diameter of 25 pixels. In the performed examinations, the size of a segment has been selected proportionally to the image with a horizontal resolution of 1200 pixels. Art perception is dependent on physical features of the human eye. Therefore, splitting the painting into smaller parts is important in syntactic processing. Research carried out using eye-tracking shows that data processing is realized in the form of fixations followed by saccades (i.e., transitions between fixations). We have created a specialized computer tool for the objective analysis of painting complexity - entropy. The painting with a low information content has a small value of entropy. According to information theory, the smaller probability of object occurrence, the greater information. Results obtained by means of the created tool have been compared with results obtained by means of eye-tracking in the form of the so-called heat maps. Heat maps represent the fixation locations and the duration of the fixations. The regions indicated by our tool, in most cases, are covered by experimental results obtained in the eye-tracking process. On

this basis, one can determine that in the syntactic analysis of the painting, most vision fixations concern regions whose structures differ from other regions of the same painting. It is the foundation of the syntactic analysis. The main advantage of the computer tool is independence from individual features. Moreover, results are not sensitive to subjective factors.

The approach presented in this paper is based on a clustering procedure using Self Organizing Feature Maps. The concept of a Self-Organizing Feature Map (SOM) was originally developed by Kohonen [9]. SOMs are neural networks composed of a two-dimensional grid (matrix) of artificial neurons that attempt to show high-dimensional data in a low-dimensional structure. Each neuron is equipped with modifiable connections. Self-Organizing Feature Maps possess interesting characteristics such as self-organization, i.e., networks organize themselves to form useful information, as well as competitive learning, i.e., network neurons compete with each other. The winners of the competition strengthen their weights while the losers' weights are unchanged or weakened. SOMs are used in a clustering process. Input data are vectors composed of m features (elements).

In our approach, each SOM is a feedforward three-layer neural network, one layer for one color component (R, G, or B). This architecture can also be used for other color models, e.g. YUV.

The training process of SOMs can be presented as a list of the following steps:

1) **Initialization**. At the beginning, weights are initialized with random values from a given interval (w_{min}, w_{max}), i.e.:
$$map(i,j,k) = random(w_{min}, w_{max}),$$
where k determines a layer of the multilayer map, i and j are coordinates in the k-th map layer. An initial value for a learning rate α is equal to α_{top}. During the learning process, a value of α is changed from α_{top} to α_{bottom} with step α_{step}, where p is a number of epochs. The initial size of the map is equal to $s_{min} \times s_{min}$ of neurons. This size is progressively increased to $s_{max} \times s_{max}$, where $s_{max} = max(s_{min}, \sqrt{2n} + 1)$.
2) **Reading input data**. Input vectors are normalized to the interval $[0, 1]$. All input vectors have the same dimension, i.e., m.
3) **Iterations**.
   a) At each iteration, a random input vector is entered to the input layer $x_{current} = \mathbf{x}(random(1, n))$.
   b) A winning Kohonen neuron is determined, i.e., the neurons compete on the basis of which of them have their associated weight vectors "closest" to $x_{current}$. The winner is selected on the basis of minimization of the mean squared error, i.e.:
   $$\min_{i,j} \sum_{k=0}^{m} \left(x_{current}(k) - map(i,j,k)\right)^2$$
   c) For the winner and direct neighbours only, weights are modified according to:
      - winner:
      $$map(i,j,k) = \alpha \left(x_{current}(k) - map(i,j,k)\right),$$
      - direct neighbours:
      $$map(i,j) = 0.6\alpha \left(x_{current} - map(i,j)\right).$$
   d) The learning rate is updated according to $\alpha_{e+1} = \alpha_{top} - e\alpha_{step}$, where e is the current epoch number indicator.
   e) The size of the map is updated:
   $$s_{e+1} = s_{max} \frac{e}{p},$$
   if s_{e+1} is greater than the current size, where p is a number of epochs.
   f) If the size of the map has been changed, weights are updated according to:
   $$map_{new}(i,j,k) = \\ = \sum_{neighbours\ of\ (i,j)} 0.6 map_{neighbour}(i,j,k) + \\ + map(i,j,k).$$

In a standard algorithm, we can distinguish the following steps. An image is recorded in the RGB format. Next, SOM is trained on the basis of the RGB components, separately for each component. However, in each step, weights of maps are also averaged (using the weighted average) for color components. Application of SOMs causes generalization of relationships between pixels of an input image by grouping similar regions close to each other. SOMs are widely used in problems demanding reduction of input data dimension. The obtained map represents classes into which input data space can be divided. In most cases, this is the last step of grouping data. The disadvantage of such an approach is a region of tolerance too broad for neighborhoods of individual classes. Generally, for each class, only its centroid is indicated.

In this paper we propose to extend the standard algorithm:

1) An input image is split into segments constituting a grid of the size $N \times N$. The size of the individual segment depends on the size of the image.
2) Each segment is independently processed. Data for a given segment are passed to the input of SOM. As a result, we obtain maps (i.e., layers of SOM) for each component: R, G, and B. SOM is trained using the procedure described earlier.
3) On the basis of maps for components, a minimal spanning tree (MST) is created using the weighted average of color components. The spanning tree includes information about correlations of pixels of the input image:
$$tree[i][j] = \begin{cases} w_{ij} & \text{if } (i,j) \text{ belongs to MST,} \\ 0 & \text{otherwise,} \end{cases}$$
where i and j are pixel indexes, w_{ij} is a correlation factor of pixels.
4) The coefficient $C_{seg}(m,n)$ is calculated for each segment (see Algorithm 1) with coordinates m and n. In

a)  b) 

Fig. 2. Example 1: a) the clustering result; b) the heat map

a)  b) 
Fig. 3. Example 2: a) the clustering result; b) the heat map

Algorithm 1: Algorithm for calculating the coefficient $C_{seg}(m,n)$

```
C_seg(m,n) ← 0;
for each pixel i do
    for each pixel j do
        if tree[i][j] > CORR_min and
        dist(i,j) < DIST then
            C_seg(m,n) ← C_seg(m,n) + 1;
        end
    end
end
```

this algorithm, pairs of pixels are compared. Moreover, $CORR_{min}$ is a threshold correlation between pixels and $DIST$ is a threshold distance between pixels (for example, the Manhattan distance).
This step enables us to omit pixels which potentially are not important for visual perception. Moreover, correlation between pixels which are far apart is not taken into consideration. Thresholds $CORR_{min}$ and $DIST$ have been determined experimentally, and they are equal to:

$$CORR_{min} \approx 2,$$

$$DIST = \frac{D_{segm}}{2},$$

where D_{segm} is the width of the segment.
The greater value of the coefficient $C_{seg}(m,n)$ indicates a more complex structure of the segment, e.g. gradients, colors, shapes, etc.

5) We search for numbers of segments with the same coefficient $C_{seg}(m,n)$. Let $VAL_{C_{seg}}$ be a set of all values of coefficients $C_{seg}(m,n)$ calculated in the previous step. For each value v in $VAL_{C_{seg}}$, we calculate its number $OCC_{C_{seg}}(v)$ of occurrences.
6) We calculate the entropy for the analyzed image:

$$H = -\sum_{v=1}^{k} p(v) \ln p(v),$$

where:

- k is a cardinality of $VAL_{C_{seg}}$,
- $p(v) = \frac{OCC_{C_{seg}}(v)}{N}$,
- $N = \sum_{v=1}^{k} OCC_{C_{seg}}(v)$.

The greater entropy indicates that the complexity of the image is greater, i.e., a number of segments with different coefficients $C_{seg}(m,n)$ is greater.

IV. Experiments

Experiments have been carried out using some well known paintings. Figures 2 - 5 present exemplary comparisons of the clustering results and the heat maps obtained in the eye-tracking process.

V. Conclusions and Further Works

In the paper, we have shown the computer tool based on Self-Organizing Feature Maps enabling us to automatically determine complexity of visual stimuli used in syntactic analysis. Such a method is necessary in diagnosis and therapy of some neuropsychological and emotional disorders using eye-tracking. This problem is the main task for our future work.

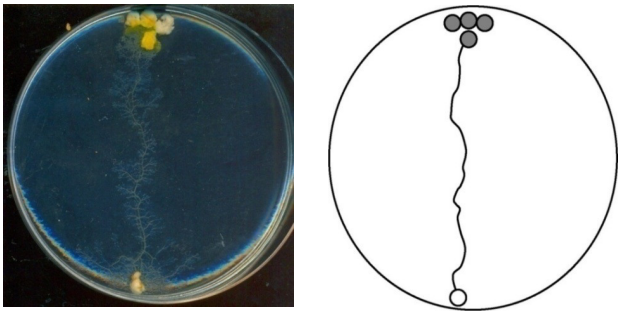
***Abstract*—In this paper we consider possibilities of simulating behavior of the group of trematode larvae (miracidiae and cercariae) by the abstract slime mould based computer that is programmed by attractants and repellents. For describing this simulation, we appeal to the language which is a kind of π-calculus called Physarum spatial logic. This language contains labels for attractants and repellents. Taking into account the fact that the behavior of miracidiae and cercariae can be programmed only by attractants (repellents for miracidiae and cercariae are not known still), we can claim that the behavior of miracidiae and cercariae is a restricted (poorer) form of Physarum spatial logic.**

I. Introduction

IN *Physarum Chip Project: Growing Computers From Slime Mould* [3] supported by FP7 we are going to implement programmable amorphous biological computers in plasmodium of Physarum. This abstract computer we are going to obtain is called *slime mould based computer*. The plasmodium behaves and moves as a giant amoeba and its behavior can be considered as a biological implementation of Kolmogorov-Uspensky machines [2]. This allows us to use the plasmodium of Physarum for solving different tasks that can be solved in Kolmogorov-Uspensky machines as well. The slime mould based computer is programmed using attractants and repellents (fig. 1). On the one hand, it was experimentally proved that the slime mould prefers substances with potentially high nutritional value, e.g. it is attracted by peptones, aminoacids phenylalanine, leucine, serine, asparagine, glycine, alanine, aspartate, glutamate, and threonine. On the other hand, repellents for Physarum polycephalum can be presented by some illumination-, thermo- and salt-based conditions. Usually the plasmodium forms a congregation of protoplasm in food sources to surround them, secret enzymes and digest the food. Slime mould based computer can be regarded as a parallel computing substrate complementary to existing massive-parallel reaction-diffusion chemical processors [1].

In papers [15; 16] we showed that the behavior of plasmodium of *Physarum polycephalum* has an own spatial logic which is one of the natural implementations of π-calculus. This logic called *Physarum spatial logic* can be used as a programming language for the slime mould based computer. Taking into account the fact that within π-calculus we can formalize and describe different concurrent processes, within Physarum spatial logic we can do the same as well.



(a) (b)

Fig. 1 An 'ideal' example of plasmodium attracted by source of nutrients. Initially an oat flake colonized by plasmodium is placed in the southern part of Petri dish, and a group of intact oat flakes in the northern part. Plasmodium propagates towards the intact flakes and occupies them. (a) Snapshot the experimental Petri dish with the plasmodium. (b) Scheme of the plasmodium attraction: initial position of the plasmodium is shown by circle, newly occupied oat flakes (attractants) by solid discs, trajectory of the plasmodium by curve. This figure is from the book [20]. *Courtesy of Andy Adamatzky*

In this paper we will show that the behavior of local group of the genus *Trichobilharzia* Skrjabin & Zakharov, 1920 (Schistosomatidae Stiles & Hassall, 1898) can be simulated by Physarum logic. This means that, first, a local group of Schistosomatidae can behave as a programmable biological computer, second, a biologized kind of π-calculus such as Physarum spatial logic can describe concurrent biological processes at all.

II. Physarum Spatial Logic

In this section we will consider some basics of Physarum spatial logic.

The behavior of Physarum plasmodium can be divided into the following elementary processes: inaction, fusion, cooperation, and choice, which could be interpreted as unconventional (spatial) falsity, conjunction, weak and strong disjunction respectively, denoted by *Nil*, &, |, and +. These

This research is being fulfilled by the support of FP7-ICT-2011-8.

operations differ from conventional ones, because they cannot have a denotational semantics in the standard way. However, they may be described as special spatial transitions over states of Physarum machine: inaction (*Nil*) means that pseudopodia has just stopped to behave; fusion (&) means that two pseudopodia come in contact one with another and then merge; cooperation (|) means that two pseudopodia behave concurrently; choice (+) means a competition between two pseudopodia in their behaviors.

A π-calculus for describing the dynamics of Physarum machine is presented as a labeled transition system with some logical relations.

Assume that there are N active species or growing pseudopodia and the state of species i is denoted by $p_i \in$ L. These states are time dependent and they are changed by plasmodium's active zones interacting with each other and affected by attractants or repellents. Plasmodium's active zones interact concurrently and in a parallel manner. Foraging plasmodium can be represented as a set of the following abstract entities.

- The set of actions (growing pseudopodia), T' = {α, β, ...}, localized in *active zones*. The actions from T' are called the *simplest transitions*, the latter are defined as $\{p \xrightarrow{\alpha} q : p, q \in L, \alpha \in T'\}$. Notice that we also have transitions that do not belong to T'. Assume that the set of all transitions is denoted by T.

On a nutrient-rich substrate plasmodium propagates as a typical circular, target wave, while on the nutrient-poor substrates localized wave-fragments are formed. Each action $\alpha \in$ T', starts on a state p_i, which is its current position, and says about a transition (propagation) of a state p_i to another state of the same or another computation cell. Part of plasmodium feeding on a source of nutrients may not propagate, so its transition may be *Nil*, but this part can always start moving.

- The set of *attractants* {A_1, A_2, ...} $\subset$ T \ T' are sources of nutrients, on which the plasmodium feeds. It is still subject of discussion how exactly plasmodium feels presence of attractants. Each attractant A is a function from T' to T'.
- The set of *repellents* {R_1, R_2, ...} $\subset$ T \ T'. Plasmodium of Physarum avoids light and some thermo- and salt-based conditions. Thus, domains of high illumination are repellents such that each repellent R is characterized by its position and intensity of illumination, or force of repelling. In other words, each repellent R is a function from T' to T'.
- The set of *protoplasmic tubes* {C_1, C_2, ...} $\subset$ T \ T'. Typically plasmodium spans sources of nutrients with protoplasmic tubes/veins. The plasmodium builds a planar graph, where nodes are sources of nutrients, e.g. oat flakes, and edges are protoplasmic tubes. $C(\alpha)$ means a diffusion of growing pseudopodia $\alpha \in$ T'.

Hence, T = T' $\cup$ {A_1, A_2, ...} $\cup$ {R_1, R_2, ...} $\cup$ {C_1, C_2, ...}.

Our process calculus contains the following basic operators: *Nil* (inaction), $\cdot$ (prefix), | (cooperation), \ (hiding), & (reaction/fusion), + (choice), a (constant or restriction to a stable state), $A(\cdot)$ (attraction), $R(\cdot)$ (repelling), $C(\cdot)$ (spreading/diffusion). Let T = {a, b, ...}, the set of all actions (evidently, this set is finite), be considered as a set of names. A name refers to a communication link or channel. With every $a \in$ T we associate a complementary action $\overline{a}$. Let us suppose that a designates an input port and $\overline{a}$ designates an output port. Any behavior of Physarum will be considered as outputs and any form of outside control and stimuli as appropriate inputs. For instance, T' is to be regarded just as the set of output ports and thereby T \ T' contains ports that can be interpreted under different conditions as input ports or output ports. So, for each $X \in$ {A_1, A_2, ...} $\cup$ {R_1, R_2, ...}, we take that $X(\gamma) = \delta$ is a function from T' to T' such that X is a stimulus for γ and X makes an output $\delta \in$ T' along γ. Evidently that $X(Nil) = Nil$. Let $X(\gamma)$ denote an input and $\overline{X(\gamma)}$ an output.

Define **L** be the set of labels built on T (under this interpretation, $a = \overline{\overline{a}}$). Suppose that an action a communicates with its complement $\overline{a}$ to produce the internal action τ and τ belongs to **L**, too.

We use now the symbols γ, δ, … , etc., to range over labels (actions), with $a = \overline{\overline{a}}$, and the symbols P, Q, etc., to range over processes on states p_i. The processes are given by the syntax:

$$P, Q ::= Nil \mid \gamma.P \mid A(\gamma).P \mid \overline{A(\gamma)}.P \mid R(\gamma).P \mid \overline{R(\gamma)}.P \mid C(\gamma).P \mid (P \mid Q) \mid P \setminus Q \mid P \,\&\, Q \mid P + Q \mid a$$

Each label is a process, but not vice versa, because a process may consists of many labels combined by the basic operators.

An operational semantics for this syntax is defined as follows: $\gamma ::= p_i$, where $p_i \in$ L.

$$\text{Prefix}: \frac{}{\gamma.P \xrightarrow{\gamma} P},$$

$$\frac{}{A(\gamma).P \xrightarrow{\delta} P}\ (A(\gamma) = \delta), \quad \frac{}{\overline{A(\gamma)}.P \xrightarrow{\delta} P}\ (\overline{A(\gamma)} = \delta),$$

$$\frac{}{R(\gamma).P \xrightarrow{\delta} P}\ (R(\gamma) = \delta), \quad \frac{}{\overline{R(\gamma)}.P \xrightarrow{\delta} P}\ (\overline{R(\gamma)} = \delta),$$

(the conclusion states that the process of the form $\gamma.P$ (resp. $A(\gamma).P$, $\overline{A(\gamma)}.P$, $R(\gamma).P$, $\overline{R(\gamma)}.P$) may engage in γ (resp. $A(\gamma)$, $\overline{A(\gamma)}$, $R(\gamma)$, $\overline{R(\gamma)}$) and thereafter they behave like P; in the presentations of behaviors as trees, $\gamma.P$ (resp. $A(\gamma).P$, $\overline{A(\gamma)}.P$, $R(\gamma).P$, $\overline{R(\gamma)}.P$) is understood as an

edge with two nodes: γ (resp. $A(\gamma)$, $\overline{A(\gamma)}$, $R(\gamma)$, $\overline{R(\gamma)}$) and the first action of P),

$$\text{Diffusion:}\quad \frac{P \xrightarrow{\gamma} P'}{P \xrightarrow{\gamma} C(\gamma)} \quad (C(\gamma) = P'),$$

$$\text{Constant:}\quad \frac{P \xrightarrow{\gamma} P'}{a \xrightarrow{\gamma} P'} \quad (a = P, a \in L),$$

$$\text{Choice:}\quad \frac{P \xrightarrow{\gamma} P'}{P + Q \xrightarrow{\gamma} P'}, \quad \frac{Q \xrightarrow{\gamma} Q'}{P + Q \xrightarrow{\gamma} Q'},$$

(these both rules state that a system of the form $P + Q$ saves the transitions of its subsystems P and Q),

$$\text{Cooperation:}\quad \frac{P \xrightarrow{\gamma} P'}{P \mid Q \xrightarrow{\gamma} P' \mid Q}, \quad \frac{Q \xrightarrow{\gamma} Q'}{P \mid Q \xrightarrow{\gamma} P \mid Q'},$$

(according to these rules, the cooperation | interleaves the transitions of its subsystems),

$$\frac{P \xrightarrow{\gamma} P' \quad Q \xrightarrow{\bar{\gamma}} Q'}{P \mid Q \xrightarrow{\tau} P' \mid Q'},$$

(i.e. subsystems may synchronize in the internal action τ on complementary actions γ and $\bar{\gamma}$),

$$\text{Hiding}: \quad \frac{P \xrightarrow{\gamma} P'}{P \setminus Q \xrightarrow{\gamma} P' \setminus Q} \quad (\gamma \notin Q, Q \subseteq \mathbf{L}),$$

(this rule allows actions not mentioned in Q to be performed by $P \setminus Q$),

$$\text{Fusion}: \quad \frac{}{\gamma.P \,\&\, \breve{P} \xrightarrow{\gamma} Nil}$$

(the fusion of dual processes are to be performed into the inaction, e.g. a fusion of an attractant/repellent P and appropriate repellent/attractant $\breve{P}$),

$$\frac{P \xrightarrow{\gamma} P' \quad Q \xrightarrow{\gamma} P'}{P \wedge Q \xrightarrow{\gamma} P'}, \quad \frac{P \xrightarrow{\gamma} P' \quad Q \xrightarrow{\gamma} P'}{Q \wedge P \xrightarrow{\gamma} P'}$$

(this means that if we obtain the same result P' that is produced by the same action γ and evaluates from two different processes P and Q, then P' may be obtained by that action γ started from the fusion P & Q or Q & P),

$$\frac{P \xrightarrow{\gamma} P'}{P \wedge Q \xrightarrow{\gamma} Nil + C(\gamma) + P'}, \quad \frac{P \xrightarrow{\gamma} P'}{Q \wedge P \xrightarrow{\gamma} Nil + C(\gamma) + P'}$$

(these rules state that if the result P' is produced by the action γ from the processes P, then a fusion P & Q (or Q & P) is transformed by that same γ either into the inaction or diffusion or process P').

These are inference rules for basic operations. The ternary relation $P \xrightarrow{\gamma} P'$ means that the initial action P is capable of engaging in action γ and then behaving like P'.

Now we can show that in the behavior of any local group of Schistosomatidae we can observe the same elementary processes: inaction, fusion, cooperation, and choice, which are defined in the same way.

III. Life Cycle of Schistosomatidae (Trematoda : Digenea)

All representatives of subclass Digenea Carus, 1863 (Platyhelminthes: Trematoda) are exclusively endoparasites of animals. The digenean life cycle has the form of heterogony, i.e. there is a natural alternation of amphimictic (usually synarmophytous) and parthenogenetic stages. At these stages digeneae have different outward, different means of reproduction and different adaptation to different hosts. The interchange of hosts is necessary for a successful realization of digenean flukes life cycle. The majority of representatives of this subclass have a complete life cycle with participation of three hosts: intermediate, additional (metacercarial) and definitive. Molluscs are always the first intermediate hosts, while different classes of vertebrate animals are definitive hosts.

Among digeneae there is a bunch of parasites, belonging to the family of Schistosomatidae, which represents an isolated bunch which has adapted to parasitizing in the circulatory system of vertebrate animals. Puberal representatives of this family are diecious individuals (in other digenean families maritas are hermaphrodites). The family includes the following three subfamilies: Schistosomatinae Stiles and Hassall, 1898, they parasitize a variety of birds and mammals, including human being; Bilharziellinae Price, 1929 and Gigantobilharziinae Mehra, 1940, they parasitize birds. Representatives of the first subfamily (in particular the genus *Schistosoma* Weinland, 1858) parasitize mammals, including human being. In the tropical and subtropical countries, about 200 million persons are infected by them from which 11 thousand persons annually die because of the given infestation [13]. Representatives of the latter two subfamilies, the so-called avian schistosomatidae, have been observed on all continents, including Europe. In a puberal state they parasitize birds, however they are capable to incorporate into a human organism as nonspecific host. After they penetrate human skin, where they perish, they invoke thereby allergic dermatitis. The fact of incorporation of these larvae into nonspecific hosts invokes interest to avian schistosomatidae. Therefore the simulation of behavior of their local groups can be interesting from a medicine view, be-

cause it allows to perceive better features of digenean behavior. Simulating their behavior is possible by means of Physarum spatial logic as we will show.

The life cycle of all representatives of the family Schistosomatidae is identical, it passes with participation of two hosts.

From an egg which got to water from an organism of definitive host, a miracidia hatchs. It is a settle free-swimming larval stage of parthenogenetic generation of Schistosomatidae. Miracidia for a short span should find a molluc of a certain kind to insinuate into it, otherwise it perishes. Molluscs, thus, are attractants for miracidiae. More precisely, in respect to miracidiae the chemotaxis as attractant holds (miracidia moves towards a chemical signal proceeding from a molluc). Other kinds of attractants for miracidiae are presented by light (there is a positive phototaxis) and gravitation (negative geotaxis). We will designate all miracidian attractants by $A^m_1, A^m_2, \ldots, A^m_n$.

Miracidian repellents have not been detected still, i.e. $\{R^m_1, R^m_2, \ldots, R^m_n\} = \varnothing$.

The continuation of digenean life cycle will take place just in case a miracidia detects a mollusc for which a certain kind of digeneas has a hostal specificity [10]. Otherwise the miracidia dies. Miracidiae *Trichobilharzia szidati* Neuhaus, 1952 can look for a intermediate host only for the period of 20 h at temperature 20 °C [14].

In a body of mollusc, a miracidia undergoes metamorphosis and it is transformed into a mother sporocyst in which daughter sporocysts educe. In the latter then cercariae start to be formed. This state can be called the miracidian diffusion. We will designate these diffusions by $C^m_1, C^m_2, \ldots, C^m_n$.

Now we can construct a version of Physarum spatial logic for simulating the behavior of local groups of miracidiae. The processes have the following syntax which is defined in the way of Physarum logic:

$$P, Q ::= Nil \mid \gamma.P \mid A^m(\gamma).P \mid \overline{A^m(\gamma)}\ .P \mid$$
$$C^m(\gamma).P \mid (P \mid Q) \mid P \setminus Q \mid P \,\&\, Q \mid P + Q \mid a$$

For the simulation we need also to have two sets of actions T and T^m, where T contains actions of Physarum plasmodium, T^m includes actions of local group of miracidiae. These sets should have the same number of members (the same cardinality), namely we should have the same number of active zones (growing pseudopodia and active miracidiae), the same number of attractants, and the same number of diffusions (motions of protoplasmic tubes towards food and miracidian motions towards chemical signals of eventual hosts to transform into a maternal sporocyst). For instance, if we have five molluscs in one experimental dish with water and a suspension of miracidiae, then we can try to simulate the miracidian processes by Physarum spatial logic for stimuli of five nutrient sources with similar localizations as that for molluscs.

IV. The Behavior of Cercariae of Bird Schistosomes (Genus *Trichobilharzia*)

The cercarial behavior of bird schistosomes (family *Schistosomatidae*) is well studied due to representatives of the genus *Trichobilharzia* [11]. Their behavior is characterized by specific taxises which are referred to an effective search of necessary definitive hosts. These taxises developed by evolution of larvae of bird schistosomes allow their looking for specific hosts to be successful, forward their affixion to a surface of host body as well as their incorporation into a host cutaneous covering and their penetration into a circulatory system, where a parasite reaches sexual maturity. Thus, taxises form an enough large family of attractants for cercariae.

In a resting state, cercariae are attached to a vascular wall or on a water film by means of acetabulum. Active motions are characteristic only by the strong shaking of pot or by the water interfusion. At a weak rotation of pot it is visible that the cercarial body and its tail follow the water stream, while their acetabulums keep cercariae on the pot wall. Any continuous active motion is not observed.

Cercariae of the genus *Trichobilharzia* after leaving a mollusc actively swiming in the water for an hour. Such an active behavior of larvae after leaving a mollusc provides a cercarial allocation in water space. Then cercariae pass to a passive behavior. They are attached by a ventral sucker to a surface film of water or to various subjects near a water surface, getting thus a characteristic resting state. The resting state allows cercariae in absence of specific to them stimulants to stop the search of host and to conserve their energy.

Free-swiming cercariae need to insinuate into a definitive host during the limited time interval (1–1.5 days at temperature 24°C) since otherwise larvae perish [14].

For successful search of hosts, larvae of digeneae of *Trichobilharzia* have developed by evolution a behavior facilitating this problem. They possess a positive phototaxis, negative geotaxis, chemotaxis, and also actively react to turbulence of water [7]. It means that for cercariae there are already many other attractants.

The light sensitivity of cercariae of *Trichobilharzia* is very high. As experiments show, cercariae always move towards a light source, and then take a resting state on the lighted side of capacity in which they are. The given taxis, and also negative geotaxis allow cercariae to be kept in the nature at a surface of water in expectation of suitable hosts.

Cercariae actively react to changes in intensity of illumination (shadings) and to turbulence of water [5]. These external factors, corresponding to possible appearances of definitive hosts in water, stimulate the cercarial transition from a resting state into actions that enlarge their chances to meet hosts.

Cercariae possess a chemotaxis in relation to specific hosts. On body surfaces larvae of the genus *Trichobilharzia* have chemoreceptors which receive appropriate chemical signals proceeding from a skin of potential host. The similarity of compound of fatty acids of bird and human skin leads to that cercariae equally react to the bird and human appearance in water: they move in their direction, and then

they are attached to skin and begin penetration into it [9]. So, the chemotaxis from a skin of potential hosts (surface lipids of skin of human being and swimming bird), the positive phototaxis, the negative geotaxis and the water turbulence present cercarial attractants of different degree of appeal. We will designate these attractants by $A^c_1, A^c_2, \ldots, A^c_n$.

In experimental researches it has been shown that any attachment of cercariae of *Trichobilharzia* to skin is stimulated by cholesterol and ceramides, and incorporation into skin by linoleic and linolenic acids, all these materials are present on skin of both bird and human being [12; 8]. Thereby surface lipids of human skin invoke higher frequency of cercarial incorporations into skin, than surface lipids of birds [9]. One more reason that cercariae of *Trichobilharzia* successfully insinuate into human skin is the fact of that the skin of duck foots has thicker keratinized surface which, possibly, is more difficult for overcoming, than that of human being [8].

On the basis of experiments the rate of penetration of larvae of schistosomes *Trichobilharzia szidati* into human skin [8] has been defined. The larva begins incorporation into human skin approximately in 8 seconds (range from 0 to 80 seconds) after first contacts. The process of full penetration into skin takes about 4 minutes (range from 83 till 13 minutes 37 seconds). The given numerals testify that it is enough if the person has even a short-term contact to water where there are cercariae of bird schistosomes to give them possibility to incorporate into skin.

In some cases, for example children, cercarial larvae can "chip" skin and be brought by venous blood to lungs, invoking there hemorrhages and inflammation. If cercariae are lucky to insinuate into blood and then to lungs, the disease can get harder by the pulmonary syndrome from small cough to symptoms of bronchial obstruction [18].

At the same time, repellents for cercariae have not been found yet. For example, Ludmila Akimova's experience shows that cercarial motions towards a smaller concentration of material which invokes a destruction of larvae are not observed at all. The experience principle consists in that in a small cavity with the length of 10 cm, the width and depth of 0.5 cm there is water with a suspension of cercariae. Then a thin essential oil is added in one of the side of this small cavity. Cercariae, which are nearby, quickly perish, although other cercariae do not move aside where the reacting material is absent. Cercariae simply freely float and as soon as they appear in that part where there is the reacting material they perish. Thus, $\{R^c_1, R^c_2, \ldots, R^c_n\} = \varnothing$.

In definitive hosts cercariae reach diffusion states. We will designate these diffusions by $C^c_1, C^c_2, \ldots, C^c_n$.

The behavior of local groups of cercariae can be simulated within a version of Physarum spatial logic, where the processes have the following syntax defined in section II:

$$P, Q ::= Nil \mid \gamma.P \mid A^c(\gamma).P \mid \overline{A^c(\gamma)}\ .P \mid$$
$$C^c(\gamma).P \mid (P \mid Q) \mid P \setminus Q \mid P \,\&\, Q \mid P + Q \mid a$$

The sets of actions T and T^c, where T consists of actions of Physarum plasmodium, T^c contains actions of local group of cercariae, should have the same number of members. For example, if we have three human beings in one lake with cercariae, then we can simulate the cercarial processes by Physarum spatial logic where three nutrient sources with similar localizations as that for human beings act as stimuli. Hence, the behavior of local groups of cercariae is another biological implementation of Kolmogorov-Uspensky machines. It can build planar graphs as well.

V. Arithmetic Operations in Physarum Spatial Logic and In Schistosomatidae Behavioral Logic

We know that within π-calculus we can convert expressions from λ-calculus. In particular, it means that we can consider arithmetic operations as processes. Physarum spatial logic as well as its modification in the form of behavioral logic for local groups of miracidiae (cercariae) is a biologized version of π-calculus. Therefore we can convert arithmetic operations into processes of either Physarum spatial logic or schistosomatidae behavioral logic.

Indeed, growing pseudopodia may represent a natural number *n* by the following parametric process:

$$\underline{n}(x, z) ::= \underbrace{\overline{x}.\overline{x}.\cdots.\overline{x}}_{n}.\overline{z}.Nil$$

The process $\underline{n}(x, z)$ proceeds *n* times on an output port called the successor channel $\overline{x} \in \{A_1, A_2, \ldots\} \cup \{R_1, R_2, \ldots\}$ (e.g. it is the same output of attractant) and once on the zero output port $\overline{z} \in \{A_1, A_2, \ldots\} \cup \{R_1, R_2, \ldots\}$ before becoming inactive *Nil*. Recall that it is a "Church-like" encoding of numerals used first in λ-calculus. Notice that in case of miracidiae or cercariae $\overline{x} \in \{A_1, A_2, \ldots\}$ and $\overline{z} \in \{A_1, A_2, \ldots\}$.

An addition process takes two natural numbers *i* and *j* represented using the channels *x*[*i*], *z*[*i*] and *x*[*j*], *z*[*j*] and returns their sum as a natural number represented using channels *x*[*i*+*j*], *z*[*i*+*j*]:

$$Add(x[i], z[i], x[j], z[j], x[i+j], z[i+j]) ::=$$
$$(x[i].\ \overline{x}[i+j].\ Add(x[i], z[i], x[j], z[j], x[i+j], z[i+j])) +$$
$$z[i].Copy(x[j], z[j], x[i+j], z[i+j])).$$

A multiplication process takes two natural numbers *i* and *j* represented using the channels *x*[*i*], *z*[*i*] and *x*[*j*], *z*[*j*] and returns their multiplication as a natural number represented using channels $x\left[\underbrace{i+\ldots+i}_{j}\right]$, $z\left[\underbrace{i+\ldots+i}_{j}\right]$:

$$Mult(x[i], z[i], x[j], z[j], x[i*j], z[i*j]) ::= Add(x[i], z[i],$$
$$x[j], z[j], x[i+\ldots+i], z[i+\ldots+i]).$$

The *Copy* process replicates the signal pattern on channels *x* and *y* on to channels *u* and *v*. It is defined as follows:

$$Copy(x, y, u, v) ::= (x.\ \overline{u}.\ Copy(x, y, u, v) + y.\ \overline{v}.\ Nil)$$

As we see, within Physarum spatial logic and its poorer version in the form of schistosomatidae behavioral logic we can consider some processes as arithmetic operations. Also, we can combine several arithmetic operations within one process. Let us regard the following expression:

$$(10 + 20) * (30 + 40)$$

An appropriate process is as follows:

Mult(*Add*(*x*[10], *z*[10], *x*[20], *z*[20], *x*[10+20], *z*[10+20]), *z*[10+20], *Add*(*x*[30], *z*[30], *x*[40], *z*[40], *x*[30+40], *z*[30+40]), *z*[30+40], *Add*(*x*[30], *z*[30], *x*[70], *z*[70], *x*[2100], *z*[2100])).

VI. Conclusion

We show that many biologized versions of π-calculus are possible: Physarum spatial logic, schistosomatidae behavioral logic, etc. One of its basic versions, Physarum spatial logic, can be used for constructing slime mould based computer. This logic is richer than schistosomatidae behavioral logic and may be involved for simulations of the latter. The fact that we can formalize biological behaviors as kind of logic confirms that biological processes can be considered as forms of concurrent and parallel computations.

***Abstract*—Excessive body weight, especially in the form of the so-called abdominal obesity (AO) is an important factor of the cardio-metabolic risks (CMR). The paper presents a fuzzy model of AO and CMR assessments based on such key indicators of anthropometric measurements as body mass index (BMI as a measure of the global adiposity) as well as waist circumference (WC) and waist-to-height ratio (WHtR) as AO indicators. For the construction of a membership function (MF) the Zadeh's Extension Principle (EP) and mapping of the BMI fuzzy sets into adequate AO fuzzy sets using different transformation functions have been applied. Taking advantage of the results of a screening study, the AO membership functions for adult population of Lodz (WHO-CINDI project) are presented. MF design based on the EP theory is a useful methodology for assessing the AO and, consequently for a better assessment of CMR.**

I. Introduction

OBESITY is an important risk factor for cardiovascular diseases, and a primary public health problem in many countries of the world [1]. The trend in obesity is especially alarming among children and adolescents [2].

Pol-MONICA (Multinational Monitoring of Trends and Determinants in Cardiovascular Diseases) study has shown that overweight is exhibited by about 67% of the Polish population, while approximately 30% of women and 20% of men suffer from obesity [3].

As far as obesity is concerned, its most disadvantageous form is known as abdominal obesity (AO) also called visceral or central obesity [4]. An excess of visceral fat surrounding abdominal organs substantially increases a risk of life-threatening diseases such as type 2 diabetes and heart diseases [5]. These diseases are the most common cause of death and have the greatest impact on the financial burden of both individual and public health [6].

AO evaluation based on exact measurements of visceral fat is very difficult and it is only possible to be carried out with the help of complex and expensive imaging techniques [7]. In practice, an unfavorable distribution of adipose tissue and a presence of AO are usually estimated by indirect indices such as waist circumference (WC), waist to hip ratio (WHR) or recent the waist-to-height ratio (WHtR) [8], [9], [10].

Current recommendations establish sharp boundaries between terms like overweight, obesity, etc. They are often of a contractual nature of a consensus obtained in the form of recommendation. Issues related to the assessment of the AO belong to such unspecific problems of body composition which could be well approached by a theory of fuzzy sets [11], [12]. The paper presents a concept of fuzzy AO models developed on the basis of BMI, WC and WHtR measurements. Results of the respective studies in Lodz population were used to construct AO membership function (MF) with Zadeh Extension Principle [13], [14].

II. Categorization of health risk using body mass index (BMI) and waist circumference (WC)

Both in epidemiological studies and in clinical practice, overweight is most frequently determined on the basis of the BMI value. BMI is a simple index of "weight-for-height" calculated as weight in $[kg]$ divided by squared height in meters $[m^2]$. Clinically individuals with normal weight (NO) are those with BMI is lower than 25 $[kg/m^2]$. Overweight (OW) is defined as BMI of between 25 and 30 $[kg/m^2]$ and obesity (OB) is defined as BMI of 30 $[kg/m^2]$ [1].

Recently, the WC and WHtR indices have been successfully used as effective measures of AO both in adult and in children or adolescent populations. According to WHO and to National Cholesterol Education Program-Adult Treatment Panel (NCEP-ATP III), AO in the adult population refers to: WC higher than 102 cm for men (M) and higher that 88 cm for women (F) [8], [9]. The newest criteria developed by International Diabetes Federation (IDF) are much more demanding and they recommend an identification of AO obesity at lower levels of WC (94 cm for men and 80 cm for women) [10]. For WHtR, its value > 0.5 indicating AO (central fat distribution), regardless of gender and age [8], [11].

Classification based on a combination of BMI and WC is useful in identifying people at increased CMR. Table 1 presents health risk (CMR) classification according to BMI (three stages) and WC (two stages against NCEP-ATP-III) [8].

978-83-60810-53-8/$25.00

TABLE I
HEALTH RISK CLASSIFICATION FOR ADULT MEN (M) AND FEMALE (F) ACCORDING TO BODY MASS INDEX AND WAIST CIRCUMFERENCE [8].

Waist	**Body Mass Index (BMI in $[kg/m^2]$)**		
Circumference (WC in [cm])	Normal (NO) BMI $<$ 25	Overweight (OW) 25 $\leqslant$ BMI $<$ 30	Obese (OB) BMI $\geqslant$ 30
$<$ 102 cm (M) $<$ 88 cm (F)	Least Risk **(LRisk)**	Increased Risk **(IRisk)**	High Risk **(HRisk)**
$\geqslant$ 102 cm (M) $\geqslant$ 88 cm (F)	Increased Risk **(IRisk)**	High Risk **(HRisk)**	V. High Risk **(VHRisk)**

TABLE II
CARDIO-METABOLIC RISK (CMR) CLASSIFICATION ACCORDING TO BMI AND THREE AREA OF WC (CNO - WITHOUT CENTRAL OBESITY; COW - CENTRAL OVERWEIGHT AND COB - CENTRAL OBESITY).

Waist Circumference (WC)	**Body Mass Index (BMI)**		
	Normal BMI $<$ 25	**Overweight** 25 $\leqslant$ BMI $<$ 30	**Obese** BMI $\geqslant$ 30
cNO $<$ 94 cm (M) $<$ 80 cm (F)	**(LRisk)**	**(IRisk)**	**(HRisk)**
cOW (94 - 102) cm (M) (80 - 88) cm (F)	**(IRisk)**	**(HRisk)**	**(VHRisk)**
cOB $\geqslant$ 102 cm (M) $\geqslant$ 88 cm (F)	**(HRisk)**	**(VHRisk)**	**(VHRisk)**

In the light of the proposals by Lean et al. [15] as well as the previously mentioned recommendations by NCEP-ATP III and IDF, a more appropriate classification of CMR is based on BMI and two different WC cut-offs, which define three areas of central adiposity: cNO - without central obesity; cOW - central overweight; cOB - central obesity (Table 2). Similar classification of CMR can be made on the basis of BMI and are recommended by some authors of the two levels of WHtR cut-offs (WHtR $>$ 0.5 as a cOW and WHtR $>$ 0.6 as a cOB) [11]. It should be noted that, due to the dichotomous charkter of the analyzed risk factors as well as the problem of their cut-off points, CMR classifications shown in Tables 1 and 2 constitute rather a qualitative description of the cardio-metabolic complications.

III. EVALUATION OF THE HEALTH RISK ASSOCIATED WITH OBESITY USING A FUZZY LOGIC APPROACH

A. Extension Principle theory

The extension method proposed by Zadeh, usually called Extension Principle (EP) only, is one of the basic ideas to process the extansion of the classical mathematical concepts into fuzzy ones [13], [14]. Let us consider two crisp sets X and Y and f a mapping from X to Y, f: X $\rightarrow$ Y.

Let A be a fuzzy subset of X, $A \in X$ (Figure 1). So, the EP allows to built the image of A under the crisp mapping f as a fuzzy set B:

$$B = f(A) = (y, \mu_B(y) \mid y = f(x), x \in X \qquad (1)$$

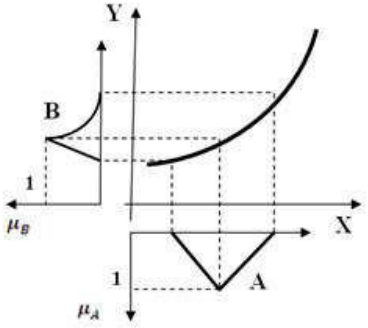

Fig. 1. Illustration of the Extension Principle for a mapping a single variable (explanations in text).

whose, membership function is given by:

$$\mu_B(y) = \begin{cases} sup\ \mu_A(x),\ if\ f^{-1}(y) \neq \emptyset \\ \\ 0,\ if\ f^{-1}(y) = \emptyset \end{cases} \quad for\ all\ y \in Y \qquad (2)$$

where: $f^{-1}(y)$ denotes the set of all points $x \in X$ such that $f(x) = y$.

In the case of X with an infinite number of elements a fuzzy set B induced by the mapping f can be expressed as:

$$B = f(A) = \int_y \frac{\mu_A(x)}{f(x)} \qquad (3)$$

Figure 1 illustrates the EP action considering the mapping $f : X \rightarrow Y$ and A a triangular fuzzy set.

B. Fuzzy models of global and abdominal obesity

The fuzzy model of global fatness was based on BMI that has a defined three fuzzy subsets (NO-normal, OW - overweight and OB - obesity) with the following MF:

$$NO = \begin{cases} 1 & for\ BMI \leq 25 \\ 6 - 0.2BMI & for\ 25 < BMI \leq 30 \\ 0 & for\ BMI > 30 \end{cases} \qquad (4)$$

$$OW = \begin{cases} 0 & for\ BMI \leq 25 \\ 0.2BMI - 5 & for\ 25 < BMI \leq 30 \\ 7 - 0.2BMI & for\ 30 < BMI \leq 35 \\ 0 & for\ BMI > 35 \end{cases} \qquad (5)$$

$$OB = \begin{cases} 0 & for\ BMI \leq 30 \\ 0.2BMI - 6 & for\ 30 < BMI \leq 35 \\ 1 & for\ BMI > 35 \end{cases} \qquad (6)$$

A graphic interpretation of fuzzy subsets of MF for NO, OW and OB is illustrated in Figure 2. Based on the defined BMI fuzzy model and EP theory described in section 3.1, the following transformation functions for men (M) and female (F) in construction of fuzzy AO subsets (cNO, cOW, cOB) have been used:

- f1: WC = f1(BMI); linear equations based on the NCAP-ATP III / IDF criteria [9].

$$f1 : \begin{cases} WC_M = 1.6 * BMI + 54 \\ WC_F = 1.6 * BMI + 40 \end{cases} \qquad (7)$$

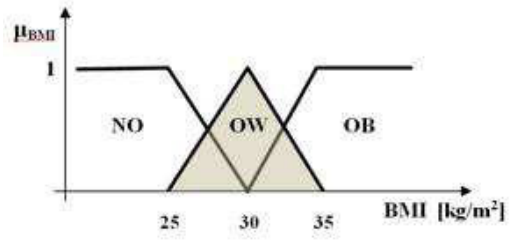

Fig. 2. Illustration of the Extension Principle for a mapping a single variable (explanations in text).

- f2: WC = f2(BMI); linear regression equations defined on the basis of epidemiological studies of the population in Lodz, designed by the WHO-CINDI (Countrywide Integrated Noncommunicable Diseases Intervention Programme: 1264 men and 1330 female aged 18 - 80 y.) [16]:

$$f2: \begin{cases} WC_M = 2.66 * BMI + 22.9 \\ WC_F = 2.27 * BMI + 23.1 \end{cases} \quad (8)$$

- f3: WHtR = f3(BMI); linear equation prepared on the basis on Ashwell recommendations [11]:

$$f3: WHtR_{M/F} = 0.02 * BMI \quad (9)$$

- f4: WHtR = f4 (BMI); regression equations defined on the basis of the WHO-CINDI population of Lodz [15]:

$$f4: \begin{cases} WHtR_M = -16 * 10^{-5} * BMI^2 + 25 * 10^{-3} * \\ \qquad * BMI - 0.012 \\ WHtR_F = -12 * 10^{-5} * BMI^2 + 22.7 * 10^{-3} * \\ \qquad * BMI + 0.0125 \end{cases} \quad (10)$$

Example: Mapping of the cOW fuzzy subset based on the proposed model and the fuzzy BMI predefined transformation functions f1-f4 ($OW_{BMI} \rightarrow cOW$).

Let:

$$OW_{BMI} = \{\frac{0}{25} + \frac{0.2}{26} + \frac{0.6}{28} + \frac{1}{30} + \frac{0.6}{32} + \frac{0.2}{34} + \frac{0}{35}\} \quad (11)$$

will be selected fuzzy numbers belonging to OW fuzzy set defined by the formula (5). Using the transformation functions f1-f4 (7 - 10) defined for men (M) let us calculate appropriate numbers belonging to a fuzzy subset cOW

- for f1:

$$\begin{aligned} cOW_{f1} &= \{\frac{0}{f(25)} + \frac{0.2}{f(26)} + \frac{0.6}{f(28)} + \frac{1}{f(30)} + \\ &+ \frac{0.6}{f(32)} + \frac{0.2}{f(34)} + \frac{0}{f(35)}\} \end{aligned} \quad (12)$$

and after substituting the values we get:

$$\begin{aligned} cOW_{f1} &= \{\frac{0}{94} + \frac{0.2}{95.6} + \frac{0.6}{98.8} + \frac{1}{102} + \\ &+ \frac{0.6}{105.2} + \frac{0.2}{108.4} + \frac{0}{110}\} \end{aligned} \quad (13)$$

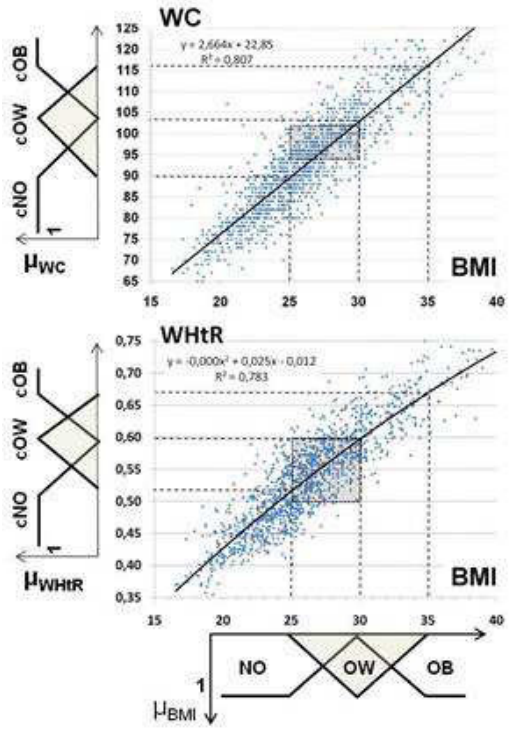

Fig. 3. Example of mapping the WC (top) and WHtR (bottom) fuzzy sets for a men population from Lodz [15]. The regression equations were used as a transformation functions. The gray rectangles - the cOW areas based on the NCEP-ATPIII/IDF recommended classification [8],[9].

- for f2:

$$\begin{aligned} cOW_{f2} &= \{\frac{0}{89.5} + \frac{0.2}{92.1} + \frac{0.6}{97.4} + \frac{1}{102} + \\ &+ \frac{0.6}{105.2} + \frac{0.2}{108.4} + \frac{0}{110}\} \end{aligned} \quad (14)$$

- for f3:

$$\begin{aligned} cOW_{f3} &= \{\frac{0}{0.5} + \frac{0.2}{0.52} + \frac{0.6}{0.56} + \frac{1}{0.6} + \\ &+ \frac{0.6}{0.64} + \frac{0.2}{0.68} + \frac{0}{0.7}\} \end{aligned} \quad (15)$$

- for f4:

$$\begin{aligned} cOW_{f4} &= \{\frac{0}{0.51} + \frac{0.2}{0.53} + \frac{0.6}{0.56} + \frac{1}{0.59} + \\ &+ \frac{0.2}{0.62} + \frac{0.2}{0.65} + \frac{0}{0.67}\} \end{aligned} \quad (16)$$

Example of the construction fuzzy sets AO (cNO, cOW, cOB) based on regression relationships WCM = f2 (BMI) (formula 8) and $WHtR_M$ = f4 (BMI) (formula 10) for the population of Lodz are presented in Figure 3 and Figure 4. WC and WHtR cut - off points designated for men (M) and females (F) based on mapping functions f1 - f4 are summarized in Table 3. As we can notice, the cut-off points for the fuzzy

TABLE III

18.5	83,6	69,6	72,1	65,1			0,396	0,391
25	94	80	89,4	79,8	0,5	0,5	0,513	0,504
30	102	88	102,7	91,2	0,6	0,6	0,594	0,585
35	110	96	116	102,6			0,667	0,659

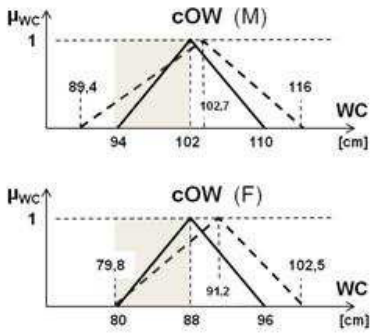

Fig. 4. Graphical form of triangular membership function for the fuzzy set "central overweight" (cOW) for men (M) and females (F). Solid line - developed based on NCEP-ATP III and IDF criteria (function f1); dotted line - developed for the population of Lodz (function f2).

subsets AO are different between themselves and depend on the transforming function. For example, with respect to the triangular MF describing the fuzzy subset cOW of the Lodz inhabitants, both for men and women (Figure 4) we observed the relation:

$$Supp(cOW)_{f1} < Supp(cOW)_{f2} \tag{17}$$

In case of the fuzzy subset cOW determined by WHtR, this relation is not so evident (Table 3). Both for men and women from Lodz, the WHtR cut-off points determined with the use of correlation functions f4 were more close to the current experts recommendations described by function f3.

IV. FINAL REMARKS

Adipose tissue, especially centrally distributed in the body, meets the complex and difficult to unambiguously describe regulatory functions. The excess of visceral fat is the cause of many cardio-metabolic disturbances mainly in the form of insulin resistance and secondary hyperinsulinemia [11], [16]. The current AO classifications are based mainly on the arbitrarily defined WC or WHtR cut-off points, which often are not fully adequate for the characteristic distribution of these indicators for a given population (region).

The paper presents a fuzzy models of AO developed on the basis on simple anthropometric indices such WC and WHtR. For the construction of a MF, the Zadeh's Extension Principle and mapping of the BMI fuzzy sets into adequate AO fuzzy sets using different transformation functions have been applied. The results obtained for the population of Lodz indicate the potential usefulness of the fuzzy set theory in the evaluation of both, the AO and the CMR. For the construction of the MF fuzzy subsets describing the AO it is reasonable to apply the Zadeh's Extension Principle and as a mapping function, the population-specific correlation function.

The results of our study may be a starting point for the construction of more complex fuzzy inference system for the assessment of global cardiovascular or cardiometabolic risk where AO is one of the more important risk factor. Taking into account the growing scale of the adverse health consequences of the obesity epidemic in the world, the artificial intelligence methods including particular fuzzy inference systems should be more widely used.

***Abstract*—The principal goal of information technologies application in medicine is improvement and conditioning of medical care. Modern healthcare systems have to perfect the care of a patient. Therefore, the healthcare system has to be characterized, first of all, by high reliability and reliability analysis of such a system is an important problem. The new method for estimation of system reliability is considered in this paper. This method permits to investigate the influence of any system component failure to the system functioning.**

I. Introduction

INITIATIVES for implementing healthcare systems based on the information technologies are now a principal part of the development in medicine. The development of these systems depends on organization of the healthcare provision in each country and the presence of the information and telecommunication technologies in the healthcare sector [1–3]. There is one principal characteristic for all healthcare systems. It is reliability that is defined as the probability that a system will perform its intended function during a period of running time without any failure. A fault is an erroneous state of the system. The system reliability is a complex characteristic that depends on the functioning of separate parts (components) of the system.

Based on bibliography in reliability analysis of the healthcare domain, we can show two principal approaches. The first of them is reliability estimation of medical equipment and devices that includes reliability quantification of hardware and software of the healthcare system [4–6]. The second approach agrees with examination of human errors [7, 8]. However, independent evaluation of these principal parts of the healthcare system does not allow providing detail and actual reliability analysis. In [9], new tendencies in reliability engineering are considered. According to [9], the reliability analysis has to be based on joint evaluation of all principal parts (components).

The typical healthcare system structure consists of some principal components from the point of view of reliability analysis [4, 7, 9]. In [4], two of them have been defined: equipment/device and human factors. We need to note that the human factor has been considered as errors of operators of medical equipment or devices in [4]. A detailed structure of the human factor and human errors for the healthcare system is presented in [7]. The healthcare system structure includes three components: technical, human and organization [9]. The technical component includes two types of medical devices/equipment that are based on special and standards-based technologies according to [10]. For example, the first type is the medical decision support system, the system for integrating electronic medical records or picture archiving communication systems. The second type is the special medical device and equipment that can be used for a special operation only (as magnetic resonance imaging scanners, for example). The human component of the healthcare system causes medical errors. The organization component of the system joins management aspects and maintenance of the healthcare system.

In this paper, we develop results that have been presented in [9] as well as methods proposed for estimation of system components based on a single approach. Particularly, we consider the Importance Analysis of the healthcare system. This analysis allows investigation of every system component functioning/failure into the system reliability. In Section II, the typical approach for the reliability examination from the step of mathematical modelling to the calculation of the reliability indices is considered basing on an example of the mathematical model of performance shaping factors for human errors in the healthcare system. The Direct Partial Logic Derivatives are also proposed in this section for description of the system behaviour. Section III presents most frequently used importance measures that allow defining the system component with minimal or maximal influence to the system reliability. The algorithms for calculation of these measures based on Direct Partial Logic Derivatives are developed in this section. The new algorithm for calculation of one of the possible importance measures is proposed in Section IV. The possible development of the proposed methodology is analysed in Conclusions.

II. Mathematical Background

The reliability analysis of a system includes three principal steps [11]:

- the quantification of the system model;
- the representation and modelling of the system;

This work is supported by the grant of Slovak Research and Development Agency SK-PL-0023-12

- the representation, propagation and quantification of the uncertainty in the system behaviour.

I. Quantification of the System

Quantification of the system is a principal step and it causes development of a mathematical model. There are two approaches to the quantification in reliability engineering.

The first of them defines only two states of the system reliability: the functioning and failure. The mathematical model for the representation of this quantification is called a Binary-State System (BSS). The system and its components are allowed to have only two possible states (completely failure and functioning) in BSS (Fig. 1). This approach is well known and widely used in reliability engineering. The system failure can be investigated in detail based on this quantification. However, the analysis of other performance levels, before the system failure, has some difficulties for BSS. In this case, the quantification of the system reliability to some performance levels is used. The mathematical model with some performance levels is called a Multi-State System (MSS).

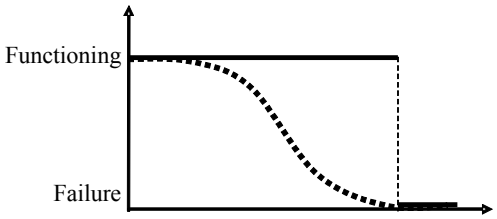

Fig. 1 System reliability interpretations for BSS

MSS reliability analysis is a more flexible approach to evaluating system reliability, as it can be used when both the system and its components may experience more than two states, including, for example, completely failed, partially failed, partially functioning and perfect functioning (Fig. 2). The MSS scientific achievement has been documented in [11 – 13]. However, a mathematical approach to analysing such a system is complex. In many applications, the definition of the system failure is the principal problem. Therefore, the system quantification can be simplified and considered as the BSS (Fig. 1).

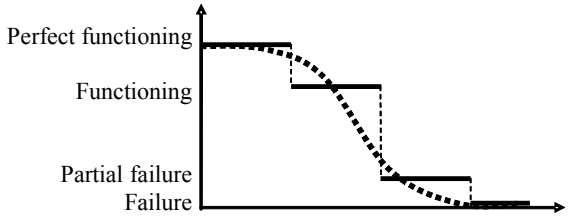

Fig. 2 System reliability interpretations for MSS

The BSS permits to investigate the system failure that has the high priority in reliability engineering. Therefore, mathematical models and methods for the estimation of the system failure are developed dominantly based on the system representation by BSS, because MSS complicates the system failure investigation.

In this paper, the analysis of the healthcare system failure is considered on the basis of the use of BSS.

II. Modelling of the System

The next step, after the definition of quantification, is the mathematical model development. There are some types of the BSS representation as the mathematical model. These representations (mathematical models) correlate with the mathematical methods for the calculation of the system reliability indices and measures. One of these representations is the structure function. This function allows the mathematical description of a system with any complexity [12, 13].

The system reliability in the stationary state depending on component states is defined by *structure function* [14]:

$$\phi(x_1,...,x_n) = \phi(x) : \{0,1\}^n \rightarrow \{0,1\}. \qquad (1)$$

A coherent system is considered in the paper below. The important assumptions for this system [12, 14] are as follows: (a) the structure function (1) is monotone, and (b) the system component failure does not improve the system reliability.

In the considered mathematical model, every system component x_i is characterized by probability of the reliability:

$$p_i = \Pr\{x_i = 1\}. \qquad (2)$$

The system component unreliability is defined as:

$$q_i = \Pr\{x_i = 0\} = 1 - p_i. \qquad (3)$$

For example, the structure function of the human sub-system (component) can be defined on the basis of the mathematical model of performance shaping factors for human errors in the healthcare system that is proposed in [10]. According to the model in [10], the analysis of the human error has to include social, personal, organization and technological aspects (Fig. 3). We can interpret this model as the structure function:

$$\varphi(x) = x_1 \wedge \left((x_2 \wedge x_3) \vee (x_2 \wedge x_4) \vee (x_3 \wedge x_4) \right), \qquad (4)$$

where $\wedge$ and $\vee$ are symbols of the operations AND and OR accordingly.

The structure function (4) defines correlation of the social, technical and organizational aspects as the system 2-out-of-3, that is to say, the combination of these aspects is dependable if two or more of these aspects are reliable. These aspects and the personal aspect are correlated as the series system. We use the term "component" for any of these aspects and indicate as x_i in this paper in the examples below.

The BSS behavior specified by the structure function is described by the Direct Partial Logic Derivative. In this case, the structure function variables are interpreted as the component state, and the function value is agreed with the system state (reliability).

The Direct Partial Logic Derivative with respect to variable x_i for the BSS structure function (1) permits to

The mathematical model of performance shaping factors for human errors

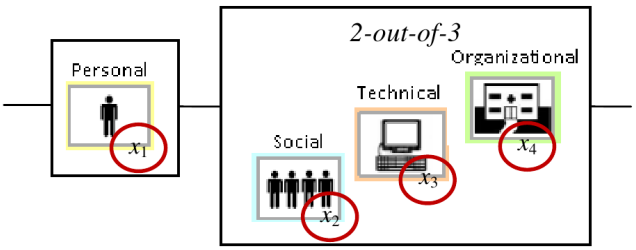

Fig. 3 The structure function for the healthcare system human component

analyse the system reliability change from j to $\bar{j}$ when the i-th component state changes from a to $\bar{a}$ [14]:

$$\partial\varphi(j\to\bar{j})/\partial x_i(a\to\bar{a})= =\begin{cases}1, & if\ \varphi(a_i,x)=j\wedge\varphi(\bar{a}_i,x)=\bar{j}\\ 0, & otherwise\end{cases} \quad (5)$$

where $\phi(a_i, \boldsymbol{x}) = \phi(x_1,\ldots, x_{i-1}, a, x_{i+1},\ldots, x_n)$; $\phi(\bar{a}, \boldsymbol{x}) = \phi(x_1, \ldots, x_{i-1}, \bar{a}, x_{i+1},\ldots, x_n)$; $a, j \in \{0, 1\}$ and $\bar{a} = 1-a$, $\bar{j} = 1-j$.

Let us consider the system failure in the Direct Partial Logic Derivative terminology. The system failure is represented as a change of the structure function value $\phi(\boldsymbol{x})$ from state 1 into 0. This change can be caused by the i-th variable change from 1 to 0 if we consider a coherent system. Therefore the Direct Partial Logic Derivative for the BSS failure analysis is defined by the equation

$$\partial\varphi(1\to0)/\partial x_i(1\to0)= =\begin{cases}1, & if\ \varphi(1_i,x)=1\ and\ \varphi(0_i,x)=0,\\ 0, & otherwise.\end{cases} \quad (6)$$

The Direct Partial Logic Derivative (6) $\partial\varphi(1\to0)/\partial x_i(1\to0)$ allows investigating boundary states of this system for which failure of one component x_i causes the system breakdown. For example, these states for the system in Fig. 3 are shown in Table 1. Therefore, there are 4 boundary states for the first component and 2 states for every other component of the mathematical model of performance shaping factors for human errors in the healthcare system.

The Direct Partial Logic Derivative can be used for the investigation of the influence of the system components failure to the failure of BSS. This investigation is a subject of the Importance Analysis in the reliability engineering [12–15].

III. Mathematical Method

Importance analysis allows examining different aspects of reliability changes and the uncertainty in the system failure. In particular, the importance analysis is used for BSS reliability estimation depending on the system structure and its component states. The various evaluations of the BSS component importance are called Importance Measures (IMs). IM quantifies the criticality of a particular component within BSS. They have been widely used as tools for identifying system weaknesses, and to prioritise reliability improvement activities.

The most frequently used IMs as Structural Importance (SI), Birnbaum importance (BI), Fussell-Vesely Importance (FVI) are shown in Table II [12, 13].

TABLE II.
IMPORTANCE MEASURES

Short name	Description
SI	SI concentrates on the topological structure of the system and determines the proportion of working states of the system in which the working of the i-th component makes the difference between system failure and working state.
BI	BI of a given component is defined as the probability that such a component is critical to MSS functioning and represents loss in MSS when the i-th component fails.
FVI	FVI quantifies the maximum decrement in MSS reliability caused by the i-th system component state deterioration and if $a = 0$, the measure allows estimating system performance level decrease for full unreliability of the i-th system component.

Calculation of IMs is based on different mathematical approaches and the Direct Partial Logic Derivative is one of them. This approach has been proposed in [14]. According to [14], the Direct Partial Logic Derivative has been used for calculation of SI and BI. The FVI definition is based on the minimal cuts of BSS. In this paper, a new algorithm for calculation of the minimal cuts of the system based on the Direct Partial Logic Derivative is proposed.

III. IMPORTANCE MEASURES

IV. Structural Importance

SI is one of the simplest measures of the component importance and this measure focuses on the topological aspects of the system. According to the definition in [16], this measure determines the proportion of working states of the system in which the working of the i-th component makes the difference between system failure and its working:

$$IS_i=\frac{\rho_i}{2^{n-1}} \quad (7)$$

where ρ_i is a number of system states when the change component state results in the system failure.

For example, calculated IMs (7) based on Direct Partial Boolean Derivatives for the system are shown in Fig. 3. Values of SI (8) and intermediate values of ρ_i are shown in Table III. According to this table, the first component has maximal influence to the system reliability from the point of view of the system topology.

TABLE III.
STRUCTURAL IMPORTANCE FOR THE SYSTEM IN FIG.3

i	ρ_i	IS_i
1	4	4/8 = 0.500
2	2	2/8 = 0.250
3	2	2/8 = 0.250
4	2	2/8 = 0.250

V. Birnbaum Importance

BI of a given component is defined as the probability that the system is sensitive to inoperative of the *i*-th system component [17]. Let us consider the Direct Partial Logical Derivatives for calculation of BI. In [14], BI has been defined as

$$IB_i = \Pr\left\{\partial\varphi(1\to 0)/\partial x_i(1\to 0)=1\right\} \qquad (8)$$

For example, let us consider the system shown in Fig. 3. Probabilities of the system element reliability and unreliability are shown in Table IV. According to the data in Table I, elements of this system have the following values of BIs:

$$IB_1=\Pr\{\partial\phi(1\to 0)/\partial x_1(1\to 0)=1\}=$$
$$=q_2q_3p_4+ q_2p_3q_4+ q_2p_3p_4+ p_2q_3q_4+ p_2q_3p_4+ p_2p_3q_4+ p_2p_3p_4=0.964;$$

$$IB_2=\Pr\{\partial\phi(1\to 0)/\partial x_2(1\to 0)=1\}=p_1q_3q_4=0.096;$$

$$IB_3=\Pr\{\partial\phi(1\to 0)/\partial x_3(1\to 0)=1\}=p_1q_2q_4=0.072.$$

$$IB_4=\Pr\{\partial\phi(1\to 0)/\partial x_4(1\to 0)=1\}=p_1q_2q_3=0.096.$$

BI for the first component has the maximal value. The BIs, as the SIs, show that the first system component is more important for reliability.

TABLE IV.
PROBABILITIES OF ELEMENTS FOR THE SYSTEM IN FIG.3

	x_1	x_2	x_3	x_4
p_i	0.80	0.70	0.60	0.70
q_i	0.20	0.30	0.40	0.30

VI. Fussell-Vesely Importance

FVI represents the contribution of each component to the system failure probability and for BSS it is calculated by the following equation [17]:

$$I_{FV}(x_i)=\frac{F_{\min\ cut}(x_i)}{Q} \qquad (9)$$

where $F_{\min\ cut}(x_i)$ is the system minimal cut that includes the *i*-th system component, Q is the function of the system unreliability [14, 17]:

$$Q = \Pr\{\phi(\boldsymbol{x})=0\}. \qquad (10)$$

Therefore, for calculation of this measure, the minimal cut set is needed. In the next section, we propose a new algorithm for calculation of the minimal cut set for BSS by Direct Partial Logic Derivatives.

IV. MINIMAL CUT SET IN IMPORTANCE ANALYSIS

VII. Minimal Cut Set and Minimal Cut Vector

Let us consider the conception of the cut set. The cut set is the set of the system components whose simultaneous failure results in the system failure (if the system has been functioning). As a rule, the number of the cut set components k is changed from 1 to n. The system failure is caused by one component reduction only if $k = 1$ and all components have to fail that to cause the system failure if $k = n$. The minimal cut set is a cut set in which any subset remaining after the removal of any of its components is no longer the cut set.

Let $\boldsymbol{a} = (a_1 \ldots a_n)$ and $\boldsymbol{b} = (b_1 \ldots b_n)$ be two state vectors for system component states or values of structure function (1). The vector $\boldsymbol{a} < \boldsymbol{b}$ if $a_i < b_i$ for $i = 1, \ldots, n$.

The state vector $\boldsymbol{a} = (a_1 \ldots a_n)$ is a cut set vector if $\phi(\boldsymbol{a}) = 0$.

The cut set vector $\boldsymbol{a}$ is minimal, if $\phi(\boldsymbol{b}) = 1$ for any $\boldsymbol{b} > \boldsymbol{a}$.

For example, the system shown in Fig. 3 has 12 cut set vectors (if $\phi(\boldsymbol{x}) = 0$, $\phi(\boldsymbol{x})$ is defined by (4)) and 4 minimal cut set vectors:

$$\{(x_1), (x_2\ x_3), (x_2\ x_4), (x_3\ x_4)\}. \qquad (11)$$

Therefore, FVI for this system, according to (9), is calculated as:

$$IFV_1=\Pr\{(x_1)\}\ /\ Q = q_1\ /\ Q = 0.492$$

$$IFV_2=\Pr\{(x_2\ x_3), (x_2\ x_4)\}\ /\ Q = q_2q_3 + q_2q_4\ /\ Q = 0.517$$

$$IFV_3=\Pr\{(x_2\ x_3), (x_3\ x_4)\}\ /\ Q = q_2q_3 + q_3q_4\ /\ Q = 0.591$$

$$IFV_4=\Pr\{(x_2\ x_4), (x_3\ x_4)\}\ /\ Q = q_2q_4 + q_3q_4\ /\ Q = 0.517$$

where the system unreliability Q (10) is calculated as:

$$Q = \Pr\{\phi(\boldsymbol{x})=0\} = q_1 + p_1(q_2q_3 + q_2q_4 + q_3q_4) = 0.4064.$$

FVI of the first component has the minimal value. Therefore, the first component does not have most significant influence to the system reliability if the component combination failure is considered. According to value IFV_3, the third component refuse causes the system failure in combination with other component refuses predominantly.

FVI is an alternative measure of Importance Analysis that allows estimating influence of the particular component to the system reliability and functioning. However, the minimal cut sets for the calculation of this measure are needed.

VIII. Minimal Cut Set Vectors and Direct Partial Logic Derivatives

Let us compare two definitions of the Direct Partial Logic Derivatives and minimal cut set vectors. Let the Direct Partial Logic Derivative be $\partial\phi(1\to0)/\partial x_i(1\to0)$. This derivative permits to determine the structure function state vectors that are boundary for the structure function value with respect to the variable x_i. The minimal cut set vector is the boundary state vector too, but for some variables (components). Therefore, the set of Direct Partial Logic Derivatives with respect to some variables can be defined by the minimal cut set vector. This supposition has been verified and tested. The result of testing confirms the supposition.

The Direct Partial Logic Derivative $\partial\phi(1\to0)/\partial x_i(1\to0)$ indicates state vectors $(0_i, \boldsymbol{x})$, in which improvement of component i results in the system improvement. To identify minimal state vectors, i.e., state vectors for which improvement of any broken component results in the improvement of the whole system, we have to compute $\partial\phi(1\to0)/\partial x_i(1\to0)$ (5) for every component and then compute the intersection of these derivatives. To compute the intersection, the modified type of derivative has to be used that is defined as:

$$\partial\varphi(j\to\bar{j})/\partial x_i(s\to\bar{s})=$$
$$=\begin{cases}1 & \text{if } x_i=s \text{ and } \varphi(s_i,x)=j \text{ and } \varphi(\bar{s}_i,x)=\bar{j}\\ 0 & \text{if } x_i=s \text{ and } \varphi(s_i,x)=\varphi(\bar{s}_i,x)\\ * & \text{if } x_i\neq s\end{cases} \tag{12}$$

The rule for intersection of two modified derivatives (11) is defined in Table V. This intersection identifies state vectors, in which improvement of both components (if the component can be repaired) results in improvement of the system.

Let us continue the hand calculation example for the mathematical model of performance shaping factors for human errors in the healthcare system (Fig. 3) that is defined by the structure function (4). The Direct Partial Logic Derivatives $\partial\phi(1\to0)/\partial x_i(1\to0)$ for system components have been calculated and shown in Table I. The intersection of these derivatives, according to the rule in Table V, allows getting 4 cut set vectors:

$$\{0***,\ *00*,\ *0*0,\ **00\},$$

which are consistent with the minimal cut sets (12).

TABLE V.
DEFINING THE INTERSECTION OF TWO MODIFIED DPLD

		$\partial\varphi(j\to\bar{j})/\partial x_i(s\to\bar{s})$		
		*	0	1
$\partial\varphi(j\to\bar{j})/\partial x_i(s\to\bar{s})$	*	*	0	1
	0	0	0	0
	1	1	0	1

The test of the proposed algorithm has been implemented on the basis of the sets of the benchmarks LGSynth91 [18]. Testing characteristic is a number of cut set vectors and time for computation (Fig. 4). The numbers in the left part of the graphs indicate the time and the numbers in the right part are numbers of the cut set vectors for the system. There is the proportional correlation between the number of cut set vectors in the system and time for the computation.

V. CONCLUSION

In this paper, the problem of calculation of IMs is considered. The IM definitions based on the Direct Partial Logic Derivatives [4] are provided. A new algorithm for calculation of FVI by the Direct Partial Logic Derivatives is presented in this paper. The experimental investigation corroborates the possible application of this algorithm for investigation of the large dimension system and computation of the IMs. The development of the presented result in future investigation will be adaptation of this algorithm for analysis of Multi-State System. This system allows the analysis of some (more than two) states in the reliability [12].

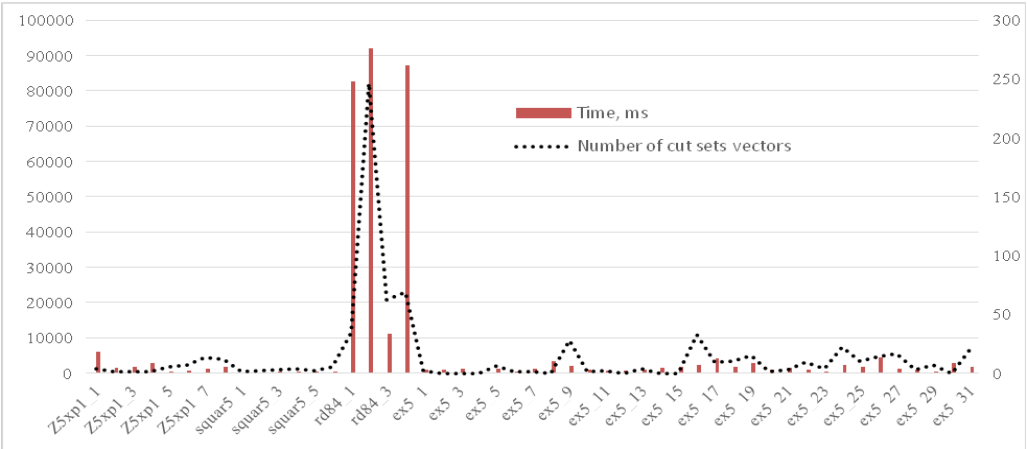

Fig. 4 Computational complexities

Reliability analysis of the health care system is an important issue. The principal problem in this analysis is the development of methodology that permits to investigate every system component and the system based on united approaches. This conception has been presented in details in [9, 15]. We propose and develop one of possible approaches that allow investigating the healthcare system component importance. The mathematical background of this approach is Direct Partial Logic Derivatives. The advantage of this approach is the possibility to use it for estimation of every system that is defined by the structure function.

3rd International Workshop on Advances in Semantic Information Retrieval

Recent advances in semantic technologies form a solid basis for a variety of methods and instruments that support information retrieval, knowledge representation, and text analysis. They influence the way and form of representing documents in the memory of computers, approaches to analyze documents, techniques to mine and retrieve knowledge. The abundance of video, voice and speech data also raises new challenging problems to information retrieval systems.

We believe that our workshop will facilitate discussion of new research results in this area, and will serve as a meeting place for researchers from all over the world. Our aim is to create an atmosphere of friendship and cooperation for everyone, interested in computational linguistics and information retrieval. The second ASIR workshop will continue to maintain high standards of quality and organization, set in the previous year. We welcome all the researchers, interested in semantics and information retrieval, to join our event.

Topics

The workshop addresses semantic information retrieval theory and important matters, related to practical Web tools. The topics and areas include, but not limited to:

- Domain-specific semantic applications.
- Evaluation methodologies for semantic search and retrieval.
- Models for document representation.
- Natural language semantic processing.
- Ontology for semantic information retrieval.
- Ontology alignment, mapping and merging.
- Query interfaces.
- Searching and ranking.
- Semantic multimedia retrieval.
- Visualization of retrieved results..

***Abstract*—One of the biggest problems facing Web-based Information Systems (WIS) is the complexity of the information searching/retrieval processes, especially the information overload, to distinguish between relevant and irrelevant content. In an attempt to solve this problem, a wide range of techniques based on different areas has been developed and applied to WIS. One of these techniques is the information retrieval. In this paper we described an information retrieval mechanism (only for structured data) with a client/server implementation based on the Query-Searching/Recovering-Response (QS/RR) model by means of a trading model, guided and managed by ontologies. This mechanism is part of SOLERES system, an Environmental Management Information System (EMIS).**

I. Introduction

Nowadays, *Web-based Information Systems* (WIS) have become popular as they favour universal access to the information, helping their users to analyze the information from different viewpoints and support group work, decision-making, etc. However, one of the biggest problems of this kind of systems is the complexity of the information searching/retrieval processes, largely due to the huge amount of information they manage.

Their users depend on web sites, digital libraries, engines and other information searching/retrieval systems [1], [2] to help them in this tedious process and, even so, they deal with an overload of information in which they must distinguish between the relevant and irrelevant content. In an attempt to solve this problem, a wide range of techniques based on different areas has been developed and applied: information retrieval, information filtering, studies on information search behavior, etc. Of all these techniques, we focused on the information retrieval in a client/server model for Web systems. In this context, the term "information retrieval" refers to a set of techniques that satisfy the users' information requirements [3].

The main WIS information retrieval mechanism, based on the client/server model, is *the Query-Searching/Recovering-Response* (QS/RR), showed in Figure 1. On one hand, the term "Query" refers to the whole process of creating and formulating the client's request. The term "Searching" refers to the process of locating the data sources (repositories, data storage or databases, regardless of the model) where the information is found, and the term "Recovering" refers to the process of locating, identifying and selecting the data from these sources. Finally the term "Response" refers to the whole process of formulation, preparation and creation of the response by the server to the client. The "Query-Searching" pair is a process that goes from the client to the server. The "Recovering-Response" pair goes from the server to the client.

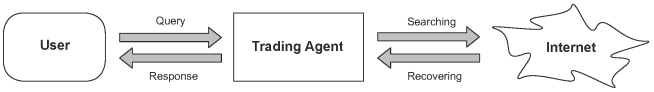

Fig. 1. Overview of the QS/RR mechanism.

A solution to QS/RR mechanism is the UDDI (*Universal Description Discovery and Integration*) specification and WSDL (*Web-Services Definition Language*) for SOA (*Service Oriented Architecture*). They are based on client/server implementations for Web systems. Nevertheless, these techniques allow us to respect a *subscribe/publish/response* model (a QS/RR information retrieval approach) for locating WSDL documents (i.e., XML specifications of web-services) and connecting web services in WIS, but not for different types of information (non-WDSL information). Traders [4] are another solution for open and distributed systems that extend the OMA (*Object Management Architecture*) ORB (*Object-Request Broker*) mechanism. From the viewpoint of the *Open Distributed Processing* (ODP), a Trader (also called trading service, trading function or mediator) is the software object that mediates between objects that offer certain capacities or services and other objects that demand their use dynamically. As is shown in Figure 2, objects that offer their services are called "exporters" and provide the Trader with a description (extra-functional aspects) and an interface (functional aspects) of their service, whereas objects that demand these services are called "importers" and ask the Trader for services with certain characteristics. The function of the Trader, therefore, consists of checking the characteristics required in the descriptions of the services

This work has been supported by the EU (FEDER) and the Spanish Ministry MINECO under grant of the TIN2010-15588, and also by the JUNTA DE ANDALUCÍA excellent project TIC-6114. http://acg.ual.es.

offered (stored in a local repository) and indicating the importer the interfaces of the selected services for his interaction with the exporter.

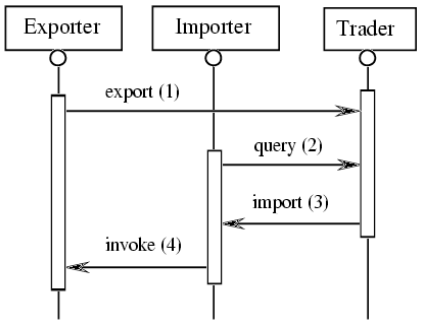

Fig. 2. Roles of the ODP Trader.

There is a large number of studies in which the trading service follows the ODP specification. For instance, in [5] a trading service called DOKTrader is presented, which acts on a federated database system called *Distributed Object Kernel* (DOK). Another example is found in [6]. This study concentrates on the creation of a framework to develop distributed applications for a *Common Open Service Market* (COSM), making use of a *Service Interface Description Language* (SIDL) to describe the services manipulated by the trader. These approaches of the ODP trading implementations have several shortcomings like component interactions, object communications or language description, which have been improved using **ontologies**.

The use of ontologies in trading services has spread, especially in web information services. Ontologies are being used to describe the services offered as well as communication primitives employed by system components. In [7] authors present the design of a market managed by ontologies. Within this system, an ontological communication language is used to represent queries, offers and agreements. Furthermore, in [8], ontologies are used to describe information shared by different system components. To achieve greater operability and autonomous, many systems have chosen to encapsulate the trader object within a software agent. In [9] the MinneTAC agent is described, like a trading agent developed to participate in the Trading Agent Competition (TAC). Through the description of this agent, implementation of a trader as a software agent is shown to maximize benefits from scenarios that require cooperation and negotiation between the trader and the rest of the system components, as well as systems that require communication among various trading objects, making use of ontologies to represent information shared by the agents, whether to describe data and the relationships among variables, as is the case in [10], or defining communication primitives and interaction among agents [11].

In this paper, we propose the Ontological Web Trading (OWT) model that implements a mechanism for solving the complexity of information retrieval in the SOLERES system by means of a trading model for WIS, guided and managed by ontologies. OWT has been implemented in this system as a software agent. SOLERES [12] is an Environmental Management Information System (EMIS) based on satellite images, neural networks, cooperative systems, multi-agent architectures and commercial components. This multi-agent system implements a user Information Retrieval mechanism that implements the QS/RR model and uses the SPARQL query language and the OWL ontology description language to operate. In this system, the ontologies are used in two different contexts: (a) to represent the application domain information itself (**data ontology**), and (b) to request services between agents during their interaction (**service ontologies**). Although a trader agent has five interfaces (i.e., Lookup, Register, Link, Proxy and Admin), this paper discusses only the service and data ontology design features of the Lookup interface, which is used for searching and recovering information. This information should be only structured data. All research work presented here is part of a complete design strategy for *Ontology-Driven Software Engineering* (ODSE) that we are developing in SOLERES.

The remainder of the paper is organized as follows. Section 2 shows the SOLERES system architecture. Section 3 identifies the requirements that an ontological trading service should meet for open and distributed environments as well as the operation models it may carry out. Section 4 describes the Web Trading Agent. Section 5 shows the Lookup ontology used by such agent. We end with some conclusions and prospects for future work in section 6.

II. A Case Study: The SOLERES System

This section presents the main SOLERES system architecture (Figure 3), a spatio-temporal information system for environmental management (an example of EMIS). The general idea of the system is a framework for integrating the disciplines above for "Environmental information" as the application domain, specifically ecology and landscape connectivity. The system has two main subsystems, SOLERES-HCI and SOLERES-KRS. The first is the framework specialized in human-computer interaction. This subsystem is beyond the scope of this article and will not be described. On the other hand, SOLERES-KRS is used to manage environmental information. Examining Figure 3, the `IMI Agent` is like a gateway between the user interface and the rest of the modules, and is responsible for the management of user demands.

Given the magnitude of the information available in the information system, and that this information may be provided by different sources, at different times or even by different people, the environmental information (i.e., the knowledge) can be distributed, consulted, and geographically located in different ambients (i.e., locations, containers, nodes or domains) called Environmental Process Units (`EPU`). Thus the system is formed by a cooperative group of knowledge-based EPUs. These groups operate separately by using an agent to find better solutions (queries on ecological maps).

We accomplished the distributed cooperation of these EPUs by developing a Web Trading Agent (WTA) based on the ODP trader specification and extended to agent behavior.

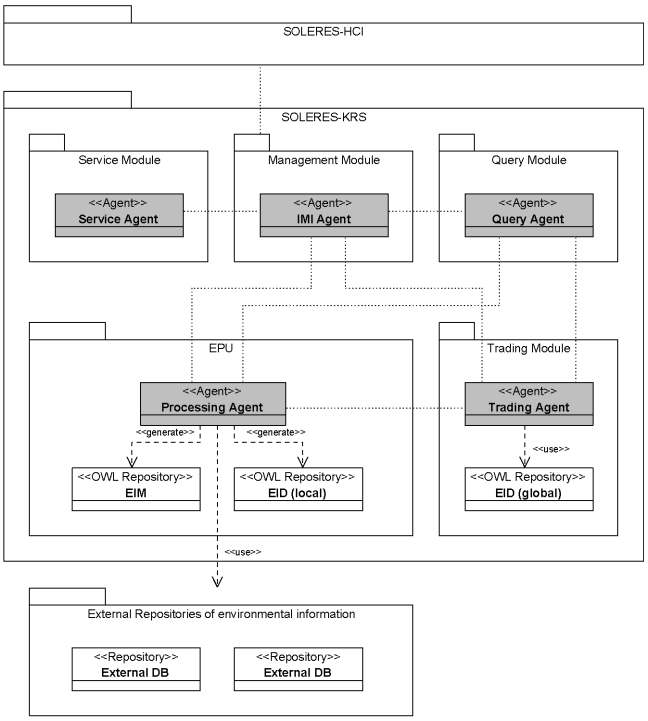

Fig. 3. SOLERES architecture.

Our trading agent mediates between HCI requests and EPU services. EPUs manage two local repositories of environmental information. One of these repositories contains metadata of the information in the domain itself (i.e., basically information related to ecological classifications and satellite images), called *Environmental Information Map* data: EIM documents (`EIM`). This information is extracted from external databases (`External DB` repository in the Figure). The EIM documents are specified by an ontology in OWL [13] (`<<OWL Repository>>`). These EIM documents are the first level of information in SOLERES-KRS.

The second repository contains metadata called Environmental Information metaData, or EID documents (`EID`). These documents contain the most important EIM metadata that could be used by the information retrieval service, and further, incorporate other new metadata necessary for agent management itself. To a certain extent, an EID document represents a "template" with the basic metadata from the EIM document. The EID documents have also been specified by an ontology to accomplish open distributed system requirements. EID documents represent the second level of information in the KRS subsystem. Each EPU keeps its own EID document (or sets of documents) locally and also registers them with the Web Trading Agent (WTA). This way, the WTA has an overall repository of all the EID documents from all EPUs in an ambient and can thereby offer an information search service, as described in the following sections.

III. Requirements and Trading models for OWT

The OWT model developed here is based on the traditional functionality of a trading service, adapted to the management of any type of information (not only on services) through ontologies. Next we will identify a set of requirements necessary for the design of an ontological trading service for open and distributed environments. Later on, we will describe the trading models implemented in our model.

I. Requirements for OWT

For the design of an OWT model, we established a set of properties or requirements that must be met. Table I shows a list of such properties from the ODP standard constraints.

TABLE I. OWT PROPERTIES.

Property	Name
#1	Heterogeneous data model
#2	Federation
#3	Composition and adaptation of services
#4	Weak pairing
#5	Usage of heuristics and metrics
#6	Extensible and scalable
#7	"Storage and forwarding" policy
#8	Delegation
#9	Push and pull storage model

Property **#1** (Heterogeneous data model) means that a trading service should be able to work with different data models and platforms and should not be restricted to just one data model. Thus it should be able to mediate with different protocols of access to information and adapt to the evolution of current and future models.

Property **#2** is related to the federation. For the cooperation among traders there should exist a federation among trading services by using different strategies. For instance, a "repository-based" federation strategy allows more than one service to read and write on the same repository, each being unaware of the presence of others inside the federation, and thus allowing a scalable approach.

Current trading services use "one-to-one" pairing according to the clients' demands and availability of services stored in the repositories they can access. Nevertheless, the ontological trading service should also provide "one-to-many" pairing linking (property **#3**), where a client's query should be satisfied through the composition of two or more instances of metadata available in the repositories.

In the trading service processes, especially those working for open systems (like Internet) where methods and operations refer to the services offered, it is essential to consider the kind of pairing imposed (weak or accurate) (property **#4**), as services are chosen randomly, in an unstandarized way and without agreement. That is why a trading service, when getting the list of chosen metadata during the information searching/retrieval processes, should allow using partial pairing to select (from repositories) those metadata that completely adapt to the request for information or just to a part of it.

Property **#5** points out that a trading service should allow users to specify heuristics and metrics functions when searching for metadata, especially for weak pairing. Thus, among other aspects, the trading service would return results organized according to a search conditions.

Property **#6** defines the extensibility and scalability characteristics of a trading service. Here the trading service should consider any piece of information on services (or metadata) such as data of creators, marketing information and so on, and allow users to independently include new pieces of information for metadata they export (register). In turn, it should be able to use the new piece of information as part of the exported metadata.

In view of a client metadata query, a trading service should retrieve a result. Such result can refer either to a list of chosen metadata that satisfy the query or to a "fail" message if there is no search result. In the latter case, we should also be able to require a trading service to compulsorily satisfy the query or, if that is not the case, store it with the information available by that time and postpone the response until one (or several) metadata providers register (export) a metadata that satisfies the client query. This "response-query" behavior is called behavior "on hold" or "storage-and-forwarding" behavior (property **#7**).

Regarding the previous property, a trading service should also allow delegating (property **#8**) (complete or partial) queries to other trading services if the trading service itself were not able to satisfy such queries.

Property #9 defines the push and pull storage models of a trading service. A push model is the model in which exporters directly get in touch with the trading service to register their metadata. An alternative for metadata registration, suitable for trading services, which work in open and distributed environments on a broad scale, consists of making use of a pull storage model. Here, exporters do not get in touch with traders but rather publish metadata on their websites so that the trading services themselves later on "track" the network in search of new metadata.

Now that the requirements demanded of the trading service have been identified, the OWT model operations in the query process can be described.

II. OWT Model Operations

Let us now see how the OWT model operates in the query process, since an object or component makes a query until the results are retrieved.

This model is a trading-based version of the three-level client/server model. It is comprised basically of a series of elements <I,T,D>, each of which intervenes on a different level, depending on the treatment of the query. Level 1 (L1) is like the client side. Queries are generated and dealt with by an interface object (I). Level 3 (L3) is the server side. System data (D) reside on this level. In our case, these are the EIM repositories with the environmental information. Level 2 (L2) is the middleware that enables the source information to be located. This is the level where the trader objects (T) operate. Associated with the trader (T), the EID repositories with the source environmental information metadata (EIM) also reside there. All three objects use the Lookup ontology (described later) to communicate between them. As the premise for their functioning, an interface object must be associated with a trader object. However, a trader object can also be associated with one or more external data sources or resources, in our case, with the environmental source data (which reside in the EPU, as discussed above). This "trader-information source" association arises from the production of environmental information, where each EPU has an associated trader in which a subset (metadata) of environmental information generated by it is registered. On the other hand, each trader can be associated with one or more traders in federations.

In this three-level architecture, three operating scenarios are possible: *Trading Reflection*, *Trading Delegation*, and *Trading Federation*. Figure 4 shows the three levels (L1, L2, L3), where the three basic objects (I,T,D) reside, and the three scenarios permissible in OWT, as described below.

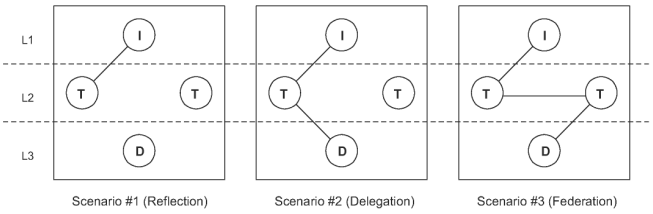

Fig. 4. Operational models of trading.

The **Trading Reflection** scenario in which the query may be solved directly by the trader. The query is generated on the interface and the information can be reached by the metadata that reside in the repository associated with the trader. In this case, the model <I,T> pair intervenes.

The **Trading Delegation** scenario indirectly mediates with the trader. The query is partly resolved by the trader. A query is generated on the interface level that goes on to the trading level (T). The trader locates the data source (or sources) (D), inferring this information from its metadata repository. Therefore, the trader delegates the query to the outside data source (D). In this case, the object series is <I,T,D>.

Finally, the **Trading Federation** scenario is a case in which two or more trader objects are able to federate. As in the cases above, the query remains preset on the interface. This query is passed on to the associated trader object. It can propagate the query to another federated trader object, who locates the external data source (D). In this case the object series intervening is <I,T,T,D>.

For design reasons, the three basic OWT model levels <I,T,D> have been implemented by agents using the JADE platform in the following way. The interface (I) was implemented by means of two agents: the Interface Agent and the IMI Agent. The trading level (T) was implemented by using two other agents: Query Agent and Trading Agent (WTA). The data level (D) was implemented by means of a Resource Agent. From the work perspective presented here, we are interested in the information searching/retrieval

processes, so that the explanation concentrates only on the WTA and the Lookup ontology used for it.

IV. Web Trading Agent

This section describes the internal structure of our Trading Agent and some details about its design and implementation. It should be emphasized that this agent, like all SOLERES system agents, was modeled, designed and implemented based on run-time management of the ontologies used. The trader therefore manages two kinds of ontologies, data and service (or process):

(a) The first is related to the ecological information repositories the trader can access. The information is distributed in different OWL repositories on two levels, as described in *Section II-A*. Some of them contain environmental metadata (EIM repositories) and others contain metadata from the first (EID repositories). A trader manages an EID repository.

(b) The second kind of ontology refers to trader functionality, that is, actions it can do and demand from others. In this case, behavior and interaction protocols must also be defined. These definitions set the operating and interaction rules for agents, governing how the functions the trader provides and demands to work (behavior) are used and the order they are called up in (protocols/choreography).

Figure 5 shows a data ontology from an EID repository (described formally in UML). Let us recall that the application domain to be modeled is ecological information (a type of environmental information) on cartographic maps and satellite images. Advanced algorithms based on neuronal networks find correlations between satellite and cartographic information. For the calculation of this correlation, prior treatment of the satellite images and maps is necessary (an image classification, `Classification`).

A cartographic map stores its information in layers (`Layer`), each of which is identified by a set of variables (`Variable`). For instance, we are using cartographic maps classified in 4 layers (climatology, lithology, geomorphology and soils) with over a hundred variables (e.g., scrubland surface, pasture land surface, average rainfall, etc.).

Satellite images work almost the same way. The information is also stored in layers, but here they are called bands. An example of satellite images is the LANDSAT image, which has 7 bands (but no variables stored in this case). Finally, both the cartographic and satellite classifications have geographic information associated (`Geography`), which is made at a given time (`Time`) by a technician or group of technicians (`Technician`).

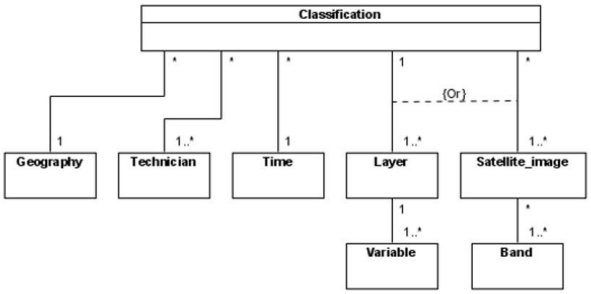

Fig. 5. Ontology of the EID metadata that traders use.

As a complement and formalization of this conceptual model, Table II shows the complete assertions of the eight ontology entities expressed in OCL (*Object Constraint Language*). As an example, we can describe two assertions. The assertion #2 for the `Classification` entity shows it has two required properties, `Classification_id` and `Classification_name`. This entity (classification) is related: (i) either with at least one `Layer` or `Satellite_image` entity (never with both entities simultaneously) through the `classification_shows_layer` or `classification_uses_satellite_image` relationships, respectively; (ii) always with one `Geography` entitythrough the `classification_shows_geography` relationship; (iii) with at least one `Technician` entity through `classification_is_made_by_technician`; and (iv) also with two `Time` entities, `classification_starts_time` and `classification_ends_time`. Analogously, the assertion #4 for the `Layer` entity indicates that it has two

TABLE II. EID ONTOLOGY ASSERTIONS IN OCL.

#	Entity	Assertions
#1	Band	(band_id **exactly** 1) **and** (band_is_shown_by_satellite_image **min** 0) and (band_name **exactly** 1)
#2	Classification	(classification_id **exactly** 1) **and** ((classification_shows_layer **min** 1) **or** (classification_uses_satellite_image **min** 1)) **and** (classification_ends_time **exactly** 1) **and** (classification_is_made_by_technician **min** 1) **and** (classification_name **exactly** 1) **and** (classification_shows_geography **exactly** 1) **and** (classification_starts_time **exactly** 1)
#3	Geography	(geography_id **exactly** 1) **and** (geography_is_shown_by_classification **min** 0) **and** (geography_locality **exactly** 1) **and** (geography_name **exactly** 1) **and** (geography_town **exactly** 1)
#4	Layer	(layer_id **exactly** 1) **and** (layer_has_variable **min** 1) **and** (layer_is_shown_by_classification **exactly** 1) **and** (layer_name **exactly** 1) **and** (layer_observations **max** 1)
#5	Satellite_image	(satellite_image_id **exactly** 1) **and** (satellite_image_is_used_by_classification **min** 0) **and** (satellite_image_shows_band **min** 1)
#6	Technician	(technician_id **exactly** 1) **and** (technician_first_name **exactly** 1) **and** (technician_last_name **exactly** 1) **and** (technician_makes_classification **min** 0) **and** (technician_organization **max** 1)
#7	Time	(time_id **exactly** 1) **and** (time_day **exactly** 1) **and** (time_month **exactly** 1) **and** (time_year **exactly** 1) **and** (time_is_started_by_classification **min** 0)
#8	Variable	(variable_id **exactly** 1) **and** (variable_name **exactly** 1) **and** (variable_is_had_by_layer **exactly** 1)

required properties, `layer_id` and `layer_name`, as well as another optional, `layer_observations`, and it is always related with `layer_is_shown_by_classification` and, at least with one `Variable` through `layer_has_variable`.

The functionality of our trader [14], [15] is divided into three clearly differentiated components (see Figure 6): (a) a component that manages the agent-communication mechanism (**Communication**); (b) a parser that codes and decodes the trading ontology-based messages exchanged (**Parser**); and (c) trading itself (**Trader**).

The third component is inspired by the ODP specification, which indicates how offers and demands must be implemented among objects in a distributed environment and proposes grouping all the different functionalities that a trader may include. Although the standard specifies five trader interfaces (i.e., Lookup, Register, Admin, Link and Proxy), its specification does not demand a trader to implement these five interfaces to work. In fact, we have only developed ontologies for the Lookup, Register, Admin and Link interfaces, but none has been implemented for the last one yet. The Lookup interface offers the search-information in a repository under certain query criteria. The Register interface enables objects in this repository to be inserted, modified and deleted. The Admin interface can modify the main parameters of the trader configuration, and finally, the Link interface makes trading agent federation possible.

As previously explained, this paper focuses on identifying and explaining how ontologies appear and intervene in the Web Trading Agent. Of the interfaces implemented, we only explain here the Lookup interface works, because it takes part in the search, which is the primary subject of this article.

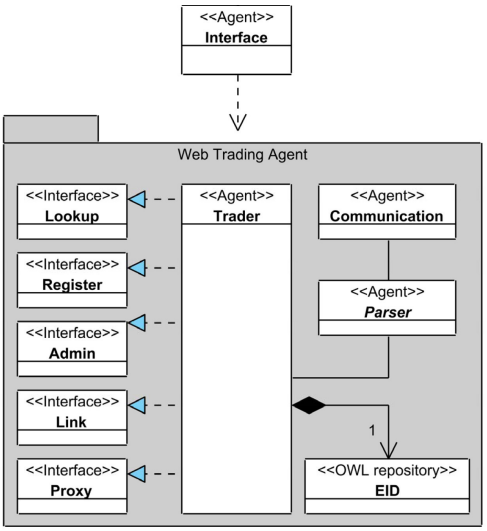

Fig. 6. Web Trading Agent view.

V. The Lookup ontology in OWT

The Lookup ontology (Figure 7) is used between system objects. The trader uses the `Query` action and the `QueryForm` concept. The `QueryForm` concept expresses the query in a specific language, whose properties, among others are: an `id` (a query identifier) and an `uri` (reference to the file where the query is stored). In addition, there could be a set of query policies (`Policy`) through the `PolicySeq` concept, and each "policy" is represented by means of a tuple (name, value). For instance, some of the tuples implemented are:

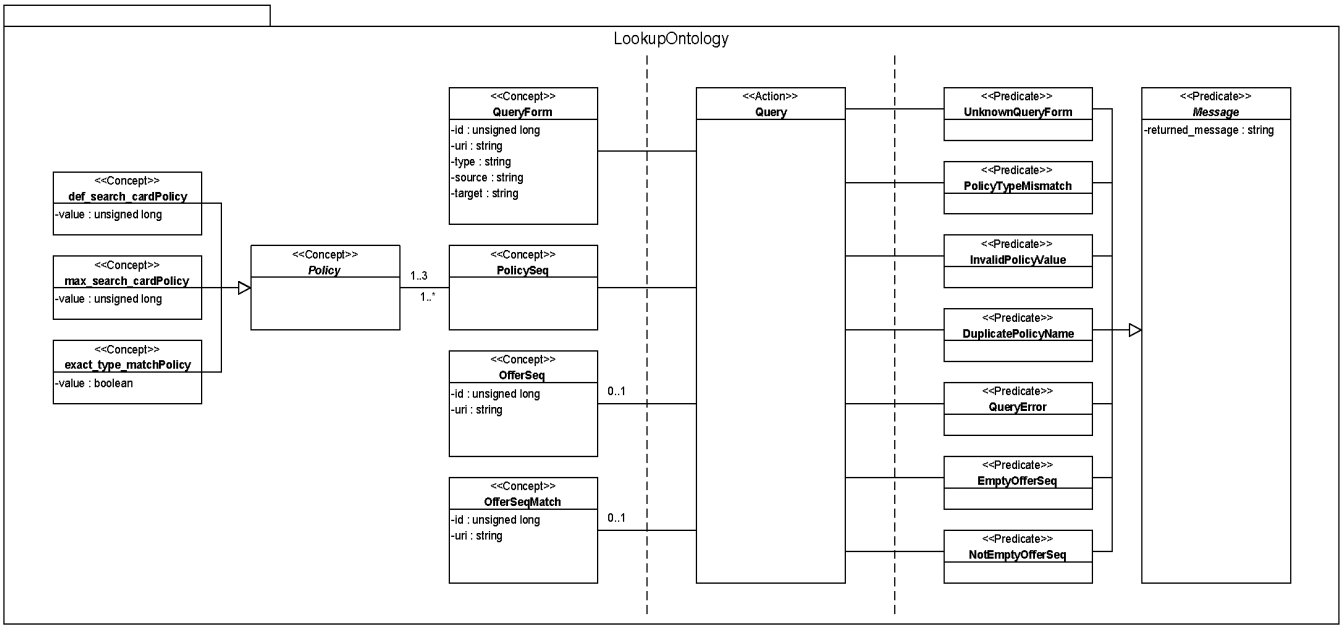

Fig. 7. Lookup Ontology metamodel expressed in UML.

`def_search_cardPolicy` or `max_search_cardPolicy`, indicating the number of records to be located by default, and the maximum number of records to be located in the query, respectively. It is possible some exceptions.

Thus, `UnknownQueryForm` indicates that the query cannot be answered because the file specified in the `uri` is not accessible; `PolicyTypeMismatch` indicates that the type of value specified is not appropriate for the `Policy`; `InvalidPolicyValue` indicates that the Policy value specified is not within the permissible value range for that Policy; `DuplicatePolicyName` indicates that more than one value for the same `Policy` has been specified in the `PolicySeq`; and `QueryError` indicates that an error has occurred during the query. If there is no exception and the query is successfully executed, either the `EmptyOfferSeq` predicate is used when no record is returned by the query, or the `NotEmptyOfferSeq` predicate, when it is. This, in turn, uses the `OfferSeq` concept to represent the set of records located in the query, the properties of which are the query "`id`" and the file "`uri`" where the found records are stored.

VI. Conclusion

Today, web-based EMIS greatly facilitate information search and retrieval, favoring user cooperation and decision-making. Their design requires the use of standardized methods and techniques that provide a common vocabulary to represent the knowledge in the system and a capability for mediation to allow interaction (communication, negotiation, coordination, etc.) of its components. Ontologies are able to provide that shared vocabulary, and trading systems can improve the interoperability of open and distributed system.

The present paper shows how traditional traders, properly extended to operate in WIS, are a good solution for information retrieval. For that we have introduced Ontological Web-Trading (OWT), an extension of the traditional ODP trading service to support ontological information retrieval issues on Web-based EMIS, as is the case of the SOLERES system.

Future work will focus on the implementation of SOLERES-HCI (Human-Computer Interaction). This subsystem of our EMIS is defined by means of the Computer Supported Cooperative Work (CSCW) paradigm [16] and implemented by using an innovative technology of intelligent agents and multi-agent architectures. Furthermore, we are working on this subsystem and studying how to decompose the user tasks into actions that will have to be performed by the SOLERES-KRS subsystem for retrieval of the information requested and the ontology mapping problems involved.

Finally, we would like to study, develop and incorporate new evaluation and validation techniques, such as measuring the precision of data returned to queries, response time in executing the query, usability, etc.

***Abstract*—The work presented in this paper concerns discourse structure analysis and its applications to intra- and inter-document search. In a typical application, which could be called "rhetorical browsing", the system will provide assistance to a journal reader in order to focus on texts and passages presenting certain *kind* of information and comments, according to his/her current interest: may be raw information, possibly with chronological dimension, or on contrary analyses, recommendations, debates, etc.. The discourse model can be related to Swales's "discourse moves" and the derived "argumentative zoning" procedures for scientific documents. However due to the nature of the considered texts, zones are defined in more "generalist" terms, following the classic Narration-Description-Argumentation-Prescription typology and especially C. Smith's notion of "discourse modes". The paper presents some preliminary steps performed in order to test the feasibility of the project. First of all, in order to ground our research on firm observations, we decided to build a corpus of journalistic texts, annotated according to the discourse model in view. Quantified results concerning the organization of discourse modes within texts could be obtained thanks to these annotations. In a second step, an experimental procedure for automatic tagging of text passages according to discourse modes has been designed, implemented and tested on the corpus.**

I. Introduction

ONE can currently observe an increasing interest for discourse structure analysis in the NLP community, both for applicative purposes (improvement of document indexation, summarization, document browsing, passage extraction...) and corpus-based linguistic studies. A very popular approach tries to capture text organization in terms of successive "homogeneous" blocks, representing the succession of "topics" addressed in the text. This so-called *thematic segmentation* has received many implementations and experimentations, in the line of Hearst's *Text Tiling* [1].

Rhetorical zoning is a less represented but developing matter. Notably, a number of on-going works are based on Swales' notion of "discourse moves" [2]. Attempts to automatically discover such structures by means of machine learning techniques notably count the pioneer work of [3] for scientific texts, and extensions to other kinds of texts as in [4]. In order to adapt these ideas to our journalistic corpus, we consider a refinement of the Descriptive-Argumentative-Narrative-Prescription model considered (with many variants) in literary studies [5], [6], [7]. According to this model, texts or passages of texts can be labeled by such a *discourse* (or *rhetoric*) *mode*.

Our interest is strongly related with practical concerns. As news readers we observe that, from one reading to another, we may be interested in a different kind of content: maybe raw information, with possibly strong chronological aspects, or on contrary analyses and explanations, recommendations, etc. And not only different papers will match our expectations, but even, especially in long articles, specific passages in them. Hence an interesting consequence of our work would be inter- and intra- document browsing, according to rhetorical and not only topical criteria.

In order to ground our research on firm observations, we decided to build a corpus annotated according to the discourse model in view. The corpus is composed of in-depth articles in economy and politics from the French newspaper *Le Monde*. The annotation task consisted in a labeling of texts passages with a selected set of discourse modes. Quantified results concerning the organization of discourse modes within texts could be obtained thanks to these annotations. In a second step, an experimental procedure for automatic tagging of text passages according to discourse modes has been designed, implemented and tested on the corpus.

The paper is organized as follows. We first describe the corpus, the discourse model, and the annotation procedure. Quantified results concerning the organization of discourse modes within texts are then presented, completed by the description of the automated tagging procedure.

II. Corpus, model and annotation procedure

A. Texts, annotators and tools

The corpus in view is composed of journalistic texts from *Le Monde*, year 1994. This choice is due both to applicative goals and to the linguistic quality of the journal. We randomly selected 30 texts (mainly in politics and economy) of different sizes. The corpus totalizes 46689 words and was shared out among 3 categories: *Small*: less than 1000 words (15 texts); *Medium*: between 1000 and 3000 words (10 texts); and *Large*: more than 3000 words (5 texts). Each text has been annotated by 3 different annotators from a group of 5 with a random distribution between annotators in each size categories. Our 5

978-83-60810-53-8/$25.00

annotators were students in the master degrees of Linguistic and Computer Science.

The annotation was performed under the *Glozz* platform[1]. *Glozz* is based on a generic meta-model which allows to define any specific set of units (segments) and relations with editable features. It proposes a graphical environment and an SQL export, allowing annotations mining through standard database tools [8].

B. Rhetorical and annotation model

The approach of rhetorical structure we consider is coarse-grained and segment-oriented (rather than relation-driven and bottom-up oriented as in discourse models such as RST [9] or SDRT [10]). Generally speaking, a *rhetorical segment* can be defined as filling a specific communicative function. Such segments can be defined in different ways.

One, following [2], is based on the notion of *discourse move*. Moves are conventional parts of the message, specific of a given genre[2]; for example, in scientific articles: context of the study, aim and hypotheses, experiments, results and discussion. In NLP, such a model has been notably worked out in [3] and adapted to other kinds of texts, such as administrative letters, in [4].

Another approach, in a sense more "universalist" is the classic *Narration-Description-Argumentation-Prescription* model [5], [6], [7]. Such *discourse modes* (according to Smith's denomination) may be considered as characterizations applying to full texts or, better, to parts of them. This model appeared to be well suited to our corpus and to the practical goals in view.

However, some adaptations were made. We observe that, in general, several discourse modes are simultaneously present in a same portion of text; for example description is intertwined with argumentation, or with narration. Rather than defining single characterizations of text segments (descriptive *or* argumentative *or* narrative...), discourse modes rather act as "colors" or "shades" that can combine.

Thus, the task of *rhetorical tagging* is described as follows. We make the hypothesis that paragraphs can be considered as relevant textual units: clearly, this hypothesis could be reconsidered but it seems an acceptable first approximation. Rhetorical tagging consists in identifying which discourse modes are present in a given paragraph and with which intensity. We proposed a set of seven discourse modes divided into two main dimensions, *representational* (or *ideational*) and *interpersonal*[3]. Annotators had to allocate a score to seven fields representing the intensity these seven discourse modes.

a) Representational dimension: It concerns the semantic content of the message, the representations construed by the reader. Four graded fields where proposed relative to four rhetoric modes.

Description: Indicates the weight of factual information in the paragraph.
Argumentation-Explanation: Represents to which extent the paragraph is about convincing or explaining something to the reader. We considered that the mechanisms of argumentation and explanation are the same, even if the goals are not.
Chronology: Indicates the weight of temporally marked information in the paragraph.
Prospection: Represents to which extent the paragraph projects the reader into the future.

b) Interpersonal dimension: It concerns the relation between the writer and the reader in the communicative process and includes three fields:
Personal commitment: Does the paragraph reflect the author's personal opinion or is it rather presented as objective ?
Prescription: To what extent the paragraph is about advising or instructing the reader to do something ?
Polyphony: Indicates the weight of directly or indirectly reported speech in the paragraph.
Each of the seven fields is given a score between 0 and 2. **0:** the discourse mode is absent or marginally present; **1:** it is present, but not essential to understand the paragraph; **2:** it constitutes a major key to understand the paragraph.

C. Annotators agreement

We are in the standard situation of a known set of items (for each paragraph, the seven fields corresponding to the seven discourse modes) that receive some "tags" (0, 1 or 2 reflecting the presence and intensity of the mode in this particular paragraph) so that a Kappa measure will do well. *Fleiss' kappa* [11] coefficients for each text are presented in table I. For each text, the given score is the mean value of the scores of all its segments.

TABLE I
FLEISS *kappa* ON RHETORICAL MODES

Text	κ	Text	κ
Large		Small	
0101_31	0.23	0101_1	0.42
0108_96	**0.48**	0101_14	0.41
0204_34	0.31	0101_20	0.36
0628_49	0.29	1229_33	0.39
1220_101	0.28	1230_90	0.33
Average	0.32	1231_75	0.49
Medium		1231_86	0.32
0126_121	0.26	1231_93	0.39
0718_138	−0.01	1231_70	**0.59**
0820_12	**0.41**	1231_84	0.52
0831_135	0.23	1231_89	0.30
1230_24	0.21	0101_13	0.37
0131_108	0.31	0101_19	0.36
0801_108	0.06	0101_6	0.23
0829_120	0.32	1230_3	0.28
0929_135	0.15	Average	0.39
1231_92	0.35		
Average	0.23		

The scores show an average agreement quality ranging from a "low fair" (medium texts) to "almost moderate" (small

[1] http://www.glozz.org/

[2] Where "genre" should be interpreted in a very narrow sense, and better called "micro-genre"

[3] The term "representational" is inspired by Adam's terminology and "ideational" by Halliday's one.

texts)[4]. They may look "modest", but one must keep in mind the highly interpretative nature of the task. Also remind that annotators had to choose between three possibilities; when considering only if the rhetorical color is present or absent all κ raise by, at least, 0.1 (except for one text), leading to a global factor of 0.42, "moderate". The worst score on medium texts seems - according to the post-annotation debriefing - due to a particularly open interpretation of some of these texts.

On the overall, these results seem to show that a form of "convergence" does exists, pleading for the relevance of the model. Improvements could probably be obtained thanks to a better and less ambiguous definition of the discourse modes, for which a careful analysis of the present discrepancies should be helpful. Also differentiated analyses according to the different modes could be interesting: are some of them less controversial than others?

III. The dynamic of discourse modes

All along this section we will use abbreviations indicated in table II to designate the rhetorical modes: DESC for Description, ARGU for Argumentation-Explanation, etc. The first column of the table presents a first bunch of raw observations, namely the distribution of modes along all texts and all annotators. Let us insist that it counts *scores*, i.e. the number of paragraphs annotated according to a particular mode, ponderated by the intensity factor given by the annotator. The sum of all scores for one mode is compared to the sum of all scores for all modes.

Two modes, DESC and ARGU are massively preeminent, while interpersonal ones are globally under-represented. This is clearly related to the kind of texts in the corpus, rather of "objective" nature, which do not include editorials for example, or forums. Let's consider now more elaborate questions.

A. Preferred positions of discourse modes.

Figure 1 shows the repartition of rhetorical modes (evaluated as always in terms of scores) in the beginning, middle and final parts of texts. The global impression may corroborate primary intuitions. One can see two symmetric groups: CHRONO and DESC prefer the beginning with no marked preference for the other two: they present "facts" to be discussed later; while POLY, ARGU, PROS and PRES (which constitute such discussions) rather occur in the end. COMM is more equally distributed.

B. Interdependence relations between discourse modes

Some correlations, positive or negative, between discourse modes may be conjectured from the previous table and observed on specific texts. For example a kind of contravariance between DESC and ARGU. The question arises whether such observation could be confirmed and generalized some way: are DESC and ARGU "generally" contravariant ? Are there other such pairs? In order to investigate this question we computed a statistical correlation coefficient.

[4]According to the interpretation grid of [12]: $\kappa < 0$: poor, $0 < \kappa < 0.2$: slight, $0.2 < \kappa < 0.4$: fair, $0.4 < \kappa < 0.6$: moderate, $0.6 < \kappa < 0.8$: substantial, $0.8 < \kappa < 1$: almost perfect

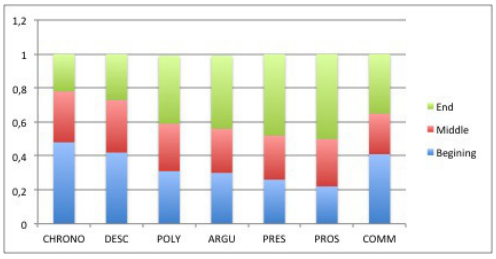

Fig. 1. Distribution of discourse modes along texts.

Results are shown in table III, limited to the four most representative rhetorical modes.

Three, low but perceptible correlations appear: a negative one between argumentation and description, as expected from our "manual" observations; a positive one between argumentation and personal commitment, which is not surprising; and a negative one again, between personal commitment and polyphony: stating other people positions is somewhat exclusive from expressing one's own. It is worth mentioning that, if the correlations are weak in value, the annotators agree on their direction, positive or negative, with one exception out of 18 pair annotator/mode: a fact that tends to strengthen the relevance of the results.

TABLE II
RHETORICAL MODES AND TOPIC TRANSITIONS. (1) THIS MODE/ALL MODES, ANYWHERE. (2) THIS MODE/ALL MODES, RESTRICTED TO TRANSITIONS. (3) THIS MODE IN TRANSITIONS / THIS MODE ANYWHERE. DESC: DESCRIPTION, ARGU: ARGUMENTATION-EXPLANATION, CHRO: CHRONOLOGY, PROS: PROSPECTIVE, POLY: POLYPHONY, PRES: PRESCRIPTIVE, COMM: PERSONAL COMMITMENT

	(1)	(2)	(3)
DESC	0.25	0.26	0.62
ARGU	0.27	0.28	0.6
PROS	0.06	0.04	0.41
CHRO	0.07	0.06	0.52
POLY	0.13	0.15	0.68
PRES	0.1	0.08	0.45
COMM	0.12	0.12	0.59
ALL	1	1	0.58

	ARGU	DESC	COMM	POLY
ARGU	-	-0,18	0.22	0
DESC	-	-	-0,08	0,08
COMM	-	-	-	-0,16
POLY	-	-	-	-

C. Rhetorical profiles.

One can produce graphics such as figures 2 and 3, useful to study the distribution of rhetorical modes along a given text. Rates of the 7 rhetorical modes (vertical axe) are displayed in relation with the successive paragraphs (horizontal axe)[5]. The first graphic concerns a historical-narrative text: the biography

[5]In this example, each graphic concerns a single annotator.

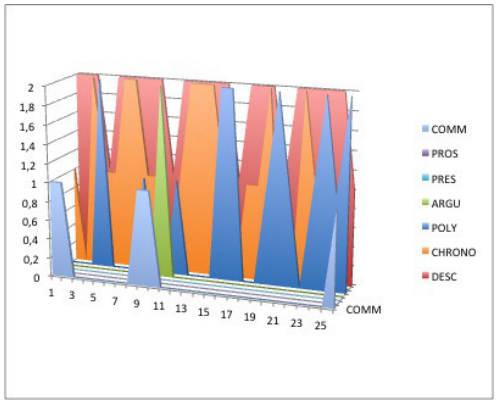

Fig. 2. The dynamic of discourse modes: Biography of an Israel spy.

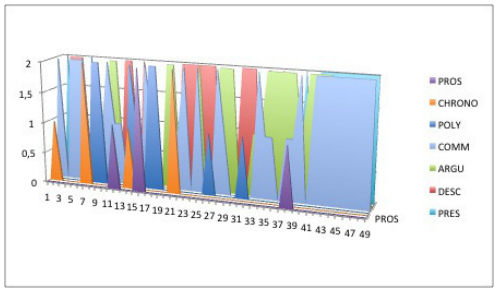

Fig. 3. The dynamic of discourse modes: "How to save Bosnia".

of an Israel spy; the second is an analytic paper about the war in Bosnia. The first thing that appears is the difference in their dominant modes: DESC, CHRONO and POLY for the first, PRES, DESC and ARGU for the second, with also COMM, which more or less coincides with PRES and is hidden by it on the figure. A closer look shows informations about the plan of the texts.

In figure 2 we have a "ground" of descriptive-chronological discourse all along the text, with mainly in the second half a strong polyphonic component (which correspond to discussions and conjectures about the "real" life and activity of this spy). In figure 3 we have a concentration of prescriptive and argumentative discourse (with strong personal commitment) in the second part, while descriptive-chronology-polyphony is rather concentrated in the beginning (stating the history and the problem). These quick observations tend to show, first that a rhetorical dynamic can be analyzed in terms of discourse modes, and second that "text profiles" can be inferred.

IV. Discourse modes and text segmentation

Going further, we can consider the question whether discourse modes by themselves may determine text segmentation i.e. allow to define a succession of segments being "rhetorically homogeneous" in some way. This question was addressed in two different assumptions: a strong one, where a segmentation would be (strictly) determined by changes in the configuration of salient discourse modes - the result seems to be negative; and a weak one, where we consider the contribution of discourse modes to some general "thematic segmentation" - and interesting correlations can be put to light.

A. Attempt towards a pure rhetorical segmentation

We imagined the following experiment. Drawing a parallel with conventional methods in thematic segmentation [1] we considered rhetorical modes as a set of descriptors: the scores given by an annotator to some paragraph defines a *vector* which represents its rhetorical orientation. We can compute angles between successive blocks and deduce continuity or discontinuity according to the angle being smaller or greater than some threshold. Unfortunately the first results are not very convincing: if some "relatively homogeneous" contiguous regions of some extent (several paragraphs) may appear, such text ranges are rather scarce. More subtle measures could probably be considered but in fact the transcription of topical segmentation techniques, based on a geometry of rhetorical descriptors, does not seem to be the good idea.

B. Topical structures and discourse modes

Another way to consider the role of discourse modes in text organization is to look for possible correlations with the topical structure of a text. Here, we took advantage of another annotation of the corpus, performed simultaneously, where annotators were asked to cut out the texts into geat "parts" according to their reader's intuition [13] . This could be called "spontaneous segmentation", as performed by an attentive reader, more or less consciously. The general question is to know what, in this operation, is relative to the "subject" (knowledge domain, discourse referents...) and what to rhetorical features. We were in this matter especially interested in the transitions between "spontaneous" segments and asked the annotators to mark sentences that, according to them, signaled such transitions[6].

Two kinds of investigations were made. The first one continues the geometrical model as above (A), searching for a possible coincidence between rhetorical gaps - measured as angles between "rhetorical vectors" - and topical changes. Unfortunately, at first sight at least, the test fails: there are cases where topical changes are accompanied with large rhetorical angles and cases where not. And the core of topical segments shows both low and hight rhetorical gaps. Again, looking for global configurations of discourse modes appears not to be the right way.

Then we decided to have a more individuated view on each discourse mode and to concentrate on annotated *transitions*: do such zones have specific rhetorical characteristics? Results are figured out in columns 2 and 3 of table II ("Transition" means "paragraph containing an annotated transition zone"). Column (2), when compared to (1), would induce a rather negative result: modes distribution does not reveal significant difference between transitions and other blocks. But (3) shows more positive results.

[6]See for instance [14], [15], [16] for studies on the linguistic characteristics of topical changes.

First we see that introductory blocks contribute for 0.58 to the total score: an important ratio since they constitute only one third of all paragraphs. Beginnings of topical segments are more strongly marked than the others on the rhetorical ground. Then we see that POLY and, with lower strength, DESC clearly prefer transitions. On the opposite side, PROS, PRES and to some extent CHRO are less represented in this position. In other words writers like to begin a new topic by the presentation of different viewpoints or descriptive information and tend to reject prospective, prescriptive or chronological considerations out of this position.

Hence, as one could expect and despite the results of our first test, there seems to be real hints for an implication of rhetorical concerns in topical organisation. On a practical ground, these results could also help in automated segmentation procedures, provided one could find reliable marks of the four distinguished modes, a question addressed in the last part of the paper.

C. Conclusion: what kind of rhetoric zoning?

Gathering the results of sections 3 and 4, some information can be synthesized concerning the organization of discourse modes along texts. The negative - but, still, informative - result is that no clear segmentation (in contiguous blocks) is likely to be based on *global* configurations of discourse modes.

Contrastively, different experiments have shown that, taken *individually*, discourse modes do determine some *zones* according to their salience - which is most important w.r.t. our targeted application. And finally we have seen that the combination of topical and rhetorical features is relevant to the spontaneous segmentation of texts by readers, which might provide hints for improvements in thematic segmentation.

V. Towards an automatic tagging of discourse modes

A. Procedure and implementation

An automatic tagging of text passages w.r.t. the given set of discourse modes appears as a necessary complement to the previous study, both in order to contribute to the validation of the model, and as the basis for the application in view. A first step was performed in this direction as follows [17]. We listed a set of features whose count allows to assign a score to each mode in each paragraph. This score is supposed to reflect the force of the considered mode. In this first experimental attempt, we considered simple features, essentially lexical and morphological ones, as illustrated by the following sample.

- Description: verb tenses representing durative processes (imparfait, présent[7]), spatial locative connectives (prepositions sur/ *on*, dans / *in*...), adjectives and relative pronouns, demonstrative pronouns, named entities.
- Chronology: verb tenses of the past (passé simple, passé composé, participe passé), temporal connectives (conjonctions and adverbials: quand / *when*, puis / *then*, ce matin / *this morning*...), dates.
- Prospection: verb tenses of future and unrealised (futur, conditionnel), cue words (à l'avenir / *in the future*, hypothèse / *hypothesis*, prévoir / *forsee*...)
- Argumentation-Explanation: logical and argumentative connectives (cependant / *however*, donc / *hence*, d'abord / *first*, ensuite / *then*, parce que / *because*...), other cue words (impliquer / *imply*, problème / *problem*, réponse / *answer*...)
- Polyphony: quotation marks, proper names and social functions (as indicating possible authors of reported speech), declarative verbs.
- Prescription: verb mode (impératif), modal verbs (pouvoir / *can*, falloir / *must*, devoir / *must*), other cue terms (important / *important*, essentiel / *essential*...)
- Personal Commitment: logical connectives, epistemic verbs at 1st person (penser / *think*, douter / *doubt*...), other cue terms (respect / *respect*, inquiétude / *concern*...).

One can remark that some features are shared by several modes: it is the co-presence of other ones of the same family that determines *in fine* their rhetorical orientation. The scoring takes this phenomenon into account as illustrated by the following example.

Text : En août, explique Hugues Portelli, qui veille sur les courbes d'opinion au sein du cabinet du premier ministre, il y a eu le consensus monétaire après la crise de juillet et, pour cette fin d'année, le premier ministre a profité, à la fois, de la gestion du conflit d'Air France, des actions menées par Charles Pasqua, notamment contre le FIS, et, enfin, du résultat obtenu sur le GATT.

In August, says Hugues Portelli, who watches over the curves of opinion within the PMO, there was consensus after the monetary crisis in July and, for this season, the Premier took the opportunity in the same time of the conflict management at Air France, the actions taken by Charles Pasqua, especially against the FIS, and finally the result of the GATT.

- Clues for Polyphony: Hugues Portelli, Charles Pasqua [named entities for persons], Expliquer [cue verb]. Score = 3.
- Description: Hugues Portelli, Charles Pasqua, Air France, FIS, GATT [named entities], qui [relative pronoun], sur, au sein de [spatial connective], premier ministre [function name], et [conjonction] (twice), Score = 11.
- Argumentation-Explanation: Expliquer [cue verb], après, et (twice), pour, à la fois, notamment, enfin [logical connectives]. Score = 8.
- Chronology: il y a eu, profité, obtenu [past tense], en août , après, juillet, fin, année, à la fois, enfin [temporal terms]. Score = 10.
- Other modes: 0 clue.

The procedure was tuned on a corpus made of some thirty texts from *Le Monde*, disjoint from the annotated ones, then tested on the later. In this first experiment we limited ourselves to identify the three modes most representative of each paragraph (Description, Argumentation-Explanation and Chronology in the example). An XML output allows to insert

[7]For obvious reasons, tenses are given their French name.

TABLE IV
AUTOMATIC AND HUMAN RHETORICAL TAGGING OF A TEXT

	Annot.1	Annot. 2	Annot. 3	*Automated Annot.*
§1	1. ARGU 2. DESC 3. POLY	1. ARGU 2. COMM 3. POLY	1. POLY 2. PRES	*1. ARGU* *2. DESC* *3. POLY*

this result in the text.

B. First results and evaluation

We compared our automatic labeling to the manual annotations of the corpus. The result, still qualitative, is that our annotation does not scatter more than what can be noted between human annotators themselves (see an example for a single text in Table IV). In other words, the automatic tagging does not seem better or worse that the manual ones, and is in fact consistent with them. If the evaluation procedure clearly requires to be refined, as well as the manual tagging itself, we believe that this first test may be considered encouraging concerning the feasibility of the task. An important issue to highlight is the underrepresentation of certain modes: Prospection and modes of the interpersonal dimension (with the exception of Polyphony). In the future we therefore need to go beyond the three prevailing modes and probably separate representational and interpersonal ones.

VI. CONCLUSION AND FUTURE WORK

In this paper we have presented a set of investigations on the rhetorical structure of journalistic texts, based on the constitution of an annotated corpus Our first positive result consists in the corpus itself since there is a recognized lack for such resources[8]. The inter-annotators agreement seems acceptable, considering the strongly interpretative nature of the task: generally speaking we believe that, in the case of discourse structure, we have to learn how to cope with this variability rather that try to reduce it to null.

The rhetorical model was designed in terms of discourse modes, due to the application in view, a specific kind of document browsing adapted to journalistic texts. It was correctly received by the annotators, which provides an encouraging hint of its relevance. In particular the idea of a combination of discourse modes in a same passage, with graduation of their salience, seems to receive confirmation.

Several quantified observations, performed thanks to the annotated corpus, give useful informations on the distribution of discourse modes and their contribution to text zoning of some kind. A notion of "rhetorical profile" emerges, combining global dominant modes with the "dynamic" of modes distribution along the text.

[8]Glozz annotations are "stand off" and may be obtained for free from the authors, provided the applicant has him/herself acquired the rights on *Le Monde* corpus.

Finally, a first step was performed towards an automatic tagging in relation to the model.

Further work should include the following questions.

1. An extension of the corpus, in order to give a firmer value to our analyses. A careful examination of the discrepancies between annotators could provide useful hints in order to tune the model and remove ambiguities in its description. Achieving a better inter-annotators agreements would be a good confirmation of these improvements. Another issue would be to split the corpus into different more homogeneous subtypes.

2. Improving the automatic labeling. Other linguistic parameters should be considered. Especially interesting would be aspectual values as described in [6]. Machine learning issues should be considered, but need clearly a great effort in corpus annotation.

3. Finally, the application itself should be considered, which implies to convert "pragmatic" requirements of readers into configurations of rhetorical modes.

***Abstract*—The article discusses abstract spaces of concepts and features. Concepts correspond to real-world objects. Concepts are described by their features. The study is devoted to relations in the space of concepts and in the space of features. Of greatest interest is similarity of structures in the concepts and features spaces. There is a direct link between features and concepts. Therefore, similarity may be analyzed through structures of both concepts and features. Authors propose generalized similarity relation, applicable to the developed framework. In addition, similarity of nested sets of the space of features and concepts is discussed. Authors introduce an algorithm, which calculates similarity of two structures of nested structures. Developed semantics leads to the set-theoretic model, which allows to flexibly describe abstract information.**

I. Introduction

SIMILARITY is one of the most important dependencies in our environment. In this article developed framework for constructing generalized similarity relations is presented.

Similarity estimation has to involve narrowing the focus on chosen aspects of compared objects. In our nomenclature object is called concept, object's attribute is a feature. We chose these names intentionally, to highlight that our model may be applicable to modeling in various areas of science. In sections II-A and III the core of developed framework of phenomena description is depicted. We start from the space of features - pieces of information, that describe concepts. In section III-B our own approach to similarity relations modeling in the fuzzified space of concepts and features is introduced. Similarity relations for features vectors are discussed. We introduce also an algorithm for computing similarity of linear orders in the space of features.

The goal of the paper is to present the research on concepts and features spaces descriptions and similarity modeling. Valuation mappings and similarity relations able to process fuzzified descriptions of real-world objects are introduced.

II. Preliminaries

In our approach a start point are features - descriptions of concepts. Features are gathered in vectors. We operate in the namespace of features and in the space of their evaluations rather than on the concepts (objects) themselves. We are interested in similarity of descriptions of concepts, i.e. in vectors of features' evaluations. We assume, that each hypothetical or real concept can be described with qualitatively the same set of features, but evaluated differently.

Due to space limitations we do not present literature review on this topic. Interesting research on similarity can be found not only, but also in: [2], [5], [6], [8] and [9]. It is important to mention, that approaches present in the literature are suitable for similarity based on features. Our model is concepts' oriented in its nature. Therefore, it is necessary to include relations between concepts and features.

We have developed a framework for describing the space of concepts and the space of features. We have also proposed similarity measures dedicated for this model, which we present in the next paragraphs.

A. The space of concepts and the space of features

1) The space of features: A concept corresponds to a real-world object. Usually, due to various constraints and complexity of real-world phenomena, we do not operate directly on concepts. Instead, we describe them with their features. In the developed model the space of features is defined as follows:

$$\mathcal{D} = \{(\mu_1, \ldots, \mu_n) : \mu_i \in [0,1],\ i = 1, \ldots, n,\ n \in \mathcal{N}\} \quad (1)$$

Under our assumptions features are imprecise. Concepts correspond to real-world objects. One of many imprecise information representation models known in literature may be applied, for example: [1] or [3]. Authors treat imprecise information analogically to the uncertainty in the sense of Zadeh. We are aware that there are other frameworks (i.e. probability theory) that are able to describe uncertainty, which we are not recalling here.

Features evaluations are expressed through their degree of membership as a single numerical value from the $[0,1]$ interval. Features vectors belong to the namespace of features. There is unlimited amount of features vectors evaluations, but in our application there is finite amount of features. Of interest is possibility of features space structuring by introducing certain relations, like inclusion, exclusion and overlapping.

2) The space of concepts: $\mathcal{C}$ is the set of all concepts fulfilling some logical conditions, e.g. consumers from a city, pixels from certain images, musical symbols of some score.

$$\mathcal{C} = \{c_1, c_2, \ldots, c_r\} \quad (2)$$

978-83-60810-53-8/$25.00

such that $r \in \mathcal{N}$ is the number of concepts in the space $\mathcal{C}$. The source of information about concepts may be for example measurement devices or questionnaire surveys.

The space of concepts is limited. We are interested in structuring the space of concepts through the space of features, the space of their evaluations and dependencies in these spaces as well as in their subsets. Concepts' space analysis will be performed using relations of similarity, inclusion, exclusion and others.

In the next section similarity relations customized for the developed model are proposed. Presented technique aims at mimicking human way of how similarity is estimated. Concepts are described with their features, comparison happens in a feature-wise fashion. The strength of belongingness of a particular feature to the concept (corresponding to the degree of membership) influences similarity measure.

III. Similarity in the space of concepts and in the space of features

In this section we introduce similarity measures adjusted for spaces of concepts and features.

A. The valuation mapping

Firstly, let us discuss the valuation mapping. It is a relation, that for every vector of features assigns a set of concepts.

$$V : \mathcal{D} \to 2^{\mathcal{C}} \tag{3}$$

For instance, the simplest valuation assigns all concepts with a given features' vector $(\mu_1, \ldots, \mu_n)$ to this vector of features:

$$V(\mu_1, \mu_2, \ldots, \mu_n) = \{c \in \mathcal{C} : d(c) = (\mu_1, \mu_2, \ldots, \mu_n)\} \tag{4}$$

where the mapping $d : \mathcal{C} \to \mathcal{D}$ defines features for concepts. Valuation mapping V generates a subset of the space of concepts, such that each i-th feature of selected concepts was evaluated exactly the same, as the respective i-th feature from analyzed vector $(\mu_1, \mu_2, \ldots, \mu_n)$. Valuation mapping defined in formula 4 is called *pointwise valuation mapping*.

Alternatively, we propose generalized approach to valuation mappings called *filling up valuation mapping* defined as follows:

$$V_I(\mu_1, \ldots, \mu_n) = \big\{c \in \mathcal{C} : d(c) = (\mu_{c1}, \ldots, \mu_{cn}) \text{ and } \mu_{ci} \leqslant \mu_i \text{ for } i = 1, \ldots, n\big\} \tag{5}$$

Filling up valuation mapping generates a subset of the space of concepts, that groups objects, which each i-th feature was not evaluated as greater than respective feature in given features vector. In other words, filling up approach is a generalization of pointwise valuation mapping V, which translates features vectors into groups of concepts. As a result, we extract objects, which description satisfy certain conditions to some point, but not beyond that point. In this study conditions are between 0 and 1, but they may be different if we assume other information representation model (for example: balanced fuzzy sets defined in [3] utilize $[-1, 1]$ interval, intuitionistic fuzzy sets defined [1] employs doubled unit interval $[0, 1]$).

Valuation mappings V and V_I are semantic mappings. They allow transformation from the namespace of features and the space of their evaluations to subsets of the space of concepts. In practice, we use valuation mappings to generate subsets of the space of concepts, in which we are interested in. The key, by which subsets are generated, are features - and that was our initial goal, to describe concepts and groups of concepts by their features.

B. Similarity relations

In this section we introduce similarity relation for features' vectors. Let us assume that we have two vectors of features:

$$\mu_A = (\mu_{A1}, \mu_{A2}, \ldots, \mu_{An})$$
$$\mu_B = (\mu_{B1}, \mu_{B2}, \ldots, \mu_{Bn})$$

Below we introduce a generalized similarity measure $s_{G(eneralized)}$ of two vectors of features.

$$s_G(\mu_A, \mu_B) = \frac{\big|V_I(\mu_A) \cap V_I(\mu_B)\big|}{\big|V_I(\mu_A) \cap V_I(\mu_B)\big| + \mathcal{V}_{A\setminus B} + \mathcal{V}_{B\setminus A}} \tag{6}$$

where:

$$\mathcal{V}_{A\setminus B} = \int_0^{\rho_{max}} \alpha(x) \cdot \mathcal{V}_{A\setminus B}(x)\, dx$$
$$\mathcal{V}_{B\setminus A} = \int_0^{\lambda_{max}} \beta(x) \cdot \mathcal{V}_{B\setminus A}(x)\, dx \tag{7}$$

and

α and β are real nonnegative functions

and

$$\mathcal{V}_{A\setminus B}(x) = \Big|\big\{c \in V_I(\mu_A) \setminus V_I(\mu_B) : \max_{i=1}^{n}\{\mu_{Ai} - \mu_{ci}\} = x\big\}\Big|$$
$$\mathcal{V}_{B\setminus A}(x) = \Big|\big\{c \in V_I(\mu_B) \setminus V_I(\mu_A) : \max_{i=1}^{n}\{\mu_{Bi} - \mu_{ci}\} = x\big\}\Big|$$

and

$$\rho_{max} = \min\big\{\rho \geqslant 0 : (\forall\, i = 1, 2, \ldots, n)\ \mu_{Bi} + \rho \geqslant \mu_{Ai}\big\}$$
$$\lambda_{max} = \min\big\{\lambda \geqslant 0 : (\forall\, i = 1, 2, \ldots, n)\ \mu_{Ai} + \lambda \geqslant \mu_{Bi}\big\}$$

and

$$\mu_c = \big(\mu_{c1}, \mu_{c2}, \ldots, \mu_{cn}\big)$$

is the vector of features of the concept c.

Valuation mapping V_I transforms vectors of features into subsets of the space of concepts satisfying certain conditions (as in formula 5). Generalized similarity s_G is calculated as a fraction. Similarity is enlarged as the size of intersection of compared subsets of the space of concepts grows. Similarity becomes smaller as the number of elements that do not belong to sets' intersection grow. The decreasing effect of features, which are not shared, is conditioned on the difference between these features and vectors μ_A and μ_B. We integrate on the space of features. Integration is done separately for concepts in $V_I(\mu_A) \setminus V_I(\mu_B)$ and in $V_I(\mu_B) \setminus V_I(\mu_A)$. The domain of integration spans from 0 to ρ_{max} or to λ_{max} respectively for these two cases. Functions α and β allow to introduce more

punishing effect of $V_I(\mu_A) \setminus V_I(\mu_B)$ and $V_I(\mu_B) \setminus V_I(\mu_A)$ on the similarity value. α and β may be also used to enhance nonsymmetry of relation s_G.

Let us also introduce a discretized version of similarity relation s_G (named $s_{D(iscretized)}$). For any $0 < \rho$ and $0 < \lambda$ the value of similarity is based on estimations of integrals from the formula 6 in a following manner:

$$\mathcal{V}_{A\setminus B}(x) = \sum_{j=1}^{\rho_{max}} \Big(\alpha(j) \cdot \mathcal{V}_{Aj}\Big)$$
$$\mathcal{V}_{B\setminus A}(x) = \sum_{j=1}^{\lambda_{max}} \Big(\beta(j) \cdot \mathcal{V}_{Bj}\Big) \tag{8}$$

where:

$$\mathcal{V}_{Aj} = \left|\Big\{c \in V_I(\mu_A) \setminus V_I(\mu_B) : \tau_{\rho j}\big(\max_{i=1}^{n}\{\mu_{Ai} - \mu_{ci}\}\big)\Big\}\right|$$
$$\mathcal{V}_{Bj} = \left|\Big\{c \in V_I(\mu_B) \setminus V_I(\mu_A) : \tau_{\lambda j}\big(\max_{i=1}^{n}\{\mu_{Bi} - \mu_{ci}\}\big)\Big\}\right|$$

and

$$\tau_{\rho j}(\text{exp}) \;\equiv\; \rho \cdot (j-1) < \text{exp} \leqslant \rho \cdot j$$
$$\tau_{\lambda j}(\text{exp}) \;\equiv\; \lambda \cdot (j-1) < \text{exp} \leqslant \lambda \cdot j$$

and

$$\rho_{max} = \min\Big\{j{=}1,\ldots : (\forall\, i{=}1,\ldots,n)\ \mu_{Bi} + \rho \cdot j \geqslant \mu_{Ai}\Big\}$$
$$\lambda_{max} = \min\Big\{j{=}1,\ldots : (\forall\, i{=}1,\ldots,n)\ \mu_{Ai} + \rho \cdot j \geqslant \mu_{Bi}\Big\}$$

Analogously to the formula 6, we use filling up valuation mapping V_I. It produces a subset of the space of concepts, that satisfies given conditions to the extent not greater than the conditions stated in the input features vector. By analogy, in the s_D compared sets intersection and outlying parts ($V_I(\mu_A) \setminus V_I(\mu_B)$ and $V_I(\mu_B) \setminus V_I(\mu_A)$) are accounted. Concepts not present in sets' intersection are lying in one of the two remaining parts. They decrease the value of similarity in a nonsymmetrical fashion (through functions $\alpha(j)$ and $\beta(j)$). The decreasing impact of concepts lying in sets' differences is conditioned on the difference between the particular concept μ_c and μ_A or μ_B. We may visualize such „outlying" concepts as crescent-shaped hulls around sets' intersection. These crescent-shaped hulls are divided into up to ρ_{max} and λ_{max} segments. The greater amount of concepts fall to the furthest part of such crescent, the more decreasing effect there is on the similarity value.

We may simplify formula s_D further on. Instead of functions α and β under the sum in formulas 8, we may multiply coefficients by parameter λ or ρ and by j in a following way:

$$\mathcal{V}_{A\setminus B}(x) = \sum_{j=1}^{\rho_{max}} \Big(\rho \cdot j \cdot \mathcal{V}_{Aj}\Big)$$
$$\mathcal{V}_{B\setminus A}(x) = \sum_{j=1}^{\lambda_{max}} \Big(\lambda \cdot j \cdot \mathcal{V}_{Bj}\Big) \tag{9}$$

The proposed idea relies on relation built around sets' intersection and concepts lying beyond this intersection. Alignment of the outlying concepts influences similarity value. Similarity relation's codomain is $[0, 1]$. Note, that it is reflexive. The relation s_G was also intentionally constructed to be nonsymmetric, but they can be adjusted to be symmetric. Asymmetry of similarity relation is a highly desirable property from the applicational point of view. Due to space limitations we do not elaborate on similarity relation properties.

In given definition of valuation mapping V_I, what strikes immediately, is that the similarity relation induced by this mapping may also create linear orders (chains) in the space of subsets of $\mathcal{D}$. In this article we discuss linear orders only. Of interest is similarity of such nested structures. In the next section we present this nontrivial modeling problem to a greater extent.

C. Similarity of linear orders in the space of concepts

In this paragraph we investigate such subsets of the space of features $\mathcal{D}$, that this mapping computes the same value for all features' vectors included in such subset, i.e. $\mathcal{A} \in \mathcal{D}$ is such subset if $(\forall\, \mu_1, \mu_2 \in \mathcal{A})\, V_I(\mu_1) = V_I(\mu_2)$. The structures of such subsets can be formally described as linear orders. Let us recall that linear order is a pair $(X, \leqslant)$, where X is a set of elements and $\leqslant$ is a binary relation satisfying axioms of: antisymmetry, transitivity and totality.

Let us introduce a similarity relation able to compare subsets of the space of features nested in the sense explained above, i.e. $(\forall\, \mathcal{B}, \mathcal{A} \in \mathcal{D})\ \mathcal{B} \leqslant \mathcal{A} \equiv V_I(\mathcal{B}) \subset V_I(\mathcal{A})$. Also, whenever $\mu_A = (\mu_{A1}, \ldots, \mu_{An}) \in \mathcal{A}$ and $\mu_B = (\mu_{B1}, \ldots, \mu_{Bn}) \in \mathcal{B}$ and $\mu_{Bi} \leqslant \mu_{Ai},\ i = 1, \ldots, n$, then $\mathcal{B} \leqslant \mathcal{A}$.

Comparing nested subsets of the space of features requires taking into account not only cardinality of compared subsets, but also actual elements lying inside. Therefore, measures of similarity operating only on cardinalities are not satisfactory to describe such structures. We need to compare actual content of each subset.

In order to compare nested subsets of the space of features we have developed an algorithm, which we describe here. Features nesting is understood in a following way: given features vector $\mu_A = (\mu_{A1}, \mu_{A2}, \ldots, \mu_{An})$ nests features vector $\mu_B = (\mu_{B1}, \mu_{B2}, \ldots, \mu_{Bn})$ if:

$$\mu_{Bi} \leqslant \mu_{Ai},\ i = 1, 2, \ldots, n \tag{10}$$

The space of features (see formula 1) and subsets of the space of concepts (see formula 2) generated with valuation mapping V_I (defined in formula 5) are recalled here. Nested features, through filling up type of transformation enforced by the valuation mapping, generate nested subsets of the space of concepts. Structure of nested sets in the space of concepts corresponds to features' nesting.

If sets of concepts are nested, then each bigger set contains each concept from each smaller set and optionally several more concepts. Let us analyze an exemplar order E_o, which contains following 3 subsets of some space of concepts:

$$P_1 = \{c_1, c_2\}$$
$$P_2 = \{c_1, c_2, c_4\}$$
$$P_3 = \{c_1, c_2, c_4, c_7, c_8\}$$

where P_1 is a subset generated with $V_I(\mu_{P_1})$, P_2 is a subset generated with $V_I(\mu_{P_2})$ and P_3 is a subset generated with $V_I(\mu_{P_3})$. μ_{P_1}, μ_{P_2} and μ_{P_3} are particular features vectors evaluations. For clarity of algorithm description, nomenclature used later refers only to subsets of the space of concepts named as P_m. The method of obtaining these subsets, through valuation mapping V_I, is assumed by default. In the given example of E_o following structure is observed: $P_1 \subseteq P_2 \subseteq P_3$.

In the developed algorithm, written to compare two nested structures of the space of concepts, as input data we have two such structures (denoted as $E1$ and $E2$):

$$E1 = P_{i_1}, \ldots, P_{i_k}$$
$$E2 = P_{j_1}, \ldots, P_{j_l}$$

where $P_{i_1}, \ldots, P_{i_k}, P_{j_1}, \ldots, P_{j_l}$ are subsets of the space of concepts. $E1$ and $E2$ are linear orders, so $P_{i_1} \subseteq \ldots \subseteq P_{i_k}$ and $P_{j_1} \subseteq \ldots \subseteq P_{j_l}$. We do not make any assumptions about the length of orders E1 and E2. $P_{i_1}, \ldots, P_{i_k}, P_{j_1}, \ldots, P_{j_l}$ contain concepts. $P_{i_1}, \ldots, P_{i_k}, P_{j_1}, \ldots, P_{j_l}$ are sets, so the order of appearance of concepts in each set can be omitted. Hence, we always use alphabetical order, to improve efficiency of our algorithm. Each order E can be written as a sequence of concepts, starting from the „deepest" of the nested sets.

The input data to our algorithm are two linear orders $E1$ and $E2$ written as sets in a form (convention) described above.

1) Start with order E, which has last set smaller. If cardinalities of last sets of both orders are equal, choose one order at random. Denote this order as $E_{f(irst)}$ and its last subset as P_{f_u} (it is either P_{i_k} or P_{j_l}).
2) Denote the second order as $E_{s(econd)}$. Denote last (biggest) set of order E_s as P_{s_v}. Search for such set in the order E_s, which shares the biggest number of the same elements (concepts) with P_{f_u} and is the largest. We assumed inclusion (see formula 10), so the last set of E_s, which is P_{s_v} will be always chosen. It is either P_{i_k} or P_{j_l}, the one not chosen in the above point.
3) Collate E_f and E_s in a following way: set P_{f_u} corresponds to set P_{s_v}, set $P_{f_{u-1}}$ corresponds to set $P_{s_{v-1}}$ and so on. If sets from one order run out, assume $\varnothing$.
4) For each pair of sets P_{f_i} and P_{s_i} compute $s_D(P_{f_i}, P_{s_i})$. The formula for s_D is given in 6 with redefined nonoverlapping parts defined by formulas 8 (see section III-B).
5) Similarity of linear orders E_f and E_s is equal to aggregated similarities computed as in point 4, i.e. $\text{aggr}\{s_D(P_{f_i}, P_{s_i}), i = 1, 2, \ldots, \max\{f_u, s_v\}\}$, with some aggregation operator aggr. Note that for linear orders, as in discussed case, collated are simply P_{i_k} and P_{j_l}, $P_{i_{k-1}}$ and $P_{j_{l-1}}$ etc.

Properties of the developed algorithm depend on assumed information representation model, on the similarity relation applied in step 4 and on the aggregating operator calculated in step 5. Due to space constraints we do not compare here various possibilities, which may be chosen in steps 4 and 5. In our first attempt as aggregating function we took mean, as it is very intuitive and normalized measure of dependency between real numbers (and the sum of all $s_D(P_{f_i}, P_{s_i})$ gives us a real number). To maintain comparability, aggregating function should produce normalized values of similarity.

IV. Conclusions

The article discusses developed model of features and concepts spaces. Of interest is similarity between descriptions of real-world objects, which we call concepts. Such descriptions (features vectors evaluations) through valuation mapping generate subsets of the space of concepts. Valuation mapping from the namespace of features into subsets of the space of concepts can be performed in a point-wise fashion or in an filling up way. All concepts form the universe of discourse, on which we do not directly operate. Instead, we use features, which describe concepts.

Two similarity relations developed for this model are introduced. First one is a generalized similarity relation between features vectors. Second one is a discretized version of the generalized similarity relation. Presented measures take into account fuzziness of analyzed information.

In this paper an algorithm of evaluating similarity between structures of nested features vectors based on generalized similarity relation and valuation mapping is introduced.

***Abstract*—We report on experiments that demonstrate the relevance of our *AntiSocial Behavior* (ASB) corpus as a machine learning resource to detect antisocial behavior from text. We first describe the corpus and then, by using the corpus for training machine learning algorithms, we build a set of binary classifiers. Experimental evaluations revealed that classifiers built based on the ASB corpus produce reliable classification results with up to 98% accuracy. We believe that the dataset will be valuable to researchers and practitioners working in preventing, controlling and diagnosing antisocial behavior and related problems.**

I. Introduction

'WHAT is said' is important and can reveal a lot about a person's thoughts, emotions and behavior. It particularly is important, when what is said, expresses feelings or thoughts of harming another. As Biber [1] points out, a writer's thoughts, opinions and attitudes about a topic can be explicitly or implicitly expressed through the choice of word and grammatical constructions. Due to the proliferation of the Internet and Web 2.0, written information on how people feel and their plans and interests is more readily available to researchers studying natural language.

The feelings and actions of harming other human beings can be considered as manifestations of *antisocial behavior* (ASB). ASB is broadly defined as any unconsidered action taken against individuals or groups of individuals that may cause harm or distress to society [2]. Often individuals involved in ASB have disclosed in advance their emotions and plans through oral or written language [3]. Reputedly, the Internet has been used as the outlet for the expression of such emotional states and / or plans of violent acts through the use of blogs or video sites [4]. Moreover, online communication is often used as a way of shouting out their intentions before engaging in their acts of violence [5].

The wealth of antisocial and criminal activity taking place on the Web has resulted in a surge of research interest in the automatic detection of this negative and destructive content. Being able to automatically detect negative content is beneficial, for instance, to managers of websites that allow users to post content or as part of an early warning system to authorities on possible threats to public safety. The automatic detection of ASB could also give rise to self-awareness systems for the individuals that are expressing thoughts or emotions related to ASB.

Identifying the individuals who pose danger to a community involves collecting and analyzing information pertaining to their attitude, thoughts on violence, descriptions of criminal activity and threats among others, including information about homicidal or suicidal ideation [6]. However this information is often difficult to obtain. Reasons such as privacy, legality of the often sensitive information, affect its availability to researchers for analysis.

Hence, albeit the problems antisocial behavior causes, there still does not exist a publicly available corpus of ASB texts. However, research projects that focus on ASB and that have been motivated, for instance by the occurrence of school shootings, require a domain relevant corpus for learning linguistic features that may be used for recognizing future risks of antisocial and destructive behavior from texts.

In this paper, we present such a collection of documents, aimed to remedy the situation. To our knowledge, this is the first attempt to build a corpus with a wide variety of types of antisocial, criminal and extremist content; the previous works have concentrated on a single type of antisocial content such as cyberbullying [7] or forms of extremism [8].

Furthermore, we use our corpus to address the problem of detecting ASB for texts by applying *machine learning* (ML) and text mining techniques. We train ML algorithms with positive examples obtained from the ASB corpus, and with negative examples of antisocial behavior collected from the ISEAR [9], Movie reviews [10] and Wikipedia [11] corpora.

Our experimental results show that classification based on content features discriminates ASB texts from non-ASB texts with accuracy up to 98%. Thus we demon-

This work was supported by: 1) "Detecting and visualizing emotions and their changes in Text" project, No.14166, funded by the Academy of Finland; 2) JSPS KAKENHI Grant Number 25330410.

strate that the ASB corpus can serve as a valuable resource for an ongoing antisocial behavior research.

II. Related Work

While the detection of spam in e-mail messages and web content dates back to the early days of the Internet, detection of antisocial content is a new and emerging area of research interest. The methods applied in the detection of antisocial content draw from the ones developed for detecting spam. In discussing related work, as no previous general models for detecting antisocial behavior from text exist, we provide an overview of the work done in the context of detecting cyberbullying, terrorism and criminal behavior.

Perhaps the most notable related work has been carried out in a research project entitled "Intelligent information system supporting observation, searching and detection for security of citizens in urban environment" (INDECT) [12]. The project aimed at automatic detection of terroristic threats and recognition of serious criminal behavior or violence based on multi-media content. Within the context of INDECT, criminal behavior as "behavior related to terrorist acts, serious criminal activities or criminal activities in the Internet".

Our work differs from the one done in the INDECT project in the focus of the research. While INDECT aims at using the analysis of images, video, and text, our focus is on the analysis of text data.

In their cyberbullying study, Dinakar et al. [7] made use of YouTube comments that involved sensitive topics related to race and culture, sexuality and intelligence. Moreover, Yin et al. [13] in their research made use of online forums for detecting online harassment. Bogdanova et al. [14] in their cyberpedophilia research made use of online perverted journal texts on which to learn models to discriminated pedophiles from non-pedophiles.

Thus, although the corpora used in the studies reported above contain negative behaviors, no corpus has yet addressed the more broad antisocial behavior which as Hanrahan [15] explains is characterized by covert and overt hostility and intentional aggression toward others.

III. Corpora

Textual data is required for analyzing what is said, thought or felt in texts. Unfortunately, when it comes to analyzing antisocial behavior, a suitable text collection is difficult to find. Many of the document collections, for example, those from YouTube and MySpace are generic collections and need to be filtered according to the research area.

It was because of the difficulty and lack of a domain-relevant corpus that we sought to create our own. The corpus can further drive the study of linguistic patterns and emotional content present in ASB texts.

The following subsections describe each corpus used in the experimental study. As we are firstly concerned with the binary classification analysis (that is either a document is deemed as being antisocial behavior or it is not), we therefore collected both positive (Subsection A) and negative (Subsections B-D) examples of non-antisocial behavior texts. To obtain the negative examples of antisocial behavioral, we used popular sentiment corpus (movie reviews [10]), emotion annotated corpus (ISEAR [9]) and factual Wikipedia texts extracts [11]. Table 1 summarizes the documents collected.

A. Antisocial Behavior Corpus

As part of a bigger project that involves detecting antisocial behavior from text, we have created a corpus of aggressive, violent, and hostile texts[1]. Two researchers searched online content in order to collect the documents from various blog posts and news-websites which they could conclusively identify as being ASB. In total 148 documents were identified as ASB. The collection is all English texts, having topics such as: serial killer manifestos, antisocial texts, terrorism, violence-based texts, and suicide notes.

Importantly, the messages in these documents are reflective of the author's thoughts and emotions. The corpus was collected specifically for the purpose of detecting antisocial behavior, conflict, crime and violence behavior from text documents. The collection is based on the research on antisocial behavior that has shown that aggression, violence, hostility, and lack of empathy are among the traits that are most directly associated with ASB [16], [17]. Antisocial behavior also has strong links to negative emotions, such as anger, frustration, arrogance, shame, anxiety, depression, sadness and fear [18]. The link of emotions to antisocial behavior will guide our future research.

B. International Survey on Emotion Antecedents and Reactions (ISEAR)

The ISEAR corpus is a collection of student reports on situations in which the respondents felt any of the seven major emotions: joy, fear, anger, sadness, disgust, shame, and guilt. The responses include descriptions of how they appraised the situation and how they reacted [9].

C. Movie Reviews

This collection consists of 2000 movie reviews. They are labeled in respect to their polarity: negative and positive. The corpus was first used in [10], and now is often applied in sentiment analysis and opinion mining research as a standard development and test set.

D. Wikipedia Text Extracts

We searched and collected Wikipedia articles by using similar concepts such as those we found to be characteristic ASB: killing, terror, violence, aggression, and frustration. The aim of including these texts was to observe how

[1] The current work-in-progress version of the corpus is available upon request.

well our classification algorithms could distinguish between antisocial behavior texts and informative texts containing similar keywords.

TABLE I
CORPORA DESCRIPTION WITH SOURCE, NUMBER OF FILES AND AVERAGE FILES SIZE

Corpus	Source	Documents	Avg. File Size (characters)
ASB	blog posts	148	680
ISEAR	[9]	265	110
Movie reviews	[19]	178	390
Wikipedia extracts	[11]	212	680
Total		803	

IV. EXPERIMENTAL SETUP

In order to test the corpus, we approached the ASB detection problem as a classification task. We performed the step-by-step process outlined in Figure 1.

A. Preprocessing Data

We processed each collected online entry or blog post as a whole. That is we assigned the whole text or message as being antisocial behavior or not. From the corpora, we have two fields; a text field consisting of the message and a binary class label (1 = antisocial behavior, 0 = non-antisocial behavior).

The message field needs to be preprocessed because it contains unstructured text. We applied further preprocessing using WEKA utility (StringToWordVector) that performs tokenization, stemming, and stop/frequent word removal.

B. Machine Learning-Based Classification

For classifying the documents into the two classes, we experimented with three supervised ML classifiers: Naïve Bayes Multinomial, SMO for the implementation of Support Vector Machines, and J48 for Decision Trees. The three selected algorithms have shown to be effective in various text classification studies. We made use of the WEKA tool for the above classifiers.

As a first experiment with the corpus, we used a Vector Space Model approach so as to consider the words as independent entities. The model makes an implicit assumption that the order of words in document does not matter, also called the Bag-of-Words (BoW) assumption [20]. The approach is sufficient for the classification task, as the collection of words appearing in the document (in any order) is usually sufficient to differentiate between semantic concepts [20]. Each document in the corpora was represented as a feature vector composed of binary attributes for each word that occurs in the file.

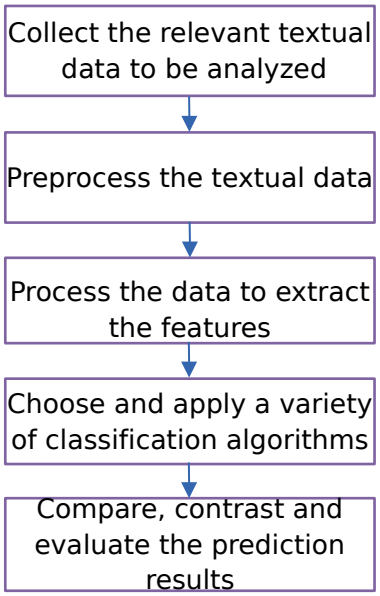

Fig 1. Process map. (Adapted from [20])

Let $\{f_1, \ldots, f_m\}$ be a predefined set of m features that can appear in a document. Let $n_i(d)$ be the number of times f_i occurs in a document d. Then each document d is represented by the document vector $d:=(n_1(d), n_2(d), \ldots, n_m(d))$ [10]. If a word appears in a given file, its corresponding attribute is set to 1, otherwise it is set to 0. Generally, the BoW approach works well for text classification. However, it does not take into consideration any semantic and contextual information.

Moreover, in order to reduce the number of words in the BOW representation we used the LovinsStemmer in order to replace each word by its stem.

We experimented with the three classifiers:

Multinomial Näive Bayes (NBM). With the Näive Bayes classifier, the input is assumed to be independent. The NB classifier, given the data estimates the probability of a class which is proportional to the probability of the class times the probability the data given the class [20]. In other words, the NB classifier assigns a given document d the class $c^* = \text{argmax}_c\ P(c|d)$ [10]. We used the Multinomial Näive Bayes classifier implemented in WEKA, which uses a multinomial distribution for each of the features.

Support Vector Machine (SVM). The classification method of SVM is based on the maximum margin hyperplane rather than probabilities as the Naïve Bayes [20]. In particular, the SVM classifier in a binary classification case aims to find a hyperplane, represented by a vector that maximally separates the document vectors in one class from those in the other [10].

J48 Decision Tree (J48). This classifier is an implementation of the C4.5 decision tree in WEKA. Decision trees are predictive machine models that are used for classification tasks by starting at the root of tree and moving through it until a leaf is encountered [21]. The decision

tree is built from the input training data using the property of information gain or entropy to build and divide nodes of the decision tree in a manner that best represents the training data and the feature vector [7].

The evaluation of the classifiers is discussed in the next section.

V. Results

For an exploratory purpose, we conducted four experiments using the ASB corpus for classifying emotional sentences.

We made use of three corpora as negative examples of ASB: ISEAR, Movie reviews, and Wikipedia extracts as described in Subsection B together with the positive examples of ASB to train supervised ML algorithms. In the first experiment, binary classifiers using the three algorithms were trained on ASB+ISEAR, in the second on ASB+Movie reviews, and in the third on ASB+Wikipedia extracts. Finally, all the corpora were combined.

The performance of the classifiers was then compared in terms of accuracy, precision, recall amd F-measure. For baseline values, we made use of the ZeroR classifier from WEKA which classifies data into the most frequent class in the training set. We made use of ten-fold cross validation whereby samples of data are randomly drawn for analysis and the classification algorithm then computes predicted values [20]. Table 2 displays the average of the ten-fold cross validation results on the corpora for each of the ML techniques.

Based on the results shown in Table 2, the ML algorithms NBM, SMO, and J48 clearly surpass the baseline performance. They further show that for our experiments the NBM and SMO algorithms have the highest accuracy rates. The use of the global corpus (All) also resulted in high accuracy results, as it contains heterogeneous data, however, the difference between the SMO accuracy results and the baseline is much lower. With the global corpus, SMO is statistically better than the next-best classifier (NBM) with a confidence level of about 96% based on the accuracy rate. Its F-measure (0.96), a function of both precision and recall, further indicates a high accuracy.

The experimental results illustrate that from our collected corpus, we can successfully classify antisocial behavior type of texts.

VI. Conclusion and Future Work

In this paper, we applied text classification techniques for the detection of antisocial behavior. In order to accomplish our task we applied various classification algorithms.

Our experimental results show that the task can be successfully accomplished. Experiments show that we achieve high accuracy using Naïve Bayes Multinomial and SMO.

In this paper we have used individual words as features without any additional syntactic or semantic knowledge. In future we are planning to incorporate emotion related information that may positively affect the accuracy of the task.

Ideally, text mining techniques are applied to corpora containing thousands or even millions of documents. In

Table II.
Results for the ASB corpora using the accuracy rate (%)

Corpora	Classifier	Accuracy	Precision	Recall	F-measure
ASB + ISEAR	NBM	**94.91**	**0.95**	**0.94**	**0.95**
	SMO	93.94	0.94	0.93	0.93
	J48	87.89	0.87	0.87	0.87
	Baseline	64.16	0.41	0.64	0.50
ASB + Movie Review	NBM	**98.61**	**0.98**	**0.98**	**0.98**
	SMO	95.83	0.95	0.95	0.95
	J48	90.27	0.90	0.90	0.90
	Baseline	58.88	0.34	0.58	0.43
ASB + Wikipedia	NBM	95.15	0.95	0.95	0,95
	SMO	**95.64**	**0.95**	**0.95**	**0.95**
	J48	88.13	0.88	0.88	0.88
	Baseline	64.16	0.41	0.64	0.50
All	NBM	94.82	0.81	0.93	0.87
	SMO	**96.46**	**0.96**	**0.96**	**0.96**
	J48	92.92	0.92	0.92	0.92
	Baseline	81.31	0.66	0.81	0.72

this case, fewer than 200 records were used that could be confidently identified as antisocial behavior. For further linguistic pattern analysis, a larger corpus will need to be attained. In order to attain a larger corpus, we will incorporate semi-automated methods that will ensure that each topic in the corpus is sufficiently represented.

With the larger corpus, researchers can identify features such as the presence of emotions, causal events or linguistic patterns that pertain to ASB which can be used to train ML algorithms. The main purpose of the corpus is for it to be used as a ML resource.

However, despite these limitations, the created corpus proved to be effective in training ML algorithms.

***Abstract*—We introduce the architecture and the data model of the software for integrated access to music searching web services. We illustrate our approach by developing a mobile accessed application which allows users of Android running touch screen devices accessing several music searchers including *Musipedia*, *Music Ngram Viewer*, and *FolkTuneFinder*. The application supports various styles of music input query. We pay special attention to query style transformation aimed to fit well the requirements of the supported searching services. By examples of using developed tools we show how they are helpful while discovering citations and similarity in music compositions.**

I. Introduction

A VARIETY of multimedia resources constitutes considerable part of the present-day Web information content. The searching services usually provide special features to deal with different types of media such as books, maps, images, audio and video recordings, software, etc. Together with general-purpose searching systems, there are solutions using specialized interfaces adopted to the subject domains. Truly, quality of a searching service depends both on the efficiency of algorithms it relies on, and on user interface facilities. As shown in our previous work, such interfaces include special syntax forms, user query visualization facilities, interactive assisting tools, components for non-textual query input, interactive and "clickable" concept clouds, and so on [1]. Depending on searching tasks, specialized user interfaces may support different kinds of input like mathematical equations or chemical changes, geographic maps, XML-based resource descriptions, software source code fragments, editable graphs, etc.

In text searching such aspects as morphological and synonymic variations, malapropisms, spelling errors, and time dependency condition particular difficulties of a searching process. In the music searching domain there are specific complications like tonality changes, omitted or incorrectly played notes or intervals, time and rhythmic errors. Thus, although there are eventual similarities between text and music information retrieval, they differ significantly [2].

In our previous work (see [3]) we analyzed and developed an improved EMD algorithm used to compare single voice and polyphonic music fragments represented in symbolic form.

Human ability to recognize music is strongly interrelated to listener's experience which may be considered itself to be a product of music intelligent perception [4], [5]. Recently (see [6]) we also analyzed internal models of music representation (with most attention to a function-based representation) being the foundation of various algorithms for melody extraction, main voice recognition, authorship attribution, etc. Music processing algorithms use the previous user experience implicitly. As examples, we could cite the *Skyline* melody extraction algorithm [7] based on the empirical principle that the melody is often in the upper voice, or *Melody Lines* algorithms based on the idea of grouping notes with closer pitches [8].

The remaining text of the article is organized as follows. In section II we review music searching systems and approaches of the day. We also introduce our experience in the domain of human centric computing and refer to some recent related works. In section III we describe music query input styles and analyze possible transformations of music input forms so as to fit the requirements of searching services. Section IV contains the description of the developed Android application architecture. We show how it works and make an attempt to analyze the searching output from the point of view of a musicologist.

II. Background and Related Works

Apart from searching media by metadata descriptions (like author, title, genre, or production year information), main scenarios of music searching are the following:

1) Searching music information by existing audio fragment considered as an input.
2) Searching music by the written note score.
3) Searching compositions by human remembrance represented in a form of singed, hummed, tapped or anyhow else defined melody or rhythm fragment.

Searching by given audio fragments is supported by many specialized search engines such as *Audiotag*, *Tunatic* or *Shazam*[9]. As a rule, it is implemented on the basis of so called audio fingerprinting technique. The idea of this approach is to convert an audio fragment of fixed length to a low-dimensional vector by extracting certain spectral features from the input signal. Then this vector (being a kind of audio spectral fingerprint) is compared to fingerprints stored in some database [10], [11].

978-83-60810-53-8/$25.00

TABLE I
ACCESSING MUSIC SEARCHING WEB SERVICES

Name	*Access*				
	GUI	*Micro*	*Text*	*Soft*	*Web*
Audiotag	+	–	–	–	+
Tunatic	+	+	–	–	–
Shazam	+	+	Partially	–	+
Midomi	+	+	–	–	+
Musipedia	+	+	Partially	SOAP	+
Ritmoteka	+	–	–	–	+
Songtapper	+	–	–	–	+
Music Ngram Viewer	+	–	+	REST/JSON	+
FolkTuneFinder	+	–	+	REST/JSON	+

The second scenario *Searching by note score* implicates two possibilities. The first one is to look for a given music fragment in the note sheet databases (this is beyond the scope of this paper). The main difficulty demanding using special music oriented algorithms is that the note score may contain user errors. The second possibility is to convert the melody into one of forms discussed hereafter so as to use existing searching facilities.

Finally, in the case of *Searching by human remembrance*, a system deals with main voice, rhythm, melody contour or interval sequence which is usually not perfectly defined. Hence, it's impossible to search directly within the binary contents of audio resources: we have no faithful audio fragment.

Thus, there are numerous ways to provide music input for a searching system. The extensive description of input styles used by music search engines may be found in [12]. Presently there are many searching web services allowing customers using one of several possible styles to input a music query including such services like *Midomi*, *Musipedia*, *Ritmoteka*, *Songtapper*, *Music Ngram Viewer*, and *FolkTuneFinder*.

Table I represents possible ways to access different music web searching services and pays attention to the following facilities:

- **GUI** Graphical user interface
- **Micro** Using microphone
- **Text** Text mode
- **Soft** Access for software applications by SOAP or similar software interaction protocols
- **Web** Web interface

As you can see, nowadays many services are accessible via browsers since they support Web interface features. Another important issue is the possibility to access some services from inside the software applications by using open protocols. It gives the way to create tools which allow users not to be limited by only one service at a time. Due to such tools we are able to use integrally different features of different searchers, to access additional resources such as *youtube* clips, and to deal with additional search attributes like genres, styles, time periods, etc.

Particularly, *Musipedia* service uses SOAP protocol described in [13]. *FolkTuneFinder* and *Music Ngram Viewer*

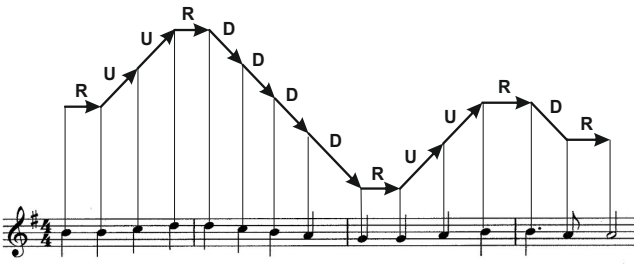

Fig. 1. Beethoven's "Ode to Joe" fragment represented in Parsons code

(both are also used in our work as target searching services) are based on the REST architectural style and their responses are wrapped in JSON format. Detailed description of the API usage rules and examples for *Music Ngram Viewer* service may be found in [14].

In respect to music inputs styles, existing tools support the following opportunities to define a music fragment:

- To sing or to hum the theme and to transfer the recording to the music search engine.
- To write notes by using one of known music notations directly (e.g. music score, Helmholtz or American pitch notation, MIDI notation, etc.).
- To tap the rhythm.
- To play the melody with the use of a virtual keyboard.
- To use MIDI-compatible instrument or it's software model.
- To enter Parsons code, or to set the melody contour by using "U, R, D" instructions [1] as shown in Figure 1.
- To define keywords or enter text query.

Table II lists some known music web searching services together with information about supported music query input styles, namely:

- **Audio** Audio fragment
- **Notes** Music score or pitch notation
- **Hum** Singing or humming
- **Rhythm** Tapping the rhythm
- **VKB** Virtual keyboard generating note sequence with rhythm
- **URD** Parsons code
- **MIDI** MIDI-piano
- **Text** Keywords or text query

III. MUSIC QUERY INPUT STYLES

As shown in the above section, we may define the music query by using different input styles. For a searching frame-

[1]Each pair of consecutive notes is coded as **U** ("sound goes Up") if the second note is higher than the first note, **R** ("Repeat") if the consecutive pitches are equal, and **D** ("Down") otherwise. Some systems use **S** ("the Same") instead of **R** to designate pitch repetition. Rhythm is completely ignored.

TABLE II
MUSIC SEARCHING WEB SERVICES INPUT STYLES

Name	*Web link*	*Input style*							
		Audio	*Notes*	*Hum*	*Rhythm*	*VKB*	*URD*	*MIDI*	*Text*
Audiotag	http://www.audiotag.info	+	–	–	–	–	–	–	–
Tunatic	http://www.wildbits.com/tunatic/	+	–	–	–	–	–	–	–
Shazam	http://www.shazam.com	+	–	–	–	–	–	–	+
Midomi	http://www.midomi.com	–	–	+	–	–	–	–	+

Music Ngram Viewer	http://www.peachnote.com	–	–	–	–	+	–	–	–
FolkTuneFinder	http://www.folktunefinder.com	–	–	–	+	+	+	+	+

work, the important issue is not only featuring different input interfaces but transforming one query form to the another depending on searching service availability and it's communication schema.

Different input styles are useful since the user music qualification differs. Melody definition by using a virtual or real keyboard is one of the most exact ways to represent the query, since it accumulates most melody components. However it is not common that users are skilled enough to use the piano keyboard as well as to write adequate note score.

Contrariwise, tapping a rhythm seems to be relatively simple way to define music searching query. The problem is that the number of possible rhythm patterns is evidently less than the number of compositions. It means that even if we succeed to tap the rhythm correctly, we may apparently have a list of thousands titles in return [6].

For the melody contour schema it is possible to choose pitch and time quantization so that the pitch-time representation is equivalent to piano-roll notation [15].

Symbolic pitch notations may be useful if we are limited by only text user controls.

The development of mobile devices with touch screens affects strongly the usage aspects of music searching interfaces. Such devices make possible simulating many kinds of music instruments, although the virtual piano-style keyboard remains the most popular interface. MIDI standards supports transferring of the simulated playing signals between applications regardless the kind of simulated musical instrument. In contrast to the work [16] we don't propose a novel music search engine based on improved music input technologies. Our research is focused on creating middleware application which helps to communicate with existing searchers.

A. Input Styles Transformations

We represent relationships between music query input styles in form of an oriented graph shown in Figure 2. Every transition arc shows the possible transformation from one input style to another, together with indication which note information has to be extracted.

Since the virtual keyboard based query implicitly includes such note attributes as it's duration and it's pitch, there is no much difficulty to transform the keyboard input into the

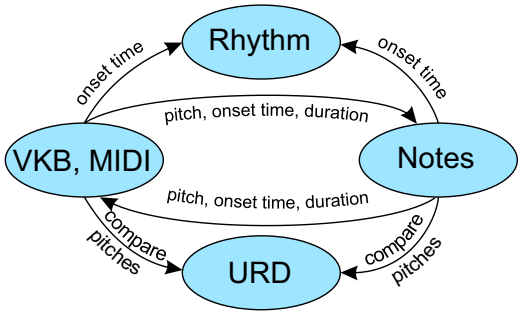

Fig. 2. Graph of music query transformations

rhythm or pitch notation. Next we are able to get the music contour from the sequence of sound pitches.

Clear that in such a way we restrict the user query, and therefore it seems we couldn't expect better searching results. However such transformations may have sense for at least two reasons:

- We attempt to emphasize the meaning of special melody attributes.
- We would like to try to connect a searching service which probably uses quite different music database (e.g. specialized on some music genre[2]) although it supports only restricted input methods (e.g. rhythm or pitch notation).

Regarding to the user interface issues, the ability to move from one input style to another renders possible to switch easily between different searching systems within the framework of one mobile or web application without re-entering the query.

B. Models We Use to Represent Queries

Despite the fact that in our earlier works we argued for the function based representation as one of the best way to describe music, this form seems to be too complicated to be employed directly at a user interface level. Usually user queries are relatively short (and it is true not only for the case of

[2]We turn our attention to the example of such a case in the following section of this paper.

music [17]), so we use sequence of *Note* objects to represent the searching query.

The attributes of a *Note* object are the following:

- *Note name* according to the American pitch notation
- Its *Octave number*
- Its *Onset time*
- Its *End time*

Values necessary for different input styles (such as a note duration or its MIDI value) may be computed on the base of above information. A series of onset time values may be used to generate a rhythm sequence.

IV. Introducing Android Application for Access to Music Searching Services

Nowadays, people are happy to use their mobile devices to access different searching services at any time from any place. They use different types of such devices which may have different input mechanisms like phone keys, *qwerty*-keyboards, touch screens, voice recognition devices, and so on. The variety of devices running on Android operating system is rapidly increasing during last years, so we decided to use Android platform for our music searching application.

For our implementation we selected some music searchers which may be accessed programmatically, particularly: *Musipedia*, *Music Ngram Viewer*, and *FolkTuneFinder*. For three searching systems we implemented four user query input styles:

- Note score editor supporting one voice definition
- Parsons code
- Rhythm tapping
- Piano style virtual keyboard with additional representation of American pitch notation[3]

A. Application Architecture

Despite general application construction ideas are common for various operating platforms, there is obvious specificity of the Android applications: the application architecture and its activities life cycle is governed by the operating system and the Android API. So the solution being discussed in this article isn't platform independent. However let us note that the Android application can serve as a model for implementing flexible human centric interface which is oriented to present-day style of using hardware and software facilities of various mobile devices.

That's why we skip the description of the specific Android implementation details like how to define resources, or how to support different screen resolutions and orientations. We don't discuss component layout control and internal data models either. Being limited by the paper scope, we only describe the principal Android application activities, their interaction and their connection to user interface components.

Figure 3 represents main components of our music searching helper application.

[3]In fact, it means that we support symbolic pitch notation input too.

The main activity *InputStyleSelection* provides the interface for input style choice. According to the selected input style the respective activity (*MelodyContour*, *MusicScore*, *VirtualPiano*, or *RhythmTapper*) opens and provides the corresponding input interface. The user input is stored as a list of *Note* objects used to construct the query as required. Classes *FolkTuneFinder*, *PeachNote* and *Musipedia* transfer the user input to one of supported search engines and filter their outputs.

B. Web Protocol Adapters

With respect to searching services' application interfaces mentioned in section II, the web information exchange protocol adapters have been implemented as Figure 4 illustrates.

The SOAP protocol is not recommended for mobile devices since it uses verbose XML format and may be considerably slower in comparison with other middleware technologies. Unfortunately it is the only way to communicate with the *Musipedia* system. In our case, the mentioned SOAP disadvantages shouldn't case concern since the exchange occurs relatively rarely, only when the respective button is pressed by a user, and there is small amount of information being transferred. We use *org.ksoap2* Java package [18] containing classes required for handling SOAP envelopes and literal XML content. To implement interaction with other searching services (based on the REST architecture and wrapping their responses in JSON format which is typically more compact in comparison with XML) we use *Google Gson* Java library [19]. It allows converting Java objects into their JSON representation as well as backward converting JSON strings to equivalent Java objects.

C. Usage Example

The application starts with a welcome screen for the preferred input style selection (Figure 5).

Then the respective activity starts as shown in Figure 6 representing the example of a virtual keyboard interface. As described earlier (see section III) the user actions are being stored in form of a note sequence with respect to the following related data:

- A *pitch* represented in the American pitch notation (note name and octave number
- The pitch *onset time*
- The pitch *end time*

Other properties may be computed depending on the requirements of a music searcher. Let us illustrate this by the input represented in form of a simplified timing chart (with respect to the note names rather than sound frequencies). The chart in Figure 7 represents some first notes of the well known Russian folk song "Birch Tree".

For the reason that *Musipedia* searcher requires a sequence of triplets containing an onset time, a MIDI pitch and its duration, the user input shown in Figure 7 is converted to the following query data:

0.0, 76, 0.54; 0.66, 76, 0.47; 1.21, 76, 1.43; 1.72, 76, 0.50; 2.41, 74, 0.98; 3.57, 72, 0.27; 3.89, 72, 0.52; 4.62, 71, 0.81; 5.57, 69, 0.75;

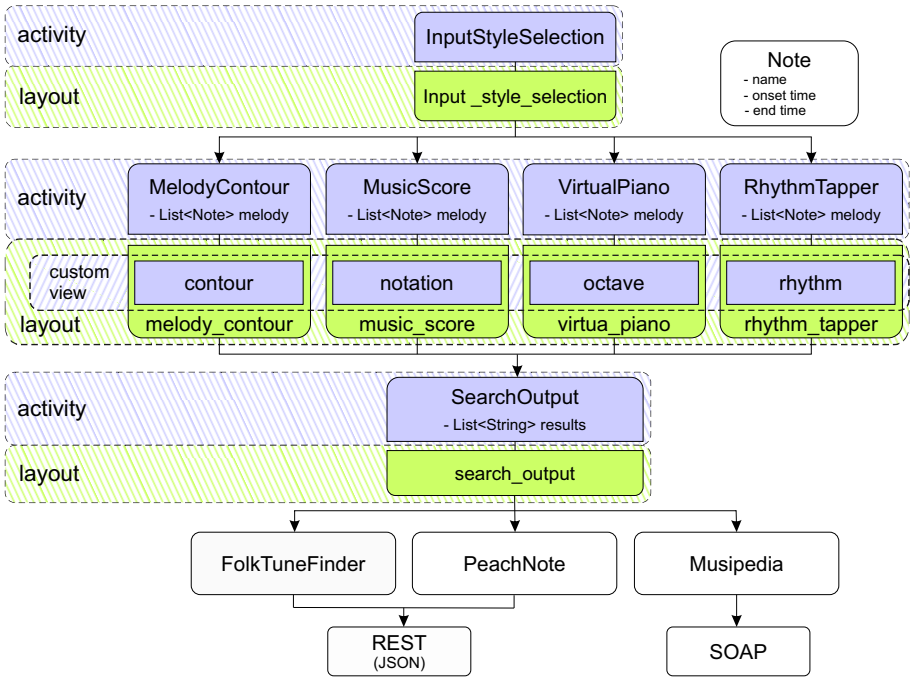

Fig. 3. Android music searching application architecture

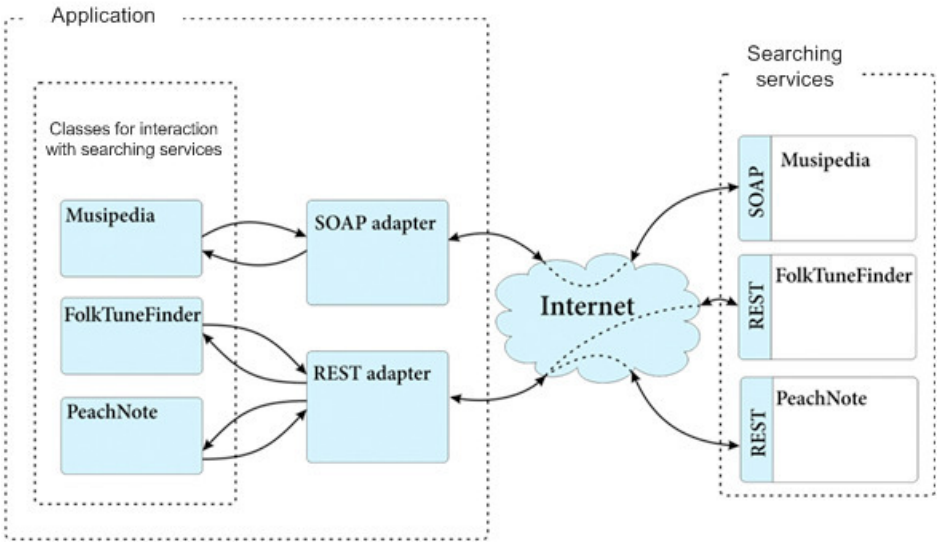

Fig. 4. Web protocol adapters

After this the respective information is included to the SOAP request which is subsequently sent to the *Musipedia* server. As a result, the searching system returns the list of retrieved compositions as shown in Figure 8 [4]. We see the confirmation of the known fact that this melody was used by Piotr Tchaikovsky in the 4th movement of his Symphony No.4 in F-moll (compare with the fragment of the symphony note score shown in Figure 9).

Using other searching engines may enhance searching results by taking into account other music genres. Let us take the *FolkTuneFinder* service which requires a sequence of MIDI pitches. Hence the user input is transformed into the sequence of MIDI pitches as follows:

76, 76, 76, 76, 74, 72, 72, 71, 69

[4]We selected Tchaikovsky's work, but as you can see, the similar theme may also be recognized in some other known compositions.

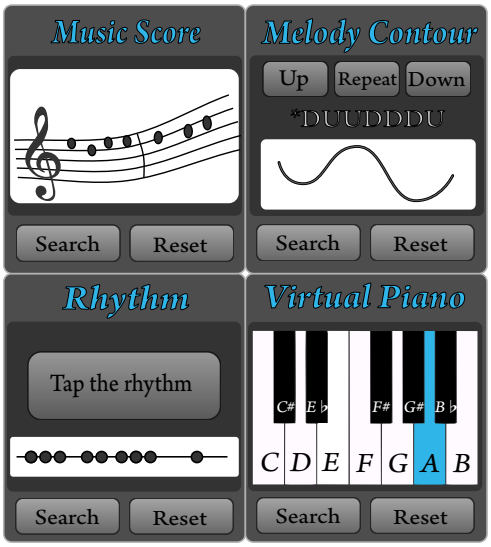

Fig. 5. Main activity: input style selection

Fig. 6. Virtual keyboard input

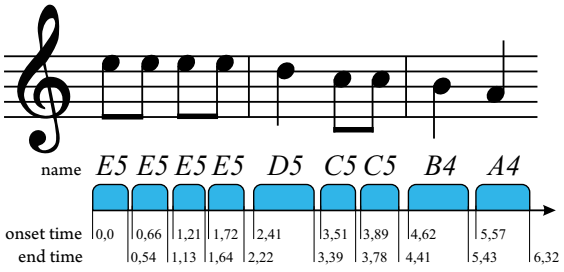

Fig. 7. Test melody: note score representation and timing chart

For the case of the melody contour defined with using Parsons code, the user input is the following *"RRRDDRDD"*.

Fig. 8. Result retrieved by *Musipedia* searcher: *Symphony No. 4*

Fig. 9. Birch Tree song cited by Tchaikovsky in his 4th symphony

We implemented the interface component which allows constructing the URD-query by pushing buttons *Up*, *Down* and *Repeat* with synchronous demonstration of the respective graphical contour which is being generated automatically[5]. As you see in Figure 10 the resulting output also contains the "Birch Tree" among other compositions. Note that since the melody contour is a less exact input method (comparing to direct melody definition), it is normal that we don't have the desired melody in the very first lines.

The example we selected for the illustration shows well one important aspect of music searching process, although in a slightly simplified manner. When we discover the composition corresponding to the given request, we may expect obtaining even more information than simply a desired piece of music. Fast every Russian knows the "Birch Tree" song since the early childhood years. But only those who listen to the classical music discover this theme in one motive of Tchaikovsky's symphony. In contrast to this, western music lovers may listen this motive first just in the Tchaikovsky's work, and after a while recognize it as a citation of the Russian folk song. Isn't it a kind of process similar to a music perception in terms of musicology?

[5]We consider to investigate possibility to support a melody contour drawing interface in future implementations.

Fig. 10. Results retrieved by *FolkTuneFinder* searcher

V. Conclusion and Future Work

In the domain of human-centric computing much attention is paid to the facilitating user interface features in relation with a kind of data being processed. As a special type of information retrieval systems, music retrieval systems demand special ways to interact with users. They include not only traditional text or media based queries but specific forms of user input facilities such as note score representations, virtual or MIDI-compatible instruments, as well as composing queries based on melody humming or rhythm tapping which may contain errors of human interpretation. Such approaches may help to overcome limitations of fingerprinting techniques which require exact or nearly exact audio fragments to proceed with searching in the databases of stored music compositions. In our work we investigated styles of user inputs used in various music searching services and applications. We applied transformation rules of query conversion from one input style to another to a software tool communicating with programmatically accessible music searching services from mobile devices running on the Android operating system.

In the current implementation we supported only those music queries which are representable in symbolic form (e.g. note score, pitch notation, note sequences, or contour symbolic description). User interface facilities may be improved if we consider other ways to interact with the user having a touch screen device. It may include, for example, melody contour or rhythm drawing facilities. Even for the searching services that we used currently, there are input styles which are still not incorporated into the existing software prototype. We investigate possibilities to support interfaces for melody singing or humming. Actually we faced the problem to pass the audio query to the searching engines via existing data transfer protocols that we are allowed to use. Ways to extend the interface may also include a support for connected MIDI-compatible devices and text-based searching facilities aimed to explore music metadata information. The another interesting improvement which could fit well especially mobile equipment interfaces is to support music tagging as described for example in [20]. Hence the key idea is to connect different kinds of searching services with rich user input facilities so as to follow better the usage style of modern mobile devices.

Acknowledgment

The authors would like to thank Joe, creator of the *FolkTuneFinder* service, for the opportunity to access his software from our application and for his kind help in organizing software interface with the *FolkTuneFinder*.

***Abstract*—The paper concerns beef production and consumption ontology (*OntoBeef*) and its applications. It is presented the three-stage *OntoBeef* evaluation process with a special focus on description of interaction of ontologists with domain experts. We also describe Linked Open Data (LOD) philosophy and show how links between *OntoBeef* and four other ontologies were established. We also present the components of *OntoBeef*-driven information system, a technology used to its creation and its functionalities. In particular we describe thesaurus component of the information system incorporating LOD connections.**

I. Introduction

THIS paper is a continuation of the one presented a year ago during WEO-DIA (FedCSIS) 2012 workshop (see [1]). In WEO-DIA 2012 paper we have described motivations to create a beef production and consumption ontology—which we call *OntoBeef* in short—and a project ProOptiBeef[1] within our research was carried out. In particular the paper contained information about the methodology of building the ontology, its content and possible applications. We have presented there ontological choices made while building the ontology and their justification. We have also shown how *OntoBeef* is used for browsing a database of articles (being indexed by the ontology concepts). In this paper we shall describe the way in which *OntoBeef* was further validated by the domain experts. We shall also present the initial stage of *OntoBeef*-driven application built by us—in particular we shall focus on its technological and functional sides.

The structure of the paper is the following. In Section II we present the three-stage *OntoBeef* evaluation process. In Section III Linked Open Data philosophy is introduced. In that section we show how links between *OntoBeef* concepts and the concepts of four other ontologies were established. Finally, in Section IV we present the components of a built by us ontology-driven information system, a technology used to its creation and its functionalities.

[1]http://www.prooptibeef.pl/

II. *OntoBeef* evaluation

OntoBeef ontology has been evaluated by seven experts: Prof. Krystyna Gutkowska (Institute of Rural and Agricultural Development PAS), Prof. Zenon Nogalski and MSc eng. Maciej Borzyszkowski (University of Warmia and Mazury), Prof. Agnieszka Wierzbicka, Dr eng. Marcin Gołębiewski, Dr eng. Eliza Kostyra and MSc eng. Rita Rakowska (Warsaw University of Life Sciences). The experts has been invited to three-stage evaluation process. In the first stage of the evaluation the experts have been choosing the concepts to be validated, in the second stage of it they have been evaluating labels assigned to each concept and finally they have been assessing the ontological relations between concepts. In what follows, we shall describe in details each of the three stages.

A. Concepts choosing

At the first stage the experts have been asked to choose among all 2344 concepts these which belong to their domains of interest. In figure 1 we can see the screen of the application used to support the process.

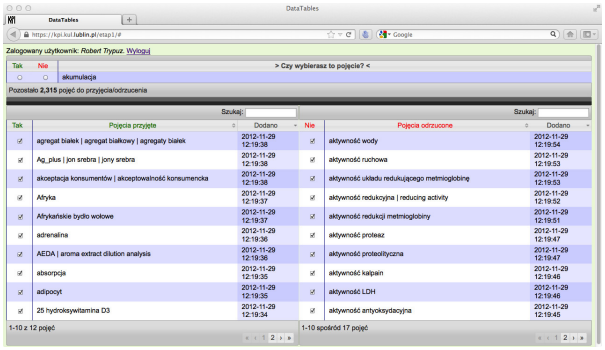

Fig. 1. First stage of *OntoBeef* evaluation

Concepts were displayed one by one. Each of them was represented by the sequence of synonymous names. An expert could choose between "Yes" (I do accept the concept and

978-83-60810-53-8/$25.00

want to take care of it later on) and “No” (I don’t accept the concept). Accepted concepts have been gathered in the table on the left and rejected concepts in the table on the right (see figure 1). An expert could always change his mind by unmarking the checkbox close to the chosen or rejected concept. It is worth noting that one and the same concept could be chosen by two or more experts (in fact there were many concepts validated by more than one expert; e.g. two experts shared even 675 concepts).

B. Labels evaluation

When all the concepts have been distributed to the experts, the second stage of the evaluations process began. During the stage the experts were asked to make an order in the labels assigned to each concept. In figure 2 we can see the screen of the application used to support the process.

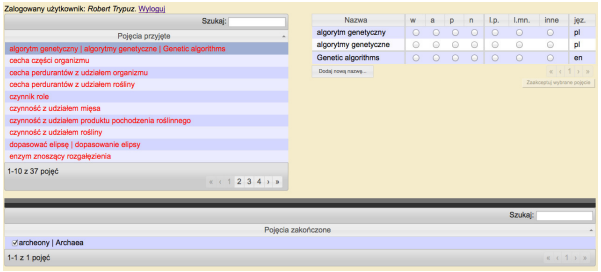

Fig. 2. Second stage of *OntoBeef* evaluation

Experts assessed each label by assigning to it one of the four label properties: “proper” (w), “adequate” (a), “common” (p) and “wrong/hidden” (n). They identify also the grammatical category of labels (“singular” or “plural”) and validated their language. Experts might also add a new synonymous label to the concept in any language. Aforementioned label properties: `proper_label`, `adequate_label`, `common_label` and `wrong_label` are instances of `owl:AnnotationProperty` and stay in relation `rdfs:subPropertyOf` to `rdfs:label`. Additionally proper label is a sub-property of adequate label. It is assumed the each class has to have exactly one proper label per language[2]. Since many concepts have been chosen by two or more experts during the first stage, we could expect that the second stage of the evaluation will lead to the emergence of conflicts. And in fact after the work of the experts has been done we found that 654 concepts meet a conflict of labels, e.g. that the same label for the concept had different characteristics (from the set of properties: proper, adequate, common and wrong) or more than one label has been recognized by experts as “proper”. Most of the conflicts were solved by using the following criteria:

1) in the case of labels in the singular and the plural forms determined as “proper”, the singular remained “proper” whereas the plural one(s) became “adequate”;
2) in case of the full name and its acronym were determined as “proper”, the full name was selected as “proper” and it acronym as “adequate”;
3) in the conflict between more than two experts, the choice proposed by majority was accepted;
4) in case the conflict could not be solved otherwise, the label which is more common in the Google search resources was chosen as “proper”;
5) indication of experts, which is not consistent with the original meaning of the term definition has been ignored.

[2]Thus `proper_label` is much like `skos:prefLabel`. Similarly `adequate_label` and `common_label` correspond to `skos:altLabel` and `wrong_label` to `skos:hiddenLabel`.

C. Evaluation of the ontological relations

The final stage of the evaluation process was analysis of the ontological relations in *OntoBeef*. In figure 3 one can see the screen of the application of this stage.

Fig. 3. The final stage of *OntoBeef* evaluation

An expert had an access to all the previously chosen concepts of the ontology and to the labels proposed by all experts during the second stage. For each concept the following information has been provided: its labels, ancestors, children, siblings and some ontological connections (e.g. “participation” or “parthood”) with other concepts. An expert could submit a comment or suggestion on concept’s labels, ancestors, etc, by clicking on “Zgłoś sugestię” button (see figure 3) – after clicking it a new window with a space for typing comment appears. All visited concepts have been colored yellow and unvisited yet—red. The result of this evaluation stage was 494 received submissions, which have been then analyzed and applied by ontologists.

D. Lesson learned

The evaluation process of *OntoBeef* by domain experts was only partially successful. During the second stage of the process (see section II-B) experts added many correct labels to the concepts, what helped us then to establish connections between *OntoBeef* concepts and LOD ontologies (see section III). But it is also true that many added labels were simply wrong, mostly because misunderstanding of the real concepts references (e.g. to the concept possessing a label “child” some expert added “calf”). Most of the remarks submitted during the last evaluation stage (344 out of 492) concerned labels.

They were constructive and improved *OntoBeef* quality. The rest of them (i.e., concerning ancestors, children, siblings and some ontological connections) were rather missing the point. One of the reasons of this state of affairs is that domain experts supporting ontologist in the project were not trained in ontological thinking and did not feel competent enough to suggest changes in the *OntoBeef* structure. Our earlier experience shows that much better results gives direct face-to-face cooperation of ontologists with domain experts. But this way of processing engages more people, is more time-consuming and as such is obviously more expensive.

III. *OntoBeef* AND LINKED OPEN DATA

After *OntoBeef* was finally validated, its concepts have been linked with other (lightweight) open ontologies. At least two meanings of "Linked Data" are known. In the first one the phrase means a method of knowledge creation and sharing[3]. In the second meaning "Linked Data" refers to "collection of interrelated datasets on the Web"[4]. Of course both definitions are compatible; Linked Data as a collection of interrelated datasets is brought about by many working agents acting according to Linked Data as a method. Linked Open Data is Linked Data which is released under an open license. (Semantic) Web visionary Tim Berners-Lee provided the following set of requirements which a data should possess to be called Linked Data[5]: 1) to be available on the web; 2)to be available as machine-readable structured data; 3) to be coded in some of open standards from W3C (e.g. RDF) to identify things; 4) to be linked to other people's data. It is also strongly suggested to register data at some open data catalogue (e.g. The Data Hub[6]), what in practice leads to a few more technical requirements (e.g. that HTTP URI of a piece of data should be dereferenceable – see [2]). *OntoBeef* has been linked with four thesauri: AGROVOC, General Multilingual Environmental Thesaurus (GEMET), National Agricultural Library's Agricultural Thesaurus (NAL), and STW Thesaurus for Economics (STW). Interlinking process has been done in two steps. In the first step for each thesaurus we have created database with two column table "concept number – label" . The same representation has been created for *OntoBeef*. Then by SQL query we have selected the concepts from thesauri and *OntoBeef* which have the same labels in common. In the second step ontology experts have validated the quality of the automatic connection of concepts and removed the wrong connections where needed. Finally *OntoBeef* has 797 links with AGROVOC, 211 links with GEMET, 546 links with NAL and 119 links with STW.

IV. APPLICATIONS

OntoBeef and its connections to other ontologies are a good starting point for building an ontology-driven information system (IS, in short). An ontology-driven IS is IS in which "ontology profitably "drives" all aspects and all components" of it [3, section 3].

In figure 4 we find four components of IS currently being developed by us within ProOptiBeef project. Semantic Oxpecker was described in the proceedings of FedCSIS 2012 (see [1, section V]). Components: "theses representation and search" and "interface to the database of results of experiments" are under development. Thesaurus component has been already created and will be described in section IV-B.

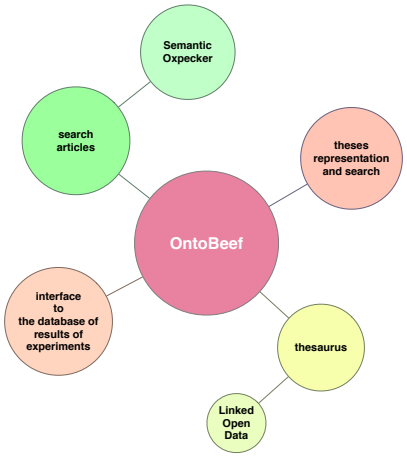

Fig. 4. Four components of information system based on *OntoBeef*

Before we started developing our IS, we have formulated a number of requirements a technology used to create the application should satisfy. The four most important of these conditions are: a) to run as the web application; b) to support OWL 2 (in which *OntoBeef* is formulated); c) to guarantee smooth application performance; d) to be flexible enough to accommodate new functionalities.

Based on our experience we chose three options initially: 1) JavaScript with jOWL framework; 2) Java Enterprise Edition ("Java EE" or "JEE", in short) with Jena framework; 3) Java EE with OWL-API framework [4]. All these technologies satisfy the first condition. Jena framework does not support OWL 2. jOWL framework does not satisfy the third condition, because it requires downloading ontology each time user's computer reloads application page. This takes time and distracts smooth application performance. Finally only OWL API framework meets all the requirements.

A. *OWL API*

In [4] we read that OWL-API is "a high level Application Programming Interface (API) that supports the creation and manipulation of OWL Ontologies". Its first version has been released in 2003. The last version 3.4.3 (which we are currently using) has been released in 2013. OWL-API is open source project managed by people from University of Manchester, written in Java programming language. It is worth noting that OWL-API was used for the development of components of a widely used ontology editor Protégé.

[3]http://aims.fao.org/standards/agrovoc/linked-open-data
[4]http://www.w3.org/standards/semanticweb/data
[5]http://www.w3.org/DesignIssues/LinkedData.html
[6]http://datahub.io

OWL-API allows to use a variety of notation: RDF/XML, OWL/XML, Turtle, Manchester and others. It supports the use of reasoners. It also "includes validators for the OWL 2 profiles – OWL 2 QL, OWL 2 EL and OWL 2 RL" [4].

B. Thesaurus component

Thesaurus component was developed within Java EE plus OWL-API framework. We shall now present how the web part of thesaurus component is running. Java EE consists of a large number of elements. In our application we use only a few selected, namely: servlets technology, JavaServer Pages (JSP) and JDBC technology. The first one handles the low-level web operations such as handling request and response, reading and writing HTTP headers. JSP allows to create the HTML pages in Java with great ease (in comparison with servlet technology). Access to the database is implemented through JDBC technology. It enables to abstract away from particular database technology (in our project MySQL RDBMS was adopted).

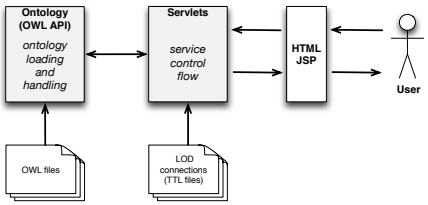

Fig. 5. The control flow diagram for thesaurus component of application

In figure 5 we can see the control flow diagram for the thesaurus component. When a user invokes the web application by writing URL address or by clicking any link on thesaurus component's page, a user's browser is sending HTTP request to a server where application is running. The server (in our case Apache Tomcat web container) receives request and runs appropriate servlet. If necessary the servlet retrieves information about the concept from OWL file by OWL-API. When the servlet obtains data about the concept it also checks Linked Open Data connections stored in TTL files. After obtaining all the necessary information, HTML page is sent to the end user. From the end user perspective the application looks as presented in figure 6. For each concept – in this case "beef"[7]– in ontology the component displays its labels: common and adequate (among them the proper ones indicated by the green color), the list of domain experts who validated the concept, the ancestors, the children, the sibling concepts and some other ontological relations as for instance parthood and participation. An end user can search for a concept. It is worth noting that a concept can be found also by typing a wrong label which are assigned to the concept (however they are invisible for the user). Application enables also registration and after log in allows reporting suggestions and comments considering concept labels, ancestors, children, siblings and other ontological properties. In the top application bar (see figure 6) there is LOD part, which displays LOD connections. In figure 6 we can see that beef class is linked with three thesauri. By linking *OntoBeef* with other resources we get for instance translations of labels to 22 languages, definitions and some related (RT), border (BT) and narrower (NT) terms to the searched one.

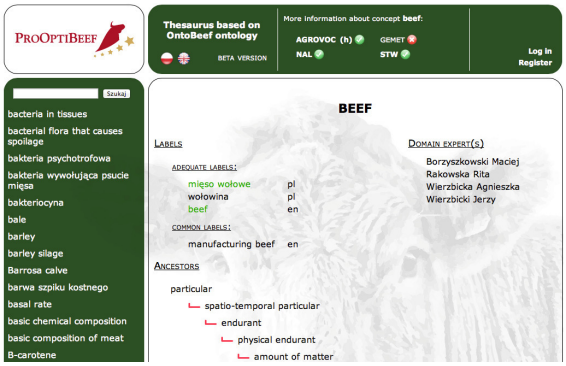

Fig. 6. *OntoBeef* thesaurus component

V. Conclusion and Perspectives

In this paper we described how *OntoBeef* ontology was validated by the domain experts. We presented the thesaurus component of *OntoBeef*-driven application. We also described the technological and functional aspects of our application. Finally the ongoing work was also described. We are very happy to notice that the researchers and practitioners working in the domain of beef production and consumption in Poland recognize the impact an ontology (as an artifact and as a methodology) had on the way they think about their domain and on the quality of their communication. There is still a lot of ontological work to be done in the field. For instance the beef sector has a lot of local carcass cuts systems which are in part mutually incompatible. We believe that their ontological implementation in *OntoBeef* will be the first step towards their comparison and integration

Acknowledgment

Research was realized within the Project no. WND-POIG.01.03.01-00-204/09 Optimizing of Beef Production in Poland According to "from Fork to Farm" Strategy co-financed by the European Regional Development Fund under the Innovative Economy Operational Programme 2007 – 2013.

***Abstract*—We often use various services for creating bookmarks, tags, highlights and other types of annotations while surfing the Web or just reading electronic documents. These annotations represent additional information on particular information source. We proposed a method for query construction to search for related documents to currently studied document. We use the document content where we concentrate on user created annotations as indicators of user's interest in particular parts of the document. Our method for query construction is based on spreading activation in a graph created from the document content. We evaluated proposed method within a service called Annota, which allows users to insert various types of annotations into web pages and PDF documents displayed in the web browser. We analyzed properties of various types of annotations inserted by users of Annota into documents. Based on these properties, we also performed a simulation to determine optimal parameters and compare proposed method against commonly used tf-idf based method.**

I. Introduction

WE OFTEN use various services for creating bookmarks, tags, highlights and other types of annotations while surfing the Web or when reading electronic documents. We use these annotations as means to store our thoughts or to organize personal collections of documents using methods such as tag-cloud. Many services supporting document bookmarking and manual annotation of documents provides us the possibility to create various types of annotation by simulating the process of annotation creation in printed documents. These services do not provide us with new types of annotations in addition to annotations we have been already creating in printed documents. They rather provide us new possibilities for annotation utilization. There is active research in the field of utilization of annotation [1], for example in support of navigation between documents. In the work presented in [2] the authors use the term social document to represent document enhanced by the user generated content such as annotations. They used the user generated content similarly to anchor texts while indexing documents. This representation of documents proved to provide improved performance in content-based mining applications on the Web such as search engines, recommendation systems etc.

User created annotations can be considered a form of user's context he creates while reading documents and traveling in digital space [3]. Great many applications use annotations as means for navigation between documents and for organizing content. For example, in [4] the authors describe an organization of learning materials and collaboration of students while learning using an educational system that provides students the possibility to attach various types of annotations to learning objects. The study of various search tasks supported by a social bookmarking service deployed in a large enterprise is presented in [5]. The authors concluded that bookmarking services and annotations attached to documents can enhance document organization and social navigation.

User generated tags are one of the most commonly used methods for organizing content. Tags are used for organizing bookmarks in services such as Diigo[1] or Delicious[2], but they are also used to organize notes[3], in various blogs and many other applications. Tags and other types of annotations are means document visitors can use to create custom navigation. They can categorize or describe resources and by this way create navigation that fits their needs without relying on navigation provided by document author.

User created annotations can be used not only to support navigation, but there are many other possible applications. Tags are used for folksonomy construction [6], annotations can play a great role for example in content enrichment and content quality improvement such as in an education system presented in [4]. In this system the authors use content error reports, user generated comments and questions, to improve course content and other types of annotations such as tags and highlights for the navigation and even the content summarization [7].

Currently, there are many services allowing users to annotate the documents. Annotations are used to support the navigation in users' collection of documents, they allow users to create their own organization of documents via tags and they help in search for documents. All of these applications motivate users to create annotations by a prospect of future improvement in inter or intra document navigation. Users benefit created annotations only after there is enough annotated documents, or when returning to once annotated document.

978-83-60810-53-8/$25.00

Problem with this approach is that there is lack of immediate reward for the annotation creation.

In this paper we propose a method for query construction from currently studied document and attached annotations. This method produces a query that can be used in related document retrieval where the query is taking into account user's interest provided by created annotations. The query is created in time the user is reading the documents and it is used to search for further documents related to the currently studied document. The reward for user creating annotations is thus provided in time of annotation creation.

II. Related Work

One of possible employment of annotations in information processing is the document search. There are two possible approaches for exploitation of annotations in search. One is to use annotations while indexing documents by expanding documents in a similar way anchor texts are used [2] or by ranking document quality using bookmarks and annotations as document quality indicators [8].

The second possible application of annotations in document search is in query expansion or query construction process. An example of annotations used for query expansion is presented in [9], where tags attached to search results are used to expand initial query similarly to pseudo-relevance feedback based query expansion. Multiple methods for query expansion in folksonomies are presented in [10]. Of particular interest are methods expanding queries by tags from folksonomies on the basis of semantic similarity between words of the query and these tags.

An example of annotations used as queries to retrieve related documents is presented in [11]. The authors asked users to read a set of documents and to create annotations into documents using a tablet. They used these annotations as queries in related document search. They used different weights for different types of annotations in query construction and they compared search precision of these queries with relevance feedback expanded queries. Queries derived from user's annotations produced significantly better results than relevance feedback queries. Whereas query expansion requires that users create an initial query, query composition using annotations does not require additional activity of readers instead it reuses annotations created with other purposes such as better understanding of the document.

In experiment presented in [11] authors let users to create annotations into documents for evaluation of their applicability in related document search. More often in search for related documents the content of source document is used to create queries. In [12] authors used the most important phrases from the source document as queries for document retrieval. Extracting most important phrases is similar to document summarization. However they used extracted phrases as queries in related documents retrieval.

Another work concerning search for related documents is described in [13]. The authors use related document search as a mean for recommendation of citations into unpublished manuscripts. They use text-based features of the document to retrieve similar documents and citation features to establish authority of documents.

Similar document retrieval has its application in document recommendation. In work presented in [14] they used list of documents similar to users visited documents to recommend related documents. To compute document similarity they used document representation based on word vector extracted from its content and similarity metric based on cosine similarity.

Searching for related documents can be useful also in the domain of plagiarism detection. In [15] query construction from the source document is used for retrieval of documents the suspicious document may be plagiarized from. In the query construction process the most frequent words from the document are used.

Document term frequency for query construction from document content is used also in popular content-based search engines ElasticSearch[4] and Apache Solr[5]. They provide special type of query interface called "more like this" query, which processes source text and returns list of similar documents. Internally, the search engine extracts the most important words using tf-idf metric from source text and it uses the most important words as a query for related documents search. By comparison to previous described method, tf-idf based method uses additionally to in-document term frequency also information about terms from the collection related documents are searched in.

In multiple works authors showed that annotations represent important source of information for document retrieval. Methods for query construction for document retrieval are however using only document content and information about document collection in query construction process. They are not using user created annotations as user's interest indicators when creating query for document retrieval. In our work we proposed and evaluated a method for query construction from the document content enhanced by user created annotations. Annotations are used as interest indicators to determine parts of the document user is mostly interested in. Using user created annotations our method creates a keyword query for related document search taking into account the user interests. Annotations are used in time of their creation and they provide immediate motivation in form of related document search.

III. Method for Query Construction

Currently the most common form of query used when searching for documents on the Web is the list of keywords. To retrieve words from the document to be used as query for related document search it is possible to use multiple different approaches. It is possible to extract most frequent terms, use tf-idf metric or various ATR algorithms [16] to extract keywords and so on. The tf-idf based method provides rather straightforward possibility to incorporate user created annotations: the source text of the document is extended by the content of created annotations possibly with various weights for different types of annotations.

[4] ElasticSearch, http://www.elasticsearch.org/
[5] Apache Solr, http://lucene.apache.org/solr/

However, the method using the tf-idf for query word extraction takes into account only the number of occurrences of words in the source document and in the document collection. We believe that not only the number of word occurrences but also the structure of the source text is important in a search query construction for related document retrieval. Especially, if we suppose that while reading the document users are most commonly interested in only a portion of the document, the portion where they attach annotations.

We use user created annotations to increase weights of annotated parts of the document in query construction process and to attach additional content to the document. We proposed a method based on spreading activation in text of studied document transformed to a graph. The method uses annotations as interest indicators to extract parts of documents the user is most interested in.

The proposed method is composed of two phases:

1. Text to graph transformation that conserves word occurrence frequency in node degree and text structure in graph edges structure.
2. Graph nodes activation introduced by annotations attached to the document and query word extraction using spreading activation algorithm in created graph.

The text to graph transformation is based on word neighborhood in the text. The graph created from text using words neighborhood conserves words importance in node degree but it also reflects the structure of the source text in the structure of edges [17]. Using various graph algorithms such as community detection, various node and edge weightings or spreading activation we can extract properties such as related words, most important terms, topics etc. We use this graph to extract words that can form queries to retrieve similar documents using spreading activation algorithm.

Text to graph transformation

To transform document text to a graph, it is firstly preprocessed in several steps: segmentation, tokenization, stop-words removal and stemming. After these steps the initial text is transformed into list of words. Every unique word from this list is transformed into single node of the graph. The edges of the graph are created between two nodes if corresponding words in the text are neighbors or they are in the predefined maximal distance. The text to graph transformation is described by the following pseudocode:

```
words=text.split.removeStopwords.stem
length=words.size
nodes=words.uniq
edges=[]
for(i=0;i<length;i++){
  for(j=i;i<min(i+dist,length-1);j++){
    edges.add(words[i],words[j])
  }    }
graph=Graph.new(nodes,edges)
```

As settings for maximal distance between words we used options described in [17], where they used two passages through the text with maximal distance set to two words and five words. By using these setting, the words with greater distance were connected and close words have more common edges at the same time.

All created edges have the same weight but by using two passages through the text, more edges are created between close words than between farther words. For the purpose of speeding up the spreading activation in the next step, we connected multiple edges between the same nodes and we set weight of the resulting edge as number of connected edges.

Query word extraction

In the text transformed to the graph we use spreading activation algorithm to find the most important nodes/words. This algorithm is commonly used for example to find most related nodes in the graph to the initially activated node. The activation introduced into the initial node is spreading through the edges and after the change in nodes activation is smaller than specified threshold, the most related nodes have the greatest amount of activation concentrated.

It is possible to use this algorithm for related nodes search but also for other application such as keyword extraction [18]. We use this algorithm to find the most important words in the graph created from the text. The initial activation is introduced to nodes, annotations are attached to. The initial activation is propagating through the graph and it is concentrating in most important words of the text. When user created annotations are used to insert initial activation, user's interest are reflected in the most important words extracted after spreading activation.

When using annotations to insert initial activation into the document graph we consider separately annotations that:

- highlighting parts of the document and
- inserting additional content into the document.

The proposed method takes into account both types. Those, which highlight parts of the document, contribute by activation to nodes representing words of highlighted part of the document. Annotations enriching content of the document are extending the document graph by adding new nodes and edges and they are inserting activation to this extended part of the graph. When inserting activation to extended parts of the document we assume that some portion of the words used in the annotation content are located in the document text as well. The activation from the extended part of the graph can then pass to the rest of the graph through common nodes. This assumption may be violated in the case where the document and the associated comments are in different languages. Therefore, in performed experiments we translated the content of every annotation using Google Translate service.

When initial activation is spreading through the created graph, the nodes where activation is concentrating are the most important words of the graph and are considered words fit into the query. In our case the activation is inserted into the graph through annotations attached to document by its reader. As we use annotations as user's interest indicators, the activation is spreading from document parts, user is most

interested in and words with highest activation level are reflecting user's interests.

The proposed method is able to extract words, which are important for annotated part of the document, but it is also able to extract globally important words, that are important for document as a whole. The portion of locally and globally important words can be controlled by number of iteration of the algorithm. With increasing number of iterations the activation is spreading from activated part of the document and extracted locally important words are changed to globally important words. When using this method it is thus important to determine when to stop the algorithm to find the best portion of globally and locally important words. It is also important to determine the right amount of activation inserted into the graph by various types of annotations.

The method for query word extraction uses annotations to insert initial activation into text transformed to graph. In case when no annotations are attached to the document, it is possible to extract globally important words from the document by activating whole document's text.

IV. Creation of the Web Page Annotation

The key element in document annotation is the selection of a method to link documents and created annotations. Multiple systems supporting annotation creation assume that documents will not change after annotations are inserted. This is very strong assumption we cannot make in a domain such as web pages. We have to use method for annotation interlinking with document content with regard to documents which may change over time. In [19] multiple criteria, which must meet the robust method for locating annotations into documents, are defined. Some of the criteria are:

- The method has to be robust to common changes in the referenced document.
- Has to be based on document content.
- Has to work with uncooperative servers.
- The information necessary to locate annotation have to be relatively small compared to the document content.

At the same time in this work they suggest several approaches that meet these criteria. One of them is to use annotation context in form of surrounding text to place the annotation into the document. The method using document content to place annotations is defined also in Open Annotation Model [20]. It is tolerant to changes in the document content and when using approximate matching of strings it as also to some extent tolerant to changes in annotation context as well.

We developed a service called Annota[6] [21], which allows users to attach annotations to arbitrary web pages or PDF documents displayed in a web browser. Annota service is realized as a browser extension through which user can create various types of annotations such as:

- tags,
- highlights,
- comments attached to text selections and
- notes attached to the document as a whole.

The service is focused on supporting visitors of digital libraries as we collect metadata on articles from selected digital libraries (ACM DL, SpringerLink, IEEE Xplore). We realized the possibility to insert annotations into arbitrary web pages and articles in digital libraries, by bookmarking and sharing documents and annotations in user groups.

The Annota service allows users to organize documents by tags or folders. It is possible to search in document's texts in user's library or library of bookmarked documents of all users. An example of web page annotated using Annota is displayed at Figure 1. The figure shows a sidebar, where it is possible to bookmark displayed page, insert tags, edit note and share bookmark with groups user is member of. Users are able to highlight text fragments of the web page and to attach comments to these text selections.

The basic scenario of the service usage follows user studying a document. The user has following possibilities of particular activities:

- Bookmarking documents.
- Highlighting parts of the text and creating other types of annotations.
- Sharing bookmarked document via group sharing.
- Collaborative annotation of documents.

The browser extension allows users to create annotations that link to document as a whole (tags, note) or to particular parts of the document (highlight). As the extension is inserting annotations into web pages and they change frequently and without notification, we had to use a method for annotation linking to specified parts of the document that is robust to changes in annotated document.

To attach annotations to document parts we use redundant representation of annotation location to support linking annotations into changing documents. To locate annotation in the text, we store highlighted text with order of its in-text occurrence together with surrounding text. The combination of selected text and text occurrence order is tolerant to changes in the document content except changes in selected text and most changes before annotation location. With usage of approximate matching this method is to some extent tolerant to changes in selected text as well.

We analyzed behavior of users of Annota while annotating documents using developed browser extension. Our experiments are based on usage data of 82 users who created 1 416 bookmarks and 399 in-text annotations during 4 months time period. They used Annota on day-to-day basis to bookmark interesting documents, to summarize them, to write down their thoughts about the document content and to highlight important parts of the document. We studied multiple parameters of created annotations and notes and we derived probabilistic distributions of these parameters. We studied properties such as the note length, number of highlights per user and per document, highlighted text length or probability of comment to be attached to highlighted text. All observed parameters were following logarithmic or geo-

[6] Annota, http://annota.fiit.stuba.sk/

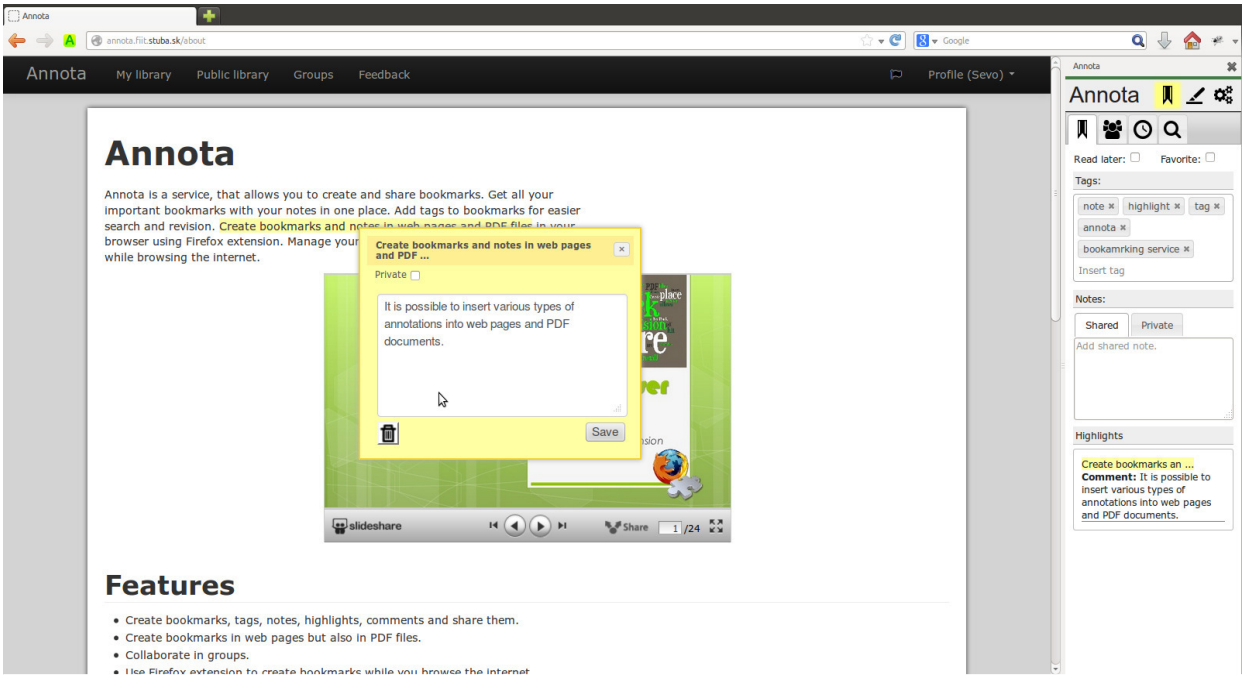

Figure 1 Web page annotated using bookmarking service Annota

metric distributions. Figure 2 represents an example of derived distribution for number of highlighted texts per document that follows logarithmic distribution.

V. Evaluation

Using various attributes of annotations and their probabilistic distributions described in previous section, we created a simulation, to find optimal weights for various types of annotations and number of iterations of proposed method for query construction from document text and attached annotations. We optimized query construction for document search precision.

The simulation was performed on the dataset we created by extracting documents from Wikipedia. We constructed

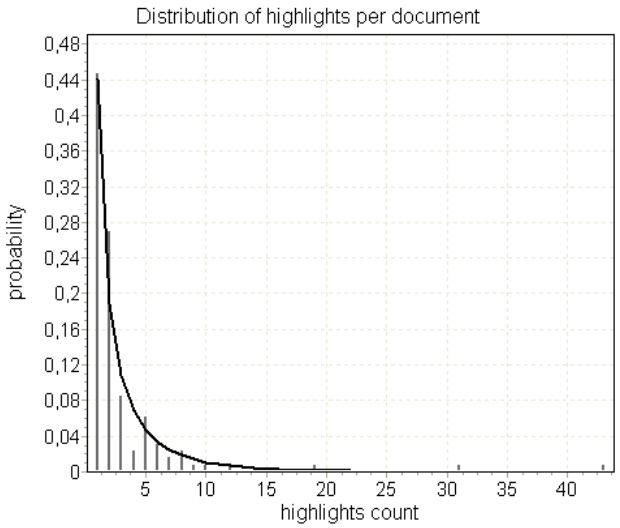

Figure 2 Logarithmic distribution of highlighted texts number per document

the source documents with aim to create documents containing several similar sections (from the point of view of used words) and with different topics. These generated documents simulate documents, where the user is interested in only a fraction of the content. To create such documents we used disambiguation pages in Wikipedia. The disambiguation page disambiguates multiple meanings of the same word and contains links to pages describing each of these meanings.

By using abstracts of pages describing different meanings of synonyms we simulate sections of the text describing multiple topics. We downloaded all disambiguation pages and we selected random subset of these pages for which we downloaded pages they are linking to. Along with these disambiguated documents we downloaded all documents, having common category with at least one of disambiguated documents.

We used search engine ElasticSearch to create an index of all downloaded documents and to search within this index. The parameters of created dataset are summarized in Table 1.

Table 1
Parameters of dataset used in simulation

Attribute	Number
All disambiguation pages	226 363
Selected disambiguation pages	86
Pages disambiguation pages are linking to	629
Categories	2 654
All downloaded pages	232 642

In the simulation we generated annotations in a way to correspond with probabilistic distributions extracted from the annotations created by users of the Annota service. From every disambiguation page and pages it was linking to, we

created one source document by combining abstracts of all pages in random order. For every source document we selected one of composing abstracts which simulated one topic user is most interested in. Into the selected abstract we generated various types of annotations, both annotations highlighting parts of the document and annotations inserting additional content. Annotations highlighting parts of the document were randomly distributed over the whole abstract. To simulate content of annotations extending content of the document (note, comments) we used random parts of the page annotated abstract was extracted from.

Generated annotations along with source document content were used to create query using proposed method based on text to graph transformation and spreading activation. Created query was used for related documents search in the index of all downloaded documents. When evaluating precision of search for related documents, we considered document to be relevant if it was from the same category as the page of annotated abstract.

We performed a simulation with several combinations of parameters and we implemented hill climbing algorithm to optimize parameter combination for the highest precision. Single iteration of performed simulation is described by following pseudocode:

```
for disambig in disambiguations do
  abstracts = disambig.pages.abstracts
  for abstract in abstracts do
    text = abstracts.shuffle.join(" ")
    graph = Graph.new(text)
    annot = Annotation.generate(abstract)
    graph.activate(annot, weights)
    graph.spread_activation
    query = graph.top_nodes
    results = ElasticSearch(query)
    cat = abstract.page.categories
    relevant = results.with_category(cat)
  end
end
```

We compared search precision for proposed method and for tf-idf based method ("more like this" query) provided by ElasticSearch when searching for 10 most relevant documents. For the purpose of comparison of proposed method with method based on tf-idf when using annotations in the query construction process, we extended rather straightforwardly the tf-idf based method to use annotations in query word extraction process. This method uses document word frequency to find most important words in the text. We extended the text of the document by text annotations were attached to and annotations content. We provided different weights for different annotations types by repeated extension of document by highlighted text and annotations content. We determined the optimal number of repetitions using parameter optimization with hill climbing algorithm.

Along with simulation using generated annotations for methods comparison, we performed two experiments to determine retrieval precision with no annotations and when whole abstract of the source document was highlighted. These experiments aimed to determine precision of compared methods when no annotations are available and when we have complete information about user's interest.

Results for simulations with generated annotations along with experiments with no annotations and with whole document fragment annotated are summarized in Table 2.

Table 2 Simulation results for spreading activation based method and tf-idf based method

Method	Precision
Tf-idf based with no annotations	21.32%
Proposed with no annotations	21.96%
Tf-idf based with generated annotations	33.64%
Proposed with generated annotations	37.07%
Tf-idf based with whole fragment annotated	43.20%
Proposed with whole fragment annotated	53.34%

Proposed method based on spreading activation obtained similar or better results to tf-idf based method in all performed experiments. The results of experiments with no annotations, where only the content of the document was used to create query, suggests that proposed method provides similar, even better results for query word extraction. These results were achieved despite the fact that proposed method is using only information from the document content and not the information about other documents in the collection by contrast to tf-idf based method. The proposed method can thus be used as an alternative to tf-idf based method when creating query from document content.

The comparison of both methods without using annotations and using generated annotations in query construction process proved that annotations are increasing precision of related documents retrieval.

The experiment with whole document fragments annotated suggests that with increasing number of annotations the precision of generated queries increases for both used methods for query word extraction.

We performed a Student's t-test on 5% level of significance for pairs of proposed method and tf-idf based method for every performed experiment to determine if we obtained statistically significant differences in mean precision for compared methods. As the computed p-value was less than 0.01% for every performed experiment, we can reject null hypothesis that the mean precisions of compared methods are equal. We obtained significant differences in mean precision for proposed method and tf-idf method for experiments using annotations in query construction process as well as for experiment with whole document fragments annotated.

To compare a real increase of precision of related document retrieval using annotations in query construction process and without using annotations, we performed a qualitative user study, where in sequence 8 volunteers were asked to annotate documents of their choice stored in the Annota service. After they annotated these documents, we generated two queries using proposed method, one using annotations and one without using annotations in query construction process. We retrieved two lists of documents using

these queries and we presented them to volunteers in random order. Volunteers were then asked to select documents describing topic related to the topic of source document from displayed lists and to select better from two presented lists.

The volunteers annotated 11 unique documents. In 9 cases they selected for more relevant the list created by method using annotations. In one case method using annotations created query in Slovak and document search returned no documents. This was caused by the fact, that in this document all annotations were written in Slovak and all documents we searched in were in English. In one case the method not using annotations obtained better results. By method taking into account annotations we obtained 34 relevant documents in total and with method not using annotations only 15.

Part of volunteers were writing annotations in Slovak, but to keep conditions the same as during document annotation out of the experiment, we allowed them to write annotations the same way they are used to. We asked one user to repeat the experiment on one document after he translated created annotations written in Slovak to English. When translated annotations were used in query construction all retrieved results were related to the source document.

In one case we asked the volunteer to repeat the experiment with increased number of annotations attached to the document. During this experiment, the volunteer doubled the number of attached annotations. In the second retrieved list of documents, the number of relevant documents retrieved increased and included one exact match with the topic user was most interested in while annotating source document. With increasing number of annotations attached to document the precision of related document retrieval is increasing.

When using annotations to create a query, the proposed method obtained better results than in the case when annotations were not used in the query construction process. When using annotations, created query retrieves more documents that describe the same topic as the source documents and more documents that describe related topics.

We used a questionnaire about user's habits when annotating documents to determine how users of Annota are creating annotations into studied documents. The majority of participants are using annotations while reading printed or electronic documents. When annotating electronic documents, they use various tools to create bookmarks, to-do lists, saving documents for later, to insert highlights, comments and other types of annotations into documents. The most frequently used types of annotations are tags and in-text highlights. The purpose for creating annotations such as notes, comments and highlights is to summarize studied documents, describe documents, highlight most important sections, to store their thoughts about studied documents and as a form of in-document navigation to support fast recollection of document when returning to previously studied document. The distribution of created in-text annotation was uniform over the whole text. In this study interviewed volunteers confirmed our assumption that using annotations users are indicating those parts of the document they are most interested in.

VI. Conclusion and future work

Annotations represent important source of information on interesting or important parts of documents. Its importance increases by possibilities of manipulating documents on the Web by the way we want to do commonly with paper documents. We studied user behavior while annotating documents on the Web and proposed a method for query construction from document content and attached annotations. In the process of query construction we considered document content and its structure by using text to graph transformation and query terms extraction using spreading activation in created graph. We used user created annotations as user's interest indicators to insert initial activation into graph created from document content.

We have developed a bookmarking service called Annota and a browser extension allowing users to insert various types of annotations into web pages and PDF documents displayed in web browser. The simulation based on probabilistic distributions of various parameters of annotations created by users of Annota proved, that annotations used when creating queries for related document retrieval can increase retrieval precision and with increasing number of attached annotations the precision rises.

We compared two methods for query word extraction. The method based on spreading activation in document text transformed to graph outperforms tf-idf based method when creating query for related documents search from source document and attached annotations. The proposed method achieved comparable results to tf-idf based method when no annotations were used in query construction. It is thus possible to use it even when no annotations are attached into the document with comparable precision as commonly used method when extracting words fit into query for related document retrieval from document content. The spreading activation based method outperformed compared method when document attached annotations were used in query construction process. The proposed method does not use information from other documents, only information from source document content and attached annotations. It is thus search engine independent and can be used to create queries for any search engine accepting queries in form of a list of keywords.

Performed user study showed that users insert annotations into document sections they are most interested in and they are use annotations to summarize documents, highlight most important parts of documents and to store their thoughts.

We evaluated proposed method for increasing related document retrieval precision of created query when using user created annotations in query construction process.

We plan to use annotations created not only by single user but also annotations created by other users when creating query for related document search. We see the potential in use of social relations such as group membership in weighting of annotations created by other users in query construction process.

In the described work, we were using annotations attached into document along with document content and we have not used user's annotations attached to other documents. By using annotations from other documents, we plan to model user's interests. Such annotation based user model can be used for further improvement of query construction process.

Moreover there are several possible enhancements related to document search process from the point of view of search engine. We plan to use annotations to enrich document content while creating index of annotated documents and we will compare performance of search in annotation enriched index against related document search in index created only from document content.

ACKNOWLEDGEMENT

***Abstract*—Nowadays, Service Oriented Architecture (SOA) might be treated as a state of the art approach to the design and implementation of enterprise software. Contemporary software developed according to SOA paradigm is a complex structure, often integrating various platforms, technologies, products and design patterns. Hence, it arises a problem of early evaluation of a software architecture to detect design flaws that might compromise expected system qualities. Such assessment requires extensive knowledge gathering information on various types of architectural decisions, their relations and influences on quality attributes. In this paper we describe SOAROAD (SOA Related Ontology of Architectural Decisions), which was developed to support the evaluation of architectures of information systems using SOA technologies. The main goal of the ontology is to provide constructs for documenting SOA. However, it is designed to support future reasoning about architecture quality and for building a common knowledge base. When building the ontology we focused on the requirements of Architecture Tradeoff Analysis Method (ATAM) which was chosen as a reference methodology of architecture evaluation.**

***Index Terms*—software architecture, ontology, SOA, ATAM, architecture assessment, architecture evaluation, enterprise architecture**

I. Introduction

NOWADAYS, Service Oriented Architecture (SOA) might be treated as a state of the art approach to the design and implementation of enterprise software, which is driven by business requirements. Within the last decade a number of concepts related to SOA have been developed, including ESB (Enterprise Service Bus), web services, design patterns, service orchestration and choreography and various security standards. Due to the fact that there are many technologies that cover the area of SOA, the development and evaluation of SOA compliant architectures is especially interesting.

SOAROAD has been designed as a methodology for the assessment of software architectures developed according to SOA principles. It is based on the Architecture Tradeoff Analysis Method (ATAM) [11], [5], which is a mature, scenario-based, early method for architecture assessment. ATAM defines a quality model, an organizational framework for evaluation process and expected results: sensitivity points, tradeoffs and risks. A limitation of the ATAM method is that it depends on experts knowledge, perception and previous experience. It may easily happen, that an inexperienced evaluator overlooks some implicit decisions and risks introduced by them.

In the SOAROAD approach the very basic set of ATAM terms used to describe architecture is enriched by including common terminology and relationships between concepts related to various aspects of service oriented architecture design and development. The gathered knowledge, formalized as an ontology, facilitates performing an assessment in more exhaustive manner, helping to ask questions, revealing implicit design decisions and obtaining more reliable results.

The contribution of the paper is a proposal of a SOAROAD ontology as a tool supporting scenario based assessment of systems following a service-orientation paradigm and service design, development and deployment.

II. Related works

Architecture evaluation has attracted many researchers and practitioners during the last 20 years. A survey paper on this topic [18] lists 37 methods of architecture evaluation, classifying them according to two dimensions: location in the software lifecycle (early vs. late) and element being analyzed (system architecture, isolated architectural style or a design pattern). The paper suggests that scenario-based methods, including SAAM [12] and ATAM [11], [5] can be considered as a mature, reliable and easy to implement in practical situations. There are several reports on successful applications of ATAM for assessment of a battlefield control system [13], wargame simulation [10], product line architecture [8], control of a transportation system [3], credit card transactions system[16] and a dynamic map system [21]. Recently, a few extensions of ATAM were proposed, including a combination with the Analytical Hierarchy Process [24] and APTIA [14].

The application of ontologies to provide a systematic and formal description of architectural decisions was first proposed by Kruchten in [15]. The ontology distinguished several types of decisions that can be applied to software architecture and its development process. Main categories included: Existence, Ban, Property and Executive decisions. The ontology defined also attributes, which were used to describe decisions, including states (Idea, Tentative, Decided, Rejected, etc.). In [7] an ontology supporting ATAM based evaluation was proposed. The ontology specified concepts covering the ATAM model of architecture, quality attributes, architectural styles and decisions, as well as influence relations between elements of

This work was supported from AGH University of Science and Technology under Grant No. 11.11.120.859

978-83-60810-53-8/$25.00

architectural style and quality attributes. The effort to structure the knowledge about architectural decisions, was accompanied by works aimed at a development of tools enabling the edition and graphical visualization of design decisions, often in a collaborative mode, e.g. [4], [6], [17].

III. A CONCEPT OF APPLICATION OF SOAROAD ONTOLOGY

The SOAROAD (SOA Related Ontology for Architectural Decisions) has four main goals, it should: (1) provide a comprehensive description of architectural views, i.e. components and their connections; (2) gather a domain knowledge providing a unified vocabulary related to SOA and enterprise architecture; (3) help to ask question about various properties of architectural design and decisions; (4) be capable of representing assignments of properties relevant to SOA compliant technologies to elements of system architecture.

It was assumed that the ontology would follow a foundational model (ontology skeleton) defining various properties corresponding to design decisions that can be attributed to components, connections, interfaces and compositions. If applicable, these design decisions can be supplemented by additional relations. The ontology would also specify design patterns.

Another assumption is related to a distribution of the knowledge between ontology TBox (set of classes, their attributes and relations) and ABox (individuals, values of their attributes and relationships). The types of elements appearing in architectural views are classified in the TBox. Concrete elements, e.g. those appearing in the diagrams of architectural views, are represented as individuals in an ABox. The ontology describes types of design decisions (properties) as classes, whereas their values as individuals that can be directly assigned to elements of architectural views or linked to form trees.

The concept of the ontology application is presented in the Fig. 1 The process of building an architecture description starts with eliciting *Architecture views ABox*, i.e. a set of linked

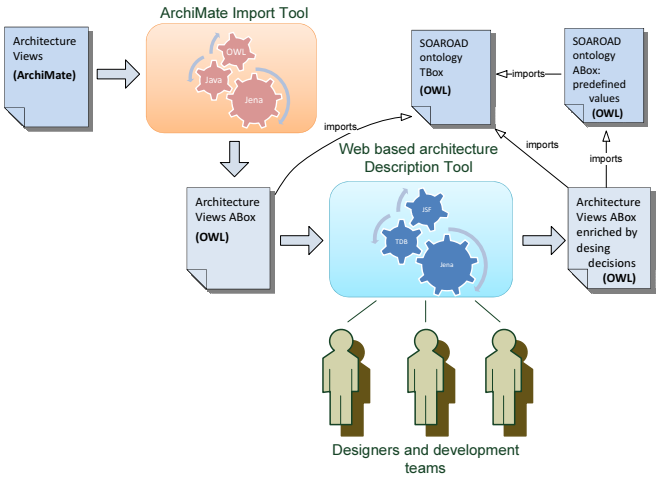

Fig. 1. A concept of application of SOAROAD ontology

components, interfaces and connections. This model can be prepared either manually or with the support of dedicated import tools converting ArchiMate [22] models of Archi editor [1] or UML [19], e.g. from VisualParadigm.

A web based tool supporting architecture description uses the classes and individuals defined in the *SOAROAD ontology Domain Description TBox* and *SOAROAD Architectural decisions ABox* to generate forms or questionnaires in which software architects or members of development teams can make assignments of property values to elements of architecture views.

The resulting *Detailed Architecture ABox* refers elements of *Architecture views ABox* and individuals defined in SOAROAD ontology (merging two input ontologies and asserting additional relations). This ontology serves as a detailed architecture documentation within a software development project. It can be examined either manually or with use of automated tools.

IV. ONTOLOGY DESCRIPTION

The SOAROAD ontology was built in three steps. Firstly, a foundational model serving as ontology skeleton was proposed. Then we manually gathered and analyzed information related to service oriented architectures, technologies, architectural approaches, design patterns, etc. originating from various sources: books, technical papers, reference manuals and Internet resources. Finally, the ontology was populated with this information by translating intermediate textual description into OWL constructs. At present the ontology consists of 110 classes, 9 object properties and 105 individuals.

The basic model of software architecture used in ATAM [2] defines it after [20] as a set of components and linking them connections. We extend this simplistic model by defining *Interfaces* and *Functions* of components as presented in Fig. 2. A connection links a component having the caller role with an interface (calee). Components, connections and interfaces can be attributed with: *ComponentProperties*, *ConnectionProperties* and *InterfaceProperties* respectively (Fig. 3). Examples of such properties are: platform, web service type, communication type, queueing and query granularity.

Composition is a coherent set of components and connectors. System architecture is itself a composition. For the purpose of analysis we may focus on a particular subset of components and connectors and describe their properties, e.g. a distribution of queries among several databases building up a composition or realization of a design pattern.

During the ATAM based evaluation the overall system architecture and properties of its parts are analyzed to establish scenario responses and achievements of corresponding quality attributes. It may be, however, observed that some architecture properties or their combinations have known influence on quality attributes, e.g. a use of asynchronous web services or applying MVC design pattern, which increases modifiability and a granularity of queries, has an impact on performance. This kind of knowledge can be expressed via *influences* relations.

Architectural decision is an assignment of a property value to a component, interface, connection or a composition. In this context the terms *property* and *architectural decision* can be used to some extent interchangeably. However, it may happen that certain decisions or components are dependent on previously assigned properties. An example of such a dependency is the composition type – a property assigned to a set (composition) of web service components. Selecting orchestration as the composition type requires that an orchestration component, e.g. BPEL capable module is used. The *required* relation or its subproperties in the ontological model express this dependency.

The assumed foundational model adopts a reification strategy while modeling various properties of an architectural design. Properties are defined as classes, whose individuals can be linked by additional relations indicating specific roles. An example of such a property is MVC design pattern, which requires the identification of components playing the roles of a Model (typically a database), a Controller (e.g. an EJB) and a View (e.g. a set of HTML pages produced by JSP scripts).

For each property, that can be treated as a class of design decision, a number of individuals (corresponding to decision values) is defined. They can be selected in assignments, e.g. *JavaEECompliantAS* (a subclass of *ComponentProperty*) has several predefined individuals: *JBoss*, *Glassfish*, *WebLogic*, *Web-Sphere*, *ColdFusion*, etc.

Example ontology assertions related to component properties are presented in Table I and Table II. A property (an ontology class) is followed by property values (individuals in the ontology) put in parentheses.

Apart from defining design decisions, the ontology specifies functions of components. Class Function contains classes of entities such as: *Routing*, *MessageMapping*, *ProtocolSwitch*, *MediationService*, *MessageValidation*, *AuditFunction*, *DatbaseIntegration*, etc.

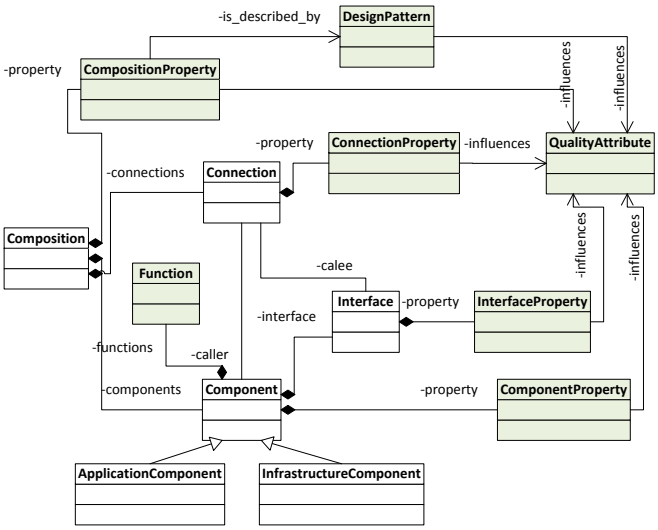

Fig. 2. Foundational model of software architecture and its properties

TABLE I
COMPONENT PROPERTIES

Property (values)	Description
PlatformTechnology (CORBA, EJB, JINI, RMI)	Set of technologies used on the platform.
ComponentLogic (flexible, fixed, rulebased)	Specifies an approach the component logic implementation.
Platform	Defines the component platform. Has several subclasses: ApplicationServer, Hardware, OperatingSystem and VirtualServer
ProgrammingLanguage (Cpp, Java, Ruby, PHP, Erlang, Python, C, C_sharp)	Define programming language used to implement a component.
StatePersistence (Stateless, Statefull)	Specifies whether a component saves internal data during and in between calls of operations on the client's behalf.

TABLE II
PROPERTIES DESCRIBING PLATFORM (SUBCLASSES OF *Platform*).

Property (values)	Description
ApplicationServer	Subclass of Platform. Defines an application server on which a component is deployed, can have such attributes, as: version (string), vendor (string)
JEECompliantAS (TomEE, Glassfish, JBoss, Interstage, JOnAS, Geronimo, SAPNeatWeaver, WebSphere, Resin, ColdFusion, WebLogic)	Subclass of ApplicationServer dedicated to JEE compliant components.
DotNetCompliantAS (AppFabric, IIS, TNAPS, Base4, Mono)	Subclass of ApplicationServer; its individuals define products for .NET enviroment
JavaAS (Jetty, Enhydra, iPlanet)	Application servers for Java environment
Hardware	Subclass of Platform. Used to specify a hardware configuration on which the component is deployed. Attributes: memory (double), processor (string), number_of_cores (int)
OperatingSystem (Windows, Unix, Linux, iOS, Android, Bada, Blackberry)	Subclass of Platform. Defines types of operating systems on which a component is executed. Attributes: version (string), vendor (string), product (string)
VirtualServer (no, yes)	Subclass of Platform. Specifies whether a component is deployed on a virtual server

The ontology provides also a taxonomy of quality attributes. A quality attribute is a nonfunctional characteristic of a component or a system. It represents the degree to which software possesses a desired combination of properties, which are defined by means of externally observable features. Some of the attributes are related to the overall system design, while others are specific to run-time or design time.

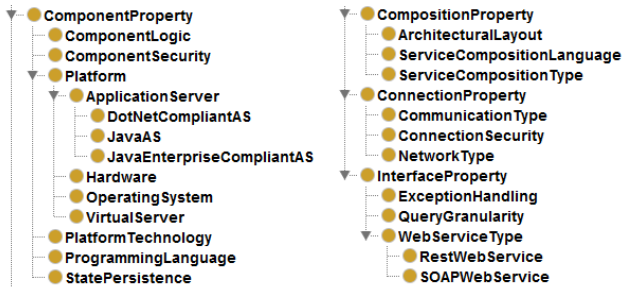

Fig. 3. Classes of properties

SOAROAD ontology defines 30 quality attributes including both terms defined in software quality model by the ISO/IEC 9126-1 norm [9] and those arising directly from requirements to architectures formulated in the SOA manifesto [1]. Examples of classes belonging to the first group are: *Functionality*, *Reliability*, *Usability*, *Efficiency*, *Maintainability* and *Portability*. The example of classes originating from SOA manifesto are *ServiceAutonomy*, *PlatformIndependency*, *LooseCoupling*, *Modularity*, *OpenStandardAdoptation*, *BusinessAgility*, etc.

When designing an applications to meet quality requirements, it is necessary to consider a potential impact of design properties on various quality attributes. SOAROAD ontology defines *influences* object property to this kind of relation.

A design pattern can be seen as a structure build of components of particular types, defining their roles and relations among them together with a set of restrictions on their usage. Design patterns do not change the functionalities of a system but only their organization or structure. One of the most important benefits of using design patterns is that they constitute standardized software building blocks with a well defined influence on quality attributes. In SOAROAD ontology the class *DesignPattern* has 56 subclasses representing patterns dedicated to SOA architecture. The examples of subclasses are: *db.EnterpriseServiceBus*, *db.EventDrivenMessaging*, *db.Orchestration*. The relation *is_described_by* links a particular *CompositionProperty* to one of the defined design patterns.

V. Conclusion

This paper describes the SOAROAD ontology and the concept of a tool supporting documentation of architectures of SOA-based systems. The proposed approach addresses the problem that can be encountered during architecture assessment: to be reliable, a reasoning about architecture qualities, must have solid foundations in a knowledge related to a particular domain: architectural styles, design patterns, used technologies and products. The idea behind SOAROAD ontology is to gather experts knowledge to enable even inexperienced users performing ATAM-based architecture evaluation. An advantage of the presented approach is that its result is a joint representation of architecture views and properties attributed to design elements formalized in OWL language.

From a software engineering perspective, such centralized information resource maintained during the software lifecycle may represent a valuable artifact, which can provide reference to design decisions throughout integration, testing and deployment phases.

On the other hand, a machine interpretable representation, constituting a graph of interconnected objects (individuals), can be processed automatically to check consistency, detect potential flaws and calculate metrics. An extensive list of metrics related to architectural design was defined in [23]. We plan to adapt them to match the structural relations in the SOAROAD ontology, as well to develop new ones.

Workshop on Computational Optimization

Many real world problems arising in engineering, economics, medicine and other domains can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints which ask for adequate computational methods.

The aim of this workshop is to stimulate the communication between researchers working on different fields of optimization and practitioners who need reliable and efficient computational optimization methods.

We invite original contributions related to both theoretical and practical aspects of optimization methods.

Topics

The list of topics includes, but is not limited to:

- unconstrained and constrained optimization
- combinatorial optimization
- global optimization
- multiobjective optimization
- optimization in dynamic and/or noisy environments
- large scale optimization
- parallel and distributed approaches in optimization
- random search algorithms, simulated annealing, tabu search and other derivative free optimization methods
- nature inspired optimization methods (evolutionary algorithms, ant colony optimization, particle swarm optimization, immune artificial systems etc)
- hybrid optimization algorithms involving natural computing techniques and other global and local optimization methods
- optimization methods for learning processes and data mining
- computational optimization methods in statistics, econometrics, finance, physics, medicine, biology, engineering etc

***Abstract*—This paper presents a linear time quasi self-stabilizing algorithm for detecting the set of fundamental cycles on an undirected connected graph modeling asynchronous distributed system. Previous known algorithm has $\mathcal{O}(n^2)$ time complexity, whereas we prove that our stabilizes after $\mathcal{O}(n)$ moves. Distributed adversarial scheduler is considered. Both algorithms assume that the depth-first search (DFS) spanning tree (DFST) of the graph is given. The output is given in a distributed manner as a state of variables in the nodes.**

***Index Terms*—Self-stabilization, fundamental cycles, fault tolerance.**

I. Introduction

A NOTION of self-stabilizing algorithms on distributed systems was introduced by Dijkstra [1] in 1974. They can model distributed systems with message passing or shared memory. A survey in the topic can be found in the paper by Schneider [2], and more details in the book by Dolev [3]. The notions from the graph theory not defined in this paper can be found in the book by Harary [4].

A distributed self-stabilizing system consists of a set of processes (i.e. computing nodes) and communication links between them. Every node in the system runs the same algorithm and can change state of local variables. These variables determine *local state* of a node. Nodes can observe the state of variables on themselves and their neighbor nodes. The state of all the nodes in the system determines the *global state*.

Every self-stabilizing algorithm should have a class of global states called *legitimate state* defined, when the system is stable and no action can be done by the algorithm itself. Every other global state is called *illegitimate* and for the algorithm to be correct there has to be some possibility to make a move if the state is illegitimate. The aim of the self-stabilizing algorithm is to bring the legitimate (desirable) state of the whole system after some alteration (from the outside of the system) of variables in the nodes or after the system has been started.

Our model of quasi self-stabilization is a modification of the classic self-stabilization. We allow the algorithm to assume that some variables have fixed value at the beginning of the computation. Similar model has been considered by Arora and Gouda [7] and Schneider [2]. It is motivated by the fact that hardware may have the so-called protected memory. This kind of memory is resistant to changes from the outside of the system.

In this paper we present an $\mathcal{O}(n)$ time modification (we call it ASFC II) of Chaudhuri's [5] algorithm (ASFC I) for detecting fundamental cycles in a graph. A set of fundamental cycles (SFC) is a collection of cycles that can be used to construct any other cycle in the graph. Given any cycle C from graph G, it can be constructed as $C = C_1 \oplus C_2 \oplus \ldots \oplus C_k$, where $C_i \in SFC(G)$ and $G_1 \oplus G_2$ is such a subgraph constructed from subgraphs G_1 and G_2 of the G graph, that each of its edges exists either in G_1 or in G_2, so it is symmetric difference.

ASFC I requires $\mathcal{O}(n^2)$ time to stabilize, where n is the number of processes in a system. It is able to start at arbitrary configuration, given that DFST is known. In fact $\mathcal{O}(n^2)$ time complexity was assumed when no information about spanning tree structure can be altered. The information about spanning tree is meant to be stored in a protected memory.

ASFC II requires additional 2-bit variable q in each process. The initial state of q should be set right after (or during) finding the DFST. It must be also stored in a protected memory. After finding DFST and setting q, the essential part of the algorithm can be started (see chapter 3 for the details).

The effects of running both algorithms are stored in a distributed manner as a state of local variables in the processing nodes; i.e. when a system running the algorithm stabilizes, each of its nodes knows how many fundamental cycles passes through it and what are their identifiers.

The rest of this article is organized as follows. Section II introduces the notation and model of computation used in next sections. Section III presents the original Chaudhuri algorithm

978-83-60810-53-8/$25.00

and our improved version. In section IV we prove convergence and time characteristic of our algorithm, and in the last section V we conclude the paper.

II. Notation and computational model

We consider a self-stabilizing system modeled by a finite, undirected graph $G = (V, E)$. Let the number of vertices be $n = |V|$ and the number of edges $e = |E|$. We think of every process as a node in the graph, whereas connection links between them are edges. There are some variables in each node. Names and types of the variables are set during design of an algorithm. Every node can also look up for the state of the variables at its neighbors.

Each node runs the same algorithm. The algorithm consists of a set of rules. A rule has the form as below.

An example rule
label: **if** *guard* **then** assignment instructions

A *guard* is a logic predicate which can refer to variables in the node itself and its neighbors. We say that a rule is *active* if its guard is evaluated to be true. A node is *active* if it contains any active rule. If there is no active node in the graph, we say that the system is *stabilized*.

A self-stabilizing system contains also a *scheduler*. Its task is to choose one process from the set of active processes and to trigger an active rule in it. Such an action we call a *move*. In this article we assume the scheduler is distributed and adversarial, so the order of activating nodes is nondeterministic. As a consequence, while describing pessimistic complexity of the algorithm (number of moves), we must take the worst case scenario of triggering actions in particular nodes.

Now we present some notation used in the paper. Most of the following notation is the same as in [5]. As mentioned before, we consider connected, undirected graph $G = (V, E)$ with the vertex set V and the edge set E. We also assume that the DFST $T(r) = (V, E')$ with the root node r is given. Note that the set of nontree edges is $E - E'$. So we have the following notation:

- $n(i)$ the set of neighbor nodes of the node i,
- $p(i)$ the parent node of i in $T(r)$ (we assume that $p(r) = null$),
- $c(i)$ the set of children of the node i in $T(r)$ (leaf nodes have $c(i) = \emptyset$),
- $nt(i)$ the set of nontree edges incident to the node i ($nt(i) = \{\{i, k\} : \{i, k\} \notin E'\}$),
- $C(i, j)$ the fundamental cycle created by the nontree edge $(i, j) \in E - E'$ together with the path between i and j in the tree $T(r)$,
- $a(i)$ the set of ancestors of the node i (we assume that $i \in a(i)$),
- $d(i)$ the set of descendants of the node i (we assume that $i \in d(i)$),
- $s(i)$ the set of all nontree edges such that each of them connects a descendant and a proper ancestor of i (more precisely $s(i) = \{\{x, y\} : \{x, y\} \in E - E', x \in d(i), y \in a(i) - i\}$),
- $su(i)$ $\bigcup_{j \in c(i)} s(j)$,
- $fc(i)$ the set of nontree edges such that the fundamental cycle created by each of them passes through i (more precisely $fc(i) = \{\{x, y\} : \{x, y\} \in E - E', x \in a(i), y \in d(i)\}$),
- $A \triangle B$ symmetric difference of the sets A and B ($A \triangle B = (A \cup B) - (A \cap B)$).

Some examples are presented in Fig. 1.

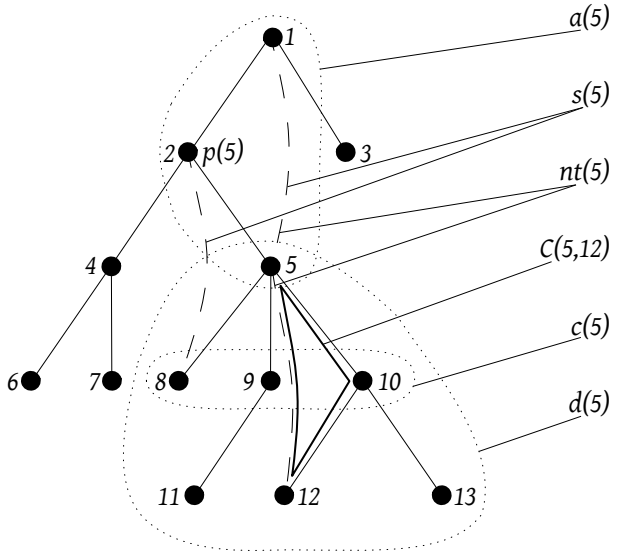

Fig. 1. Illustration of the notation for node $i = 5$: $n(5) = \{1, 2, 8, 9, 10, 12\}$, $su(5) = \{\{2, 8\}, \{5, 12\}\}$, $fc(5) = \{\{1, 5\}, \{2, 8\}, \{5, 12\}\}$. Dashed lines indicate nontree edges. Solid lines indicate tree edges.

III. The algorithm

As it was mentioned before, our algorithm (ASFC II) is a modification of Chaudhuri's original one (ASFC I). Our change alters only the starting precondition for the system and the order in which processing nodes are triggered (so the complexity changes). The difference is that ASFC I runs in $\mathcal{O}(n^2)$ time if there is DFST of the system given, and in $\mathcal{O}(n^3)$ time if there is not DFST detected yet. This situation requires running an algorithm for finding DFST. Algorithm developed by Colin and Dolev [6] can be used for that.

In contrast our ASFC II algorithm runs in $\mathcal{O}(n)$ time, but there have to be DFST given for the system and all the nodes must have the special variable $q(i)$ set to the **Stationary** state. If the DFST was not given or the information was corrupted, complexity is also $\mathcal{O}(n^3)$ because of need to run the algorithm finding DFST.

When the DFST is correct, but $q(i)$ in some nodes is wrong, complexity is $\mathcal{O}(n^2)$. That is because pessimistic scenario is quite the same as in ASFC I, and $q(i)$ can be ignored while estimating the number of moves.

All the semantics connected essentially with SFC, i.e. states of variables representing SFC in the distributed manner in ASFC II, are unaltered when compared to ASFC I. Thus we present here summary of the original algorithm; complete version can be found in [5].

Let us assume a DFST of the system is given, otherwise both algorithms must first calculate it. Two variables $p(i)$, $c(i)$ in each node state the structure of the tree and inferred from these two the value $nt(i)$.

Actually the main objective is to find $fc(i)$ for every node i in the system. The correct state of $fc(i)$ propagates along with $s(i)$ from leaves of the tree through internal nodes up to the root. The original Chaudhuri's algorithm is given as Alg. 1.

Algorithm 1: The ASFC I algorithm

leaf: **if** $c(i) = \emptyset \wedge (s(i) \neq nt(i) \vee fc(i) \neq nt(i))$ **then**
  $s(i) := nt(i)$
  $fc(i) := nt(i)$
internal: **if**
$c(i) \neq \emptyset \wedge (s(i) \neq nt(i) \triangle su(i) \vee fc(i) \neq su(i))$ **then**
  $s(i) := nt(i) \triangle su(i)$
  $fc(i) := su(i)$

Now we state the theorem, whose proof can be found in [5].

Theorem 1. *The ASFC I algorithm stabilizes the system after at most $\mathcal{O}(n^2)$ moves, under the condition that DFST is given.*

The meaning of symmetric difference in the internal rule is that as the computation passes along the treepath from leaves to the root the rule first incorporates the nontree edge to the set $s(i)$. The next time the same nontree edge is encountered (but the other end vertex of it), it is deleted from the $s(i)$ set.

A simple example of computation of the ASFC I algorithm, which exploits fully $\mathcal{O}(n^2)$ time is when DFS search gives simple path and each node is active but the scheduler every time chooses a node nearest to the root. First move would be done by the root node. Second move would be done by the unique child of the root, and then third by the root, because it was made active by triggering of its child. So in this way, the last phase would start from the unique leaf and finish in the root. There would be n phases, every i-th phase would involve i moves, so it gives $(n^2 + n)/2$ moves.

In the ASFC II algorithm the idea is not to make correction of the node's variables $fc(i)$ or $s(i)$ immediately after the fault has occurred. It would cause situation where ancestor nodes get "repaired" according to the incorrect information (not updated yet) from its children, as in the example above. Instead of this, every node is marked for updating and the update is done only if all the descendants are updated so they have correct values of $s(i)$ and $fc(i)$. A node cannot get back to **Stationary** state right after updating correct values of $s(i)$ or $fc(i)$, because it has to wait for all the nodes to be corrected (see rule 2.b). After all the nodes get updated, every node is being marked as almost stationary (root node first and then all its descendants recursively). Then all nodes can turn into stationary state — starting from leaves up to the root. An additional variable $q(i)$ for each node i is used

$$q(i) \in \{\textbf{Stationary}, \textbf{NeedUpdate}, \textbf{Updated}, \textbf{NearStationary}\}$$

(shortly: S, NU, U, NS), which represents the state of the node.

As it was mentioned above, we assume the DFST for the system is given and represented in a distributed way. According to Arora and Gouda [7] and Schneider [2], it is possible to make some precondition for a self-stabilizing system, therefore we assume a precondition such that the value of variable $q(i)$ for every node i is **Stationary**.

One can fulfill this requirement for example by putting the $q(i)$ variable in some kind of protected memory, e.g. such that this variable can be altered only by the algorithm — not by a change from outside of the system.

The ASFC II algorithm is given as Alg. 2.

Algorithm 2: The ASFC II algorithm

1.a): **if** $q(i) = \textbf{\textit{Stationary}} \wedge c(i) = \emptyset \wedge (s(i) \neq nt(i) \vee fc(i) \neq nt(i))$ **then**
  $q(i) :=$ **NeedUpdate**
1.b): **if** $q(i) = \textbf{\textit{Stationary}} \wedge c(i) \neq \emptyset \wedge (s(i) \neq nt(i) \triangle su(i) \vee fc(i) \neq su(i))$ **then**
  $q(i) :=$ **NeedUpdate**
1.c): **if** $q(i) = \textbf{\textit{Stationary}} \wedge q(p(i)) = \textbf{\textit{NeedUpdate}}$ **then**
  $q(i) :=$ **NeedUpdate**
1.d): **if** $q(i) = \textbf{\textit{Stationary}} \wedge c(i) \neq \emptyset \wedge \exists_{k \in c(i)}(q(k) \in \{\textbf{\textit{NeedUpdate}}, \textbf{\textit{Updated}}\})$ **then**
  $q(i) :=$ **NeedUpdate**
2.a): **if** $q(i) = \textbf{\textit{NeedUpdate}} \wedge c(i) = \emptyset$ **then**
  $q(i) :=$ **Updated**
  $s(i) := nt(i)$
  $fc(i) := nt(i)$
2.b): **if**
$q(i) = \textbf{\textit{NeedUpdate}} \wedge c(i) \neq \emptyset \wedge \forall_{k \in c(i)}(q(k) = \textbf{\textit{Updated}})$
then
  $q(i) :=$ **Updated**
  $s(i) := nt(i) \triangle su(i)$
  $fc(i) := su(i)$
3.a): **if**
$q(i) = \textbf{\textit{Updated}} \wedge p(i) = null \wedge \forall_{k \in c(i)}(q(k) = \textbf{\textit{Updated}})$
then
  $q(i) :=$ **NearStationary**
3.b): **if** $q(i) = \textbf{\textit{Updated}} \wedge q(p(i)) = \textbf{\textit{NearStationary}}$ **then**
  $q(i) :=$ **NearStationary**
4): **if**
$q(i) = \textbf{\textit{NearStationary}} \wedge \forall_{k \in c(i)}(q(k) = \textbf{\textit{Stationary}})$ **then**
  $q(i) :=$ **Stationary**

An illustration of the algorithm rules is presented in Fig. 2, where only tree edges are shown. The Fig. 3 presents an example execution of the algorithm.

IV. Convergence and complexity

We will show that the system stabilizes after exactly $4n$ moves if there were any faults regardless of their number.

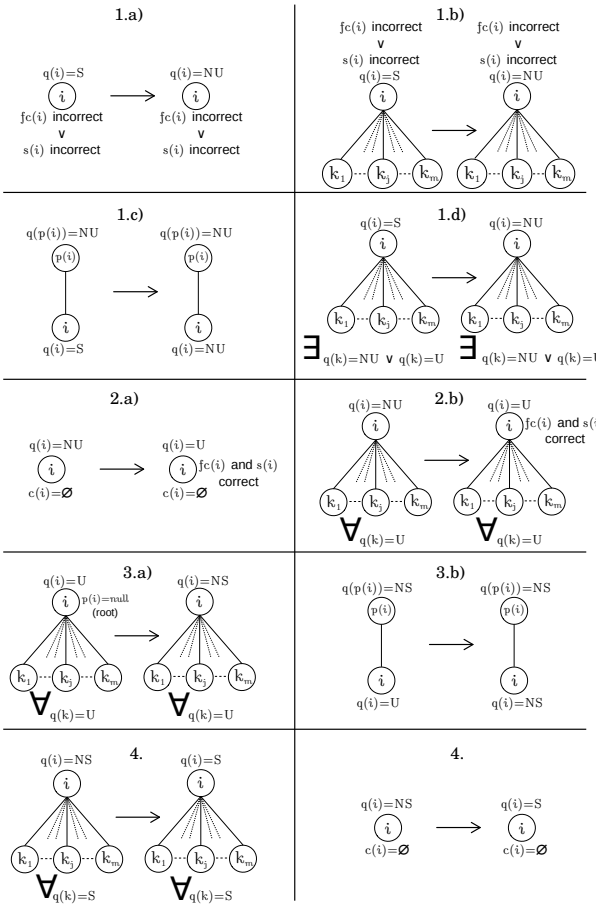

Fig. 2. An illustration of the ASFC II algorithm rules, where $k \in c(i)$.

All the time we assume the precondition $\forall_{i \in V(G)} q(i) =$ **Stationary** is fulfilled after any transient fault has occurred and a DFST of the graph is also given.

Lemma 1. *Each node i changes its state $q(i)$ cyclically from* ***Stationary*** *through* ***NeedUpdate***, ***Updated***, ***NearStationary***, *back to* ***Stationary***.

Proof: It follows from the rules of the algorithm. Only the rules 1.a)–1.d) change the state from $q(i) =$ **Stationary** and set it into state $q(i) =$ **NeedUpdate**. Next, only rules 2.a) and 2.b) change the state from $q(i) =$ **NeedUpdate** and set it into state $q(i) =$ **Updated**. Analogously, there are rules 3.a) and 3.b) changing $q(i) =$ **Updated** only into $q(i) =$ **NearStationary** and the rule 4. changing $q(i) =$ **NearStationary** into $q(i) =$ **Stationary**. ■

Lemma 2. *If a node i changes its state $q(i)$ from* ***NeedUpdate*** *to* ***Updated***, *then every its descendant has correct state of $s(i)$, $fc(i)$ and $q(i) =$* ***Updated***.

Proof: According to the rule 2.b), the non-leaf node i can change its state $q(i)$ from **NeedUpdate** to **Updated** only if every its child has the state $q(i) =$ **Updated**. For every child we can repeat our reasoning as for their parent. Going this way down to the leaves, we can see that every descendant has been in the state $q(i) =$ **Updated** at least for a while between the node i was **Stationary** and became **Updated**.

To end the proof it is now sufficient to show that a node cannot switch itself from $q(i) =$ **Updated** if its parent also has state $q(p(i)) =$ **Updated**. In other words, the node is inactive until its parent's state switches into $q(p(i)) =$ **NearStationary**. It follows from the fact that rule 3.b) is the unique rule that could change the state of the node i. But this rule cannot be active, since $q(p(i)) =$ **Updated**.

From the fact that values of $s(i)$ and $fc(i)$ are set during switching to state $q(i) =$ **Updated**, and this state propagates from leaves to the up, follows that $s(i)$ and $fc(i)$ are correct. ■

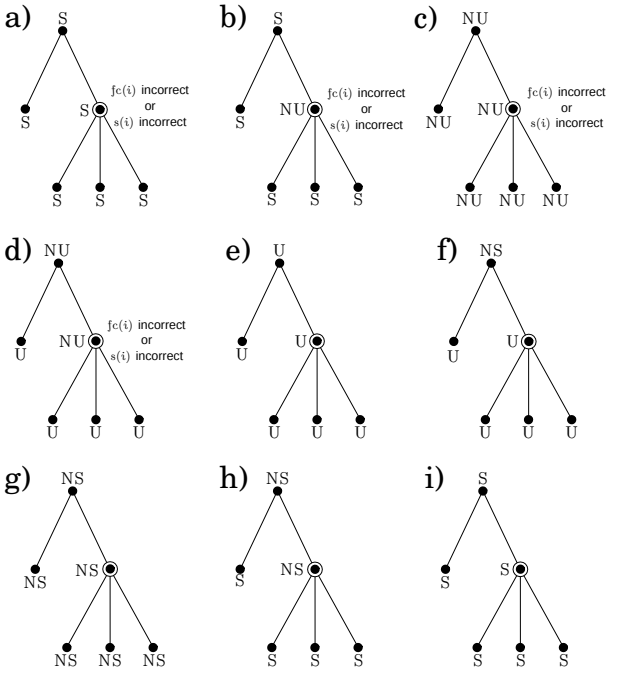

Fig. 3. An example of execution of the ASFC II algorithm:
a) there is one node i (circled in the figure) with incorrect value of $fc(i)$ or $s(i)$,
b) its state $q(i)$ changes to **NeedUpdate** (rule 1.b),
c) its ancestors (rule 1.d) and descendants (rule 1.c) also get the **NeedUpdate** state,
d) leaves get the **Updated** state (rule 2.a),
e) and it propagates through internal nodes up to the root (rule 2.b),
f) then root gets **NearStationary** state (rule 3.a),
g) which propagates down to the leaves (rule 3.b),
h) then leaves get **Stationary** (rule 4),
i) and it propagates up to the root, now system is stabilized (rule 4).

From Lemma 2 we have that if the root node changes its state to **Updated**, every other node i in the tree has updated its states $s(i)$ and $fc(i)$ to its proper values and has set the state $q(i)$ to **Updated**.

Lemma 3. *If a node is changing its state into $q(i) =$* ***NearStationary***, *then every its ascendant also has state* ***NearStationary***.

Proof: A node i must have parent's state

$q(p(i)) =$ **NearStationary**, to change its state into $q(i) =$ **NearStationary** (rule 3.b). Repeating this reasoning inductively, we have that every ascendant had state **NearStationary** at least in the past.

Now it is sufficient to show, that it could not have changed it. For change from **NearStationary** into **Stationary**, every child of a node has to be also in the **Stationary** state (rule 4). Again, repeating this reasoning down to the node i we have contrary to the fact that the node i is right about to change into state **NearStationary** from **Updated**.

■

In particular by Lemma 3 we have that a leaf gets into **NearStationary** state if every its ascendant also has **NearStationary** state. Rule 4 makes a stoppage — a node has to wait for all its children to change from **NearStationary** into **Stationary**, before it changes its state into **Stationary**. By induction we have that it holds not only for children, but for all descendants.

Once a node goes through whole sequence of changing of the own state from **Stationary**, through **NeedUpdate**, **Updated**, **NearStationary**, back to **Stationary**, it has correct values of $fc(i)$ and $s(i)$. From the Lemmas 1–3 we have that after a fault has occurred in at least one node, every node in the system has to go through all the sequence of changing. So we have the following theorem:

Theorem 2. *If there is DFST given in a system, every node has state* ***Stationary*** *and there is any number of nodes with incorrect value of fc or s, the ASFC II algorithm stabilizes the system after $4n$ moves.*

V. Conclusion

We have presented the modification of Chaudhuri's algorithm for finding a set of fundamental cycles in a graph. It demands particular precondition on the state of a system, but thanks to this, it offers linear time of the stabilization. No matter how many faults have occurred in the system, the ASFC II algorithm always performs $4n$ moves.

Motivation for the problem, apart from theoretical point of view, is applicable in computer networks. If we model a computer network as a graph, then the number of cycles passing through a node is a measure of its reliability. The more cycles go through a node, the more link failures (incident to the node) can occur whereas the graph is still connected.

***Abstract*—The Dial-a-Ride Problem (DARP) models an operation research problem related to the on demand transport. This paper introduces one of the fundamental features of this type of transport: the robustness. This paper solves the Dial-a-Ride Problem by integrating a measure of insertion capacity called Insertability. The technique used is a greedy insertion algorithm based on time constraint propagation (time windows, maximum ride time and maximum route time). In the present work, we integrate a new way to measure the impact of each insertion on the other not inserted demands. We propose its calculation, study its behavior, discuss the transition to dynamic context and present a way to make the system more robust.**

I. Introduction

TODAY, the Dial-a-Ride Problems are used in transportation services for elderly or disabled people. Also, the recent evolution in the transport field such as connected cars, autonomous transportation, and the emergence of the shared service might need to use this type of problem at much larger scales. But this type of transport is expensive and the management of the vehicles requires as much efficiency as possible, however the number of requests included in the vehicles planning can vary depending on the resolution used.

In [1] we solve the DARP by using constraint propagation in a greedy insertion heuristic. This technique obtains good results, especially in a reactive context, and is easily adaptable to a dynamic context. But, each demand is inserted one after another and the process doesn't take into account the impact of each insertion on the other not inserted demands, and so, in a dynamic context, the future demands. In this work, we present a measure of an insertion capacity named *Insertability*. We introduce its calculation by integrating the impact of an insertion on the time constraints (time windows, maximum route time and maximum ride time).

This measure may be used in different ways: selection of the demand to insert, selection of the insertion parameters, and exclusion of a demand. These three uses may be related to static as well as dynamic contexts by anticipating the future demands. The goal is to insert the current demand in order to build flexible routes for the future ones.

This paper is organized in the following manner: after a literature review, the next section will propose a model of the classic DARP. Then, we will review how to handle the temporal constraints with a heuristic solution based on insertion techniques using propagation constraints. We will continue by explaining the way to measure the *Insertability*, a calculation based on the evolution of the time windows after an insertion. Then, we will give some uses of this measure including making an appointment which minimize the time windows (cf. Figure 1). In the last part of the paper, the computational results will show the efficiency of our *Insertability*'s measure and we will report the evolution of the number of demands inserted in a resolution of some instances' sets.

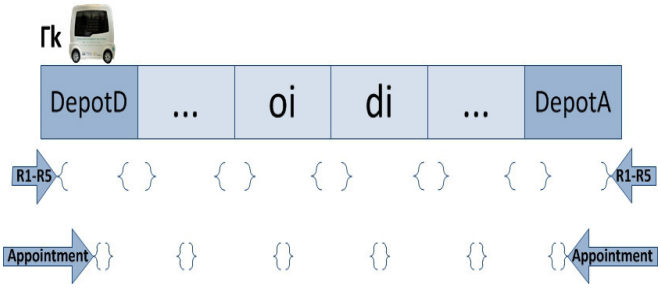

Fig. 1. Times windows' contraction

II. Literature review

The first works of the transportation optimization problem are related to the Traveling Salesman Problem ([2]). Since that time, other transportation problems have emerged as the vehicle routing and scheduling problems, and the Pick-up and Delivery Problem (PDP). The PDP is the ancestor of the problem of the Dial-a-ride problem which has been studied since the 1970's. DARP can be modeled in different ways. There are a number of integer linear programmings [3], but the problem complexity is too high to use it in a real context, most of which are NP-Hard because it also generalizes the Traveling Salesman Problem with Time Windows (TSPTW). Therefore, the problem must be handled through heuristic techniques. [4] is an important work on the subject and uses the Tabu search to solve it. Other techniques work well like dynamic programming (e.g. [5] and [6]) or variable neighborhood

978-83-60810-53-8/$25.00

searches (VNS) (e.g. [7] and [8]). Moreover, a basic feature of DARP is that it usually derives from a dynamic context. So, algorithms for static DARP should be designed in order to take into account the fact that they will have to be adapted to dynamic and reactive contexts, which means synchronization mechanisms, interactions between the users and the vehicles, and uncertainty about for-coming demands. [9], and [10] later, developed the most used technique in dynamic context or in a real exploitation is heuristics based on insertion techniques. These techniques are a good solution when the people's requests have to be taken into account in a short period of time.

III. The Dial-a-Ride Problem: model and insertion greedy algorithm

A. The general notations

This section lets to set notations used throughout this document. For any sequence (or list) Γ_k we set:

- for any z in Γ_k :
  - Succ(Γ_k, z) = Successor of z in Γ_k ;
  - Pred(Γ_k, z) = Predecessor of z in Γ_k ;
- for any z, z' in Γ_k :
  - $z \ll_k z'$ if z is located before z' in Γ_k ;
  - $z \ll_k^= z'$ if $z \ll_k z'$ or z = z'.

B. The model

A Dial a Ride Problem instance is defined by a *Demand* set $D = (D_i, i \in I)$, a fleet of *K* vehicles with a common capacity CAP, and a transit network $G = (V, E)$. *V* contains some specific node *Depot* and demands' nodes (DepotD for the departure and DepotA for the arrival). Each arc $e \in E$ is endowed with riding times give by a distance function $DIST(e)$. Each demand includes o_i an *origin* node, d_i a destination node, $F(o_i)$ and $F(d_i)$ two time windows, Δ_i a maximum ride time and Q_i a description of the load such that $Q_i = q_{o_i} = -q_{d_i}$ with q the load related to a node. Finally, the total time of the *K* vehicles planning are limited by $\Delta^k, k \in K$.

Solving a DARP with such an instance means creating a scheduling for each vehicle handling demands of D. The routes are constructed while optimizing a performance, which could be a mix of costs (e.g. total distance) and QoS criteria (e.g. ride time).

C. A greedy insertion algorithm: the insertion mechanism

In [1], we present an insertion greedy algorithm based on constraint propagation in order to contract time windows according to the time constraints. An insertion which does not imply constraint violation is said *valid* if $\Gamma = \cup_{k \in K} \Gamma_k$, the resultant collection of routes, if *load-valid* and *time-valid*. A route is *load-valid* if the capacity is not exceed, so, the *load-validity* is obtained if $ChT_k(x) \leq CAP$ with $ChT_k(x) = \sum_{y \ll_k^= x} q_y$, x and y nodes in the route *k*. The *time-validity* is obtained if there is no violation of the time constraints modeling by, for each demand *i*, $i \in D$, Δ_i the maximum ride time, $\Delta^k, k \in K$ the maximum route time and the constraints modeled by each time window $F(o_i) = [F.min(o_i), F.max(o_i)]$ and $F(d_i) = [F.min(d_i), F.max(d_i)]$. Checking the *load-validity* on $\Gamma = \cup_{k \in K} \Gamma_k$ is easy, and we show the efficiency of the constraint propagation in order to prove to *time-validity* after each planned insertion once the *load-validity* is proved. According to a current time window set *FP* = {*FP(x) = [FP.min(x), FP.max(x)]*, $x \in \Gamma_k, k = 1..K$} the *time-validity* may be performed through propagation of the five following inference rules **Ri**, i = 1..5 in a given route Γ_k:

for each *(x,y)* pair of nodes such that y is the successor of x:

- **R1** : $FP.min(x) + DIST(x,y) > FP.min(y) \models (FP.min(y) \leftarrow FP.min(x) + DIST(x,y))$,
- **R2** : $FP.max(y) - DIST(x,y) < FP.max(x) \models (FP.max(x) \leftarrow FP.max(y) - DIST(x,y))$;

for each *(x,y)* pair of nodes such that both are related to the same demand, one is the *origin* so the other the *destination* :

- **R3** : $FP.min(x) < FP.min(y) - \Delta(x) \models (FP.min(x) \leftarrow FP.min(y) - \Delta(x))$,
- **R4** : $FP.max(y) > FP.max(x) + \Delta(x) \models (FP.max(y) \leftarrow FP.max(x) + \Delta(x))$;

and for each x, $x \in \Gamma_k, k = 1..K$:

- **R5** : $FP.min(x) > FP.max(x) \models REJET \leftarrow true.$

These 5 rules are propagated in a loop while there no time windows exists *FP* modified at the last iteration. The tour Γ_k, $k = 1..K$, is *time-valid* according to the input time window set *FP* if and only if the *REJET* Boolean value is equal to *false* as initialized at the beginning of the process. In such a case, any *valid- time* value set *t* related to Γ_k and *FP* is such that: for any *x* in Γ_k, *t(x)* is the appointment's date in *FP(x)*.

The greedy insertion algorithm includes this propagation constraint technique in order to evaluate each possible insertion. Each iteration of the algorithm selects one demand according to the number of vehicle able to integrate it. Once a demand is selected, the process chooses the insertion's parameters that are the vehicle and the location of the *origin* and *destination* nodes.

IV. *Insertability* optimization

A. State of the system

In the above algorithm, each iteration selects a demand, and then, it finds the way to insert while optimizing the performance. This greedy algorithm doesn't take in account the impact of this actual insertion on the future demands integration, but only the effect on the demands already inserted. In this section, we introduce a *Insertability* calculation

by integrating this impact of an insertion related to the time constraints (time windows, maximum ride time and maximum route time).

During the insertion process, the state of the system is given by:

- a set of demands $D-D1$ already integrated in the routes, and $D1$ is the set of demands not inserted,
- a collection $\Gamma = \cup_{k\in K}\Gamma_k$ of routes including a list of nodes related to the *Depot*, *origin* and *destination* nodes,
- a exhaustive list of insertion's parameters sets. Each set gathers 5 elements : k the vehicle, *i* the demand, (x, y) the pair of insertion nodes (locating respectively o_i between x and the successor of x, and d_i between y and the successor of y), and *v* the evolution of the collection $\Gamma = \cup_{k\in K}\Gamma_k$'s cost.

B. Insertion's parameters

Given that the difficulty of the instances' problem is linked to the time constraints, we introduce an *Insertability* calculation related to the times windows contractions. During an insertion's assessment, these reductions appear once the inference rules are propagated. Here, we try to find a good triple (k, x, y), the vehicle and the location of the *origin/destination* nodes, in order to give enough space to the future demands (which have to be integrated in $\Gamma = \cup_{k\in K}\Gamma_k$).

We set *INSER(i,* Γ *)* the *Insertability* measure of the demand *I*. The quantity $U_n^k(z)$ denotes the vehicle *k* time windows' amplitude of the node *n* once it has been inserted to the right of node z. *INSER* is calculated as follows:

- $INSER(i,\Gamma) = \sum_{k\in K} INSER1(i,\Gamma_k)$;
- $INSER1(i,\gamma) = Max_{(x,y)}INSER2(i,\gamma,x,y)$, γ a tour of Γ ;
- $INSER2(i,\gamma,x,y) = U^{\gamma}_{o_i}(x).U^{\gamma}_{d_i}(y)$.

$INSER1$ gives us the maximum of the product of the time's windows amplitude at the origin i and destination i over the possible insertion positions x and y in the route γ. When *INSER1* is equal to 0, the new route γ resulting to the new insertion isn't *time-valid*.

We set $Inserted(\Gamma, i_0, k, x, y)$ the updated collection of tours Γ with the insertion of the selected demand i_0 at the locations x and y in the vehicle k. The *INSER(i,* Γ*)* measure allows us to write the *Optimization Insertability Problem* which consists to find the best insertion parameters in order to keep the vehicles' scheduling more flexible:

Optimization Insertability Problem. Find the optimal parameters *(k,x,y)* inserting i_0 and maximizing the value $Min_{i\in D1-i_0}INSER(i, Inserted(\Gamma, i_0, k, x, y))$.

For instance, the value $Min_{i\in D1-i_0}INSER(i, Inserted(\Gamma, i_0, k, x, y))$ may be used if all the demands have to be inserted. Another optimization may be process as the maximization of the sum $\sum_{i\in D1-i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y))$. The choice is made according to the homogeneity of the demands and if the problem requires to insert all the set *D*.

This problem only optimizes the variation of the *Insertability* values and doesn't include other performance criteria like the minimization of the ride times, waiting times or distances. The *Insertability* criterion can be integrated in a mix of economical cost (point of view of the fleet manager) and of QoS criteria (point of view of the users). Then, the process maximizes the function $Perf = \mu.\sum_{i\in D1-i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y)) - v(Inserted(\Gamma, i_0, k, x, y))$ with μ a criterion coefficient and *v* the performance value function mixing the costs related to the both points of view.

C. Other uses of the Insertability measure

So far, we select the demand i_0 according to the number of vehicles available (taking in account all the time and load constraints). The *Insertability* measure *INSER(*i_0, Γ*)* may be also used in order to select the next request i_1 to insert. This application could be used in a context where all the demands of D have to be integrated. The selection is based on the smallest *Insertability* measure. Once a demand is selected, the problem may solve the *Optimization Insertability Problem.* Here, the two steps may be written in a non-deterministic way. The demand may be selected randomly through a set of N1 elements with the smallest *INSER* value. The same scheme may be applied on a set of a insertion parameters of N2 elements with a best (k, x, y) elements maximizing the quantity $Min_{i\in D1-i_0}INSER(i, Inserted(\Gamma, i_0, k, x, y))$.

Also, *INSER*(i_0, Γ*)* may be useful for a larger set D. If the instance doesn't have any solution integrating all the set D, it is preferable to identify requests to exclude as soon as possible. The exclusion of a demand i_0 may be set up if its insertion results in Γ not enough flexible to include the other elements of $D1$. In other words, the demands excluded will be those that will have the most impact of future insertions. The difference $\sum_{i\in D1-i_0}(INSER(i,\Gamma) - INSER(i, Inserted(\Gamma, i_0, k, x, y)))$ of the inequality (1) takes in account the *Inserabilty* measure of $D1-i_0$ before and after the insertion of i_0 in the routes of Γ. If this difference is larger than the threshold ξ, the demand is excluded. In the experimentation' section, we will discuss the fact this threshold should be dynamic and decreases over the execution.

$$\sum_{i\in D1-i_0} (INSER(i,\Gamma) - INSER(i, Inserted(\Gamma, i_0, k, x, y))) > \xi \quad (1)$$

D. The Insertability optimization suited to the greedy insertion algorithm

The calculation of *INSER(i, Γ)*, $i \in D$, begins to be time consuming starting from a medium size of *D* once the *INSER2* value is based on the time windows' amplitude obtained after the propagation of the time constraints. So, this is important to spot each step of the process where the *Insertability* measure doesn't have to be updated. When i_0 is selected, $INSER2(i, \Gamma_k, x, y)$, $INSER1(i, \Gamma_k)$ and $INSER(i, \Gamma)$ are known for all demand in $D1 - i_0$ and all $k = 1..K$. Once i_0 is about to be inserted, the process computed the value $H(i), i \in D1 - i_0$ (cf. formulation (2)). Then, the algorithm tries the insertion of each i from $D1 - i_0$ in $Inserted(\Gamma, i_0, k, x, y)$ and deduce the value *K(i)* given in formula (3) for all $i \in D1 - i_0$ and ultimately the quantity $Val(k, x, y) = Min_{i \in D1 - i_0}(K(i) + H(i))$.

$$H(i) = INSER(i, \Gamma) - INSER1(i, \Gamma_k) \tag{2}$$

$$\begin{aligned} K(i) &= INSER(i, Inserted(\Gamma, i_0, k, x, y)) \\ &= H(i) + INSER1(i, Inserted(\Gamma, i_0, k, x, y)_k) \end{aligned} \tag{3}$$

Other calculations may be avoided. We set W_1 such that $W_1 = Min_{i \in D1 i_0} INSER\ (i, \Gamma)$. If the quantity $INSER(i, \Gamma) - INSER1(i, \Gamma_k)$ is larger than W_1, there is no need to test the impact of the insertion of i_0 on *i*.

Finally, we're able to use *INSER(i, Γ)* once we integrate the future demands presented in the next section. In a dynamic context, the *Insertability* measure helps the routes to be enough flexible for the next insertion process. Moreover, the appointments have to be set with the same purpose and *INSER(i, Γ)* is able to help to do it.

V. Introduction to the robustness in the DARP: Anticipation of the future demands and *Insertability* measure integration

The problem may have to be handled according to a *dynamic* context and the greedy insertion algorithm is easily adaptable to this context. Once the *Insertability* measure is included in the performance criteria, the system may increase its robustness. In order to accomplish this, we need to exploit knowledge about future demands. In our case, this knowledge is related to the type of on demand transportation service. In this paper, we will use a simple extrapolation of this probable demand based on the demand already broadcasted.

We won't take into account the way the system supervises its various communication components with the users. In reality, there are eventual divergences between the data which were used during the planning phases and the situation of the system.

We set $D-V$ the virtual demands, $D-R$ the real demands, and $D-Rejet$ the set of the ones excluded from the insertion algorithm such that $D-Rejet = DV-Rejet \cup DR-Rejet$. The $D-V$ formulation is given in (4). p_i gives us the number of times the demand D_i, $i \in D$, will appear for each period of each discrete planning horizon.

$$D - V = \sum_{i \in D} D_i.p_i \tag{4}$$

Then, we're able to update the formula (5) giving the performance function *Perf*.

$$\begin{aligned} Perf = \alpha. \sum_i p_i INSER(i, Inserted(\Gamma, i_0, k, x, y)) \\ +\mu. \sum_{i \in D1 - i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y)) \\ -v(Inserted(\Gamma, i_0, k, x, y)) \end{aligned} \tag{5}$$

As in the previous sections, the process may exclude some demands taking in account the future requests. We updated the inequality (1) by the (6). α is a coefficient based on the importance of the future demands.

$$\begin{aligned} \alpha. \sum_i p_i.(INSER(i, \Gamma) \\ -INSER(i, Inserted(\Gamma, i_0, k, x, y))) \\ + \sum_{i \in D1 - i_0} (INSER(i, \Gamma) \\ -INSER(i, Inserted(\Gamma, i_0, k, x, y))) > \xi \end{aligned} \tag{6}$$

VI. Discussion about the appointments and the dynamic context

Most works on vehicle scheduling problems including time window studies how to integrate a set of demands in the vehicle planning. Making an appointment anticipating the future is especially rare. Previous sections explained how to select and integrate user's request while keeping enough space for the next set of demands.

Once routes are built and integrated a first set *D*, the users expect the date when the vehicle selected will pick them up. In the lists forming the *K* routes, each node has a time window. After the appointment's date is set, each time window becomes tight with zero amplitude or equals a very small delay. How the appointments' dates are made is very important for the next insertion's process. For instance, we consider a fleet of 2 vehicles with two plannings including 5 demands while the distances are minimized (cf. Figure VI). The time windows are relatively wide so, while the distance traveled is minimized, the difference of each appointment's time between two nodes is the exact time to join them. The vehicle *k=2* from the Figure VI may integrated the node o_7 between its depot node and o_5 even if its time windows have a zero amplitude (the vehicle will only have to leave the depot earlier). On the other hand, if the difference on the appointment' times given to the users related to the nodes d_5 and o_3 equals to $DIST(d_5, o_3)$, the insertion of d_7 will be forbidden. In the same way, there will be a violation of some constraint once nodes o_6 and d_6 will be inserted in the vehicle $k = 1$.

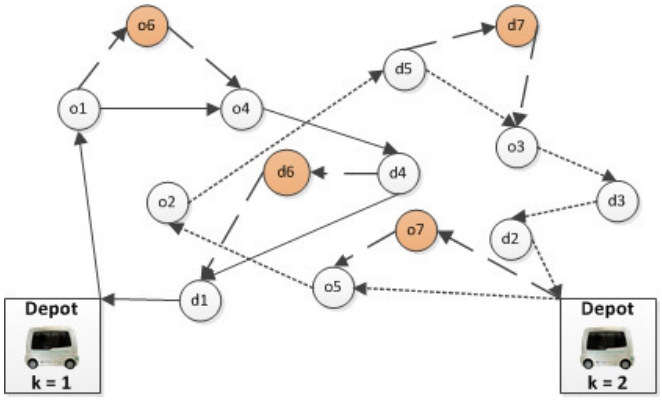

Fig. 2. New insertions after the first set of appointments

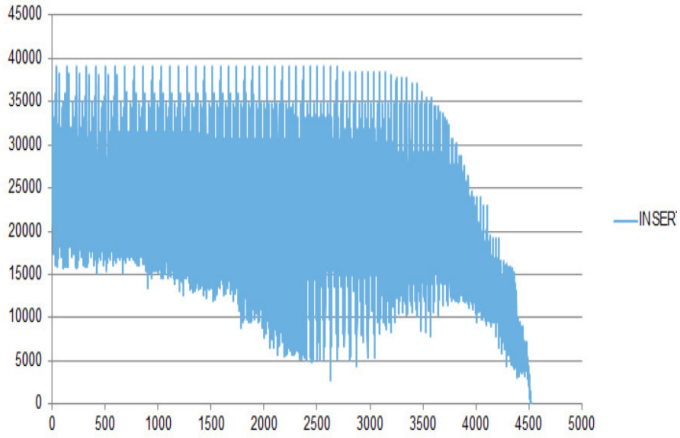

Fig. 3. INSER values on the not inserted demands

One more time, the *INSER(i, Γ)* values may be used in order to set the appointment dates without to have the problem above. The appointment's dates may be calculated once the process have inserted the virtual demands $D-V$ and the real demands $D-R$.

The previous section shows the way to anticipate the future demands $D-V$. These demands are related to a dynamic context. Note again that our greedy algorithm is easily adaptable to this context. More specifically, the technique doesn't change unlike the state of each route. The first node isn't a depot node anymore but a dynamic node related to the vehicle's location. The entire constraint propagation process is applied on these new routes. A simulation will be necessary to evaluate the anticipation of the future demands including in the dynamic context.

VII. Computational Experiments

In this section, we study the behavior of our *Insertability* measure used in the resolution of Dial-a-Ride instances. The algorithms were implemented in C++ and compiled with GCC 4.2. In [1], we solve the [4]'s instances by our greedy insertion algorithm based on constraint propagation. We obtained good results in the majority of instances, but, only 1% of the replications gave us a feasible solution on the tenth instance (*R10a*). The CPU time was smallest or equal to the best times in the literature; we don't work on this feature for this experiment.

A. First experimentation: the optimization of the selection of the demand to insert

1) INSER used in the selection of a demand: We note by R^{DARP} the rate of 100 replications which give us a feasible solution obtained by using the solution of [1]. Here, the selection of the demand is based on the lowest number of cars which are able to accept it. R^{DARP}_{Rob} is the rate obtained with the same process except that each demand is selected at each iteration by the lowest *Insertability* value *INSER*.

The *Insertability* measure is already efficient once it's used in the selection of the demands to insert. The rate obtained for the pr08, pr09, pr10 and pr19 are clearly more interesting as shown in table I (e.g. for the instance pr08, the rate increases by 56% to 91% of success).

Inst.	R^{DARP}	R^{DARP}_{Rob}
pr01	99	100
pr02	100	100
pr03	97	100
pr04	100	100
pr05	100	100
pr06	100	100
pr07	90	96
pr08	56	**91**
pr09	18	21
pr10	1	**7**
pr11	100	100
pr12	100	100
pr13	99	100
pr14	100	100
pr15	100	100
pr16	100	100
pr17	98	100
pr18	99	100
pr19	64	**99**
pr20	43	56
Av.	83,2	88.5

TABLE I
R^{DARP} VS $R^{DARPRob}$

2) INSER behaviour: Each time a replication can't integrate all the request, the *INSER* value of the demands not inserted has to be null. In Figure VII-A2, while the resolution process applied to the R10a instance, we note the evolution of more than 4500 *INSER*'s demands not inserted. The technique used is the second approach selecting the demand by the smallest *Insertability*. The values noted are from a failed replication.

One can observe big gaps between the different *INSER* until the 4000 first values. After that, for the remaining requests, the *Insertability* values decrease strongly because the routes begin to be not flexible. Between the 2500^{th} and the 3500^{th}, for some demands, the values are very low at the beginning just before increasing strongly. This is explained by the fact the process inserts the demand with the lowest

INSER but their insertion don't make a big impact on the other demands not inserted. This impact is related to the *Optimization Insertability Problem* studied below.

B. Second experimentation: the optimization of the insertion parameters

In a second experimentation, we compare the [1]'s approach and another algorithm based on the optimization of the parameters *(x,y,k)*. The selection of the request to insert is the same for both solutions. For the second one, once a demand i_0 is selected, we maximize the sum $\sum_{i \in D1-i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y))$ in order the find the best parameter *(x,y,k)* which will integrate i_0 in the route k. We don't optimize $Min_{i \in D1-i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y))$ because we create instances especially with a set *D* too large for inserting all the requests. So, the demand with the smallest value *INSER* for a given parameters *(x,y,k)* could never be integrated into the routes.

The two algorithms were applied to five sets of 5 randomly generated instances. All the instances have their time constraints related to the interval [0;400] and all the load was unit. We set by $e_{F(o)}$ and $e_{F(d)}$ the amplitude of the time windows at the *origin* and the *destination* given by the users, respectively. The other parameters are given in table II.

K	$e_{F(o)}$	$e_{F(d)}$	Δ	CAP
10	35	10	∞	10

TABLE II
PARAMETERS' INSTANCES

We generate 5 different sets of 5 instances with a variation of the number of demands $|D|$. We set by T_{Insert} and by $T_{Insert_{Rob}}$ the demand inserted's rate the first resolution and the second technique, respectively. Finally, Gap_{Insert} is the gap in percentage between each rate. Its calculation is given by $Gap_{Insert} = 100.(T_{Insert_{Rob}} - T_{Insert})/T_{Insert}$. We launched 100 replications of each technique on the 5 sets. The results are provided by the table III.

$\|D\|$	50	75	100	150	200
T_{Insert}	100	93.2	78.9	64.2	52.6
$T_{Insert_{Rob}}$	100	96.8	85.3	66.4	54.1
Gap_{Insert}	0	3.86	8.11	3.43	2.81

TABLE III
GAP BETWEEN THE *INSERT* RATES

In future experiments, we need to optimize the value $Perf = \mu.\sum_{i \in D1-i_0} INSER\ (i, Inserted(\Gamma, i_0, k, x, y)) - v(Inserted(\Gamma, i_0, k, x, y))$ to calculate each best insertion parameters. Here, we're just taken into account the *INSER* values in order to integrate the most requests possible. The results show us that the larger of $|D|$ defines if the system needs to optimize the *Insertability* measure. For $|D| = 50$, all the requests are able to be inserted easily, so, the *INSER* values doesn't have any interest. When the set is composed of 100 demands, we obtained a Gap_{Insert} of 8,11% meaning there are more than 8% more requests inserted by the second approach.

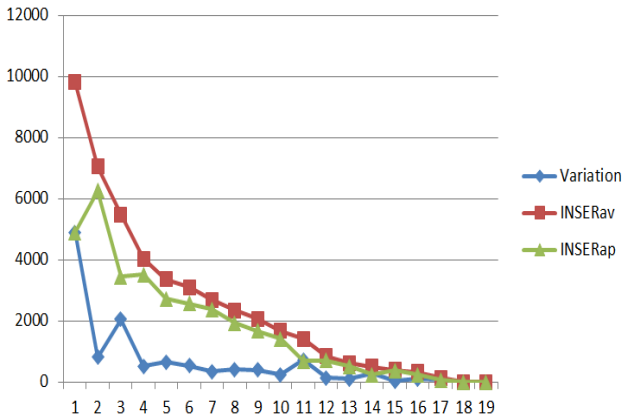

Fig. 4. Variation of the *Insertability* values between each insertion

For this set of instance, we also tried to integrate a new feature in our algorithm: we've added the ability to exclude a request if the impact of one insertion involving a significant drop of the general *Insertability's* demands from $D1 - i_0$. Before that, we study the threshold which limits the variation of *Insertability*.

We exclude a demand selected i_0 if $\sum_{i \in D1-i_0}(INSER(i, \Gamma) - INSER(i, Inserted(\Gamma, i_0, k, x, y))) > \xi$ is true with ξ a threshold. The calculation of the threshold is a difficult problem. In the figure VII-B, we report the $\sum_{i \in D1-i_0}(INSER(i, \Gamma) - INSER(i, Inserted(\Gamma, i_0, k, x, y)))$ *Variation* with *INSERav* and *INSERap* the values $\sum_{i \in D1-i_0} INSER(i, \Gamma)$ and $\sum_{i \in D1-i_0} INSER(i, Inserted(\Gamma, i_0, k, x, y))$, respectively. This figure shows us that the threshold ξ have to be calculated dynamically according to the average of *INSER*.

We used this type of dynamic threshold for the third set of instances with 100 demands. We exclude an request if the current ξ is exceeded, and only this feature is added in the second approach. We obtained a gain of 1,3% in average (from 85,3% to 86,6%) meaning approximately one more demand is able to be inserted.

VIII. CONCLUSION

The Dial-a-Ride Problem is one of the transport problems with the highest number of hard constraints like time windows. The insertion techniques are able to obtain a good solution in a reasonable time. Their adaptability to a dynamic context is easy but a lack of robustness could appear once the goal is to integrate requests as much as possible.

We have introduced a way to measure the impact of each insertion on the other demands not inserted. This *Insertability*

measure could be used in order to exclude a demand, to select a demand to insert and also to calculate the best insertion parameters. This value, named *INSER*, leads to a large amount of work opportunities. We have introduced a simple way to make the model of the future demands, and how to adapt our greedy insertion algorithm based on the constraint propagation to the dynamic context. In future work, we will develop a simulation which is necessary to show the efficiency of the demands anticipation. The final goal will be to develop the most robust algorithm possible in order to adapt it to a real context.

ACKNOWLEDGMENT

***Abstract*—In the article a new approach for control of a pressure-constrained batch reactor and a new multi-step optimization algorithm were presented. The considered batch reactor was described by both differential and algebraic equations. State constraints incorporate always difficulties into a mathematical model of the reactor, so a new algorithm based on a multiple shooting SQP-line search method was proposed and tested. The multiple shooting method was used not only to ensure a stability of the solution, but to divide a system into smaller subsystems, so a large-scale problem is considered. The considerations were made for a simultaneous approach, which allows to apply this algorithm to a wide class of differential-algebraic systems. The simulations were executed in Matlab environment using Wroclaw Centre for Networking and Supercomputing.**

***Index Terms*—optimal control, DAE systems, multiple shooting method, state constraints.**

I. Introduction

SEARCHING for controls that will result in a desired behavior of a system plays a key role in a process design [1], [2], [11]. To describe the system often only algebraic equations are enough. Especially, when changes in the state variables are slow and algebraic equations accurately reflects the behavior of the system. More complex processes are described by differential equations. Suitable numerical methods and optimization algorithms were proposed and implemented, so it is a group of well-known problems . It seems, that the most important feature of the differential systems is a existence of a solution for all initial conditions. Difficulties may, however, be caused by the instability of the equations and selection of the appropriate numerical methods for the equations [5].

Often, however, it happens that there are in the system simultaneously both algebraic and differential relations. Description with the system of equations, which can be easily divided in part consisting solely of differential equations and a group of algebraic equations is desirable for several reasons. (1) During the construction of the mathematical model one does not need to perform additional transformations to obtain allowed equations. (2) The variables in a model are known to have physical interpretation. When the equations are well scaled, then no other transformations are needed. Additionally, (3) one can explore the impact of different variables on the behavior of the model. But the searching for the solution of the initial value problem for differential-algebraic equations, which does not exist for all possible values of parameters, was always a challenge [3], [8], [9].

The main motivation of this paper is to present an algorithm, which can treat the large-scale optimal control problem. Every system with path constraints on state trajectory can be considered as an optimization problem with arbitrarily large number of variables [2]. Even systems with simple path constraints, but with large number of decision variables, may require a huge computational effort. The aim of this paper is to present a feasible-type algorithm that improves a feasible initial solution of a large-scale problem in a reasonable time. These features enable the use of this approach in the task of design and control of chemical processes.

The pressure-constrained batch reactor is usually described by the nonlinear differential-algebraic equations [6]. The control problem of the chemical reactor belongs to the group of tasks, the size of which is not clearly defined. Especially if the model takes into account constraints on the state variables. The statement that the size of the task is infinitely large does not help much in solving the problem. The practical approach leads to the use of the existing finite-dimensional methods.

To solve the control problem of the chemical reactor with the constraints on state variables, the new multi-step algorithm was designed. Its particular advantage is the possibility to take into account the large number of variables and to preserve the feasibility of all iterates, which start from the feasible initial conditions. The study was carried out on the large-scale task of about 4 000 variables and 3 000 differential equations [4]. The algorithm combines the multiple shooting method and the simultaneous approach.

The article is structured as follows. At the beginning the optimal control problem of DAE system was formulated. Then the simultaneous approach for the optimal control of differential algebraic systems and its relationship with the multiple shooting method is discussed. The Multi-step SQP-line search algorithm using the multiple shooting method is presented. The differential-algebraic model of the pressure constrained batch reactor is described and solved by the designed algorithm. Finally, the results of the large-scale simulations, which were performed using Wroclaw Centre for Networking and Supercomputing, were discussed.

II. The simultaneous approach for multiple shooting optimal control of differential-algebraic systems

In the paper the following multiple shooting optimal control problem of differential-algebraic systems is considered

$$\min_{p} \phi(p) = \sum_{l=1}^{N_T} \Phi(z^l(t_l), y^l(t_l), p^l), \tag{1}$$

subject to

$$z^{l-1}(t_{l-1}) = z_0^l = 0; \qquad l = 2, \ldots, N_T, \tag{2}$$

$$z^{N_T}(t_{N_T}) - z_f = 0; \qquad z^l(0) = z_0^l, \tag{3}$$

$$p_L^l \leq p^l \leq p_U^l, \tag{4}$$

$$y_L^l \leq y^l(t_l) \leq y_U^l, \tag{5}$$

$$z_L^l \leq z^l(t_l) \leq z_U^l; \quad l = 1, \ldots, N_T, \tag{6}$$

with the DAE system

$$\frac{dz^l(t)}{dt} = f^l(z^l(t), y^l(t), p^l); \qquad z^l(t_{l-1}) = z_0^l, \tag{7}$$

$$g^l(z^l(t), y^l(t), p^l) = 0; t \in [t_{l-1}, t_l]; l = 1, \ldots, N_T. \tag{8}$$

In equations (1)-(8) $z(t)$ denotes the differential state trajectory and $y(t)$ denotes the algebraic state trajectory. The control profile is represented as a parametrized function with coefficients that determine the optimal profil [12], [13]. The decision variables on DAE equations appear only in the time independent vector p. The assumption on the invertibility of $g(-, y(t), -)$ permits an implicit elimination of the algebraic variables $y(t) = y[z(t), p]$ [3]. While there are N_T periods in DAE equations, the time dependent bounds and other path on the state variables are no longer considered. The algebraic constraints and terms in the objective function are applied only at the beginning of each period.

The mentioned optimal control problem of the reactor is an example of wide range control problems of systems described by differential-algebraic equations (eg. [11]). The instability of this type of equation resulted in development of shooting methods. The shooting method was adjusted for solving more difficult systems and is usually known as the multiple shooting method or the parallel shooting method. As a result of the application of the shooting methods, tested systems exhibit new properties, which could not be expected considering the general formulation of the optimal control problem of DAE systems. When the multiple shooting approach is used, the time domain is partitioned into smaller time periods and the DAE models are integrated separately in each element. To provide the continuity of the states across elements, the equality constraints are added to the nonlinear program. The inequality constraints for states and controls are then imposed directly at the grid points t_l [1].

The aim of the simultaneous approach is searching for the optimal control trajectory, the differential and algebraic state trajectories in a special manner. A sketch of the sequential

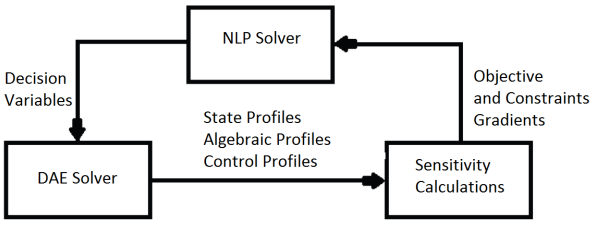

Fig. 1. Sequential dynamic optimization strategy.

dynamic optimization strategy for the problem (1)-(8) is presented on Fig. 1. At l-iteration, the variables p^l are specified by NLP solver. In this situation, when the values of p^l are known, one can treat DAE system as an initial value problem and integrate (2)-(4) forward in time for periods $l = 1, \ldots, N_T$. For these purposes Backward Differentiation Formula was used, which can solve index-1 DAEs. The Differential state profile, the algebraic state profile and the control function profile were obtained as results of this step. Next component evaluates the gradient of the objective and constraint functions with respect to p^l. Because function and gradient information are passed to the NLP solver, then the decision variables can be updated [2].

III. Dynamic optimization of the pressure-constrained batch reactor

The reactions taking place in the reactor are

$$A \xrightarrow{k_1} 2B, \tag{9}$$

$$2B \xrightarrow{k_2} A, \tag{10}$$

$$A + B \xrightarrow{k_3} D. \tag{11}$$

The dynamic optimization problem is described as follows

$$\min_{F} J = C_D(t_f), \tag{12}$$

subject to

$$\dot{C}_A = -k_1 C_A + k_2 C_B C_B + \frac{F}{V} - k_3 C_A C_B, \tag{13}$$

$$\dot{C}_B = k_1 C_A - k_2 C_B C_B - k_3 C_A C_B, \tag{14}$$

$$\dot{C}_D = k_3 C_A C_B, \tag{15}$$

$$N = V(C_A + C_B + C_D), \tag{16}$$

$$PV = NRT, \tag{17}$$

$$P \leq 340000, \tag{18}$$

$$0 \leq F \leq 8.5, \tag{19}$$

$$[C_A(0), C_B(0), C_D(0)] = [100, 0, 0]. \tag{20}$$

The rate constants are $k_1 = 0.8$ per h, $k_2 = 0.02\ m^3/(mol \cdot h)$, $k_3 = 0.003\ m^3/(mol \cdot h)$, the volume $V = 1.0\ m^3$, the temperature $T = 400\ K$. There is one path constraint on the state variable P. The process duration is 2 hours.

The task is to find the optimal flow rate profile, which is treated as a control variable, to minimize the objective function (12). There are some possibilities of parametrization of the control variable. The most popular are piecewise constant, piecewise linear with continuity, piecewise linear without continuity, piecewise quadratic with continuity [12]. In [6] the simultaneous approach with piecewise linear parametrization with continuity was considered. It means, that for 11 time intervals the size of NLP was originally 42, and 35 by model decomposition method presented in this article. Because "the optimal control is highly nonlinear which makes this problem difficult for general control parametrization methods" [6], the new control algorithm for the simultaneous approach with constant parametrization of the control variables was proposed and tested. So, there are decision variables connected only with the control function and the state variables.

IV. The Multi-step SQP line search algorithm

The designed algorithm belongs to a group of the Sequential Quadratic Programming methods [10]. Its main part is as follows.

The equality constrained problem is considered

$$\min_p f(p), \tag{21}$$

subject to

$$c(p) = 0, \tag{22}$$

where the objective function $f : \mathcal{R}^n \to \mathcal{R}$ and the vector of equality constraints $c : \mathcal{R}^n \to \mathcal{R}^m$ are smooth functions. The idea behind the SQP approach is to model (21)-(22) at the current iterate p_k by a quadratic programming subproblem. Then the subproblem is minimized and the new iterate p_{k+1} is defined.

The Lagrangian function for this problem is

$$\mathcal{L}(p, \lambda) = f(p) - \lambda^T c(p). \tag{23}$$

The matrix $A(p)$ were used to denote the Jacobian matrix of the constraints

$$A(p) = [\nabla c_1(p), \nabla c_2(p), \ldots, \nabla c_m(p)]^T, \tag{24}$$

where $c_i(p)$ is the ith component of the vector $c(p)$.

The first order KKT conditions of the equality constrained problem (21)-(22) can be written as the system on $n + m$ equations and the $n + m$ unknowns p and λ,

$$\begin{bmatrix} \nabla f(p) - A(p)^T \lambda \\ c(p) \end{bmatrix} = 0. \tag{25}$$

Any solution (p^*, λ^*) of the equality constrained problem (21)-(22) for which $A(p^*)$ has full row rank satisfies (25). The nonlinear system (25) can be solved by the Newton method.

The Jacobian of (25) with respect to p and λ is given by

$$\begin{bmatrix} \nabla^2_{pp}\mathcal{L}(p, \lambda) & -A(p)^T \\ A(p) & 0 \end{bmatrix} = 0. \tag{26}$$

The Newton step from the iterate (p_k, λ_k) is given by

$$\begin{bmatrix} p_{k+1} \\ \lambda_{k+1} \end{bmatrix} = \begin{bmatrix} p_k \\ \lambda_k \end{bmatrix} + \begin{bmatrix} d_k \\ d_\lambda \end{bmatrix}, \tag{27}$$

where d_k and d_λ solve the Newton-KKT system

$$\begin{bmatrix} \nabla^2_{pp}\mathcal{L}(p, \lambda) & -A(p)^T \\ A(p) & 0 \end{bmatrix} = \begin{bmatrix} d_k \\ d_\lambda \end{bmatrix} + \tag{28}$$

$$+ \begin{bmatrix} -\nabla f(p) + A(p)^T \lambda \\ -c(p) \end{bmatrix},$$

The Newton step is well defined when KKT matrix in (26) is nonsingular. This is satisfied, when the following assumptions hold [10]

Assumption 1: The Jacobian of the constraints $A(p)$ has full row rank.

Assumption 2: The matrix $\nabla^2_{pp}\mathcal{L}(p, \lambda)$ is positive definite on the tangent space of the constraints, that is, $d^T \nabla^2_{pp}\mathcal{L}(p, \lambda)d > 0$ for all $d \neq 0$ such that $A(p)d = 0$.

Suppose that at the iterate (p_k, λ_k) the problem (21)-(22) is modeled by the quadratic program

$$\min_p f_k + \nabla f_k^T p + \frac{1}{2}\nabla^2_{pp}\mathcal{L}_k p, \tag{29}$$

subject to

$$A_k(p) + c_k = 0. \tag{30}$$

If Assumptions 1 and 2 hold, then this problem has the unique solution (d_k, l_k) that satisfies

$$\nabla^2_{pp}\mathcal{L}_k d_k + \nabla f_k - A_k^T l_k = 0, \tag{31}$$

$$A_k d_k + c_k = 0. \tag{32}$$

The vectors d_k and l_k can be identified with the solution of the Newton equation (28).

ALGORITHM 1. Local SQP Algorithm for solving the equality constrained problem

Choose an initial par (p_0, λ_0);
  (if p_0 is given, then λ_0 is given by eq. (25))
Set $k \leftarrow 0$;
REPEAT UNTIL convergence test is satisfied
  evaluate f_k, ∇f_k, $\nabla^2_{pp}\mathcal{L}_k$, c_k, A_k;
  solve (29)-(30) to obtain d_k and l_k;
  set $p_{k+1} \leftarrow p_k + d_k$; $\lambda_{k+1} \leftarrow l_k$;
END (REPEAT)

On this basis, the new algorithm was designed.

ALGORITHM 2. The line search SQP algorithm

choose parameters $\eta \in (0, 0.5)$, $\tau \in (0, 1)$
and an initial pair (p_0, λ_0);
evaluate $f(p_0)$, $\nabla f(p_0)$, $c_i(p_0)$,
$A_0 = [\nabla c_1(p_0), \nabla c_2(p_0), \ldots, \nabla c_m(p_0)]^T$;
if a quasi-Newton approximation is used, choose
an initial $n \times n$ symmetric positive definite Hessian
approximation B_0, otherwise compute $\nabla^2_{pp}\mathcal{L}_0$;
WHILE convergence test is not satisfied DO
  compute d_k by solving (28), let λ be
  the corresponding multiplier;
  $d_\lambda \leftarrow \hat{\lambda} - \lambda_k$;
  choose μ_k to satisfy eq. (33) with $\sigma = 1$;
  set $\alpha_k \leftarrow 1$;
  WHILE $\Phi_1(p + \alpha_k d_k; \mu_k) >$
    $\Phi_1(p_k; \mu_k) + \eta\alpha_k D_1(f(p_k; \mu_k); d_k)$ DO
    reset $\alpha_k \leftarrow \tau_\alpha \alpha_k$ for some $\tau_\alpha \in (0, \tau]$;
  END (WHILE)
  set $p_{k+1} \leftarrow p_k + \alpha_k d_k$ and $\lambda_{k+1} \leftarrow \lambda_k + \alpha_\lambda d_\lambda$;
  IF a quasi-Newton approximation is used THEN
    set $s_k \leftarrow \alpha_k d_k$;
    set $\hat{y}_k \leftarrow \nabla_p \mathcal{L}(p_{k+1}, \lambda_{k+1}) - \nabla_p \mathcal{L}(p_k, \lambda_{k+1})$;
    obtain B_{k+1} by updating B_k using
    a quasi-Newton formula
    $B_{k+1} = B_k + \frac{(\hat{y}_k - B_k s_k)(\hat{y}_k - B_k s_k)^T}{(\hat{y}_k - B_k s_k)^T s_k}$
  END (IF)
END (WHILE)

The strategy for choosing μ in the Algorithm 2 considers the effect of the step on a model of the merit function, so μ has to satisfy the inequality

$$\mu \geq \frac{\nabla f_k^T d_k + \frac{\sigma}{2} d_k^T \nabla^2_{pp}\mathcal{L}_k d_k}{(1-\rho)\|c_k\|_1}. \tag{33}$$

If the value of μ from the previous iteration of the SQP method satisfies eq. (33), it is left unchanged. Otherwise, μ is increased, so that satisfies this inequality with some margin. The constant σ is used to handle the case in which Hessian $\nabla^2_{pp}\mathcal{L}_k$ is not positive definite. We define $\sigma = 1$ if $d_k^T \nabla^2_{pp}\mathcal{L}_k d_k > 0$, and $\sigma = 1$ otherwise.

The l_1 merit function for the problem (21)-(22) takes the form

$$\Phi_1(p; \mu) = f(p) + \mu\|c_k\|_1. \tag{34}$$

The directional derivative of Φ_1 in the direction d_k satisfies

$$D(\Phi_1(p_k; \mu); d_k) = \nabla f_k^T d_k - \mu\|c_k\|_1. \tag{35}$$

ALGORITHM 3. The SQP-line search algorithm for solving the equality constrained problem

BEGIN
  define a vector of decision variables $\tilde{p}$
    and its initial conditions;
  choose from vector $\tilde{p}$ a subvector p,
    which describes a subsystem
    $S = f(p)$
  solve problem (36) using Algorithm 2;
  update values of vector $\tilde{p}$ using results
    from the previous step;
END

As one can see, the Algorithm 2 can be thought as an inner loop in Algorithm 3. The last question is, what is the rate of convergence of the considered algorithm.

Assumption 3: The point p^* is a local solution of the problem (21)-(22) at which the following conditions hold.

a) The functions f and c are twice differentiable in a neighborhood of p^* with Lipschitz continuous second derivatives.

b) The linear independence constraint qualification holds at p^*.

c)The second order sufficient conditions hold at (p^*, λ^*).

Now one can call the theorem, which justifies the correctness of the presented algorithm.

Theorem ([10]): Suppose, that Assumption 3 holds and that the iterates p_k generated by Algorithm 1 with guasi-Newton approximate Hessian B_k, converge to p^*. Then p_k converges superlinearly if and only if the Hessian approximation satisfies

$$\lim_{k\to\infty} \frac{\|(B_k - \nabla^2_{pp}\mathcal{L}_*)(p_{k+1} - p_k)\|}{\|p_{k+1} - p_k\|} = 0. \tag{36}$$

Lemma 4: Algorithm 3 generates a sequence of the feasible solutions with decreasing values of the goal function. In this bounded sequence one can distinguish a subsequence, which is superlinearly convergent to the locally optimal solution p^*.

V. Numerical results

Simulations were executed on the large-scale model of the pressure-constrained batch reactor.

When the model was divided into 1 000 submodels, then for solving the KKT system more than 24 hours was needed. So, the reactor was divided into 100 parts and the solution was obtained in 12 hours. At this step the vector of decision variables was stated as follows

$$p = [u_1 \cdots u_{100}, C_{A0,2} \cdots C_{A0,100}, \tag{37}$$
$$C_{B0,2} \cdots C_{B0,100}, C_{D0,2} \cdots C_{D0,100}].$$

Solution of this model was used as the initial conditions in the further work.

The question is, how to choose the vector of decision variables, to obtain in a reasonable time a possibly greatest improvement of the solution.

Then the reactor was divide into 1 000 parts. There are 3 997 decision variables in the system (1 000 piecewise

10	37	$8.6448e-004$
20	17	$8.4317e-004$
50	6	$9.3396e-004$
100	3	$9.3396e-004$

TABLE II
RESULTS OF THE SIMULATIONS IN CASE 2.

Size of subvector p	Number of iterations	$\bar{d}$
10	130	$7.5896e-004$
20	82	$7.6063e-004$
50	40	$7.6116e-004$
100	19	$7.6136e-004$

constant control functions and 2 997 variables treated as initial conditions for differential state trajectories).

$$\widetilde{p} = [u_1 \cdots u_{1000}, C_{A0,2} \cdots C_{A0,1000}, \quad (38)$$
$$C_{B0,2} \cdots C_{B0,1000}, C_{D0,2} \cdots C_{D0,1000}].$$

The simulations were executed for 4 different possible number of variables in the subvector $\widetilde{p}$: 10, 20, 50 and 100. As decision variables only control function, especially in the initial phases of the process, were considered. This enables increase the accuracy of the calculation, when the reactions proceed quickly. The initial average discontinuity in the state variables was $\bar{d} = 1.1e-3$ and $C_D(t_f) = 10.7240\ mol/m^3$. The final value of $C_D(t_f)$ is about 8.7% better then result presented in [6].

In the simulations two different stop criteria in Algorithm 2 were used. In the implementation convergence is declared when $TolFun < \epsilon_1$ and $TolCon < \epsilon_2$. $TolFun$ denotes termination tolerance on the function value, and $TolCon$ denotes tolerance on the constraint violation.

1) Case 1: In the first case the local optimization processes were performed more precisely. So, $TolFun < 1e-6$ and $TolCon < 1e-6$.

2) Case 2: In the second case stop criterion in local optimization were no so rigorous: $TolFun < 1e-3$ and $TolCon < 1e-3$.

The main stop criterion was the performance time. When computing time exceeded 12 hours, then optimization process was stopped.

In both cases the augmented objective function was considered

$$f(p) = C_D(t_f) + \rho \sum_{l=1}^{N_T} (z_0^{l+1} - \hat{z}_l)^2, \quad (39)$$

where penalty parameter $\rho = 10^6$.

Equation (39) shows the balance in the quest to minimize the concentration of component D and to meet the continuity constraints in differential-algebraic equations.

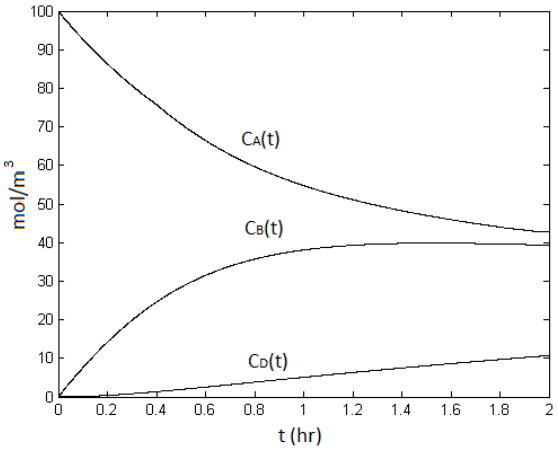

Fig. 2. Differential state trajectories. Results for size of subvector p=10. Stop criteria like in case 2.

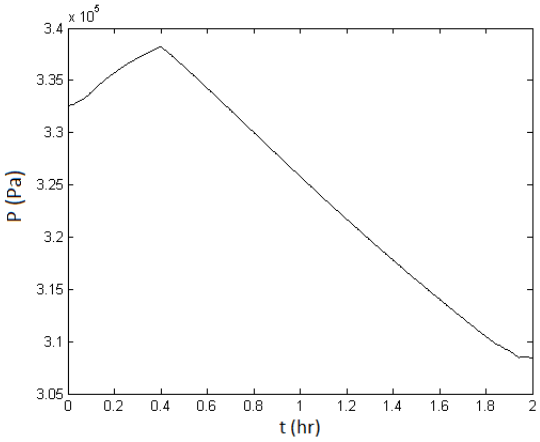

Fig. 3. The optimal pressure trajectory.

Results presented in the Table 1 and Table 2 show, that the inexact algorithm with the weak stop criteria, can obtain a better improvement of the initial solution.

As it was mentioned, in the considered problem two opposite tasks were considered. The minimization of the component D stands in opposition to fulfilment the constraints. As a result, the final concentration was improved and the obtained solution meets the constraints with high accuracy, so this method can be applied in real-life chemical processes.

The solutions obtained for size of the subvector $p = 10$ and stop criteria like in case 2 were presented on the figures 2-4. There are the differential state trajectories in the figure 2, the optimal pressure trajectory in the fig. 3 and the optimal flowrate profile in the fig. 4

VI. CONCLUSION

In the article the task of control of the pressure-constrained batch reactor was considered. The complex model of the reactor was designed using the simultaneous approach. The

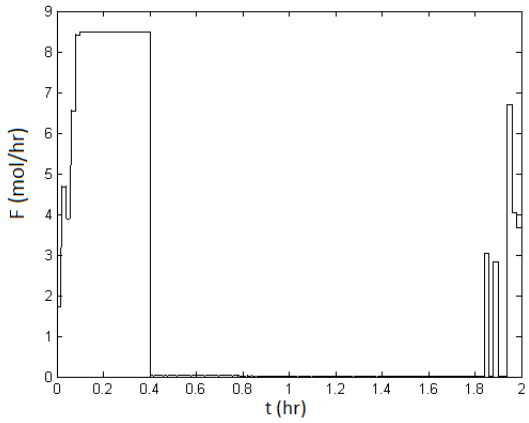

Fig. 4. Control variable - the optimal flowrate profile.

new SQP-line search algorithm was designed and tested. The algorithm, which takes in each iteration only a few number of decision variables into account, can do new iterations and improve the initial solution. But in both approaches a large number of variables were considered.

Because in the pure form, SQP algorithm is convergent to the locally solution, line search was used as a globalization approach to construct a sequence of feasible solutions with decreasing values of the objective function.

This type of algorithms can be successfully applied to the large systems, when Jacobian and Hessian matrices are dense and structure of these matrices can not be effectively used.

As the conclusion we want to pay attention to need for solver for the large-scale optimization and optimal control problems. Second order information, which can be approximated using BFGS method, can be unavailable when Jacobian matrix is difficult to calculate. This situation one can be met very often, when simultaneous approach is used. Multistep algorithms, which need feasible initial conditions, can improve the solution in considerable short time. At the end we want to emphasize the need for Jacobian-free optimization algorithm, which could solve the large-scale optimization tasks [7].

VII. Nomenclature

C	concentration (mol/m^3)
$\bar{d}$	average discontinuity in the state variables
F	flowrate (mol/hr)
f	objective function in optimization problem
g	function of algebraic constraints
k_1, k_2, k_3	rate constants
N_T	number of shots
n, m	dimensions of the space
p	vector of decision variables
S	function describing subproblem
t	time (hr)
z	state variables
y	algebraic variables
$\mathcal{L}$	Lagrangian function
$\mathcal{R}$	real numbers

Greek symbols

Φ	function describing optimization problem
ϕ	function describing system
λ	Lagrangian multipliers
ρ	penalty parameter
ϵ	tolerance

Superscripts

T	transposition of the matrix

Subscripts

A, B, D	components of the reaction
L	lower bound
U	upper bound
l	number of a shot

***Abstract*—Distribution network design deals with defining which elements will be part of the supply chain and how they will be interrelated. Many authors have studied this problem from a cost minimization point of view. Nowadays the sustainability factor is increasing its importance in the logistics operations and must be considered in the design process. We deal here with the problem of determining the location of the links in a supply chain and the assignment of the final customers considering at the same time cost and environmental objectives. We use a fuzzy bicriteria model for solving the problem, embedded in a genetic algorithm that looks for the best trade-off solution. A set of experiments have been carried out to check the performance of the procedure, using some instances for which we know a priori a good reference solution.**

I. Introduction

THE fierce competition between the different supply chains makes it necessary that efficiency be continuously pursued. One of the most important strategic decisions, and one that has a long-term impact in the economic results of the logistics operations, is the design of the distribution network.

Distribution network design is the process of determining the structure of a supply chain, defining which elements will be part of it (i.e., where locate the facilities), and what will be the interrelationships between them (i.e., the allocation of customers to facilities and how the material and products will flow in the network between the nodes in the network). For that reason the problem is often called location-allocation (e.g. [1]).

In [2], Akkerman *et al.* consider, from a hierarchical point of view, a second level called distribution network planning that includes the decisions related to fulfilling the aggregate demand (i.e., aggregate product flows and delivery frequencies)

Many authors have studied these problems, most of them (around two thirds according to [3]) by considering as the objective the minimization of the costs involved in the process. However, for different reasons (legal pressure, customers demand, ethical consciousness, etc) nowadays the sustainability factor is increasing its importance in the business management and specifically in the logistics operations, where transportation of goods is a high pollutant activity. It is therefore necessary to consider the operations impact when defining the distribution network.

The aim of this study is the formulation of a model and a solution procedure for the location-allocation problem when two criteria (cost and environmental impact of transportation) are considered at the same time.

II. Problem Setting

Let us suppose that there is an uncapacitated central plant that must distribute a single product among many customers. Those customers have uncertain (i.e. fuzzy) demands. We need to define the distribution network, choosing the capacitated intermediate warehouses to set up, and allocating each customer to one of warehouses (or to the central facility). There are two types of vehicles: large trucks (used for high demand customers and for serving the warehouses from the central plant) and smaller trucks.

We are going to consider two objective functions. One is the minimization of the logistics costs (transportation and warehouses set-up). The transportation costs will be proportional to distances and depend on type of truck used. The second objective function is the minimization of the environmental impact of the Greenhouse Gases (GHG) emissions (e.g. CO_2) due to transportation.

Note that, in principle, every customer could be served from the central facility, but if the demand is small, the cost and environmental impact of such direct shipments would be very high, likely bigger that delivering the goods from a near warehouse.

Our problem consists in deciding which of the potential warehouse locations will be opened and from which warehouse should each customer be served warehouse each customer will be allocated (considering the limited capacities of the warehouses) in such a way that total cost and GHG emissions are minimized.

III. Model Formulation

Table I shows the notation used for modeling the problem. Note that the set of potential warehouse locations are given together with the distance, unit transport cost and unit GHG emissions factor from the central plant to each potential warehouse location j. From each potential warehouse loca-

This research was funded by the Spanish Ministry of Science and FEDER, grant DPI2010-16201.

TABLE I.
NOTATION

i	Index on customers (i=1..N)
j	Index on potential warehouse locations (j=1..A)
I(j), $\hat{I}$	Subsets of customers that can be served from warehouse j and from the central plant, respectively
$\widetilde{D}_i$	Fuzzy demand of customer i. A Triangular Fuzzy Number membership function is assumed. $\mu_{D_i}(x) = \begin{cases} 0 & \text{if } x \le D_i^- \\ \frac{x - D_i^-}{D_i^0 - D_i^-} & \text{if } D_i^- \le x \le D_i^0 \\ \frac{D_i^+ - x}{D_i^+ - D_i^0} & \text{if } D_i^0 \le x \le D_i^+ \\ 0 & \text{if } x \ge D_i^+ \end{cases}$
$\widetilde{U}_j$	Fuzzy capacity of warehouse j. A decreasing linear membership function is assumed $\mu_{U_j}(x) = \begin{cases} 1 & \text{if } x \le U_j^- \\ \frac{U_j^+ - x}{U_j^+ - U_j^-} & \text{if } U_i^- \le x \le U_j^+ \\ 0 & \text{if } x \ge U_j^+ \end{cases}$
$\widetilde{L}_j$	Fuzzy minimum flow of warehouse j. An increasing linear membership function is assumed (with parameter $L_i^+ << U_j^-$). $\mu_{L_j}(x) = \begin{cases} 0 & \text{if } x \le L_j^- \\ \frac{x - L_j^-}{L_j^+ - L_j^-} & \text{if } L_i^- \le x \le L_j^+ \\ 1 & \text{if } x \ge L_j^+ \end{cases}$
f_j	Fixed cost of warehouse j
c_{ji}	Unit transport cost between warehouse j and customer i
$\hat{c}_i$	Unit transport cost between central plant and customer i
$\hat{\hat{c}}_j$	Unit transport cost between central plant and warehouse j
e_{ji}	Unit GHG emissions factor for transport between warehouse j and customer i
$\hat{e}_i$	Unit GHG emissions factor for transport between central plant and customer i
$\hat{\hat{e}}_j$	Unit GHG emissions factor for transport between central plant and warehouse j
t_{ji}	Distance between warehouse j and customer i
$\hat{t}_i$	Distance between central plant and customer i
$\hat{\hat{t}}_j$	Distance between central plant and warehouse j
x_{ji}	Amount of product shipped from warehouse j to customer i∈ I(j)
$\hat{x}_i$	Amount of product shipped from central plant to customer
y_j	Amount of product shipped from central plant to warehouse j

tion j only a subset of customers I(j) can be served. The distance, unit transport cost and unit GHG emissions factors from each warehouse location to each customer $i \in I(j)$ are given.

The membership function of the demand of each customer i is given by a Triangular Fuzzy Number (TFN) with parameters $\left(D_i^-, D_i^0, D_i^+\right)$. Each warehouse has a capacity, i.e. an upper bound on the flow of goods that it can convey from the central plant to its allocated customers. The membership function of the capacity of warehouse j is given by a linear decreasing function with parameters $\left(U_j^-, U_j^+\right)$. Each warehouse also has a lower bound on the flow that it should handle in case it is selected. This minimum flow is imposed to guarantee an economic operation of the warehouse. The membership function of the minimum flow of warehouse j is given by a linear increasing function with parameters $\left(L_j^-, L_j^+\right)$.

The proposed bicriteria optimization model consist in the minimization of both cost and GHG emissions:

$$\text{Min} \quad \sum_j f_j\, y_j + \sum_{i \in \hat{I}} \hat{c}_i\, \hat{t}_i\, \hat{x}_i + \sum_j \sum_{i \in I(j)} \left(\hat{\hat{c}}_j\, \hat{\hat{t}}_j + c_{ji}\, t_{ji}\right) x_{ji} \tag{1}$$

$$\text{Min} \quad \sum_{i \in \hat{I}} \hat{e}_i\, \hat{t}_i\, \hat{x}_i + \sum_j \sum_{i \in I(j)} \left(\hat{\hat{e}}_j\, \hat{\hat{t}}_j + e_{ji}\, t_{ji}\right) x_{ji} \tag{2}$$

subject to

$$\hat{x}_i + \sum_{\{j: i \in I(j)\}} x_{ji} = \tilde{D}_i \qquad \forall i \in \hat{I} \tag{3}$$

$$\sum_{\{j: i \in I(j)\}} x_{ji} = \tilde{D}_i \qquad \forall i \notin \hat{I} \tag{3'}$$

$$\tilde{L}_j\, y_j \le \sum_{i \in I(j)} x_{ji} \le \tilde{U}_j\, y_j \tag{4}$$

$$\hat{x}_i \ge 0 \;\; \forall i \in \hat{I} \quad x_{ji} \ge 0 \;\; \forall j \forall i \in I(j) \quad y_j \in \{0,1\} \;\; \forall j \tag{5}$$

In order to solve this model, a Fuzzy Multiobjective Optimization approach based on the additive model of Tiwari [4] is proposed. Thus, the new objective function, to be maximized, will be the sum of the membership functions of the fuzzy constraints and of the two objective functions. The latter are fuzzified using decreasing linear membership functions, between the thresholds (C^-,C^+) and (E^-,E^+), respectively. These total cost and total emissions thresholds are evaluated in the following way. For C^+, model (1),(3)-(5) is solved maximizing transportation costs and assuming all the potential warehouses are closed. Let Ψ be the resulting maximum transportation cost, then $C^+=\Psi^+ + \Sigma f_i$.

For the calculation of C^-, model (1),(3)-(5) is solved minimizing transportation costs and assuming that all the warehouses are open. Let Ψ^- be the resulting minimum transportation cost, then $C^-=\Psi^- - \Sigma f_i$. For the calculation of E^+, model (2)-(5) is solved maximizing total emissions and assuming that all the warehouses are closed. Finally, for calculating E^-, model (2)-(5) is solved minimizing total emissions and assuming that all the warehouses open.

We assume that both objectives (minimizing total costs and total emissions) are equally important. As regards the constraints we shall request that their membership function values should be higher than a lower bound μ_{min} (see [5]). The model to solve is, thus, the following

$$\text{Max} \quad \lambda_1 + \lambda_2 \tag{6}$$

subject to

$$C = \sum_j f_j\, y_j + \sum_{i \in \hat{I}} \hat{c}_i\, \hat{t}_i\, \hat{x}_i + \sum_j \sum_{i \in I(j)} \left(\hat{\hat{c}}_j\, \hat{\hat{t}}_j + c_{ji}\, t_{ji}\right) x_{ji} \tag{7}$$

$$E = \sum_{i \in \hat{I}} \hat{e}_i\, \hat{t}_i\, \hat{x}_i + \sum_j \sum_{i \in I(j)} \left(\hat{\hat{e}}_j\, \hat{\hat{t}}_j + e_{ji}\, t_{ji}\right) x_{ji} \tag{8}$$

$$\lambda_1 \le \frac{C^+ - C}{C^+ - C^-} \tag{9}$$

$$\lambda_2 \le \frac{E^+ - E}{E^+ - E^-} \tag{10}$$

$$D_i^- + \mu\left(D_i^0 - D_i^-\right) \le \hat{x}_i + \sum_{\{j: i \in I(j)\}} x_{ji} \le D_i^+ - \mu\left(D_i^+ - D_i^0\right) \;\; \forall i \in \hat{I} \tag{11}$$

$$D_i^- + \mu\left(D_i^0 - D_i^-\right) \le \sum_{\{j: i \in I(j)\}} x_{ji} \le D_i^+ - \mu\left(D_i^+ - D_i^0\right) \;\; \forall i \notin \hat{I} \tag{11'}$$

$$\mu\, y_j \le \frac{U_j^+ - \sum_{i \in I(j)} x_{ji}}{U_j^+ - U_j^-}\, y_j \qquad \forall j \tag{12}$$

$$\mu\, y_j \le \frac{\sum_{i \in I(j)} x_{ji} - L_j^-}{L_j^+ - L_j^-}\, y_j \qquad \forall j \tag{12'}$$

$$\sum_{i \in I(j)} x_{ji} \le U_j^+\, y_j \qquad \forall j \tag{12''}$$

$$0 \le \lambda_1 \le 1; \quad 0 \le \lambda_2 \le 1; \quad \mu_{min} \le \mu \le 1 \tag{13}$$

$$x_{ji}, \hat{x}_i \ge 0 \quad \forall i \in \hat{I} \, \forall j \in I(j) \quad y_j \in \{0,1\} \quad \forall j \tag{14}$$

IV. Solution procedure

In order to solve the above model a Genetic Algorithm (GA) will be used. The GA explores which warehouses are to be opened (binary variables y_j) and, for each individual, a Linear Programming (LP) solver is used to compute the corresponding fitness function selecting is the best customer allocation, using model (6)-(14) with variables y_j fixed (see Fig. 2). Note that, in principle, not every subset of warehouses is feasible, i.e., there is not always enough demand in the area of influence of the warehouses I(j) to cover the minimum flow required to open the facilities as per constraints (12'). Therefore, a check needs to be done previous to calling the optimization software that solves the LP model. In case the candidate warehouses to be opened are seen to lead to an infeasible solution, changes in the

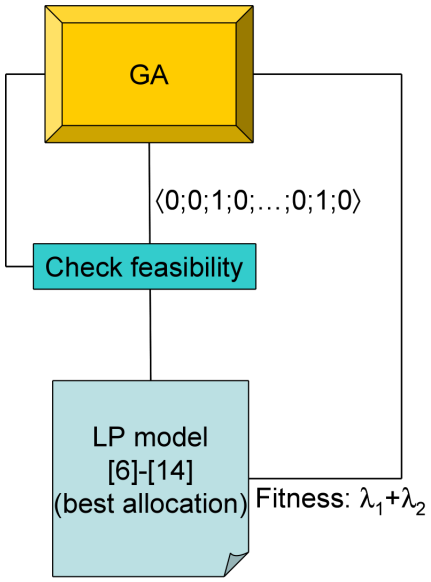

Fig. 1 GA solution procedure solves LP model for fitness evaluation

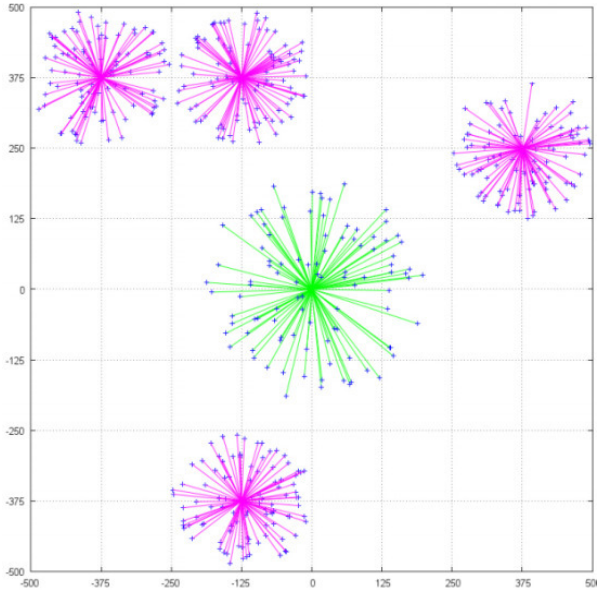

Fig. 2 Example of a priori solution with 4 warehouses

warehouses subset are made until it can be assured there that the LP optimization software will return a feasible solution. This can be seen as a repair operator, which is one of the possible ways of handling constraints in GA.

Since the solution space explored by the GA corresponds to binary variables (y_j) a binary codification of the solution is used, i.e. each chromosome is just a vector of as many components as potential warehouse locations. Each component encode whether a warehouse is open or not. In order to assign a fitness value to an individual a linear solver is used to solve model (6)-(14) also obtaining the complete specification of the solution, including the flows between the central plant and the open warehouses and from these to their allocated customers.

About the crossover and mutation operators, standard binary coding operators have been used, namely the 1-point crossover (1X crossover) and the bitwise mutation. Fitness-proportional selection (i.e. roulette wheel) is used to choose the individuals to cross over. A generational GA is used with a maximum number of generations. An additional stopping criterion consists in a limit on the number of generations without improving the best solution found.

As regards the implementation of the GA, an efficient parallel Python code has been programmed. Although the details of the parallelization strategy is out of the scope of this paper, let us just say that parallel python allows for calculating in parallel of the fitness of all the individuals in initial population as well as of the new individuals created in each generation.

V. Computational Experiments and Results

For testing the good performance of the proposed approach, we have created a testbed of instances, each one with a 7x7 square grid of potential warehouses locations and with the central plant in the middle of the grid. The size of each of the grid cells is 100 km×100 km. The data were created in such a way that we have a clue about which could be the best possible solution, and them we shall check if our procedure is able to find a solution at least as good as that. With that purpose, customers were created locating them around a specific warehouse, forming a kind of cluster. Thus, for example, Fig. 2 shows an instance with four clusters of customers generated around four chosen warehouses. An additional cluster of customers, not in the vicinity of the four chosen warehouses, is also generated, with the expectation that these customers will likely be allocated to the central plant.

Two sets of 20 instances each were created. In the first set 2 warehouses are opened and 4 in the other 4. Therefore, 40 instances were solved and compared with the corresponding a priori "cluster" solution.

For each of the N selected warehouses, a set of (500/N)·4/5 clients in a radius distance of 125 km, all with the same demand, are randomly generated. The other fifth of the warehouse customers were generated out of that neighborhood. Note that there is always a feasible solution since we assume that the central facility can always deliver goods to any client (although at a higher cost). Capacity is assigned to each warehouse in such a way that the defined solution is feasible.

For the two types of vehicles (trucks and vans) cost and emission factors are shown in Table II and include the corresponding corrections to deal with non-full truckloads. The emission factors used correspond to those computed by the LIPASTO model developed by the Technical Research Centre of Finland (VTT) ([6]).

For the GA a population size of 100 was used, mutation probability was set to 0.001, maximum number of generations was 100 but stopping before reaching that limit if 10 generations pass without improving the best solution found.

Comparing the results obtained with the clustered solution from which the instance customer data were generated, it can be seen in Fig. 3 that the GA procedure has been suc-

TABLE III.
COSTS AND EMISSIONS OF TRUCKS AND VANS DEPENDING ON DISTANCE AND LOAD

	Truck	Van	Non-full truck, from central depot, >125km	From warehouse,>125km
c_{ji}	0.00004 €/kg/km	0.00030 €/kg/km		0.00045 €/kg/km
$\hat{c}_i$	0.00004 €/kg/km	0.00030 €/kg/km	0.00006 €/kg/km	
$\hat{\hat{c}}_j$	0.00004 €/kg/km	0.00030 €/kg/km		
e_{ji}	0.0621 gr Eq-CO_2/kg/km	0.0950 gr Eq-CO_2/kg/km		0.1425 gr Eq-CO_2/kg/km
$\hat{e}_i$	0.0621 gr Eq-CO_2/kg/km	0.0950 gr Eq-CO_2/kg/km	0.1425 gr Eq-CO_2/kg/km	
$\hat{\hat{e}}_j$	0.0621 gr Eq-CO_2/kg/km	0.0950 gr Eq-CO_2/kg/km		

cessful in 27 out of the 40 instances (two thirds of the cases) location the warehouses according to the corresponding a priori clustered solution considered. Overall, the fitness of the GA solution (measured by $\lambda_1+\lambda_2$) is 2.2% below that of the a priori clustered solution. Note that as the problem complexity increases (as the number of clusters in the instance increases), it occurs more often (0% in the case of two clusters, 45% in 4 clusters case) that the GA does not find the a priori clustered solution. Different ways to compensate this effect are being studied to make the GA more robust.

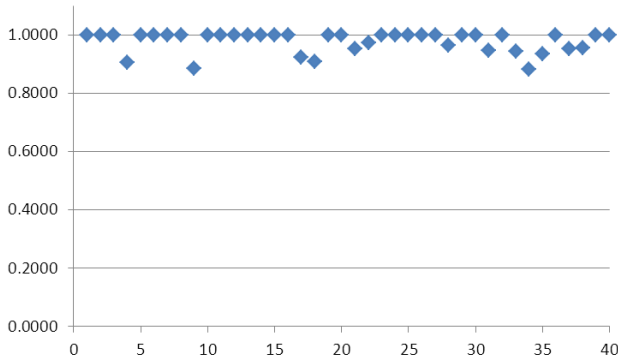

Fig. 3 Ratio between the fitness of the final GA solution and the fitness of the original clustered solution

VI. CONCLUSIONS

This research has proposed a new network design approach that aims not only at cost minimization but also at minimizing GHG emissions from goods transportation. This second objective function will contribute to the sustainability of logistics operations. The decision variables are the selection of the warehouse location (from a set of discrete potential locations) and the allocation of customers to the selected warehouses.

A fuzzy bicriteria optimization model for solving the problem has been formulated and a GA solution procedure has been implemented. The GA explores the space of solutions corresponding to the selection of warehouses to open. A binary codification has been used so that if a potential location is opened the corresponding gene is one and zero otherwise. Standard crossover and mutation operator are used. Since there are both lower and upper bounds on the capacity of the open warehouses, a repair mechanism is needed to guarantee that these constraints hold and that the individual whose fitness is to be evaluated leads to a feasible solution.

A set of experiments have been carried out to check the performance of the procedure, using some instances for which a good reference solution is known a priori. The results indicate that the proposed approach generally finds (or gets close to) this reference solution.

***Abstract*—This paper describes an efficient exact algorithm to solve Preemptive Resource Constrained Project Scheduling Problem (Preemptive RCPSP). We propose a very original and efficient branch and bound procedure based upon minimal interval order enumeration, which involves column generation as well as constraint propagation and which is implemented with the help of the generic SCIP software. We perform tests on the famous PSPLIB instances which provide very satisfactory results. To the best of our knowledge it is the first algorithm able to solve at optimality all the set of j30 instances of PSPLIB in a preemptive way. Moreover, this algorithm allows us to update several best known lower bounds for the j60, j90 and j120 instances of PSPLIB.**

I. Introduction

THIS paper deals with the *Preemptive Resource Constrained Project Scheduling Problem* (RCPSP: see [1], [2]). RCPSP aims at scheduling a set of activities, submitted to precedence and resource constraints, while minimizing the induced *makespan* (total duration of the project) value. The precedence constraints mean that some activities must be completed before others can start. The resource constraints specify that each activity requires constant amounts of renewable resources during all the time it is processed, these resources having limited capacities. This problem has been extensively studied in its non preemptive version ([3], [4]), which means that every activity has to be run as a whole, without any kind of interruption. There exist several variants of RCPSP (see [5], [6] for recent surveys). We talk about Preemptive RCPSP when an activity may be run in several steps: one may launch such an activity, interrupt it, keep on with this activity a little further, and so on. There exists few works on Preemptive RCPSP: [7] developed a branch and bound algorithm, [8] proposed a tree search procedure augmented with pruning rules (best-first tree search), [9] proposed an integer linear program which add preemption penalties, [10] and [11] dealt with preemption in an heuristic way and [12] designed a genetic algorithm for multi mode Preemptive RCPSP.

For the sake of simplicity, authors often assume that all processing times are integral and that preemption only occurs at integer valued dates. Still, one easily checks that such a hypothesis is very restrictive, and only allows to get an approximation of the optimal value of the problem. In this paper, we consider the problem under its most general form and suppose that preemption is allowed for all activities and may occur at arbitrary rational dates, and that no penalties are related to preemption.

Our approach is a Branch and Bound one which involves constraint propagation, as well as the management of specific rational *Antichain* linear program whose variables are associated with subsets of activities which may be simultaneously processed during the schedule. This LP, which was was first introduced by [13], provides us with a lower bound of both Preemptive and Non Preemptive RCPSP. But dealing with it requires implementing a pricing or column generation scheme. It was proved in [14] that if the input RCPSP instance satisfies some ad hoc properties, then any optimal solution of the *Antichain* linear program may be turned into a feasible optimal schedule, without any increase of the *makespan* value. What we do here is to use this property in order to perform a tree search which may be viewed as being embedded into the enumeration process of all minimal extensions of the precedence relation which define *interval* orders. The resulting process happens to be very efficient, since it is able to solve in an exact way all 30 activity instances of the PSPLIB library, and to improve best existing lower bounds for several 60/120 activity instances of this library.

So the paper is organized as follows: we first recall what is Preemptive RCPSP (Section II), and next introduce the theoretical tools related to the *Antichain* LP and to interval orders (Section III), which will provide us with the basis of our algorithmic approach. Section IV describes the algorithm INT-ORD-ENUM and its implementation, and Section V is devoted to a presentation of experimental results.

II. Preemptive RCPSP

An instance $I = (X, K, \ll)$ of the *Resource Constrained Project Scheduling Problem* is defined by:

- A set $X = \{1,...,n\}$ of n *activities*: $\forall\ i \in X$, d_i denotes the *duration* of activity i
- A set $K = \{1,...,m\}$ of m *resources*: $\forall\ i \in X$, $\forall\ k \in K$, r_{ik} denotes the requirement of activity i for resource k; those resources are given back to the system once the activity is over

- $\forall (i,j) \in X^2$, $i \ll j$ means that *i precedes j*: activity *j* cannot start before *i* is over (*Precedence* constraints)

In the case of *Non Preemptive* RCPSP, scheduling only means computing the starting times t_i, $i \in X$, of the activities. A schedule $\sigma = (t_i, i \in X)$ is feasible if it satisfies:

- the *Precedence* constraints;
- the *Resource* constraints: at any time *t* during the process, and for any resource *k*, the sum $\sum_{i \in Act(\sigma,t)} r_{ik}$ does not exceed the global resource amount R_k, $Act(\sigma, t) = \{i$ such that $t_i < t < t_i + d_i\}$ denoting the set of the activities currently run at time *t* according to schedule σ.

So, solving *Non Preemptive* RCPSP means computing σ with a minimal *makespan* (total duration of the process).

In case preemption is allowed, scheduling an activity *i* means first decomposing *i* into a sequence of sub-activities $i_1, .., i_{h(i)}$, with durations $d_{i,1},.., d_{i,h(i)}$, such that: $\sum_{q = 1..h(i)} d_{i,q} = d_i$, and next scheduling all these sub-activities in the sense of standard RCPSP. Since there does not exist any "a priori" restriction either on the number of sub-activities or on their durations, which may be arbitrarily small, the existence of an optimal solution of Preemptive RCPSP has to be discussed.

III. Fundamental tools

A. The Antichain Linear Program: A Lower Bound

Let $I = (X, K, \ll)$ be some Preemptive RCPSP instance, defined according to notations of Section II. We suppose (we clearly may do it) that precedence relation $\ll$ is transitive. Then we define an *antichain* as being any subset *a* of X such that there does not exist $(i,j) \in a^2$ such that $i \ll j$. We say that such an antichain is *valid* if: $\forall k \in K, \sum_{i \in a} r_{ik} \leq R_k$.
It comes that a subset $a \subseteq X$ of activities is a *valid antichain* iff activities in *a* may be simultaneously run inside some feasible schedule. We denote by A the set of all *valid antichains*.

Then we become able to set the following linear program, which we call *Antichain Linear Program* associated with Preemptive RCPSP instance $I = (X, K, \ll)$, which was already introduced in [13, 14], and which we denote by $(\mathsf{P})_{\mathsf{Ant}}$:

$$(\mathsf{P})_{\mathsf{Ant}} \quad \begin{array}{l} \text{Minimize } \sum_{a \in \mathsf{A}} z_a \\ \text{Subject to} \\ \quad \forall i \in X, \quad \sum_{a \in \mathsf{A} \mid i \in a} z_a = d_i \\ \quad \forall a \in \mathsf{A}, \quad z_a \geq 0 \end{array} \qquad \text{(C1)}$$

Explanation: if σ is any feasible schedule related to instance *I*, we may associate with σ and with any valid antichain *a*, the total amount of time $z(\sigma)_a$ during which the activities which are simultaneously run according to σ are exactly the activities of *a*. Then we see that $z(\sigma) = (z(\sigma)_a, a \in \mathsf{A})$ is a feasible solution of $(\mathsf{P})_{\mathsf{Ant}}$ since constraints (C1) express the fact that any activity *i* has to be completely done, or, equivalently, that the duration of all antichains containing *i* must be equal to the duration of *i*. It comes that the optimal value of $(\mathsf{P})_{\mathsf{Ant}}$ provides us with a lower bound of the optimal value of *I*, which we denote by *LB*(*I*).

B. Dealing with $(P)_{Ant}$: Column generation

Since the set A may be very large, even when the activity set *X* is small, we need to handle the *Antichai*n LP $(\mathsf{P})_{\mathsf{Ant}}$ through *column generation*. Column generation is an usual technique to solve a LP which contains an exponential number of variables. It consists in initializing this LP with a few number of *active* variables (which may be obtained from application of some heuristic), and then in iteratively solving the induced *restricted problem* at optimality and using the dual variables to generate a new improving primal variable. The search for this improving primal variable is called the related *Pricing* Problem. The new variable is added to the restricted problem and the process goes on until no improving variable can be found: then the solution of the restricted problem is the optimal solution. When this technique is associated to a Branch and Bound process (usually for integer formulation) it gives rise to a *Branch and Price* process. In our case, let us consider some active antichain subset $B \subseteq \mathsf{A}$, together with some dual solution λ of the restricted LP $(\mathsf{P})^B_{\mathsf{Ant}}$ defined by (we suppose that *B* is such that this program admits a feasible solution):

$$(\mathsf{P})^B_{\mathsf{Ant}} \quad \begin{array}{l} \text{Minimize } \sum_{a \in \mathrm{B}} z_a \\ \text{Subject to} \\ \quad \forall i \in X, \quad \sum_{a \in B \mid i \in a} z_a = d_i \\ \quad \forall a \in \mathrm{B}, \quad z_a \geq 0, \end{array} \qquad \text{(C1)}$$

Then solving the related pricing problem PRICE(λ) means computing some valid antichain *a*, such that:

$$\sum_{i \in a} \lambda_i > 1.$$

Though this problem is NP-Complete, it may be efficiently handled through a combination of greedy search and Integer Linear Programming (LIP). A well-fitted LIP formulation of the PRICE(λ) problem comes as follows:

Pricing LIP Formulation L-PRICE(λ)

$$\begin{array}{l} \text{Maximize } \sum_{i \in X} \lambda_i y_i \\ \text{Subject to} \\ \quad \forall (i,j) \in X^2 \mid i \ll j, \quad y_i + y_j \leq 1 \qquad \text{(C2)} \\ \quad \forall k \in K, \ \sum_{i \in X} r_{ik} y_i \leq R_k \qquad \text{(C3)} \\ \quad \forall i \in X, \ y_i \in \{0,1\} \end{array}$$

C. Turning a Solution of $(P)_{Ant}$ into a Feasible Schedule ?

Unfortunately, Linear Program $(\mathsf{P})_{\mathsf{Ant}}$ only provides us with a lower bound of Preemptive RCPSP instance *I*: if vector $z = (z_a, a \in \mathsf{A})$ is a feasible solution of $(\mathsf{P})_{\mathsf{Ant}}$, it may not be possible to turn it into a feasible solution of *I*. As a matter of fact, we may provide the valid antichain set A with an oriented graph structure $(\mathsf{A}, E_{<<})$ by setting that there exists an arc $(a, b) \in E_{<<}$ from antichain *a* to antichain b, if there exist activities $i \in a$ and $j \in b$, such that $i \ll j$.

Then we easily check that:

Theorem 1: *Let z be some feasible solution of* $(\mathsf{P})_{\mathsf{Ant}}$, *and* $\mathsf{A}(z) \subseteq \mathsf{A}$ *be the set* $\mathsf{A}(z) = \{a \in \mathsf{A}$ *such that* $z_a \neq 0\}$ *of active*

antichains according to z. Then there exists a feasible schedule σ such that z = z(σ) if and only if the subgraph (A(z), $E_{<<}$) does not contain any circuit.

Proof: Left to the reader.

Still, we may notice that program $(P)_{Ant}$ provides us with additional understanding of Preemptive RCPSP: if σ is any feasible Preemptive RCPSP schedule, if $z(\sigma) = (z(\sigma)_a, a \in A)$ is the related solution of $(P)_{Ant}$, and if $A(z(\sigma))$ is the related active antichain set, then one sees that solving the restricted linear program $(P)^{A(z(\sigma))}_{Ant}$ through Primal Simplex Algorithm provides us with another feasible schedule σ* with makespan no larger than the makespan of σ. Moreover, Linear Programming Theory tells us that the number of active antichains related to σ*, that means the cardinality of $A(z(\sigma^*))$ does not exceed the number of constraints of $(P)^{A(z(\sigma))}_{Ant}$, which is equal to the cardinality of the activity set *X*. This makes appear Preemptive RCPSP as a combinatorial problem related to the search of some acyclic subgraph (*B*, $E_{<<}$) of the antichain graph (*A*, $E_{<<}$), such that:

- Card(*B*) ≤ Card(*X*);
- The optimal value of the program $(P)^{B}_{Ant}$ is minimal.

This confirms the existence of an optimal solution.

Also, we may notice that no activity which is not in the set *Min*(*X*) of the activities which are minimal in the sense of the precedence relation ≪, may start before the time when at least one activity in *Min*(*X*) is completed. We deduce that the lower bound which derives from the resolution of the $(P)^{A}_{Ant}$ program may be improved by adding the following constraint to $(P)^{A}_{Ant}$:

$\sum_{a \in A\text{-}Min} z_a \geq \text{Inf}(d_i,\ i \in Min(X))$, with *A-Min* = {$a \in A$, such that $a \subseteq Min(X)$}.

We denote by *LB**(*I*) this improved lower bound.

D. Interval Orders

A partially ordered set (*Z*, <) is an *interval order* if the elements *z* of *Z* may be represented as closed intervals [*o*(*z*), *d*(*z*)] of the real line, in such way that, for any pair *z*, *z*' in *Z*:

- *z* < *z*' if and only if *d*(*z*) < *o*(*z*').

It is known (see [20]), that the partially ordered set (Z, <) is an interval order if and only if there does not exist *x*, *y*, *z*, *t* ∈ Z such that:

- *x* < *y* and *t* < *z*; (C4)
- there does not exist any other pair *u* < *v* with *u*, *v* ∈ {*x*, *y*, *z*, *t*} than the pairs in (C4) above.

Figure 1 below shows the forbidden pattern associated with interval orders:

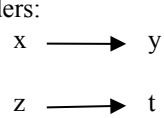

Fig. 1: Interval order forbidden pattern

If we consider now our Preemptive RCPSP instance *I* = (*X*, *K*, ≪), we see that:

Theorem 2: *If the partial order (X, ≪) is an interval order, then the oriented antichain graph (A, $E_{<<}$) is acyclic (does not contain any circuit).*

Proof: We suppose the converse, and consider some circuit Γ in (*A*, $E_{<<}$) with minimal length. Then we must distinguish two cases:

- *first case*: Length(Γ) = 2, which means that Γ contains two antichains *a* and *b*. Then we see that there must exist $i_1, j_2 \in a$, $i_2, j_1 \in b$ such that: $i_1 \ll j_1$ and $i_2 \ll j_2$. Then it becomes easy to check that i_1, j_1, i_2, j_2 define a forbidden pattern in the above sense, which induces a contradiction.
- *second case*: Length(Γ) ≥ 3, which means that Γ contains 3 consecutive antichains *a*, *b*, *c*, and that there must exist $x \in a$, y, $z \in b$, $t \in c$, such that $x \ll y$ and $z \ll t$. But we also deduce from the minimality of Length(Γ) and from the fact that *a*, *b*, *c* are antichains that *x*, *y*, *z*, *t* must define a forbidden pattern in the above sense, which induces again a contradiction. **End-Proof**.

This result will impact in a very significant way the design of the algorithm which will be presented in the next section. Clearly, if σ is a feasible schedule for the Preemptive RCPSP instance *I* = (*X*, *K*, ≪), it is possible to extend the precedence relation ≪ into an interval order $\ll_\sigma$, in such a way σ remains consistent with $\ll_\sigma$. In order to do it, we only need to set, for any activity pair *i*, *j* in *X*:

- *i* ≪* *j* iff End-Time(*i*) ≤ Start-Time(*j*).

Putting this last remark and Theorem 2 together makes appear that we only need, in order to deal with the Preemptive RCPSP instance *I*, to enumerate the extensions ≪* of the order relation ≪ which are interval orders. As a matter of fact, we may restrict ourselves to those extensions ≪* which are minimal for inclusion, that means which are such that there does not exist any extension ≪' of ≪ which is an interval order and which is such that: ≪' ⊂ ≪*, ≪' ≠ ≪*. So, next section is devoted to an accurate description of the way this enumeration process is performed.

IV. THE BRANCH/BOUND ALGORITHM INT-ORD-ENUM

A. A Reformulation of Preemptive RCPSP Instance I

Sections II and III lead us to reformulate Preemptive RCPSP instance *I* = (*X*, *K*, ≪) as follows:

> **Preemptive RCPSP Reformulation**: Compute an extension ≪* of the precedence relation ≪ which is an interval order and which is such that, if *z** is an optimal solution of the related LP $(P)_{Ant}$, obtained through Primal Simplex Algorithm and column generation, the optimal value 1.*z** is the smallest possible.

Remark: Clearly, program $(P)_{Ant}$ must be understood here with respect to ≪*and to the related *Antichain* set $A^* \subseteq A$.

So, our algorithm INT-ORD-ENUM is a Branch/Bound algorithm, which performs some enumeration of the exten-

sions $\ll^*$ of $\ll$. We must now specify the main components of such a tree search process, which are about:

- the extensions of Preemptive RCPSP instance $I = (X, K, \ll)$ which define the nodes of the related search tree;
- the way branching is performed;
- the way bounding and related filtering are performed;
- the way constraint propagation is performed;
- the branching strategy;
- the way the whole algorithm is implemented.

B. The Nodes of the INT-ORD-ENUM Search Tree

A node of the search tree induced by a branch/bound algorithm is usually defined by a set of additional constraints imposed to the initial problem. In the case of the Preemptive RCPSP instance $I = (X, K, \ll)$, those constraints are:

- additional precedence constraints $i \ll j$;
- *anti-precedence* constraints $i \dashrightarrow j$: $i \dashrightarrow j$ means that $i \ll j$ is forbidden.

So, we may identify any node of the search tree with a pair $(Add_{\ll}, Add_{\dashrightarrow})$, where $Add_{\ll}$ and $Add_{\dashrightarrow}$ are respectively the sets of additional precedence constraints and anti-precedence constraints which constrain $\ll^*$ as follows:

- $(\ll \cup Add_{\ll}) \subseteq \ll^*$;
- $(Add_{\dashrightarrow} \cap \ll^*) = \text{Nil}$.

Explanation of the *anti-precedence* constraints: it must be understood that those constraints have sense only with respect to the reformulation of subsection IV.*A*. That means that they are not going to play any role either with respect to an eventual feasible schedule or with respect to the program $(\mathsf{P})_{\mathsf{Ant}}$, but that they only will impact the way additional precedence constraints may be added to the initial ones.

Clearly, if current order relation happens to define an interval order, the related node is a terminal node (a leaf).

C. The Branching Mechanism

If current precedence relation, which is managed in such a way it always remains transitive, is not an interval order, then it must contain some forbidden pattern i_1, j_1, i_2, j_2:

- $i_1 \ll j_1$ and $i_2 \ll j_2$; (C5)
- no other pair $u \ll v$ exists with $u, v \in \{ i_1, i_2, j_2, j_1\}$ than the pairs in (C5) above.

This forbidden pattern allows us to perform a binary branching process by successively considering the 2 following alternatives:

- 1 th alternative (1 th son): insert $i_1 \ll j_2$ into $Add_{\ll}$;
- 2 th alternative (2 th son): insert $i_2 \ll j_1$ into $Add_{\ll}$ and insert $i_1 \dashrightarrow j_2$ into $Add_{\dashrightarrow}$;

D. Lower Bound, Upper Bound and Related Filtering

Lower Bound: The lower bound which derives from a current node defined by a pair $(Add_{\ll}, Add_{\dashrightarrow})$, is provided by the optimal value of the program $(\mathsf{P})_{\mathsf{Ant}}$, where valid antichains are considered as deriving from $(\ll \cup Add_{\ll})$. This problem is handled through column generation, as explained in Section III.*C*, and the Pricing problem PRICE(λ) is handled while using the ILP model of Section III.*C*. Every column which has been generated at some time during the process is kept into memory.

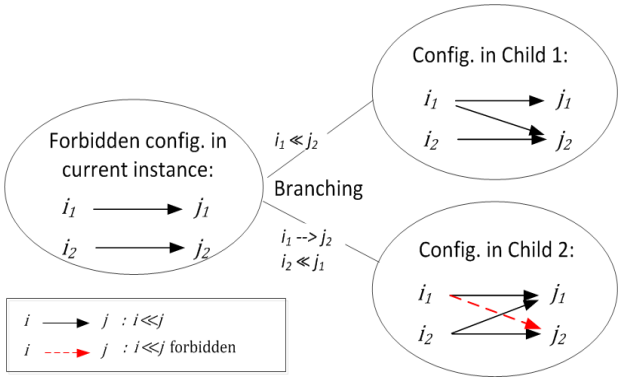

Fig. 2: the Branching Mechanism

Upper Bound: Also, we make in such a way that we are provided, as part of a pretreatment, with an initial upper bound *UB*: in order to get this initial upper bound, we apply to instance *I*, a greedy randomized algorithm designed for the Non Preemptive RCPSP (see [19]) and which, in case of 30 activity PSPLIB instances, approximates the optimal Non Preemptive RCPSP optimal value by less than 2% in average. Of course, *UB* is updated as soon as some feasible solution is computed by the INT-ORD-ENUM search process.

Related Filtering: Of course, if the optimal solution z^* of LP $(\mathsf{P})_{\mathsf{Ant}}$, is such that the subgraph $(A(z^*), E_{\ll})$ does not admit any circuit, we consider that we have been reaching some terminal node of the search tree. In case related value $1.z^*$ is smaller than the value of the current solution (current upper bound *UB* of the forthcoming section IV.*E*, we update this current solution as a feasible schedule σ such that $z^* = z^*(\sigma)$. We notice that it is sufficient to consider the subgraph $(A(z^*), E_{\ll})$ as defined with respect to initial precedence relation $\ll$, since our goal is to make possible turning a solution of $(\mathsf{P})_{\mathsf{Ant}}$, into a feasible schedule in the sense of initial precedence relation $\ll$.

E. Constraint Propagation

We apply several kind of inference rules $\alpha \models \beta$, whose semantics come as follows:

- α (precondition part) denotes constraints which are already associated with current node *S* of the three search;
- β (consequent part) denotes the additional relations which have to inserted into sets $Add_{\ll}$ and $Add_{\dashrightarrow}$..

The first class of rules deals with transitivity, and makes in such a way that, at any time during the process, current relation $\ll^* = (\ll \cup Add_{\ll})$ remains transitive:

Rule 1: $i \ll^* j, z \ll^* i \models z \ll^* j$;
Rule 1': $i \ll^* j, j \ll^* z \models i \ll^* z$;

Of course, any relation $i \ll^* i$ induces a *Failure* signal.

The second one deals in a classical way with largest paths and current upper bound *UB*. We add two dummy activities: *s* (source) and *p* (sink) defined as usual and, at every time

during the process, we are provided, for every activity i, with:

- $\pi(i)$ = earliest finish time for i, which means the length of a largest path from s to i;
- $\Pi(i)$ = the length of the largest path between the beginning of i and p: $\Pi(i)$ = UB - LS(i) where LS(i) is the latest starting time f*or i*

Doing this allows us to implement the following classical inference rules, which tend to keep the current precedence relation ($\ll \cup Add_{<<}$) from inducing the existence of a largest path with length $\geq UB$:

Rule 2: $\pi(i) = \alpha$, $i \ll * y$ *and* $\alpha+d_y > \pi(y) \models \pi(y) = \alpha+d_y$;

Rule 2': $\Pi(i) = \alpha$, $y \ll * i$ *and* $\alpha+d_y > \Pi(y) \models \Pi(y) = \alpha+d_y$;

Rules 2 and 2' update values $\pi(y)$ and $\Pi(y)$, $y \in X$, as soon as necessary. Of course, the existence of any path with length $\geq UB$ induces a Failure signal.

Rule 3: $\pi(i) = \alpha$, $\alpha + \Pi(y) > \text{UB} \models i$ ---> y ;

Rule 3': $\Pi(i) = \alpha$, $\alpha + \pi(y) > \text{UB} \models y$ ---> i;

Rules 3 and 3' forbid any additional precedence relation which would induce the existence of a largest path with length $\geq UB$ to be inserted into $Add_{<<}$.

Rule 4: $\pi(i) = \alpha$, $UB - \Pi(y) + d_y \leq \alpha - d_i \models y \ll * i$;

Rule 4': $\Pi(i) = \alpha$, $UB - \alpha + d_i \leq \pi(y) - d_y \models i \ll * y$;

Rules 4 and 4' insert into $Add_{<<}$. additional precedence relations which should be satisfied in any schedule with makespan no more than UB.

The last class of rules deals with the forbidden patterns of Section III.*D*, and aims at keeping current relation ($\ll \cup Add_{<<}$) from containing any such a pattern:

Rule 5: $i \ll * j$, $z \ll * t$ *and* z ---> $j \models i \ll * t$;

Rule 5': $i \ll * j$, $t \ll * z$ *and* i ---> $z \models t \ll * j$;

Rule 6: i ---> j, $z \ll * j$ *and* $i \ll * t \models z \ll * t$;

Rule 6': i ---> j, $i \ll * z$ *and* t ---> $z \models t$ ---> j.

We see here the true role of constraints i ---> j, which help us in inserting additional precedence constraints into the $Add_{<<}$ set, with a strong impact on the antichain set $A*$ and on the optimal value of the related linear program $(P)_{Ant}$,. Of course, any time such a pattern appears, it induces a Failure signal.

F. Branching Strategy

We described in IV.*B* the Branching mechanism, which relies on the extraction of some forbidden pattern i_1, j_1, i_2, j_2:

- $i_1 \ll j_1$ and $i_2 \ll j_2$; (C5)
- no other pair $u \ll v$ exists with $u, v \in \{ i_1, i_2, j_2, j_1\}$ than the pairs in (C5) above.

Since it is known that the way branching parameters are chosen is a critical issue as soon as Branch/bound and constraint propagation are performed. So we must now specify the strategy which is used here in order to compute a well-fitted 4-uple i_1, j_1, i_2, j_2.

As a matter of fact, we apply here the well-known "most constraint variable" principle, and focus on the shortest circuits of the subgraph (A(z*), $E_{<<}$) and on the antichains in A(z*) which are the most involved in those circuits.

As told in Section IV.*D*, branching has to be performed only if there exists some circuit in the subgraph (A(z*), $E_{<<}$), where z* is the optimal solution of the LP $(P)_{Ant}$, solved after constraint propagation has been performed. Then we distinguish two cases:

- **First case**: there exists a circuit with length 2. In such a case, circuits with length 2 define in a natural way a non oriented graph (A(z*), F) on the set A(z*): two antichains a, a' in A(z*) define an edge of this graph if they also define a circuit of the oriented graph (A(z*), $E_{<<}$), We consider an antichain a_0 which is with maximal degree $D_F(a_0)$ in the graph (A(z*), F), together with some antichain a_1, with maximal degree $D_F(a_1)$ among the F-neighbours of a_0. Then we derive the forbidden pattern i_1, j_1, i_2, j_2, according to the proof of Theorem 2 in Section III.*D* and to Figure 3 (a).
- **Second Case**: there does not exist any circuit with length 2. Then we compute the largest strongly connected component A_0 of the oriented graph (A(z*), $E_{<<}$), together with the antichain a_0, which is such that:
  - There exists at least one pair a_1, a_2, such that (a_1, a_0) and (a_0, a_2) are in the arc set $E_{<<}$, while (a_1, a_2) $\notin E_{<<}$;
  - The sum $D^-_F(a_0) + D^+_F(a_0)$ of the inner and outer degrees of a_0 in the subgraph (A_0, $E_{<<}$) induced from by A_0 is maximal.

Finally we compute some circuit Γ which contains a_0 as well as a_1, a_2 above and which is with minimal length, and we derive the forbidden pattern i_1, j_1, i_2, j_2, according to the proof of Theorem 2 in Section III.*D* and to Figure 3 (b).

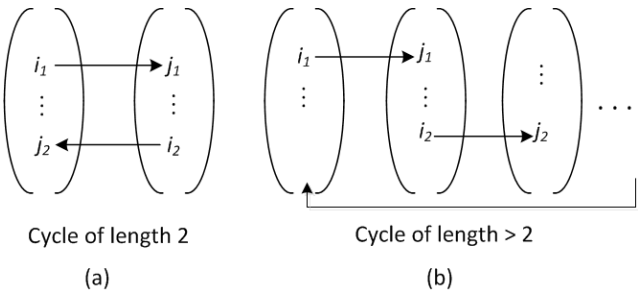

Fig. 3: Extracting a forbidden pattern

G. Implementation

The global Branch/bound algorithm INT-ORD-ENUM Branch/Bound is implemented according to a Breadth First Search strategy which may be summarized as follows:

***INT-ORD-ENUM** Algorithmic Scheme*.

1. **Pretreatment**: Compute a feasible Non Preemptive RCPSP schedule σ, while using a greedy randomized insertion flow heuristic as in [19]. Derive an upper bound UB, together with an initial antichain subset $B \subset A$, such that the linear program $(P)^B_{Ant}$ admits a feasible solution; Initialize the breadth search node list L as the list {($Add_{<<}$ = Nil, $Add_{--->}$ = Nil)};

2. **Main Process: Breadth First Tree Search**.
   Let L be the current node list, ordered according to LP $(\mathsf{P})^{B}_{\mathsf{Ant}}$ related values, and S be the first node in L; S is defined by two additional constraint sets $Add_{<<}$ and $Add_{--->}$; Delete S from L; Perform Constraint Propagation and extend $Add_{<<}$ and $Add_{--->}$; If *Failure* then go back to 2. Else go to 3.;
3. Solve the LP $(\mathsf{P})^{B}_{\mathsf{Ant}}$ related to S through column generation and test the oriented graph $(A(z^*), E_{<<})$ deriving from the obtained optimal solution z^*; If $1.z^* \geq$ UB then go to 2. Else go to 4.;
4. If the graph $(A(z^*), E_{<<})$ is acyclic then derive from z^* a feasible schedule σ, update the upper global bound UB and go back to 2. Else go to 5.;
5. Compute branching parameters i_1, j_1, i_2, j_2, according to Section IV.*F* and create both related children:
   - 1 th son: insert $i_1 << j_2$ into the set $Add_{<<}$;
   - 2 th son: insert $i_2 << j_1$ into the set $Add_{<<}$; and i_1 ---> j_2 into the set $Add_{--->}$;

   Insert those two children nodes in L, according to their related LP $(\mathsf{P})^{B}_{\mathsf{Ant}}$ value; Go back to 2.;

Process ends as soon as the LP value related to the first element of S is no smaller than UB. Then current value UB provides the optimal makespan value;

This algorithm is implemented in C++, and linear programs $(\mathsf{P})^{B}_{\mathsf{Ant}}$ and *L-PRICE(λ)* are handled by CPLEX.12 linear solver. But the global INT-ORD-ENUM process is embedded into the SCIP framework for branch cut and price algorithms [16]. The SCIP framework consists in a template library which implements through breadth first search generic branch and bound schemes involving Linear Programming together with pricing scheme. In the present case, what we mainly had to do was providing the C++ procedures which performed, for every node S, the construction of the $(\mathsf{P})^{B}_{\mathsf{Ant}}$ and *L-PRICE(λ)* programs, the constraint propagation process and the branching strategy, and assembly them inside SCIP.

H. An Example

Let us consider an instance of 6 activities and 1 resource. Each activity has a duration equal to 1 and a resource requirement equal to 1. The precedence constraints are given by the following precedence graph:

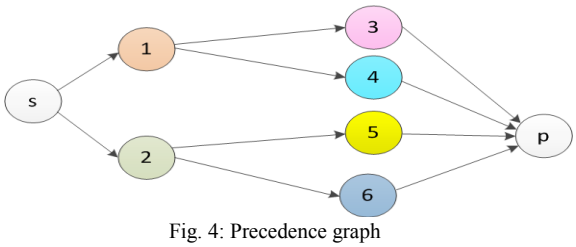

Fig. 4: Precedence graph

We initialize the set of antichains with the 6 singleton antichains. The tree constructed by our method and the branching decisions are given as below:

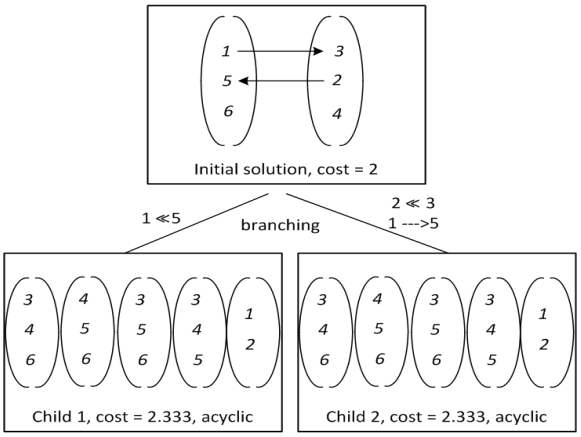

Fig. 5: Solving instance of figure 4

The resulting optimal solution is given according to the following Gantt chart.

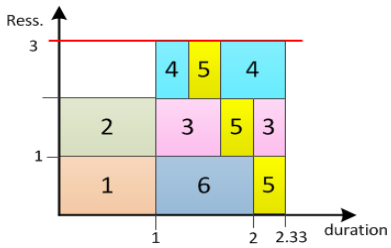

Fig. 6: Gantt chart of optimal preemptive solution

V. Numerical Experiments

Experiments were carried on in C++, on linux CentOS proc. Intel(R) Xeon(R) 2.40GHz. The instances which we used were PSPLIB instances ([17]).

Our main achievement here was to solve in an exact way and in a rather short time (never more that 95 CPU seconds) Preemptive RCPSP on all 30 activity instances of the PSPLIB library, which had been, until now, never done. This first experiment is described in coming section V.*A*.

Also, we could get an evaluation of the bounding process related to linear program $(\mathsf{P})^{B}_{\mathsf{Ant}}$, and check that in average, $LB(I)$ approximates the optimal Non Preemptive RCPSP optimal value by less than 6%. By the same way, we checked that the augmented lower bound $LB^*(I)$ hardly improve $LB(I)$ by less than 0.5%.

Finally, though we were not able to handle in an exact way all 60/120 activity instances of the PSLIB library, we could derive from the instances which we were able to handle new lower bounds for several Non Preemptive RCPSP instances of the PSPLIB library. This second part of the experiment will be described in Section V.*B*.

A. Exact results on j30

The columns of table I have the following meaning:

- *No Preemp. opt*.: optimal value for non preemptive RCPSP (available in PSPLIB website)
- *Preemp. opt*.: optimal for preemptive RCPSP (our results)
- *#nodes*: number of nodes created (0 means optimal value was found by heuristic in preprocessing and prooved to be optimal by the first constraint propagation)
- *cpu* (*s*): cpu time in seconds

TABLE I
RESULTS ON J30 INSTANCES OF PSPLIB

	No Preemp. opt.	*Preemp. opt.*	*#nodes*	*cpu*(s)
Mean	58.99	58.07	72.73	2.04
Min	34.00	34.00	0.00	< 0.1
Max	129	129	2130	94.11
std dev.	14.09	13.80	214.87	8.03

B. Comparative Analysis of LB(I), MB(I)*

The following table II provides us with average values for the 480 instances of PSPLIB with 30 activities:

TABLE II: EVALUATION OF THE BOUND *LB*(*I*)

Mean LB(*I*)	*Mean LB**(*I*)	*Mean Premp. opt.*	*Mean No Premp. opt.*
56.73	56.79	58.07	58.99

Remark: in almost 50% of the cases (exactly 236 instances among 480), the values *LB*(*I*), *Premp. Op*. and *No Premp*. *Opt*. coincide.

C. New best lower bounds

Our method gives new best lower bound for j60, j90 and j120 instances (in a limit of time of 3 hours).

The columns of table III have the following meaning:

- *best No preemp. UB*: best known upper bound for no preemptive RCPSP (available in PSPLIB website)
- *Preemp. LB*: lower bound for preemptive RCPSP (our method)
- *deduced no preemp. LB:* lower bound for no preemptive RCPSP which we deduce from *Preemp. LB*
- *Best known LB:* the best known lower bound currently available in PSPLIB website and updated with the recent results of [18].

TABLE III
NEW BEST LOWER BOUNDS

instance	best no preemp. UB	Preemp. LB	deduced no preemp. LB	Best known LB
j6013_1.sm	112	106.41	107	105
j6029_2.sm	133	126.20	127	123

j12056_3.sm	241	222.12	223	220
j12056_4.sm	222	206.62	207	205
j12056_5.sm	280	261.80	262	261
j12056_7.sm	283	263.29	264	260
j12056_8.sm	289	268.04	269	265
j12056_9.sm	288	266.34	267	264

VI. CONCLUSION

Our method is very efficient. Besides exactly solving small size Preemptive RCPSP instances, it is also able to provide us with very good lower bounds for larger scale Non Preemptive RCPSP. We are looking for adapting this method to the non preemptive RCPSP.

***Abstract*—In this paper the capacitated vehicle routing problem with time windows is tackled with a beam-search based approximate algorithm. An instance of this problem is defined by a set of customers and a fleet of identical vehicles. A time window is associated with each customer and a maximum capacity characterizes a vehicle. The aim is then to serve all the customers by minimizing the number of vehicles used as well as the total distance and by respecting the time windows.**

The proposed method follows three complementary phases: (i) dividing the set of customers into disjunctive clusters, (ii) determining a feasible solution in each cluster by using beam search, and (iii) applying a local search in order to improve the quality of the solutions. The proposed method is analyzed computationally on a set of benchmarks due to Solomon. Encouraging results have been obtained.

I. Introduction

THE *Vehicle Routing Problem* (VRP) is well known and well studied in the literature. It consists, in its simplest version, to visit or deliver a set $N = \{1, ..., n\}$ of customers by using a fleet of m vehicles $V = \{v_1, ..., v_m\}$. The objective is often to minimize the number of vehicles m as well as the sum of distances traveled by these ones. Note that if $m = 1$ then the problem becomes the *Traveling Salesman Problem* (TSP). Is some cases, a time window $W_i = [e_i, l_i]$ is associated to customer i, where e_i is the earliest time to begin the service of this customer and l_i the latest time. Parameters e_i and l_i are also known as *ready time* and *due date* respectively. The aforementioned problem is known as the *Vehicle Routing Problem with Time Windows* (VRPTW). A service time s_i can be associated with customer i, this means that the arrival time at this customer must be at most $l_i - s_i$. Furthermore, each customer $i, i \in N$ has a demand d_i and a capacity may be associated with each vehicle denoting the maximum of the sum of quantities that can be put inside the corresponding vehicle. Such a problem is called *Capacitated VRPTW* (CVRPTW).

VRP was addressed by many authors and several methods and strategies were proposed to solve its different versions. These methods can be categorized into two categories: exact methods and approximate ones. In the first category, Azi et al. [3] proposed an exact algorithm, based on column generation and branch-and-price, to solve VRPTW including multiple use of vehicle, i.e., a given vehicle may be associated with several routes. The same authors [2] proposed, several years before, another exact algorithm for a single vehicle routing problem with time windows and multiple routes. Baldacci et al. [4] employed branch-and-price in order to solve a capacitated vehicle routing problem (CVRP) by using an integer programming formulation. New lower bounds were presented and an algorithm to find the optimal solution for CVRP was given. Baldacci and Maniezzo [5] proposed exact methods based on node-routing formulations to tackle the undirected arc-routing problems. Feillet et al. [11] developed an exact algorithm for the elementary shortest path problem with resource constraints where the authors indicated an application to some vehicle routing problems.

The second category of methods consists to search for approximate solutions by using essentially heuristics and metaheuristics. Solomon [19] proposed different algorithms in order to solve the vehicle routing and scheduling problems with time window constraints. A two-stage heuristic including ejection pools was for example proposed by Lim and Zhang [14] in order to tackle VRPTW. Chen et al. [9] proposed a heuristic that combines mixed integer programming and a record-to-record travel algorithm in order to solve approximately the *split delivery vehicle routing problem*, a variant of CVRP where a customer may be served by more than one vehicle. Tan et al. [22] proposed several heuristic methods, including simulated annealing, to solve VRPTW . Insertion heuristics were proposed by Campbell and Savelsbergh [7] for vehicle routing and scheduling problems. Chao et al. [8] proposed a fast heuristic for the orienteering problem, i.e., a vehicle routing problem where a profit is associated with each customer and the objective is to visit a subset of customers in order to maximize the total benefit and by respecting some constraints. Pisinger and Ropke [16] developed a general heuristic for vehicle routing problems able to solve five different variants of VRP, including CVRP and VRPTW. A genetic algorithm

978-83-60810-53-8/$25.00

was proposed in [12], [21], and [17] for the VRPTW. Ant colony optimization is very effective and was adapted for the various variants of VRP (see for example [13] where the *open vehicle routing problem* was considered). Finally, tabu search was considered by Cordeau et al. [10] for solving VRPTW and by Brandão and Mercer [6] for solving the multi-trip vehicle routing and scheduling problem, i.e., the case where a vehicle may perform several trips.

In this work, we propose a three-phase algorithm for solving CVRPTW. The first phase consists to divide the set of customers into m clusters. After that, at phase 2, the shortest path that visits each customer once in each cluster is computed by using beam search. Each path must verify the problem constraints, i.e., must not violate the time window. In the third and last phase, a local search is applied on the solution in order to try to decrease the total distance traveled by the m vehicles.

II. Problem Statement and Mathematical Formulation

The problem to solve (CVRPTW) consists to visit n customers $i \in N = \{1, ..., n\}$, where each customer (or *vertex*) has coordinates (x_i, y_i) in the Euclidean plan. The float used contains m identical vehicles $V = \{v_1, ..., v_m\}$, each with the same maximal capacity $C_{\max}$. All the vehicles start their travel at the *depot* D, whose coordinates are (x_D, y_D) in the Euclidean plan, visit a set of distinct customers, and returns to the depot.

In addition, a demand d_i is associated with each customer $i \in N$, d_i has the same unit of measurement as the vehicle capacity, this may be a volume or a weight for example. Customer i must be served at time t_i that may be the earliest time after its ready time (e_i) and no later than its due date l_i, this corresponds to the time window $W_i = [e_i, l_i]$ associated with customer i ($l_i - e_i$ is called the *width* of the time window). A service time s_i is also defined for customer i and is equal to the time spend to serve the customer.

Each vehicle $v_j, 1 \leq j \leq m$ performs then a route R_j by visiting a number of customers or vertices. These ones correspond to a cluster denoted by $\mathcal{C}_j$. Let also denote by $\mathcal{D}_j$ the sum of distances covered by vehicle v_j. Note that the distance between to customers i and j, denoted by $dist_{ij}$ corresponds to the euclidean distance between these two points, i.e., $dist_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}$.

CVRPTW can then be formulated as follows:

$$\min\ m \tag{1}$$

$$\min \sum \mathcal{D}_j,\ 1 \leq j \leq m \tag{2}$$

subject to

$$\sum_{i \in C_j} d_i \leq C_{\max},\ \ \forall i \in C_j \tag{3}$$

$$t_i \in W_i = [e_i, l_i]\ \ \forall i \in N \cup \{D\} \tag{4}$$

Equation 1 represents the first objective to minimize, that is the number of vehicles to use. Equation 2 is the second objective to minimize and corresponds to the total distance traveled by all vehicles. The first constraint is indicated in (3) and ensures that the sum of demands for each cluster C_j is at most equal to the vehicle capacity $C_{\max}$. The second constraint (4) means that each customers i must be served inside its time window $W_i = [e_i, l_i]$, i.e., $e_i \leq t_i \leq l_i,\ \forall i \in N \cup \{D\}$. Then the depot can be considered as a customer for which the demand is null $(d_D = 0)$ and is the only point that is visited twice. The time window $W_D = [e_D, l_D]$ associated to the depot defines the *scheduling horizon* and means that each vehicle cannot leave the depot before its opening (at time e_D) and must return to the depot before its closure (at time l_D).

III. A three-phase method for solving CVRPTW

It is well known that many methods for solving vehicle routing problems often contain three phases (steps):

P1. Consists to divide the set of customers into m disjoint clusters, i.e., $C_1, ..., C_m$ such that $C_i \cap C_j = \emptyset$ for $1 \leq i < j \leq m$.

P2. Apply a given method in order to compute the shortest path, or a path of maximum benefit inside each cluster.

P3. Try to improve the solution obtained after P2, by applying another method such as local search.

A. Clustering

The first phase in solving our problem (Capacitated Vehicle Routing Problems with Time Windows) consists to divide the n customers into m disjoint sets or clusters. Then each vehicle will visit all the customers in the clusters that is assigned to it. Fig. 1 shows an example where a set containing 16 points and a depot (D) is divided into three disjoint clusters $\{C_1, C_2, C_3\}$.

There exists several methods for clustering and many of them are based on the dispersion (distribution) of the point around a central point called *centroid*. In our case we choose the well-known *k-means* method in order to compute the clusters. Actually, this is an adaptation of k-means in order to compute m clusters each of total capacity smaller than of equal to the capacity $C_{\max}$ of the vehicle.

Algorithm 1 explain how procedure k-means works. It receives the set N of customers as input parameter. The procedure's output corresponds to m disjoint clusters respecting

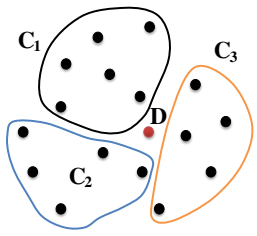

Fig. 1. An example of clustering a set of points into three disjoint clusters.

the vehicle capacity constraint. k-means begins by choosing m random points $c_1, ..., c_m$ from N (line 4), each point $c_j, (1 \leq j \leq m)$ corresponds to a centroid (belonging to cluster C_j). After that (at line 5), each not-assigned yet point $i \in N$ is assigned to the nearest centroid c_j of coordinates (x_{c_j}, y_{c_j}) in the sense euclidean distance. This means that point i of coordinates (x_i, y_i) is assigned to cluster C_j that minimizes the euclidean distance $\sqrt{(x_i - x_{c_j})^2 + (y_i - y_{c_j})^2}$, for $1 \leq j \leq m$.

After that, in the **while** loop that begins at line 6, the coordinates of the m centroids are recomputed (line 7). This is done by assigning to each $c_j, (1 \leq j \leq m)$ the center of the points belonging to cluster j. More precisely: $x_{c_j} = \frac{1}{|C_j|} \sum x_{c_k}$ and $y_{c_j} = \frac{1}{|C_j|} \sum y_{c_k}$ for all points $c_k \in C_j$. Each point $i \in N$ is after that assigned to the nearest centroid (among the new computed centroids), this is done in line 8. At line 9, if no point has moved from a centroid to another one, then a stable clustering is obtained: variable $move$ is set to the value $false$ (line 10) in order to stop recomputing of the centroids. Otherwise, this means that at least one point has moved, then instructions in lines 7–10 are repeated until a stable configuration is obtained. After that, the procedure verifies that the total capacity of each cluster does not exceed the capacity $C_{\max}$ of the vehicles. If so, then variable $found$ is set to "true" (line 14) in order to stop the procedure and return m clusters respecting the capacity constraint. If at least one cluster violates the capacity constraint, then the procedure restarts with m other random points by using the first **while** loop (line 2).

Note that the optimal number of clusters (m) is not known in the general case. So a dichotomous search can for example be used in order to test several values and determine the best one. Of course, increasing the value of m increases the probability to find clusters respecting the capacity constraint. For well-studied benchmarks, e.g. those proposed by Solomon [19], the same best value of m was found by many authors, so this value can be fixed in advance in order to save computation time.

B. Beam search for computing the shortest paths (routes)

The second phase takes place after the m clusters were generated by the k-means procedure (algorithm 1). The objective of the second phase is to compute the shortest path in each cluster. A path correspond to a route beginning at the depot D, visiting exactly once each point (customer) are returning after that to the depot. In addition, one vehicle is associated to each cluster. Fig. 2 shows an example of solution for the example indicated in figure 1.

It is to note that the time windows associated to each customer as well as the capacity of the vehicle make the problem hard to solve, harder than the traveling salesman problem (TSP) in which there are no time windows and no limit to the vehicle capacity.

Remember that the objective in CVRPTW is to minimize the sum of distances traveled by the m vehicles. In order to compute the shortest paths, we propose to use beam search on each cluster. Beam search is a tree search and is a modified version of the well known branch-and-bound method.

Algorithm 1 Procedure k-means for CVRPTW

Require: Set N containing n points (customers);
Ensure: m disjoint clusters each of total capacity $\leq C_{\max}$;
1: $found \leftarrow$ false;
2: **while** ($found =$ false) **do**
3: $move \leftarrow true$;
4: Choose randomly m distinct points $\{c_1, ..., c_m\}$ from N. Let these points be the m centroids (clusters);
5: Assign each point $i \in N$ to the nearest centroid c_j, $1 \leq j \leq n$;
6: **while** ($move$ = true) **do**
7: Recompute the coordinates (x_{c_j}, y_{c_j}) of each centroid, i.e., each c_j becomes the center of the points assigned to that centroid;
8: Assign each point $i \in N$ to the nearest centroid c_j, $1 \leq j \leq n$;
9: **if** no point has moved from a cluster to another one **then**
10: $move \leftarrow$ false;
11: **end if**
12: **end while**
13: **if** the capacity of each a cluster $\leq C_{\max}$ **then**
14: $found \leftarrow$ true;
15: **end if**
16: **end while**

Beam search was used to solve different combinatorial problems, such as Scheduling [15] and Cutting–and–Packing problems [1]. In its width–first implementation, the method starts by creating the root node which may contains an initial (starting) partial solution. After that, each node at level ℓ generates a set of descendants, these correspond to level $\ell+1$. Each node of the new level is then evaluated by using an evaluation criterion and only a subset containing the ω best nodes are retained, the other nodes are discarded. Parameter ω is known as the *beam width*. If a node contains a final solution, then this one is evaluated and stored. The corresponding node is after that deleted because no branching is possible from it (leaf). The beam search stops when no branching becomes possible from any node of the current level. The best solution, among the different solutions obtained, is then retained as the final result.

1) Content of a node in the search tree: Let $V = \{v_1, ..., v_{|C_j|}\}$ be the set of vertices (customers) in cluster C_j $(1 \leq j \leq m)$.

It is important to define clearly the content of a node in the beam search tree. Each node η_ℓ at level ℓ contains the following elements:

- The set of vertices (customers) already visited $V^+ = \{v_1^+, ..., v_\ell^+\}$.
- The set of vertices that have not yet been visited $V^- = V \backslash V^+$.
- The distance $dist$ corresponding to the length of the path

$D \rightarrow v_1^+ \rightarrow v_2^+ \rightarrow ... \rightarrow v_\ell^+$.

Note then that if a node corresponds to a complete solution, then the path obtained is $D \rightarrow v_1^+ \rightarrow ... \rightarrow v_{|C_j|}^+ \rightarrow D$ and the total distance is the sum of euclidean distances of the corresponding arcs in the path.

As a result, a node η_ℓ at level ℓ in the search tree can be designated by the elements described above, i.e, $\eta_\ell = \{V^+, V^-, dist\}$, where $|V^+| = \ell$ and $|V^-| = |C_j| - \ell$.

2) Selection criterion for the next customer to visit: As explained above, branching from a node η_ℓ (or more exactly from the last node v_ℓ^+ in the path under construction) consists to choose the successors of the vertex v_ℓ^+ among the vertices in V^-. The next vertex $v_i \in V^-$ may be for example the closest one to v_ℓ^+ in the sense of euclidean distance or the time window interval $[e_i, l_i]$. For example, for the two sets of instances examined in this work (see Section IV below), the next vertex to visit is the closest one in the sense of parameter e_i (the earliest time) in the time window. For beam search, all the successors v_i^- are ranked in increasing value of parameter e_i and then the ω first ones are chosen to create ω distinct branches.

Of course, others criteria were tested, including the latest time l_i and/or the distance between the current customer and the remaining customers to visit, but the experimentations showed that the criterion based on parameter e_i is the best one for the instances tested.

3) Algorithm Beam Search: Algorithm 2 explains how beam search works in order to compute a route. Note that the capacity constraint is not taken into account in the algorithm since the sum of the capacities of the vertices in each cluster is less or equal to the vehicle capacity. The capacity constraint is always respected after the clustering phase (see Section III-A), then only the time window constraint is checked.

Algorithm 2 receives three input parameters: the cluster C_j, i.e., the set of vertices or customers to visit (to serve), the value of the beam width ω, and the selection criterion ρ that will serve to sort the nodes at each level of the tree and then to determine the *best* ones according to this criterion. As output, the algorithm computes the best route (path) R_j of minimal distance beginning at the depot D, visiting each customer once, and then returning to the depot.

The root node η_0 of the search tree is created in line 1. This node contains the set of vertices already visited ,i.e. the depot D (so $V^+ = \{D\}$), and the set of vertices not already served $V^- = V$. Since no customer has been already visited, then the distance is equal to 0.

Set B (line 2) corresponds to the nodes at the current level of the search tree. Each node $\eta \in B$ contains a partial route (path) from the depot to a given customer (set V^+) as well as the set of remaining customers to visit V^-. The total distance to the current customer is also known since this distance is updated each time a new customer is visited and then added to the path (route). B is initialized to η_0 (line 4). Set B_{off} (line 3) contains the offspring nodes after branching from each node in B.

Algorithm 2 Beam Search for computing the shortest path in a cluster

Require: Cluster C_j, the beam width ω, and the selection criterion ρ;

Ensure: The best shortest route R_j starting from the depot D, visiting all the vertices of the cluster, and returning to the depot;

1: Let $\eta_0 \leftarrow \{\{D\}, V, 0\}$ be the root node;
2: Let B be the set containing the nodes at a given level of the tree;
3: Let B_{off} the offspring nodes (descendants of nodes in B);
4: $B \leftarrow \{\eta_0\}$;
5: $\ell \leftarrow 0$;
6: $\eta^* \leftarrow \eta_0$; (the best solution found)
7: $\eta^*.dist \leftarrow +\infty$; (best distance)
8: **while** $(B \neq \emptyset)$ **do**
9: Branch out of each node $\eta_{\ell_i} = \{V_i^+, V_i^-, dist_i\} \in B$ and create the offspring nodes B_{off} (each node in B_{off} must respect the time windows);
10: $\ell \leftarrow \ell + 1$;
11: **if** $(V_i^- = \emptyset$ for a node $\eta_{\ell_i} \in B_{\text{off}})$ **then**
12: Add vertex D (depot) to that node and compute the total distance;
13: **if** $(\eta_{\ell_i}.dist < \eta^*.dist)$ **then**
14: $\eta^* \leftarrow \eta_{\ell_i}$;
15: Remove η_{ℓ_i} from B_{off};
16: **end if**
17: **end if**
18: Sort the nodes in B_{off} according to parameter ρ and then keep only the $\min(\omega, |B_{\text{off}}|)$ first nodes, remove the other nodes from B_{off};
19: $B \leftarrow B_{\text{off}}$;
20: $B_{\text{off}} \leftarrow \emptyset$;
21: **if** there is a node $\eta_{\ell_i} \in B$ for which V_i^- contains a vertex with a violated time window **then**
22: Remove η_{ℓ_i} from B;
23: **end if**
24: **end while**

Since the current level ℓ is 0 (root node), then this is indicated in line 5, while the best solution η^* is initialized to the root node η_0 at line 6. The best distance $\eta^*.dist$ is set equal to $+\infty$ (line 7) because this value is to be minimized.

At line 8 the **while** loop starts. So at a given level ℓ of the tree, B contains at most ω distinct partial paths (routes) computed in parallel from the depot (root node). Then branching from a node η_{ℓ_i} (line 9) consists to explore the successors of the last visited vertex (customer) and to create as many nodes as there are successors with nonviolated time windows. So each node in B may have several descendants. Each descendant is then inserted into the set of offspring node B_{off}, that corresponds to level $\ell + 1$. This is why the level is incremented at the next line (10).

After that, at line 11, if there is a node in B_{off} in which all the customers were served $(V^- = \emptyset)$, then the complete

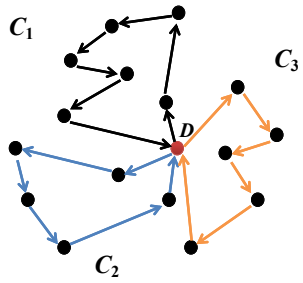

Fig. 2. An example of solution obtained after the second phase (beam search).

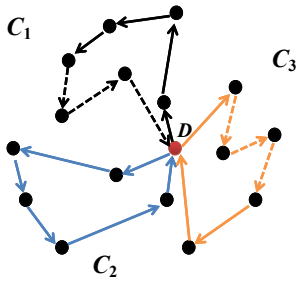

Fig. 3. A solution obtained after the third phase (local search).

solution is computed by adding the returning arc to the depot (line 12). The total distance for the obtained complete solution is then computed and compared to the best known one (line 13). If a lower distance is obtained then the best solution is updated (line 14) and the corresponding node is removed from B_{off} (line 15).

The most important instruction in beam search is certainly that given in line 18. Indeed, this step consists to sort the nodes according to the selection criterion ρ from the most important node to the least important one. Then the ω first nodes are kept and the other ones are removed from B_{off}. Note that if there are less than ω nodes in B_{off} then all the nodes are kept. After that set B_{off} is assigned to B and B_{off} reset to the empty set (lines 19–20). The last instruction in algorithm 2 consists to remove from B all the nodes that cannot lead to feasible solutions, i.e, that containing violated time windows.

The algorithm stops when set B becomes empty meaning that there is no node to explore or more precisely no customer to serve. Two cases can be distinguished: the algorithm has computed a feasible solution and this one is indicated in node η^* as well as the best corresponding distance, or there is no solution (if the distance in node η^* is equal to $+\infty$).

Fig. 2 shows an example of a solution that may be obtained after the second phase (beam search) on the example (clusters) shown in Fig. 1.

C. Local search for improving solution quality

In order to try to improve the result obtained after the second phase (beam search), a local search is performed on each cluster. This consists to execute the well-known 2-opt algorithm on each cluster (route).

2-opt is an iterative method that consists, at each iteration, to *break* two nonconsecutive arcs in the route and to link the four extremities in order to form another path and by respecting the time windows of course. The replacement is kept if the obtained solution is better.

The 2-opt method is given in algorithm 3. In each iteration, the algorithm examines each two distinct arcs $v_i \rightarrow v_{i+1}$ and $v_j \rightarrow v_{j+1}$ in the route R. These two arcs are replaced by the arcs $v_i \rightarrow v_j$ and $v_{i+1} \rightarrow v_{j+1}$ if and only if the distance decreases and the time windows are not violated. This process is repeated as long as there is improvement. Fig. 3 shows an example of improvement obtained by the 2-opt procedure on the solution of fig. 2. The arcs that had changed are indicated in dotted lines.

D. The three-phase algorithm (3PA) for solving CVRPTW

The three-phase algorithm based on clustering, beam search, and 2-opt local search is given in algorithm 4. It receives as input parameters the set of customers N, the depot D, and the number of vehicles. The algorithm's output corresponds to a set containing m feasible routes (respecting the constraints) of minimum distance, each one starts and ends at the depot D.

At line 1, the clustering phase (algorithm 1) is called in order to create m distinct clusters. The selection criterion (ρ), that serves to choose the next customer to serve is set at line 2. Then, algorithm 2 (beam search) is executed on each cluster (line 5), and this for several values of the beam width, i.e., for all values $\omega \in [1, ..., \omega_{\max}]$. The local search (algorithm 3) is then executed (line 6) on each solution computed by beam search.

Algorithm 3 2-opt algorithm

Require: A route $R = v_0 \rightarrow v_1 \rightarrow \ldots \rightarrow v_{|C_j|} \rightarrow v_{|C_j|+1}$;
Ensure: A route R' with a length at most equal to that of V;
1: $improvement \leftarrow$ true;
2: **while** ($improvement$ = true) **do**
3: $improvement \leftarrow$ false;
4: **for each** vertex $v_i \in R$ **do**
5: **for each** vertex $v_j \in R$ $(j \neq i-1, j \neq i+1)$ **do**
6: **if** $(\text{dist}(v_i, v_{i+1}) + \text{dist}(v_j, v_{j+1}) > \text{dist}\ (v_i, v_j) + \text{dist}(v_{i+1}, v_{j+1})$ **AND** the time windows will not be violated) **then**
7: Replace arcs $(v_i \rightarrow v_{i+1})$ and $(v_j \rightarrow v_{j+1})$ by arcs $(v_i \rightarrow v_j)$ and $(v_{i+1} \rightarrow v_{j+1})$;
8: $improvement \leftarrow$ true;
9: **end if**
10: **end for**
11: **end for**
12: **end while**

Algorithm 4 The three-phase algorithm 3PA for solving CVRPTW

Require: A set $N = \{1, ..., n\}$ of customers, the depot D, and m the number of vehicles (clusters).

Ensure: A set of routes minimizing the total distance and respecting the capacity and the time windows constraints.

1: Call the clustering phase (algorithm 1) and create m clusters $\{C_1, ..., C_m\}$ respecting the vehicle capacity constraint;
2: Define the selection criterion ρ;
3: **for each** cluster $C_j, (1 \leq j \leq m)$ **do**
4: **for** $\omega = 1$ to $\omega_{\max}$ **do**
5: Call algorithm 2: Beam-Search(C_j, ω, ρ);
6: Apply algorithm 3 (2-opt) on the solution returned by Beam-Search;
7: **end for**
8: **end for**

IV. Computational results

The proposed method is coded in C++ and the program run under Microsoft Windows environment on a computer with 2 GB of RAM and a 2.26 GHz Intel processor.

The algorithm was tested on two sets of instances, namely C1 and C2, proposed by Solomon. The characteristics of the two sets are summarized in table I. Each instance of each set contains 100 customers (column 2), they have also all the same service time (time needed to serve a customer) which is equal to 90 (column 4). The depot D has also the same coordinates for all the instances.

The first common characteristic between two distinct instances of the same set is the customer *demand*, i.e., the quantity to deliver to each customer. This value is fixed in each set for a given customer. More precisely, for two distinct instances in the same set (C1 or C2) each customer i has the same demand d_i. The second common characteristic is that a given customer i has the same coordinates (x_i, y_i) in two distinct instances of the same set (C1 or C2).

The third common characteristic appears in the scheduling horizon (column 3) of Table I, which is *short* for instances of set C1 (1236) and *large* for the instances of set C2 (3390). This means for example that the tours in instances C1 will all finish at most after 1236 units of time and at most after 3390 units of time for the instances of set C2. Finally, the fourth common characteristic concerns the vehicle capacity (column 5) of table I. In set C1, vehicles of capacity $C_{\max} = 200$ are used while this capacity is equal to 700 for instances of set C2.

TABLE I
Characteristics of the C1 and C2 instances

Set	Number of customers	Scheduling horizon	Service time	Vehicle Capacity
C1	100	1236	90	200
C2	100	3390	90	700

From these characteristics Solomon designed several instances in the same set by changing the time windows from an instance to another one. More precisely, there are nine instances C101–C109 in the first set C1 and eight instances C201–C208 in the second set C2. For two distinct instances in the same set (C1 or C2) we have:

- the same coordinates for a given customer i as well as for the depot D
- the same demand for a given customer i
- the same vehicle capacity
- different time windows

For more details, the reader can refer to Solomon's web site [20].

Then, one can surmise that less vehicles (clusters) will be needed for instances of set C2 comparing to set C1 because of the larger value of the capacity and the greater length of the time windows. This is in fact the case as proven in different works published in the literature.

Finally, note that the value of m (number of clusters or vehicles) is fixed to the best value found by several authors in the literature. More precisely, $m = 10$ for instances C1 and $m = 3$ for set C2.

Table II shows the results obtained on the 17 instances where column 1 indicates the name of each instance. Columns 2–4 contain the best known results in the literature (to our knowledge). Column 2 shows the best value for m (the number of vehicles) and column 3 the best distance. Column 4 (Ref.) indicates the reference to the paper where the best values for m and Dist were obtained. Columns 5–7 contain the results obtained by a method based on goal programming and genetic algorithm (GP-GA) proposed by Ghoseiri and Ghannadpour [12]. So columns 5 and 6 indicate the best value for m and the best distance respectively. Column 7 corresponds to the gap between the distance obtained by GP-GA (column 6) and the best known distance in the literature (column 3). This gap is computed as follows: $\text{gap} = 100\% \times (\text{Dist}_{\text{bestknown}} - \text{Dist}_{\text{GP-GA}})/\text{Dist}_{\text{bestknown}}$. Columns 8–12 summarize the results obtained by the proposed algorithm 3PA. Column 8 indicates the minimum number of vehicles m while column 9 shows the best minimum distance obtained by algorithm 3PA. Column 10 ($\omega_{\max}$) corresponds to the maximum value of the beam width used for each instance, then $\omega_{\max} = 50$ means that beam search was executed for each value $1 \leq \omega \leq 50$. The next column (time) indicates the total computation time needed for the execution of algorithm 3PA (in seconds). The last column (gap) indicates the difference (in %) between the solution obtained by the proposed method 3PA and the best known solution in the literature (column 3). More precisely $\text{gap} = 100\% \times (\text{Dist}_{\text{Best known}} - \text{Dist}_{\text{3PA}})/\text{Dist}_{\text{best known}}$. Finally, the last row of table II indicates the average gap for the two compared methods (GP-GA and 3PA). As expected, the number of vehicles needed for C1 instances (10) is larger than that needed for instances of set C2 (only 3 vehicles).

C201	3	**591.56**	[12]	3	**591.56**	0.0	3	**591.56**	50	176	0.00
C202	3	**591.56**	[12]	3	**591.56**	0.0	3	**591.56**	50	240	0.00
C203	3	**591.17**	[12]	3	**591.17**	0.0	3	**591.17**	100	13 210	0.00
C204	3	**590.60**	[17]	3	599.96	-1.58	3	591.17	100	12 390	-0.10
C205	3	**588.16**	[21]	3	588.88	-0.12	3	588.49	50	528	-0.06
C206	3	**588.49**	[17]	3	588.88	-0.07	3	**588.49**	2000	286 700	0.00
C207	3	**588.29**	[18]	3	591.56	-0.56	3	588.32	2000	291 600	-0.01
C208	3	**588.32**	[18]	3	**588.32**	0.0	3	588.88	50	618	-0.09
Average						-0.14					**-0.05**

The results of table II indicate that the proposed method 3PA reached the best known results in 11 cases out of 17. In the six other cases, the result is very close to the best known value since the gap is often smaller of equal to -0.11%, except for instance C104 where the gap reaches -0.50%. Note that even if the GP-GA method reaches the best known results in 13 cases out of 17, its average gap (-0.14%) is worst then that obtained by algorithm 3PA (-0.05%).

Concerning the computation time of algorithm 3PA, it is at most 183 seconds for instances of set C1 (except for C108 which was hard to solve). Each cluster in instances of set C1 contains about 10 customers. The computation time is generally greater for the second set C2, this is due to larger number of customers in each cluster (which is about 30) and then the number of combinations in each cluster (route) becomes larger.

But how to determine the maximum value for the beam width $\omega_{\max}$, especially for new instances. One can for example fix the maximum value to 50 or 100 or use a limited computation time.

Table III indicates, for each of the 17 solutions of table II the best value ω^* that gave the best solution for each cluster $C_j,\ j = 1,..,m$. We can see for example that $w^* = 1$ for all $j = 1,..,10$ for instance C101, but the values of ω^* are heterogeneous for instances C103 and C104 for example, meaning that these two instances are harder to solve (due to the characteristics of the time windows).

Fig. 4 shows an example of solution obtained after the second step of the algorithm (beam search), i.e., the output of algorithm 2 on instance C206. The total distance obtained after this step is equal to 597.35. Fig. 5 indicates improvement of the solution of fig. 4 (instance C206) by the 2-opt procedure (algorithm 3). The new distance was decreased from 597.35 to 588.49, i.e., an improvement of 1.48%. The 2-opt phase has changed several arcs in clusters 1 and 2 while the third cluster

has not changed.

V. Conclusion and future work

In this work a three-phase algorithm denoted by 3PA is proposed in order to solve the capacitated vehicle routing problem with time windows (CVRPTW). The central phase is that computing the shortest paths in a given cluster. To do so, a beam search is proposed. The most characteristic of beam search is that it explores several paths in parallel and increases then the probability to find *good* paths. The results obtained on the instances used show that the method is competitive since the computations revealed that algorithm 3PA was better than a method based on goal programming and genetic algorithm (GP-GA). Indeed, 3PA obtained a gap closer to the best known results in the literature than the gap obtained by GP-GA.

As a future work, it will be interesting to add a global evaluation criterion for beam search in order to provide solutions of better quality before calling the local search (third) phase and then to improve the overall solution.

***Abstract*—Fiber To The Home (FTTH) deployment is crucial for telecommunication operators for both economical and quality of service reasons. This paper deals with a real-life Passive Optical Network (PON) design problem focusing on optical cabling constraints. This decision problem is formulated as an integer linear program (ILP) and several solving approaches are designed. Tests performed on real instances assess the efficiency of the proposed solution algorithms.**

***Index Terms*—Fiber optics, cables, integer programming.**

I. Introduction

INNOVATIVE bandwidth-requiring services lead telecommunication operators to the renewal of their fixed copper access networks, with the introduction of optical fibers. Among the optical fiber-based architectures, most telecommunication companies favor the PON architecture, appearing the best long-term technological solution [2]. In this paper, we thus focus on the design of FTTH-PON access network as experienced by field deployment teams from France Telecom-Orange. This decision problem arises as a joint optimization problem of optical splitters location, and cable routing and dimensioning.

Access network design problems have been intensively studied in the past decades. For a relevant survey, the reader can refer to [1]. To our knowledge, most papers related to PON design focus on fiber-oriented models i.e. skipping thus the cabling issues for later considerations (see. [3], [4]). Despite these problems being highly combinatorial, strengthened formulations of fiber-oriented PON design problems prove to be fairly tractable in practice (see. [4]). With regards to cabling issues, closest related work remains from Kim et al. [5] who propose ILP formulations for a global PON with cables design problem in a tree graph and a two-dimensional heuristic. The real-life PON deployment problem which is here dealt with, has at least two major differences: first no assumption is made on the underlying existing infrastructure except being with sufficient capacity (i.e. uncapacitated), and second, we exclude the possibility of gathering fibers with different types of end points (splitters or demand points) into the same cable, as well as fibers with different direction. Notice that this last possibility may appear as our underlying graph is not a tree. As far as the numerical experiment is concerned, the size of the instances and the set of available cables are as well very different in Kim et al. work compared to the present article. Those differences seem to us major requirements of an operational cabling policy. Formulated as an ILP, this problem proves intractable due to the specific cabling constraints. Therefore, we aim at proposing branch and bound-based algorithm based on its "fiber-oriented" relaxation, taking benefit from the practical tractability of the latter.

The remaining of this paper is organized as follows. Section II is dedicated to the modeling of the problem, proposing ILP formulations for both the real-life problem and its "fiber-oriented" relaxation. Section III reports for numerical tests performed on 4 real instances, before concluding in Section IV.

II. Problem modeling

In this section, we introduce a model for the PON deployment with cable constraints problem. Then, we show our decomposition approach to solve it more efficiently.

A. Main model and Real life constraints

Let $G = (V, E)$ be an undirected graph representing the infrastructure where the PON shall be deployed. Give orientation to each edge of G to obatin the directed graph $\overrightarrow{G} = (V, A)$ where for each edge $ij \in E$ define two reverse arcs ij and $ji \in A$. This architecture is modelled as in [4] under the form of an integer multiflow. Every edge has a length D_{ij} and every node has a demand a_i. We define 2 kinds of demand : a_i^h for "high" ones and a_i^l for "low" ones. High (respectively low) demands are defined as such if they exceed (respectively do not exceed) a given threshold t. For high demands, splitters of capacity m must be put directly on the demand node. Then, we have to transform the initial client demand into the last level splitter demand for the same node. For a given node $i \in V$, if $a_i < t$ (resp. $a_i \geq t$), then $a_i^h = \lceil \frac{a_i}{m} \rceil$ and $a_i^l = 0$ (resp. $a_i^h = 0$ and $a_i^l = a_i$. Low

978-83-60810-53-8/$25.00

demands are to be filled with fibers coming from an optical splitter. Splitters have a given capacity m, cost C_s and can be put on every nodes and are denoted by s_i^l. Fibers are coming out from a single node called the Optical Line Termination (OLT), of index 0. For the low demands architecture, there are 2 fiber levels. The level 1 fibers denoted by $f_{ij}^{l_1}$ (for all arcs $(i,j) \in A$), are used by splitters to produce level 2 fibers, denoted by $f_{ij}^{l_2}$ (for all arcs $(i,j) \in A$). For high demand nodes, technological concerns impose to put splitters on the demand node. It implies that there are only level 1 fibers to route for high demand nodes. We denote these fibers by f_{ij}^h (for all $(i,j) \in A$). Fibers are aggregated within cables of respective capacities $q \in Q$ (given in decreasing order, with $q_0 = \max_Q q$). We denote by $c_{ij}^{k,q}$ the number of cables of level $k \in \{1,2\}$ of capacity $q \in Q$ routed along the arc $(i,j) \in A$. Cables of capacity q cost C_c^q. Finally, we introduce the boolean variable b_{ij}^k which controls whether the arc $(i,j) \in A$ is used or not.

$$z_{cable} = \min_{c_{ij}^{k,q}, s_i} \sum_{ij \in E} (D_{ij} \cdot \sum_{\substack{k \in \{1;2\} \\ q}} C_c^q \cdot c_{ij}^{k,q}) + \sum_{i \in V} C_s \cdot s_i \quad (1)$$

$$c_{ij}^{k,q} \in \mathbb{N}, f_{ij}^{l_1} \in \mathbb{N}, f_{ij}^{l_2} \in \mathbb{N}, f_{ij}^h \in \mathbb{N}, s_i \in \mathbb{N}, b_{ij}^k \in \mathbb{N} \quad (2)$$

$$\forall i \in V \setminus \{0\} : s_i = \sum_{j \neq i} f_{ji}^{l_1} - \sum_{j \neq i} f_{ij}^{l_1} \quad (3)$$

$$\forall i \in V : a_i^l \leq \sum_{j \neq i} f_{ji}^{l_2} - \sum_{j \neq i} f_{ij}^{l_2} + m s_i \quad (4)$$

$$\forall i \in V : a_i^h = \sum_{j \neq i} f_{ji}^h - \sum_{j \neq i} f_{ij}^h \quad (5)$$

$$\forall k \in \{1;2\}, \forall i \in V : \sum_{j \neq i} b_{ji}^k \leq 1 \quad (6)$$

$$\forall k \in \{1;2\}, \forall ij \in A : b_{ij}^k \geq \frac{\sum_q c_{ij}^{k,q}}{N} \quad (7)$$

$$\forall ij \in A : \sum_{q \in Q} q \cdot c_{ij}^{1,q} \geq f_{ij}^{l_1} + f_{ij}^h \quad (8)$$

$$\forall ij \in A : \sum_{q \in Q} q \cdot c_{ij}^{2,q} \geq f_{ij}^{l_2} \quad (9)$$

$$\forall k \in \{1;2\}, \forall ij \in A : \sum_{q \in Q \setminus Q_0} c_{ij}^{k,q} \leq 1 \quad (10)$$

The objective function is denoted by z_{cable}. In the model presented above, constraints (3)-(5) ensure flow conservation for all level of fibers, according to the number of splitters and demand. Constraints (6) and (7) ensure that only one edge incident to a node will be used, in order for the deployed network to have tree properties. Constraints (8) and (9) allow aggregation of fibers within cables. Constraints (10) ensure that only one cable is routed through each edge (except for the biggest cables q_0).

B. Decomposing and using a warm start

The $\mathcal{P}_c$ model proves intractable on real-size instances (refer to section III), but it can be decomposed so that we obtain a model easier to solve. A fiber-based model, denoted by $\mathcal{P}_f$, can be derived from $\mathcal{P}_c$ as follows:

1) discard variable $c_{ij}^{k,q}$ describing the cables,
2) discard inequalities (8) to (10),
3) optimize along the objective function z_{fiber} instead of z_{cable}, that is replace equation (1) by equation (11) with C_f^k the cost[1] of fiber f^k for all $k \in \{h; l_1; l_2\}$.

$$z_{fiber} = \min_{f_{ij}^k, s_i} \sum_{ij \in E} (D_{ij} \cdot \sum_{k \in \{h;l_1;l_2\}} C_f^k \cdot f_{ij}^k) + \sum_{i \in V} C_s \cdot s_i \quad (11)$$

Solving $\mathcal{P}_f$ allows us to get values for fibers and splitters variables, so a solution of $\mathcal{P}_f$ is almost a feasible solution of $\mathcal{P}_c$ in a sense that only cable variables remain to be set. Therefore we design two solution algorithms based on feasible solution of $\mathcal{P}_f$.

- $\mathcal{P}_f + \mathcal{H}_c$: given any feasible solution of $\mathcal{P}_f$, we set cable constaints by use as much maximum capacity cables as necessary and cover the remaining fibers with the smallest cable whose capacity is greater than the number. $\mathcal{H}_c$ is delailed in Algorithm 1.
- $\mathcal{P}_f + \mathcal{P}_c$: given any feasible solution of $\mathcal{P}_f$, we set arbitrarily large values to c^k variables to satisfy the cable constraints (8) to (10) and be able to set a warm start to $\mathcal{P}_c$.

Algorithm 1 Heuristic H_c

[1]Note that this cost is "virtual" in a sense as it should depend on the size of the cable which will be used for each level of fiber. In practice we will assume that capacity of cables are decreasing with the level of fiber and, given the concave cost structure of the cables, we will have decreasing fiber cost (with respect to their level)

III. Numerical results

Our goal is to be efficient on our very specific operational data. That is the reason why we have not conducted any experiments on any public Network or MIP library. In this context, we present numerical results from experiments on 4 data sets, named $Data1$ the smallest one, to $Data4$ the biggest one. The underlying infrastructure G and the constants (such as cables costs C_c^q or demands a_i^h and a_i^l) have been set to their actual values; splitters capacity set to $m = 8$, and the cables capacities are chosen in $Q = \{288 = q_0; 144; 96; 72; 48; 36; 24; 12\}$, while N is set to 1000. The Linear Programming and the branch and bound were performed by CPLEX 12.2 running on an AMD Athlon II X3 powered by a Linux 2.6 kernel. Computation times were set to 1800 seconds for $\mathcal{P}_f$ and $\mathcal{P}_c$, meanwhile $\mathcal{H}_c$ runs quite instantly. Table (I) and (II) summaries some numerical experiments.

TABLE I
Experimentation $\mathcal{P}_f$, 1800 seconds

Data	$\lvert V\rvert$	$\lvert E\rvert$	Demand	Cost $\mathcal{P}_f + \mathcal{H}_c$
$Data1$	583	838	8285	45606
$Data2$	808	2528	46294	110269
$Data3$	1232	3119	28080	105062
$Data4$	1624	2711	23774	110554

TABLE II
Experimentation $\mathcal{P}_c$, 1800 seconds

Data	Cost $\mathcal{P}_c$	Gap	Cost $\mathcal{P}_f + \mathcal{P}_c$	Gap	Δ
$Data1$	34624	23.95	34348	22.42	-24%
$Data2$	N/A	N/A	60202	27.94	-45%
$Data3$	N/A	N/A	71668	34.06	-32%
$Data4$	N/A	N/A	106372	52.46	-3%

Let us explain some results shown in table (I). $\mathcal{P}_c$ finds a feasible solution only on $Data1$, the smallest. Hence, by solving $\mathcal{P}_f$ first, we help to find a feasible solution even on biggest data sets. And then by solving $\mathcal{P}_c$ we lower the cost a lot more than by solving $\mathcal{H}_c$ for the three smallest data sets as shown in column Δ where Δ quantifies the difference between the cost of $\mathcal{P}_f + \mathcal{H}_c$ and $\mathcal{P}_f + \mathcal{P}_c$.

Moreover, since for $Data1$ the cost of $\mathcal{P}_c$ and $\mathcal{P}_f + \mathcal{P}_c$ are about the same, we think that the warm start helps to find a solution as good as the one that would have been found without it on other data sets.

Let us discuss about $Data4$. For this data set the gap is almost twice the gap on smaller data sets, and the value in column Δ is rather small. We think the number of vertices $|V|$ is too big for CPLEX to solve efficiently the branch and bound process. This thought is also supported by the fact that for model $\mathcal{P}_c$, if the computing time increases up to 10800 seconds, this does not achieve any improvement more than 1% gap. We expect to find a more efficient decomposition technique in order to lower the gap on big data sets. We should remark as well that for $\mathcal{P}_f$, gaps vary from 1% to 4%, which is very small.

IV. Conclusion

In the present article we have shown that by using a decomposition and a warm start, we make possible to solve a MIP model describing a PON access network design problem with cable constraints, even on very big data sets. We have shown that for some data sets, the entire model performs a good optimization once a warm start is given. The solutions found are admissible in an operational point of view, that means conform and checkable, fast to compute and easy deploy; moreover far cheaper than the best solution found by another mean.Notice that cable constraints (8) to (10) make the problem hard to solve on our large size of data sets. Notice that although it is easy to find a deployable, feasible solution without any computer assistance the price found by our model is around 50% of the best cost found by hand.

We think that the warm start could be improved by finding a good heuristic or by studying the link between objective function (1) and (11). To test wether this could help CPLEX to find a better solution on the entire problem is an open question. Some other constraints are post-processed after the MIP has been solved; we wish to encompass them inside the main model. Finally, since the gap for some data sets is quite large and that running CPLEX a long time doesn't lower it, we wish as well to better understand the decomposition used for the warm start in order to improve this step and achieve a better gap.

***Abstract*—The Molecular Distance Geometry Problem (MDGP) is the one of finding an embedding of a molecular graph in the three dimensional space, where graph vertices represent atoms and edges represent known distances between some pairs of atoms. The MDGP is a constraint satisfaction problem and it is generally cast as a continuous global optimization problem. Moreover, under some assumptions, this optimization problem can be discretized and so that it becomes combinatorial, and it can be solved by a Branch & Prune (BP) algorithm. The solution set found by BP, however, can be very large for some instances, while only the most energetically stable conformations are of interest. In this work, we propose and integrate the BP algorithm with two new energy-based pruning devices. Computational experiments show that the newly added pruning devices are able to improve the performance of the BP algorithm, as well as the quality (in terms of energy) of the conformations in the solution set.**

I. Introduction

THE Molecular Distance Geometry Problem (MDGP) is the one of finding the possible three-dimensional conformations of a molecule from the information about the relative distances between some pairs of its atoms [1], [2]. Let $G = (V, E, d)$ be a weighted undirected graph representing an instance of the MDGP. The vertex set describes the atoms forming the molecule, and there is an edge joining two vertices if and only if the distance between the two corresponding atoms is known. The MDGP can be seen therefore as the problem of finding a function $x : V \longrightarrow \Re^3$ such that

$$\forall (u, v) \in E, \qquad ||x(u) - x(v)|| = d_{uv},$$

where $||\cdot||$ represents the computed Euclidean distance between the coordinates $x(u)$ and $x(v)$, whereas d_{uv} is the weight of the edge (u, v). The MDGP is NP-hard [3].

By its nature, the MDGP is a constraint satisfaction problem that is generally formulated as a global optimization problem in a continuous space [4]. When some particular assumptions are satisfied, moreover, the search space of the optimization problem can be discretized, so that it becomes combinatorial. We refer to a subclass of MDGPs that can be discretized as the Discretizable MDGP (DMDGP) [5], [6], [7]. Instances of the DMDGP can be solved by applying an ad-hoc Branch & Prune (BP) algorithm [8].

The basic idea behind BP is as follows. Suppose that possible positions have already been computed for all the atoms of a given molecule that have rank smaller than i (we suppose that a total order relationship for the vertices of G exists). Because of the discretization assumptions, there are up to two possible positions for the current atom i, that can be obtained by intersecting three spheres centered in the already placed atoms $i-3$, $i-2$ and $i-1$, and having radii $d_{i-3,i}$, $d_{i-2,i}$ and $d_{i-1,i}$ respectively. In this way, a binary tree can be defined, which is the conformational search space of the discretized problem, where branches duplicate in number when passing on higher level layers. By using some additional information about the distances (that are not considered in the tree construction), the feasibility of the atomic positions can be verified, so that branches of the tree can be pruned in case they contain infeasible positions. Moreover, additional pruning devices can be conceived for improving the performance of the BP algorithm [9], [10].

In this paper, we propose two new pruning devices to be included in the BP algorithm in order to improve its performance. For the first time, we consider pruning devices that are based on the chemical nature of MDGP instances; in other words, in these new pruning devices, we exploit the chemical structure of the molecule, and not only the distance information. We will present two new pruning devices. The former basically considers the van der Waals (vdW) radii [11] and forbids any configuration where non-bonded atoms are too close to each other, by verifying the relative distances between spheres centered in the atoms and having as radii the corresponding vdW radii. The latter pruning device is instead based on the well-known Lennard Jones (LJ) potential [12], which is related to the internal energy of the molecule.

The rest of the paper is organized as follows. In Section II, we will briefly describe the BP algorithm and we will focus our attention on the symmetry properties of BP trees, that will be exploited later in the paper. Section III will introduce the two new pruning devices, while computational experiments will be presented in Section IV. Conclusions and future works will be discussed in Section V.

16:    end if
17: end if
```

II. The BP algorithm

The BP algorithm [8] is an exact algorithm for the solution of DMDGPs. It explores recursively the discrete search domain (a binary tree) of the DMDGP and it prunes infeasible branches of such a tree as soon as they are discovered. Alg. 1 gives a sketch of the algorithm. In the algorithm call, $v \in V$ is the current vertex for which we are looking for a position, n is the cardinality of V, and d represents the weights associated to the edges. During each call, the two possible positions for the vertex v, x'_v and x''_v, are computed, and their feasibility is verified. If, for example, x'_v is feasible, then this position could be part of a solution, and therefore the branch of the binary tree rooted at x'_v needs to be explored. In this case, the algorithm invokes itself for exploring the branch rooted at x'_v. Instead, if for example x''_v is not feasible, then the current branch does not contain any solution. It is therefore pruned: the algorithm does not invoke itself in this case.

The conditions in the two **if** control structures (see lines 3 and 11 of Alg. 1) can be verified by employing the so-called *pruning devices*. The easiest to conceive and to implement (and probably the most efficient) is the Direct Distance Feasibility (DDF) pruning device. DDF simply verifies whether additional distances (that are not employed in the computation of x'_v and x''_v) are satisfied by the obtained candidate positions. In the following, we will refer to such additional distances as *pruning distances*. The BP algorithm, together with the DDF pruning device, was shown to be very efficient for the solution of protein-like instances [5].

Fig. 1 shows a BP tree for a small instance and the set of solutions obtained when only the DDF pruning device is employed. In the following, we will say that this is the DDF solution set, in order to make a distinction between this solution set and the ones that we will obtain while employing the new pruning devices. In the tree representation, a solution is given by a path from the tree root to one of its leaf nodes.

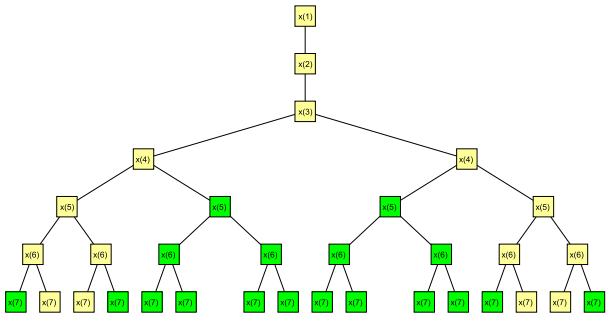

Fig. 1. The BP tree for a 7-atom instance, and the DDF solution set (in yellow).

As it is graphically shown in the picture, DDF solution sets are symmetric, i.e. one solution can be obtained from another by replacing a branch with its symmetric one [13], [14].

On the other hand, BP trees are highly symmetric: when no additional distances are available for applying the DDF pruning device, then every tree branch has a symmetric branch. A pair of symmetric branches shares the following property: given two vertices v and w, in the two branches, even if their coordinates are different, their relative distance is the same. Conversely, if we consider a vertex u having rank smaller than the common root of the two symmetric branches, its distance from any vertex v on the two branches is branch-dependent.

Let us consider a pair of symmetric branches of the BP tree that are rooted at the vertex v. If there is a vertex with rank $u < v$ and another vertex $w > v$ (which belongs to the two branches) such that the pruning distance d_{uw} is available, then, with probability 1, at most one of the two coordinates for w (one on the first branch, another on the second one) can satisfy this distance [15]. As a consequence, this kind of pruning distances are able to break the symmetries in BP trees, so that only a subset of symmetries is left in the DDF solution set. An easy test for verifying the presence of a symmetry in the solution set (before its explicit computation) is to check the existence of this kind of pruning distances. As reported in [13], there is a symmetry on the layer v of the solution set if and only if the vertex v belongs to the set

$$B = \{v \in V : \nexists (u, w) \text{ s.t. } u + 3 < v \leq w\}.$$

In this work, we will exploit these symmetry properties for generating instances having a predefined minimum number of solutions, and we will also discuss a possible improvement for the LJ pruning device which exploits the symmetries in BP trees.

III. Energy-based pruning devices

In this section, we propose two new pruning devices to be included in the BP algorithm. The first one is based on vdW radii (see Section III-A), while the second one is based on LJ energy (see Section III-B).

A. vdW radii pruning device

In this work, we consider the very common representation for an atom through the coordinates of its center. An atom, however, fills a certain portion of space: its nucleus, consisting of neutrons and protons, has a predetermined volume, while electrons orbit around this nucleus, at a given distance from it. Therefore, an atom can be seen as a sphere centered in its nucleus (which corresponds to the center of the atom) and having radius equal to the distance between the nucleus and the orbiting electrons. This distance can be estimated for each kind of atoms, and it is generally referred to as *atomic radius*. It is common to say that these electrons form a sort of *cloud*.

When two atoms are chemically bonded, their clouds of electrons tend to overlap. If they are not bonded, however, repulsion forces do not allow them to be too close to each other. The half of the distance (between atoms of the same kind) for which the attraction and repulsion forces are in equilibrium is called *van der Waals* (vdW) radius [11]. The vdW pruning device is therefore based on this simple idea: when two atoms are not bonded, their relative distance should be greater than the sum of the two corresponding vdW radii. This verification can be applied to all pairs of atoms for which no pruning distance is available.

Notice that, differently from the DDF pruning device, a precise distance is not available but rather only a lower bound for this distance. When the relative distance between two vertices u and v, with $u < v$ just positioned somewhere, goes below the predefined threshold, then the candidate position for v can be pruned. In the practice, we consider a relaxed condition, by setting the threshold to the 80% of the sum of the vdW radii. In the experiments presented in Section IV, we will consider instances containing Carbons (C) and Nitrogens (N) only. The vdW radius for C is set to 1.875; the vdW radius for N is set to 1.688. These values were extracted from the default parameters of the force field described in [16].

B. LJ pruning device

This pruning device is based on the overall internal energy of a molecule. As it is well-known, an accurate description of all interactions among the atoms in a molecule can be very complex, so that the overall energy can be only approximated by taking into consideration the most important interactions.

The vdW interactions between pairs of non-bonded atoms [17] are usually modeled by the Lennard Jones energy. In this case, we consider both repulsion and attraction forces, and for modeling the overall energy, we use the sum of pairwise LJ potentials 12–6 [12] :

$$E_{LJ} = \sum_{uv} 4\varepsilon_{uv} \left[\left(\frac{\sigma_{uv}}{d_{uv}} \right)^{12} - \left(\frac{\sigma_{uv}}{d_{uv}} \right)^{6} \right], \qquad (1)$$

where ε_{uv} and σ_{uv} are two parameters that can be defined by the relationships between the pairs of atoms u and v. The parameter σ_{uv} is the distance where the pair potential is zero, whereas ε_{uv} is the well depth. The minimum value for the LJ pair potential is $-\varepsilon_{uv}$ achieved in $r_{uv} = 2^{1/6}\,\sigma_{uv}$ (which corresponds to the sum of vdW radii).

During the execution of the algorithm, every time a leaf node is reached (on the layer n), a complete conformation is found, and its energy E_n can be computed. Let us suppose that $\hat{E}_n$ is the lowest energy found so far. The basic idea behind the LJ pruning device is to verify in advance whether new branches of the tree can actually contain conformations with an energy that can be potentially smaller than $\hat{E}_n$. This can be done by computing a lower bound on the energy concerning all the conformations belonging to a common branch.

Depending on the range in which the inter-atomic distances can vary, however, we can compute an accurate lower bound for the actual value. In case the BP algorithm is currently positioned on the layer v, then we have a partial energy value $E_{n(\leq v)}$ (computed by using the available coordinates) and a lower bound $L_{(>v)}$ on the energy $E_{n(>v)}$ (approximated by summing the minimum values given by the Lennard Jones terms for which no distance is available yet). Therefore, if $E_{n(\leq v)} + L_{(>v)} > \hat{E}_n$, there is no hope to identify a conformation with an energy smaller than $\hat{E}_n$ while exploring the current branch of the tree. This branch can be therefore pruned.

Notice that the LJ pruning device considers implicitly the vdW pruning device (see previous section). If a distance between a pair of atomic coordinates (for the atom v and a previous one) is small enough for the atomic position x_v to be pruned by the vdW pruning device, then the corresponding LJ potential is large, so that the LJ pruning device declares the atomic position infeasible as well. Therefore, when the vdW and LJ pruning devices work together, it is appropriate to apply LJ only after vdW.

IV. Computational experiments

This section presents some computational experiments where the BP algorithm is integrated with the new proposed pruning devices. All codes were written in C programming language and all the experiments were carried out on an Intel Core 2 Duo @ 2.4 GHz with 2GB RAM, running Mac OS X. The codes have been compiled by the GNU C compiler v.4.0.1 with the `-O3` flag.

In this paper, we suppose that all considered instances consist of a list of precise distances between some pairs of atoms of the molecule. This is an unrealistic assumption [18], because this information can be obtained through experiments of Nuclear Magnetic Resonance (NMR), where lower and upper bounds on the distances are actually provided. This assumption, however, allowed us to begin the investigation of new ideas that are potentially able to help in the solution of real instances of the problem (see Section V).

The instances considered in this paper are artificially generated by using the following procedure. Protein conformations are downloaded from the Protein Data Bank (PDB) [19] and the backbone atoms N–C_α–C of such proteins are extracted from such conformations. Distances are then computed between each possible pair of atoms, and the distances that are greater than 5Å are rejected (this is done because NMR data only consists of short range distances). As previously remarked

in [5], the obtained set of distances forms a DMDGP instance in the majority of the cases (this is always the case for the proteins considered in this paper).

Successively, for all generated instances, a certain number of pruning distances is discarded. Let $\hat{V} \subset V$, containing K randomly selected vertices. For each $v \in \hat{V}$, all the pruning distances d_{uw} such that $u + 3 < v < w$ are removed from the instance. In this way, a symmetry in the DDF solution set is generated, and this makes the total number of solutions increase (see Section II). An instance generated by using this procedure has at least 2^K solutions [15], [13].

Table I shows some computational experiments. The name of each instance is composed by its label on the PDB, plus a number, representing the cardinality K of $\hat{V}$. For every instance, we also provide the number of atoms ($n = |V|$), and the total number of available distances ($m = |E|$).

The experiments are performed for different setups of the BP algorithm. We consider the four following setups:

- only the DDF pruning device is exploited;
- DDF is integrated with the vdW pruning device;
- DDF is integrated with the LJ pruning device;
- the three pruning devices are considered together.

For every setup and for every instance, we monitor the total number of BP calls necessary for enumerating the whole solution set, the number #L of times that BP reaches a leaf node of the search tree (#L corresponds to the cardinality of the solution set when only DDF is employed), and finally the CPU time, in seconds. CPU times in bold are used to mark the fastest executions.

The quality of the obtained solutions can be evaluated in two ways. In order to verify whether all available distances are satisfied, we use the Largest Distance Error (LDE) function:

$$LDE(x) = \sum_{(u,v)\in E} \frac{1}{m} \frac{|\,||x(u) - x(v)|| - d_{uv}\,|}{d_{uv}}.$$

In this work, moreover, it is of interest to verify the LJ energy of the obtained solutions, by employing Equation (1). In the presented experiments, the LJ energy is computed even when the LJ pruning device is disabled. The partial energy $E_{(>k)}$ is computed at each recursive call of BP, because we noticed empirically that this is more efficient than computing the LJ energy for the whole DDF solution set after the execution of the algorithm. For lack of space in the table, LDE and LJ values are omitted for all experiments, but some examples will be given in the text.

The experiments show the effectiveness of the two new pruning devices. Even if very simple, the vdW pruning device is able to reduce the total number of BP calls, as well as the computational time, because it can identify infeasible branches that were not selected by DDF. A similar observation can be done for the LJ pruning device. It is interesting to remark that, when the two new pruning devices are considered together with DDF, the performance of BP is similar to the case in which only the vdW pruning device is considered. As a consequence, the repulsive term in LJ, which dominates the potential for small distances (also considered in vdW), plays the most important role during the pruning process. However, notice that #L decreases when vdW and LJ work together: fewer leaf nodes are reached during the execution of BP.

Fig. 2 shows two solutions for the instance 1mbn-2. The leftmost conformation has minimum LDE value 1.79e-10 (energy -131.21), but it does not correspond to the solution having the smallest energy value. In fact, as it can be seen from the figure, one helix in this conformation slightly diverges from the rest of the molecule, so that some energetic terms increase in value. The rightmost conformation is the one with minimum LJ potential energy: -136.12, while the LDE value is 5.36e-08.

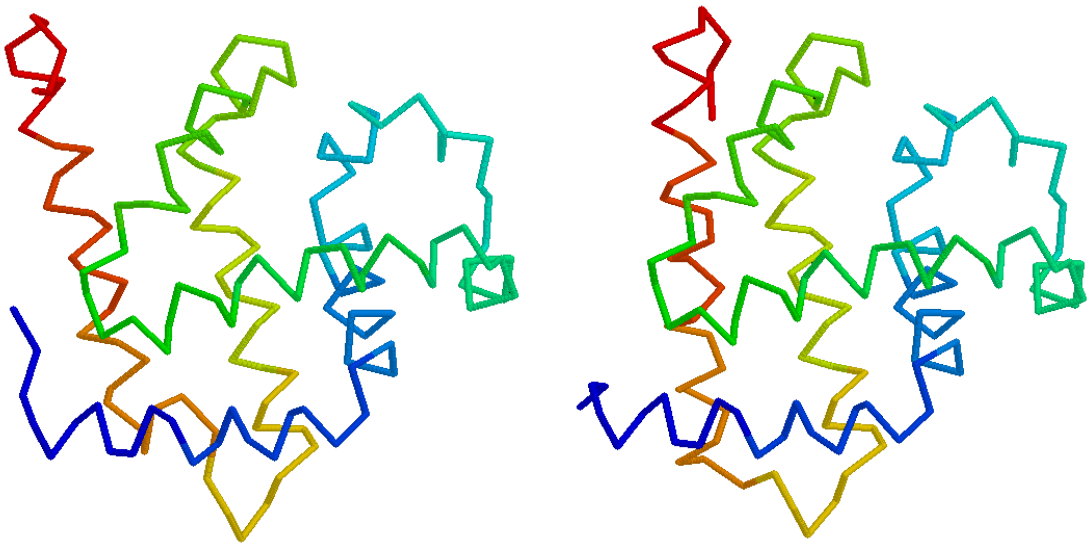

Fig. 2. Two solutions for the instance `1mbn-2`. The leftmost conformation has minimum LDE value, while the rightmost conformation has minimum LJ energy.

V. Conclusions and future works

We introduced two new pruning devices that are based on internal energy in molecules. We showed, through computational experiments, that they are able to improve the pruning capabilities of BP algorithm. The energetically most stable conformations, that previously could be selected from the entire DDF solution set, can be actually obtained by employing these two new pruning devices. The solution set is therefore reduced to energetically stable conformations only, while the performance of BP improves.

This work represents the first step for the integration of energy-based pruning devices inside BP. Next step will consist in testing such new pruning devices on instances of the problem containing interval data. As mentioned above, this kind of instances is more realistic, because, in biological applications, experimental data are generally imprecise. While the adaptation of these pruning devices to interval data is rather trivial, their impact on the performance of the algorithm is expected to be much more pronounced.

When working with interval data, the number of branches in BP trees increases because, instead of 2 possible positions for the current atom, we have $2D$ possible positions, where D corresponds to the number of samples in the discretized interval distance [20]. Thus, it is also expected an increase in the computational cost for the execution of these new pruning devices. For this reason, it will be worth implementing suitable strategies for making the new pruning devices more efficient. In the LJ pruning device, for example, the quality of the lower bound $L_{(>v)}$ can be improved by taking into consideration the symmetry properties of BP trees. Distances between pairs of atoms belonging to two symmetric branches coincide, and therefore their LJ energy is the same. Once one of the two branches has been explored, and its total energy has been computed, it is known in advance that the second branch has the same energy. This property can therefore help in finding better approximations of the lower bound $L_{(>v)}$. Unfortunately, when using this strategy in BP with exact distances, the trade-off between increased cost and performance improvement is not relevant.

VI. Acknowledgments

We wish to thank Thérèse Malliavin for the fruitful comments on this paper. We are also thankful to Brittany Region (France), for funding a 1-year postdoc for DG, and to UNICAMP, CNPq, FAPESP and INRIA, for partial financial support.

***Abstract*—A partial Latin square (PLS) is an assignment of n symbols to an $n \times n$ grid such that, in each row and in each column, each symbol appears at most once. The partial Latin square extension (PLSE) problem asks to find such a PLS that is a maximum extension of a given PLS. The PLSE problem is NP-hard, and in this paper, we propose a heuristic algorithm for this problem. To design a heuristic, we extend the previous $\frac{1}{2}$-approximation algorithm that utilizes the notion of maximum matching. We show the empirical effectiveness of the proposed algorithm through computational experiments. Specifically, the proposed algorithm delivers a better solution than the original one and local search. Besides, when computation time is limited due to an application reason, it delivers a better solution than IBM ILOG CPLEX, a state-of-the-art optimization solver, especially for large scale "hard" instances.**

I. Introduction

THROUGHOUT the paper, we consider the *partial Latin square extension* (PLSE) problem. Let n denote a natural number. Suppose that we are given an $n \times n$ grid. A *partial Latin square* (*PLS*) is a partial assignment of n *symbols* to the grid so that the *Latin square condition* is satisfied. The Latin square condition requires that, in each row and in each column, each symbol should appear at most once. Given a PLS, the PLSE problem asks to find such a PLS that is a maximum extension of the given one in terms of the number of the filled cells. Specifically, we are asked to assign symbols additionally to as many empty cells as possible so that the Latin square condition is satisfied. The PLSE problem is NP-hard since its decision problem version is NP-complete [1]. The problem has various applications (e.g., scheduling, optical routers [2]) and was first introduced by Kumar, Russel and Sundaram [3], where they proposed several constant-factor approximation algorithms.

In this paper, we propose a heuristic algorithm for the PLSE problem. Assuming practical use, we aim to develop such a heuristic algorithm that delivers better solutions for more instances. We are interested just in empirical performance. We do not make theoretical analysis on approximation ratio, as previous studies for the PLSE problem do.

Let us explain the reason why we dare to propose such a heuristic algorithm. Researchers from discrete optimization or operations research may see that the problem can be formulated as a 0-1 integer programming (IP) problem. The global optimal solution can be found within practical time by the state-of-the-art optimization solvers (e.g., Gurobi optimizer [6], IBM ILOG CPLEX [7]) only when n is moderately small (e.g., no more than 30 in our experience). When n is larger, the solvers may not find even a feasible solution within practical time. For such large scale instances, a heuristic algorithm that delivers a good solution quickly is an alternative. For another application example, a heuristic algorithm may assist the work of the solvers. Many modern solvers admit us to input an initial solution. The solvers utilize the input solution as the first incumbent solution in the branch-and-bound tree. During the solution search, they may prune the solution subspaces where there is no hope of finding a better solution than the incumbent one, which may improve the efficiency of the search. Then the solver that is given a good initial solution is expected to find a better solution than the solver that is given no initial solution (or a poor initial solution) within the same time limit. An effective heuristic algorithm may help us generate a good initial solution.

Our heuristic algorithm is based on the $\frac{1}{2}$-approximation algorithm proposed in [3] that determines the assignment of symbols by solving the n relevant maximum matching problem instances iteratively. We try to improve its empirical performance by extending the model and by giving a reasonable scheme to decide the order in which the maximum matching problem instances are solved.

There are two approximation algorithms that have better approximation ratios than $\frac{1}{2}$. The best bound is $\frac{2}{3}-\varepsilon$, achieved by Hajirasouliha, Jowhari, Kumar and Sundaram [4], where ε is any positive constant. Their algorithm is based on local search, and the constant ε is automatically determined by the parameter on the neighborhood scale. The smaller ε we wish, the longer the running time becomes since we need to set the neighborhood scale large. For example, to beat the second best bound $1-\frac{1}{e}$, achieved by Gomes, Regis and Shmoys [5], the running time becomes $O(n^{26})$, which is surely polynomial but not practical. The second best algorithm [5] employs the linear programming (LP) relaxation approach. The idea is sophisticated but it is not easy to realize the mechanism to improve the empirical performance. On the other hand, the empirical performance of the maximum matching based

978-83-60810-53-8/$25.00

$\frac{1}{2}$-approximation algorithm can be improved by a smaller ingenuity. This is the highlight of the paper.

We show the empirical effectiveness of the proposed algorithm through computational experiments. Specifically, the proposed algorithm tends to deliver a better solution than the original one and the local search based approximation algorithm. Besides, when computation time is limited, as is often the case in practice, the proposed algorithm tends to deliver a better solution than IBM ILOG CPLEX for large scale "hard" instances.

The paper is organized as follows. In Section II, we prepare terminologies and notations. Then we present the proposed heuristic algorithm in Section III. We report the results of the computational experiments in Section IV, and then give concluding remarks in Section V.

II. Preliminaries

A. The PLSE Problem

First we introduce notations on the $n \times n$ grid. The grid consists of n^2 cells. Let us denote $[n] = \{1, 2, \ldots, n\}$. For any $i, j \in [n]$, we denote the cell in the row i and in the column j by (i, j). We denote the set of the n cells in the row i by R_i, and the set of the n cells in the column j by C_j, i.e.,

$$R_i = \{(i, 1), (i, 2), \ldots, (i, n)\} \text{ and}$$
$$C_j = \{(1, j), (2, j), \ldots, (n, j)\}.$$

We also denote the family of R_i'-s by $\mathcal{R}$, and the family of C_j'-s by $\mathcal{C}$, i.e.,

$$\mathcal{R} = \{R_1, R_2, \ldots, R_n\} \text{ and } \mathcal{C} = \{C_1, C_2, \ldots, C_n\}.$$

Clearly we have $\bigcup_{R_i \in \mathcal{R}} R_i = \bigcup_{C_j \in \mathcal{C}} C_j = [n]^2$.

Next we introduce notations on assignment of symbols to the grid. For simplicity, we represent the n symbols by the integers $1, 2, \ldots, n$ in the set $[n]$. We represent an assignment of symbols by an $n \times n$ array, denoted by L. For each cell (i, j), we denote the assigned symbol by $L_{i,j} \in [n] \cup \{0\}$, where $L_{i,j} = 0$ indicates that (i, j) is empty. We define the *domain of* L as $\mathrm{Dom}(L) = \{(i, j) \in [n]^2 \mid L_{i,j} \neq 0\}$. The cardinality $|\mathrm{Dom}(L)|$ equals to the number of the cells that are assigned symbols by L. For simplicity, we may write $|\mathrm{Dom}(L)|$ as $|L|$. An assignment L is an *extension* of L' if $\mathrm{Dom}(L) \supseteq \mathrm{Dom}(L')$ and $L_{i,j} = L'_{i,j}$ holds for any $(i, j) \in \mathrm{Dom}(L')$. When L is an extension of L', we write $L \geqslant L'$. We call L a *partial Latin square* (*PLS*) if, in each row and in each column, every symbol appears at most once. In particular, if all the cells are assigned symbols (i.e., $\mathrm{Dom}(L) = [n]^2$), then we simply call L a *Latin square* (*LS*). We call a PLS L *extensible* (resp., *blocked*) if there exists (resp., does not exist) a PLS $L' \geqslant L$ $(L' \neq L)$. Two PLSs L and L' are *compatible* if the following two conditions hold:

(i) For each (i, j), at least one of $L_{i,j} = 0$ and $L'_{i,j} = 0$ holds.

(ii) The assignment $L \oplus L'$ defined as follows is a PLS;

$$(L \oplus L')_{i,j} = \begin{cases} L_{i,j} & \text{if } L_{i,j} \neq 0 \text{ and } L'_{i,j} = 0, \\ L'_{i,j} & \text{if } L_{i,j} = 0 \text{ and } L'_{i,j} \neq 0, \\ 0 & \text{otherwise.} \end{cases}$$

An assignment of symbols can be also represented by a set of triples. Let T be a subset of $[n]^3$. The membership $(i, j, k) \in T$ represents that the symbol k is assigned to (i, j). In order to avoid duplicate assignments on the same cell, we assume that, for any different triples (i, j, k) and (i', j', k') in T, at least one of $i \neq i'$ and $j \neq j'$ holds. To convert the triple set representation into the array representation, we define the array $A(T)$ as follows;

$$A(T)_{i,j} = \begin{cases} k & \text{if there is } k \in [n] \text{ such that } (i, j, k) \in T, \\ 0 & \text{otherwise.} \end{cases}$$

For $(i, j, k), (i', j', k') \in T$, when at least two of $i \neq i'$, $j \neq j'$ and $k \neq k'$ hold, we say that they are compatible. Then T is a PLS if any two triples in T are compatible. Let us simplify some notations. When L and $A(T)$ are compatible, we may say that L and T are compatible, and use the expression $L \oplus T$ instead of $L \oplus A(T)$. When a singleton $T = \{(i, j, k)\}$ is compatible with L, we say that (i, j, k) (instead of $\{(i, j, k)\}$) is compatible with L.

We summarize the PLSE problem as follows.

The Partial Latin Square Extension (PLSE) Problem	
Input:	A PLS L_0.
Output:	A PLS $L \geqslant L_0$ that attains the maximum $\lvert L \rvert$.

A polynomial time algorithm for the PLSE problem is called a *ρ-approximation algorithm* if, for any input PLS L_0, it finds $L \geqslant L_0$ such that;

$$\frac{|L| - |L_0|}{|L^*| - |L_0|} \geq \rho,$$

where L^* denotes a global optimal solution. The bound ρ is called the *approximation ratio*.

B. Graph, Maximum Matching, Independent Set

An *undirected graph* (or simply a *graph*) $G = (V, E)$ consists of a set V of *nodes* and a set E of unordered pairs of nodes, where each element in E is called an *edge*. The *degree* of a node $v \in V$ is the number of the edges incident to v. A graph is *bipartite* when V can be partitioned into two disjoint nonempty sets, say V_1 and V_2, so that every edge joins a node in V_1 and a node in V_2. When we emphasize that G should be bipartite, we may write $G = (V_1 \cup V_2, E)$.

A *matching* E' is a subset of E such that no two edges in E' have a node in common. A *maximum matching* is such a matching that attains the largest cardinality. In particular, a maximum matching is called a *perfect matching* if it covers all the nodes in the graph. The size of maximum matching is called a *matching number*, and is denoted by $\nu(G)$. Suppose that the graph $G = (V, E)$ is bipartite. We can find a maximum matching in $O(\sqrt{|V|}|E|)$ time [8]. Note that maximum matching is not necessarily unique. Any edge e in E is classified into one of the following three classes with respect to how it appears in the possible maximum matchings:

Mandatory edge:	e appears in every maximum matching.
Admissible edge:	e appears in at least one (but not every) maximum matching.
Forbidden edge:	e appears in no maximum matching.

The sets of mandatory, admissible and forbidden edges in G are denoted by $ME(G)$, $AE(G)$ and $FE(G)$, respectively. The edge set E of a bipartite graph G can be decomposed into three disjoint sets $ME(G)$, $AE(G)$ and $FE(G)$ by the Dulmage-Mendelsohn decomposition technique [9]. The computation time is dominated by finding a maximum matching, and thus the decomposition can be made in $O(\sqrt{|V|}|E|)$ time. The proposed algorithm repeatedly solves maximum matching problems on bipartite graphs such that $|V_1| = |V_2| = n$. We denote the upper bound on the computation time for one bipartite graph by τ_n, i.e., $\tau_n = O(n^{5/2})$.

Let $G = (V, E)$ be a general graph (not necessarily bipartite). An *independent set* is a subset of V such that any two nodes in the subset are not adjacent. A *maximum independent set* is such an independent set that attains the largest cardinality. The problem of finding a maximum independent set is known as NP-hard [10]. The proposed algorithm solves this problem for a certain purpose. To construct a nearly maximal independent set, we employ the $(\Delta + 2)/3$-approximation algorithm [11], where Δ denotes the maximum degree in the graph. The algorithm is a greedy method such that, starting from $S = \emptyset$, it inserts a node of the smallest degree into S and removes the inserted node and all the adjacent nodes (along with all the incident edges) from the graph. The process is repeated until all nodes are removed from the graph, and finally S is output. The computation time is linear in the numbers of nodes and edges [11].

III. A Heuristic Algorithm for the PLSE Problem

In this section, we propose a heuristic algorithm for the PLSE problem. The algorithm runs like a typical heuristic algorithm for a packing problem; we are given several containers (what we call *compatibility graphs*), each of which is given its capacity (matching number). Then we are asked to pack as many objects (matching edges) in the containers as possible, where packing an object in a container may decrease the capacities of other containers. To construct an approximate solution, we repeat choosing a certain container and packing the objects up to the capacity. The proposed algorithm is inspired by the $\frac{1}{2}$-approximation algorithm that was given in [3]. First we describe the $\frac{1}{2}$-approximation algorithm in Section III-A. Then in Section III-B, we present the proposed algorithm.

A. The Maximum Matching Based $\frac{1}{2}$-Approximation Algorithm

The $\frac{1}{2}$-approximation algorithm works as follows; starting from $L = L_0$, we repeat choosing a PLS L' that is compatible with L and updating $L \leftarrow L \oplus L'$ iteratively. For convenience, when L is updated to $L \oplus L'$, we say that L' is *added* to the PLS L. To decide L', the algorithm utilizes a maximum matching of what we call a compatibility graph. Given a PLS L, the compatibility graph is constructed for any symbol $k \in [n]$. The *compatibility graph for the symbol* k is denoted by $G_L^{\mathrm{symb},k} = (\mathcal{R} \cup \mathcal{C}, E_L^{\mathrm{symb},k})$, where $\mathcal{R}$ and $\mathcal{C}$ are the node sets and $E_L^{\mathrm{symb},k}$ is the edge set such that;

$$E_L^{\mathrm{symb},k} = \big\{\{R_i, C_j\} \subseteq \mathcal{R} \cup \mathcal{C} \mid (i,j,k) \text{ is compatible with } L\big\}.$$

Let $M \subseteq E_L^{\mathrm{symb},k}$ denote any matching of $G_L^{\mathrm{symb},k}$. We define the triple set $T(M)$ as follows;

$$T(M) = \big\{(i,j,k) \mid \{R_i, C_j\} \in M\big\}.$$

Any two triples (i,j,k) and (i',j',k') in $T(M)$ satisfy $i \neq i'$ and $j \neq j'$ since M is a matching of $G_L^{\mathrm{symb},k}$. Thus $T(M)$ is a PLS. Each $(i,j,k) \in T(M)$ is compatible with L from the definition of $E_L^{\mathrm{symb},k}$. Then $T(M)$ and L are compatible.

In the order $k = 1, 2, \ldots, n$, the algorithm finds a maximum matching M^* of $G_L^{\mathrm{symb},k}$ and adds $T(M^*)$ to L iteratively. We show the algorithm in Algorithm 1. Naïvely implemented, the algorithm runs in $O(n\tau_n) = O(n^{7/2})$ time.

Algorithm 1 The $\frac{1}{2}$-approximation algorithm given in [3]

```
L ← L_0
for k = 1, 2, ..., n do
    M* ← a maximum matching of G_L^{symb,k}
    L ← L ⊕ T(M*)
end for
output L
```

B. The Proposed Algorithm

Let us describe our idea for how we improve the empirical performance of the above approximation algorithm. We have denoted the available symbols by integers $1, 2, \ldots, n$ only for convenience. Their numerical order does not have any significant meaning, whereas the above algorithm chooses k in that order. Thus there is room for developing a smart criterion to choose a compatibility graph. (The approximation ratio is still guaranteed even if we choose k arbitrarily; see the proof in Section 5.2 of [3] for detail.)

Besides, the compatibility graphs for the symbols are not the only "containers" in which we can "pack" the maximum matching to increase the objective value. Motivated by the fact that the dimensions of PLS in the triple set representation are symmetric, we introduce the compatibility graph also for each row and for each column. The *compatibility graph for the row* i is denoted by $G_L^{\mathrm{row},i} = (R_i \cup [n], E_L^{\mathrm{row},i})$, where R_i and $[n]$ denote the node sets and $E_L^{\mathrm{row},i}$ is the edge set such that;

$$E_L^{\mathrm{row},i} = \big\{\{(i,j),k\} \subseteq R_i \cup [n] \mid (i,j,k) \text{ is compatible with } L\big\}.$$

Similarly, the *compatibility graph for the column* j is denoted by $G_L^{\mathrm{col},j} = (C_j \cup [n], E_L^{\mathrm{col},j})$, where C_j and $[n]$ denote the

node sets and $E_L^{\mathrm{col},j}$ is the edge set such that;

$$E_L^{\mathrm{col},j} = \big\{\{(i,j),k\} \subseteq C_j \cup [n] \mid (i,j,k) \text{ is compatible with } L\big\}.$$

We show an example of the compatibility graphs in Fig. 1. Let us denote any matching of $G_L^{\mathrm{row},i}$ or $G_L^{\mathrm{col},j}$ by M. We define the triple set $T(M)$ as follows;

$$T(M) = \big\{(i,j,k) \mid \{(i,j),k\} \in M\big\}.$$

Analogously with the case of $G_L^{\mathrm{symb},k}$, the triple set $T(M)$ is a PLS and compatible with L. Thus $T(M)$ can be added to L.

Finally, given a PLS L, we have $3n$ compatibility graphs. Using all of them as containers, we expect to obtain a better solution than the case when we use only the n compatibility graphs for symbols. We denote the set of the n compatibility graphs for symbols by $\mathcal{G}_L^{\mathrm{symb}} = \{G_L^{\mathrm{symb},1}, \ldots, G_L^{\mathrm{symb},n}\}$, the set of the n compatibility graphs for rows by $\mathcal{G}_L^{\mathrm{row}} = \{G_L^{\mathrm{row},1}, \ldots, G_L^{\mathrm{row},n}\}$ and the set of the n compatibility graphs for columns by $\mathcal{G}_L^{\mathrm{col}} = \{G_L^{\mathrm{col},1}, \ldots, G_L^{\mathrm{col},n}\}$. We also denote the union of these graph sets by $\mathcal{G}_L = \mathcal{G}_L^{\mathrm{symb}} \cup \mathcal{G}_L^{\mathrm{row}} \cup \mathcal{G}_L^{\mathrm{col}}$.

Let us introduce the criterion by which we choose one of the $3n$ compatibility graphs. Recall that any edge corresponds to a triple $(i,j,k) \in [n]^3$. When $L_{i,j} = k$, no edge corresponding to (i,j,k) appears in any compatibility graph. For any compatibility graph $G_L \in \mathcal{G}_L$, we denote by $\rho(G_L)$ the number of node pairs that do not appear as edges due to $L_{i,j} = k$. For example, when G_L is the compatibility graph $G_L^{\mathrm{symb},k}$ for the symbol k, $\rho(G_L^{\mathrm{symb},k})$ is defined as follows;

$$\rho(G_L^{\mathrm{symb},k}) = \big|\big\{\{R_i, C_j\} \subseteq \mathcal{R} \cup \mathcal{C} \mid L_{i,j} = k\big\}\big|.$$

In other words, $\rho(G_L^{\mathrm{symb},k})$ indicates the number of cells to which L already assigns the symbol k. Analogously, $\rho(G_L^{\mathrm{row},i})$ and $\rho(G_L^{\mathrm{col},j})$ indicate the numbers of cells in the row i and in the column j to which L assigns certain symbols, respectively. Now we define the criterion function $f(G_L)$ as follows.

$$f(G_L) = \begin{cases} \nu(G_L) + \rho(G_L) & \text{if } \nu(G_L) > 0, \\ 0 & \text{otherwise.} \end{cases} \quad (1)$$

Basically, our heuristic algorithm runs as follows; starting from $L = L_0$, the algorithm chooses the compatibility graph $G_L \in \mathcal{G}_L$ such that $f(G_L)$ is the largest. Finding a maximum matching M^* of the chosen graph, the algorithm updates the solution by $L \leftarrow L \oplus T(M^*)$. The above operation is repeated while L is extensible. The repetition is at most $3n$ times; suppose that a compatibility graph G_L^s is chosen at a certain step of the algorithm, where s denotes the superscript of the compatibility graph. Let us denote the updated PLS by $L' = L \oplus T(M^*)$. For any extension $L'' \geqslant L'$, there is no edge in the compatibility graph $G_{L''}^s$. Then we have $\nu(G_{L''}^s) = 0$ and $f(G_{L''}^s) = 0$. Thus $G_{L''}^s$ is never chosen in the rest execution of the algorithm. Finally, when $f(G_L) = 0$ holds for all the $3n$ G_L'-s, L is blocked and the algorithm halts.

The algorithm utilizes the function f in (1) as the criterion to choose a compatibility graph. It may prefer a compatibility graph G_L such that more triples can be added (i.e., larger $\nu(G_L)$) and/or more cells are already assigned symbols (i.e., larger $\rho(G_L)$). The only matching number $\nu(G_L)$ appears to be a more natural criterion. However, it did not yield good results in our preliminary experiments.

We summarize the heuristic algorithm in Algorithm 2. The structure is as above stated, but in Line 3, we introduce the subroutine named COLLECTME for further improvement. The subroutine constructs a PLS that is compatible with L, from the triples of mandatory edges over the $3n$ compatibility graphs. Then it adds the PLS to L, before adding the triple set of a maximum matching of a certain compatibility graph to L.

Let us describe the motivation. Recall that a maximum matching is not necessarily unique in a graph. For example, given the PLS L in Fig. 1, there are 4 maximum matchings in the compatibility graph $G_L^{\mathrm{symb},1}$. We denote these 4 maximum matchings by $M_1^*, \ldots, M_4^*$, where we define;

$$M_1^* = \big\{\{R_1, C_4\}, \{R_2, C_1\}, \{R_3, C_2\}, \{R_4, C_3\}\big\},$$
$$M_2^* = \big\{\{R_1, C_2\}, \{R_2, C_1\}, \{R_3, C_4\}, \{R_4, C_3\}\big\},$$
$$M_3^* = \big\{\{R_1, C_2\}, \{R_2, C_3\}, \{R_3, C_4\}, \{R_4, C_1\}\big\},$$
$$M_4^* = \big\{\{R_1, C_4\}, \{R_2, C_3\}, \{R_3, C_2\}, \{R_4, C_1\}\big\}.$$

The greedy method would choose $G_L^{\mathrm{symb},1}$ for the container since $f(G_L^{\mathrm{symb},1})$ is the largest (which is 4) among all the compatibility graphs. Then the maximum matching algorithm finds arbitrary one M_x^* $(x = 1, \ldots, 4)$ and $T(M_x^*)$ is added to L. No matter which $T(M_x^*)$ is added, the symbol 1 is assigned to exactly 4 cells. Then the symbols 2 and 3 are assigned to the remaining empty cells, and the final solution is obtained. How many cells are filled in the final solution depends on which $T(M_x^*)$ is added. More precisely, when either $T(M_1^*)$ or $T(M_2^*)$ is added, the final solution becomes worse than the case when either $T(M_3^*)$ or $T(M_4^*)$ is added. To analyze the reason, see Fig. 2 for the final solutions that are obtained by extending $L \oplus T(M_1^*)$, $\ldots$, $L \oplus T(M_4^*)$. For $L \oplus T(M_3^*)$, there is another final solution such that the symbol 2 is assigned not to $(4,3)$ but to $(4,4)$, but it does not matter since we discuss how many cells are filled. We claim that the problem should come from the number of the bold cells occupied by the symbol 1. The bold cells in each grid correspond to the mandatory edges in $G_L^{\mathrm{symb},2}$ and $G_L^{\mathrm{symb},3}$, that is, $\{R_3, C_4\}, \{R_4, C_3\} \in E_L^{\mathrm{symb},2}$ and $\{R_1, C_4\}, \{R_2, C_1\} \in E_L^{\mathrm{symb},3}$; see also these graphs in Fig. 1. The matching number $\nu(G_L^{\mathrm{symb},k})$ gives an upper bound on the number of cells that the symbol k is assignable. Occupying bold cells by the symbol 1 may diminish the matching numbers of $G_L^{\mathrm{symb},2}$ and $G_L^{\mathrm{symb},3}$. When $T(M_1^*)$ or $T(M_2^*)$ is added, 3 out of the 4 bold cells are occupied by the symbol 1, while only 1 bold cell is occupied when $T(M_3^*)$ or $T(M_4^*)$ is added.

Based on the above, we consider that mandatory edges should be treated with a greater care in order to approach a

better solution. Our idea is to add as many triples coming from mandatory edges to L as possible. Let ME_L denote the set of all the mandatory edges over the $3n$ compatibility graphs in $\mathcal{G}_L$. We would like to add all the triples in $T(ME_L)$ if possible, but we cannot always do so since there are incompatible triples in $T(ME_L)$ in general. Let us define the graph $H_L = (T(ME_L), F_L)$ such that the triple set $T(ME_L)$ is the node set and the edge set F_L is defined as follows;

$$F_L = \big\{\{(i,j,k),(i',j',k')\} \subseteq T(ME_L) \mid (i,j,k) \text{ and } (i',j',k') \text{ are incompatible}\big\}.$$

Clearly, any independent set of H_L is a PLS and compatible with L. This motivates us to solve the maximum independent set problem on H_L. Since the problem is NP-hard, we find a nearly maximum solution by the greedy algorithm [11] that we described in Section II-B.

We summarize the subroutine CollectME in Algorithm 3. The subroutine repeats enumerating all mandatory edges over the $3n$ compatibility graphs, computing a nearly maximum independent set, and adding the independent set to L until there is no mandatory edge in any compatibility graph.

4:     if ME_L = ∅ then
5:         break the loop
6:     end if
7:     construct the graph H_L = (T(ME_L), F_L)
8:     I ← an independent set in the graph H_L
9:     L ← L ⊕ I
10: end loop
11: return L
```

C. Computational Complexity

We claim that the proposed algorithm should run in $O(n^{11/2})$ time. The algorithm consists of the main routine in Algorithm 2 and the subroutine COLLECTME in Algorithm 3. In the main routine, the most time-consuming task is to find maximum matchings of all the compatibility graphs. Since the iteration times of the main routine is at most $3n$, the running time is $3n \times 3n \times \tau_n = O(n^{9/2})$.

The iteration times of the subroutine amounts to $O(n^2)$ over the whole execution of the algorithm since there are at most $3n^2$ mandatory edges; there are $3n$ compatibility graphs, and in each graph, there are at most n mandatory edges. The most time-consuming task is not the greedy algorithm for the maximum independent set problem but to find maximum matchings of all the compatibility graphs; one can see that the former takes $O(n^3)$ time, whereas the latter takes $O(n^{7/2})$ time. Then the running time is $O(n^2) \times O(n^{7/2}) = O(n^{11/2})$.

IV. COMPUTATIONAL EXPERIMENTS

In this section, we present some experimental results to show how the proposed algorithm is effective in practice. Specifically, we show that the proposed algorithm tends to deliver a good solution quickly in comparison with other approximation algorithms. We also show that, when computation time is limited, the proposed algorithm tends to deliver a better solution than IBM ILOG CPLEX [7], a state-of-the-art optimization solver.

A. Experimental Settings

We describe how to generate problem instances. This issue has been studied in the field of *constraint programming*. In our experiments, we generate PLSE instances based on the QCP (quasigroup completion problem) framework that was discussed in [12]. An instance is characterized by two parameters. One is a natural number n, the side length of the grid, and the other is p $(0 \leq p \leq 1)$, which is the ratio of the number of pre-assigned cells over n^2. The QCP framework starts with the empty $n \times n$ grid and assigns a random symbol to a random empty cell so that the resulting assignment is PLS. The assignment is repeated until $\lfloor pn^2 \rfloor$ cells are assigned symbols. In the context of the decision problem, when the pre-assigned ratio p is small (resp., large), an instance is more (resp., less) likely to be satisfiable since there are less (resp., more) constraints. Many papers have reported the easy-hard-easy phase transition with respect to p (e.g., [13]); the instances are less computationally tractable when p is intermediate, e.g., $0.4 \leq p \leq 0.7$.

We refer to the proposed algorithm as OURS. For comparison, we will consider the algorithm that does not call the subroutine COLLECTME. We refer to this version of the algorithm to OURS-NOSUB. We also use 4 methods: MATCHING, LS, CPMATH and CPCP. The point is that MATCHING and LS are approximation algorithms that do not necessarily provide a global optimal solution, whereas CPMATH and CPCP are such softwares that retain exact algorithms.

a) MATCHING: The $\frac{1}{2}$-approximation algorithm [3] that forms the basis of the proposed algorithm and was explained in Section III-A.

b) LS: The $\frac{2}{3} - \varepsilon$ approximation algorithm [4] based on local search that achieves the best approximation ratio among those studied so far. Let T_0 denote the triple set representation of the given PLS L_0. Suppose that a non-negative number r is given. For any set $T \subseteq [n]^3$ of triples such that $T \geqslant T_0$, we denote the *neighborhood of* T by $\mathcal{N}_r(T)$ that is defined as follows;

$$\mathcal{N}_r(T) = \{T' = (T \setminus S) \cup S' \mid S \subseteq T \setminus T_0,\ |S| \leq r,\ S' \subseteq [n]^3,\ |S'| = |S| + 1,\ T' \text{ is a PLS}\}.$$

We call r the *radius* of neighborhood. LS starts with $T = T_0$ and iterates choosing a solution $T' \in \mathcal{N}_r(T)$ and updating $T \leftarrow T'$ until no solution exists in the neighborhood, i.e., $\mathcal{N}_r(T) = \emptyset$. The larger r is, the better the approximation ratio is, but at the same time, the more the computation time may become. Although $r \geq 7$ defeats the second best bound $1 - \frac{1}{e}$ given in [5], the time bound becomes $O(n^{26})$ in naïve implementation $(r = 7)$, which is not practical. We use $r \leq 4$ since any larger r was too time consuming in our preliminary experiments.

c) CPMATH: IBM ILOG CPLEX Optimizer (version 12.4) that solves the PLSE problem by means of mathematical programming. The PLSE problem can be formulated as a 0-1 integer programming problem. See [3] for the formulation. We set the time limit parameter to 6.0×10^2 seconds, i.e., if the computation time exceeds 6.0×10^2 seconds, the computation is terminated and the best solution found so far is output. We set all the other parameters to default values.

d) CPCP: IBM ILOG CPLEX CP Optimizer (version 12.4) that solves the PLSE problem by means of constraint programing. We formulate the PLSE problem as a constraint optimization problem as follows.

$$\begin{array}{ll} \text{maximize} & |L| \\ \text{subject to} & \forall i \in [n],\ \text{all-different\_except\_0}(L_{i,1}, \ldots, L_{i,n}), \\ & \forall j \in [n],\ \text{all-different\_except\_0}(L_{1,j}, \ldots, L_{n,j}), \\ & \forall (i,j) \in [n]^2,\ (L_0)_{i,j} \neq 0 \Rightarrow L_{i,j} = (L_0)_{i,j}, \\ & \forall (i,j) \in [n]^2,\ L_{i,j} \in [n] \cup \{0\}. \end{array}$$

In the above formulation, the all-different_except_0 constraint [14] is a special case of the typical all-different constraint, requiring that the variables should take all-different values except the variables assigned 0. We set the level of default inference (`DefaultInferenceLevel`) and the level of all-different inference (`AllDiffInferenceLevel`) to `extended`, i.e., the most sophisticated constraint propagation technique is used. We set the time limit parameter to 6.0×10^2 seconds. We set all the remaining parameters to default values.

All the experiments are conducted by our PC that carries 2.80 GHz CPU and 4GB main memory.

B. Results

First, we compare OURS with OURS-NOSUB and MATCHING. We generate 1000 instances for each pair (n, p) such that $n \in \{10, 20, \ldots, 80\}$ and $p \in \{0.1, 0.2, \ldots, 0.9\}$. We solve all the generated instances by each algorithm and compare the algorithms in terms of $|L|$. We show the typical results in Table I. The table shows the numbers of wins, ties and losts of OURS against the other algorithms over the 1000 instances. When n is small (i.e., $n = 10$), OURS is competitive with OURS-NOSUB in general, except that it is rather worse for $p = 0.6$. OURS outperforms MATCHING for smaller p, and for larger p, they are rather competitive. When n is larger, OURS is more likely to outperform the rest two algorithms. In particular, when $n = 80$, OURS wins over OURS-NOSUB in more than 80% of the instances and wins over MATCHING in almost all the instances. Based on these, we claim that the subroutine COLLECTME should play a significant role in improving the solution especially when n is large. We also claim that OURS should be superior to MATCHING, the original approximation algorithm. Let us discuss the computation time. MATCHING takes less than 1 seconds in all the instances from $n = 10$ to 80. Given the side length n, OURS takes more computation time for the instances that are generated by smaller pre-assigned ratio p. For every $n = 10, 20, \ldots, 80$, the average computation time for $p = 0.1$ is twice to three times of that for $p = 0.9$ approximately. For example, when $n = 10$ (resp., 80), the average computation time for $p = 0.1$ is 7.7×10^{-3} (resp., 2.0×10^{1}) seconds, whereas that for $p = 0.9$ is 4.1×10^{-3} (resp., 7.5×10^{0}) seconds. We consider the reason as follows; when p is smaller, there are more edges in the compatibility graphs in the earlier steps of the algorithm. Then it should take more time to compute a maximum matching since the algorithm runs in $O(\sqrt{|V|}|E|)$ time, which is proportional to the number of edges, while $|V| = 2n$ holds for any compatibility graph. The current implementation of OURS is rather naïve, and we believe that it is possible to improve the computation time to some extent by devising the data structure. This is left for future work.

Next, we compare OURS with LS. This time we generate 100 instances for given n and p. We solve each instance by OURS once, whereas we solve it by LS 10 times; in our implementation, LS proceeds to a solution randomly chosen from the neighborhood. Changing the seed of pseudo random numbers, we solve the instance by executing LS 10 times. We examine the $100 \times 10 = 1000$ cases to count the number of wins, ties and losts of OURS. We show the results in Table II, along with the values of the radius r. We describe the reason why we set r to the indicated values. The computation time of LS is affected by r significantly. LS is just a heuristic, and its computation time should be shorter than the time needed for the optimization solvers (i.e., CPMATH or CPCP) to find global optimum solutions. We set the radius r based on this philosophy. For example, when $n = 30$ and $p = 0.2$, the solvers find global optimum solutions in only 1.0×10^{1} seconds for any instance. However, when $r = 3$, LS takes at least 3.0×10^{2} seconds until it outputs a local optimal solution, which we infer from our preliminary experiments. Thus we set $r = 2$ even though the average computation time is still 2.4×10^{1} seconds. Note that OURS is much faster than LS; it takes less than 1 second to solve any instance. As expected from Table II, OURS should outperform LS in this perspective for $n \geq 30$ and $p \leq 0.7$. Note that this range includes "hard" instances in the context of the phase-transition.

Finally, we compare OURS with CPMATH and CPCP. When n gets larger, the solvers are less likely to find global optimum solutions in practical time. To illustrate this, in Table III, we show the number of instances such that the solvers can find global optimum solutions in 6.0×10^{2} seconds. In this experiment, we generate 100 instances for each (n, p). It is shown that, when p is smaller (resp., larger), CPCP finds global optimal solutions in more (resp., less) instances than CPMATH. When p is intermediate ($p = 0.6$ and 0.7 in particular), the solvers hardly find global optimum solutions. When the solvers cannot find a global optimum solution within the time limit, they output the best solution among those searched. In such cases, OURS yields better solutions than the solvers although the computation time is much shorter. We illustrate this for $n = 60$ in Fig. 3. The figure shows the average of $|L|$ (vertical axis) with respect to the change of p (horizontal axis). OURS+CPCP represents CPCP that is given an incumbent solution generated by OURS. In the

TABLE III
THE NUMBER OF INSTANCES THAT THE OPTIMIZATION SOLVERS CAN FIND A GLOBAL OPTIMAL SOLUTION WITHIN 6.0×10^2 SECONDS

		the pre-assigned ratio p						
		0.2	0.3	0.4	0.5	0.6	0.7	0.8
$n = 40$	CPMATH	0	1	3	71	7	0	100
	CPCP	100	100	99	89	3	0	0
$n = 50$	CPMATH	0	0	0	0	0	0	100

	CPCP	92	66	25	1	0	0	0

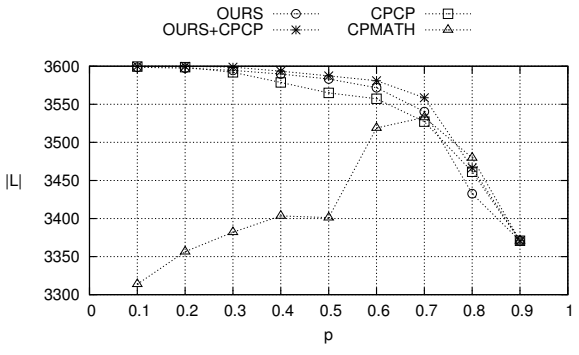

Fig. 3. The averaged objective value $|L|$ with respect to the change of p ($n = 60$)

solution search, CPCP retains the incumbent solution to prune solution subspaces such that there is no hope of finding a better solution. Giving a good incumbent solution may improve the efficiency of the search, or equivalently, it may result a better solution than the default CPCP within the same time limit. When $p \leq 0.2$, OURS and OURS+CPCP are competitive with CPCP and are much better than CPMATH. In this case, CPCP finds a global optimal solution within the time limit in almost all instances (see Table III), and thus OURS is also expected to do so. Surprisingly, when $0.3 \leq p \leq 0.7$ (i.e., "hard" instances), OURS is better than the solvers, and OURS+CPCP is even better. Note that OURS solves an instance with $n = 60$ within only 6.0×10^0 seconds on average, while the solvers take at most 6.0×10^2 seconds. We claim that these results should show the empirical effectiveness of the proposed algorithm.

V. CONCLUDING REMARKS

In this paper, we proposed a heuristic algorithm for the PLSE problem by extending the $\frac{1}{2}$-approximation algorithm [3] that utilizes the notion of maximum matching. We showed how the proposed algorithm is effective in practice through computational experiments.

This paper just shows the possibilities of our approach for the PLSE problem. We believe that the algorithm can be improved further by analyzing its behavior for various instances and the structures of compatibility graphs carefully. It is an alternative to apply metaheuristic techniques such as *genetic algorithm* and *simulated annealing* (*SA*). In fact, SA was applied to *sudoku* problem [15] that asks to find a PLS that is a maximum extension of a given PLS and that satisfies additional constraints. Different from SA, there is no adjustable parameter in the proposed algorithm whose tuning is often exhaustive. Being rather simple, the proposed algorithm delivers a good solution quickly. We can say that the proposed algorithm is a $\frac{1}{3}$-approximation algorithm since it delivers a blocked PLS and any blocked PLS is a $\frac{1}{3}$-factor solution [3]. It is interesting and challenging future work to analyze a nontrivial approximation ratio of the proposed algorithm.

The decision problem version of the PLSE problem has been studied in the field of constraint programming intensively. The problem is whether there is a Latin square that is an extension of a given PLS L_0. The answer is yes only when there is a perfect matching for every compatibility graph G_{L_0}. Any forbidden edge can be ignored in the solution search and the typical constraint programming technique eliminates all of the forbidden edges [16]. Our algorithm is different from this in that ours does not utilize forbidden edges but utilizes mandatory edges.

We have considered a heuristic algorithm for the PLSE problem, assuming practical use. We hope that other researchers take interest in this problem and work on it in the nearest future.

***Abstract*—In this paper we address a mining operation problem that is a special case of Quadratic Assignment Problem and which belongs to the class of facility layout problems. The considered problem is static and discrete, but the set of possible locations is larger than the set of facilities. We distinguish multiple types of equal-area facilities (mines, processing and auxiliary facilities). Mines can be placed only on selected locations (deposits of various resources), and the production volume of each type of facility depends on the adjacency of other facilities. We examine two situations: when the number of each type of facility is given, and when only the total number of facilities is specified. The goal is to maximize the production. This problem is multi-objective and we use advanced aggregation operators (OWA/WOWA) to achieve fair solutions. A comparison of results obtained with list-based threshold accepting meta-heuristic and simulated annealing algorithm is presented.**

I. Introduction

THE facility layout is a broad class of problems that has been a subject of interest for researches around the world due to many real-life applications as well as significant scientific value. Layout problems are generally NP-Hard [1], which makes them perfect test ground for various optimization algorithms and heuristic approaches. Because of different assumptions and vast variety of considerations, it is difficult to arrive at one, common definition that would encompass all possible kinds of problems associated with finding an optimal placement of facilities in some predefined area.

In terms of layout evolution, the problem can be static, i.e. the key information about the problem (e.g. parameters and relationship between facilities) are constant, or dynamic, when possible changes over subsequent time periods additionally have to be taken into account (see [2] for both formulations).

By analyzing the layout formulations, we can classify the problems as continuous, in which the facilities can be placed anywhere within the designated area [3], or discrete, when the facilities can be placed only in specified locations [4]. The discrete formulation can be considered as a Quadratic Assignment Problem (QAP) [5], in which the assignment function is a bijection, i.e. the number of facilities is equal to the number of possible locations. Moreover, in QAP for each pair of locations a distance is specified and for each pair of facilities a weight is given.

In the literature we can find many different models with single criterion, e.g. total material handling cost, travel time of parts, travel distance, and problems with multiple criteria, for which at the same time different objectives are minimized, e.g. material handling, tools and information flow. For the latter problems, most researchers use a simple aggregation function, e.g. a weighted sum ([6], [7]).

In a great number of articles about the facility layout problems a meta-heuristic is chosen to solve the underlaying optimization problem. The evolutionary algorithms, and most notably genetic algorithms, are the most popular choice [3], [4], [8], [9], [10], [11]. The other group of approximated approaches that attract the interest of researchers are the random search methods - tabu search ([12], [13]) and simulated annealing ([14], [15]).

In this paper we address a layout problem that is static and discrete, but contrary to QAP the considered assignment function is not a bijection. Moreover, we define the relationship between the facilities and their location in a more complex way.

The goal of the facility layout problem considered in this paper is to find a non-overlapping planar arrangement of n rectangular facilities within a given rectangular site that maximizes the production of facilities, and unlike [11], [13] we assume equal-area facilities.

Furthermore, we distinguish multiple types of facilities (and therefore multiple types of products), hence the problem is multicriterial. We show that the application of the ordered weighted averaging (OWA) aggregation introduced by [16] is a consistent, reasonable and fairness-preserving approach to model a multicriteria facility layout problem.

To solve the problem, we propose a novel (not mentioned in the recent reviews and surveys on facility layout problems [17], [18]) heuristic approach based on the threshold accepting algorithm – a list-based threshold accepting meta-heuristic, that was successfully applied in a job-shop scheduling problem [19]. We compare the effectiveness of this algorithm with our design of simulated annealing ([20], [27]).

The paper is organized as follows. In Section 2, we present the definition of the multicriteria facility layout problem that we discuss in this article. Sections 3 briefly portrays the fair aggregation operators. In Section 4, we describe list-based threshold accepting and simulated annealing algorithms, and explain the implementation details for the problem at hand.

The results of the experiments are shown in Section 5, and the concluding remarks are presented in Section 6.

II. Problem definition

A. Basic notation and definitions

The facility layout problem that we discuss in this paper can be simply described as a problem of choosing a location $l \in \mathcal{L}$ for each facility $f \in \mathcal{F}$ so that the objective function (that will be defined later on) is maximized.

Remark 2.1: We assume equal-area facilities which are placed within a rectangular $n \times m$ grid. Each location is thus a cell in the grid and the considered problem is combinatorial in nature.

Remark 2.2: We assume $|\mathcal{L}| > |\mathcal{F}|$ so that the problem does not boil down to simply finding a correct permutation of facility locations. In consequence, the assignment function is not a bijection, as in QAP formulation.

We distinguish three main classes of facilities : $\mathcal{F} = \mathcal{P} \cup \mathcal{A} \cup \mathcal{M}$, where $\mathcal{P} = \bigcup_{t \in \mathcal{T}} \mathcal{P}_t$ is the set of $|\mathcal{T}|$ types of processing facilities, $\mathcal{A} = \bigcup_{v \in \mathcal{V}} \mathcal{A}_v$ is the set of $|\mathcal{V}|$ types of auxiliary facilities, and $\mathcal{M} = \bigcup_{u \in \mathcal{U}} \mathcal{M}_u$ denotes the set of $|\mathcal{U}|$ types of mines.

Remark 2.3: We assume $|\mathcal{T}| > 1$ and $|\mathcal{U}| > 1$, i.e. there are at least one processing facility and at least one mine.

Corollary 1: The problem is multicriterial in nature.

Remark 2.4: Throughout this paper we will commonly denote $\mathcal{C} = \mathcal{T} \cup \mathcal{U}$ as the set of all the facility types that are responsible for production, and $\mathcal{D} = \mathcal{T} \cup \mathcal{V} \cup \mathcal{U}$ as the set of all possible facility types.

The set of locations is divided into two subsets $\mathcal{L} = \mathcal{S} \cup \mathcal{E}$, respectively locations $\mathcal{S}$ for processing/auxiliary facilities, and extraction sites $\mathcal{E} = \bigcup_{r \in \mathcal{R}} \mathcal{E}_r$ where deposits of $|\mathcal{U}|$ types of resources $\mathcal{R} = \bigcup_{u \in \mathcal{U}} \mathcal{R}_u$ are located, and where the corresponding types of mines can be placed.

Remark 2.5: We assume that $\mathcal{S} \cap \mathcal{E} = \emptyset$ (i.e. a processing/auxiliary facility cannot be placed on an extraction site and a mine can be located only at one of the resource deposits).

In our facility layout problem the objective is to maximize the production output of processing facilities and mines.

Definition 1 (Basic production output): The basic production output denoted by $O_c^B, c \in \mathcal{C}$ is a production volume of a specified type of facility (processing facility or mine) regardless of its location and the locations of other facilities.

The auxiliary facilities by definition are not producing anything themselves, nevertheless they play an important role by affecting production of other facilities. Moreover, we assume that resource deposits have an impact on the facilities production as well and that in general the facilities themselves can positively affect each other.

Definition 2 (Distance function): The relationship between facilities is based on a binary distance function $d : \mathcal{L} \times \mathcal{L} \to \{0, 1\}$, i.e. either a pair of locations is adjacent or not. The facilities are placed in cells of a rectangular grid, and thus we assume that a relationship exists only between two adjacent facilities and facilities adjacent to resource deposits.

Definition 3 (Adjacent location): The set of all locations adjacent to a location $l \in \mathcal{L}$ will be denoted by $\delta_l(l) \subset \mathcal{L}$.

Definition 4 (Adjacent facility): The set of all facilities of type $d \in \mathcal{D}$ adjacent to a facility placed on location l will be denoted by $\delta_d^F(l) \subset \mathcal{F}$.

Definition 5 (Adjacent resource deposit): The set of all resource deposits of type $u \in \mathcal{U}$ adjacent to a facility f placed on location l will be denoted by $\delta_u^R(l) \subset \mathcal{R}$.

Definition 6 (Extra production output - facility): The extra production output denoted by $O_{cd}^F : \mathbb{N} \to \mathbb{R}$ is an additional production volume of a processing facility/mine $c \in \mathcal{C}$ proportional to the number of surrounding (adjacent) facilities $d \in \mathcal{D}$.

Definition 7 (Extra production output - resource deposit): The extra production output denoted by $O_{cu}^R : \mathbb{N} \to \mathbb{R}$ is an additional production volume of a processing facility/mine $c \in \mathcal{C}$ proportional to the number of surrounding (adjacent) resource deposits $u \in \mathcal{U}$.

Definition 8 (Processing facility production output): The (final) production output of a processing facility is defined as follows:

$$o_c(l) = O_c^B \left(\sum_{d \in \mathcal{D}} O_{cd}^F(\delta_d^F(l)) + \sum_{u \in \mathcal{U}} O_{cu}^R(\delta_u^R(l)) \right) \quad c \in \mathcal{C} \tag{1}$$

B. Optimization model

The mining operation problem considered in this article can be formulated as follows:

$$\max_x \ [o_1, o_2, \ldots, o_{|\mathcal{C}|}] \tag{2}$$

$$o_c^B = \sum_{l \in \mathcal{L}} O_c^B x_{lc} \quad c \in \mathcal{C} \tag{3}$$

$$o_c^F = \sum_{l \in \mathcal{L}} \sum_{i \in \delta(l)} \sum_{j \in \mathcal{D}} O_{cj}^F x_{ij} \quad c \in \mathcal{C} \tag{4}$$

$$o_c^R = \sum_{l \in \mathcal{L}} \sum_{i \in \delta(l)} \sum_{j \in \mathcal{U}} O_{cj}^R x_{ij} \quad c \in \mathcal{C} \tag{5}$$

$$o_c = o_c^B(o_c^F + o_c^R) \quad c \in \mathcal{C} \tag{6}$$

$$\sum_{c \in \mathcal{C}} x_{cl} = 1 \quad l \in \mathcal{L} \tag{7}$$

$$\sum_{l \in \mathcal{L}} \sum_{c \in \mathcal{C}} x_{cl} = |\mathcal{F}| \tag{8}$$

$$\sum_{l \in \mathcal{L}} x_{cl} = \alpha_c \quad c \in \mathcal{C} \tag{9}$$

$$x_{cl} \in \{0, 1\} \quad c \in \mathcal{C}, l \in \mathcal{L} \tag{10}$$

where α_c is a parameter that denotes the designated number of each facility type (the constraint (9) is optional).

III. Ordered weighted averaging

In the ordered weighted averaging aggregation of outcomes (OWA) $\mathbf{y} = (y_1, \ldots, y_m)$ the weights $\mathbf{w} = (w_1, w_2, \ldots, w_m)$ are assigned to the ordered values (i.e., to the smallest value,

the second smallest and so on) rather than to the specific criteria:

$$A_w = \sum_{i=1}^{m} w_i \theta_i(\mathbf{y}) \tag{11}$$

where $(\theta_1(\mathbf{y}), \theta_2(\mathbf{y}), \ldots, \theta_m(\mathbf{y}) = \Theta(\mathbf{y})$ is the ordering map $R^m \to R^m$ with $\theta_1(\mathbf{y}) \leq \theta_2(\mathbf{y}) \leq \ldots \leq \theta_m(\mathbf{y})$ and there exists a permutation τ of set I such that $\theta_i(\mathbf{y}) = y_{\tau(i)}$ for $i = 1, 2, \ldots, m$. The OWA operator provides a parameterized family of aggregation operators, which include many of the well-known operators such as the maximum, the minimum, the k-order statistics (including Conditional Value at Risk), the median and the arithmetic mean. The OWA satisfies the properties of strict monotonicity, impartiality and, in the case of monotonic increasing weights $w_1 > w_2 > \ldots > w_{m-1} > w_m$, the property of equitability [21] (satisfies the principle of transfers – equitable transfer of an arbitrary small amount from the larger outcome to a smaller outcome results in a more preferred achievement vector). Every solution maximizing the OWA function is then an equitably efficient solution to the original multiple criteria problem. Moreover, for linear multiple criteria problems every equitably efficient solution can be found as an optimal solution to the OWA aggregation with appropriate weights. Thus the OWA-based optimization generates the so-called equitably efficient solutions (cf. [22] for the formal axiomatic definition). According to [22] and [23], equitable efficiency expresses the concept of fairness, in which all system entities have to be treated equally and in the stochastic problems equitability corresponds to the risk aversion [24].

For the facility layout problem (2)–(10) the final OWA aggregation of the outcomes p_i for all types of production facilities $i \in \mathcal{C}$ can be stated as the following LP model:

$$\max \sum_{k=1}^{|\mathcal{C}|} k w'_k t_k - \sum_{k=1}^{|\mathcal{C}|} \sum_{c \in \mathcal{C}} w'_k d_{ck} \tag{12}$$

subject to

$$d_{ck} \geq t_k - o_c,\ d_{ck} \geq 0 \quad k = 1, 2, \ldots, |\mathcal{C}|,\ c \in \mathcal{C} \tag{13}$$

$$\mathbf{o} \in O \tag{14}$$

where coefficients w'_i are defined as $w'_m = w_m$ and $w'_i = w_i - w_{i+1}$ for $i = 1, 2, \ldots, m-1$, $\mathbf{o} = [o_c]_{c \in \mathcal{C}}$ and O is a feasible set of production output vectors defined by (3)–(10).

The weighted ordered weighted averaging (WOWA) aggregation is a generalization of the OWA aggregation, that allows assigning importance weights to specific criteria [25]. Those weights could express, for example, relative importance of different facility types. The weights assigned to ordered values will be further called preferential weights.

Let $\mathbf{p} = (p_1, \ldots, p_m)$ be an m-dimensional vector of importance weights such that $p_i \geq 0$ for $i = 1, \ldots, m$ and $\sum_{i=1}^{m} p_i = 1$. The corresponding Weighted OWA aggregation of vector $\mathbf{y}$ is defined [11] as follows:

$$A_{w,p} = \sum_{i=1}^{m} \omega_i \theta_i(\mathbf{y}) \tag{15}$$

with

$$\omega_i = w^*\Big(\sum_{k \leq i} p_{\tau(k)}\Big) - w^*\Big(\sum_{k<i} p_{\tau(k)}\Big), \tag{16}$$

where w^* is an increasing function interpolating points $(i/m, \sum_{k \leq i} w_k)$ together with the point $(0, 0)$ and τ representing the ordering permutation for $\mathbf{y}$ (i.e. $y_{\tau(i)} = \theta(\mathbf{y})$). Moreover, function w^* is required to be a straight line when the points can be interpolated in this way. We assume the piecewise linear interpolation function w^* which is the simplest form of the required interpolation.

Note, that the piecewise linear functions may be built with various number of breakpoints, not necessarily equal to number of criteria m [25]. Thus, any nonlinear function can be well approximated by a piecewise linear function with appropriate number of breakpoints. Therefore, we will consider weights vectors $\mathbf{w}$ of dimension n not necessarily equal to m. It is even possible to define a generalized WOWA aggregation where the preferential weights w_k are allocated to an arbitrarily defined grid of ordered outcomes defined by quantile breakpoints (see [25] and references therein).

As shown in [25], maximization of an equitable WOWA aggregation with decreasing preferential weights $w_1 \geq w_2 \geq \ldots \geq w_n$ may be implemented as the LP expansion of the original problem. In the case of the facility layout problem (2)–(10), this can be stated as follows:

$$\max \sum_{k=1}^{n} w'_k \left[\frac{k}{n} t_k - \sum_{c \in \mathcal{C}} p_c d_{ck} \right] \tag{17}$$

subject to

$$d_{ck} \geq t_k - o_c,\ d_{ck} \geq 0 \quad k = 1, 2, \ldots, n,\ c \in \mathcal{C} \tag{18}$$

$$\mathbf{o} \in O \tag{19}$$

If the importance weights are equal $p_c = 1/|\mathcal{C}|$, the model reduces to the OWA aggregation.

IV. Algorithms

A. List-based threshold accepting

List-based threshold accepting algorithm (LBTA) [19] is an extent of threshold accepting meta-heuristic, which belongs to the randomized search class of algorithms. The search trajectory crosses the solution space by moving from one solution to a random neighbor of that solution, and so on. Unlike the greedy local search methods which consist of choosing a better solution from the neighborhood of the current solution until such can be found (hill climbing), the threshold accepting allows choosing a worse candidate solution based on a threshold value. In the general concept of the threshold accepting algorithm it is assumed that a set of decreasing threshold values is given before the computation or an initial threshold value and a decrease schedule is specified.

Algorithm 1 Creating the list of threshold values

Require: Initial solution s_1, list size S, set of move operators $m \in M$

$i \leftarrow 0$
while $i < N$ **do**
  $m \leftarrow random(M)$
  $s_2 \leftarrow m(s_1)$
  if $C(s_1) \leq C(s_2)$ **then**
    $\Delta \leftarrow (C(s_2) - C(s_1))/C(s_1)$
    $list \leftarrow list \cup \{\Delta\}$
    $i \leftarrow i + 1$
  else
    $s_1 \leftarrow s_2$
  end if
end while
return $list$

The rate at which the values decrease controls the trade-off between diversification (associated with large threshold values) and intensification (small threshold values) of the search. It is immensely difficult to predict how the algorithm will behave when a certain decrease rate is applied for a given problem without running the actual computation. It is also very common that the algorithm with the same parameters works better for some problem instances and significantly worse for others. These reflections led to the list-based threshold accepting branch of threshold accepting meta-heuristic.

In the list-based threshold accepting approach, instead of a predefined set of values, a list is dynamically created during a presolve phase of the algorithm. The list, which in a way contains knowledge about the search space of the underlying problem, is then used to solve it.

1) Creating the list of threshold values: The first phase of the algorithm consists of gathering information about the search space of the problem that is to be solved. From an initial solution a neighbor solution is created using a move function (perturbation operator) chosen at random from a predefined set of functions. If the candidate solution is better than the current one, it is accepted and becomes the current solution. Otherwise, a threshold value is calculated as a relative change between the two solutions:

$$\Delta = (C(s_2) - C(s_1))/C(s_1) \tag{20}$$

and added to the list, where $C(s_i)$ is the objective function value of the solution $s_i \in S$, and S is a set of all feasible solutions. For this formula to work, it is silently assumed that $C : S \rightarrow \mathbb{R}_+ \cup \{0\}$. This procedure is repeated until the specified size of the list is reached. For the algorithm overview see Algorithm 1.

2) Optimization procedure: The second phase of the algorithm is the main optimization routine, in which a solution to the problem is found. The algorithm itself is very similar to that of the previous phase. We start from an initial solution, create new solution from the neighborhood of current one using one of the move function, and compare both solutions.

Algorithm 2 LBTA optimization procedure

Require: Initial solution s_1, thresholds list L, set of move operators $m \in M$

$i \leftarrow 0$
$s^* \leftarrow s_1$
while $i \leq N$ **do**
  $m \leftarrow random(M)$
  $s_2 \leftarrow m(s_1)$
  $i \leftarrow i + 1$
  if $C(s_2) \leq C(s_1)$ **then**
    if $C(s_2) \leq C(s^*)$ **then**
      $s^* \leftarrow s_2$
    end if
    $s_1 \leftarrow s_2$
    $i = 0$
  else
    $\Delta_{new} \leftarrow (C(s_2) - C(s_1))/C(s_1)$
    if $\Delta_{new} < max(list)$ **then**
      $list \leftarrow list \setminus \{max(list)\}$
      $list \leftarrow list \cup \{\Delta_{new}\}$
      $s_1 \leftarrow s_2$
      $i = 0$
    end if
  end if
end while
return $list$

If the candidate solution is better, it becomes the current one. Otherwise a relative change is calculated. To this point algorithms in both phases are identical. The difference in the optimization procedure is that we compare the threshold value with the largest value from the list. If the new threshold value is larger, then the new solution is discarded. Otherwise, the new threshold value replaces the value from the list, and the candidate solution is accepted to next iteration. The best solution found during the optimization process is considered final.

The list-based threshold accepting algorithm also incorporates early termination mechanism: after a (specified) number of candidate solutions is subsequently discarded, the optimization is stopped, and the best solution found so far is returned.

The optimization procedure of the list-based threshold accepting algorithm is shown in Algorithm 2.

B. Simulated annealing

The optimization process of the simulated annealing algorithm can be described in the following steps. At the start, an initial solution is required. Then, repeatedly, a candidate solution is randomly chosen from the neighborhood of the current solution. If the candidate solution is the same or better than the current one, it is accepted and replaces the current solution. Even if the generated solution is worse than the current one, it still has a chance to be accepted with, so called, acceptance probability. This probability is a function of difference between objective value of the current and

Algorithm 3 Simulated Annealing

Require: Initial solution s_1
1: $s^* \leftarrow s_1$
2: **for** $i = 1$ **to** N **do**
3: **for** $t = 1$ **to** N_{const} **do**
4: $s_2 \leftarrow perturbate(s_1)$
5: $\delta \leftarrow C(s_2) - C(s_1)$
6: **if** $\delta \leq 0$ or $e^{-\delta/k\tau} > random(0,1)$ **then**
7: $s_1 \leftarrow s_2$
8: **end if**
9: **if** $C(s_2) < C(s^*)$ **then**
10: $s^* \leftarrow s_2$
11: **end if**
12: **end for**
13: $\tau \leftarrow \tau * \alpha$
14: **end for**
15: **return** s^*

the candidate solution and depends on a control parameter taken from the thermodynamics, called temperature. The temperature is decreased after a number of iterations, and the process continues as described above. The optimization is stopped either after a maximum number of iterations or when a minimum temperature is reached. The best solution found during the annealing process is considered final.

For the algorithm overview see Algorithm 3.

In order to apply the simulated annealing algorithm to the facility layout problems, the annealing process must be adapted and the parameters adjusted appropriately. Similarly to the threshold decrease rate in LBTA, the temperature decrease (also known as the cooling process) in simulated annealing consists of decreasing the temperature by a so called reduce factor. The parameters associated with this mechanism are:

1) Initial temperature.
2) Function of temperature decrease in consecutive iterations.
3) The number of iterations at each temperature (Metropolis equilibrium).
4) Minimum temperature at which the algorithm terminates or alternatively the maximum number of iterations as the stopping criterion.

Let τ be the temperature and α be the reduce factor. Then the annealing scheme can be represented as the following recursive function:

$$\tau^{i+1} = \alpha * \tau^i, \tag{21}$$

where i is the number of current iteration in which the cooling schedule takes place.

Second building block of SA that has to be customized is the acceptance probability function, which determines whether to accept or reject candidate solution that is worse than the current one. The most widely used function is:

$$p(\delta, \tau) = e^{-\delta/k\tau}, \tag{22}$$

TABLE I
SIMULATED ANNEALING PARAMETERS

Parameter	Description	Value
α	Reduce factor	$1 - \frac{5}{N}$
τ^0	Initial temperature	0.99
δ^0	Minimal difference between solutions	1
p^0	Initial acceptance probability	1
N_{const}	Number at each constant temperature	10
N	Number of SA iterations	100000

where $\delta = E(s_2) - E(s_1)$ is the difference between the objective value (denoted by E) of the candidate (s_2) and the current solution (s_1), and k is the Boltzmann constant found by:

$$k = \frac{\delta^0}{\log \frac{p^0}{\tau^0}}, \tag{23}$$

where δ^0 is an estimated difference between objective values of two solutions, p^0 is the initial value of the acceptance probability and τ^0 is the initial temperature. Notice that we use decimal logarithm rather than natural, which is most widely seen in the literature and, rather than average, we use minimal difference between solutions.

For the overview of the parameters applied in the facility layout problem, see Table I.

C. Neighborhood function

The most problem-specific mechanism of both the SA and the LBTA algorithm that always needs a different approach and implementation is the procedure of generating a candidate solution from the neighborhood of the current one, which is called a perturbation scheme, transition operation/operator or a move function. Although there are many ways to accomplish this task, we have examined the following techniques:

1) Interchange two adjacent processing facilities.
2) Interchange two processing facilities at random locations.
3) Move a single processing facility to an adjacent, empty location.
4) Change type of the facility.
5) Move a mine from current resource deposit to another deposit that is not occupied.

In order to generate a new solution, the LBTA algorithm applies one of the aforementioned operators chosen at random to the current solution. SA on the other hand uses only one, compound operator (a combination of operators which together allow to make a transition from initial to any feasible solution) during the whole optimization procedure.

D. Implementation details

1) Zero elements: In the first phase of the list-based threshold accepting algorithm the list is populated with values of relative change between two solutions $\Delta \geq 0$. After careful consideration, we believe that including zeros in the list is a misconception. In the actual optimization procedure, i.e. the second phase, the threshold value is computed only if the new solution is worse than the current one, which means that the

calculated relative change will always have a positive value ($\Delta_{new} > 0$). The new threshold value is compared with the largest value from the list (T_{hmax}). Thus, we can distinguish three cases:

1) $T_{hmax} = 0$: since thresholds are non-negative from definition, in this case the list contains all zero elements and it will not change throughout the whole procedure (T_{hmax} is constant). Comparing a positive threshold value Δ_{new} against zero yields in discarding the candidate solution. The conclusions are as follows:
   a) it does not matter how many zeros are in the list, the effective size of the list is equal to one,
   b) the algorithm is reduced to hill climbing algorithm that accepts candidate solutions which are at least as good as the current one.
2) $T_{hmax} > 0$ and $\Delta_{new} < T_{hmax}$: the largest (positive) threshold value from the list T_{hmax} is replaced by a smaller (positive) threshold value Δ_{new}. The number of zero elements in the list remains the same throughout the whole procedure and therefore is completely irrelevant to the optimization process. The effective list size is equal to the number of positive elements.
3) $T_{hmax} > 0$ and $\Delta_{new} \geq T_{hmax}$: the new solution is discarded and the list remains unchanged.

The main idea behind the list is to control the diversification and intensification of the search process. In the early stage of the search the algorithm should allow to cover as much solution space as possible, which means that the thresholds in the list are expected to be large enough to make that happen. In the middle stage, the algorithm should slowly stop fostering the diversification and begin to foster the intensification of the search. In the end stage, the intensification should be the strongest, i.e. the list is supposed to contain smaller and smaller threshold values, which induces discarding of worse solution candidates. In consequence, the algorithm is converging to a local or possibly even a global optimum.

2) Stopping criterion: Even though equipped with an early-termination mechanism, the LBTA algorithm does not have a solution space independent stopping criterion. If the number of subsequently discarded worse solutions is set too high, the algorithm will run for an unacceptable long time (it has been observed during preliminary tests). Hence, we propose to use a global counter of iterations so that when a limit is reached, the algorithm will terminate gracefully.

V. Numerical experiments

The numerical experiments were performed on a number of randomly generated different size problems. Each instance is defined by the number of locations $|\mathcal{L}|$, which in turn determines the number of facilities: $|\mathcal{F}| = |\mathcal{L}|/2$, and the number of resource deposits: $|\mathcal{R}| = |\mathcal{L}|/5$ (the number of resource deposits of each type are equal or differ by one). However, the following settings were the same for every instance, regardless of the problem size:

1) the number of types of processing facilities $|\mathcal{T}| = 2$,
2) the number of types of auxiliary facilities $|\mathcal{V}| = 2$,
3) the number of types of mines/resources $|\mathcal{U}| = 2$,
4) the extra production output depending on adjacent facilities is defined for pairs of processing facility type t_i and auxiliary facility type v_i: $O^F_{t_i v_i} = 0.4, i = 1, 2$ and for one pair of processing facility types: $O^F_{t_1 t_2} = 0.2$ (the relationship is not symmetrical),
5) the extra production output depending on adjacent resource deposits is defined for pairs of processing facility type t_i and resource deposit type u_i: $O^R_{t_i u_i} = 0.5, i = 1, 2$,
6) the total basic production output is constant, and is randomly distributed among the (basic) production output of processing facilities and mines.

Algorithm 4 Random distribution algorithm

Require: Number of elements N, value to distribute v
1: $list \leftarrow v$
2: **for** $i = 1$ **to** N **do**
3: $x_0 \leftarrow max(list)$
4: $list \leftarrow list \setminus \{x_0\}$
5: $x_1 \leftarrow random(x_0)$
6: $x_2 \leftarrow x_0 - x_1$
7: $list \leftarrow list \cup \{x_1\} \cup \{x_2\}$
8: **end for**
9: $list \leftarrow shuffle(list)$
10: **return** $list$

The algorithm of random distribution of total number of facilities among the facilities of each type, and distribution of total basic production output among the basic production output of different types of processing facilities and mines has been based on bisecting technique described in [26]. For the overview see Algorithm 4.

For the WOWA aggregation operator we have chosen already examined weights generation methodology ([27]): all the weights, except two, are strictly decreasing numbers with the step 0.1, while the two selected weights ($k = \lfloor n/3 \rfloor$ and $k = \lfloor 2n/3 \rfloor$) differ from the previous ones by 0.5.

After preliminary tests, based on the objective value and iteration number at which the best solution was found, we have arrived at the list size of 2000, for which the LBTA algorithm works at peak performance.

The algorithms were implemented in Java, and all the experiments were performed on a 3.1 GHz processor. The results are the average of 30 tries for each instance.

We have examined two situations: when the number of each type of facility is given (constraint (9)) – see Table II, and when only the total number of facilities is specified – the results are presented in Table III.

Both algorithms produced similar results in terms of both the solution quality (mean value and standard deviation) and computation time. For instances with fixed number of each facility type, SA has smaller standard deviation, but when it comes to instances with fixed total number of facilities, it is the other way around.

TABLE II
LAYOUT PROBLEMS WITH THE NUMBER OF EACH TYPE OF FACILITY GIVEN

VI. CONCLUSION

We are not convinced that one algorithm supersedes the other, which only means that both heuristics are equally good and can be successfully applied to difficult, combinatorial problems, like the one considered in this paper.

By considering only the idea behind the algorithm, we find the LBTA meta-heuristic a little bit more appealing than SA because of the concept of the list. The list holds the key to control the optimization process. The larger the list, the longer the diversification stage will last, because there will be more threshold values to replace and higher probability of that happening. On the other hand, the smaller the list, the stronger the intensification, which in some cases can be more desired (e.g. when the algorithm cannot find a good solution within the given number of iterations). This gives the unique possibility to the algorithm designer to control the whole optimization process with just one parameter.

***Abstract*—In many areas of application it is important to estimate unknown model parameters in order to model precisely the underlying dynamics of a physical system. In recent years, Sequential Monte Carlo (SMC) methods have become a very popular tool for Bayesian parameter estimation. In this case, the problem of finding the best parameters configuration comes to the optimization issue which is to determine the best fit. In this paper, the application of this approach to the classical global optimization problem is described. We consider the situation when optimized functions are dynamical i.e. the global extremum is changing in time. For this purpose, we adapt two dimensional Ackley and four-dimensional Wood functions. Our aim is to find the most probable localization of the extremum in each time with the use of the Bayesian approach joined with the Markov Chain Monte Carlo (MCMC) and SMC algorithms. We propose a mechanism for dynamic tuning of the proposal distribution in SMC. The approach is based on the Metropolis-Hastings algorithm, combined with a resampling mechanism to achieve better results. We have examined different version of the proposed SMC and MCMC algorithms in terms of effectiveness to estimate the probabilistic distributions. The effect is demonstrated using two benchmark optimization problems. Computed results show that the proposed mechanisms can significantly improve optimization results compared to standard MCMC.**

I. Introduction

CONSIDER the general optimization problem (OP) designed with a time aspect i.e. the global extremum is changing its position with time (see e.g. Fig. 1). Suppose that various possibilities for a OP are defined by some parameters $\phi \in \Phi$, where Φ denotes the bounded space of parameters. As far as we have uncertainty connected with the best parameters configuration which provides optimum, we can express it in a form of a probability density function $P(\phi|D)$. $P(\phi)$ is the prior probability function that we can estimate based on the currently available information D [1]. Moreover, if new data D, related to the behavior of the optimization function, become available, it can be used for updating the prior distribution of searched parameters value $P(\phi)$ using Bayes theorem. This way we can obtain the posterior distribution $P(\phi|D)$ i.e. the distribution updated by the new information. In design optimization algorithms, the goal is to find the optimal values of the parameters set that minimizes (maximizes) the considered function. We consider that effectiveness of searching for the function extremum in subsequent time step can be increased by taking advantage from the information about the location of extremum in previous stages.

Previously, we have applied the methodology combining Bayesian inference with Markov Chain Monte Carlo (MCMC) methods to the problem of the contaminant source localization based only on the substance concentrations registered by distributed sensors network ([2] and [3]).

In this paper, we propose the application of the Sequential Monte Carlo (SMC) methods combined with the Bayesian inference to the global optimization problem. We present the possibility to connect MCMC and SMC to provide additional benefit in the process of event reconstruction. Proposed algorithms were tested on two benchmark functions where optimum was moving with time.

II. Optimization algorithm theoretical preliminaries

A. Bayesian inference

A good introduction to Bayesian theory can be found in [4] and [5]. Bayes' theorem, as applied to optimization problem:

$$P(\phi|D) = \frac{P(D|\phi)P(\phi)}{P(D)} \tag{1}$$

where ϕ represents possible configuration of optimization function parameters and D is the value of the optimized function at given point.

For our problem, Bayes' theorem describes the conditional probability $P(\phi|D)$ of optimum parameters (configurations of variables ϕ) given observed value of function under consideration (D). This conditional probability $P(\phi|D)$ is also known as the posterior distribution and is related to the probability of the D conforming to a given parameters configuration $P(D|\phi)$, and to the possible model configurations $P(\phi)$, before updating by new information D. The probability $P(D|\phi)$, for fixed D, is called the likelihood function, while $P(\phi)$ is the prior distribution. $P(D)$ is the marginal distribution of D and is called prior predictive distribution. $P(D)$ serves as a scaling factor and is this case is equal 1. So, in our case the

978-83-60810-53-8/$25.00

Bayes theorem can be written as follows:

$$P(\phi|D) \propto P(D|\phi)P(\phi) \tag{2}$$

To estimate the unknown function's optimum parameters ϕ using (2), the posterior distribution $P(D|\phi)$ must be sampled. $P(D|\phi)$ quantifies the likelihood of a set of measurements D given the function's optimum parameters ϕ.

We use a sampling procedure with the Metropolis-Hastings algorithm to obtain the posterior distribution $P(\phi|D)$. This way we completely replace the Bayesian formulation with a stochastic sampling procedure to explore the optimized function parameters' space and to obtain a probability distribution for the optimum location.

B. The likelihood function

A measure indicating the quality of the current state of Markov chain is expressed in terms of a likelihood function. This function is proportional to considered global optimization function $H(.)$:

$$ln[P(D|\phi)] = ln[\lambda(\phi)] \propto H(\phi) \tag{3}$$

After calculating value of the likelihood function for the proposed state its acceptance is performed as follows:

$$\frac{ln(\lambda_{prop})}{ln(\lambda)} \geq U(0,1) \tag{4}$$

where λ_{prop} is the likelihood value of the proposal state, λ is the previous likelihood value, and $U(0,1)$ is a random number generated from a uniform distribution in the interval $(0,1)$.

It is important to note that condition (4) is more likely to be satisfied if the likelihood of the proposal is only slightly lower than the previous likelihood value. It gives a chance to choose even a little "worse" state, because the probability of acceptance depends directly on the quality of proposed state.

C. Posterior distribution

The posterior probability distribution (2) is computed directly from the resulting samples defined by the algorithm described below and is estimated with

$$P(\phi|D) \equiv \hat{\pi}^N(\phi) = \frac{1}{N}\sum_{i=1}^{N}\delta(\phi_i - \phi). \tag{5}$$

$P(\phi|D)$ represents the probability of a particular parameters configuration ϕ. Equation (5) is a sum over the entire samples set of length N of all the sampled values ϕ_i. Thus $\delta(\phi_i - \phi) = 1$ when $\phi_i = \phi$ and 0 otherwise. Consequently, if a Markov chain spends several iterations at the same location value of $P(\phi|D)$ increases through the summation (increasing the probability for those optimum parameters).

D. Sequential Monte Carlo

Sequential Monte Carlo (SMC) is designed to sample from dynamic posterior distributions. The SMC methods are easy to parallelize - the different Monte Carlo proposals can be generated and evaluated in parallel. A good introduction to SMC is present in [6], [7], [8] .

E. Sequential importance resampling

Sequential importance resampling (SIR) is a sequential version of importance sampling (IS) and combines IS with resampling procedure [9] . At the center of the SMC approach in our case is the generation of a weighted sample using IS method. IS uses a proposal distribution $q(.)$, that is close to target distribution $\pi(.)$ and from which it is easy to generate samples. The basic methodology is given below.

1) Generate a sample of size N from the proposal distribution $q(\phi)$:
$$\phi_{(i)} \sim q(\phi), i = 1, ..., N \tag{6}$$
2) Compute the importance weights:
$$\breve{w}(\phi_{(i)}) \propto \frac{\pi(\phi_{(i)})}{q(\phi_{(i)})}, i = 1, ..., N \tag{7}$$
and define
$$w(\phi_{(i)}) = \frac{\breve{w}(\phi_{(i)})}{\sum_{j=1}^{N}\breve{w}(\phi_{(j)})} \tag{8}$$
3) The distribution $\pi(\cdot)$ is then approximated by
$$\breve{\pi}^N(\phi) \equiv \sum_{i=1}^{N} w(\phi_{(i)})\delta(\phi_i - \phi) \tag{9}$$
which places the probability mass $w(\phi_{(1)}), ..., w(\phi_{(N)})$ on the support points $\phi_{(1)}, ..., \phi_{(N)}$.

Hence, the weights would be proportional to the value of likelihood. In our case to calculate the weight we use of the following formula,which is related to the likelihood function (3):

$$\breve{w}(\phi_{(i)}) \propto \frac{1}{ln[\lambda(\phi_{(i)})]}, i = 1, ..., N \tag{10}$$

Resampling is used to avoid the situation when almost all (except only a few) of the importance weights are close to zero (problem of degeneracy of the algorithm). Basic idea of resampling methods is to eliminate samples which have small normalized importance weights and to concentrate upon samples with large weights. So,:

1) for $i = 1, ..., N$ are chosen samples with indexes $k(i)$ distributed according to the discrete distribution with N elements satisfying
$$P(k(i) = l) = w(\phi_{(i)}) \tag{11}$$
for $l = 1, ..., N$,
2) then for $i = 1, ..., N$ for samples $M_{k(i)}$ are assigned the weights
$$w(\phi_{k(i)}) = \frac{1}{N}. \tag{12}$$

A sufficient number of draws is called Effective Sample Size (ESS) and is equal:

$$\hat{N}_{eff} = \frac{1}{\sum_{i=1}^{N} w(\phi_{(i)})^2}. \tag{13}$$

where $w(\phi_{(i)})$ are normalized weights. If all weights are equal $1/N$ then effective sample size is N. In the contrast to a situation where all weights $= 0$, except for one weight $= 1$, effective sample size is equal 1.

F. MCMC prior to SMC

The SMC algorithm needs some set of samples to be initialized. An ideal way to generate this initial sample is using MCMC data from first K iterations in all time steps. The resulting equally weighted MCMC set of samples can then be passed on to SMC for processing in the subsequent iteration.

First, the scanning algorithm starts from the randomly chosen values of parameters ϕ (i.e. first we start from the "flat" priori). This assumption reflects lack of knowledge about the function optimum parameters. For the actual state ϕ likelihood function λ is calculated. Then we apply random walk procedure "moving" our Markov chain to the new position. Precisely, we change each model ϕ parameter by the value draw from the Gaussian distribution with the zero mean and variance σ_ϕ^2 each parameter. Standard deviations for sampling parameters are determined by the problem's domain size and refined with a trial and error procedure to ensure that the Markov chains had access to realistic ranges with minimal occurrences of stuck problem. Problem of stuck in chains can occur when the standard deviations chosen for the next iteration lead to a large number of rejected samples, causing that the chain remains in a given position for many iterations. For the proposal state the likelihood function λ_{prop} is again estimated. We compare this two values λ and λ_{prop} according to (4). If comparison is more favorable than the previous chain location, the proposal is accepted (Markov chain "moves" to the new location). If the comparison is "worse", new state is not immediately rejected. Random variable from binomial distribution is used to decide whether or not to accept the new state of chain. After K iteration we pass all the samples (from all m chains)to the sequential procedure. We compute importance weights by (10) and normalize them. Next we use roulette procedure to draw N samples from the set generated by Markov Chain.

This random component is important because it prevents the chain from becoming trapped in a local minimum. The pseudo code for one time step of the algorithm is given below.

One of the important aspects of stochastic procedure of calculating the posterior distribution is choosing burn-in phase. The burn-in factor represents the number of samples needed at the beginning for the Markov chain to actually reach the search state where it is sampling from the target distribution.

Statistical convergence (to the posterior distribution) is monitored by computing between-chain variance and within-chain variance [4]. If there are m Markov chains of length N, then we can compute between-chain variance B with

$$B = \frac{N}{m-1}\sum_{j=1}^{m}(\bar{\phi_j} - \bar{\phi})^2 \tag{14}$$

where $\bar{\phi_j}$ is the average value along each Markov and $\bar{\phi}$ is the average of the values from all Markov chains. The within-chain variance W is

$$W = \frac{1}{m}\sum_{i=1}^{m} s_i^2 \tag{15}$$

where

$$s_i^2 = \frac{1}{N-1}\sum_{i=1}^{N}(\phi_{ij} - \bar{\phi_i})^2 \tag{16}$$

The convergence parameter R is then computed as

$$R = \frac{var(\phi)}{W} \tag{17}$$

where $var(\phi)$ is estimate variance of ϕ and is computed as

$$var(\phi) = \frac{N-1}{N}W + \frac{1}{N}B. \tag{18}$$

In this paper, we consider the following variants of scanning algorithms:

1) **Classic MCMC**
   In this algorithm, the parameter space scan in each time step t is independent form the previous ones. So, in this case we don't use information from past calculations. Classic MCMC don't use sequential mechanism.

2) **SMC via Maximal Weights**
   As the first location of Markov chain ϕ_0^t it select the set of ϕ parameters for which weight in previous time step procedure was the highest. So, for $t > 1$:
   $$\phi_0^t \sim \ arg\ (\phi \in \{\phi_0^{t-1}, ..., \phi_n^{t-1}\})\ max\{w(\phi_i^{t-1})\} \tag{19}$$
   With this approach, we always start with the best values found so far.

3) **SMC via Rejuvenation and Extension**
   In contrast to SMC via Maximal Weights this algorithm as the first location of Markov chain ϕ_0^t at the time $t > 1$ chooses the set of parameters ϕ selected randomly from previous realization of resampling procedure in $t-1$ with use of the uniform distribution:
   $$\phi_0^t \sim U(\phi_0^{t-1}, \phi_1^{t-1}, ..., \phi_n^{t-1}) \tag{20}$$
   $$a\ uniform\ distribution\ \{1, ..., n\}$$
   Applying the new knowledge (new measurements) the current chain is "extended" starting from selected position with use of the new information in the likelihood function calculation.

III. Algorithms results for selected optimization problem

A. Two-dimensional (2D) Ackley function

We have benchmark the proposed global optimization algorithms with use of the 2D version of Ackley function Fig. 2.

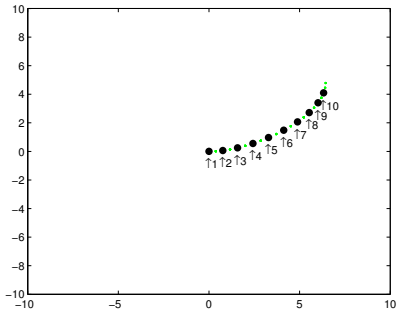

Fig. 1. Trajectory of the optimum of Ackley function

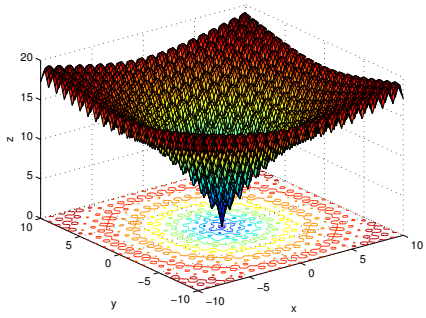

Fig. 2. Surf of two-dimensional Ackley benchmark function

$$H_1(x,y) = -20\exp(-0.2\sqrt{0.5(x^2+y^2)}) - \exp(0.5(cos(2\pi x)+\cos(2\pi y))) + 20 + e \quad (21)$$

The proposed optimization algorithms are designed to search for the optimum of the dynamical functions. To achieve the dynamical nature of the process described by the considered function we have ascribe the displacement of the optimum in 10 subsequent time steps. The assumed trajectory of the searched function optimum is presented in Fig. 1.

Based on the dynamical Ackley function we would like to compare the performance of two described in previous chapter SMC algorithms (i.e. SMC via Maximal Weights and SMC via Rejuvenation and Extension) in compare with a well-known stochastic simulation method i.e. classic MCMC. Since we are interested in runtime of all algorithms for optimization problems we use exactly the same parameters. The number of iteration for each algorithm is equal $K = 2000$. This number was chosen based on the numerical experiments as the number of iteration needed to reach convergence for each sampled dimension ($R \approx 1$) Fig. 3. The same way we tuned the rest of the algorithm parameters which adequately are equal: number of chains M=10; burn-in factor=500.

Fig. 5, and 6 presents the probability distributions of x and y optimum parameters in each time step for classic MCMC algorithm. Fig. 7 and 8 presents the same results for SMC via Maximal Weights and Figs. 10 and 11 for SMC via

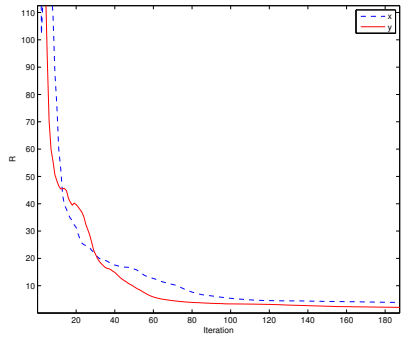

Fig. 3. R convergence parameter for x and y. The samples came from results of MCMC algorithm.

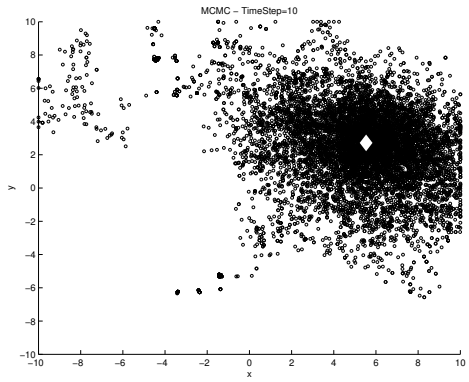

Fig. 4. The traces of three Markov chains in the x,y space. The global minimum is marked by diamond. The samples came from results of MCMC algorithm.

Rejuvenation and Extension, respectively. The target value of search optimum parameters are denoted by vertical lines. One can see that for the 2D Ackley dynamical function all algorithms successfully generate samples in the vicinity of the optimal solution. If we look carefully we can denote the difference of its probability values for the search parameters x and y. Moreover, the posteriori distributions of MCMC algorithm are much flatter than for SMC algorithms. For SMC via Maximal Weights and SMC via Rejuvenation and Extension the maximum value of the probability distribution x and y is close to 0.05 while for MCMC it is ≈ 0.027.

In both SMC algorithms transmission of the information in subsequent time steps about "fleeing minimum" effect enlarge the concentration of the samples around the target optimum. Resampling mechanism can be seen in Fig. 4 and Fig. 9. Fig. 4 presents the traces of the Markov chains for classic MCMC and Fig. 9 for SMC via Rejuvenation and Extension in the last time step. One can see that MCMC algorithm consider samples spread out far from the the searched optimum values, at the same time the SMC method in subsequent time steps choose samples close to the target value, which results in the increase of its probability.

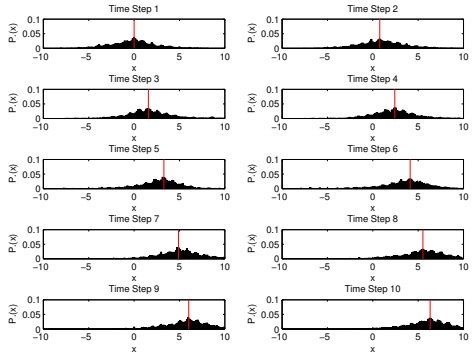

Fig. 5. Posterior distribution of x parameter in subsequent time steps for MCMC algorithm. Vertical line represents the target value of x.

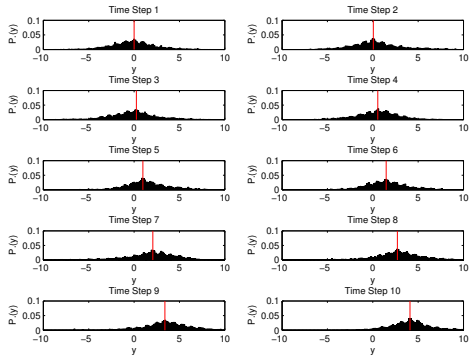

Fig. 6. Posterior distribution of y parameter in subsequent time steps for MCMC algorithm. Vertical line represents the target value of y.

B. Optimization problem - 4D Wood function

The previous example showed that the SMC algorithms give impute to the value of the probability of the searched optimum parameters (the probability is doubled). However, the classic MCMC also reached the target value of optimum. We would like to check if the proposed algorithms increase their efficiency in the case of the multidimensional space.

To test the effectiveness of SMC for optimization problem

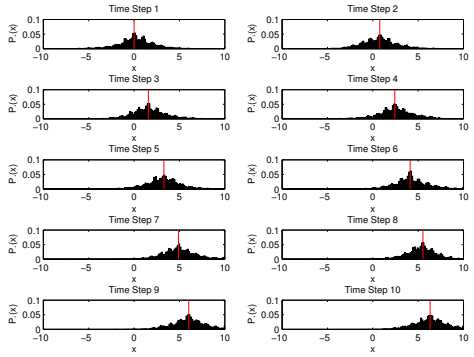

Fig. 7. Posterior distribution of x parameter in subsequent time steps for SMC via Maximal Weights. Vertical line represents the target value of x.

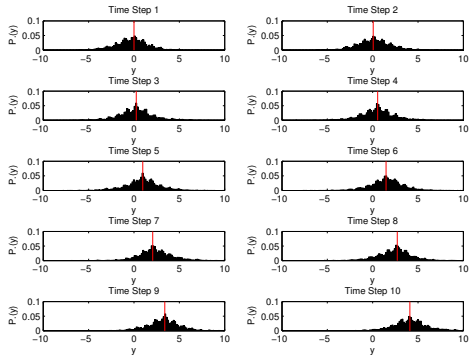

Fig. 8. Posterior distribution of y parameter in subsequent time steps for SMC via Maximal Weights. Vertical line represents the target value of y.

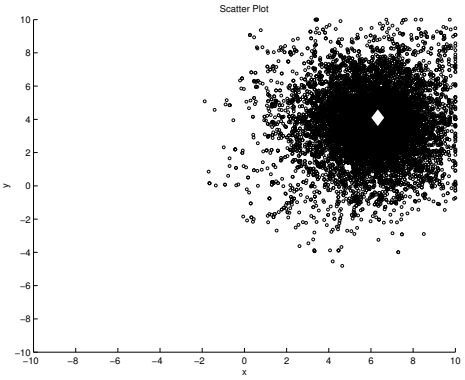

Fig. 9. Scatter plot of samples in the x,y space. The global minimum is marked by diamond. The samples came from results of SMC via Rejuvenation and Extension

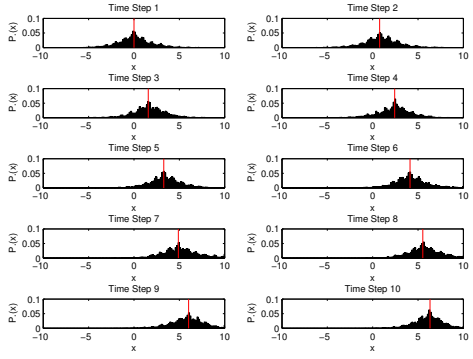

Fig. 10. Posterior distribution of x parameter in subsequent time steps for SMC via Rejuvenation and Extension. Vertical line represents the target value of x.

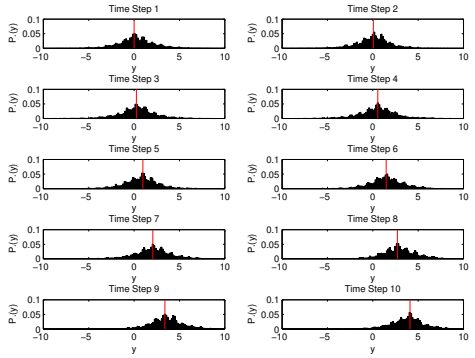

Fig. 11. Posterior distribution of y parameter in subsequent time steps for SMC via Rejuvenation and Extension. Vertical line represents the target value of y.

with higher dimensions, we consider the four-dimensional (4D) Wood function in our second benchmark test:

$$H_2(x_1,x_2,x_3,x_4) = 100({x_1}^2 - x_2)^2 + (x_1-1)^2 + (x_3-1)^2 + 90({x_3}^2 - x_4)^2 + 10.1((x_2-1)^2 + (x_4-1)^2) + 19.8(x_2-1)(x_4-1) \quad (22)$$

In this test we also assume that the optimum initial value $x = (1,1,1,1)$ moves in 6 subsequent time steps reaching at last $x = (3.84, 6.89, 3.84, 6.89)$. In this test for all considered algorithms we take: number of iteration $K = 20000$, number of chains $M = 10$; burn-in factor $= 2000$.

Figs. 12- 22 presents the marginal probability distributions for all four optimum parameters of the considered 4D Wood dynamical function. The target minimum location in each dimension is marked by the vertical red line. One can see that for the 4D Wood function efficiency of the classic MCMC is decreased. This method do not mark the target value of x_2 and x_4 parameters as the values with the highest probability (Figs. 13, 15). At the same time the results obtained from the two SMC algorithms are better than the MCMC algorithm. However, one can note than the SMC via Rejuvenation and Extension algorithm seems to be more efficient than SMC via Maximal Weights. The reason is that the SMC via Maximal Weights results for parameter x_2 (Fig. 17)are a bit worse than obtained from SMC via Rejuvenation and Extension (Fig. 21). Moreover, the SMC via Rejuvenation and Extension denotes the target values of the x_1 ,x_3 and x_4 parameter with higher probabilities than SMC via Maximal Weights.

It is worth to mention that SMC via Maximal Weights, SMC via Rejuvenation and Extension use the probability distributions obtained based on information from previous time steps to update the probability distributions with use of the new information. This causes a significant increase in convergence of the algorithm to the target location of the function's optimum in the subsequent time steps. This methodology makes these algorithms more effective for optimization of multidimensional dynamical functions than classic MCMC.

IV. Conclusion

We have presented a methodology to solve the global optimization problem of dynamical functions with use of the Bayesian approach joined with SMC algorithms. The presented method combines Bayesian inference with SMC sampling and produces posterior probability distributions of the searches extremum's parameters. We have examined two version of the SMC algorithms i.e. SMC via Maximal Weights, SMC via Rejuvenation and Extension and compare its efficiency to estimate the probabilistic distributions of optimum parameters for 2D and 4D optimization functions. We compared the effectiveness of the proposed SMC algorithms with classic MCMC and have shown the advantage of the SMC algorithms that in different ways use the probability distributions of possible optimum parameters obtained basing on samples generated in previous time steps. We have shown that efficiency of proposed SMC algorithms increases with increasing the dimension of the optimized dynamical function. We conclude that proposed methodology joining the Bayesian inference with SMC algorithms is effective for optimization of multidimensional dynamical functions.

***Abstract*—In this paper, an investigation of the influence of the population size on the genetic algorithm (GA) performance for a model parameter identification problem, is considered. The mathematical model of an *E. coli* fed-batch cultivation process is studied. The three model parameters – maximum specific growth rate (μ_{max}), saturation constant (k_S) and yield coefficient ($Y_{S/X}$) are estimated using different population sizes. Population sizes between 5 and 200 chromosomes in the population are tested with constant number of generations. In order to obtain meaningful information about the influence of the population size a considerable number of independent runs of the GA are performed. The observed results show that the optimal population size is 100 chromosomes for 200 generations. In this case accurate model parameters values are obtained in reasonable computational time. Further increase of the population size, above 100 chromosomes, does not improve the solution accuracy. Moreover, the computational time is increased significantly.**

I. Introduction

METAHEURISTICS, such as genetic algorithms (GA), are widely used to solve various optimization problems. The GA are highly relevant for industrial applications, because they are capable of handling problems with non-linear constraints, multiple objectives, and dynamic components – properties that frequently appear in the real-world problems [15]. Since their introduction and subsequent popularization [16], the GA have been frequently used as an alternative optimization tool to the conventional methods and have been successfully applied in a variety of areas, and still find increasing acceptance [1], [3], [7], [11], [23], [28], [29].

The metaheuristic algorithms require of setting the values of several algorithm components and parameters. These parameters values have great impact on performance and efficacy of the algorithm [13], [22], [30], [14]. Therefore, it is important to investigate the algorithm parameters influence on the performance of the developed metaheuristic algorithms. The aim is to find the optimal parameters values for the considered optimization problem. The optimal values for the parameters depend mainly on i) the problem; ii) the instance of the problem to deal with and iii) the computational time that will be spend in solving the problem. Usually in the algorithm parameters tuning a compromise between solution quality and search time should be done.

For the parameter setting of metaheuristics, several automated approaches exist. These methods use i) a single step of parameter tuning (prior to the practical use of the algorithm), or parameter control (self adaptation to the problem being optimized) [19]. Parameter control is well suited when one wants good average performances across diverse problems, but the needed computation overhead leads to less efficiency on specific problems, compared to parameter tuning [9]. Best known parameter tuning techniques are racing [8], sequential parameter optimization [5] and meta-parameter setting (sometimes referred as meta-algorithm [5]).

Population sizing has been one of the important topics to consider in evolutionary computation [2], [12], [31]. Various results about the appropriate population size can be found in the literature[25], [27]. Researchers usually argue that a "small" population size could guide the algorithm to poor solutions [17], [24], [31] and that a "large" population size could make the algorithm expend more computation time in finding a solution [17], [20], [21]. Due to significant influence of population size to the solution quality and search time [27] a more thorough research should be done for this GA parameter.

The main goal of this research is to carry out investigation of the influence of one of the key GA parameters – population size (number of chromosomes) – on the algorithm performance for identification of a cultivation process model. Parameter identification of non-linear cultivation process models is a hard combinatorial optimization problem for which exact algorithms or traditional numerical methods do not work efficiently. A non-linear mathematical model of fed-batch cultivation process of the most important host organism for recombinant protein production — bacteria *Escherichia coli* – is considered [27].

The paper is organized as follows. The problem formulation is given in Section 2. The numerical results and a discussion

978-83-60810-53-8/$25.00

are presented in Section 3. Conclusion remarks are done in Section 4.

II. Problem Formulation

A. E. coli Fed-batch Cultivation Model

Application of the general state space dynamical model [6] to the *E. coli* cultivation fed-batch process leads to the following nonlinear differential equation system [27]:

$$\frac{dX}{dt} = \mu_{max}\frac{S}{k_S + S}X - \frac{F_{in}}{V}X \tag{1}$$

$$\frac{dS}{dt} = -\frac{1}{Y_{S/X}}\mu_{max}\frac{S}{k_S + S}X + \frac{F_{in}}{V}(S_{in} - S) \tag{2}$$

$$\frac{dV}{dt} = F_{in} \tag{3}$$

where X is the biomass concentration, [g/l]; S is the substrate concentration, [g/l]; F_{in} is the feeding rate, [l/h]; V is the bioreactor volume, [l]; S_{in} is the substrate concentration in the feeding solution, [g/l]; μ_{max} is the maximum value of the specific growth rate, [h^{-1}]; k_S is the saturation constant, [g/l]; $Y_{S/X}$ is the yield coefficient, [-].

The initial process conditions are [4]:

- t_0 = 6.68 h,
- $X(t_0)$ = 1.25 g/l and $S(t_0)$ = 0.8 g/l,
- S_{in} = 100 g/l.

For the considered non-linear mathematical model of *E. coli* fed-batch cultivation process the parameters that should be identified are:

- maximum specific growth rate (μ_{max}),
- saturation constant (k_S),
- yield coefficient ($Y_{S/X}$).

B. Genetic Algorithm

GA was developed to model adaptation processes mainly operating on binary strings and using a recombination operator with mutation as a background operator. The GA maintains a population of chromosomes, $P(t) = x_1^t$, ..., x_n^t for generation t. Each chromosome represents a potential solution to the problem and is implemented as some data structure S. Each solution is evaluated to give some measure of its "fitness". Fitness of a chromosome is assigned proportionally to the value of the objective function of the chromosomes. Then, a new population (generation $t+1$) is formed by selecting more fit chromosomes (selection step). Some members of the new population undergo transformations by means of "genetic" operators to form new solution. There are unary transformations m_i (mutation type), which create new chromosomes by a small change in a single chromosome ($m_i : S \to S$), and higher order transformations c_j (crossover type), which create new chromosomes by combining parts from several chromosomes ($c_j : S \times \ldots \times S \to S$). After some number of generations the algorithm converges – it is expected that the best chromosome represents a near-optimum (reasonable) solution. The combined effect of selection, crossover and mutation gives so-called reproductive scheme growth equation [15]:

$$\xi(S, t+1) \geq$$

$$\xi(S,t) \cdot eval(S,t) / \bar{F}(t) \left[1 - p_c \cdot \frac{\delta(S)}{m-1} - o(S) \cdot p_m\right]$$

The structure of the herewith used GA is shown by the pseudocode below (Figure 1).

begin
  $i = 0$
  Initial population $P(0)$
  Evaluate $P(0)$
  while (not done) **do**
  (test for termination criterion)
  begin
    $i = i + 1$
    Select $P(i)$ from $P(i-1)$
    Recombine $P(i)$
    Mutate $P(i)$
    Evaluate $P(i)$
  end
end

Fig. 1. Pseudocode for GA

Three model parameters are represented in the chromosome – μ_{max}, k_S and $Y_{S/X}$. The following upper and lower bounds of the model parameters are considered [29]:

$$0 < \mu_{max} < 0.7,$$

$$0 < k_S < 1,$$

$$0 < Y_{S/X} < 30.$$

Roulette wheel, developed by Holland [16] is the herewith used selection method. The probability, P_i, for each chromosome is defined by:

$$P[\text{Individual } i \text{ is chosen}] = \frac{F_i}{\sum_{j=1}^{PopSize} F_j}, \tag{4}$$

where F_i equals the fitness of chromosome i and $PopSize$ is the population size.

To reproduce the chromosomes simple crossover and binary mutation according to [29] are applied. In proposed genetic algorithm fitness-based reinsertion (selection of offspring) is used.

For the considered here model parameter identification, the type of the basic operators in GA are as follows [29]:

- encoding – binary,
- fitness function – linear ranking,
- selection function – roulette wheel selection,
- crossover function – simple crossover,
- mutation function – binary mutation,
- reinsertion – fitness-based.

The values of GA parameters are [29]:

- generation gap, ggap = 0.97,
- crossover probability, xovr = 0.75,
- mutation probability, mutr = 0.01,
- maximum number of generations, maxgen = 200.

C. Optimization Criterion

In practical view, modelling studies are performed to identify simple and easy-to-use models that are suitable to support the engineering tasks of process optimization and, especially of control. The most appropriate model must satisfy the following conditions:

(i) the model structure should be able to represent the measured data in a proper manner;

(ii) the model structure should be as simple as possible compatible with the first requirement.

The optimization criterion is a certain factor, whose value defines the quality of an estimated set of parameters. To evaluate the mishmash between experimental and model predicted data the Least Square Regression is used.

The objective consists of adjusting the parameters (μ_{max}, k_S and $Y_{S/X}$) of the non-linear mathematical model function (Eq. (1) - Eq. (3)) to best fit a data set. A simple data set consists of n points (data pairs) (x_i, y_i), $i = 1, 2, \ldots, n$, where x_i is an independent variable and y_i is a dependent variable whose value is found by observation. The model function has the form $f(x, \beta)$, where the m adjustable parameters are held in the vector β, $\beta = [\mu_{max}\ k_S\ Y_{S/X}]$. The goal is to find the parameter values for the model which "best" fits the data. The least squares method finds its optimum when the sum S of squared residuals:

$$S = \sum_{i=1}^{n} r_i^2$$

is a minimum. A residual is defined as the difference between the actual value of the dependent variable and the value predicted by the model. A data point may consist of more than one independent variable. For an example, when fitting a plane to a set of height measurements, the plane is a function of two independent variables, x and z, say. In the most general case there may be one or more independent variables and one or more dependent variables at each data point.

$$r_i = y_i - f(x_i, \beta).$$

III. Numerical Results and Discussion

All computations are performed using a PC/Intel Core i5-2320 CPU @ 3.00GHz, 8 GB Memory (RAM), Windows 7 (64 bit) operating system and Matlab 7.5 environment.

A series of numerical experiments are performed to evaluate the influence of the population size in GAs on the accuracy of the obtained solution. Using mathematical model of the *E. coli* cultivation process (Eq. (1) - Eq. (3)) the model parameters – maximum specific growth rate (μ_{max}), saturation constant (k_S) and yield coefficient ($Y_{S/X}$) – are estimated. For the identification procedures consistently different population sizes (from 5 to 200 chromosomes in the population) are used. The number of generations is fixed to 200. Because of the stochastic characteristics of the applied GA series of 30 runs for each population size are performed.

TABLE I
ALGORITHM PERFORMANCE FOR VARIOUS POPULATION SIZES - OBJECTIVE FUNCTION VALUES

Population size	Objective function S		
	Average	Best	Worst
5	6.1200	4.8325	9.2958
10	5.8000	4.8548	9.6175
20	4.7660	4.4753	5.3634
30	4.6519	4.4816	5.0094
40	4.6359	4.4437	4.9669
50	4.6070	4.4488	4.8636
60	4.5886	4.4625	4.8013
70	4.5648	4.4384	4.7357
80	4.5782	4.4474	4.7463
90	4.5711	4.4496	4.7211
100	4.5406	4.4252	4.7017
110	4.5455	4.4332	4.7319
150	4.5511	4.4575	4.6717
200	4.5453	4.4359	4.7206

TABLE II
ALGORITHM PERFORMANCE FOR VARIOUS POPULATION SIZES - COMPUTATIONAL TIME

Population size	Computational time, s		
	Average	Best	Worst
5	4.9457	4.5552	5.6004
10	6.0039	5.6316	6.3648
20	7.6482	7.3008	7.9561
30	11.1115	10.8265	11.5129
40	12.9824	12.4957	13.3537
50	14.9087	14.3989	15.5377
60	17.2766	16.6141	20.3113
70	19.7601	19.1725	20.0617
80	22.1880	21.7153	22.6669
90	24.3414	23.9150	24.8198
100	26.8644	26.4890	27.8306
110	29.7057	29.1878	30.2642
150	39.7273	39.1407	40.3887
200	52.4782	51.3087	55.8952

In the Table I, obtained average, best and worst objective function values for considered population sizes, are presented. The results observed for computational time are listed in Table II.

The numerical experiments show that increasing the size of the population of 5 to 100 chromosomes significantly improves the resulting value of the objective function (average results) – from 6.1200 to 4.5406 (see Table I). The further increase in the size of population (more than 100 chromosomes) does not lead to more accurate results. The subsequent increase in the population size leads only to an increase in computational time without improving the value of the objective function (average results) – from 26.8644 s (100 chromosomes) to 52.4782 s (200 chromosomes) vs. $S = 4.5406$ to $S = 4.5453$ (see Table II).

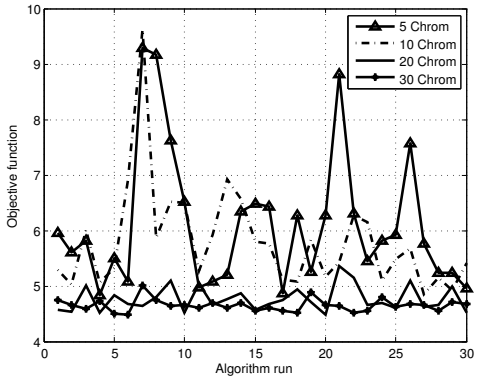

Fig. 2. Objective function values obtained during the 30 algorithm runs for 5, 10, 20 and 30 chromosomes in the population

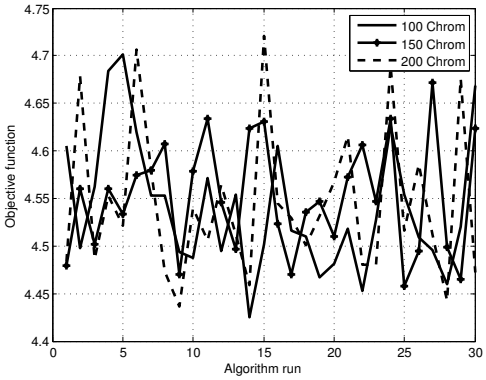

Fig. 3. Objective function values obtained during the 30 algorithm runs for 100, 150 and 200 chromosomes in the population

For better interpretation the obtained numerical results are graphically visualized in the next figures. On Figure 2 the objective function values, obtained during the 30 GA runs for 5, 10, 20 and 30 chromosomes in the population, are shown. The graphical results show that the GA could not find accurate solution using small population size – 5 or 10 chromosomes. It is need at least 20 chromosomes in population for achieving a better solution. On Figure 3 the objective function values, obtained during the 30 algorithm runs for 100, 110, 150 and 200 chromosomes in the population, are shown. Here, it could be seen that using large population size (110, 150 or 200 chromosomes) did not result in an improvement of the objective function values. The ANOVA test is applied and the values of the objective function for population size equal and more than 100 are statistically equal. Moreover, as can be seen from Figure 5 increasing the population size result in an acceleration of computational time. When the population size increases it leads to increase of the needed computational resources like time and memory which can be a problem for large-scale tests. Therefore we can conclude that populations with 100 individuals is optimal with respect to the value of the objective function and the needed computational resources.

All numerical experiments for the influence of the population size on the objective function value and on the computational time are summarized in Figure 4 and Figure 5. It can be concluded that for the considered here non-linear cultivation model parameter identification problem the optimal population size is 100 chromosomes in the population (for 200 generations).

In the Table III the best parameter values (μ_{max}, k_S and $Y_{S/X}$), obtained using GA with 100 chromosomes in the population, are presented. According to [10], [18], [32] the values of the estimated model parameters are in admissible boundaries.

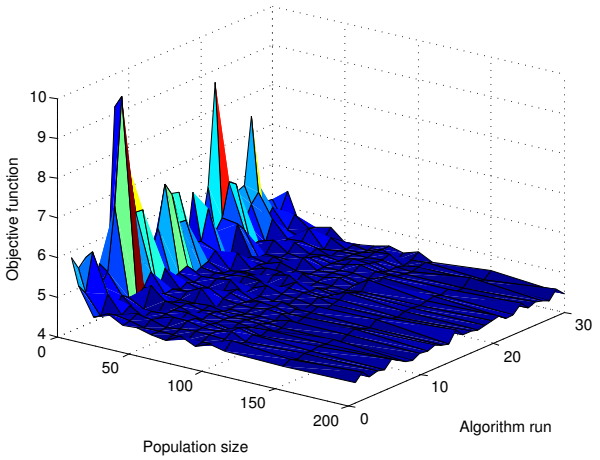

Fig. 4. Influence of the population size on the objective function value

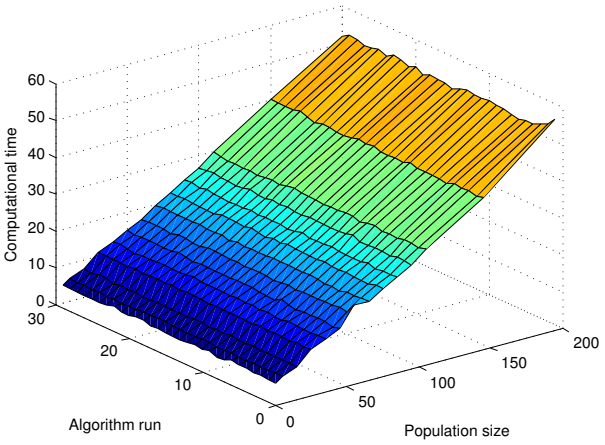

Fig. 5. Influence of the population size on the computational time

IV. Conclusion

A good selection of the GA parameters improve both computation time and solution accuracy. Finding good parameter values is not a trivial task and requires human expertise as

TABLE III
BEST PARAMETER VALUES OF THE MODEL (100 CHROMOSOMES)

Parameter	Value
μ_{max}, [1/h]	0.4881
k_S, [g/l]	0.0120
$Y_{S/X}$, [-]	2.0193

well as time. In this paper, the influence of the one of key GA parameters (population size) on the GA performance, is studied. As a test problem, the *E. coli* fed-batch cultivation model parameter identification, is considered. The three model parameters (maximum specific growth rate (μ_{max}), saturation constant (k_S) and yield coefficient ($Y_{S/X}$)) are identified. For a fixed number of the generations (200) different population sizes of the GA are explored. The numerical experiments are started with 5 chromosomes in the population and consistently increased to 200 chromosomes. The obtained results show that the optimal population size, for the considered here case study, is 100 chromosomes. Thus, accurate model parameters values are obtained with reasonable computational efforts. The use of smaller populations result in lower accuracy of the solution, obtained for a smaller computational time. The further increase of the population size increases the accuracy of solution. This effect is observed to a population size of 100 chromosomes. The use of larger populations does not improve the solution accuracy and only increase the needed computational resources.

***Abstract*—In this paper we present a Column Generation approach to the Quadratic Traveling Salesman Problem. Given a graph and a function that maps every pair of edges to a cost, the problem consists in finding a cycle that visits every vertex exactly once and such that the sum of the costs over all pairs of consecutive edges of the cycle is minimum. We propose a Linear Programming formulation that has a variable for each cycle in the graph. Since the number of cycles is exponential in the graph size, we solve our formulation via column generation. Computational results on some set of instances used in the literature show that our approach is promising. As it obtains a lower bound close to the optimal solutions for all instances.**

I. Introduction

THE TRAVELING SALESMAN PROBLEM (TSP) is one of the most studied optimization problems. Given an undirected graph $G = (V, E)$ with costs $c_e, e \in E$, the problem consists in finding a cycle C that visits each vertex in V exactly once, and such that the sum of the costs c_e of each edge in C is minimum. In its most common form, the TSP has a linear cost function.

In this paper we study a variant of the TSP that has a quadratic cost function, the so-called Quadratic TSP (QTSP). The input of this problem is an undirected (or directed) graph $G = (V, E)$ and a cost function $r : E \times E \to \Re^+$ that maps every pair of edges (or arcs) to a non-negative cost. The QTSP consists in finding a cycle C of minimum cost that visits every vertex of G exactly once. This problem is NP-hard [4]. We distinguish between Asymmetric QTSP and Symmetric QTSP, depending on the fact that the direction of the cycle matters.

The QTSP was introduced with an application to bioinformatics [4] and also has application in robotics and telecommunications. The QTSP can be viewed as a generalization of the Reload Cost TSP (RTSP) introduced in [1]. In the RTSP, one is given a graph whose every edge is assigned a color and there is a *reload* cost when passing through a node on two edges that have different colors.

The QTSP has been tackled in [4] with heuristic algorithms based on well-known heuristics for the TSP, with an ad-hoc branch-and-bound solver, and with a branch-and-cut approach based on a linearization of a 0-1 Quadratic Programming formulation of the problem. In [2] and [3], a polyhedral study is used to develop a branch-and-cut algorithm for symmetric and asymmetric QTSP respectively that are the current state-of-the-art for QTSP.

In this paper we present a Linear Programming formulation of the QTSP with an exponential number of variables that is solved via Column Generation (CG). The basic idea is to have a variable for each cycle of G. This yields a pricing subproblem that consists in finding a cycle of minimum quadratic cost. We formulated the pricing subproblem as a 0-1 Quadratic Program, which is linearized and solved with standard techniques. We resort to stabilization techniques to overcome the tailing-off effect of CG approach.

In Section II we present mathematical formulations and some linearized models for the symmetric QTSP and the asymmetric QTSP. In Section III we present our Linear Programming formulation of the problem. In Section IV we solve the LP model presented in Section III by a column-generation technique and present different formulations of the pricing subproblems for both the symmetric and the asymmetric cases. Computational results are discussed in Section V.

II. The Quadratic Traveling Salesman Problem

In this section we present mathematical formulations for both symmetric QTSP (SQTSP) and asymmetric QTSP (AQTSP). We denote the edge incident with vertices i and j as $\{i, j\}$ in the symmetric case while in the asymmetric case the arc from vertex i to vertex j is denoted as (i, j).

A. The Symmetric QTSP and a Linearized formulation

Consider a complete undirected graph G on a vertex set $V = \{1, 2, \ldots, n\}$ and let $r : E \times E \to \Re^+$ be a cost function that maps a pair of edges to a non-negative cost. The cost of a subgraph in G is equal to the sum of the costs of the pairs of edges incident in the same vertex. The SQTSP seeks a tour (i.e., a cycle passing through each vertex exactly once) of minimum cost. We define the binary variable x_{ij} that is equal to 1 if edge $\{i, j\}$ belongs to the minimum cost tour,

978-83-60810-53-8/$25.00

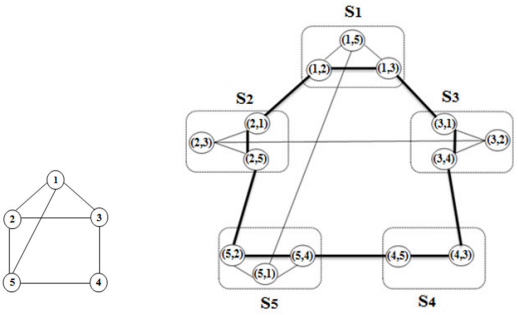

Fig. 1. Graph G and its corresponding *Gadget* graph $\hat{G}$. Note that we assume G to be complete, but this example shows the connections in the gadget graph when G is not complete, or when some of its edges have infinite cost

and 0 otherwise. The SQTSP can be modeled as a integer linear programming (ILP) problem as follows:

$$\min \quad \sum_{\{i,j\}\in E} \sum_{\{j,k\}\in E} r_{ijk} x_{ij} x_{jk} \tag{1}$$

$$\text{s.t.} \quad \sum_{j:\{i,j\}\in E} x_{ij} = 2 \quad \forall i \in V \tag{2}$$

$$\sum_{\substack{\{i,j\}\in E:\\ i\in S, j\in S}} x_{ij} \leq |S| - 1 \quad \emptyset \neq S \subset V \tag{3}$$

$$x_{ij} \in \{0,1\} \quad \forall \{i,j\} \in E. \tag{4}$$

The objective function is straightforward and considers all costs between edges incident on the same vertices. Constraints (2) ensure that each vertex has degree two in the tour, and constraints (3) ensure that no subtour is formed among the subsets of vertices.

A simple linear relaxation of (1)–(4) can be obtained by replacing the term $x_{ij}x_{jk}$ with a binary variable u_{ijk} subject to the following constraints.

$$u_{ijk} \leq x_{ij}, \quad u_{ijk} \leq x_{jk}, \quad \text{and} \quad u_{ijk} \geq x_{ij} + x_{jk} - 1.$$

Motivated by the desire to develop a linearized formulation, we reformulate the SQTSP by creating a new graph $\hat{G} = (\hat{V}, \hat{E})$, called the Gadget graph, as follows:

- For each edge in the graph G, create two nodes $\langle i,j\rangle$ and $\langle j,i\rangle$ and add them to $\hat{V}$.
- For each node $i \in V$ in G, define a super node $S_i = \{\langle i,j\rangle : j = 1,2,\ldots,n, j \neq i\}$. This is only an aggregation of nodes of $\hat{V}$.
- For any $i,j,k \in V$, create an edge between each two nodes $\langle i,j\rangle$ and $\langle i,k\rangle$ in the super node S_i and assign the weight r_{jik} to it.
- For any $i,j \in V$, create an edge between each two nodes $\langle i,j\rangle$ and $\langle j,i\rangle$ in super node S_i and S_j respectively and assign null weight to it.

In Figure 1 we present an example of a graph G and the corresponding *Gadget* graph $\hat{G}$.

By introducing the decision variables u_{jik} to indicate whether edge $\{\langle i,j\rangle, \langle i,k\rangle\}$ in super node S_i is selected or not in the optimal solution, we can rewrite the SQTSP on graph G as the following integer linear problem on the graph $\hat{G}$:

$$\min \quad \sum_{i\in V} \sum_{\substack{j,k\in V:\\ \{\langle i,j\rangle,\langle i,k\rangle\}\in S_i}} r_{jik} u_{jik} \tag{5}$$

$$\text{s.t.} \quad \sum_{\substack{j,k\in V:\\ \{\langle i,j\rangle,\langle i,k\rangle\}\in S_i}} u_{jik} = 1 \quad \forall i \in V \tag{6}$$

$$\sum_{\substack{\langle i,k\rangle\in S_i:\\ k\neq j}} u_{jik} - \sum_{\substack{\langle j,k\rangle\in S_j:\\ k\neq i}} u_{ijk} = 0 \quad \forall \langle i,j\rangle \in \hat{V} \tag{7}$$

$$\sum_{i\in S} \sum_{\substack{\{\langle i,j\rangle,\langle i,k\rangle\}\in \hat{E}:\\ j,k\in S}} u_{jik} \leq |S| - 1 \quad S \subset V \tag{8}$$

$$u_{jik} \in \{0,1\} \quad \forall \{\langle i,j\rangle, \langle i,k\rangle\} \in \hat{E}. \tag{9}$$

Constraints (6) guarantee that within every super node we select exactly one edge, constraints (7) indicate that the number of the edges incident on node $\langle i,j\rangle$ is equal to the number of incident edges on node $\langle j,i\rangle$, and constraints (8) are the subtour elimination constraints. Note that in terms of feasible solutions in the *Gadget graph*, a tour is called *feasible* if it is simple and passes through each super node S_i by visiting exactly one edge of S_i. In the example shown in Figure 1, the bold lines illustrate a feasible tour (a subtour of $\hat{G}$) corresponding to the feasible tour $\{(1,2),(2,5),(5,4),(4,3),(3,1)\}$ in the original graph G.

An alternative model in the case of reload costs spanning tree was studied in [10], where it is assumed that the triangle inequality holds for reload costs at each node of the graph.

B. The Asymmetric QTSP and Linearized formulation

Suppose that the given graph G is a complete directed graph on the vertex set $V = \{1,2,\ldots,n\}$, and let $r : E \times E \to \Re^+$ be a cost function that maps every pair of arcs to a non negative integer cost. The Asymmetric QTSP (AQTSP) can be modeled as follows:

$$\min \quad \sum_{(i,j)\in E} \sum_{(j,k)\in E} r_{ijk} x_{ij} x_{jk} \tag{10}$$

$$\text{s.t.} \quad \sum_{(i,j)\in E} x_{ij} = 1 \quad \forall i \in V \tag{11}$$

$$\sum_{(i,j)\in E} x_{ij} = 1 \quad \forall j \in V \tag{12}$$

$$\sum_{i\in S, j\notin S:(i,j)\in E} x_{ij} \geq 1 \quad S \subset V \tag{13}$$

$$x_{ij} \in \{0,1\} \quad \forall (i,j) \in E, \tag{14}$$

where the binary variable x_{ij} is equal to 1 if the arc (i,j) belongs to the minimum cost tour. Constraints (11) and (12) force to select a single outgoing arc and a single incoming arc for each node, respectively, and constraints (13) are the well known subtour elimination constraints.

In order to linearize the model, we follow the idea of constructing an auxiliary graph as in the symmetric case. We

call this auxiliary graph the *extended graph* and denote it as $\overline{G}$. For each arc (i,j) in the graph G we create a node $\langle i,j\rangle$ in $\overline{G}$, a link between each two nodes $\langle i,j\rangle$ and $\langle j,k\rangle$ in $\overline{G}$ and assign a weight r_{ijk} to each edge $(\langle i,j\rangle,\langle j,k\rangle)$ in $\overline{G}$. If in $\overline{G}$ we partition the set of nodes into n clusters $\mathcal{V}_1,\mathcal{V}_2,\dots\mathcal{V}_n$ such that $\mathcal{V}_i=\{\langle i,j\rangle : j=1,2,\dots,n, j\neq i\}$ for $i=1,2,\dots,n$, then all arcs are defined between nodes $\langle i,j\rangle$ and $\langle j,k\rangle$ from different clusters such that $r_{ijk}>0$; therefore there are no intra-set arcs.

Proposition 2.1: Any feasible tour in G corresponds to a tour in $\overline{G}$ that goes through each cluster exactly once.

Figure 2 represents the extended graph, $\overline{K}_4$, of a directed complete graph, K_4. The bold lines illustrate a feasible tour.

Definition 2.1: Given a directed graph $G=(V,E)$ and a partition $\{\mathcal{V}_i : i=1,\dots,k\}$ of the set V such that $\bigcap_{i=1}^{k}\mathcal{V}_i=\emptyset$ and $\bigcup_{i=1}^{k}\mathcal{V}_i=V$, the *Asymmetric Generalized* TSP (AGTSP) can be stated as the problem of finding a feasible cycle $T\subset E$ which includes exactly one node from each cluster $\mathcal{V}_i$, $i=1,\dots,k$, and whose global cost $\sum_{e\in T}r_e$ is minimum. Therefore the AGTSP involves two related decisions: (i) choosing a node subset $S\subset V$ such that $|S\cap\mathcal{V}_i|=1$ for all $i=1,2,\dots,n$ and (ii) finding a minimum cost Hamiltonian cycle in the subgraph of G induced by S.

Corollary 2.2: Solving the AQTSP on graph G is equivalent to solving the AGTSP on $\overline{G}$.

Using Corollary 2.2, instead of solving the original AQTSP one can solve an AGTSP on graph $\overline{G}$ which is again NP-hard, as it can be reduced to an Asymmetric TSP [8], [9].

We can formulate an integer linear programming model for the AGTSP. Variables u_{ijk} indicate whether arc $(\langle i,j\rangle,\langle j,k\rangle)$ is selected or not in the optimal solution, and variables y_{ij} indicate whether node $\langle i,j\rangle$ is visited or not. The problem is displayed as follows:

GTSP1:

$$\min \sum_{(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}} r_{ijk}u_{ijk} \tag{15}$$

$$\text{s.t.} \sum_{\substack{j\in V:\\ \langle i,j\rangle\in\mathcal{V}_i}} y_{ij}=1 \quad \forall i\in V \tag{16}$$

$$\sum_{\substack{k\in V:\\ \langle j,k\rangle\in\overline{V}}} u_{ijk}=y_{ij} \quad \forall\langle i,j\rangle\in\overline{V} \tag{17}$$

$$\sum_{\substack{k\in V:\\ \langle k,i\rangle\in\overline{V}}} u_{kij}=y_{ij} \quad \forall\langle i,j\rangle\in\overline{V} \tag{18}$$

$$\sum_{i\in S}\sum_{\substack{j\notin S:\\ \langle i,j\rangle\in\mathcal{V}_i}}\sum_{\substack{k\in V:\\ \langle j,k\rangle\in\mathcal{V}_j}} u_{ijk}\geq 1 \quad S\subset V \tag{19}$$

$$u_{ijk}\in\{0,1\} \quad \forall(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E} \tag{20}$$

$$y_{ij}\in\{0,1\} \quad \forall\langle i,j\rangle\in\overline{V}. \tag{21}$$

Constraint (16) guarantees that from every cluster we select exactly one node. Constraints (17) and (18) require a solution to include exactly one of the arcs entering and exactly one of the arcs leaving the node $\langle i,j\rangle$ if this node is visited. Finally, constraint (19) eliminates all subtours.

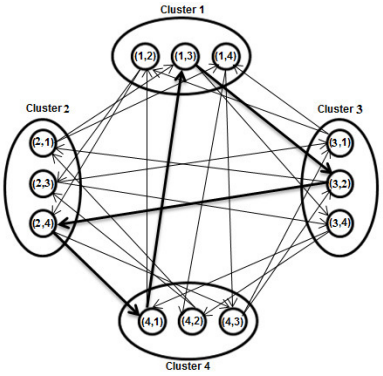

Fig. 2. Extended graph $\overline{K}_4$ of the complete graph K_4

Note that relaxing the integrality requirement on the variables u_{ijk} for all $(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}$ does not have any effect on problem GTSP1.

By eliminating variables y_{ij} we can write the problem as follows:

GTSP2:

$$\min \sum_{(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}} r_{ijk}u_{ijk} \tag{22}$$

$$\text{s.t.} \sum_{j\in V}\sum_{\substack{k\in V:\\ (\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}}} u_{ijk}=1 \quad \forall i\in V \tag{23}$$

$$\sum_{k\in V}\sum_{\substack{j\in V:\\ (\langle k,i\rangle,\langle i,j\rangle)\in\overline{E}}} u_{kij}=1 \quad \forall i\in V \tag{24}$$

$$\sum_{\substack{k\in V:\\ \langle j,k\rangle\in\overline{V}}} u_{ijk}-\sum_{\substack{k\in V:\\ \langle k,i\rangle\in\overline{V}}} u_{kij}=0 \quad \forall\langle i,j\rangle\in\overline{V} \tag{25}$$

$$(19),(20). \tag{26}$$

Constraint (23) requires a solution to include exactly one of the arcs entering a cluster, while constraint (24) requires a solution to include exactly one of the arcs leaving a cluster. Constraint (25) is equivalent to network flow conservation constraints and ensure that a solution tour is uninterrupted and continuous.

Theorem 2.3: Constraints (23) in problem GTSP2 are redundant and can be removed from the model.

Proof: Suppose u^* is a feasible solution for problem GTSP2 after removing constraint (23) and define, for each $i\in V$,

$$\epsilon_i=\sum_{j\in V}\sum_{\substack{k\in V:\\ (\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}}} u^*_{ijk}.$$

We show that $\epsilon_i=1$ for all $i\in V$.

Consider cluster $\mathcal{V}_s$. Then constraint (24) is satisfied for

cluster $\mathcal{V}_s$ by u^*, i.e.,

$$\sum_{k\in V} \sum_{\substack{j\in V \\ (\langle k,s\rangle,\langle s,j\rangle)\in\overline{E}}} u^*_{ksj} = 1.$$

Therefore there exists a node $\langle s,t\rangle \in \mathcal{V}_s$ with in-degree one in the tour, while the in-degree of all other nodes in cluster $\mathcal{V}_s$ is zero. Hence by (25) the out-degree of node $\langle s,t\rangle$ must be equal to one while the out-degree of all the other nodes in the same cluster must be zero. ■

As a consequence of Theorem 2.3 GTSP2 simplifies as follows:

$$\text{GTSP3:} \quad \min \sum_{(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}} r_{ijk}u_{ijk} \tag{27}$$

$$\text{s.t.} \quad (24), (25), (26). \tag{28}$$

III. Cycle Reformulation of QTSP

In this section we present a new formulation of the QTSP which is based on a cycle generation approach in the given graph. Let C be a cycle of G represented by the set of edges (arcs) that appear in the cycle. The cost of cycle C is $r(C) = \sum_{i,j,k\in V:(i,j),(j,k)\in C} r_{ijk}$, i.e. the sum of the costs of the pairs of consecutive edges (arcs) contained in the cycle. Let $\mathcal{C}$ and $\mathcal{T}$ denote the collection of all cycles and all tours of G, respectively. Clearly, we have that $\mathcal{T} \subseteq \mathcal{C}$, and hence $\min_{C\in\mathcal{C}} c(C) \leq \min_{T\in\mathcal{T}} c(T)$.

Following the approach of Held and Karp to the TSP [6], we add a penalty π_i to every vertex i in V, and denote by $\pi(C) = \sum_{i\in C} \pi_i$. Let us consider a new cost function defined as follows: $d(C) = c(C) + \pi(C)$. Let T^* denote an optimal tour of G, i.e. $c(T^*) = \min_{T\in\mathcal{T}} c(T)$. Then, the following relations hold:

$$\min_{C\in\mathcal{C}} d(C) = \min_{C\in\mathcal{C}}\{c(C) + \sum_{i\in C}\pi_i\} \leq d(T^*) = c(T^*) + \sum_{i\in V}\pi_i$$

$$\min_{C\in\mathcal{C}}\{c(C) - \sum_{i\in V\setminus C}\pi_i\} \leq c(T^*).$$

For any vector of penalty terms π we get a lower bound. However, we are interested in finding π that maximizes the lower bound:

$$\max_{\pi\in\Re^n} \min_{C\in\mathcal{C}} \{c(C) - \sum_{i\in V\setminus C}\pi_i\}. \tag{29}$$

We describe an LP equivalent to (29) by introducing a variable z as follows:

$$\text{P: max} \quad z \tag{30}$$

$$\text{s.t.} \quad z + \sum_{i\in V\setminus C}\pi_i \leq c(C) \qquad \forall C\in\mathcal{C} \tag{31}$$

$$z, \pi \text{ unrestricted.} \tag{32}$$

Let λ_C be the dual multiplier of constraint (31). The dual of problem P is called master problem and has the following form:

$$\text{D1: min} \quad \sum_{C\in\mathcal{C}} c(C)\lambda_C \tag{33}$$

$$\text{s.t.} \quad \sum_{C\in\mathcal{C}:i\notin C} \lambda_C = 0 \qquad \forall i\in V \tag{34}$$

$$\sum_{C\in\mathcal{C}} \lambda_C = 1 \tag{35}$$

$$\lambda_C \geq 0 \qquad \forall C\in\mathcal{C}. \tag{36}$$

Since all multipliers in (34) are non-negative, and, in each iteration of a column generation approach, exactly one column is generated (as we explain in Section IV), an optimal solution to the problem must satisfy $\lambda^*_C = 1$ for some $C^* \in \mathcal{C}$ and $\lambda^*_C = 0$ for all $C \in (\mathcal{C} \setminus C^*)$. It follows that the cycle C^* (single or multiple) is optimal and $c(C^*)$ provides a lower bound for the original QTSP.

By subtracting each constraint (34) from (35) and removing (35) from D1, one can find a relaxation of the problem D1 as follows:

$$\text{D2: min} \quad \sum_{C\in\mathcal{C}} c(C)\lambda_C \tag{37}$$

$$\text{s.t.} \quad \sum_{C\in\mathcal{C}:i\in C} \lambda_C = 1 \qquad \forall i\in V \tag{38}$$

$$\lambda_C \geq 0 \qquad \forall C\in\mathcal{C}. \tag{39}$$

Problem D2 seeks a minimum-weight "combination of cycles" such that each vertex appears, on average, in one cycle.

IV. Column Generation Approach

In this section we develop a column generation approach to solve problems D1 and D2. Since the number of cycles in $\mathcal{C}$ is exponential with respect to the number of vertices, we first consider a restricted version of the master problem (RMP) with a feasible subset of cycles, $\bar{\mathcal{C}} \subseteq \mathcal{C}$. Note that the subset $\bar{\mathcal{C}}$ for problem D1 must include at least one tour, while an initial set $\bar{\mathcal{C}}$ for problem D2 must satisfy constraints (38). Let us first start with problem D1 and suppose that $\pi = (\pi_1, \pi_2, \ldots, \pi_n)$ and z are the dual variables corresponding to constraints (34) and (35) respectively. The reduced cost of the variable λ_C for each $C \in \mathcal{C}$ is $\overline{r(C)} = r(C) - (\pi(C))' - z$, where $(\pi(C))' = \sum_{i\notin C}\pi_i$. A column to enter the basis can be found by computing a minimum cost cycle with respect to $r_{ijk} + \pi_j$ for each $(i,j) \in E, (j,k) \in E$. Let $\overline{r(C^p)} = \min_{C\in\mathcal{C}} \overline{r(C)}$. If $\overline{r(C^p)} \geq 0$ then the current solution is optimal. Otherwise we select column C^p to enter the basis.

Theorem 4.1: If the column C^p to enter the basis corresponds to a tour, then it is an optimal tour.

Proof: Consider any cycle C. Since column C^p is the selected column to enter the basis we have

$$\overline{r(C^p)} = r(C^p) - (\pi(C^p))' - z \leq r(C) - (\pi(C))' - z. \tag{40}$$

If cycle C is also a tour, then $r(C^p) \leq r(C)$. ■

Note that for problem D2, the reduced cost of the variable λ_C for each $C \in \mathcal{C}$ is modified to:

$$\overline{r(C)} = r(C) - \pi(C). \tag{41}$$

A. Pricing subproblems

A column to enter the basis can be found by computing a minimum cost cycle in the original graph G with respect to $r_{ijk} + \pi_j$. Looking for a cycle having minimum negative cost with respect to a quadratic objective is itself an interesting combinatorial optimization problem, which is NP-hard [5]. In this section we explain how to update the linearized models, presented in Section II, to solve the pricing problems. In order to define a suitable model for the pricing subproblem of the restricted master problem D1, we consider the SQTSP and AQTSP separately.

a) Symmetric case: Consider the pricing problem of D1 in the symmetric case. As we mention in Section II-A, instead of looking for a cycle in the original graph one can easily find a cycle in the *Gadget* graph; i.e., finding a negative reduced cost of problem D1 is the same as finding a negative cost feasible cycle in the Gadget graph. Defining a binary variable w_i to indicate whether the super node S_i is on the cycle or not, the minimum negative cost cycle is then found by solving the following problem:

$$\min \quad \sum_{i\in V} \sum_{\{\langle i,j\rangle,\langle i,k\rangle\}\in S_i} r_{jik}u_{jik} - \sum_{i\in V}\pi_i(1-w_i) - z$$

$$\text{s.t.} \quad \sum_{\substack{j,k\in V:\\ \{\langle i,j\rangle,\langle i,k\rangle\}\in S_i}} u_{jik} = w_i \quad \forall i \in V \tag{42}$$

$$(7)-(9) \tag{43}$$

$$w_i \in \{0,1\} \quad \forall i \in V. \tag{44}$$

Considering the definition of the w variables, one can obtain an equivalent formulation for the pricing problem by replacing constraint (42) with the so-called resource constraint $\sum_{\substack{j,k\in V\\ \{\langle i,j\rangle,\langle i,k\rangle\}\in S_i}} u_{jik} \le 1$ and removing the variables w from the model. Also, it should be observed that by forcing the solution of the pricing problem to be a cycle with negative cost one can easily remove the constraint (8) from the pricing model. Therefore, finding a cycle with negative reduced cost is simply a matter of finding a path between each node of the *Gadget* graph and itself with a negative cost which satisfies the resource constraint. Since the dual variables π are defined on each super node of the *Gadget* graph, the problem of finding a negative reduced cost cycle can be formulated as resource-constrained elementary shortest path problem. Let q_{st} denote the cost of the resource-constrained elementary shortest path from origin node $\langle s,t\rangle$ to itself in the *Gadget* graph. The pricing problem can be written as: $\min_{\langle s,t\rangle\in\hat{V}}\{q_{st}\}$, where q_{st} is the optimal value of the following problem.

$$\min \quad \sum_{i\in V} \sum_{\{\langle i,j\rangle,\langle i,k\rangle\}\in S_i} (r_{jik}+\pi_i)u_{jik} - \sum_{i\in V}\pi_i - z \tag{45}$$

$$\text{s.t.} \quad \sum_{\substack{j\in V:\\ \{\langle s,t\rangle,\langle s,j\rangle\}\in S_i}} u_{tsj} = 1 \tag{46}$$

$$\sum_{\substack{j\in V:\\ \{\langle s,j\rangle,\langle s,t\rangle\}\in S_i}} u_{jst} = 1 \tag{47}$$

$$\sum_{\substack{\langle i,k\rangle\in S_i:\\ k\neq j}} u_{jik} - \sum_{\substack{\langle j,k\rangle\in S_j:\\ k\neq i}} u_{ijk} = 0 \quad \forall \langle i,j\rangle \neq \langle s,t\rangle \tag{48}$$

$$\sum_{\substack{j,k\in V\\ \{\langle i,j\rangle,\langle i,k\rangle\}\in S_i}} u_{jik} \le 1 \quad \forall i \in V \tag{49}$$

$$u_{jik} \in \{0,1\} \quad \forall\{\langle i,j\rangle,\langle i,k\rangle\} \in \hat{E}. \tag{50}$$

Constraints (46), (47), (48) and (50) find a path from the source node $\langle s,t\rangle$ to itself. The resource constraint (49) guarantee that each super node S_i is visited at most once.

b) Asymmetric case: In the asymmetric case, finding a negative reduced cost directed cycle for problem D1 is equivalent to solving the modified version of the GTSP1 or GTSP3 explained in Section II-B. Here we provide a version of the latter so that the resulting problem gives the most negative directed cycle.

$$\min \quad \sum_{(\langle i,j\rangle,\langle j,k\rangle)\in\overline{E}} r_{ijk}u_{ijk} - \sum_{i\in V}\pi_i(1-t_i) - z$$

$$\text{s.t.} \quad \sum_{k\in V} \sum_{\substack{j\in V\\ (\langle k,i\rangle,\langle i,j\rangle)\in\overline{E}}} u_{kij} = t_i \quad \forall i \in V$$

$$(20),(25),(24)$$

$$t_i \in \{0,1\} \quad \forall i \in V.$$

The binary variable t_i is equal to 1 if cluster i is visited, otherwise it is zero. Following the same process as the symmetric case, one can obtain an equivalent formulation based on resource-constrained elementary shortest path problem in the extended graph.

The solution of the subproblems provides either a certificate of optimality of the current solutions (λ,π,z) or a new column C^p that will be added to the master problem. It is worth pointing out that solving the subproblem to optimality is only needed to prove optimality of the current primal and dual solutions; one can stop solving the subproblem whenever a negative reduced cost column is found [16]. This happens because adding this column to $\bar{C}$ ensures that the new dual solution (π,z) will be different, and therefore the termination of the algorithm.

B. Stabilized column generation

Column generation methods usually suffer from slow convergence to the optimal solution. Primal degeneracy, dual degeneracy and instability in the behavior of dual variables are well known to cause slow convergence and *tailing off* effects to column generation procedures [11], [12].

To control the dual variables during the solution process, we use the stabilized column generation approach proposed in [15]. This approach combines the box step method [14] with a

kind of descent method proposed in [13]. The box step method introduces a box around the previous dual vector and modifies the master problem such that the feasible dual space is limited to the area defined by these boxes, while the latter tries to adapt the master problem so that the distance separating a dual solution from the previous optimal dual solution is linearly penalized.

In order to present the idea, let us rewrite the restricted version of the master problem D1, for $\bar{\mathcal{C}} \in \mathcal{C}$, as the following model:

$$\text{RD1: min} \quad \sum_{C \in \bar{\mathcal{C}}} c(C)\lambda_C \tag{51}$$

$$\text{s.t.} \quad \sum_{C \in \bar{\mathcal{C}}: i \in C} \lambda_C \geq 1 \qquad \forall i \in V \tag{52}$$

$$(35), (36).$$

Note that since the set partitioning constraints allow negative dual values which can be problematic for the sub-problem, we used a relaxed version of the problem as the first step of the stabilization approach.

Consider the dual variables π associated with the constraints (52) and bound each π_i in the interval $[\delta_i^-, \delta_i^+]$. These bounds are first given as parameters to the model and then automatically updated during the process. The dual variable π_i can take values outside the given bounds, but the dual objective is then penalized by $\varepsilon_i^-(\delta_i^- - \pi_i)$ if $\pi_i < \delta_i^-$ and by $\varepsilon_i^+(\delta_i^+ - \pi_i)$ if $\pi_i > \delta_i^+$. The dual of the problem RD1 then becomes:

$$\text{SP: max} \quad z + \sum_{i \in V} \pi_i - \varepsilon_i^- w_i^- - \varepsilon_i^+ w_i^+ \tag{53}$$

$$\text{s.t.} \quad z + \sum_{i \in C} \pi_i \leq c(C) \qquad \forall C \in \bar{\mathcal{C}} \tag{54}$$

$$\pi_i + w_i^- \geq \delta_i^- \qquad \forall i \in V \tag{55}$$

$$\pi_i - w_i^+ \leq \delta_i^+ \qquad \forall i \in V \tag{56}$$

$$\pi, w^-, w^+ \geq 0, \ z \text{ unrestricted.} \tag{57}$$

The primal of the stabilized restricted master problem, and hence the dual of SP, is:

$$\text{SD1: min} \quad \sum_{C \in \bar{\mathcal{C}}} c(C)\lambda_C + \sum_{i \in V} -\delta_i^- \mu_i^- + \delta_i^+ \mu_i^+ \tag{58}$$

$$\text{s.t.} \quad \sum_{C \in \bar{\mathcal{C}}: i \in C} \lambda_C - \mu_i^- + \mu_i^+ \geq 1 \quad \forall i \in V \tag{59}$$

$$\sum_{C \in \bar{\mathcal{C}}} \lambda_C = 1 \tag{60}$$

$$\mu_i^- \leq \varepsilon_i^- \quad \forall i \in V \tag{61}$$

$$\mu_i^+ \leq \varepsilon_i^+ \quad \forall i \in V \tag{62}$$

$$\lambda, \mu^-, \mu^+ \geq 0. \tag{63}$$

This method is referred to as BoxPen stabilization since the bounds (δ^-, δ^+) on the original dual variables π can be represented by a bounding box containing the current dual solution. Note that the stabilized version of the problem D2 is the same as SD1 without the convexity constraint (60) and is called SD2. In order to use the stabilized models efficiently, one must initialize and update the parameters correctly. With desire to reduce the dual variables' variations, select $[\delta^-, \delta^+]$ to form a small box containing the current dual solution, and solve the problem SD1 (SD2). At the first iteration, when no solution is available to the problem, the dual variables π can be simply estimated. If the new π lies in the box $[\delta^-, \delta^+]$, reduce its width and augment the penalty given by ε^- and ε^+. Otherwise, enlarge the box and decrease the penalty. The update could be performed in each iteration, or alternatively, each time a dual solution of currently best value is obtained. In Section V we discuss more about the updating process.

V. Computational Experiments

In this section we present our computational experiments on a class of randomly generated instances with size rating from $n = 5$ to $n = 25$ introduced in [4]. All instances consist of complete graphs with n vertices and $m = n(n-1)/2$ edges. The cost function $r : E \times E \to \Re_0^+$ for both symmetric and asymmetric instances is defined as an integer number which is chosen from the set $\{0, 1, ..., 10000\}$ uniformly for all $(i, j), (j, k) \in E$ such that $i \neq k$ and set to infinity for all $(i, j), (j, i) \in E$. We used the AMPL modeling language [17] with GUROBI 5.0.0 [18] as linear solver for the RMP and as a mixed integer linear solver for the pricing problem on an Intel Core i5-2410M CPU with 2.30 GHz and 6 GB RAM in single processor mode.

A. Stabilization

We implemented the stabilized column generation approach using different sets of initial values. In the following we present the results of some preliminary experiments whose purpose was to initialize and update the parameters for both SD1 and SD2.

For the problem SD1, we initialized δ^- and δ^+ at -1000 and 1000 respectively. The vector parameter ε^- and ε^+ were selected as -5 and 5 respectively and were kept fixed throughout the solution process. We updated the parameter (δ^-, δ^+) from $(-1000, 1000)$ to $(\tilde{\pi} - 100, \tilde{\pi} + 100)$, ($\tilde{\pi}$ is the current dual solution), only if the column returned by the subproblem had a non-negative reduced cost and $(\mu^-, \mu^+) \neq (0, 0)$. The stopping criteria of the stabilized column generation algorithm is $\overline{r(C)} \geq 0$ and $(\mu^-, \mu^+) = (0, 0)$.

In order to find potentially good initial values of (δ^-, δ^+) for problem SD2, we first solved the problem D2 with a feasible subset of cycles. By using the dual variables $\tilde{\pi}$ of problem D2, we initialized (δ^-, δ^+) with $(\tilde{\pi} - 10, \tilde{\pi} + 10)$. The vector parameter ε^- and ε^+ were initially set to 0.0001. If the subproblem is able to find negative reduced cost cycle, then the values of ε^- and ε^+ were increased by 10%. However, when there was no more such column and $(\mu^-, \mu^+) \neq (0, 0)$, the values of ε^- and ε^+ were decreased by dividing each one by 100 and the parameter (δ^-, δ^+) were updated to $(\tilde{\pi} - 100, \tilde{\pi} + 100)$, where $\tilde{\pi}$ is the current dual solution of the SD2. The stopping criteria of the stabilized column generation algorithm is the same as case of problem SD1.

TABLE I
COMPUTATIONAL TIME OF COLUMN GENERATION (CG) AND STABILIZED CG APPROACHES FOR BOTH THE SQTSP THE AQTSP INSTANCES

	CPU time (Symmetric)				CPU time (Asymmetric)			
size	CG2	SCG2	CG1	SCG1	CG2	SCG2	CG1	SCG1
10	2.15	1.91	4.36	4.12	3.91	3.26	8.93	7.35
20	43.57	33.34	205.94	60.70	97.43	34.92	508.53	271.81

In order to show the effectiveness of stabilization, we compare the computational time of column generation to its stabilized version on two instances of different dimensions in Table I. Each row of the table reports the average computational time over ten instances of the same size. CG1 and CG2 stand for Column Generation approach to the problem SD1 and SD2 respectively. SCG1 and SCG2 are for the stabilized version of the CG1 and CG2 respectively. The results show that stabilization is effective for both symmetric and asymmetric instances.

B. Lower bound Computation

As we mentioned in Section III, a solution of the pricing problem, which may contain a single or multiple cycles, is optimal for the master problem $RD1$ if it covers all the nodes $i \in V$. Since looking for a single cycle in the pricing problem requires some kind of subtour elimination constraint, we restrict the search to find a cycle (single or multiple) with negative cost. In other words, we allow subtours in the optimal solution of the original QTSP, which is in fact a relaxation of the problem. Therefore, when no more new columns can be priced out, a solution of the master problem RD1 gives a lower bound on the original problem. Note that the optimal value of the problem RD2 always gives a lower bound on the original problem, regardless of the solution being a single cycle or multiple ones.

In Table II we present computational results of the lower bounding schemes for both the symmetric and the asymmetric QTSPs. Each row of the tables reports the average results over ten instances of the same size. The problem size is found in the first column of the table. The second column shows the average optimal values (opt) of the 10 instances for each dimension. We compare three different average lower bounds (LB) on the optimal objective values, their computing time (time), number of iterations (iter), and the average gap. The first lower bound LB(LP) in column three is the lower bound obtained with the linear relaxation of problem (5) – (9) and the linear relaxation of problem GTSP3 for the SQTSP and the AQTSP respectively. The computation time of the LP relaxation is less than two seconds for all instances; therefore we did not mention it in the table. The second lower bound is obtained via the Stabilized Column Generation approach to the problem SD2 (SCG2); and the third lower bound is obtained via the Stabilized Column Generation approach apply to the problem SD1 (SCG1). Columns four to seven and columns eight to eleven represent the optimal value, computation time, number of iterations needed to identify the optimal solution and the gap. The formula we used to compute these gaps is $(opt - LB(SCG))/(opt - LB(LP))$, where opt and $LB()$ stand for the optimal value and the lower bound, respectively. We can see in this table that the bounds obtained by SCG1 outperforms the other two in all instances and are close to the optimal values in both the SQTSP and the AQTSP. Also the lower bond obtained by SCG2 is indeed better than the one obtained with LP relaxation except for the instances of dimension five, for which the LP relaxation gives on average a tighter bound. On average the ratio of gap between the lower bound obtained by SCG2 and the optimal solution, and the gap between the lower bound obtained by linear relaxation and the optimal solution for the symmetric instances is 0.72, while this ratio for the asymmetric instances is 0.73. As we see, on average, the improvement of lower bound by applying the SCG2 for both symmetric and the asymmetric cases is almost the same, while the computational time for the asymmetric instances is more than the computational time for the symmetric ones.

According to Table II, applying SCG1 yields a considerable improvement of the lower bounds in both the symmetric and the asymmetric cases, i.e., on average the ratio of gap between the lower bound obtained by SCG1 and the optimal solution over the gap between the lower bound obtained by linear relaxation and the optimal solution for the symmetric instances is 0.09, and for the asymmetric instances is 0.20. These gaps show the improvement of lower bounds in both the symmetric and asymmetric cases in compare to the SCG2. Also it should be noted that the improvement of the lower bounds and also the computational time in the symmetric case is more attractive than in the asymmetric case.

VI. CONCLUSIONS

In this paper we first proposed two different linearization models to the SQTSP and the AQTSP. We also presented a different cycle formulation for the QTSP (in general) and solved the resulting LP problem by Column Generation approach. We have shown how the linearized formulations can be applied to finding the negative reduced cost in the pricing problem. To overcome the problems of instability in the behavior of dual variables of the presented master problem, we used a stabilized column generation approach. Our experiments show that our column generation approach outperforms the LP relaxation of the QTSP in both the symmetric and the asymmetric cases. The main goal of this paper is to show the advantage of column generation and the weakness of the LP relaxation in finding a good lower bound for the QTSP.

***Abstract*—The paper presents a concept and the outline of the implementation of a hybrid approach to modeling and solving constrained problems. Two environments of mathematical programming (MP) and logic programming (LP) were integrated. The strengths of integer programming (IP) and constraint logic programming (CLP), in which constraints are treated in a different way and different methods are implemented, were combined to use the strengths of both. The proposed approach is particularly important for the decision models with an objective function and many discrete decision variables added up in multiple constraints.**

To validate the proposed approach, two illustrative examples are presented and solved. The first example is the authors' original model of cost optimization in the supply chain with multimodal transportation. The second one is the two-echelon variant of the well-known Capacitated Vehicle Routing Problem, 2E-CVRP.

I. Introduction

THE vast majority of models [1]–[4] of decision support and/or optimization in manufacturing, distribution, supply chain management, etc., have been formulated as the mixed integer linear programming (MILP) or integer programming (IP) problems and solved using the operations research (OR) methods. Their structures are similar and proceed from the principles and requirements of mathematical programming. The constraint-based environments have the advantage over traditional methods of mathematical modeling in that they work with a much broader variety of interrelated constraints (resource, time, technological, and financial) and allow producing "natural" solutions for highly combinatorial problems.

A. Constraint-based environments

We strongly believe that the constraint-based environment [5]–[7] offers a very good framework for representing the knowledge and information needed for the decision support. The central issue for a constraint-based environment is a constraint satisfaction problem. Constraint satisfaction problems (CSPs) are the mathematical problems defined as a set of elements whose state must satisfy a number of constraints. CSPs represent the entities in a problem as a homogeneous collection of finite constraints over variables, which are solved using constraint satisfaction methods. CSPs are the subject of intense study in both artificial intelligence and operations research, since the regularity in their formulation provides a common basis for analyzing and solving the problems of many unrelated families [5]. Formally, a constraint satisfaction problem is defined as a triple (X,D,C), where X is a set of variables, D is a domain of values, and C is a set of constraints. Every constraint is in turn a pair (t,R) (usually represented as a matrix), where t is an n-tuple of variables and R is an n-ary relation on D. An evaluation of the variables is a function from the set of variables to the domain of values, $v:X \rightarrow D$. An evaluation v satisfies constraint $((x_1, \ldots,x_n),R)$ if $(v(x_1),..v(x_n)) \in R$. A solution is an evaluation that satisfies all constraints.

Constraint satisfaction problems on finite domains are typically solved using a form of search. The most widely used techniques include variants of backtracking, constraint propagation, and local search. Constraint propagation embeds any reasoning that consists in explicitly forbidding values or combinations of values for some variables of a problem because a given subset of its constraints cannot be satisfied otherwise [26].

CSPs are frequently used in constraint programming. Constraint programming is the use of constraints as a programming language to encode and solve problems.

Constraint logic programming (CLP) is a form of constraint programming (CP), in which logic programming is extended to include concepts from constraint satisfaction. A constraint logic program is a logic program that contains constraints in the body of clauses. Constraints can also be present in the goal. These environments are declarative.

The declarative approach and the use of logic programming provide incomparably greater possibilities for decision problems modeling than the pervasive approach based on mathematical programming.

B. Paper contents

In this paper we focus on the problem of modeling and solving decision problems using the novel hybrid approach. Having combined the strengths of MILP and CP/CLP (II, III), we developed the environment that ensures the better and easier way of problem modeling and implementation and that provides the more effective search solution (IV). In

978-83-60810-53-8/$25.00

order to verify the proposed approach, two illustrative examples are presented (V).

II. Motivation

Based on [1]–[4], and our previous work [6], [8]–[12], we observed some advantages and disadvantages of these environments.

An integrated approach of constraint programming (CP) and mixed integer programming (MIP) can help to solve optimization problems that are intractable with either of the two methods alone [13]–[16]. Although operations research (OR) and constraint programming (CP) have different roots, the links between the two environments have grown stronger in recent years.

Both MIP/MILP/IP and finite domain CP/CLP involve variables and constraints. However, the types of the variables and constraints that are used, and the way the constraints are solved, are different in the two approaches [16].

MILP relies completely on linear equations and inequalities in integer variables, i.e., there are only two types of constraints: linear arithmetic (linear equations or inequalities) and integrity (stating that the variables have to take their values in the integer numbers). In finite domain CP/CLP, the constraint language is richer. In addition to linear equations and inequalities, there are various other constraints: disequalities, nonlinear, symbolic (*alldifferent, disjunctive, cumulative* etc).

The motivation behind this work was to create a hybrid approach for supply chain modeling and optimization instead of using integer programming or constraint programming separately. We developed the hybrid framework for modeling and optimization of supply chain problems. In both MILP/MIP and CP/CLP, there is a group of constraints that can be solved with ease and a group of constraints that are difficult to solve. The easily solved constraints in MILP/MIP are linear equations and inequalities over rational numbers.

Integrity constraints are difficult to solve using mathematical programming methods and often the real problems of MIP / MILP make them NP-hard.

In CP/CLP, domain constraints with integers and equations between two variables are easy to solve. The system of such constraints can be solved over integer variables in polynomial time. The inequalities between two variables, general linear constraints (more than two variables), and symbolic constraints are difficult to solve, which makes real problems in CP/CLP NP-hard. This type of constraints reduces the strength of constraint propagation. As a result, CP/CLP is incapable of finding even the first feasible solution.

It follows from the above that what is difficult to solve in one environment can be easy to solve in the other.

The motivation was to offer the most effective tools for model–specific constraints and solution efficiency.

III. State Of The Art

As mentioned in Chapter I, the vast majority of decision-making models for the problems of production, logistics, supply chain are formulated in the form of mathematical programming (MIP, MILP, IP).

Due to the structure of these models (summing of discrete decision variables in the constraints and the objective function) and a large number of discrete decision variables (integer and binary) they can only be applied to small problems. Another disadvantage is that only linear constraints can be used. In practice, the issues related to the production, distribution and supply chain constraints are often logical, nonlinear, etc. For these reasons the problem was formulated in a new way,

In our approach to modeling and optimization of constrained search problems we proposed the optimization environment, where:

- knowledge related to the problem can be expressed as linear and logical constraints (implementing all types of constraints of the previous MILP/MIP models [10]–[14] and introducing new types of constraints (logical, nonlinear, symbolic etc.));
- the optimization model solved using the proposed framework can be formulated as a pure model of MILP/MIP or of CP/ CLP, or it can also be a hybrid model;
- the problem is modeled in CP/CLP, which is far more flexible than MIP/MILP/IP;
- the novel method of constraint propagation is introduced (obtained by transforming the optimization model to explore its structure);
- constrained domains of decision variables, new constraints and values for some variables are transferred from CP/CLP into MILP/MIP;
- the efficiency of finding solutions to the problems of larger sizes is increased.

As a result, we obtained the more effective search solution for a certain class of decision and optimization constrained problems.

IV. Hybrid solution environment

Both environments have advantages and disadvantages. Environments based on the constraints such as CLPs are declarative and ensure a very simple modeling of decision problems, even those with poor structures if any. The problem is described by a set of logical predicates. The constraints can be of different types (linear, non-linear, logical, binary, etc.). The CLP does not require any search algorithms. This feature is characteristic of all declarative backgrounds, in which modeling of the problem is also a solution, just as it is in Prolog, SQL, etc. The CLP seems perfect for modeling and solving any decision problem.

In OR numerous models of decision-making have been developed and tested, particularly in the area of decision optimization. Constantly improved methods and mathematical programming algorithms, such as the simplex algorithm,

branch and bound, branch-and-cost [20] etc., have become classics now.

The proposed method's strength lies in high efficiency of optimization algorithms and a substantial number of tested models. The decision problems we deal with in this paper, very common in manufacturing, logistics, supply chain, etc., have a number of decision variables, including binary and integer ones, which are aggregated in the constraints.

Traditional methods when used alone to solve complex problems provide unsatisfactory results. This is related directly to different treatment of variables and constraints in those approaches (II). The proposed hybrid approach, a composition of methods as described in Chapter III offers the optimal system for specific contexts.

A. Architecture and Implementation of Hybrid Solution Environment

This Hybrid Solution Environment (HSE) consists of MIP/MILP/CLP/Hybrid models and Hybrid Solution Framework (FSE) to solve them (Fig. 1). The concept of this framework with its phases (P1 .. P5, G1 .. G3) is presented in Fig. 2.

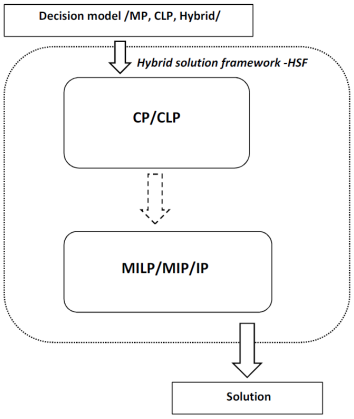

Fig. 1 Scheme of the hybrid solution environment (HSE)

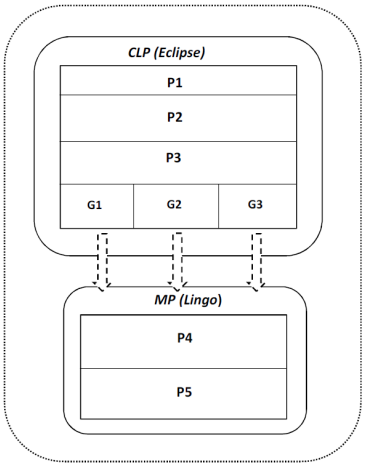

Fig. 2 Detailed scheme of the hybrid solution framework (HSF)

A detailed description of the phases in the order of execution is shown in Table I.

From a variety of tools for the implementation of the CP/CLP in HSE, ECL^{i}PS^e software [21] was selected. ECL^{i}PS^e is an open-source software system for the cost-effective development and deployment of constraint programming applications. Environment for the implementation of MILP/MIP/IP in HSE was LINGO by LINDO Systems. LINGO Optimization Modeling Software is a powerful tool for building and solving mathematical optimization models [22].

TABLE I
DESCRIPTION OF PHASES

Phase	**P1**
Name	Implementation of decision model
Description	The implementation of the model in CLP, the term representation of the problem in the form of predicates.
Phase	**P2**
Name	Transformation of implemented model for better constraint propagation (optional)
Description	The transformation of the original problem aimed at extending the scope of constraint propagation. The transformation uses the structure of the problem. The most common effect is a change in the representation of the problem by reducing the number of decision variables, and the introduction of additional constraints and variables, changing the nature of the variables, etc.
Phase	**P3**
Name	Constraint propagation
Description	Constraint propagation for the model. Constraint propagation is one of the basic methods of CLP. As a result, the variable domains are narrowed, and in some cases, the values of variables are set, or even the solution can be found.
Phase	**G1**
Name	Generation of MILP/MIP/IP model
Description	Generation of the model for mathematical programming. Generation performed automatically using CLP predicate. The resulting model is in a format accepted by the system LINGO.
Phase	**G2**
Name	Generation of additional constraints (optional)
Description	Generation of additional constraints on the basis of the results obtained in step P3
Phase	**G3**
Name	Generation domains of decision variables and other values
Description	Generation of domains for different decision variables and other parameters based on the propagation of constraints. Transmission of this information in the form of fixed value of certain variables and/or additional constraints to the MP.
Phase	**P4**
Name	Merging MILP/MIP/IP model
Description	Merging files generated during the phases G1, G2, G3 into one file. It is a model file format in LINGO system.
Phase	**P5**
Name	Solving MILP/MIP/IP model
Description	The solution model from the previous stage by LINGO. Generation of the report with the results and parameters of the solution.

ECL^{i}PS^e software is the environmental leader in HSE. ECL^{i}PS^e was used to implement the following phases of the framework: P1, P2, P3, G1, G2, G3 (Fig. 2, Table I.). The transformed files of the model were transferred from ECL^{i}PS^e to LINGO where they were merged (P4). Then the complete model was solved using LINGO efficient solvers (P5). Constraint propagation (phase–P3) greatly affected the efficiency of the solution. Therefore phase P2 was introduced. During this phase, the transformation was performed using the structure and properties of the model. This is an optional phase that depends on the modeled problem. The details of this phase will be presented in one of the illustrative examples in Chapter V (cost optimization of supply chain).

V. Illustrative Examples

The proposed HSE environment was verified and tested for two illustrative examples. The first example is the authors' original model of cost optimization of supply chain with multimodal transport (section A). The second is a 2E-CVRP model (section B). It is the known benchmark of a very large number of sets/instances of data and their solutions.

A. Cost optimization of supply chain with multimodal transport

A detailed description of the cost optimization of supply chain models, their constraints, parameters and decision variables etc. are presented in [17] and Table II.

During the first stage, the model was formulated as a MILP problem [9], [10], [17] in order to test the proposed environment (Fig. 1,2) against the classical integer-programming environment [22]. The next step involved the implementation and solving of the hybrid model. Indices, parameters and decision variables in the models together with their descriptions are provided in Table II. The simplified structure of the supply chain network for this model, composed of producers, distributors and customers is presented in Fig.3.

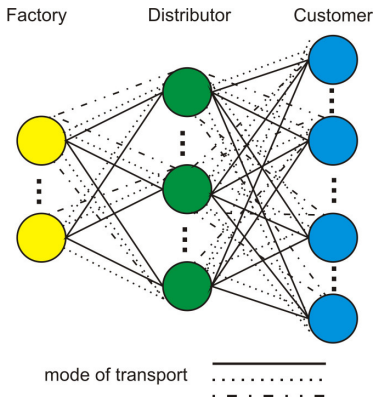

Fig. 3 The simplified structure of the supply chain network

The proposed models are the cost models that take into account three other types of parameters, i.e., the spatial parameters (area/volume occupied by the product, distributor capacity and capacity of transport unit), time (duration of de-

TABLE II
Summary Indices, Parameters and Decision Variables

Symbol	Description
Indices	
k	product type (k=1..O)
j	delivery point/customer/city (j=1..M)
i	manufacturer/factory (i=1..N)
s	distributor /distribution center (s=1..E)
d	mode of transport (d=1..L)
N	number of manufacturers/factories
M	number of delivery points/customers
E	number of distributors
O	number of product types
L	number of mode of transport
Input parameters	
F_s	the fixed cost of distributor/distribution center *s*
P_k	the area/volume occupied by product *k*
V_s	distributor *s* maximum capacity/volume
$W_{i,k}$	production capacity at factory *i* for product *k*
$C_{i,k}$	the cost of product *k* at factory *i*
$R_{s,k}$	if distributor *s* can deliver product *k* then R_{sk}=1, otherwise R_{sk}=0
$Tp_{s,k}$	the time needed for distributor *s* to prepare the shipment of product *k*
$Tc_{j,k}$	the cut-off time of delivery to the delivery point/customer *j* of product *k*
$Z_{j,k}$	customer demand/order *j* for product *k*
Zt_d	the number of transport units using mode of transport *d*
Pt_d	the capacity of transport unit using mode of transport *d*
$Tf_{i,s,d}$	the time of delivery from manufacturer *i* to distributor *s* using mode of transport *d*
$K1_{i,s,k,d}$	the variable cost of delivery of product *k* from manufacturer *i* to distributor *s* using mode of transport *d*
$R1_{i,s,d}$	if manufacturer *i* can deliver to distributor *s* using mode of transport *d* then $R1_{i,s,d}$=1, otherwise $R1_{i,s,d}$=0
$A_{i,s,d}$	the fixed cost of delivery from manufacturer *i* to distributor *s* using mode of transport *d*
$Koa_{i,s,d}$	the total cost of delivery from manufacturer *i* to distributor *s* using mode of transport *d*
$Tm_{s,j,d}$	the time of delivery from distributor *s* to customer *j* using mode of transport *d*
$K2_{s,j,k,d}$	the variable cost of delivery of product *k* from distributor *s* to customer *j* using mode of transport *d*
$R2_{s,jd}$	if distributor *s* can deliver to customer *j* using mode of transport *d* then $R2_{s,j,d}$=1, otherwise $R2_{s,j,d}$=0
$G_{s,j,d}$	the fixed cost of delivery from distributor *s* to customer *j* using mode of transport *d*
$Kog_{s,j,d}$	the total cost of delivery from distributor *s* to customer *j* using mode of transport *d*
Od_d	the environmental cost of using mode of transport *d*
Decision variables	
$X_{i,s,k,d}$	delivery quantity of product *k* from manufacturer *i* to distributor *s* using mode of transport *d*
$Xa_{i,s,d}$	if delivery is from manufacturer *i* to distributor *s* using mode of transport *d* then $Xa_{i,s,d}$=1, otherwise $Xa_{i,s,d}$=0
$Xb_{i,s,d}$	the number of courses from manufacturer *i* to distributor *s* using mode of transport *d*
$Y_{s,j,k,d}$	delivery quantity of product *k* from distributor *s* to customer *j* using mode of transport *d*
$Ya_{s,j,d}$	if delivery is from distributor *s* to customer *j* using mode of transport *d* then $Ya_{s,j,d}$ =1, otherwise $Ya_{s,j,d}$ =0
$Yb_{s,j,d}$	the number of courses from distributor *s* to customer *j* using mode of transport *d*
Tc_s	if distributor *s* participates in deliveries, then Tc_s=1, otherwise Tc_s=0
CW	Arbitrarily large constant

livery and service by distributor, etc.) and the transport mode.

The main assumptions made for the construction of these models were as follows:

- the shared information process in the supply chain consists of resources (capacity, versatility, costs), inventory (capacity, versatility, costs, time), production (capacity, versatility, costs), product (volume), transport (cost, mode, time), demand, etc;
- a part of the supply chain has the structure as in Fig. 3.;
- the transport is multimodal (several modes of transport, a limited number of means of transport for each mode);
- the environmental aspects of use of transport modes are taken into account;
- different products are combined in one batch of transport;
- the cost of supplies is presented in the form of a function (in this approach, linear function of fixed and variable costs);
- models have linear or linear and logical (hybrid model) constraints;
- logical constraints of hybrid model allow the distribution of exclusively one of two selected products in the distribution center and allow the production of exclusively one of two selected products in the factory.

Details of both mathematical models for cost optimization of supply chain are presented in [17].

Objective function

The objective function defines the aggregate costs of the entire chain and consists of five elements. The first element comprises the fixed costs associated with the operation of the distributor involved in the delivery (e.g. distribution centre, warehouse, etc.). The second element corresponds to environmental costs of using various means of transport. Those costs are dependent on the number of courses of the given means of transport, and on the other hand, on the environmental levy, which in turn may depend on the use of fossil fuels and carbon-dioxide emissions.

The third component determines the cost of the delivery from the manufacturer to the distributor. Another component is responsible for the costs of the delivery from the distributor to the end user (the store, the individual client, etc.). The last component of the objective function determines the cost of manufacturing the product by the given manufacturer.

Formulating the objective function in this manner allows comprehensive cost optimization of various aspects of supply chain management. Each subset of the objective function with the same constrains provides a subset of the optimization area and makes it much easier to search for a solution.

Constraints

The model was based on constraints (2) .. (24) Constraint (2) specifies that all deliveries of product k produced by the manufacturer i and delivered to all distributors s using mode of transport d do not exceed the manufacturer's production capacity.

Constraint (3) covers all customer j demands for product k ($Z_{j,k}$) through the implementation of delivery by distributors s (the values of decision variables $Y_{i,s,k,d}$). The flow balance of each distributor s corresponds to constraint (4). The possibility of delivery is dependent on the distributor's technical capabilities - constraint (5). Time constraint (6) ensures the terms of delivery are met. Constraints (7a), (7b), (8) guarantee deliveries with available transport taken into account.

The hybrid model was additionally enriched with logical constraints.

First logical constraint allows the distribution of exclusively one of the two selected products in the distribution center s. Second logical constraint allows the production of exclusively one of the two selected products in the factory i.

These constraints stem from technological, marketing, sales or safety restrictions. Therefore, some products cannot be distributed and/or produced together. The constraint can be re-used for different pairs of product k and for some or all of the distribution centers s and factories i. A logical constraint like this cannot be easily implemented in a MILP model.

Model transformation

Due to the nature of the decision problem (adding up decision variables and constraints involving a lot of variables), the constraint propagation efficiency decreases dramatically. Constraint propagation is one of the most important methods in CLP affecting the efficiency and effectiveness of the CLP and hybrid optimization environment (Fig. 1, Table I). For that reason, research into more efficient and more effective methods of constraint propagation was conducted. The results included different representation of the problem and the manner of its implementation.

The classical problem modeling in the CLP environment consists in building a set of predicates with parameters.

Each CLP predicate has a corresponding multi-dimensional vector representation. While modeling both problems, quantities i, s, k, d and decision variable $X_{i,s,k,d}$ were vector parameters (Fig. 4a). As shown in Fig. 4b, for each vector there were 5 values to be determined, defining the size of the delivery, factories, distributors involved in the delivery and the mode of transport.

[Z_n,P,M,D,F,Tu,Tu,Oq,X,T]

Fig. 4a Representation of the problem in the classical approach-definition

[[z_1,p1,m1,_,_,_,_,10,_,8],
[z_2,p1,m2,_,_,_,_,20,_,6],…]

Fig. 4b Representation of the problem in the classical approach- the process of finding a solution

The process of finding the solution may consist in using the constraint propagation methods, variable labeling and the

backtracking mechanism. The numbers of parameters that must be specified/labeled in the given predicate/vector critically affect the quality of constraint propagation and the number of backtracks. In both models presented above, the classical problem representation included five parameters: *i, s, k, d* and $X_{i,s,k,d}$. Considering the domain size of each parameter, the process was complex and time-consuming. In addition, the above representation (Fig. 4a, Fig. 4b) arising from the structure of the problem is the cause of many backtracks.

Our idea involved the transformation of the problem by changing its representation without changing the very problem. All permissible routes were first generated based on the fixed data and a set of orders, then the specific values of parameters *i, s, k, d* were assigned to each of the routes. In this way, only decision variables $X_{i,s,k,d}$ (deliveries) had to be specified (Fig. 5). This transformation fundamentally improved the efficiency of the constraint propagation and reduced the number of backtracks. A route model is a name adopted for the models that underwent the transformation.

[[name_1,f1,p1,c1,m1,s1,s1,5,12,100,_],
[name_2,f1,p1,c1,m1,s1,s2,6,14,100,_],

Fig. 5 Representation of the problem in the novel approach- set of feasible routes

Symbols necessary to understand both the representation of the problem and their descriptions are presented in Table III.

TABLE III
SYMBOLS USED IN THE REPRESENTATION OF THE PROBLEM

Symbol	Description
Z_n	order number
P	products, P∈ $\{p_1,p_2, \ldots ,p_o\}$
M	customers, M∈$\{m_1,m_2, \ldots m_m\}$
D	distributors, D∈$\{c_1,c_2, \ldots c_e\}$
F	factories, F∈$\{f_1,f_2, \ldots f_n\}$
Tu	transport unit, Tu∈$\{s_1,s_2, \ldots s_l\}$
T	delivery time/period
Oq	order quantity
X	delivery quantity
Name_	routes name-number

B. Two-Echelon Capacitated Vehicle Routing Problem

The 2E-CVRP is proposed as a benchmark verifying the presented approach. The Two-Echelon Capacitated Vehicle Routing Problem (2E-CVRP) is an extension of the classical Capacitated Vehicle Routing Problem (CVRP) where the delivery depot-customers pass through intermediate depots (called satellites). As in CVRP, the goal is to deliver goods to customers with known demands, minimizing the total delivery cost in the respect of vehicle capacity constraints. Multi-echelon systems presented in the literature usually explicitly consider the routing problem at the last level of the transportation system, while a simplified routing problem is considered at higher levels [18], [19], [23].

In 2E-CVRP, the freight delivery from the depot to the customers is managed by shipping the freight through intermediate depots. Thus, the transportation network is decomposed into two levels (Fig. 6): the 1st level connecting the depot (*d*) to intermediate depots (*s*) and the 2nd one connecting the intermediate depots (*s*) to the customers (*c*). The objective is to minimize the total transportation cost of the vehicles involved in both levels. Constraints on the maximum capacity of the vehicles and the intermediate depots are considered, while the timing of the deliveries is ignored.

From a practical point of view, a 2E-CVRP system operates as follows (Fig. 6):

- freight arrives at an external zone, the depot, where it is consolidated into the 1st-level vehicles, unless it is already carried into a fully-loaded 1st-level vehicles;
- each 1st-level vehicle travels to a subset of satellites that will be determined by the model and then it will return to the depot;
- at a satellite, freight is transferred from 1st-level vehicles to 2nd-level vehicles;

The mathematical model (MILP) was taken from [17]. It required some adjustments and error corrections. Table IV shows the parameters and decision variables of 2E-CVRP. Figure 6 shows an example of the 2E-CVRP - transportation network.

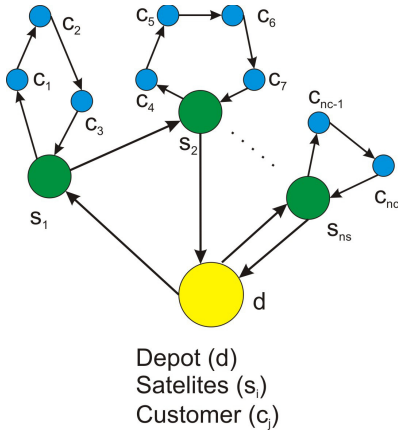

Fig. 6 Example of 2E-CVRP transportation network

The transformation of this model in the hybrid approach focused on the resizing of $Y_{k,i,j}$ decision variable by introducing additional imaginary volume of freight shipped from the satellite and re-delivered to it. Such transformation resulted in two facts. First of all, it forced the vehicle to return to the satellite from which it started its trip. Secondly, it reduced decision variable $Y_{k,i,j}$ to variable $Y_{i,j}$ which decreased the size of the combinatorial problem.

VI. NUMERICAL EXPERIMENTS

A. Cost optimization of supply chain with multimodal transport

In order to verify and evaluate the proposed approach, many numerical experiments were performed. All the examples relate to the supply chain with two manufacturers

TABLE IV
SUMMARY INDICES, PARAMETERS AND DECISION VARIABLES

Symbol	Description
Indices	
n_s	Number of satelites
n_c	Number of customers
$V_0 = \{v_o\}$	Deport
$V_s = \{v_{s1}, \ldots, v_{sns}\}$	Set of satellites
$V_c = \{v_{c1}, \ldots, v_{cnc}\}$	Set of customers
Input parameters	
m_1	Number of the 1st-level satelites
M_2	Number of the 2nd-level satelites
k_1	Capacity of the vehicles for the 1st level
k_2	Capacity of the vehicles for the 2nd level
d_i	Demand required by customer i
$c_{i,j}$	Cost of the arc (i,j)
s_k	Cost of loading/unloading operations of a unit of freight in satelite k
Decision variables	
$X_{i,j}$	Is an integer variable of the 1st-level routing and is equal to the number of 1st-level vehicles using arc (i, j).
$Y_{k,i,j}$	Is a binary variable of the 2nd-level routing and is equal to 1 if a 2nd-level vehicle makes a route starting from satellite k and goes from node i to node j and 0 otherwise
$Q1_{i,j}$	freight flow arc ij for the 1st-level
$Q2_{k,i,j}$	freight arc ij where k represents the satellite where the freight is passing through.
$z_{k,j}$	Binary variable that is equal to 1 if the freight to be delivered to customer j is consolidated in satellite k and 0 otherwise

(i=1..2), three distributors *(s=1..3)*, five customers *(j=1..5),* three modes of transport *(d=1..3),* and ten types of products *(k=1..10).* Other parameter values are shown in Appendix A1 [17].

The first series of experiments was designed to show the advantages of the hybrid approach used.

The experiments began with six examples: E1, E2, E3, E4, E5, E6 for the problem formulated in MILP (V) [17]. Two approaches were used to implement the proposed model: mathematical programming (LINGO) and the hybrid approach (LINGO, Eclipse, transformation). The examples E1 .. E6 varied in terms of the number of orders (*No*). The set of all orders for calculation examples are given in Appendix A.

The experiments were conducted to optimize examples E7, E8, which are implementations of the hybrid model (with logical constraints) in the hybrid approach.

The implementation of logic constraints for the hybrid model was as follows: product $k = 5$ cannot be distributed with product $k= 6$; product $k = 2$ cannot be distributed with product $k = 8$, and these products cannot be produced together. The results in the form of the objective function, the computation time, the number of discrete decision variables and constraints are shown in Table V.

TABLE V
THE RESULTS OF NUMERICAL EXAMPLES FOR BOTH APPROACHES

E(No)	MILP-LINGO				MILP-Hybrid			
	Fc	***T***	***V***	***C***	***Fc***	***T***	***V***	***C***
E1(5)	6680	7	1389	1351	6680	2	117	172
E2(10)	20439	28	1389	1621	20439	3	173	172
E3(15)	29107	55	1389	1891	29107	9	245	172
E4(20)	45710*	600**	1389	2161	45654	18	301	172
E5(25)	46660*	600**	1389	2431	46150	235	376	172
E6(30)	48946*	600**	1389	2701	48006	375	429	172
P(No)	**Hybrid-Hybrid**							
	Fc	***T***	***V***	***C***				
E7(10)	21143	194	193	202				
E8(20)	46069	366	321	202				

Fc	the optimal value of the objective function
T	Solution finding time
V/C	the number of integer variables/constraints
*	the feasible value of the objective function after the time T
**	calculation was stopped after 600s

The analysis of the outcome indicates that the hybrid approach provided better results in terms of the time needed to find the solution in each case, and to obtain the optimal solution in some cases, which was impossible to do within the acceptable time limits using the traditional approaches.

B. Two-Echelon Capacitated Vehicle Routing Problem

For the final validation of the proposed hybrid approach, the benchmark (2E-CVRP) was selected. 2E-CVRP, a well described and widely discussed problem, corresponded to the issues to which our hybrid approach was applied.

The instances for computational examples were built from the existing instances for CVRP [24] denoted as E-n13-k4. All the instance sets can be downloaded from the website [25]. The instance set was composed of 5 small-sized instances with 1 depot, 12 customers and 2 satellites. The full instance consisted of 66 small-sized instances because the two satellites were placed over twelve customers in all 66 possible ways (number of combinations: 2 out of 12).

All the instances had the same position for depot and customers, whose coordinates were the same as those of instance E-n13-k4. Small-sized instances differed in the choice of two customers who were also satellites (En13-k4-2 (1,3), En13-k4-6 (1,6), En13-k4-61 (9,10) etc.).

The analysis of the results for the benchmark instances demonstrates that the hybrid approach may be a superior approach to the classical mathematical programming. For all examples, the solutions were found 2-16 times faster than they are in the classical approach.

As the presented benchmark was formulated as a MILP problem, the HSF was tested for the solution efficiency. Owing to the hybrid approach the 2E-CVRP models can be extended over logical, nonlinear, and other constraints.

TABLE VI
THE RESULTS OF NUMERICAL EXAMPLES FOR BOTH APPROACHES

*	the feasible value of the objective function after the time T

VII. CONCLUSION AND DISCUSSION ON POSSIBLE EXTENSION

The efficiency of the proposed approach is based on the reduction of the combinatorial problem and using the best properties of both environments. The hybrid approach (Table V, Table VI) makes it possible to find solutions better solutions in the shorter time.

In addition to solving larger problems faster, the proposed approach provides virtually unlimited modeling options.

Therefore, the proposed solution is recommended for decision-making problems in the supply chain that has a similar structure to the presented model (V). This structure is characterized by the constraints and objective function in which the decision variables are added together. Further work will focus on running the optimization models with non-linear and logical constraints, multi-objective, uncertainty etc. in the hybrid optimization framework.

***Abstract*—A biased random key genetic algorithm (BRKGA) is an efficient method for solving combinatorial optimization problems. It can be applied to solve both single-objective and multi-objective optimization problems. The BRKGA operates on a chromosome encoded as a key vector of real values between $[0, 1]$. Generally, the chromosome has to be decoded by using a single decoding method in order to obtain a feasible solution. This paper presents a hybrid decoding, which combines the operation of two single decoding methods. This hybrid decoding gives two feasible solutions from the decoding of one chromosome. Experiments are conducted on realistic instances, which concern acquisition scheduling of agile Earth observing satellites.**

I. Introduction

THIS PAPER proposes a hybrid decoding to apply with a biased random key genetic algorithm (BRKGA) for solving multi-objective optimization problems. We experiment on instances of multi-user observation scheduling problem for agile Earth observing satellites (EOSs).

The biased random key genetic algorithm (BRKGA) was first presented in [1]. BRKGA combines the concept of random key and the principles of genetic algorithms. The random key vector represents one solution. In the process to apply BRKGA for solving combinatorial problems, there is a step, which depends on the considered problem. It is a decoding step, which is used to decode the random key chromosome to become a feasible solution. The efficient decoding method can obtain a good solution. Hence, the specification of the decoding step is an important issue for BRKGA.

BRKGA was used to solve combinatorial optimization problems in various domains (e.g. communication, transportation, scheduling) [3]. For example, BRKGA was applied to solve the fiber installation in an optical network optimization problem [4]. The objective function was to minimize the cost of the optical components necessary to operate the network. In [5], a resource-constrained project scheduling problem with makespan minimization was solved by BRKGA. Nevertheless, all these works address optimization problems involving a single objective function. This paper considers multi-objective optimization. Several real world problems, e.g., in the area of engineering research and design, can be modeled as multi-objective optimization problems. When many objectives are considered, the search will not give a unique solution but a set of solutions. Hence, our idea for improving the efficiency of BRKGA for solving multi-objective optimization problems, is to combine the importance of its decoding step and the need of a non-unique solution of multi-objective optimization.

A hybrid decoding, which combines two single decoding methods, is proposed in this paper. A hybrid decoding can obtain more than one solution from the decoding of one chromosome. Two separate single-decoding and the hybrid decoding are experimented on the multi-user observation scheduling problem for agile Earth observing satellites.

The mission of Earth observing satellites (EOSs) is to obtain photographs of the Earth surface satisfying users' requirements. When the ground station center receives the requests from users, it has to manage the requirements by selecting and scheduling a subset of photographs and transmit the schedule, which consists of a sequence of selected photographs, to the satellites. We consider an agile satellite, which has only one on-board camera that can move around three axes: roll, pitch, and yaw. The starting time of each photograph is not fixed; it can slide within a given visible time interval. The problem description of agile EOSs scheduling problem is presented in the ROADEF 2003 challenge [10]. This challenge required the scheduling solutions that maximize total profit of the acquired photographs for a single user and have to satisfy all physical constraints of agile EOSs. Algorithms based on simulated annealing [11] and tabu search [12] were particularly proposed for this challenge. In [13], multiple users have been considered. However, a single objective is considered.

The originality of our work also lies in the consideration of multi-user requests, but we need to optimize two objectives. The ground station center should maximize the total profit of the acquired photographs and simultaneously share fairly the satellite resources for all users by minimizing the maximum profit difference between users. In [9], we proposed a biased random-key genetic algorithm (BRKGA) with a single decoding method to solve this multi-objective optimization problem. BRKGA with a single decoding succeeded to obtain quite good solutions. However, the average value of the obtained hypervolumes and the range of the solutions should be improved.

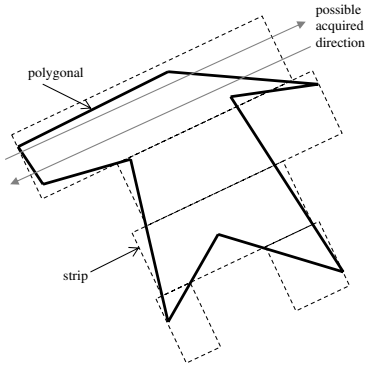

Fig. 1. A polygon is decomposed into several strips; one of two possible directions can be selected for the acquisition of each strip

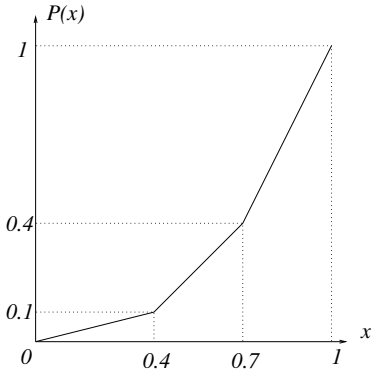

Fig. 2. Piecewise linear function of gain $P(x)$ depending on the effective ratio x of acquired area [10]

For our study, the ROADEF 2003 instances of the observation scheduling problem for agile EOSs are modified in order to consider in case of multi-user requirements. Two possible shapes of area can be required: spot or polygon. The polygon is a big area that the camera cannot take instantaneously. Hence it has to be decomposed into several strips of rectangular shape with fixed width but variable length, as shown in Figure 1. Among two possible directions, one acquisition can be selected for each strip. Two types of photograph can be required: a mono photograph is taken only once, whereas a stereo photograph should be acquired twice in the same direction but from different angles.

The possible starting time interval for taking each acquisition is calculated, depending on the acquired direction, its earliest/latest visible time of the two extremities and the taking duration time of the strip. Moreover, adjacent selected acquisitions must also respect a sufficient transition time. It is a necessary time in order to move the camera from the ending point of the previous acquisition to the beginning point of the next acquisition. These imperative constraints have to be satisfied for finding the feasible solutions, which are the sequences of the selected acquisitions for being transmitted to the satellite. For each solution, the two objective function values can be calculated by using a piecewise linear function of gain. This function is associated with a partial acquisition of the acquired request, as illustrated in Figure 2.

The article is organized as follows. Section II explains the BRKGA for solving multi-objective optimization problems. The proposed hybrid decoding is presented in Section III. Section IV reports the computational results. Finally, conclusions are discussed in Section V.

II. Biased Random Key Genetic Algorithm for Multi-objective Optimization Problems

A genetic algorithm is a metaheuristic method, which operates on several individuals in a population. Individuals should spread through the search space. The genetic algorithm uses the concept of survival of the fittest to find the optimal solutions. Each individual consists of a chromosome, which represents a solution. The process of genetic algorithm is started by generating an initial population with its size equal to p. For generating the next generations, selection, crossover, and mutation operators are applied. The iterations are repeated until a stopping criterion is satisfied.

A biased random key genetic algorithm (BRKGA) was first presented in [1]. The BRKGA has different ways to select two parents for the crossover operation, compared with the original of random key genetic algorithm (RKGA) [2]. For BRKGA, the random key chromosome is formed by several genes, which are encoded by real values in the interval $[0, 1]$. Then, the chromosome is decoded in order to obtain the solution. The decoding strategy is problem dependent. The fitness value of solution is computed in this decoding step. The current population is divided into two groups by using the selection mechanism. Selections are applied to choose p_e preferred chromosomes from the current population to become the elite set. The remaining chromosomes will be stored in the other group of non-elite chromosomes. Then, the process to generate the population in the next generation begins.

The standard procedure for BRKGA can be found in [3]. We will now explain how BRKGA was adapted for multi-objective optimization [9]. We will focus on the selection phase, fitness computation, and population recombination.

A. Population generation for the next iteration

The population of the new generation is generated from three parts, as in Figure 3. The first part is an elite set, which contains p_e preferred chromosomes. The second part is a set of p_m chromosomes, which are generated to avoid the entrapment in a local optimum. These chromosomes are called mutant. They are randomly generated by the same methods, which is used to generate the initial population. The last part is filled by generating offspring from the crossover operation of the elite set and another solution from the current population. Each element in the offspring is obtained from the element of elite parent with the probability ρ_e. Otherwise, the element of offspring is copied from the non-elite parent. Hence, the size of crossover offspring set is equal to $p - p_e - p_m$. The recommended parameter value setting is displayed in Table I.

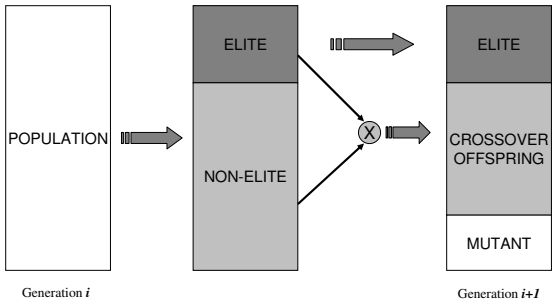

Fig. 3. The population of the new generation by using BRKGA

TABLE I
RECOMMENDED PARAMETER VALUES OF BRKGA [3]

Parameter	Recommended value
p	$p = a.n$, where $1 \leq a \in \mathbb{R}$ is a constant and n is the length of the chromosome
p_e	$0.10p \leq p_e \leq 0.25p$
p_m	$0.10p \leq p_m \leq 0.30p$
ρ_e	$0.5 \leq \rho_e \leq 0.8$

In [3], BRKGA is applied to solve optimization problems arising in several applications. However, all problems consider only one objective. In this work, we study BRKGA for solving a multi-objective optimization problem. The fitness of each chromosome must be taken into account for all objective functions. Algorithms for selecting the preferred chromosomes are needed.

B. Algorithm to select the preferred chromosomes in the context of a multi-objective optimization problem

Three strategies are proposed to select individuals.

1) Fast nondominated sorting and crowding distance assignment: Fast nondominated sorting and crowding distance assignment methods were proposed in the Nondominated Sorting Genetic Algorithm II (NSGA-II) [6]. In our work, the fast nondominated sorting method is used to find the nondominated solutions. If the number of nondominated solutions is more than the parameter setting value of maximum size of elite set, the crowding distance assignment method is applied to select some solutions from the nondominated set to become the elite set. Otherwise all nondominated solutions will become the elite set.

2) $\mathscr{S}$ metric selection evolutionary multi-objective optimization algorithm: $\mathscr{S}$ metric selection evolutionary multi-objective optimization algorithm (SMS-EMOA), which was proposed in [7], is applied to select some solutions in the current population to become the elite set. In our work, we use SMS-EMOA combining with the fast nondominated sorting from NSGA-II. The fast nondominated sorting is applied in order to find the nondominated solutions and SMS-EMOA compute the hypervolume as selection criterion for limiting the size of elite set. The hypervolume selection discards the solution, which obtains the least hypervolume in the set of nondominated solutions and the remaining solutions will become the elite set.

3) Indicator-based evolutionary algorithm based on the hypervolume concept: The use of an indicator based on the hypervolume concept was proposed in the Indicator-Based Evolutionary Algorithm (IBEA) [8]. The indicator based method is used to assign fitness values based on the hypervolume concept to the population members. Then, some solutions in the current population are selected to become elite set for the next population. The indicator based method performs binary tournaments for all solutions in the current population. The selection is implemented environmentally by removing the worst solution from the population and updating the fitness values of the remaining solutions. The worst solution is removed repeatedly until the number of remaining solutions satisfies the recommended size of elite set for BRKGA.

III. DECODING METHODS

In this section, the decoding methods, which are used for obtaining the solutions from the random key chromosomes, are described. A chromosome consists of several genes. Each gene represents one job, which needs to be scheduled. When the processes of genetic algorithm finish, the chromosome is decoded in order to obtain a sequence of jobs, which become the solution of the problem. In this decoding step, the sequence of jobs will be generated. The order to consider each job depends on the priority, which is computed from its associated gene value. The job, which has the highest priority, will be firstly considered to be assigned in a sequence. Then, the next jobs are considered according to the priority order. The considered job can be scheduled in the sequence, only if all constraints are satisfied. Three decoding methods for assigning the priority are studied in this paper. The three methods are:

A. Basic decoding (D1)

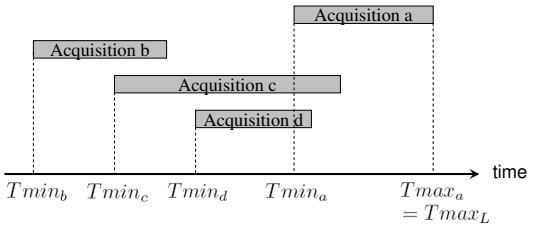
The first decoding method is a basic decoding: the priority is assigned by using directly the gene value:

$$Priority_j = gene_j \tag{1}$$

This decoding method was implemented in the context of multi-objective optimization in [9]. Albeit it gave quite good results, we are convinced that the results regarding average values and standard deviations of hypervolumes can be yet improved. Thus, we searched for an idea to apply some useful data of the problem for assisting the basic decoding.

B. Decoding of gene value and ideal priority combination (D2)

This decoding is presented in [5]. It considers the priority depending on the gene value, and also an ideal priority. For the concept of the ideal priority, the job, which has the earliest possible starting time, should be selected firstly and be scheduled at the beginning of the sequence. Hence the ideal priority gives a higher priority to select and schedule the job



Acquisition	a	b	c	d
Ideal priority	$\frac{Tmax_L - Tmin_a}{Tmax_L}$	$\frac{Tmax_L - Tmin_b}{Tmax_L}$	$\frac{Tmax_L - Tmin_c}{Tmax_L}$	$\frac{Tmax_L - Tmin_d}{Tmax_L}$

Fig. 4. Example of ideal priority calculation

which has the earlier possible starting time. This ideal priority is the real value in the interval $[0, 1]$ which is given by

$$\frac{LLP_j}{LCP}, \tag{2}$$

where LLP_j is the longest length path from the beginning of job j to the end of the project and LCP is the length along the critical path of the project.

The factor that adjusts the priority to account for the gene values of the random key chromosome is given by $(1 + gene_j)/2$. Thus, the second decoding expression of each job j is

$$Priority_j = \frac{LLP_j}{LCP} \times \left[\frac{1 + gene_j}{2}\right] \tag{3}$$

This second decoding method was applied to solve the resource-constrained project scheduling problem with makespan minimization in [5]. In our paper, the second decoding will be implemented to the considered multi-objective optimization problem, which is the multi-user observation scheduling problem for agile Earth observing satellites. Hence, the second decoding expression of each acquisition j becomes:

$$Priority_j = \frac{Tmax_L - Tmin_j}{Tmax_L} \times \left[\frac{1 + gene_j}{2}\right] \tag{4}$$

where $Tmax_L$ is the latest starting time of the last possible acquisition and $Tmin_j$ is the earliest starting time of acquisition j.

The example of the ideal priority calculation of the second decoding method is shown in Figure 4. It is applied to the multi-user observation scheduling problem for agile Earth observing satellites, which needs to select and schedule four acquisitions, which are acquisitions a, b, c, and d. For this example, the sequence of the acquisitions according to the ideal priority, is b, c, d, and a.

C. Hybrid decoding (HD)

Finally, we propose the third decoding method which is the hybrid method. It combines together the first and the second decoding methods. This hybrid method obtains two solutions from one chromosome. When applying the hybrid decoding, the methods to manage the elite set, must be defined. Three methods are tested for selecting the elite set.

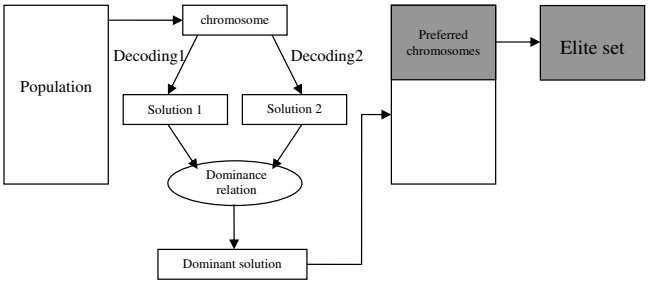


Fig. 5. Elite set management for hybrid decoding - method 1

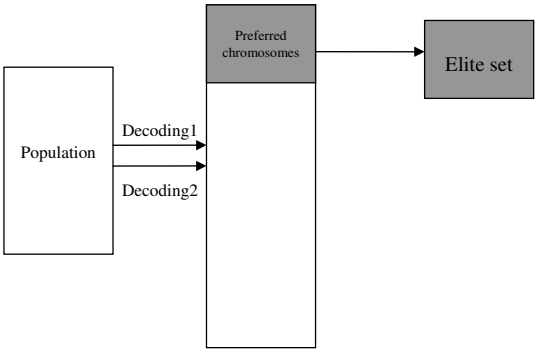

Fig. 6. Elite set management for hybrid decoding - method 2

1) Elite set management - Method 1 (M1): Both solutions, obtained by the two decodings, are compared by using the dominance relation in the Pareto sense. If a solution can dominate the other one, the dominant solution is selected to be stored in the set of solutions. Otherwise, one of the two solutions is selected randomly. The decoding process is repeated until all chromosomes in the population are decoded. When it finishes, the size of the solution set is equal to p. Then, the p_e solutions are selected to become the elite set by using the same methods with only one decoding. The principle of elite set management - method 1 is shown in Figure 5.

2) Elite set management - Method 2 (M2): All chromosomes in the population are decoded by using the two decoding methods. Two solutions are obtained from the decoding of one chromosome. Both of them are stored in the solution set. Hence, the size of the solution set is equal to $2p$, when all chromosomes from the current population are decoded. Then, the p_e solutions are selected from the solution set to become the elite set. The principle of elite set management - method 2 is shown in Figure 6.

3) Elite set management - Method 3 (M3): Each chromosome in the population is firstly decoded by using the priority equation of basic decoding, and the obtained solution is stored in the first solution set. Similarly, the same chromosome is decoded by using the priority equation of the decoding of gene value with ideal priority combination. Then, the obtained solution from this decoding is stored in the second solution set. When all chromosomes in the population are decoded and the solutions are stored into two solution sets, the selection

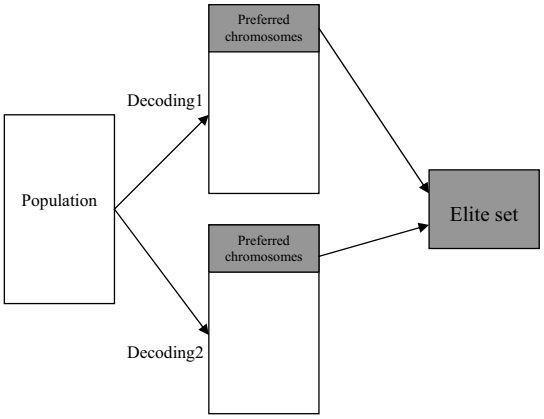

Fig. 7. Elite set management for hybrid decoding

methods are applied to select p_e solutions for becoming the elite set. Hence, the $p_e/2$ preferred solutions must be chosen from each solution set, as shown in Figure 7.

In the decoding step for solving the multi-user observation scheduling problem for agile Earth observing satellites, the priorities for selecting and scheduling each acquisition are computed depending on the decoding methods as previously presented. Then, the solution, which is the sequence of the selected acquisitions, can be generated. The imperative constraints are verified for each acquisition sequentially according to its priority. Each considered acquisition can be assigned in the sequence, only if the obtained sequence can satisfy all constraints. The flowchart of constraint verification and acquisition assignment is depicted in Figure 8. The example of one solution from the smallest size instance is shown in Figure 9. This instance consists of two strips. Hence the number of random key genes, which are associated with the acquisitions, equals to four. This example shows the solution, which is decoded from the basic decoding (the priority to select and schedule of each acquisition equals to its gene value). This decoding step is used to obtain the sequence of the selected acquisitions and the values of the two objective functions.

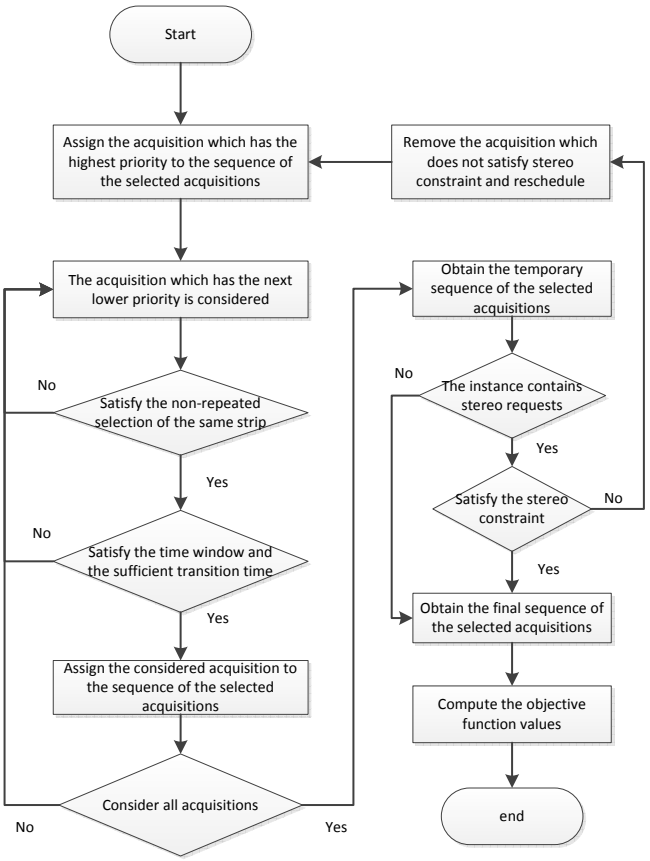

Fig. 8. Flowchart of constraint verification and acquisition assignment

Random-key chromosome	Acquisition0	Acquisition1	Acquisition2	Acquisition3
	0.6984	0.9939	0.6885	0.2509
Sequence of the selected acquisitions	1 | 2			
Total profit	1.04234e+007			
Maximum profit difference	0

IV. Computational Results

The ROADEF 2003 challenge instances (Subset A) are modified for 4-user requirements. The format of instance names are changed to `a_b_c`, where `a` is the number of requests, `b` is the number of stereo requests, and `c` is the number of strips.

For the proposed biased random-key genetic algorithm (BRKGA), parameter values of the algorithm were experimentally tuned for our work. The population size of BRKGA is set equal to the length of the random-key chromosome or twice the number of strips. The sizes of the three parts, which are generated to become the population in the next generation, are set in accordance with the recommended values in Table I. The size of the elite set is equal to the number of non-repeating schedules from the nondominated solutions, but it is not over $0.15p$. The size of mutant set is equal to $0.3p$. The probability of elite element inheritance for crossover operation is set to 0.6. In each iteration, the nondominated solutions are stored in an archive. If there is at least one solution from the current population that can dominate some solutions in the archive, the archive will be updated. Therefore, we use the number of iterations since the last archive improvement to be a stopping criterion. We opt for 50 iterations. Moreover, the computation time is used to be the second stopping criterion. It is adapted to the instance size. The iteration of BRKGA will be stopped, when one of the two stopping criteria is satisfied. The algorithm is implemented in C++ and ten runs per instance are tested. The hypervolumes of the approximate Pareto front are computed by using a reference point of 0 for the first objective (maximizing the total profit) and the maximum of the profit summations of each user for the second one (minimizing the

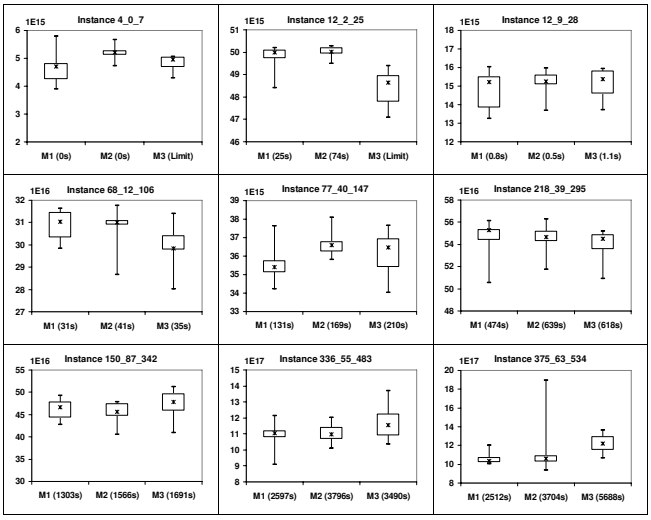

Fig. 10. Comparison of the results of the three methods for management of the elite set for hybrid decoding (M1, M2, and M3) by using the method for elite set selection borrowed from NSGA-II

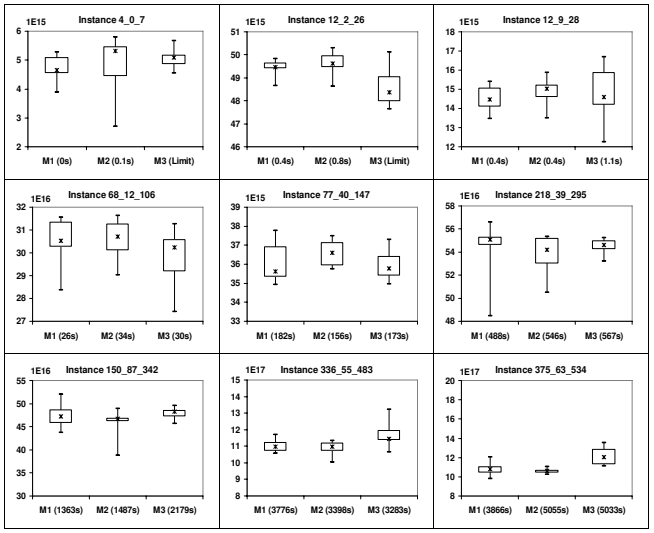

Fig. 11. Comparison of the results of the three methods for management of the elite set for hybrid decoding (M1, M2, and M3) by using the method for elite set selection borrowed from SMS-EMOA

profit difference between users). Three elite selecting methods from three efficient algorithms: NSGA-II, SMS-EMOA, and IBEA, are applied to select some solutions to become the elite set. The set of testing instances consists of ten instances. However, the results of the smallest instance (instance `2_0_2`) cannot be reached, when using the population size equal to the length of the chromosome or twice of number of strips, because the population size is too small for generating the new population from the three sets of chromosomes in BRKGA process. Hence, the results of nine instances will be presented in the experimental results.

Firstly, the three methods of elite set management for hybrid decoding (M1–M3) are tested. The results, which are obtained from each method, are compared. The hypervolume values of the approximate Pareto front are computed. The maximum value, the median value, the minimum value, and the interquartile range are displayed in box plot. The box plots and the average computation times associated with the mechanisms of NSGA-II, SMS-EMOA, and IBEA are reported in Figures 10, 11, and 12, respectively.

The results show that the three methods obtain similar solutions regarding the hypervolume values. Each method has advantages in different instances. However, M2 spends more computation time for the large instances, especially, when using the elite set selection method borrowed from IBEA. Furthermore, M3 spends more computation time for the small instances, particularly when using the elite set selection method borrowed from NSGA-II or SMS-EMOA. Therefore, in the sequel only method M1 will be kept to compare the results between the hybrid decoding (HD-M1) and the two single ones (D1 and D2).

Secondly, the three decoding methods (D1, D2, and HD) are tested and the obtained results are compared. The box plots from the three elite set selection methods, which borrowed

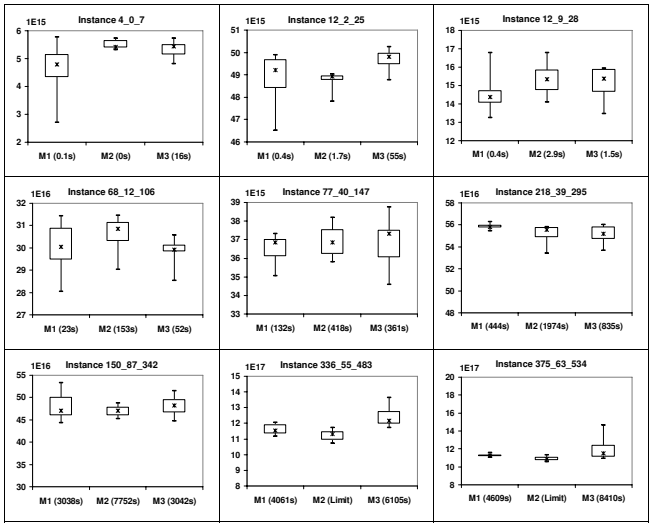

Fig. 12. Comparison of the results of the three methods for management of the elite set for hybrid decoding (M1, M2, and M3) by using the method for elite set selection borrowed from IBEA

from NSGA-II, SMS-EMOA, and IBEA, are reported in Figures 13, 14, and 15, respectively. The graph illustrates the box plots of the hypervolume values, and the average computation times are presented.

Most of the results show that the hybrid decoding obtains the results close to the best ones, when comparing the two single decodings. Indeed, it can preserve the advantages of the two single decodings for all instances. For example, in instance `12_2_26`, the first decoding method obtains better results than the second one, thus the hybrid decoding obtains results similar to the first one. For instance `77_40_147`, the hybrid decoding obtains results similar to the second decoding,

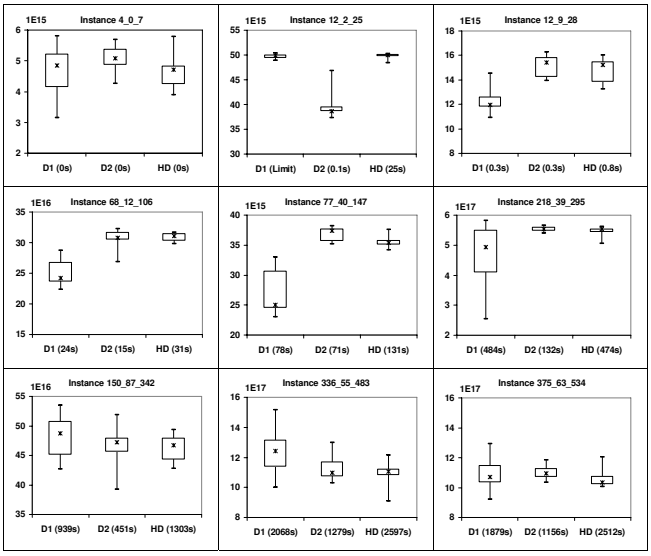

Fig. 13. Comparison of the results of the three decoding methods (D1, D2, and HD-M1) by using the method for elite set selection borrowed from NSGA-II

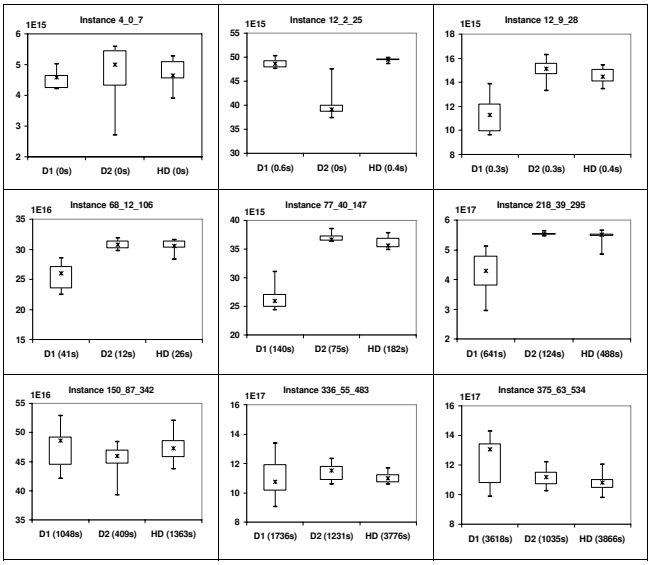

Fig. 14. Comparison of the results of the three decoding methods (D1, D2, and HD-M1) by using the method for elite set selection borrowed from SMS-EMOA

which obtains better results than the first one. Thus, the hybrid decoding method is efficient for solving most of the instances. Compared with D1, it can reduce the range of hypervolume values. This means that the hybrid decoding can provide results with better standard deviations. Moreover, for some instances where the second decoding entraps in local optima, the hybrid decoding is able to reach the global optimum. Regarding the computation time, the hybrid decoding method spends longer time in each iteration, however it can obtain good solutions in a reasonable computation time, which is limited by the second stopping criterion of BRKGA process.

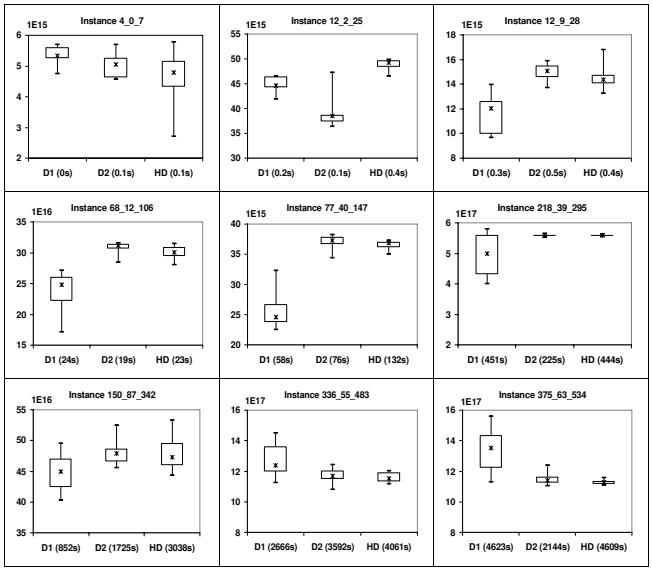

Fig. 15. Comparison of the results of the three decoding methods (D1, D2, and HD-M1) by using the method for elite set selection borrowed from IBEA

V. Conclusions

A biased random-key genetic algorithm or BRKGA is used for solving a multi-objective optimization problem. The BRKGA works on a chromosome encoded as a key vector. The chromosome consists of several genes, which are encoded by the real values in the interval $[0, 1]$. During each iteration of BRKGA, the chromosomes are decoded to obtain the feasible solutions. A hybrid decoding, which combines two single decodings, is proposed in this paper. Two solutions are obtained from the decoding of one chromosome, when using the hybrid decoding. Thus, the methods for elite set management have to be defined and three methods are tested.

The experiments are conducted on the multi-user observation scheduling problem for agile Earth observing satellites. The requests are required from multiple users. The objectives of this problem are to maximize the total profit and simultaneously minimize the maximum profit difference between users for ensure the sharing fairness. Three elite selecting methods, which are borrowed from NSGA-II, SMS-EMOA, and IBEA, are used for selecting a set of preferred solutions to become the elite set of the population. For the three elite selecting methods, the hypervolume values, which are obtained from two single decodings and the hybrid decoding, are compared. The hybrid decoding can preserve the advantages of the two single decodings, since it obtains results close to the best results of the two single decodings in reasonable computation times. Moreover, it can improve the standard deviation of the hypervolume values and avoid to entrap in local optima. Finally, the hybrid decoding is proper to be applied in BRKGA process for solving multi-objective optimization problems, which need several feasible solutions on the Pareto front.

***Abstract*—The rising costs and demand of electricity for high-performance computing systems pose difficult challenges to system administrators that are trying to simultaneously reduce operating costs and offer state-of-the-art performance. However, system performance and energy consumption are often conflicting objectives. Algorithms are necessary to help system administrators gain insight into this energy/performance trade-off. Through the use of intelligent resource allocation techniques, system administrators can examine this tradeoff space to quantify how much a given performance level will cost in electricity, or see what kind of performance can be expected when given an energy budget. A novel algorithm is presented that efficiently computes tight lower bounds and high quality solutions for energy and makespan. These solutions are used to bound the Pareto front to easily trade-off energy and performance. These new algorithms are shown to be highly scalable in terms of solution quality and computation time compared to existing algorithms.**

I. Introduction

THE race for increased performance in high-performance computing (HPC) systems has resulted in a large increase in the power consumption of these systems [1]. This increase in power consumption can cause degradation in the electrical infrastructure that supports these facilities, as well as increase electricity costs for the operators [2]. The goals of HPC users conflict with the HPC operators in that the users' goal is to finish their workload as quickly as possible. That is, the small energy consumption desired by the system operator and the high system performance desired by the users are conflicting objectives that require the sacrifice of one to improve the other. Balancing the performance needs of the users with energy costs proves difficult without tools designed to help a system administrator choose from among a set of solutions.

A set of efficient and scalable algorithms are proposed that can help system administrators quickly gain insight into the energy and performance trade-off of their HPC systems through the use of intelligent resource allocation. The algorithms proposed have very desirable run times and produce schedules that are closer to optimal as the problem size increases. As such, this approach is very well suited to large scale HPC systems.

The focus of our work is on a common scheduling problem where the users submit a set of independent tasks known as a *bag of tasks* [3]. The tasks will run on a dedicated set of interconnected machines. A task runs on only one machine and, likewise, a machine may only process one task at any one time. This class of scheduling problems is often referred to as *static scheduling* because the full bag of tasks is known a priori [4]. Task execution and power consumption are deterministic in this model. The HPC systems of primary interest have highly heterogeneous task run times, machines, and power consumption which are known as *heterogeneous computing* (HC) systems. Some machines in the HC systems are often special purpose machines that can perform specific tasks quickly, while other tasks might not be able to run at all on that hardware. Another cause of heterogeneity is differing computational requirements, input/output bottlenecks, or memory limitations, and therefore cannot take full advantage of the machine. The machines may further differ in the average power consumed for each task type. Machines may have different architectures, leading to vastly different power consumption characteristics. For instance, a task that runs on a GPU might consume less energy to complete, but often more power, than the same task run on a general purpose machine, due to the shorter execution time. We assume one objective is to minimize the maximum finishing time of all tasks, which is known as the *makespan*. The heterogeneity in execution time of the tasks provides the scheduler degrees of freedom to greatly improve the makespan over a naïve scheduling algorithm. Similarly the heterogeneity in the power consumption allows the schedulers to decrease the energy consumption.

The contributions of this paper are:

1) The formulation of an algorithm that efficiently computes tight lower bounds on the energy and makespan and quickly recovers near optimal feasible solutions.
2) Finding a high quality bi-objective Pareto front.
3) An evaluation of the scaling properties of the proposed algorithms.

978-83-60810-53-8/$25.00

4) The addition of idle power consumption to the formulation of the energy/makespan problem in [3].

The rest of this paper is as follows: first the lower bound on the objectives is described in Subsection II-B. Then algorithms are presented in Subsections II-C, II-D, and II-E that reconstruct a feasible schedule from the lower bound. In Subsection II-F, the complexity of the algorithm is analyzed. Algorithm scaling quality and runtime results are shown in Section III. Section IV shows how these bounds can be used with any scalarization technique to form a Pareto front. Section V compares these algorithms to the NSGA-II algorithm.

II. Approximation Algorithms

A. Approach

The fundamental approach of this paper is to apply *divisible load theory* (DLT) [5] to ease the computational requirements of computing a lower bound solution on the energy and makespan. For the lower bound, a single task is allowed to be divided and scheduled onto any number of machines. After the lower bound on the energy and makespan is computed, a two phase algorithm is used to recover a feasible solution from the infeasible lower bound solution. The feasible solution serves as the upper bound on the optimal energy and makespan.

Often HC systems have groups of machines, usually purchased at the same time, that have identical or nearly identical performance and power characteristics. Even when every machine is different, the uncertainty in the system often allows one to model similar machines as groups of machines of the same type. A *machine group* is a collection of machines that have virtually indistinguishable performance and power properties with respect to the workload. Machines within a machine group may differ vastly in feature sets so long as the task performance and power consumption of the tasks under consideration are not affected. Tasks often exhibit natural groupings as well. Tasks of the same *task type* are often submitted many times to perform statistical simulations and other repetitive jobs. In fact, having groupings for tasks and for machines permits less profiling effort to estimate the run time and power consumption for each task on each machine.

Traditionally this static scheduling problem is posed as assigning all tasks to all machines. The classic formulation is not well suited for recovering a high quality feasible solution. The decision variables would be binary valued (assigned or not assigned) and rounding a real value from the lower bound to a binary value can change the objective significantly. Complicated rounding schemes are necessary to iteratively compute a suitable solution. Instead, the problem is posed as determining the number of tasks of *each type* to assign to each *machine group*. With this modification, decision variables will be large integers $\gg 1$, resulting in only a small error to the objective function when rounding to the nearest integer. This approximation holds well when the number of tasks assigned to each machine group is large. For this approximation, machine groups need not be large. In addition to easing the recovery of the integer solution, another benefit of this formulation is that it is much less computationally intensive due to solving the higher level assignment of tasks types to machine groups with DLT, before solving the fine grain assignment of individual tasks to machines. As such, this approach can be thought of as a hierarchical solution to the static scheduling problem.

B. Lower Bound

The lower bound is given by the solution to a linear bi-objective optimization (a.k.a. vector optimization) problem and is constructed as follows. Let there be T task types and M machine types. Let T_i be the number of tasks of type i and M_j be the number of machines of type j. Let x_{ij} be the number of tasks of type i assigned to machine group j, where x_{ij} is the primary decision variable in the optimization problem. Let $\boldsymbol{ETC}$ be a $T \times M$ matrix where ETC_{ij} is the estimated time to compute for task type i on machine type j. Similarly let $\boldsymbol{APC}$ be a $T \times M$ matrix where APC_{ij} is the average power consumption for task type i on machine type j. These matrices are frequently used in scheduling algorithms [4], [6]–[8].

The lower bound of the finishing time of a machine group is found by allowing tasks to be divided among all machines to ensure the minimal finishing time. With this conservative approximation all tasks in machine group j finish at the same time, namely:

$$F_j = \frac{1}{M_j} \sum_i x_{ij} \mathrm{ETC}_{ij} \,. \tag{1}$$

Sums over i always go from 1 to T and sums over j always go from 1 to M, thus the ranges are omitted.

Given that F_j is a lower bound on the finishing time for a machine group, the tightest lower bound on the makespan is:

$$\mathrm{MS}_{\mathrm{LB}} = \max_j F_j \,. \tag{2}$$

Energy consumed by the bag of tasks is $\sum_i \sum_j x_{ij} \mathrm{APC}_{ij} \mathrm{ETC}_{ij}$. To incorporate idle power consumption, one must have a time duration for machines not running any tasks. In this model, the makespan is used for the time the machines' power must be accumulated. Not all machines will finish executing tasks at the same time. All but the last machine(s) to finish will accumulate idle power. When no task is executing on machine j, the power consumption is given by the idle power consumption, $APC_{\emptyset j}$. The equation for the lower bound on the energy consumed, incorporating idle power, is given in:

$$\begin{aligned} E_{\mathrm{LB}} &= \sum_i \sum_j x_{ij} \mathrm{APC}_{ij} \mathrm{ETC}_{ij} \\ &\quad + \sum_j M_j \mathrm{APC}_{\emptyset j} (\mathrm{MS}_{\mathrm{LB}} - F_j) \\ &= \sum_i \sum_j x_{ij} \mathrm{ETC}_{ij} \left(\mathrm{APC}_{ij} - \mathrm{APC}_{\emptyset j} \right) \\ &\quad + \sum_j M_j \mathrm{APC}_{\emptyset j} \mathrm{MS}_{\mathrm{LB}} \end{aligned} \tag{3}$$

where the second term in the first equation accounts for the idle power.

The resulting bi-objective optimization problem for the lower bound is:

$$\begin{array}{lll} \underset{x_{ij},\,\mathrm{MS_{LB}}}{\text{minimize}} & \begin{pmatrix} E_{\mathrm{LB}} \\ \mathrm{MS_{LB}} \end{pmatrix} & \\ \text{subject to:} & \forall i & \sum_j x_{ij} = T_i \\ & \forall j & F_j \leq \mathrm{MS_{LB}} \\ & \forall i, j & x_{ij} \geq 0 \end{array} \quad . \tag{4}$$

The objective of (4) is to minimize E_{LB} and $\mathrm{MS_{LB}}$, where $\boldsymbol{x}$ is the primary decision variable. $\mathrm{MS_{LB}}$ is an auxiliary decision variable necessary to model the objective function in (2). The first constraint ensures that all tasks in the bag are assigned to a machine group. The second constraint is the makespan constraint. Because the objective is to minimize makespan, the $\mathrm{MS_{LB}}$ variable will be equal to the maximum finishing time of all the machine groups. The third constraint ensures that there are no negative assignments in the solutions. This vector optimization problem can be solved to find a collection of optimal solutions. It is often solved by weighting the objective functions to form a *linear programming* (LP) problem. Methods to find a collection of solutions are presented in Section IV.

Ideally this vector optimization problem would be solved optimally with $x_{ij} \in \mathbb{Z}_{\geq 0}$. However, for practical scheduling problems, finding the optimal integral solution is often not possible due to the high computational cost. Fortunately, efficient algorithms to produce high quality sub-optimal solutions exist.

C. Allocation Reconstruction

For infeasible solutions obtained from (4), an algorithm is necessary to recover from each a feasible solution or full allocation. Numerous approaches have been proposed in the literature for solving integer LP problems by first relaxing them to real-valued LP problems [9]. The approach here follows this common technique combined with computationally inexpensive techniques tailored to this particular optimization problem. The problem is broken up into two phases. The first phase rounds the solution while taking care to maintain feasibility of (4). The second phase assigns tasks to actual machines to build the full task allocation.

D. Rounding

Due to the nature of the problem, the optimal solution $\boldsymbol{x}^*$ often has few nonzero elements per row. Usually all the tasks of one type will be assigned to a small number of machine groups. In the original problem, tasks are not divisible so one needs to have an integer number of tasks to assign to a machine group. When all the tasks of a given task type are assigned to one machine group, that row of $\boldsymbol{x}$ has one nonzero value which is equal to T_i, an integer. When tasks are split between machine groups, an algorithm is needed to compute an integer solution from this real-valued solution. The following algorithm finds $\hat{x}_{ij} \in \mathbb{Z}_{\geq 0}$ such that it is near x^*_{ij} while maintaining the task assignment constraint. Algorithm 1 finds $\hat{\boldsymbol{x}}$ that minimizes $\| \hat{x}_{ij} - x^*_{ij} \|_1$ for a given i.

Algorithm 1 Round to the nearest integer solution while maintaining the constraints

for $i = 1$ to T **do**
  $n \leftarrow T_i - \sum_j \lfloor x^*_{ij} \rfloor$
  $f_j \leftarrow x^*_{ij} - \lfloor x^*_{ij} \rfloor$
  Let set K be the indices of the n largest f_j
  if $j \in K$ **then**
    $\hat{x}_{ij} \leftarrow \lceil x^*_{ij} \rceil$
  else
    $\hat{x}_{ij} \leftarrow \lfloor x^*_{ij} \rfloor$
  end if
end for

Algorithm 1 operates on each row of $\boldsymbol{x}^*$ independently. The variable n is the number of assignments in a row that must be rounded up to satisfy the task assignment constraint. Let f_j be the fractional part of the number of tasks that must be assigned to machine j. The algorithm simply rounds up those n assignments that have the largest fractional parts. Everything else is rounded down. The result is an integer solution $\hat{\boldsymbol{x}}$ that still assigns all tasks properly and is near to the original solution from the lower bound.

E. Local Assignment

The last phase in recovering a feasible assignment solution is to schedule the tasks already assigned to each machine group to actual machines within that group. This scheduling problem is much easier than the general case because all machines in a group are the same. This problem is formally known as the multiprocessor scheduling problem [10]. One must schedule a set of heterogeneous tasks on a set of identical machines. The *longest processing time* (LPT) algorithm is a very common algorithm for solving the multiprocessor scheduling problem [10]. Algorithm 2 uses the LPT algorithm to independently schedule each machine group.

Algorithm 2 Assign tasks to machines using LPT per machine group

for $j = 1$ to M **do**
  Let z be an empty list
  for $i = 1$ to T **do**
    $z \leftarrow$ join(z, (task type i replicated $\hat{x}_{ij}$ times))
  end for
  $y \leftarrow \mathrm{sort}_{\text{descending by ETC}}(z)$
  for $k = 1$ to $\| y \|$ **do**
    Assign task y_k to earliest ready time machine in group j
    Update ready time
  end for
end for

Each column of $\hat{\boldsymbol{x}}$ is processed independently. List z contains task type i, $\hat{x}_{ij}$ times. The tasks are then sorted

in descending order by execution time to find y. Next the algorithm loops over y one element (task) at a time and assigns it to the machine that has the earliest ready time. The *ready time* of a machine is the time at which all tasks assigned to it will complete. This heuristic packs the largest tasks first in a greedy manner. Algorithms exist that will produce a more optimal solution, but it will be shown that the effect of the sub-optimality of this algorithm on the overall performance of the systems considered is insignificant.

F. Complexity Analysis

The complexity analysis of this algorithm shows some desirable properties that are now discussed. One must solve a real-valued LP problem to compute the lower bound. Using the simplex algorithm to solve the LP problem yields exponential complexity (i.e. traversing all the vertices of the polytope) in the worst case; however the average case complexity for a very large class of problems is polynomial time. Recall that there are T task types and M machine types. The lower bound LP problem has $T + M$ nontrivial constraints and $TM + 1$ variables. The average case complexity of computing the lower bound is $(T+M)^2(TM+1)$. Next is the rounding algorithm. The outer loop iterates T times, and the rounding is dominated by the sorting of M items. Thus the complexity of Algorithm 1 is $T(M \log M)$. The task assignment algorithm outer loop is run M times. Inside this loop there are two steps. The first step is sorting $n_j = \sum_i x_{ij}$ items which takes $n_j \log n_j$ time. The second step is a loop that iterates n_j times and must find the machine with the earliest ready time each iteration, which is a $\log M_j$ time operation. The worst case complexity of Algorithm 2 is thus $M \max_j (n_j \log n_j + n_j \log M_j)$.

The complexity of the overall algorithm to find both the lower bound and upper bound (full allocation) is driven by either the lower bound algorithm or the local assignment algorithm. Complexity of the lower bound and Algorithm 1 are independent of the number of tasks and machines. Those algorithms depend only on the number of task types and machine types. This is a very important property for large scale systems. Millions of tasks and machines can be handled easily so long as the machines can be reasonably placed in a small number of homogeneous groups and, likewise, tasks can be grouped by type. Only the upper bound's complexity has a dependence on the number of tasks and machines. This phase is only necessary if a full allocation or schedule is required. Furthermore, Algorithm 2 can be trivially parallelized because each machine group is scheduled independently. The lower bound can be used to analyze much of the behavior of the system at less computational cost.

III. Scaling Results

An important property of a scheduling algorithm is its ability to scale well as the size of the problem grows. Simulation experiments were carried out to quantify how the relative error and the computational cost of the algorithm scales. These experiments are used to validate the complexity analysis results from Section II-F. **ETC** and **APC** are needed to test the algorithms. **ETC** and **APC** are based on a set of five benchmarks executed over nine machine types [11]. Then the method found in [7] was used to construct larger **ETC** and **APC** matrices. Nominally there are 1100 tasks made up of 30 task types. There are 36 machines made up of nine machine types. A complete description of the systems and output from the algorithms are available in [12].

The number of tasks, task types, and machine types are swept independently to generate a family of figures. For this size system it is too expensive to solve for the optimal makespan but one can compare bounds on the makespan to gain insight into the algorithm. Each of the three parameter sweeps is computed by taking random subsets with replacement to handle the sweep variable. These results are averaged over 50 Monte Carlo trials. The experiments where performed on a mid-2009 MacBook Pro with a 2.5 GHz Intel Core 2 Duo processor. The code is written in Mathematica 9 and the LP solver uses the simplex method which forwards to the C++ COIN-OR CLP solver [13]. The scaling experiments all optimize makespan while ignoring the energy objective.

Fig. 1 shows the relative change in makespan as the number of tasks increase. The number of task types, machines, and machine types are held constant and are the same as the original nine machine system. The relative increase in makespan is shown from the lower bound ($\mathrm{MS}_{\mathrm{LB}}$) to the makespan after rounding. Also shown is the increase in makespan from the integer solution to the full allocation. The relative increase in makespan from the lower bound to the upper bound or full allocation is also shown. The loss in quality of the makespan from the rounding algorithm is relatively low. Most of the increase in makespan is caused by Algorithm 2. However, Fig. 1 also shows that the relative increase in makespan diminishes as the number of tasks increase. This is because the approximation that tasks are divisible has less of an impact on the solution as the number of tasks increase.

The run time of the scheduler as a function of the number of tasks is shown in Fig. 2 to quantify computational efficiency of the various algorithms. The blue (bottom) portion of the graph is the time taken to compute the lower bound (solve the LP problem). The green (middle) portion is the time it takes to round the solution. Both of the computations required to compute the lower bound and the integer solution do not depend on the number of tasks. This corresponds to the results derived for the complexity of the algorithm. The red (top) portion of the figure shows the full allocation that seems to scale linearly with the number of tasks. Recall that the complexity of Algorithm 2 has a dependency on the number of tasks which is linear or log linear depending on the parameters.

Fig. 3 shows the same three curves as Fig. 1, however this time varying the number of task types. The number of tasks, machines, and machine types are held constant for this experiment. Fig. 3 shows that again the local assignment algorithm is causing most of the degradation in makespan. The relative error in makespan does not tend to zero because increasing the number of task types does not improve the quality of the approximation.

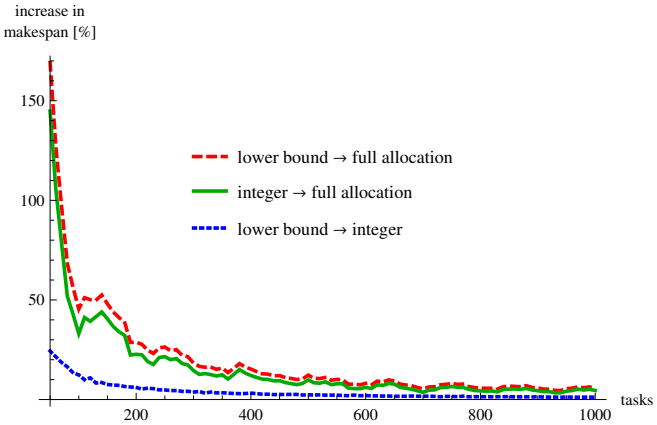

Fig. 1. Relative percent increase in makespan as a function of the *total number of tasks*: The quality of the solution improves as more tasks are used.

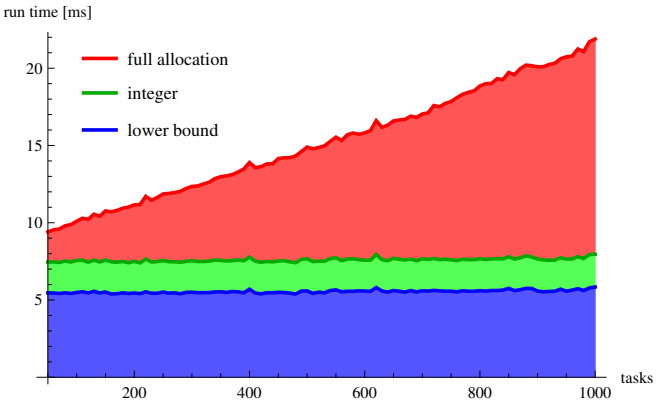

Fig. 2. Algorithm run time versus *total number of tasks*: Both the lower bound and the rounding algorithms are independent of the number of tasks. The local assignment, used to obtain the full allocation, is linearly dependent on the number of tasks.

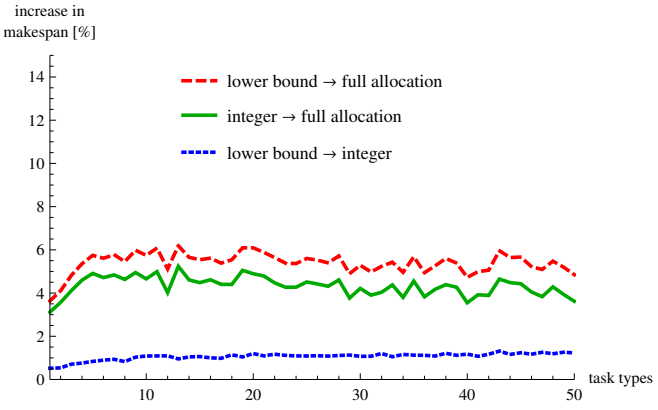

Fig. 3. Relative percent increase in makespan as a function of the *number of task types*: Quality of the solutions are roughly independent of the number of task types.

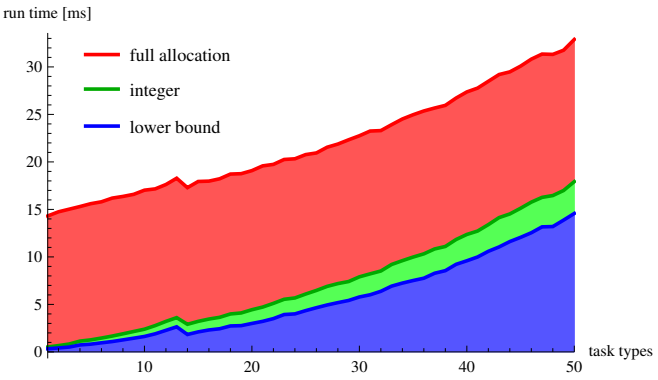

Fig. 4. Algorithm run time as a function of *number of task types*: The complexity of the lower bound and rounding algorithms grows super linearly with the number of task types.

Fig. 4 shows the run time of the three phases. Here the lower bound has super linear dependence on the number of task types. According to the complexity analysis this should be cubic. The rounding algorithm seems to increase linearly, which corresponds to the analysis. The full allocation phase seems to be independent of the number of task types. This agrees with the analysis because the complexity is not a function of the number of task types T, but instead a function of the number of tasks n_j assigned to a group, regardless of the type of task.

Fig. 5 shows the relative increase in makespan as the number of machine types varies. In the previous parameter sweeps, the number of tasks of a particular type may be zero if the random sampling selected that configuration. Allowing the number of machines in a machine group to be zero is more difficult due to (1) because some constraint coefficients will be ∞ in the linear programming problem. Practically, an $M_j = 0$ means that the j^{th} column of **ETC** and **APC** should simply be removed and the solution should never assign a task to that group because it has no machines. To avoid this case altogether each machine group has to have at least one machine (so that there are no degenerate machine groups). Fig. 5 also shows that the quality of the rounding algorithm decreases as the number of machine groups increase. This is expected because there are less tasks to assign to each machine's group making the approximation weaker. At 36 machine types there is one machine per group. There is only one solution to that scheduling problem (assign all tasks to the one machine), resulting in no increase in makespan in that phase.

Fig. 6 shows the run time as the number of machine types is increased. As expected, the lower bound grows roughly cubicly. The rounding algorithm grows roughly linearly also as expected. The time spent scheduling for each group decreases because fewer tasks are scheduled to less machines as the number of machine types increases so it effectively has little dependence on the number of machine types.

Even though the performance of these polynomial time algorithms are desirable, there is some prior work on theoretical bounds that should be noted. In [14] it is proven that there exists no polynomial algorithm that can provably find a schedule that is less than 3/2 the optimal makespan, unless

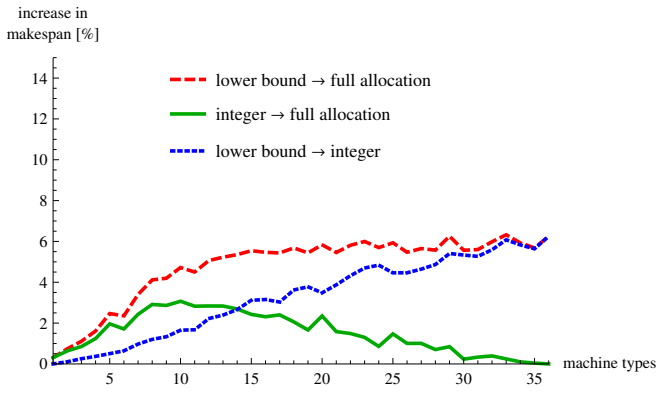

Fig. 5. Relative percent increase in makespan as a function of the *number of machine types*: Overall performance is roughly independent of the number of machine types.

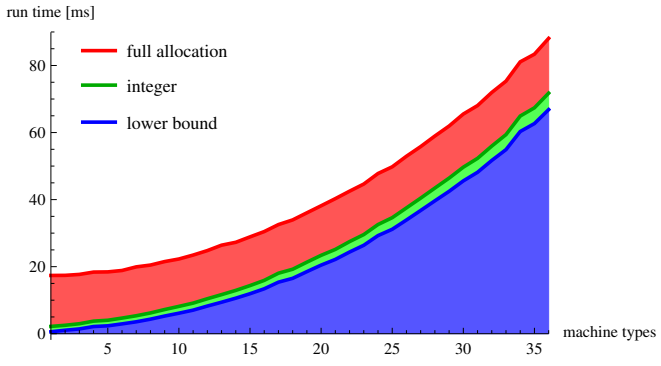

Fig. 6. Algorithm run time versus the *number of machine types*: Lower bound algorithm complexity is super linear in the number of machines types. The rounding and local assignment algorithms are roughly independent.

$P = NP$. Even though Figures 1-6 suggest that one can do better then 3/2, this is only the case on average. In the next section these algorithms are used to generate the Pareto fronts.

IV. Pareto Front Generation

Multi-objective optimization is challenging because there is usually no single solution that is superior to all others. Instead, there is a set of superior feasible solutions that are referred to as the non-dominated solutions [15]. Feasible solutions that are dominated are of little interest because one can always find a better solution in all objectives by picking a solution from the non-dominated set. Formally, a feasible solution x dominates a feasible solution y when:

$$\begin{aligned} \forall i \quad & f_i(x) \leq f_i(y) \\ \exists i \quad & f_i(x) < f_i(y) \end{aligned} \tag{5}$$

where $f_i(\cdot)$ is the i^{th} objective function. The non-dominated solutions, also known as *outcomes*, compose the Pareto front.

Finding the Pareto front can be computationally expensive because it means solving variations of the optimization problem numerous times. Most algorithms use scalarization techniques to convert the multi-objective problem into a set of scalar optimization problems. Major approaches to scalarization include the hybrid method [16], elastic constraint method [16], Benson's algorithm [17] [18], and Pascoletti-Serafini scalarization [19]. Pascoletti-Serafini scalarization is a generalization of many common approaches such as normal boundary intersection, ϵ-constraint, and weighted sum. The focus of our work is on the weighted sum algorithm. The weighted sum algorithm can find all the non-dominated solutions for problems with a convex constraint set and convex objective functions [19]. Weighted sum is used for the linear convex problem in (4) thus all non-dominated solutions can be found. A known issue with the weighted sum algorithm is that it does not uniformly distribute the solutions along the Pareto front. The solutions are often clustered together, but this does not present a problem for our particular use case.

Finding the optimal schedule for makespan alone is NP-Hard in general [4], thus finding the optimal (true) Pareto front is NP-Hard as well. Computing tight upper and lower bounds on the Pareto front is still possible. Specifically, a lower bound on a Pareto front is a set of solutions for which no feasible solution dominates any of the solutions in this set. An upper bound on the Pareto front is a set of feasible solutions which do not dominate any Pareto optimal solutions.

A. Weighted Sum

The weighted sum algorithm simply forms the positive convex combination of the objectives and sweeps the weights to generate the Pareto front. The first phase is to compute the lower bound solution for energy and makespan independently of each other. Next ΔE_{LB}, which is the difference between the maximum and minimum values of energy, is computed. Likewise, $\Delta \text{MS}_{\text{LB}}$ is computed. The scalarized objective is:

$$\min \frac{\alpha}{\Delta E_{\text{LB}}} E_{\text{LB}} + \frac{1-\alpha}{\Delta \text{MS}_{\text{LB}}} \text{MS}_{\text{LB}} \,. \tag{6}$$

A lower bound on the Pareto front can be generated by using several values of $\alpha \in [0, 1]$. Weighted sums will produce duplicate solutions (i.e., $\boldsymbol{x}$ is identical for neighboring values of α). Duplicate solutions are removed to increase the efficiency of the subsequent algorithms. Each solution is rounded by Algorithm 1 to generate an intermediate Pareto front. Rounding often introduces many duplicates that can be safely removed. Each integer solution is converted to a full allocation with Algorithm 2 to create the upper bound on the Pareto front.

B. Non-dominated Sorting Genetic Algorithm II

NSGA-II [20] is an adaptation of the Genetic Algorithm (GA) optimized to find the Pareto front of a multi-objective optimization problem. Similar to all GAs, the NSGA-II uses mutation and crossover operations to evolve a population of chromosomes (solutions). Ideally this population improves from one generation to the next. Chromosomes with a low fitness are removed from the population. The NSGA-II algorithm modifies the fitness function to work well for discovering the Pareto front. In prior work [3], the mutation

and crossover operations were defined for this problem. The NSGA-II algorithm will be seeded in two ways in the following results. The first seeding method is to use the optimal minimum energy solution, sub-optimal minimum makespan solution (from the Min-Min Completion Time [4] algorithm), and a random population as the initial population. This is the original seeding method used in [3]. The second seeding method is to use the full allocations from Algorithm 2 as the initial population for the NSGA-II.

V. Pareto Front Results

The system used for these experiments is the same as in Section III, unless stated otherwise. All 1100 tasks, 30 task types, 36 machines, and nine machines types are used as described in [8]; the complete description of the system and output data files from the new algorithm are available in [12]. The hardware used for running the NSGA-II experiments is a 2011 Sager NP7280 with an Intel Core i7 980 @ 3.33 Ghz. The NSGA-II code is implemented in C++.

Fig. 7 shows the Pareto fronts generated from the various algorithms without idle power consumption. The figure shows the actual solutions as markers that are connected by lines. The lower bound, integer, and full allocation are nearly indistinguishable at the lower portion of the plot. This means that the true Pareto front is tightly bounded even though it is unknown. The curve that is dominated by all other curves is the Pareto front generated by the NSGA-II using the first seeding method. The NSGA-II took hours to find that sub-optimal Pareto front. In contrast, the lower and upper bounds were found in ~ 10 seconds. The last Pareto front is the NSGA-II seeded with the full allocation. Seeding with the full allocation allows the NSGA-II to both converge to an improved Pareto front as well as decreasing the run time necessary to converge. The NSGA-II attempts to evenly distribute the solutions along the Pareto front and tries to find solutions that are in the convex regions as can be seen in Fig. 7. All the algorithms seem to perform well when minimizing energy alone because computing the optimal minimum energy solution is relatively easy. One simply assigns each task to the machine that requires the lowest energy to execute that task. Solving for the optimal makespan is difficult in practice. Fig. 7 shows that all the algorithms agree in the energy dimension, however in the makespan dimension there are significant distinctions in solution quality. Pareto fronts for other representative systems were also computed with similar results. The new algorithms produced better quality Pareto fronts in significantly less time.

Fig. 8 illustrates how the solutions progress through the three phases of the algorithm when there is no idle power consumption. The lowest line represents the lower bound on the Pareto front. Each orange arrow represents a solution as it is rounded. In every case, the makespan increases but the energy may increase or decrease. As $\boldsymbol{x}$ is rounded, machines will finish at different times increasing the makespan. Each blue arrow represents a solution that is being fully allocated. The energy in this case does not change because the local assignment algorithm does not move tasks across

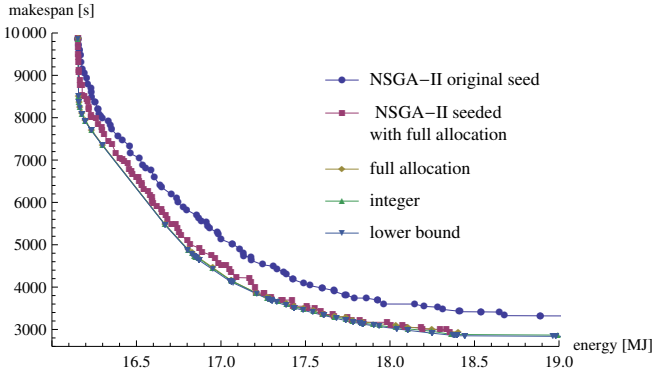

Fig. 7. Pareto front for lower bound, integer, upper bound, and NSGA-II. The lower bound does truly lower bound the other curves. The full allocation or upper bound is very near the lower bound so the optimal Pareto front is tightly bounded. The NSGA-II with the original seed solution quality is rather poor and expensive to compute, however the NSGA-II seeded with the full allocations produces a reasonable result, close to the full allocation, in much less time, but still not as good as the full allocation in places.

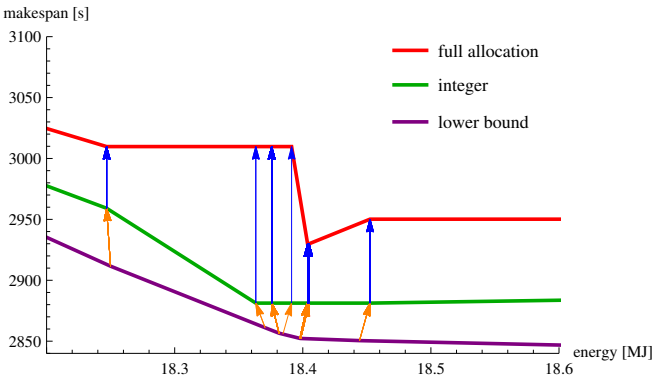

Fig. 8. Progression of solutions from lower bound to integer to upper bound (no idle power)

machine types thus the power consumption cannot change. The makespan increases are highly varying. The full allocation solution second to the right dominates the one on the far right. In this case the solution on the far right is taken out of the estimate of the Pareto front.

Fig. 9 shows the progression of the the solutions with non-zero idle power. The idle power consumption is set to 10% of the mean power for each machine type, specifically $\mathrm{APC}_{\emptyset j} = \frac{0.1}{T} \sum_i \mathrm{APC}_{ij}$. As the makespan increases, more machines will be idle for longer, so the idle energy increases. The local assignment phase now negatively affects the energy consumption because it will often have machines idle for some time.

Fig. 10 shows the effect of idle power on the Pareto front. The curves show the lower bound on the optimal Pareto front with different idle powers. The penalty for having a large makespan increases as the idle power increases. The optimal energy solutions now must have a shorter makespan to reduce energy usage. This causes the Pareto front to contract in the makespan dimension and shift to the right slightly.

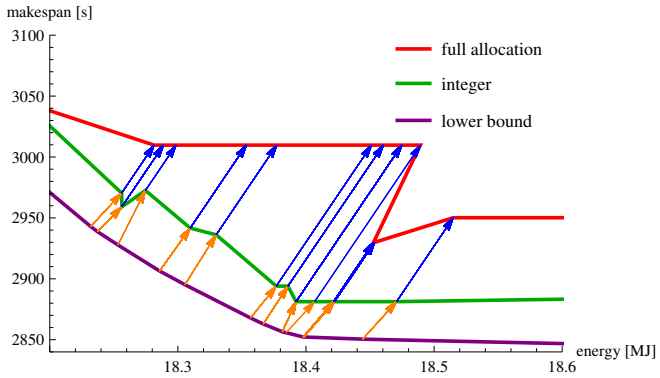

Fig. 9. Progression of solutions from lower bound to integer to upper bound (10% idle power)

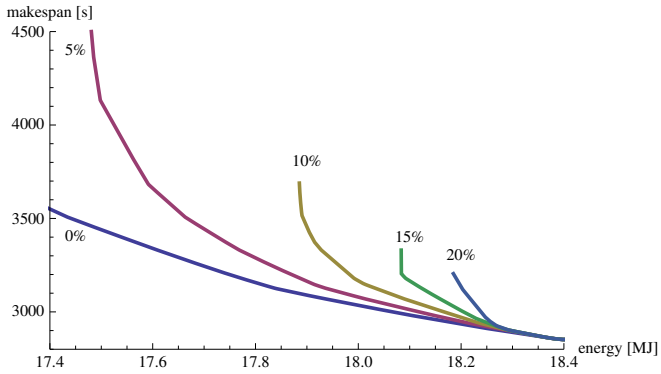

Fig. 10. Pareto front lower bounds when sweeping idle power: Idle power is swept from 5% increments as labelled on the figure. As idle power increases the reward for improving makespan also increases.

VI. Conclusions

A highly scalable scheduling algorithm for the energy and makespan bi-objective optimization problem was presented. The complexity of the algorithm to compute the lower bound on the Pareto front was shown to be independent of the number of tasks. The quality of the solution also improves as the size of the problem increases. These two properties make this algorithm perfectly suited for very large scale scheduling problems. Algorithms were also presented that allow one to efficiently recover feasible solutions. These feasible solutions serve as the upper bound on the Pareto front and can be used to seed other algorithms. This upper bound was compared to the solution found with the NSGA-II algorithm and shown to be superior in solution quality and algorithm run time. These algorithms allow the decision makers to more easily trade-off energy and makespan to reduce operating costs and improve efficiency of HPC systems.

Efficient Models for Special Types of Non-Linear Maximum Flow Problems

Marina Tvorogova

***Abstract*—In this paper, we consider the maximum flow problem on networks with non-linear transfer functions. We consider special types of transfer functions, which are particularly relevant for applications. For concave transfer functions, we reduce the NL-flow problem to the generalized flow problem and solve it using a polynomial-time approximation scheme. For convex, s-shaped and monotonically growing piecewise linear (PWL) transfer functions (the latter can always be divided into s-shaped fragments), we present an equivalent network representation that allows us to build a MILP model with a better performance than if we were using standard MILP formulations of PWL functions. The latter requires additional variables and constraints to force the correct (depending on the amount of flow) linear segment of PWL functions to be taken. In our model, the correct segment in an s-shaped fragment is chosen automatically due to the network's structure. For the case when transfer functions are non-linear, we provide an error estimation for the approximated solution.**

I. Introduction

IN THIS paper, we consider flows in networks with non-linear losses (NL-flow problem). We have a directed graph $D = (V, A)$, where V is a set of vertices and A is a set of edges. The maximum flow that we can send through edge $a \in A$ is bounded by the edge's capacity $u_a \in R_+$. Each edge a of graph D has an associated non-linear function $F_a(f_a)$ that defines how outflow depends on inflow: we assume that if we send f_a units of flow into edge $a = (v, w)$, then $F_a(f_a)$ units of flow arrive at the head of edge a (that is node w).

In the classical maximum flow problem, the goal is to send as much flow as possible from the source node(s) to the target node(s), taking capacity and flow conservation constraints into account. *Transfer function* $F_a(f_a)$ defines the outgoing flow from edge a depending on the incoming flow f_a to edge a, $a \in A$. For the classical case, flow does not change while going through an edge, i.e. $F_a(f_a) = f_a$. This problem is well-studied, see e.g. Korte and Vygen [4].

The generalized flow problem (GFP) is a step closer to the NL-flow problem. The goal of the generalized maximum flow problem is to maximize flow at the target node. In a generalized graph, flow changes its value while going through edges. Outgoing flow $F_a(f_a)$ from edge a linearly depends on the incoming flow f_a to edge a, $a \in A$. Transfer functions corresponding to this type of flow are linear, i.e. $F_a(f_a) = \gamma_a \cdot f_a$, where γ_a is the proportionality coefficient corresponding to edge a. The GFP has already been studied by Onaga [6] and Truemper [9]. There are fully polynomial-time approximation schemes for GFP, see e.g. Fleischer and Wayne [2] and Oldham [5], and polynomial algorithms for GFP with assumptions about transfer coefficients, see Radzik [7] and Tardos and Wayne [8].

In this paper, we introduce flows with affine-linear transfer functions, i.e. $F_a(f_a) = \gamma_a \cdot f_a + b_a$, where k_a and b_a are constants corresponding to edge a, $a \in A$. We call optimization problems that correspond to this type of flow, *affine generalized flow problems* (AGFP).

For non-linear PWL functions, there exist standard ways to present them in mixed-integer formulations (see Vielma et al. [10]). Our representation is more efficient than representations applied to the general type of PWL functions. Standard ways use extra variables to force the use of the right segment of the PWL functions. We modify the network in such a way that by flow maximizing, the right segment will be chosen automatically. This allows us to get a problem formulation of significantly reduced size. The main contribution of this paper is that for a wide range of applications, we propose a solution, which deals with large MILP formulations arising by modeling problems with non-linearities. We propose efficient formulations of the maximum flow problem for networks with transfer functions of special types.

The remainder of this paper is organized as follows. In Section II-C, we introduce the required definitions and terms. We describe how to build a residual network for flows with NL functions and provide flow decomposition theorem for flows with NL losses. In Section III, motivated by the applications areas, we distinguish three special types of transfer functions: *concave, convex* and *s-shaped*. In Section IV, we design an equivalent problem representation of the original instance for the considered types of transfer functions. We show that the optimal solution of the maximization problem for this problem representation and the optimal solution of the maximization problem for the original instance are the same. For the problem with concave transfer functions, we propose a fully polynomial-time approximation scheme. For convex and s-shaped transfer functions we replace edges with NL transfer functions by network structures, where transfer functions of the edges are affine-linear. In Section V, we introduce MILP models for AGFP. In Section VI, we evaluate our MILP model. In section VII we consider the case of non PWL transfer functions and estimate the solution error,

978-83-60810-53-8/$25.00

which arises by approximating the original transfer functions by PWL functions. Section VIII completes our paper with the conclusions.

II. Preliminaries

A. Problem Formulation

We can formulate the maximization problem for flows with NL as follows:

Problem 1:

Given $D = (V, A)$, $u_a\ \forall a \in A$, $F_a\ \forall a \in A$.
Find an $s-t-$flow, that
maximizes
$$\sum_{a\in\delta^-(t)} F_a(f_a)$$
subject to
$$\sum_{a\in\delta^+(v)} f_a - \sum_{a\in\delta^-(v)} F_a(f_a) \leq 0, \forall v \in V\backslash\{s,t\} \quad (1)$$
$$0 \leq f_a \leq u_a, \forall a \in A. \quad (2)$$

Equation (1) describes the flow conservation law, inequality (2) the edge capacity constraints.
Here, we allow positive excess at nodes. This does not contradict flow maximization at the target node.

B. Assumptions

Inspired by the applications of the NL-flow models (see Section III for details), we make the following assumptions on the type of transfer functions. The considered transfer functions are loss functions ($\gamma_a(f_a) \leq 1$). Increasing flow f_a incoming to edge a increases the outgoing flow $F_a(f_a) = \gamma_a(f_a) \cdot f_a$. Thus, the transfer functions are strictly monotonically growing functions. The next natural assumption is $F_a(0) = 0$.

The considered networks have no flow generating-cycles. In the context of our applications, flow-generating cycles would refer to perpetual flow sources, which is not possible in practice.

C. Definitions

Definition 1: The transfer multiplier $\gamma_a(f_a)$: $R_+ \to R_+$ is a quotient of the edge's transfer function $F_a(f_a)$ and flow f_a entering the edge:

$$\gamma_a(f_a) = \frac{F_a(f_a)}{f_a}, \text{ for } f_a \neq 0.$$

If $f_a = 0$, $\gamma_a(f_a)$ may be assigned an arbitrary number. Let's assume for this paper that if $f_a = 0$, then $\gamma_a(f_a) = 0$.
$\gamma_a(f_a)$ can be interpreted as the efficiency of sending flow f_a through edge a.

Definition 2: A transfer function is called *loss function* (flow decreases) if the transfer multiplier corresponding to this function is less than or equal to one, i.e.

$$\gamma_a(f_a) \leq 1\ \forall f_a \in R_+.$$

Proposition 1: The optimization problem on a graph with multiple source nodes and multiple target nodes can always be transferred to the optimization problem on a graph with one source node and one target node.

Proof: The solution of the flow maximization problem (also for flows with NL-losses) is not influenced by the following two operations.

T is a set of the target nodes and S is a set of the source nodes.
g_i is the flow at node i. $g_i = 0$ for $g_i \in V\backslash\{S,T\}$. $g_i < 0$ for $g_i \in S$. $g_i > 0$ for $g_i \in T$.

- We can add an integrated source node s and an extra edge $a = (s, w)$ with $\gamma_a(\cdot) = 1$, $u_a = g_w$ to all nodes $w \in S$; node w becomes a transfer node, $g_s = \sum_{w\in S} g_w$ and g_w is assigned to zero.
- We can add an integrated target node t and an extra edge $a = (v, t)$ with $\gamma_a(\cdot) = 1$, $u_a = \infty$ to all nodes $v \in T$; node v becomes a transfer node, $g_t = \sum_{v\in T} g_v$ and g_v is assigned to zero.

■

Using Proposition 1 without loss of generality, we assume that the graph D has only one target node and only one source node.

Definition 3: An $s-t-$flow is a flow from the supply nodes s to target nodes t.

Definition 4: Let us call *flow at node* v the difference between flow outgoing from node v ($\sum_{a\in\delta^+(v)} f_a$) and flow incoming to node v ($\sum_{a\in\delta^-(v)} F_a(f_a)$), where $\delta^-(v) := \{(u, v) \in A\}$ is a set of edges entering node v and $\delta^+(v) := \{(v, w) \in A\}$ is a set of edges leaving node v.

Definition 5: The *affine-generalized network* is the network, in which edges have transfer functions of type $F_a(f_a) = f_a \cdot k_a + b_a$.

Definition 6: A network flow distribution $X : R_+^A \to R_+$ defines for all edges $a \in A$ *partition coefficients* $x_a : A \to [0, 1]$, which denote the ratio of the flow leaving node v and the flow sent through edge $a = (v, w)$, i.e.

$$x_a = \begin{cases} 0, \text{ if } \sum_{a\in\delta^+(v)} f_a = 0, \\ \frac{f_a}{\sum_{a\in\delta^+(v)} f_a}, \text{ otherwise.} \end{cases}$$

A feasible flow through the network f determines a flow distribution X.

Definition 7: A flow distribution X (for the given supply) is *feasible* if the corresponding flow is feasible, i.e. the flow does not violate flow feasibility constraints (1) and (2).

Lemma 1: The flow at the source node together with the feasible flow distribution X uniquely determine the flow at each edge of the given graph.

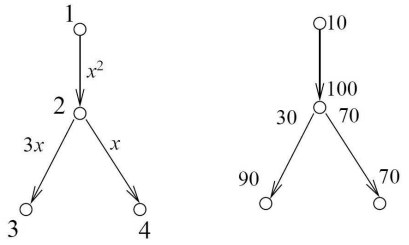

Fig. 1. Graph G and flow on it.

D. Decomposition theorem for NL flows

Here, we introduce the decomposition theorem for flows with NL transfer functions. This theorem will be used in the proof of Theorem 3.

Definition 8: We define the *residual capacity* for flow function $f_a : V \longrightarrow R_+$ as

$$u_a^R = u_a - f_a, a \in A, \tag{3}$$

$$u_{\overline{a}}^R = F_a(f_a), \overline{a} \in \overline{A}, \tag{4}$$

where $\overline{A}$ is a set of backward edges.

Definition 9: The residual function for backward edges can be found as:

$$F_{\overline{a}}^R(l) = f_a^* - F_a^{-1}(F_a(f_a^*) - l), \tag{5}$$

where f_a^* is the current flow on edge a, $l = f_{\overline{a}}$, we use notation l for better observability.

Definition 10: The residual function for forward edges can be found as:

$$F_a^R(g) = F_a(g + f_a^*) - F_a(f_a^*), \tag{6}$$

where f_a^* is the current flow on edge a, $g = f_a$, we use notation g for better observability.

Theorem 1: For every feasible flow f on a graph $D = (A, V)$, there exists a collection of $k \leq m = |A(D)|$ elementary residual flows $\mathcal{F} = \mathcal{F}(1), \ldots, \mathcal{F}(k)$ such that $f_a = \sum_{i=1..k} \mathcal{F}_a(i)$ for all $a \in A$. Elementary residual flows are residual flows on a path, on a unit-gain cycle, on a cycle-path, on a path-cycle or on a bicycle.

We omit the prove of the theorem, but give an example of decomposition.

Given graph G and flow on it, see Figure 1. We want to decompose the current flow to flow $\mathcal{F}(1)$ (through path $1-2-3$) and to flow $\mathcal{F}(2)$ (through path $1-2-4$) so that $f_a = \sum_{i=1,2} \mathcal{F}(i)$. Consider the graph and flow $f = (10, 30, 70)$ on it. Calculate the residual transfer function and the residual capacities for backward edges using formulas 4 and 5. $F_{21}^R(f) = f_{12} - \sqrt{(f_{12})^2 - f}$, where $f_{12} = 10$, $F_{32}^R(f) = \frac{1}{3}$, $F_{42}^R(f) = x$. $u_{21}^R(f) = 100$, $u_{32}^R(f) = 90$, $u_{42}^R(f) = 70$.

a is a part of the flow at the source node, that forms $\mathcal{F}(1)$, b is a part of the flow at the source node, that forms $\mathcal{F}(2)$, $a, b \in [0, 1]$, $a + b = 1$.

There are two ways to define $\mathcal{F}(1)$ and $\mathcal{F}(2)$ depending on the order of augmentation. Let us call the flow after the first augmentation $f(1)$, after the second augmentation $f(2)$.

1: We first augment $a \cdot f_{12}$ units of flow along path $1-2-3$ and then $b \cdot f_{12}$ units of flow along path $1-2-4$. Augment the flow along path $4-2-1$ by $F_{24}(f_{24})$ units. $F_{24}(f_{24}) = u_{1-2-4} = 70$. After augmenting, $f_{24}(1) = 0$, $f_{12}(1) = 10 - F_{21}^R(F_{42}^R(70)) = 10 - 10 + \sqrt{10^2 - 70} = \sqrt{30}$. $\mathcal{F}_{24}(1) = f_{24} = 70$, $\mathcal{F}_{12}(1) = f_{12} - f_{12}(1) = 10 - \sqrt{30}$.

We augment the current flow along path $3-2-1$ by $F_{23}(f_{23})$ units of flow. $F_{23}(f_{23}) = u_{1-2-3} = 90$. After augmenting, $f_{23}(2) = 0$, $f_{12}(2) = \sqrt{30} - F_{21}^R(F_{32}^R(90) = \sqrt{30} - \sqrt{30} + \sqrt{\sqrt{30}^2 - \frac{1}{3} \cdot 90} = 0$.

$\mathcal{F}_{23}(2) = f_{23} = 30$, $\mathcal{F}_{12}(2) = f_{12}(1) - f_{12}(2) = \sqrt{30}$.

Thus, we obtain $\mathcal{F}(1) = (10 - \sqrt{30}, 30, 0)$ and $\mathcal{F}(2) = (\sqrt{30}, 0, 70)$.

2: We first augment $a \cdot f_{12}$ units of flow along path $1-2-3$ and then $b \cdot f_{12}$ units of flow along path $1-2-4$. Augment the flow along path $3-2-1$ by $F_{23}(f_{23})$ units of flow. $F_{23}(f_{23}) = u_{1-2-4} = 90$. After augmenting, $f_{23}(1) = 0$, $f_{12}(1) = 10 - F_{21}^R(F_{42}^R(70)) = 10 - 10 + \sqrt{10^2 - \frac{1}{3} \cdot 90} = \sqrt{70}$. $\mathcal{F}_{24}(1) = f_{23} = 30$, $\mathcal{F}_{12}(1) = f_{12} - f_{12}(1) = 10 - \sqrt{70}$.

We augment the current flow along path $4-2-1$ by $F_{24}(f_{24})$ units of flow. $F_{24}(f_{24}) = u_{1-2-4} = 70$. After augmenting, $f_{24}(2) = 0$, $f_{12}(2) = \sqrt{70} - F_{21}^R(F_{32}^R(70) = \sqrt{70} - \sqrt{70} + \sqrt{\sqrt{70}^2 - 70} = 0$.

$\mathcal{F}_{24}(2) = f_{24} = 70$, $\mathcal{F}_{12}(2) = f_{12}(1) - f_{12}(2) = 10 - \sqrt{70}$.

Thus, we obtain $\mathcal{F}(1) = (\sqrt{70}, 0, 70)$ and $\mathcal{F}(2) = (10 - \sqrt{70}, 30, 0)$.

III. Special types of transfer functions and their applications

In this section, we consider three types of PWL transfer functions, which are especially interesting from the application point of view. We list them together with the application examples of the models, which use those types of transfer functions. Further, we use the special properties of these functions to find the solution of the maximum flow problem.

A. Convex transfer functions

In this case, the slope of the transfer function (and, thus, the transfer efficiency) grows as the amount of flow we send increases.

One application of convex transfer functions is modeling of information flows with "learning" effects. The flow passing along the graph represents information. Transfer functions model information transmission processes with "learning" effect, e.g. handwriting recognition, face recognition, speech

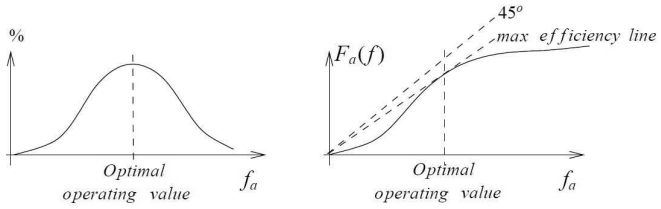

Fig. 2. Efficiency around optimal operating value and the corresponding S-shaped transfer function.

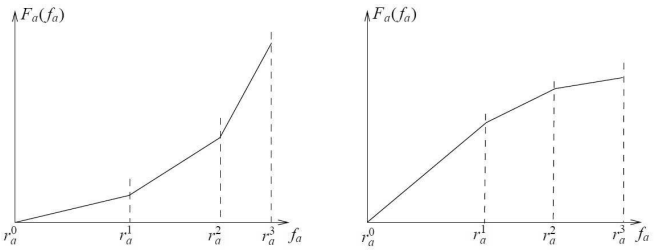

Fig. 3. PWL convex and concave functions.

recognition. Efficiency of the information recognition/transmission process increases together with the amount of information.

B. Concave transfer functions

For this case, the slope of the transfer function (and thus, the transfer efficiency) shrinks as the amount of flow we send increases.

We can use concave transfer functions, e.g., in traffic flow modeling. It is a maximum NL-flow problem to find a flow routing with minimal overall flow-losses (deceleration). Edges represent road segment. Flow corresponds to the number of vehicles passing a reference point per unit of time. Transfer functions describe the flow-deceleration effect, which increases as flow approaches the capacity of a road segment.

C. S-shaped transfer functions

S-shaped transfer functions are used to model processes with optimal operating value. The slope of the transfer function grows until it reaches the optimal operating value. As we increase the amount of flow beyond the optimal operating value, the slope decreases.

S-shaped transfer functions are interesting for modeling energy flows. Nodes represent different types of energy (e.g. raw materials, electricity or heat energy), flow is energy (in different forms), edges represent transformation of one type of energy into another. Technical equipment that enables energy transformations usually has an optimal operating value, at which this equipment reaches its maximum efficiency. Thus, transfer functions show how the efficiency of the energy transformation first grows until the optimal operating value and then shrinks (see Fig. 2).

IV. Design of equivalent problem representations

In this section, we modify the underlying network in such a way that *Problem 2* from subsection IV-C has the same optimal solution for the original (*Problem 1*) and for the modified network. Further, in the next section, we use this modified network for establishing an efficient MILP formulation.

In the procedure described below, we replace a single edge $a = (v, w)$ by a set of p parallel edges $(a_1, a_2, \dots a_p)$.

Proposition 2: Edges $((v, w)_1, (v, w)_2, \dots (v, w)_p)$ are parallel edges between nodes v and w. Flow f is a flow that optimally solves the maximum flow problem (non-linear, generalized or classical). If flow f between nodes v and w is positive, then the capacity of the edges $(v, w)_i$, $i \in 1..p$, with higher efficiency is exhausted first.

A. Convex transfer functions

Let function F_a be a PWL convex function consisting of p segments defined by breakpoints: $0 = r_a^0 < r_a^1 < r_a^2 < r_a^3 < \dots < r_a^p$, for all $a \in A$ (see Fig. 3, left). Let us denote the function in the interval $[r_a^k, r_a^{k+1}]$ as F_a^k. F_a^k is a linear function of type $F_a^k = \gamma_a^k \cdot f + b$, where γ_a^k is the slope of function F_a^k. Since function F_a is convex, the slopes of the segments are related as follows:

$$\gamma^1 < \gamma^2 < \dots < \gamma^p. \tag{7}$$

We replace edge a by p parallel edges. The transfer function of the k-th edge is F_a^k, $a \in [1..n]$. The capacity of the k-th edge is equal to u_a.

Let us show that this replacement does not influence the optimal solution.

Function F_a^* is convex. Thus, the efficiency of sending flow through edge a grows as the amount of flow through edge a increases.

Since we maximize flow at the target node and, according to Proposition 2, prefer higher efficiency, only one edge of p parallel edges will be used.

$$F_a(f_a) = \begin{cases} \gamma_a^i \cdot f_a^i + b_a^i, & \text{if } f_a \in [r_a^{i-1}, r_a^i], \\ 0, & \text{if } f_a = 0 \end{cases} \tag{8}$$

If we send an amount of flow f_a through edge a and $f_a \in [r_a^k, r_a^{k+1}]$, the k-th edge will be used, because transfer functions F_a^i, $i > k$ or $i < k$ provide lower efficiency for f_a.

Thus, the replacement of edge a by p parallel edges in the way described above does not influence the solution of the maximization problem.

Now, the transfer functions of the edges are of type $\gamma f + b$ and the problem can be transformed to MILP-form (see Section V).

B. Concave transfer functions

Let function F_a be a PWL concave function consisting of p segments defined by breakpoints: $0 = r_a^0 < r_a^1 < r_a^2 < r_a^3 < \dots < r_a^p$, for all $a \in A$. Let us denote the slope of a PWL function in the interval $[r_a^k, r_a^{k+1}]$ as γ_a^k. Since function F_a is concave, the slopes of the segments are related as follows:

$$\gamma^1 > \gamma^2 > \dots > \gamma^p. \tag{9}$$

Flow f_a along edge a is the sum of flows along its segments.

$$f_a = \gamma^1 \cdot f_a^1 + \gamma^2 \cdot f_a^2 + \cdots + \gamma^p \cdot f_a^p = \sum_{k \in \{1..p\}} \gamma_a^k \cdot f_a^k \quad (10)$$

The capacity of the edge representing the k-th segment of edge a is equal to $r_a^k - r_a^{k-1}$. The flow along the k-th segment can be found as follows:

$$f_a^k = \begin{cases} 0, & \text{if } f_a \le r_a^{k-1} \\ f_a - r_a^{k-1}, & \text{if } r_a^{k-1} \le f_a \le r_a^k \\ r_a^k - r_a^{k-1}, & \text{if } f_a \ge r_a^k \end{cases}$$

Every segment a^k can be represented as an edge with transfer function $F_a^k = f_a \cdot \gamma_a^k$ and assigned capacity $(r_a^k - r_a^{k-1})$. An edge a can be replaced by p parallel edges corresponding to the segments of F_a, for all $a \in A$. This replacement is an equivalent replacement, because the edges with the higher γ will be used (exhausted) first when flow is maximized.

The transfer function corresponding to the edges of the modified network are linear. Now we can transform the problem to LP-form and use standard LP-solvers or apply algorithms for the GFP-case.

For example, we can use the algorithm from [2], which takes $O(\epsilon^{-2} m^* (m^* + n \log m^*) \log n)$ time to compute the ϵ-optimal flow on a network with no flow-generating cycles. If we model energy flows, flow generating cycles refer to perpetual energy sources, which is not possible in practice. Flow is ϵ-optimal if $SOL(F) \ge (1-\epsilon) OPT(F)$, $m = |A|$, $n = |V|$ and m^* is the amount of edges in the modified network.

There are two ways to reduce the algorithm's complexity:

1: The generalized shortest-path problem is a subroutine of the GFP. On a graph with no flow-generating paths, it takes $O(m + n \log m)$ time to find a shortest path. We search for the shortest path on the residual graph. We can speed up this algorithm by a special way to set a residual graph. We use the idea described in [1] for convex cost functions. In the residual network, we do not need to consider all $2p$ (p forward and p backward) copies of edges between nodes v and w; it is sufficient to maintain only two edges: the first is for increasing flow through edge (v, w), the second edge is for decreasing flow on it.

Thus, it takes only $O(\epsilon^{-2} m^* (m + n \log m) \log n)$ time to compute the ϵ-optimal flow.

2: The second way to improve the computational performance of the algorithms is to use scaling of the transfer functions. The polynomial-time algorithm for convex cost (with integer costs) flow problems based on this method is presented in [1]. In the first scaling phase, we linearize a concave function $F_{(v,w)}$ by a PWL function consisting of 2 segments of length $\frac{u_{(v,w)}}{2}$. In the second phase, we linearize a concave function $F_{(v,w)}$ by a PWL function consisting of 4 segments of length $\frac{u_{(v,w)}}{4}$, and so on until we reach a segment length of $\frac{u_{(v,w)}}{2^n} \le \epsilon$. Thus, we conduct n scaling phases, $n \ge \lceil \log \frac{U}{\epsilon} \rceil$, where $U = \max_{(v,w) \in A} u_{(v,w)}$. After each scaling phase, we make sure that the flow on the linearized residual network is maximum. It can be shown (analogously to the proof from [1]) that to keep the flow on the network maximum in k-th scaling phases, it is enough to increase or decrease the flow on every edge by $\frac{u_{(v,w)}}{2^k}$ units. There can be at most $O(m)$ augmentations in each scaling phase. The overall algorithm takes $O(m \lceil \log \frac{U}{\epsilon} \rceil)$ augmentations and requires $O(m + n \log m)$ time to find a shortest path, thus, runs in $O(m \lceil \log \frac{U}{\epsilon} \rceil (m + n \log m))$ time.

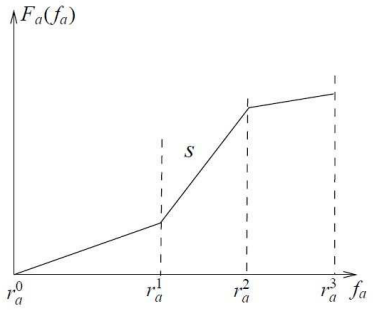

Fig. 4. S-shaped transfer function of edge a.

Algorithm 1 How to find inflection segment

Require: S-shaped PWL function
Ensure: Number of the inflection segment, s
lower bound of s s_b:=1;
upper bound of s s_e:=p;
while $s_b \neq s_e$ **do**
  s_m:=$\lfloor \frac{s_e - s_b}{2} \rfloor$;
  if $\gamma_a^{s_b+s_m} > \gamma_a^{s_b+s_m+1}$ **then**
    slope decreases, continue search on the left part
    s_e:=$s_b + s_m$;
  else
    slope grows, continue search on the right part
    s_b:=$s_b + s_m + 1$;
  end if
end while
s:=s_e; (s_b=s_e, thus s=s_b).

C. S-shaped transfer functions

Let function F_a be an s-shaped PWL function consisting of p segments defined by breakpoints: $0 = r_a^0 < r_a^1 < r_a^2 < r_a^3 < \cdots < r_a^p$, for all $a \in A$. Let us denote the slope of a PWL function in the interval $[r_a^k, r_a^{k+1}]$ as γ_a^k.

First, we divide the s-shaped function in two parts: a concave part and a convex part. With the help of Algorithm 1, which uses the fact, that $\gamma_a^j \neq \gamma_a^{j+1}$, $a \in A$, $j \in [1..p-1]$, we can easily find the number of the *inflection segment* s for edge a in $O(\lceil \log p \rceil)$ time. s is the number of the first segment, where the slope of the following segment is lower than the slope of the current segment. The inflection segment corresponds to the highest slope.

We use Algorithm 2 to build an equivalent representation of an s-shaped PWL transform function, see Fig 5. The new representation fits into MILP framework. The solution of the

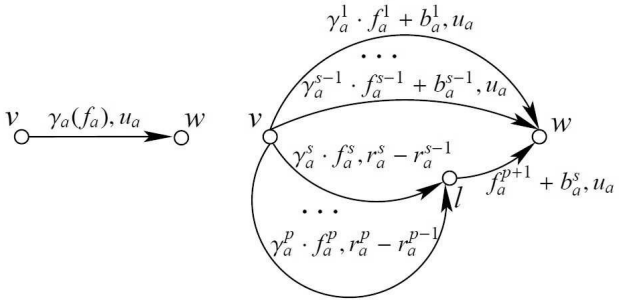

Fig. 5. An equivalent representation of edge a with an s-shaped transfer function.

Algorithm 2 How to find the equivalent representation for s-shaped PWL transfer functions

Require: Initial underlying graph G=(V,A)
Ensure: Equivalent representation of graph G
m:=| V |
for $a = 1 \to m$ **do**
  apply Algorithm 1 for function F_a to find the number of inflection segment for transfer function of edge $a = (v, w)$
  for $i = 1 \to s-1$ **do** {the convex part of the function}
    add edge (v, w) with $F_a^i = \begin{cases} \gamma_a^i \cdot f_a^i + b_a^i, \text{if} f_a^i > 0, \\ 0, \text{otherwise} \end{cases}$ and $u_a^i = u_a$;
  end for
  for $i = s \to p$ **do** {the concave part of the function}
    add edge (v, l) with $F_a^i = \gamma_a^i \cdot f_a^i$ and $u_a^i = r_a^i - r_a^{i-1}$;
  end for
  add edge (l, w) with $F_a^{p+1} = f_a^{p+1} + b_s$ and $u = \infty$.
end for

flow maximization problem on the new representation (by summing over edges a^i, $i \in [1..p]$) and on the initial underling network will be equivalent.

The transfer function of edge a can be found as

$$F_a(f_a) = \begin{cases} 0, \text{if } f_a = 0, \\ \gamma_a^i \cdot f_a^i + b_a^i, \text{if } f_a \in [r_a^{i-1}, r_a^i] \text{ and } i < s, \\ \gamma_a^s \cdot f_a^s + b_a^s, \text{if } f_a \in [r_a^{i-1}, r_a^i] \text{ and } i = s, \\ \sum_{j \in [s..i-1]} \gamma_a^j \cdot u_a^j + \gamma_a^i \cdot f_a^i + b_a^s, \\ \qquad \text{if } f_a \in [r_a^{i-1}, r_a^i] \text{ and } i > s. \end{cases}$$

Capacity limitation edge. To maintain the capacity limit on edge a, $a \in A$, we introduce a total capacity limitation on edges a_i, $i \in [1..p_a]$.

$$\sum_{i \in [1..p]} u_{a_i} \le u_a.$$

We can either integrate this constraints into the MILP formulation for all $a \in A$ or add a bottleneck edge with capacity u_a to node v so that all flow incoming to node v must first pass through this bottleneck edge. For convex and concave cases, the number of edges on the expanded graph per edge on the original graph p_a^+ becomes $p_a + 1$. For s-shaped transfer functions, p_a^+ becomes $p_a + 2$.

We can formulate the maximization problem on the modified network as follows:

Problem 2:

Given $D = (V, A)$, $u_a \ \forall a \in A$, $F_a \ \forall a \in A$.
Find an $s - t-$flow, that
maximizes
$$\sum_{a \in \delta^-(t)} \sum_{i \in 1..p_a^+} F_a^i(f_a)$$
subject to
$$\sum_{a \in \delta^+(v)} \sum_{i \in 1..p_a^+} f_a^i - \sum_{a \in \delta^-(v)} \sum_{i \in 1..p_a^+} F_a^i(f_a^i) \le 0, \forall v \in V \backslash \{s, t\}$$
$$0 \le f_a^i \le u_a^i, \sum_{i \in [1..p_a]} u_a^i \le u_a, \forall a \in A, i \in 1..p_a^+.$$

Theorem 2: The optimal solution of the flow maximization problem for *Problem 1* with s-shaped transfer functions can be generated from the optimal solution of the flow maximization problem for *Problem 2*.

Proof: If we send an amount of flow f_a through edge a and $f_a \in [r_a^{k-1}, r_a^k]$ and $k < s$, then (like for the standard convex case) the k-th edge will be used, because transfer functions F_a^i, $i > k$ or $i < k$, provide lower efficiency for f_a. And if we send flow $f_a < r_a^{s-1}$, maximization of the flow leads us to choose one of the edges in new representation, and send the whole flow f_a through this edge.

If we send $f_a \in [r_a^k, r_a^{k+1}]$ and $k \ge s$, then we are on the concave part of the function. Segment s is less efficient as any segment of the concave part. The function, which describes the s-shaped PWL function of segment s, can be written as $F_a^s = \gamma_a^s + b_a^s$. Per definition of concavity, for $i > s$ any following segment is less efficient than the previous and, thus, $\gamma_a^i > \gamma_a^{i+1}$ and $\gamma_a^i + b_a^s > \gamma_a^{i+1} + b_a^s$ for $i > s$. In the other words, if we send flow $f_a \ge r_a^{s-1}$, we first fulfill edge s, and only then, if $u_s < f_a$, the following edges. Then, $f_a = \sum_{i=s \ldots p_a} f_a^i$. ■

Parallel edges. By allowing parallel edges, we meet some notational difficulties, because an edge cannot be uniquely specified by its tail and its head. We can use the following to build the equivalent network without using parallel edges. If there are parallel edges between node v and w, we replace all but one of these edges by a pair of series-connected edges. The first edge in the pair stays as original, the second one gets a transfer function equal to one and capacity equal to ∞. For implementation, instead of ∞, we use a big number, which guarantees no capacity limitation on this edge. Flow at any edge of our network is less than $\sum_{a \in \delta_-(s)} f_a$. Thus, in order not to create capacity limitations, we can use any number greater than $\sum_{a \in \delta_-(s)} f_a$. Thus, we can easily replace a graph with parallel edges by an equivalent graph without parallel edges. A negative effect of this replacement is that it expands the underlying network. For convex and concave cases, the number of edges on the expanded graph per edge on the original graph p_a^+ becomes $p_a + 1 + p_a - 1 = 2 \cdot p_a$.

For s-shaped transfer functions, in the subgraph replacing edge a, there are two sets of parallel edges, thus, p_a^+ becomes $p_a + 2 + p_a - 2 = 2 \cdot p_a$.

Graph expansion. If the PWL function of any edge $a \in A$ consists of p segments, the number of edges in the expanded graph becomes $m \cdot 2p$, where m is the amount of edges in the initial graph (with NL PWL transfer functions). If the number of segments in the approximation function p_a is different for every edge a, the number of edges in the modified network becomes $\sum_{a \in A} 2 \cdot p_a$ Let us denote the number of edges in the modified network as m^*.

D. Monotonically growing transfer functions

Monotonically growing PWL transfer functions can be divided into s-shaped fragments. For each s-shaped fragment, we establish an equivalent network representation as described in section IV-C. Thus, the correct segment within each s-shaped fragment is chosen automatically due to the network's structure. We need to use the extra variables only to force the right (depending on the amount of flow) s-shaped fragment to be taken.

V. MILP-model for max-flow problems on AGFP network

In this section, we present the formulation of the maximum flow problem on affine-linear generalized network in MILP form.

In the model, we have to integrate the following properties of F_a:

$$F_a = \begin{cases} f_a \cdot \gamma_a + b_a, & \text{if } f_a > 0 \\ 0, & \text{if } f_a = 0 \end{cases}$$

To do this, we use binary variables $f_a^* \in \{0,1\}$, $a \in A$. If $f_a^* = 1$, then flow f_a is greater then zero. If $f_a^* = 0$, then flow f_a is zero. The capacity of flow f_a through edge a is set to zero unless $f_a^* = 1$.

Given $D^* = (V, A)$ (D^* is an expanded/modified graph), u_a, k_a, b_a, r_a $\forall a \in A$.
Find an $s-t-$flow, that
maximizes

$$\sum_{a \in \delta^-(t)} (f_a \cdot \gamma_a + b_a \cdot f_a^*)$$

subject to

$$\sum_{a \in \delta^+(v)} f_a - \sum_{a \in \delta^-(v)} (f_a \cdot \gamma_a + b_a \cdot f_a^*) = 0, \forall v \in V \backslash \{s,t\}$$

$$f_a^* \in \{0,1\}, \forall a \in A$$

$$0 \le f_a \le u_a \cdot f_a^*, \forall a \in A$$

VI. Model Evaluation

Vielma et al. [10] study different ways to model PWL functions in MILP form. They consider the disaggregated convex combinations model, the logarithmic model, the logarithmic disaggregated model and other models. These models are characterized by size of the formulation. Since the quantitative measurement of constraints, continuous and binary variables in formulations is ambivalent (e.g. some models require less constraints, but need more binaries), computational experiments were conducted and presented in [10]. The performance of the logarithmic model was considered the best. According to [10], the crucial parameter that defines time performance is the number of additional continuous variables. Our model, which uses the special properties of the considered PWL functions, does not need additional continuous variables to choose the right edge. Remember, the right edge is the edge that corresponds to the segment of a PWL function that would be chosen if we sent $\sum_{i \in [1..p_a]} f_a^i$ through edge a. Thus, we reduce the number of continuous variables, and thus, improve the computational performance.

VII. Error Estimation

Let us consider the situation in which the original transfer functions $F(\cdot)$ are not PWL functions. Non-linear monotonically increasing functions can be approximated by monotonically increasing PWL functions ($F^A(\cdot)$), and the approach described in this paper can be applied. Obviously, the optimal solution for the original transfer functions $OPT(F)$ does not have to be equivalent to the optimal solution for the approximating transfer function $OPT(F^A)$. It is important to be able to estimate how the approximation quality influence dependence between $OPT(F)$ and $OPT(F^A)$.

The approximation error from above, $\epsilon^\uparrow$, can be defined as follows:

$$\epsilon^\uparrow = \max_{a \in A} \max_{0 \le f_a \le u_a} \left(\frac{\gamma_a^{A\uparrow}(f_a) - \gamma_a(f_a)}{\gamma_a(f_a)} \right) =$$

$$= \max_{a \in A} \max_{0 \le f_a \le u_a} \left(\frac{\gamma_a^{A\uparrow}(f_a)}{\gamma_a(f_a)} - 1 \right),$$

i.e. $\epsilon^\uparrow \ge \frac{\gamma_a^{A\uparrow}(f_a)}{\gamma_a(f_a)} - 1, \forall a \in A, 0 \le f_a \le u_a$.
The latter can be reformulated as follows:
$(\epsilon^\uparrow + 1)\gamma_a(f_a) \ge \gamma_a^{A\uparrow}(f_a), \forall a \in A, 0 \le f_a \le u_a$.

The approximation error from below, $\epsilon^\downarrow$, can be defined as follows:

$$\epsilon^\downarrow = \max_{a \in A} \max_{0 \le f_a \le u_a} \left(\gamma_a(f_a) - \frac{\gamma_a^{A\downarrow}(f_a)}{\gamma_a(f_a)} \right) =$$

$$= \max_{a \in A} \max_{0 \le f_a \le u_a} \left(\frac{1 - \gamma_a^{A\downarrow}(f_a)}{\gamma_a(f_a)} \right),$$

i.e. $\epsilon^\downarrow \ge 1 - \frac{\gamma_a^{A\downarrow}(f_a)}{\gamma_a(f_a)}, \forall a \in A, 0 \le f_a \le u_a$.
The latter can be reformulated as follows:
$(1 - \epsilon^\downarrow)\gamma_a(f_a) \le \gamma_a^{A\downarrow}(f_a), \forall a \in A, 0 \le f_a \le u_a$.

Theorem 3:

$$\frac{OPT(\gamma^{A\uparrow})}{(1+\epsilon^\uparrow)^z} \le OPT(\gamma) \le \frac{OPT(\gamma^{A\downarrow})}{(1-\epsilon^\downarrow)^z},$$

where z is the amount of edges in the longest $s-t$-path, at most $|A|$.

Proof: We split the proof into two parts.

Part 1. We prove that $OPT(\gamma) \geq \frac{OPT(\gamma^{A\uparrow})}{(1+\epsilon^{\uparrow})^z}$.

Suppose we know the optimal solution[1] $f^{A\uparrow}_{OPT}$ for $\gamma^{A\uparrow}(\cdot)$. According to the flow decomposition theorem (Theorem 1), we can decompose $f^{A\uparrow}_{OPT}$ into l paths, $l \leq |A|$. The amount of flow we send through path $P_i = a_1, a_2, \ldots, a_{ki}$, $i \in [1, l]$ is f_i. The amount of flow that reaches the target node through path P_i is $\gamma^{A\uparrow}_{P_i}(f_i)$[2].

Let us take the same amount of flow at the source node as we use to obtain $OPT^{A\uparrow}$ and send it through the network with transfer functions $\gamma(\cdot)$ according to distribution $X(f^{A\uparrow}_{OPT})$ (Def. 6). This yields flow f. Now, let us apply the same path representation (which was obtained by flow decomposition) in its distribution form X to flow f. Thereby, we do a valid decomposition of flow f into l paths. The flow we send through path P_i stays f_i, flow arriving at the target node through path P_i is $\gamma_{P_i}(f_i) = \gamma_{ki}(\gamma_{ki-1} \ldots \gamma_1(f_i))$.

Assume that we have a limit on the rate of transfer function growth, $\gamma'_a(f_a)$, $0 \leq f_a \leq u_a$, $a \in A$. Then, $\gamma_k(\gamma_j(x)(1 + \epsilon^{\uparrow})) \leq \gamma_k(\gamma_j(x))(1 + \epsilon^{\uparrow})$, $\epsilon^{\uparrow} \geq 0$, $j, k \in A$.

Then, $\gamma^{A\uparrow}_{P_i}(f_i) \leq \gamma_{ki}(\gamma_{ki-1}(\ldots\gamma_1(f_i)(1+\epsilon^{\uparrow}))(1+\epsilon^{\uparrow}))(1+\epsilon^{\uparrow}) \leq \gamma_{ki}(\gamma_{ki-1}(\ldots\gamma_1(f_i)))(1+\epsilon^{\uparrow})^{ki} = \gamma_{P_i}(f_i)(1+\epsilon^{\uparrow})^{ki}$. Taking into account that $OPT(\gamma) \geq \sum_{i\in[1..l]} \gamma_{P_i}(f_i)$, we can state the following:

$OPT(\gamma^{A\uparrow}) = \sum_{i\in[1..l]} \gamma^{A\uparrow}_{P_i}(f_i) \leq \sum_{i\in[1..l]} \gamma_{P_i}(f_i)(1+\epsilon^{\uparrow})^{ki} \leq OPT(\gamma) \cdot (1+\epsilon^{\uparrow})^z$. q.e.d.

Part 2. We prove that $\frac{OPT(\gamma^{A\downarrow})}{(1-\epsilon^{\downarrow})^z} \geq OPT(\gamma)$.

This part of the proof is analogous to the first part.

First, we suppose to know the optimal solution for $\gamma(\cdot)$. Let us take a flow decomposition for this solution and apply it to $\gamma^{A\downarrow}(\cdot)$. By this, no capacity constraint is broken. The amount of flow at the target node for the second solution is greater than for the first. The optimal solution for $\gamma^{A\downarrow}(\cdot)$ is the solution that provides the greatest amount of flow at the target node for the graph with $\gamma^{A\downarrow}(\cdot)$. Thus, we can compare $OPT(\gamma^{A\downarrow})$ and $OPT(\gamma)$.

$OPT(\gamma) = \sum_{i\in[1..l]} \gamma_{P_i}(f_i) \leq \sum_{i\in[1..l]} \frac{\gamma^{A\downarrow}_{P_i}(f_i)}{(1+\epsilon^{\downarrow})^{ki}} \leq \frac{OPT(\gamma^{A\downarrow})}{(1+\epsilon^{\downarrow})^z}$. q.e.d.

■

[1]Remember, that the solution is the amount of flow at all edges a, $a \in A$, and $OPT(\cdot)$ is the amount of flow at the target node.

[2]Here, we do not consider transfer functions, but residual transfer functions. We omit writing next to each transfer function that it is a residual function to avoid overloading notations. Remember, if flow on an edge is zero, then the residual transfer function of this edge is equal to the transfer function of this edge, i.e. $F^R(0) = F$.

VIII. Conclusions

Better performance of the model introduced in this paper is based on the usage of the characteristics of special types of PWL functions.

For the maximum flow problem on networks with concave transfer functions, we propose a polynomial-time approximation scheme.

For the maximum flow problem on networks with monotonically growing transfer functions (this case can be reduced to convex and s-shaped transfer functions), we propose to split the transfer functions into s-shaped segments and then, with the help of extra variables, force only the right s-shaped fragment to be taken. We establish such a network representation that the correct segment within each s-shaped fragment is chosen automatically due to the network's structure. This yields to MILP model with better performance than if we were using standard MILP formulations of PWL functions, e.g. the logarithmic model. Moreover, it is worth to mention that our model is simple and transparent, which makes implementation easy.

***Abstract*—Evolutionary optimization algorithms and their hybrid forms have become popular for solving multimodal complex problems which are very difficult to solve by traditional methods in the recent years. In the literature, many hybrid algorithms are proposed in order to achieve a better performance than the well-known evolutionary optimization methods being used alone by combining their features for balancing the exploration and exploitation goals of the optimization algorithms. This paper proposes a novel hybrid algorithm composed of Differential Evolution algorithm, Particle Swarm Optimization algorithm and Harmony Search algorithm which is called HDPH. The proposed algorithm is compared with these three algorithms on the basis of solution quality and robustness. Numerical results based on several well-studied benchmark functions have shown that HDPH has a good solution quality with high robustness. Also, in HDPH all parameters are randomized which prevents the disadvantage of selecting all possible combination of parameter values in the selected ranges and of finding the best value set by parameter tuning.**

I. Introduction

IN RECENT years, many different optimization techniques have been proposed for solving the complex, multimodal functions in several fields [1-4]. Some of the well-known optimization algorithms are the Genetic Algorithm (GA), Particle Swarm Optimization (PSO) algorithm, Ant Colony Optimization (ACO) algorithm, Differential Evolution (DE) algorithm, and Harmony Search (HS) algorithm. These algorithms are used in various fields by many researchers to obtain the optimum value of the problems [5-10]. Each optimization algorithm uses different properties to keep a balance between the exploration and exploitation goals which can be a key for the success of an algorithm. Exploration attribute of an algorithm enables the algorithm to test several areas in the search space. On the other hand, exploitation attribute makes the algorithm focus the search around the possible candidates. Although the optimization algorithms have positive characteristics, it is shown that these algorithms do not always perform as well as it is desired [11]. Because of this, hybrid algorithms are growing area of interest since their solution quality can be made better than the algorithms that form them by combining their desirable features. Hybridization is simply the combination of two or more techniques in order to outperform their performances by the use of their good properties together. Hybridization has been done in several different ways in the literature and it is observed that the new hybridization techniques are very efficient and effective for optimization [11-16].

A novel hybrid algorithm proposed in this paper is called HDPH and it is a combination of three well known evolutionary algorithms, namely Differential Evolution (DE) algorithm, Particle Swarm Optimization (PSO) algorithm, and Harmony Search (HS) algorithm. It merges the general operators of each algorithm recursively. This achieves both good exploration and exploitation in HDPH without altering their individual properties.

HDPH is compared with the three algorithms that form it on the basis of the solution quality and the robustness on random initialization of a solution set. The set of well studied benchmark functions which are Multimodal (M)/Separable (S) or Multimodal (M)/Non-separable(N) are used for the evaluation.

The rest of the paper is organized as follows; Section II describes the HDPH algorithm that is proposed in detail. Section III presents the performances of the hybrid algorithm and the algorithms that generate it together and also our discussions. In the last section, Section IV, the concluding remarks of the paper are given.

HDPH Algorithm

In the literature, many different ways of combining the well-known algorithms are performed to obtain more powerful optimization algorithms [11-16]. The main aim of the hybridization is to use different properties of different algorithms to improve the solution quality.

Among the well-known algorithms, DE, PSO and HS algorithms are the three algorithms that are used in many fields by researchers and these algorithms are proven to be very powerful optimization tools [5-8]. Each algorithm has different strong features. As an example, DE usually requires less computational time and also has better approxi-

978-83-60810-53-8/$25.00

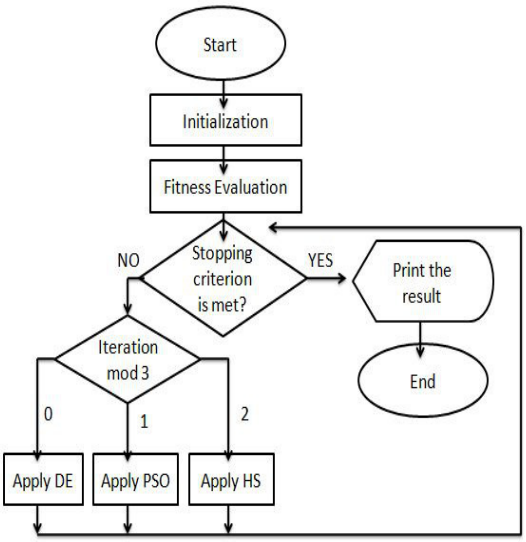

Fig. 1.Flowchart of HDPH

mation of solutions for most of the problems. PSO generally avoids the solution from trapping into local minima by using its diversity. HS on the other hand, is an efficient algorithm that has a very good performance on different applications.

HDPH uses the operators of these three algorithms with randomly selected parameters consecutively and by not altering their properties. The new candidate set, obtained by each algorithm, is used as a new solution set for the other algorithm. Fig.1 shows the HDPH algorithm in the form of a flowchart which demonstrates the main steps of the process.

The summarized steps of HDPH can be given as follows:

Step 1. *Generation of the candidate population with given dimensions:* Initialize the candidate population $X_{i,j}$ in a given range.

Step 2. *Crossover and mutation operators of DE:* The mutation and crossover operators are applied to find the better approximation to a solution by using (1), (2), and (3).

The mutant vector V_{ij} is calculated as corresponding to each member in population using (1) where *a, b,* and *c* are distinct numbers. Mutant vector V_{ij} is crossoverred with X_{ij} and trial vector U_{ij} is generated by using (2) where r_j is a uniformly distributed number for each j^{th} parameter of X_i. Also, *F* and *CR* are the main control parameters of DE.

$$V_i = X_a + F(X_b - X_c) \tag{1}$$

$$U_{ij} = \begin{cases} V_{ij} & if \;\; r_j \le CR \\ X_{ij} & otherwise \end{cases} \tag{2}$$

$$X_i = \begin{cases} U_i & if \;\; f(U_i) < f(X_i) \\ X_i & otherwise \end{cases} \tag{3}$$

Selection process determines U_{ij} to survive to the next generation by using (3).

30	Schwefel	$\left[\sum_{i=1}^{n} -x_i \sin\left(\sqrt{\lvert x_i \rvert}\right) \right]$	-418.9*D
10	Michalewicz 10	$\left[-\sum_{i=1}^{n} \sin(x_i) * \left(\sin\left(\frac{ix_i^2}{\pi} \right) \right)^{2m} \right]$ $m = 10$	-9.6602
2	Schaffer	$\left[0.5 + \frac{\sin^2\left(\sqrt{x_1^2 + x_2^2}\right) - 0.5}{\left(1 + 0.001\left(x_1^2 + x_2^2\right)\right)^2} \right]$	0
2	Six Hump Camel Back	$\left[4x_1^2 - 2.1x_1^4 + \frac{1}{3}x_1^6 + x_1x_2 - 4x_2^2 + 4x_2^4 \right]$	-1.03163
2	Shubert	$\left[\left(\sum_{i=1}^{5} i\cos((i+1)x_1 + i) \right) * \left(\sum_{i=1}^{5} i\cos((i+1)x_2 + i) \right) \right]$	-186.73
30	Griewank	$\left[\frac{1}{4000}\sum_{i=1}^{n} x_i^2 - \prod_{i=1}^{n} \cos\left(\frac{x_i}{\sqrt{i}} \right) + 1 \right]$	0
30	Ackley	$\left[-20\exp\left(-0.2\sqrt{\frac{1}{n}\sum_{i=1}^{n} x_i^2} \right) - \exp\left(\frac{1}{n}\sum_{i=1}^{n} \cos(2\pi x_i) \right) + 20 + e \right]$	0
30	Penalized	$\left[\frac{\pi}{n} \left\{ 10\sin^2(\pi y_1) + \sum_{i=1}^{n-1} (y_i - 1)^2 \left[1 + 10\sin^2(\pi y_{i+1}) \right] + (y_n - 1)^2 \right\} + \sum_{i=1}^{n} u(x_i, 10, 100, 4) \right]$ $y_i = 1 + \frac{1}{4}(x_i + 1)$ $u(x_i, a, k, m) = \begin{cases} k(x_i - a)^m, x_i > a \\ 0, -a \le x_i \le a \\ k(-x_i - a)^m, x_i < a \end{cases}$	0

Step 3. *Particle movement by PSO:* The randomly selected parameters are applied on the velocities by using (4). When a better solution is being discovered, all particles improve their positions by using (5). This movement avoids the particles to be trapped to the local minima by increasing the diversity of solution. V_{ij} refers to the velocity values and for each row is calculated according to the control parameters c_1, c_2, and w by using (4). $global_{best}$ is the best position obtained by any particle and P_{best} is the personal best of a particle. X_{ij} refers to current positions of a particle and can be updated by using (5) for each row.

$$V_i = w * V_i + c_1 * (P_{best} - X_i) + c_2 * (global_{best} - X_i) \quad (4)$$

$$X_i = X_i + V_i \quad (5)$$

Step 4. *Choosing a neighboring value by HS:* HS can search in different zones of the search space by using the control parameters that are *hmcr, par* and *fw*. With a given probability of *hmcr*, a value is selected from the candidate population. With a given probability of 1-*hmcr*, a random candidate is generated in the given range. The population can have non-updated candidates to keep the diversity in the population with a given probability of 1-*par*. With a given probability of *par,* the candidates are updated by applying (6) where *rand()* is a random number $\in$ (-1,1).

$$X_i = X_i + rand() * fw \quad (6)$$

Step 5. Consecutively Step 2, Step 3, and Step 4 are applied.

The algorithm is performed until the termination criterion is not satisfied. Elitism is included in HDPH by keeping the best solution at the end of each iteration.

III. Numerical Results and Discussions

The proposed hybrid algorithm HDPH is tested using 10 well known benchmark functions with different characteristics and is compared for the solution quality and robustness for random initialization of the population with the three algorithms used to form it. The benchmark functions are selected as Multimodal (M)/Separable (S) and Multimodal (M)/Non-separable (N). These benchmark functions are presented in Table I. The population size for the functions is fixed to 100 for all algorithms.

The two control parameters of DE algorithm which are *F* and *CR* are selected from the sets given as follows; *F* $\in$ {0.3, 0.5, 0.7, 0.8, 0.9, 1.2, 1.4} and *CR* $\in$ {0.1, 0.2, 0.4, 0.6, 0.8, 0.9}. The three control parameters that are used in PSO algorithm are selected from the sets as given; *c1* and *c2* $\in$ {0.3, 0.6, 0.9, 1.2, 1.5, 1.8}, and *w* $\in$ {0.4, 0.5, 0.6, 0.7, 0.8, 0.9}. For the HS algorithm, the control parameters called *hmcr* and *par* are selected from the sets as follows; *hmcr* $\in$ {0.7, 0.8, 0.9, 0.93, 0.96, 0.98} and *par* $\in$ {0.01, 0.02, 0.05, 0.1, 0.2}. The control parameter *fw* is adjusted as 0.01, 0.05, 0.1, and 0.2 times the upper bound of each function in HS. Each possible combination of control parameters is selected and each selection is run for 20 times for each algorithm. The selected parameter ranges are chosen similar to the commonly used ranges in the literature. For each function, the control parameter values that are closest to the optimum solution are selected and the function is further evaluated around these selected control parameters. By doing this, we try to achieve a good parameter tuning.

For the HDPH model, instead of selecting the eight control parameters discretely from the sets used for three algorithms, they are selected randomly from the parameter ranges that are formed by selecting the minimum and maximum elements of each parameter set as the lower and upper bounds of the ranges for these parameters respectively. This is done because it would have been very difficult to test all possible combination of parameter values otherwise. The results are obtained only by running the hybrid model for 20 times.

In Tables II and III, the performances of these algorithms over 10000 function evaluations are shown. For each algorithm, the best value (*BestVal*), the average (*Avg*) of the 20 runs for the selected best value parameters and the standard deviations (*Stdev*) are shown. In case that there are more than one control parameter values that give the best value, the one that has a closer average to the optimal value and smaller standard deviation is chosen.

The results that are obtained for the selected MS functions are shown in Table II. The best values obtained using HDPH, except Rastrigin function, are either better or similar to the best values obtained by the other three algorithms. The standard deviations and the averages of HDPH for Schwefel and Michalewicz10 functions are substantially better than the other three algorithms. However, for the Rastrigin function, the standard deviation and the average of HS algorithm are better than HDPH and for the Booth function, all three algorithms have a better standard deviation values compared to HDPH.

In Table III, the results for MN functions are tabulated. For Griewank, Ackley, and Penalized functions, the best values obtained using HDPH outperform the other three algorithms. For these three functions, when both the average and standard deviation values are taken into consideration, the HDPH gives better results than DE and PSO algorithms. When it is compared by the HS algorithm, except Ackley function which gives similar results, HDPH is again better than HS algorithm. For the Schaffer, Six Hump Camel Back and Shubert functions, both the best values and standard deviations are comparable for all four algorithms.

It can be seen from the results that HDPH generally worked as good as or sometimes better than other three algorithms in terms of solution quality and robustness. This is achieved by running the HDPH algorithm only 20 times. For the other three algorithms, the tabulated results are obtained by running the programs 20 times for all possible combinations of parameters, finding the parameter set that gives the best performance, making a parameter tuning around those values and using those parameters that has achieved the best performance. This point is a verification of the good performance of HDPH algorithm.
